Ethnobotany of Alaska: A Southwestern Alaska Perspective. Appendix: Glossary of Native Plant Names (Continued)

Scientific Name	Common Name	Yup'ik	Cup'ig	Siberian Yup'ik
Senecio pseudo-Arnica	Ragwort, Fleabane		qugyugguat	
Sphagnum spp.	Sphagnum moss	uruq		
Streptopus amplexifolius	Twisted Stalk		atsarrlug	
Vaccinium uliginosum	Alpine Blueberry, Bog Blueberry	curaq	cur'at	siugak
Vaccinium vitis-idaea	Lingonberry, Low-bush Cranberry	tumagliq	tumaglir	kitmik
Valeriana spp.	Valerian			ahseukpuk

[a]Name references same species but possibly different subspecies.

E

local flora was routinely incorporated into the Yup'ik diet in addition to Native pharmacology and utilitarian tasks.

There are few native elders with knowledge of traditional plant use in the Yukon–Kuskokwim Delta, and younger generations have not expressed a strong interest in preserving this data. Except for the continuing harvest of a few popular plant species (e.g., *Angelica lucida* [wild celery], *Rumex arcticus* [sour dock], *Caltha palustris* [marsh marigold], *Rubus chamaemorus* [cloudberry]), much traditional knowledge is not being passed on and will likely disappear with the passing of today's elders. It is important that additional research efforts to record traditional use of plants occur before knowledge of such use is forgotten.

Ethnobotany of the Aztecs

JAN G. R. ELFERINK

Scope

The Aztecs represented the ruling empire in Mexico when the Spaniards arrived there in 1519. It was their culture that came in close – and for the Aztecs disastrous – contact with the Europeans. The Aztecs were a rather young culture. Starting as a small tribe in the thirteenth century, they developed into the ruling culture in Mexico. At the arrival of the Spaniards in 1519, the Aztecs ruled Central Mexico from their splendid capital Tenochtitlan, situated at the place where Mexico City is now located.

Ethnobotany in its broadest sense is the part of botany that deals with the use of plants in religion, medicine, all aspects of social life, and their interrelationships. The Aztecs used a very large number of plants. We know that because a lot were written down in the early years after the conquest. Because of space limitations, only a few aspects of Aztec ethnobotany will be dealt with in this article. The focus is on some plants that were especially important for the Aztecs. The relationship between medicinal plants and religion will also be discussed. A number of publications provide more detailed information about Aztec ethnobotany. These include the works of Ortiz de Montellano, Martínez, several articles in the work of Schultes and von Reis, and the comments by Emmart in the *Codex Badianus*. See also: ▶http://www.lib.utexas.edu/benson/bibnot/bn-92.html and ▶http://maya.ucr.edu/pril/reprints_agp/raiceetn.html. For the pre-Columbian use of plants in criminal practices see ▶http://www.drugtext.org/library/articles/elferink01.htm.

Ethnobotany of the Aztecs. Fig. 1 In the Mexican codices plants (especially flowers) are often depicted, such as here in the Codex Nuttall. They are probably connected with medicine, but their exact meaning is often unclear.

Sources

A number of sources deal with the use of plants by the Aztecs. These works are more detailed than for the Mayas or Incas, so we know a lot about their plant use. By far the most extensive source is the work of Hernández. He focused on medicinal plants; he described about 2000 of them, but he also gave information about a large number of other plants. Hernández was the personal physician of Philip II of Spain. Philip sent him in 1570 to Mexico with a quite clear and specific order: to get as much information as possible from the indigenous herbalists, physicians, and other people involved in medicine. The work of Bernardino de Sahagún, a Franciscan monk, is by far the most valuable source of general information about the Aztecs. His work deals with all aspects of Aztec culture, but it also includes a lot of information about the use of plants. The importance of Sahagún lies not only in the abundance of information which he wrote down. It is especially his reliability, because of the procedure that he followed using Aztec informants. The *Codex Badianus* is an Aztec herbal, written by an Aztec physician in honor of and for Charles V of Spain. It contains colored figures of plants, and a description of the treatment of several groups of diseases. The importance of magic in Aztec medicine is quite clearly illustrated in this manuscript. For understanding the role of religion and magic in the use of medicinal plants two chroniclers are of special importance. These two, Hernando Ruiz de Alarcon and Jacinto de la Serna, wrote their works in the seventeenth century. This might seem late, but the mere fact that they tried to eradicate the ancient customs and beliefs demonstrates that they dealt with the beliefs and attitudes of the ancient Mexicans. In both works ample attention has been paid to the use of *ololiuhqui*, *peyotl*, *picietl* and other plants in medicine and religion. In addition a number of other chroniclers mention the use of plants, but mostly their contribution is modest as compared with those mentioned before (Fig. 1).

The Aztec Interest in Plants

Botanical Gardens

The appreciation of the leading Aztecs for botany, and especially for medical botany, is demonstrated by the presence of botanical gardens in ancient Mexico. Their wealth in species and choice was so large that the Spanish conquerors were deeply impressed. One of the most important gardens was near the palace of the ruler Montezuma. He did not want any food plant or fruit tree in his garden. Those, he believed, were for slaves and merchants. The garden contained medicinal plants, beautiful flowers, and odorous trees and herbs. Montezuma ordered his physicians to use the medicinal plants for the nobles at court (Cervantes de Salazar 1971: 320). According to Solis the botanical gardens contained herbs for all types of diseases and ailments, and although the Aztec physicians had little knowledge of the cause of diseases, they knew quite well with which plants certain diseases had to be treated. The medicinal plants from these gardens were distributed freely to all those who suffered from diseases (Solis 1996: 172).

The king of the city-state Texcoco (which had a treaty with the Aztec capital Tenochtitlan) was Nezahualcoyotl; he lived in the fifteenth century. He is described as a constructor, a poet, a wise and clever statesman, and a righteous ruler who codified a number of laws (Clavijero 1970: 115). He was also a special expert on medicinal plants. Those plants which he did not have in his vicinity – Texcoco is situated near present-day Mexico City at an altitude of about

2000 m – were painted. Hernández used these paintings when he prepared his treatise on the materia medica of Mexico; in the original version he meticulously copied figures of plants.

Clavijero (1970: 231, 232) states that there were many botanical gardens in ancient Mexico. He mentions as the most important those of the capital Tenochtitlan, and that of Texcoco, and of the lords of Iztapalapa and of Huaxtepec. Cortés and Bernal Diaz expressed their admiration for the garden of Iztapalapa, and Hernández described a number of the plants from this garden. More important and also much larger than the garden of Iztapalapa was the botanical garden of Huaxtepec. The garden not only contained local plants but also many which were imported from regions far away. After the conquest the Spaniards conserved the garden for many years, and used the medicinal plants in the hospital which they had established in the region (Clavijero 1970: 232). Clavijero stressess that many of the plants in this garden were taken from remote areas. The transportation of several types of trees from remote areas to the core of the Aztec empire was only one of the many classes of products which were transported. The conquered tribes had to pay a lot of tribute consisting of a large variety of goods, to the Aztecs. In addition the Aztec merchants, who traveled a lot abroad, transported valuable items (which could be plants) from the region where they practiced commerce, to the capital.

Medicinal Plants

Knowledge of medicinal plants was essential for the Aztecs because their treatment of diseases relied heavily on their use. The principal quality or application of the plant determined their nomenclature. That could be a color, the place where it was found, the beauty of the flower, but also its preferential application against a certain disease. The Aztecs often gave a plant the suffix *patli* when it was used as a medicine; *patli* means "medicine," but gives by itself no further specification. The reference to a disease or target was often given in the remaining part of the name. In this nomenclature the plant *axixpatli* was a medicine which caused urination (a diuretic). In the same way the plant *atonahuizpatli* was a remedy against fever. In such a name the ability of the plant to act as a medicine against fever is stressed, but it does not necessarily mean that the plant had no other properties. Sometimes a large number of different plants had the same name. The disease *nanahuatl*, probably syphilis or a related disease, was very important in ancient Mexico (Fig. 2). Hernández gives not fewer than eight different plants which were called *nanahuapatli*. The Aztecs also had a medicine called *nanahuaquahuitl* or "tree against *nanahuatl*," and *nanahuaxochitl* or "flower against *nanahuatl*."

Ethnobotany of the Aztecs. Fig. 2 It is striking that the *Guayacum officinale* or *guayacan* was not described as one of the *nanahuapatli* (medicines against syphilis). The guayacan became a major medicine for the Europeans who suffered from syphilis. This picture is from *Köhlers Medizinal-Pflanzen*.

The Aztecs had a clear idea about the origin of their knowledge of medicinal plants. They were convinced that they had inherited this knowledge from the Toltecs, a tribe that resided in the valley of Mexico before the Aztecs arrived, and to whom the Aztecs were related. About the Toltecs Sahagún writes:

> …the Toltecs had much experience and knowledge, they knew the properties and virtues of herbs, they knew which were harmful and poisonous… and through the large experience they had [of these plants] they passed on [the knowledge of] those which are now used for curing, because they were the first physicians, and especially the first of this kind who were called Oxomoco, Cipactonal, Tlaltetecuin, and Xochicauaca who were so competent in knowing medicinal herbs that they were the first inventors of medicine, and the first physician–herbalists…(Sahagún 1969: 10-XXIX).

The description underlines the importance of medicinal plant knowledge, in a way that demonstrates that medicine and botany could not be separated.

Plants in Religion and Medicine: Divine Plants

The Aztecs venerated a large number of gods, and a number of them had a close relation with plants. The goddess Toci was venerated by all those who had a profession related to medicine (Sahagún 1969: 1-VIII and IX). She was the goddess of medicines and medicinal plants. Like other social entities in the Aztec society the pharmacists venerated their own deity. This was primarily the goddess Tzapotlatena. The fact that she had invented the *uxitl*, a highly appreciated medicinal resin derived from pines, was the reason that the pharmacists venerated her. For the invention of the resin she was immortalized and incorporated in the Aztec pantheon of gods and goddesses. Because of the importance of maize as a food plant, some gods were especially associated with maize: Cinteotl, and the related deities Xilonen (Fig. 3). Aztec tobacco or *picietl* was also closely linked to religion. It was believed that tobacco was the body of a goddess called Cihuacoatl (Mendieta 1973: 66, 67).

Some time after the conquest a number of priests tried to eradicate the ancient beliefs of the Aztecs (Ruiz de Alarcon 1953; Serna 1953). These priests reported about their activities, and from these reports we can learn how high the Aztecs appreciated a number of plants. In fact, the priests described these plants as divine plants, because they were venerated as (minor) gods. They were invoked by means of incantations or prayers, for help with diseases. Among these were *ololiuhqui* (*Rivea corymbosa*), *peyotl* (*Lophophora williamsii*), *picietl* (*Nicotiana* sp.), *huauhtli* (amaranth, A*maranthus leucocarpus*), and *yauhtli* (*Tageta lucida*). They had in some way or other a connection with the supernatural. Some of them were hallucinogens, and could be used to get into a trance to make contact with supernatural powers (Fig. 4). These hallucinogens were used not only for divination purposes, but also in medicine. The religious relevance of the plants varied; the ololiuhqui was especially venerated as a kind of god. On the other hand, the picietl (tobacco) was used most frequently against a variety of diseases. The peyotl was mostly considered in conjunction with ololiuqui, while the yauhtli could sometimes substitute for picietl. Yauhtli (more correctly spelled: iyauhtli) was considered an important medicinal plant (Elferink 1988) (Fig. 5). Hernández mentions more than 20 applications in Aztec medicine. A priest who asked the plant for a cure especially invoked picietl. At the same time it was applied to the patient. Occasionally other medicinal plants were invoked for special complaints. For example, the *poztecpatli* was a medicine against bone fractures. It was invoked in an incantation while the priest–physician applied the plant in the form of a plaster (Ruiz de Alarcon 1953: 189).

A plant that was not hallucinogenic but nevertheless highly venerated by the Aztecs was *huauhtli*. The connection of huauhtli with religion was complex. It derived its importance not from incantations but from a special application in Aztec religion. From huauhtli a dough was made that was called *tzoalli*. From this tzoalli statues of gods were made. The statues were venerated and subsequently consumed in religious ceremonies as a kind of communion. Huauhtli was also an important food plant, and used against diseases such as eye complaints, swellings and pain in the chest.

Some hallucinogenic plants, namely ololiuhqui and picietl, had still another connection with medicine. They were principal ingredients of *teotlaqualli*. This

Ethnobotany of the Aztecs. Fig. 3 One of the maize goddesses, named Xilonen, depicted in the Codex Nuttall.

Ethnobotany of the Aztecs. Fig. 4 Besides the hallucinogens mentioned in the text the Aztecs used *teonanacatl*, the divine mushroom. In the lower part of the picture (Codex Nuttall) the mushroom is depicted, as well as a man who eats it and an unknown deity.

Ethnobotany of the Aztecs. Fig. 5 The Aztecs sacrificed many humans, as depicted here in the Codex Nuttall. On a few occasions they were stunned before they were sacrificed. According to Sahagún the *yauhtli* was used for this purpose.

was an unction that was offered to the gods, for whom it served as food. The Aztec priests smeared themselves with this unction, to dispel fear and to reach the appropriate state of mind to serve the Aztec gods. A few cases are reported in which the Aztec emperor or soldiers were smeared with teotlaqualli. It is suggested that the black color of some Aztec deities, as depicted in the codices, was due to an ointment with teotlaqualli. In addition to its use for psychoactive purposes, teotlaqualli was applied in medicine under the name *teopatli* (Elferink 1999).

Some Plants with Special Interest for the Aztecs

Maize

The name maize comes from the language spoken in the Caribbean; the Aztec name was *tlaolli* (*Zea mais*). It was by far the most important food plant of the Aztecs. Its importance can be derived from the large number of Aztec gods that were associated with maize. Its use in medicine was rather limited, although a number of chroniclers had a different opinion. They were convinced that the consumption of maize products was the cause of the low incidence of kidney and bladder complaints among the Aztecs. From maize a porridge called *atolli* was prepared. It was usually prepared together with other plants, and so a large number of different types of atolli were known. The *chillatolli*, for example, was atolli mixed with chili pepper. This atolli was an aphrodisiac, probably due to the pepper. Hernández describes nearly 20 different types of atolli, some of which were applied in medicine. It is hard to say whether their supposed medicinal action was due to maize or to the other added products.

Picietl

There are few plants which played such a decisive role in Aztec medicine and religion as the *picietl* (*Nicotiana sp*.). *Nicotiana rustica* is often given as identification of picietl or Aztec tobacco, but the properties of *N. rustica* do not correspond with those of picietl. This refers especially to the mind-altering properties of picietl, and these properties especially determined its role in religion, magic, and curing with medical incantations as mentioned before. Many chroniclers have noted these psychoactive properties, so that there is little doubt about this property in ancient times. It is therefore not surprising that diviners used picietl to get intoxicated, so that they could make divinations. In addition to magic-religious applications in medicine, picietl was just applied as a medicinal plant. Hernández mentions its use against more than 20 different ailments, particularly ailments associated with pain. An interesting application was the use of tobacco as an antidote against the bite of various poisonous animals and the cleansing of wounds with tobacco juice. A particular application of tobacco was the stunning of dangerous snakes with tobacco powder, so that they could be caught for religious purposes (Elferink 1983).

The Aztecs considered tobacco a sacred plant, and it was highly appreciated because of its use in medicine and its psychoactive properties. In this context it is relevant to realize that the Aztecs did not use the tobacco for recreational purposes as we use tobacco today. The Aztecs did not experience the negative effects of smoking, although they knew too that excessive use was dangerous.

Metl

The name *metl* or *maguey* was used for several Agave species. The metl was in more than one respect an important plant. It provided fiber that could be used for preparing clothes, sandals, and other materials. It was used to prepare a good quality of paper. The thorns were used as needles. A specific application of these thorns was the pricking in the ears or genitals to obtain blood for an offering to the gods. Metl was the basis for the preparation of *octli*, today better known as the *pulque*, an alcoholic drink made by fermenting a honey-like secretion of the plant. Although the use of alcoholic beverages was forbidden under normal conditions, octli was so important in Aztec society that several Aztecs gods were associated with it. It was frequently used as an offering. Consumption of octli occurred mainly during festivities of some octli-gods. Both metl and octli were applied in medicine, the octli mainly as vehicle for the intake of other medicines. Pregnant women were allowed to consume octli outside religious festivals, because of the supposed strengthening action of the beverage (Fig. 6).

Ethnobotany of the Aztecs. Fig. 6 From maize a beverage was prepared that was called *octli* (later it got the name *pulque*). Its consumption was forbidden under normal conditions but during some religious feasts it was taken in large quantities. Here the preparation and consumption of octli, as depicted in the Codex Nuttall.

Ulli

Ulli or *hule* was the resin of the *olcahuitl* (or *holquahuitl*) tree (*Castilla elastica*), one of the rubber-producing trees of the Aztecs. It had a number of applications. The hule was the product from which balls were made for the ritual ball game. It was further used in a number of religious customs. One of them was related to medicine. If someone recovered from a disease he wanted to honor the god who was associated with the disease. For that purpose he went to a soothsayer-priest to select a suitable day. On that day the former patient burnt in his home pieces of paper on which the soothsayer had painted with ulli the picture of the god who had to be venerated (Sahagún 1969). The use of ulli as an offering to the gods is confirmed by other chroniclers (Durán 1967: Calendario, V). The ulli was sold in the markets by special vendors, who sold nothing except ulli (Sahagún 1969: 10-XXIV). One of the most important medical applications of the ulli was to treat dysentery and diarrhea (Hernández 1959; Relaciones Geográficas México 1985: 318; Relaciones Geográficas Tlaxcala 1984: 271). For that purpose the ulli was often mixed with cacao. It was further used against a number of other ailments such as abscesses, eye diseases, inflammations, intestinal problems, urinary complaints, colic, pain, headache, and eye diseases (Sahagún 1969: 11-VI; Hernández 1959). Hernández describes a peculiar application of the ulli, which he apparently had learnt from indigenous physicians. Mixed with *axin* it was taken to improve the agility and speed of the joints. The informants told him that the bones were loosened in a sense that turns and movements were facilitated so that acrobatic abilities were obtained (Hernández 1959).

Coanenepilli

Another plant, which is often mentioned by the chroniclers because of its frequent use by the indigenous population, is the *coanenepilli*. The name “serpent tongue” refers to the form of the leaves which are bilobed (Emmart, in *Codex Badianus* 1940: plate 59). As might be expected, the name was used for completely different plants, namely *Dorstenia contrayerba*, and a *Passiflora sp*. For medicinal purposes the first one was by far the most important. In the *Codex Badianus* coanenepilli was prescribed against obstruction of the urinary tract. An important application of coanenepilli was its application as an antidote. For that reason it was called *contrayerba* by the Spaniards. If a snake or a scorpion bit someone, the Indians anointed the bite with the coanenepilli, while the juice of the plant was drunk (*Relaciones Geográficas México* 1986: 150; *Relaciones Geográficas Michoacan* 1987: 43). Another important application of coanenepilli was against fever (*Relaciones Geográficas México* 1985: 280, 306, 312). The Aztec informants of Sahagún stress the ability of the coanenepilli to purge: bad humors were expelled by mouth and via stool (Sahagún 1969: 10-XXVIII).

Shortly after the conquest it was also applied against typhus (*Relaciones Geográficas Tlaxcala* 1985: 205; Serna 1953: 283; Mendieta 1973: 98). The Aztecs desperately tried a number of medicines against the new diseases which were imported by the Spaniards. These diseases decimated the number of Indians, and caused depopulation of large parts of the country (see chapter XIII). Among the few medicines used by the Indians against these new diseases, the *Relaciones Geográficas* mentions the coanenepilli. The frequent application of this plant could suggest that the Indians had some benefit from it. On the other hand, the number of casualties could hardly have been higher than it was, so the new drug had only a limited curative value (*Relaciones Geográficas Tlaxcala* 1985: 51, 54, 59). The reason for the use of this plant against epidemics was probably that the coanenepilli was regarded as a good remedy against feverish conditions. Because the postconquest epidemics were accompanied by fever, the choice for the coanenepilli was evident (*Relaciones Geográficas Tlaxcala* 1985: 84, 205).

Coanenepilli was popular in the combined treatment of diseases with medicinal plants and magic-religious incantations. If someone experienced chest pain because of an accident, the powdered root of coanenepilli was applied, and the patient had to drink a potion of the plant thickened with ground maize. At the same time an incantation was spoken where the coanenepilli was invoked in the name of the god Pahtecatl (Andrews 1984: 177–178). Combined with magic incantations the coanenepilli was further applied against fever and against cutaneous eruptions (Serna 1953: 292, 293, 283, 289; Andrews 1984: 195–199).

Iztauhyatl

The *iztauhyatl*, in Mexican folk medicine called *estafiate*, is botanically known as *Artemisia mexicana*. According to the Florentine Codex the plant was a remedy against many diseases (Florentine Codex 1950–1969: 11-VII). Relapsing fever, cough and anxiety are mentioned. The plant was useful for treating anxiety (Sahagún 1969: 11-VII). It was also a part of complex medicines. In the Codex Badianus the iztauhyatl was part of a remedy against some diseases which we do not always know exactly what was meant: weakness of the hands, ailment of the fundament, injury of the feet, lassitude, excessive heat, lightning stroke, and phthiriasis of the head (Codex Badianus 1940: plates 43, 61, 65, 66, 79, 91, 102). Hernández indicates that the name iztauhyatl was used for more than one plant. In most cases, however, the plant described as iztauhyatl was *Artemisia mexicana*.

Magic power was ascribed to the iztauhyatl, and it was considered a sacred herb (Aguirre Beltran, 1987: 124–126). According to Aguirre Beltran the name of the plant is derived from *iztahua* (deity of the salt), and *atl* (water). The indigenous physicians called *techichinani*, who cured by sucking the illness from the body, chewed the iztauhyatl before they started the sucking of the disease. As a sacred plant the iztauhyatl was invoked in cases of troubles in love affairs. The magic power of the iztauhyatl was called for assistance when a pregnant woman or her husband wanted to trespass some rules, such as leaving the house during the night. The result was quite nasty for the child to be born who would cry a lot or become ill. To prevent these dangers the woman had to wear a bag with some copal or iztauhyatl, and the man had to wear a bag with picietl, when they went out during the night (Serna 1953: XIII; Sahagún 1969: 5-XIX).

Against one of the most severe epidemics of the postconquest time, mostly referred to as *cocoliztli*, no medicines were available. Among the few which were tried with unknown success were the iztauhyatl. Some of the authors of the *Relaciones Geográficas* mention the plant as a remedy; it was put in water, and the water was used to wash the patient (*Relaciones Geográficas Mexico* 1986: 135).

Ethnobotany in China

Georges Métailié

Ethnobotany is the study of the links that human beings, as individuals or societies, have maintained and maintain with plants. China is a country with more than 50 different national minorities, with very different traditional cultures, languages, food habits, etc. Chinese ethnobotany could thus be the juxtaposition of the different ethnobotanies of all the ethnic groups living in China. On the other hand, one generally understands "Han" when one says "Chinese." This term, which is the name of the second dynasty after unification of the empire (206 BCE–AD 220) is also the name of the main ethnic group in China, with about 96% of the population. It is the ethnobotany of the Han Chinese that we are going to present here.

With 3,692,000 square miles, China is about the same size as the United States. Its relief can be roughly compared to stairs going down from the western plateaux to the plains of the east and the south. Its climate is under the double influence of a huge continental mass and the strong impact of the summer monsoon: generally the winters are cold to very cold – except for the extreme south-east – and dry. The summers are very warm with high rainfall and moisture. The diversity of climates and reliefs has probably favored a particular richness in vegetation. With about 25,000 species of higher plants, 2,600 species of ferns, 2,100 species of mosses and liverworts, and some 5,000 species of fungi, China has the third richest flora of the world after Malaya and Brazil.

In Chinese mythical history, the beginning of the relation between man and plants is so strong that it is considered the first step into "civilization." Speaking of Shennong, the Divine farmer, one of the three mythical emperor creators of the Chinese civilization, one says that "before him, men did not know cereal grains, they ate animals and drank their blood. Then Shennong tasted the herbs, sorted cereals, and taught the art of tilling to the people. Then he tasted herbs again and sorted simples to save the people from illness." Eventually, the Yellow Emperor, successor of Shennong, taught cooking and medicinal prescriptions. In the Chinese tradition, the access of mankind to civilization was achieved when man became a tiller and a gatherer; agriculture supplied what was needed for basic food, and gathering gave access to the complementary plants, medicinal, and pot herbs. Actually, the local biodiversity appears to have been rather well appreciated and exploited all through Chinese history, because China is one of the main centers of domestication of plants and possesses a very rich *materia medica*. The local richness did not prevent a great interest in plant introduction. However, introduced plants, like corn, sweet potato, tomato, and potato, have been used mainly as complementary food and never caused any fundamental change in food habits, as happened in Europe, for instance, with American plants. Among the 116 botanical species cultivated as vegetables today in China, at least 37 would have been locally domesticated. Also, considering the cultivars – which are the form under which these species are cultivated – their number amounts to several thousands. As for trees and shrubs, more than 300 species are exploited today – even if they are not all cultivated – for their fruits, eaten fresh or, more frequently, after transformation or preparation.

There is a traditional opposition between crops cultivated on dry lands – millets, wheat, barley, sorghum – in Central and Northern China, and rice and various tubers cultivated in irrigated fields of the south. Nowadays, thanks to agricultural hydraulic development, rice is also cultivated in northern parts of the country, where climatic conditions permit it. On the other hand, corn, following irrigation development, replaced traditional millet crops. The ordinary diet consists of large amounts of a basic food, called *fan*, made from steamed or boiled grains, such as rice, millet, or sorghum, or various kinds of noodles made from wheat, pulses, rice, etc. It is accompanied by *cai* (dishes), generally made from vegetables and soya bean in the form of *tofu*. Among these dishes, fish or meat, important for special occasions, are still not very frequent in everyday life, especially in the countryside.

As for clothing, even if today synthetic fibers, wool and silk have become more and more important, in the sixties, in mainland China, cotton was the only material used for common suits and even shoes. In the countryside, some work clothes, sun hats, and raincoats are still frequently made of bamboo or palm leaves. They combine several advantages: since they are not heavy, they provide good shelter and allow the air to circulate freely. The use of wood for buildings is entirely limited by the resources of the environment: it is a wooden framework which bears the roof of the traditional standard Chinese house, the nonweight-bearing walls being made of brick or tamped earth. However, from its shoots eaten as a delicacy, to the chopsticks used to eat, from the scaffolding, drill-hafts and brine conduits of the salt-fields in Sichuan to irrigation flumes, and from ordinary furniture to the most exquisite pieces of wickerwork, bamboo is probably the member of the vegetable kingdom which plays the most important part in the material life of the Chinese.

Traditional Chinese medicine uses as *materia medica* some 4,773 products of plant origin, 740 of animal origin, and 82 minerals.

Chinese people are also very interested in the beauty of plants. Varieties of some 12 ornamentals are particularly valued: tree-peony (*Paeonia suffruticosa* Andr.), Japanese apricot (*Prunus mume* Sieb. et Zucc.), hybrid roses, camellias, rhododendrons, Wintersweet (*Chimonanthus praecox* Link.), Chrysanthemums [*Dendranthema morifolium* (Ramat.) Tzvel.], orchids (*Cymbidium* sp.), daffodils (*Narcissus tazetta* var. *chinensis* Roem.), hybrid gladioli, pinks (*Dianthus caryophyllus* L.) and Indian lotus (*Nelumbo nucifera* Gaertn.). Besides a great number of other "traditional" ornamentals like bamboos or cockscombs (*Celosia argentea cristata*), new varieties appear frequently. Grafted succulents became very popular and, more recently, Kaffir lilies (*Clivia* sp.). Just for the pleasure of watching new flowers or to be photographed in front of a blossoming magnolia or plum, crowds of people will visit public parks in the spring, while in autumn it would be unthinkable not to go and admire the red leaves of maples in the nearby hills of the city of Nanking, for instance.

Plants obviously play a very important part in the life of the Chinese people, but one may wonder whether there is any particular kind of relation which would define a "Chinese ethnobotany." A first striking point, which can be well appreciated in agriculture and horticulture, is the closeness of the human-to-plant relation. This is obvious with a crop like rice where, after the nursery stage, every seedling in the paddy is transplanted to the field where it will ripen. Propagating other plants like yams or taros also necessitates the individual handling of every cutting. The sowing of all the plants cultivated in gardens, like cucurbits and beans, is individual, and even for crop plants like millets or wheat it is remarkable that a sowing machine allowing seed by seed control has existed at least since the thirteenth century. Grafting seems to have begun during the first centuries AD but it became very important in horticulture as early as the sixth century and was much used for fruit and flower production. Professional horticulturists have used grafting since the Song dynasty (960–1279) when it was believed it could create new varieties of flowers (tree-peonies and chrysanthemums) for amateurs who would pay fortunes just to watch the most beautiful. Another example of individual treatment of a plant is the technique of tree-potting (*penzai, bonsai* in Japanese): to keep the tree in small proportions, it is necessary to prune its branches and roots every year and to look after it day after day.

In ancient China, scholars also developed a very exclusive relation with plants. They would rank them from the most precious to the lowest. Following their personal taste, men of letters would develop real "friendships" with the ones they appreciated most and which would live in their studios, along with "the books and the cithar (zither)." Joseph Needham and Li Hui-Lin have shown that this interest in special plants led to various monographs on them. Plants have also been a favorite theme for literature and poetry. Since the thirteenth century several encyclopedic books have been composed entirely with quotations from texts dealing with plants. One famous book, published in 1231, *Portraits of the Plumflower*, is devoted only to the Japanese apricot (*Prunus mume* Sieb. et Zucc.). The author, Sun Boren, through a hundred ink drawings, each accompanied by a poem, evokes the feelings that he experienced watching the flower, from its bud stage to the fall of the last petal. Actually, in the painting of flowers, Chinese artists were more concerned with emotion than representation. Using a brush and black ink, they were looking for the essence, more than for the true form of, bamboos, pine trees, orchids, or plum-flowers. Zou Yigui (1696–1772), a famous painter, criticized the Western paintings he had seen at the imperial court as being too realistic, and he considered their authors not painters, although they possessed skill, but simple artisans.

In ancient China, plants as medicine were not distinct from minerals or animals and belonged to a system of classification where the whole *materia* *medica* was separated into three ranks, *san pin*, for nonpoisonous products, good for the health and used to “nourish life,” to very active products, generally highly toxic and used only under very strict conditions. During the sixth century, Tao Hongjing, a famous physician, developed this classification: within each of the three grades, plants were subdivided into herbs, trees, grains, potherbs, and fruits. At the end of the sixteenth century, another physician, Li Shizhen (1518–1593) in a famous book called *Bencao gangmu* (Classified Pharmacopaeia, 1596), changed the basis of this classification. Considering almost obsolete the three ranks system, he reorganized the whole materia medica “from the lowest to the most precious,” from minerals to man. He kept the five categories mentioned above for plants but in a new order – herbs, grains, vegetables, fruits, and trees – and divided those into 33 subgroups following various criteria like ecology, taste, and toxicity. Besides this learned system, created and used by physician–scholars, there was a folk taxonomy not exclusive from the previous classification, where the ethnobotanical data were distributed into six ranks. Following Brent Berlin’s vocabulary, they are:

– *Kingdom* marked by two words meaning plant, *caomu* (herb tree) and *zhiwu* (planted thing);
– *Life-form* with three main taxa, *cao* (herb), *mu* (tree) and *teng* (vine) and the ambiguous statute of *chu* (bamboo) “neither herb nor tree”;
– *Intermediate* where groups are named by juxtaposition of terms used for taxa of generic rank, like *tao-li* (peach-prune), *song-bai* (pine-cypress);
– *Generic* marked by monosyllabic terms like *tao* (peach), *xing* (apricot), *zao* (jujub);
– *Specific* where one finds some of the monosyllabic terms also used for generic taxa but with a narrower meaning like *xing* (apricot: *Prunus armeniaca* L.). However, terms of this rank are generally polysyllabic. They may be *secondary plant names*, lexical extensions on the basis of a generic term, like *yinxing* (silver apricot: *Ginkgo biloba* L.), or *jiazhutao* (narrow bamboo peach: oleander, *Nerium odorum* Soland.). They may also be *primary plant names* like *Lu meiren* (the beautiful lady of Lu: poppy, *Papaver rhoeas* L.), *mudan* (male cinnabar: tree peony, *Paeonia suffruticosa* Andr.);
– *varietal* a system, already described in the first encyclopedia *Erya* (third–second centuries BCE) is still effective today.

The long tradition of observation, culture, and use of plants along with a fair knowledge of plant life never led to a systematic approach. Among the rich literature about plants one cannot find anything like a primer of botany. Up to the middle of the nineteenth century, plants, in China, were considered in their cultural environment. Besides horticulture, agriculture, or art, concern with plants was philological: considering plant names with obscure meanings occurring in ancient texts, literati would try to find which plants would fit these names. To do so, they compared textual evidence or interpretation with the results of inquiries they made among their contemporary countrymen. Chinese traditional scholars’ plant knowledge can be described as cultural botany.

Ethnobotany in Ethiopia

Mesfin Tadesse

Ethiopia is located in the horn of Africa between 3°N and 15°N latitude and 33°E and 48°E longitude. Generally the central parts of the country are mountainous with the highest mountain peak, i.e., 4,620 m, being at Ras Dejen (Ras Daschen) in the Semien Mountains.

The coastal areas are low-lying plains. An area in the northeastern part of the country called the Afar depression is about 115 m below sea level.

Botany

The beginning of an organized study of the plant resources of Ethiopia can be traced to about 1,850 when Achille Richard (1847–1851) described the first flora of the country. *Tentamen Florae Abyssinicae* consists of descriptions of about 1,700 species of plants from particularly the northern parts of the country. This was followed, a hundred years later, by the work of Cufodontis (1952–1972), *Enumeratio Plantarum Aethiopiae Spermatophyta*. Almost 20 years after the completion of this checklist, the *Flora of Ethiopia* and later on the *Flora of Ethiopia and Eritrea* was started. This is still in progress although most of the volumes have been published (Hedberg and Edwards 1989, 1995; Edwards et al. 1995, 1997, 2000; Hedberg et al. 2003). What was and is being attempted in the above-cited publications is the documentation of the higher plants of Ethiopia and Eritrea, with the *Enumeratio* also providing information on plants found in Somalia.

Ethnobotany

The focus of this article is not on the total plant life of Ethiopia but only on the cultivated plants, i.e., the domesticated, wild and semi-wild food and medicinal plants. This usually falls under the umbrella of agronomy in agriculture and ethnobotany in plant biology. In order to understand the origin of ethnobotany in Ethiopia more completely, one has to look into the beginnings of agriculture. This, however, is a broad subject and will not be attempted here. (Ed. note: see Alexia Smith's article on Ancient Methods of Agriculture in this volume.)

Cultivation and domestication of plants have taken place in a number of spots in the world. Although naturalists like Darwin (1868) and De Candolle (1882) had written about cultivated plants, the first person to provide extensive documentation was the Russian scientist, Vavilov (1935), between 1926 and 1937. Vavilov considered the Ethiopian highlands as one of the eight centers of origin of cultivated plants with the major plants being Abyssinian hard wheat, poulard wheat, emmer, Polish wheat, barley, grain sorghum, pearl millet, African millet, cowpea, flax, sesame, castor bean, garden cress, coffee, okra, myrrh, teff, pea, and indigo.

In an overview of the origin of agriculture, Harlan (1998) wrote:

> From our review of the agricultures of the world, they seem to be centered on the Near East, Ethiopia, sub-Saharan Africa, China, Mesoamerica, highland South America, and lowland South America. Each has its own suite of cultivated plants. People associated with them, their cultures and religions, are closely intertwined with the main crops they grow. This appears to be the pattern on a global scale.

This view does not differ very much from the patterns described by Vavilov. A little bit has been added here and there but the overall conclusions are very similar.

It is believed that the first cultivated plants were selected from wild plants for their desired values and then domesticated (i.e., manipulated for purposes of mass production, a process of selective breeding). Domesticated plants are often associated with humans and do not occur in the wild, e.g., maize, tobacco, soybeans; others are still found as wild or semiwild plants, e.g., coffee, niger seed (noug), etc. Here I will select only five of these plants from Ethiopia to illustrate their use and how some of them spread to other countries. Further reading material is also provided after the references.

Coffea arabica L.: Rubiaceae (*Bunna* in Amharic)

The southwestern Ethiopian highlands (in Illubabor and Keffa) are believed to be the centers of proliferation and probably also of origin of *C. arabica* (Richard 1847–1851; Meyer 1965a, 1965b, 1969; Fernie 1966). As early as 1848, Richard considered arabica coffee as spontaneous in forests in Ennarya and Keffa and introduced elsewhere in Ethiopia. Other contenders of origin are the Boma Plateau in adjacent southern Sudan (Thomas 1944), Mt. Marsabit in Kenya and the highlands of Yemen. From all the available evidence and from theories regarding the place of origin of plant and animal species, it is believed that arabica coffee originated within the confines of present-day Ethiopia in general and the Keffa–Illubabor region in particular and then it was taken first to Yemen.

The coffee seeds or seedlings that were taken from the Ethiopian highlands were planted in the irrigated fields and terraces in Yemen (Old Arabia Felix). It appears that Yemen had been the only supplier of cultivable coffee to the world, and the Netherlands the first European country to acquire the first planting material from Aden in 1690. But it is also known that earlier on, in 1616, a coffee plant was taken to Holland from Mocha (Haarer 1962). The Dutch started planting coffee in Sri Lanka (formerly Ceylon) in 1658. Wellman (1961) wrote that the Portuguese had also introduced coffee into Sri Lanka before 1600. Wrigley (1988: 39) indicated that "Baba Budan, a Muslim saint," is believed to have taken a few seeds (seven according to Wellman 1961) into India (Malabar) around 1600. Plants were shipped from Malabar to Java in 1696. These supplied the first commercially grown beans to Europe. In 1706, a coffee plant was sent to the Amsterdam Botanical Garden from Java and seeds and seedlings that were produced from this single introduction were distributed to the major botanical gardens in Europe (Haarer 1962) and South America.

How did the drinking of coffee spread? This aspect is closely related to the brewing of coffee but as there are conflicting views on where the brewing started, it is also assumed that there will be similar hypotheses about the spread of coffee drinking. May be it is best to start with how coffee was utilized at first.

From a questionnaire survey made in 1989–1990 by the author in many coffee growing areas in Ethiopia, it appears that the earliest use of coffee in Ethiopia was in the form of small balls from roasted ground beans. These were then mixed with butter and kept in the mouth, between the cheek and the jaw, while making long journeys. While at home or in the vicinity of home, roasted coffee beans that were dipped in butter were chewed. This practice goes together with other rituals such as thanksgiving, celebrating the birth of a new child, etc., in this part of Ethiopia even to the present day. It also appears that this habit did not cross the borders of present-day Ethiopia. Similar modes of use have been reported for other species of plants, e.g., the early use of coca (*Erythroxylon coca*) in the Andes of South America (Brucher 1989: 175; Simpson and Ogorzaly 1986: 363–364).

Genetically, *C. arabica* is tetraploid, meaning that it has four times the original (haploid) number of chromosomes. It is believed to have originated by polyploidy, a process of speciation by doubling chromosomes, from a diploid ancestor. However, up to now no diploid plant has been found in the wild and the parents that might have given rise to it are assumed to have become extinct.

Brucea antidysenterica J. F. Mill: *Simaroubaceae* (*Waginos in Geez*, or *Yedega Abalo in Amharic*)

The root barks of this plant have been used since a long time ago in northern Ethiopia to treat dysentery. Today, there is a lot of useful information on the medicinal value of this species. Antitumor chemicals and cytotoxic antileukemic alkaloids have been isolated from it (Fukamiya et al. 1986).

There is an interesting story about how this species became popular. According to Pankhurst (1982) a Scottish traveler called James Bruce who stayed in Ethiopia from 1769 to 1771 was attacked by dysentery when he was about to leave Ethiopia. He tried to cure himself with the help of the medicines he had brought along from Europe but was not successful. When observing that he would not be able to make it to Europe traveling through the hot landmass of Sudan and Egypt, the Chief of Ganjar of Shanquilla informed him to take a well-established local drug known as *Waginos* (Geez name, the root of the current Amharic and Tigrigna languages of Ethiopia) or *Yedega Abalo* (name in Amharic, the official language of Ethiopia). The root bark of this plant was cleaned, dried in the sun, and ground into powder. James Bruce was then made to take two spoonfuls of the powder with camel's milk. After the sixth or seventh day, Bruce regained his health and was able to continue his journey to England. On his way back, he took some of the powder and fruits of Waginos. He used the powder whenever he or his companions fell sick on the way. The fruits were delivered to a botanist at the British Museum of Natural History called Daniel Solander, who, noting that it represented a species not known in Europe then had it planted in several British gardens. The plant was later named by Miller *Brucea antidysenterica* to commemorate James Bruce with the specific epithet indicating the medicinal property of the plant.[1]

Hagenia abyssinica (Bruce) J. F. Gmel: *Rosaceae* (*Kosso* in Amharic)

This is a large tree with smooth flaking bark known from Ethiopia, Kenya, and Uganda. The plant produces male and female flowers on separate clusters. The female flowers, known as *Kosso*, are used in eliminating tapeworm from human intestines. First the flowers are sun dried and an infusion of half an ounce is prepared in a glass of water. This should be drunk early in the morning before breakfast. The patient is not allowed to take food during the day, and, if the bowel movement is not free during that day, a physic should be taken at night.

Here there is also an interesting story on how the plant was introduced into the international world of medicine as an age-old tested medicament. According to Pankhurst (1975), "the first foreign medical man to interest himself in Kosso" was a French physician called Dr A. Brayer around 1816. Brayer's first acquaintance with Kosso was from a contact he had with an old Armenian merchant called Karabet in Constantinople (now Istanbul) who told him that the "…Ethiopians cured themselves with the aid of the flowers of a plant which…was known by the word which also signified the taenia itself." The plant was then called *Brayera anthelmintica* Kunth to commemorate the physician, Dr Brayer, and also to indicate its anthelmintic (antiworm) properties. Today, the chemistry is well known and the active compounds are Brayerin (a bitter, acrid resin), volatile oil, and tannin.

[1] More information on the chemical constituents of *Brucea antidysenterica* may be obtained from the *Journal of Natural Products,* e.g., Fukamiya et al. (1986) and Imamura et al. (1995); *Current Medicinal Chemistry*, e.g., Jung et al. (2000), and medicinal databases.

Since *B. anthelmintica* described by Kunth in 1824 is preceded by *Banksia (Bankesia) abyssinca* described by Bruce in 1790, the first name applied to the Kosso plant, today we use the later specific epithet transferred from *Banksia* to *Hagenia* (1791) following the International Code of Botanical Nomenclature. The genus name *Banksia* was published in 1781 by the son of Carolus Linnaeus (often called the father of botany) for an entirely different plant and thus could not be used in conjunction with the specific epithet of the Kosso plant. Hence, the next available genus name in the *Rosaceae* is *Hagenia*.

Guizotia abyssinca (L. F.) Cass.: Asteraceae (*Noug* in Amharic)

This is an annual herb that usually grows between 50 and 100 cm, but it may grow up to 2 m. It produces small yellow flowers at the apices of branches and stems. The marginal flowers are 6–8 in number (rarely up to 15) and strap-shaped, while the central flowers are numerous and tubular. It is from these centrally located flowers that the oil-producing fruits are obtained. The fruits are black, a few millimeters long, up to 1-mm wide and without hair when fully mature. Six out of the seven species in the genus (Mesfin Tadesse 2004) are found in Ethiopia; it is assumed that the genus originated in Ethiopia.

Noug has been domesticated in Ethiopia for a long time. The oil is used in cooking and as a source of candlelight. The cake is used as part of animal fodder. The plant was introduced in India, where it is also grown as an oilseed crop plant, and in other countries. In Australia, it has been found growing around overseas shipping containers areas. In the United States (Wisconsin), the Winnebago Company introduced it as wild bird seed, and in Ohio (Butler County), it was found as a weed in flower beds, near where bird feeders had been over the preceding winter. In Ethiopia, it is grown as an oilseed crop on a rotational basis with cereals and pulses. "It constitutes about 50% of Ethiopian and 3% of Indian oilseed production" (Getnet and Sharma 1996). Today it is reported as being used in paint and soap production as well.

James Bruce was the first person to take the fruits of *Guizotia abyssinca* to Europe. The earliest name applied to plants grown from these fruits in gardens in Paris was *Verbesina oleifera* by Buchoz in 1775, probably as part of a polynomial (cf. Baagoe 1974: 3). Consequently this name is invalid, but it indicated the property of the plant as used then and now. A plant cultivated in Sweden from among the fruits supplied by James Bruce formed the basis for the first valid name applied to this oil-bearing plant, i.e., *Polymnia abyssinica* L. f. (1781). For a thorough analysis on how the present name was adopted, the reader is referred to the works of Baagoe (1974).

Eragrostis tef (Zucc.) Trot.: *Poaceae* (*Teff* in Amharic)

This is one of the economically most important members of the grass family in Ethiopia. It is an annual plant widely cultivated in Ethiopia as a staple cereal crop, but it also occurs as an escape from cultivation. It is easily recognized by "its panicle of oblong, nonshattering spikelets full of plump grains retained within the swollen florets" (Phillips 1995). A large number of cultivars have been recognized based on the color of the grains with the major types being white, red, or black.

The genus *Eragrostis* consists of about 350 species (Phillips 1995). *Eragrostis tef* is an allotetraploid ($2n = 4x = 40$) and its origin is as yet unknown although it is closely related both morphologically and genetically to the widespread and weedy *Eragrostis pilosa* (Ingram and Doyle 2003).

The grains of *Eragrostis tef* are finely ground or milled and Ethiopians prepare thin and flat pancake- or chappati-like "bread" called *injera* or *yetef injera* from the flour. Injera is utilized throughout highland Ethiopia and currently also it is being utilized in certain low-lying parts of the country, e.g., among the Somali population in eastern Ethiopia. Outside of Ethiopia, the Borana people (Oromo ethnic group) of northern Kenya use the grains as a staple food.

The chaff is also used mixed with clay in the construction of wall material for mud houses in Ethiopia. It is also used as feed for domestic animals. Thus no part of this plant is wasted. This latter use of the plant has recently gained ground in other countries. Teff is now widely grown in South Africa and Australia for hay production and in India as a green fodder. It is also grown as a health food product and as forage for livestock in South Dakota and Montana (Stallknecht et al. 1993) in the USA. The immigrant Ethiopian community in the USA also utilizes the grains of plants mostly cultivated in Idaho in the preparation of injera.

The specific epithet *tef* is taken from the Amharic vernacular name Teff. The first cultivated teff plant in Europe was in the botanical gardens at Firenze (Florence) in Italy from grains collected by James Bruce in Ethiopia. It was subsequently named *Eragrostis tef* by Zuccagni in 1775. A large number of studies have been published on the biology and chemistry of *Eragrostis tef* (Ingram and Doyle 2003; Ketema 1997; Bekele et al. 1995 (as Bekele, Endashaw in ref.), as examples).

Ethnobotany of the Incas

Jan G. R. Elferink

The conquest of America resulted in a considerable enrichment of the number of plants that could be used by Europeans in medicine and nutrition. Important examples are the potato, maize, beans, cacao, chili pepper, quinine, and so on. All these plants were widely used by the pre-Columbian peoples, among which were the Incas. The Incas were only one of the many highly developed civilizations that developed in the Andes and the Peruvian shore of the Pacific Ocean. Like the Aztecs in Mexico, the Incas were a young culture, starting their development in the thirteenth century. When the Spanish conqueror Pizarro arrived in Peru in 1531, the empire of the Incas was enormous, stretching from what is now Colombia in the North, to the middle of Chile in the South.

Information about the use of plants in all aspects of daily life by the Incas (i.e., Inca ethnobotany) comes mainly from the Spanish chroniclers who accompanied or followed the Spanish conquerors. Unfortunately their information is far more limited than of the chroniclers of the Aztec region. As a consequence we know less about Inca ethnobotany than about Aztec ethnobotany. The chronicler Cobo gave the most extensive description of Inca plants. Some indigenous chroniclers, such as Poma de Ayala, gave some original applications of plants by the Incas. A very late work by Losa contains material that was mostly derived from ancient sources (including Cobo), and thus provides information about the use of plants that is probably of pre-Columbian origin. Besides the information written down by the chroniclers, an increasing quantity of information comes from archeological findings.

Although the amount of information about the use of plants by the Incas is limited, the amount is far too large to cover in a short paper. Therefore only a restricted number of items of Inca ethnobotany will be dealt with. These items come from the use of plants in medicine, and in connection with their role in magic and religion. There is excellent additional information about Inca ethnobotany. These include the works of Yacovleff and Herrera, Towles, Alarco de Zadra, Bastien, Brack Egg, Valdizan, and Maldonado. Unfortunately some of these works are not easily accessible. A very good website about the potential economic applications of Inca food plants is ►http://www.nap.edu/books/030904264X/html/.

Medicinal Plants

The Inca Herbalist-Physician: Hampicamayok

In his description of the Inca physician, Cobo (1964: 256) underlines the importance of the knowledge of medicinal plants for this profession.

> …Their physicians were in general old people and highly experienced… They had little knowledge about the nature of the diseases and about their specific names… [They knew] many herbs to cure them. They had more knowledge about wounds and sores… and the particular herbs to cure them. They never used complex drugs, they cured with simple herbs, and between them there were many great herbalists… from whom we learned the virtues of many plants which we now use in our cures. With these simple drugs they also used to make fomentations and perfumes, which they applied in fever and other ailments…

Other chroniclers such as Garcilaso confirm the importance of knowing plants among the Inca physicians. Though Garcilaso is sometimes contradictory in his descriptions of the medical abilities of the Incas he praises the herbalists. There were "great herbalists who were very famous in the days of the Incas. These herbalists learned the virtues of many herbs and taught them by tradition to their sons; they were regarded as physicians…" (Garcilaso 1966: 121).

The most common name for this type of physician was the *hampicamayoc*, literally "official in charge of medicines" (Poma de Ayala 1980; Gonçalez Holguin 1952; Morua 1946: 113). Calancha states that the (h) anpicamayos, who were called *oquetlupuc* in some coastal regions, were physicians with good reputations (Calancha 1974: 1248).

Besides Cobo some other chroniclers made statements which give an idea of the knowledge about medicines of the indigenous herbalists. Without referring directly to the herbalist, Blas Valera stresses the large number of medicinal plants of the Incas. He says that if they were all known there would be no need to bring herbs from Spain or elsewhere, but that the Spanish doctors set so little store by them that even those which were known to be used by the Indians have in the main been forgotten (Valera 1992: 132). It is not quite clear if the Kallawayas, the traveling herbalists of the Andean regions in Bolivia and Peru, knew the hampicamayok. About these Kallawayas (or Callawayas or Callahuayas) a large amount of information is available concerning their role in folk medicine of the last few centuries (Bastien 1987).

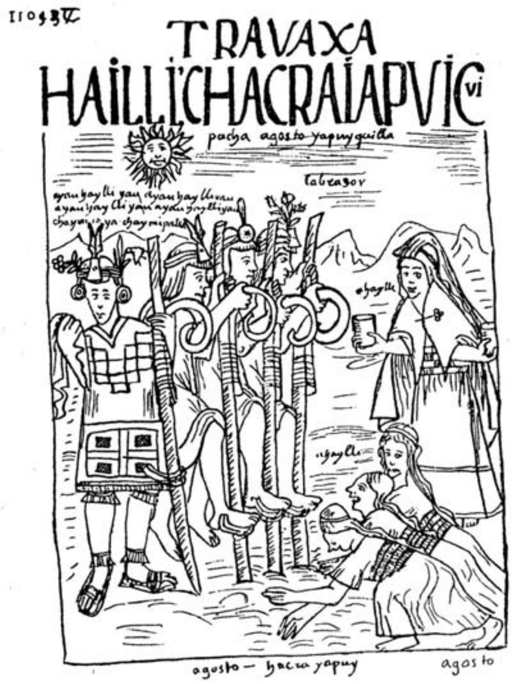
Plants Used in Medicine

In contemporary Peruvian folk medicine a very large number of medicinal plants are used, but the chroniclers described only a relatively small number of them, only a few hundred. That does not mean that the Incas did not use them. It is more an indication that the chroniclers for the Inca region were far less competent than those of the Aztecs. Cobo has especially described many Inca plants. Among these were a few that were

Ethnobotany of the Incas. Fig. 1 Maize or *sara* was an important food plant. According to the chroniclers, the consumption of maize products was the reason for a low incidence of gout among the Incas. This and the other botanical pictures are from *Köhlers Medizinal-Pflanzen*.

more important in Inca medicine than others. Maize or *sara* (*Zea mais*) was not only an important diet staple but was also an important medicine, as was the slightly alcoholic beverage called *chicha* that was prepared from maize (Fig. 1). According to several chroniclers the consumption of maize and chicha was the reason that they saw very few kidney and bladder complaints among the Incas (Fig. 2).

In the work of most chroniclers only a few plants are mentioned. It seems likely that those few plants mentioned repeatedly by different authors were of special importance and widely used. If this reasoning is correct then *molle* (*Schinus molle*) was one of the most used medicinal plants (►http://www.herreros.com.ar/melanco/elferink.htm). Contreras y Valverde (Contreras y Valverde 1965: 11, 12) states that the Indians considered the molle as a universal medicine against all their ailments. The differential use of molle is a good example to show that Inca physicians were quite aware that the eventual medicinal effect was dependent on preparation and means of application. The tree exudates a resin that was taken as a purgative and against melancholy; the resin in wine was against dropsy (Lizarraga 1968: 81; *Relaciones Geográficas* 1965: I-349; Vazquez de Espinosa 1969: 432). To cure leishmaniasis the resin and the bark of the tree were boiled in water until the water remained colored, and from this fluid the Indians took a portion on an empty stomach, and a second portion in the afternoon (Cobo 1964: 6-LXXVIII). The



Ethnobotany of the Incas. Fig. 2 Ploughing by special implements as preparation for sowing maize was ceremonially initiated by the Inca ruler and his family, recognizable by the large earrings.

Ethnobotany of the Incas. Fig. 3 *Datura stramonium* or *chamico* was used in medicine and in malevolent practices.

dried and pulverized resin was applied against ulcers. Lizarraga describes the resin as an excellent remedy for diseases of the respiratory system; he had tried the resin on himself (Lizarraga 1968: 81). The leaves, cooked and applied in a bath, were used for gout, and the crushed leaves were applied on wounds (Cobo 1964: 6-LXXVIII). The liquid made by boiling the leaves in water was a good remedy for eczema (Garcilaso 1966: 504). From the leaves a kind of oil was prepared that was useful for pain in the joints and for ailments of the stomach (*Relaciones Geográficas* 1965: I-349). A decoction of the leaves was applied as a bath for the treatment of the swollen legs of dropsy patients, and for gout. A plaster of the fruits was supposed to be effective for stomach complaints (Cobo 1964: 6-LXXVIII). The fruits of the molle were crushed and the juice gave a beverage that was taken for kidney and bladder complaints (Garcilaso 1966: 504). The fruit was also used to prepare a kind of *chicha*, which was more intoxicating than the chicha made from maize, and which was highly esteemed by the Indians (Cobo 1964: 6-LXXVIII). Besides medicinal properties the molle possessed some other qualities. Its wood was preferred as the basis for charcoal. This was the reason that it lost its importance in colonial times. Before the conquest the tree was very common, but a few years after the conquest it had decreased dramatically (Garcilaso 1966: 504) because of the need of charcoal for brasiers.

Another plant with widespread application was the *quinua* (*Chenopodium quinoa*). The plant was an important food-plant; it was especially attractive because it grew at high altitude. It was also used in medicine for a number of ailments such as stomach complaints, inflammations, spasms, swellings, fever, liver complaints and so on (Losa 1983: 71, 72; Calancha 1974: 138; Garcilaso 1966: 500). Another attractive feature was the possibility of preparing a good quality of inebriating chicha.

The *chamico* (*Datura stramonium*) was a strongly hallucinogenic plant (Fig. 3). In low doses the plant was used against fever, insomnia, inflammations, and to abate pain. According to Cobo the chamico was taken to get inebriated. Higher doses were used in criminal practices, a custom that has persisted till modern times. According to Cobo the chamico was secretly administered to victims who became intoxicated, and thus could be robbed easily. The chroniclers do not report about the use of chamico in religion, in contrast with other psychoactive plants.

Some plants, such as *coca*, *sayri* (tobacco) and potatoes were especially important in social life as food plants or in religion as offerings (▶http://www-personal.umich.edu/~jlvoris/thesis.html). However, all of them were also used as medicine. Chewing of coca leaves was practiced to ease hunger, thirst and tiredness, and this habit became especially important after the conquest (Fig. 4). Coca leaves were applied

Ethnobotany of the Incas. Fig. 4 The coca plant played a role in Inca religion and medicine. Its use in pre-Hispanic times, however, was strongly regulated by the Inca ruler.

externally to strengthen broken bones and to cure wounds and ulcers. The decoction was taken against diarrhea and to combat stomach complaints. The dried pulverized leaves were used for asthma. Coca was added to tobacco and chewed maize in an ointment to treat the bites of poisonous animals (Lope de Atienza 1931: 75). Two types of tobacco were distinguished: a cultivated and a wild form. It seems likely that these two forms correspond with *Nicotiana tabacum* and *Nicotiana rustica*, respectively (Wilbert 1987; ►http://www.hoboes.com/html/Politics/Prohibition/Notes/Shamanism.html). Both were used in medicine, but mostly it is not indicated which form was used. The root of the wild form was called *coro*, and was especially suited for a number of diseases, including syphilis. Tobacco was usually smoked, but the Indians used the tobacco also as snuff (Cobo 1964: 4–LVI). Tobacco was used to treat headache and migraine, and to improve sight. Poma de Ayala states that tobacco, in the form of snuff, was used against fever and cold (Poma de Ayala 1980: 769). One of the main applications of tobacco was to treat bites of poisonous animals (Apuntes 1987: 14; Maroni 1988: 157). The medical applications of potatoes were limited. Cooked potatoes were applied against gout. Potatoes were freeze-dried for conservation, and the resulting product was called *chuñu*. The chuñu was considered an excellent remedy against ulcers, spasms, pain of syphilis, and verruga (Cobo 1964: 4-XIII). The Incas knew many tubers that were very important as food plants. All these plants, among which are potato, *oca* (*Oxalis tuberosum*), *maca* (*Lepidium meyenii*), *ulluco* (*Ullucus tuberosum*) and *añu* (*Tropeaolum tuberosum*), were also applied in medicine. About the economic aspects of these plants an excellent internet source is available (►http://www.nap.edu/books/030904264X/html/).

Procreation and Plants

A number of plants were used to modulate fertility, or to induce sterility. The use of plants was mostly combined with magic. Among the plants that were applied to induce fertility were the *cabega*, the *vilca* (*Anadenanthera colubrina*), the *espinco* (*Medicago hispida*), and the *mocomoco*. Murua (1987: 435) states in a general way that the Indians used many plants and potions, not only to procure fertility, but also to induce sterility. In a society where having children was important, the administration of sterility-inducing plants was a severe crime that was punishable by death (Casas 1939: 147; Elferink 1999). Because those who induced sterility saw few reasons to be communicative, the chroniclers write in general terms about it and give no concrete names of plants. A colonial source reports that the Peruvian Indians considered the consumption of an infusion of the leaves of the *sogue* (*Salix humboldtiana*) a means to cause sterility in women (Losa 1983: 110). It is noteworthy that the Incas used the plant for several medicinal purposes, but that for these applications the infusion of the leaves was not taken orally.

Both plants and magic were applied to increase or to decrease libido (Elferink 2000). Acosta warned that the excessive consumption of *uchu* or *ají* (chili pepper, *Capsicum annuum*) by youngsters was undesirable, because of the aphrodisiac action of the plant (Fig. 5). This pepper was applied frequently to spice meals. Its use was so common that abstaining from consuming ají was considered fasting. Other plants described as an aphrodisiac were the *cuchuchu*, the *siaya*, the *tocoracas* and the *itapallo*. The *añu*, presently better known as *mashua* (*Tropaeolum tuberosum*), has been described as an anaphrodisiac (Cobo 1964: 171; Garcilaso 1966: 501). The Inca ruler gave the roots of the plant (it is an important food plant) to their soldiers as food, so that they forgot their wives. A later source describes the plant as an aphrodisiac (Losa 1983: 133). From the plant called *pencácuc* (*Mimosa* sp.) a male and a female form existed. Cobo describes the aphrodisiac properties of this plant, and he states that only the roots of the male form of the plants were stimulating; the roots of the female form had the opposite effect. A comparable peculiar difference between the male and female form of a plant has been ascribed to the *chutarpo* (or *huanarpo*). The male form, *huanarpo macho* (*Jatropha*

Ethnobotany of the Incas. Fig. 5 *Capsicum annuum* or chili pepper was an important food plant. It was considered a medicine and also an aphrodisiac.

macrantha), was known to act as an aphrodisiac. The female form, *huanarpo hembra* (*Cnidoscolus peruvianus*), acted in the reverse way, and could be used as an anaphrodisiac to annul the effect of the former (Santa Cruz Pachacuti 1992). Although the effects of these plants have not been investigated, the description suggests that the plants possessed a magic action rather than a real one. However, in contemporary folk medicine the huanarpo macho is still used as an aphrodisiac for men, while the huanarpu hembra is considered an aphrodisiac for women and a desaphrodisiac for men (Brack Egg 1999: 145). The *maca* (*Lepidium meyenii*) is a plant that has gained a lot of interest in recent times because of its supposed aphrodisiac and other properties. Because it can stand low temperatures, it was a favorite food plant of high altitudes. Descriptions about its use as an aphrodisiac in ancient Peru are scarce. Cobo (1964: 4-XVI) suspects that the relative increase of the population in the province of Chincha-cocha was due to the "hot" properties of this plant.

Magic Plants

Plants–Religion–Magic

A few plants played roles in Inca religion because they were used as offerings. Coca and tobacco were most frequently used (Fig. 6). Much information is available about coca and the Incas. The plant was important, but mainly for the upper social classes, because common men were not permitted to chew coca except with the ruler's permission. In some regions the *espingo* was

Ethnobotany of the Incas. Fig. 6 Tobacco was considered a medicine rather than a recreational drug. Two types of tobacco were used. The wild tobacco was probably identical with *Nicotiana rustica*.

frequently used as an offering (Arriaga 1968: 211). In many burial mounds of the Chimus (the Chimu kingdom was conquered by the Incas) strings of espingo seeds have been found. Priests used espingo in chicha to get very drunk, suggesting that the plant had psychoactive properties. The identification of the plant is not certain. In an indirect sense maize was the most important plant in religion, because chicha prepared from maize was used by all important and not-important ceremonies as an offering. Furthermore, maize was the basis of *sanco*, a kind of dough or bread that was used in religious ceremonies as a kind of communion.

Maize, coca and potatoes were so important that figures were made from them. These were called *saramama*, *cocamama*, *papamama* (or *axomama*), respectively, and were venerated as objects with supernatural powers. The veneration had a practical background: it was meant to have a good crop of the product from which the figure was made (Arriaga 1968: 200, 204, 205, 273; Albornoz 1988: 165). The religious importance of these plants is probably connected with the appreciation that the Incas had for these plants: coca as a psychoactive plant, and maize and potato as important food plants. In addition, all three plants were used in medicine.

Divination

Some plants played a decisive role in Inca divination. To obtain an idea about the importance of divination in Inca society we only have to look at the different types of diviners described by the chroniclers: more than 50 Quechua names are reported. The absolute number of diviners was also very large, as indicated by Acosta (1954: 172) and others (Morua 1946: 72; *Relación de los Agustinos* 1992: 8) who simply state that there were innumerable diviners. Cobo confirms that there were many diviners of several types (Cobo 1990: 160–163). In every town there were many of them, a statement that earlier was also made by Cieza de Leon (1962: LV). Citing another source, Cobo gives the figure of 475 people in Cuzco who had no other occupation than just divining. Intuitive divination was among the principal types of divination, and was often mediated by oracles in the form of *huacas*. A number of (mostly psychoactive) plants were applied to facilitate contact with the supernatural. Diviners called *yacarcaes*, who recruited spirits from fire, took coca leaves. They pronounced spells with which they summoned the spirit of the person from whom they wanted information. After a few other rituals the "devil" (as the chroniclers describe it) came and without being seen spoke to the attendants. He told them that he was the spirit of the person to whom they wanted to speak (Cobo 1990: 169). The procedure was followed in divinations where potential dangers for the Inca ruler or the empire were determined. That could be threat of rebellion or a plot against the Incas. The procedure resembles the one that was used by Inca sorcerers in love affairs. Here tobacco in combination with coca was applied. The person who wanted the love of another went to these sorcerers with a piece of clothing of that person. The sorcerers used coca and tobacco to get into a trance and raise the spirits of persons who had to become the beloved one.

Vilca (*Anadenanthera colubrina*) was very popular among diviners, who consumed the drug in the alcoholic beverage chicha (Cobo 1990: 169), to get intoxicated and attain the right psychic condition to make divinations (Fig. 7). According to Acosta (1954: 172) vilca, alone or in combination with chicha, was applied for all types of divinations. Among the questions which had to be answered, were predicting future events such as the outcome of certain enterprises, whether one would stay healthy or become ill and die. Another purpose was to find stolen or lost goods. For the same purposes the *achuma*, now better known as San Pedro cactus (*Trichocereus pachanoi*), was used. Murua has described the divination ceremony.

> To perform these superstitions and divinations they locked themselves in a house that was closed from within. There they started to drink and to get intoxicated until they lost their senses, and after a day they gave answers to the questions. To reach this effect they smeared their body with certain ointments. The sorcerers first talked with the devil in an obscure place in a way that the people heard a voice, but did not see who talked. They performed many ceremonies and offerings, and answered the questions with yes or no, as they liked it. For this purpose they used vilca or achuma. (Murua 1987: 432–434).

Ethnobotany of the Incas. Fig. 7 A number of psychoactive plants were used in divination practices. Among these was the *vilca* or *Anadenanthera colubrina*. Vilca was also the name of certain idols. Here the Inca ruler talks with the vilcas and huacas.

Currently some other psychoactive plants such as *ayahuasca* (*Banisteriopsis caapi*) are used in divination, in addition to those mentioned before. It is not sure however, if ayahuasca was used in Inca times.

Ethnobotany in India

N. C. Shah

Ethnobotany is the use of plants in material or abstract form among ethnic communities or tribal people. Sometimes, it is regarded as ethnographical or anthropological or tribal botany. India is a vast country with a variety of topographies, climates, vegetation, and people. When discussing ethnobotany in India, we can consider two groups of people, those living in small cities or rural villages and tribal peoples who live in remote villages. India has a population of 102 million, out of which about 50 million people belong to 550 tribal communities. There are 325 total languages with a large number of dialects spoken within the country, of which 18 are official including English, Sanskrit, and Urdu.

Ethnobotany is a combination of ethnography and botany. Ethnographers describe the people of a region including their race, language, and their uses of plants:

- Food and its methods of preparations
- Medicine
- Extraction of fatty oils
- Edibles and non-edibles
- Condiments and spices
- Seasoning material for food
- Drinks and beverages
- Incense
- Household furniture
- Agricultural tools
- Utensils

In abstract form plants can be used in socio-religious and socio-cultural ceremonies, in worship, songs, sayings, similes, riddles, proverbs, and in mythology.

In the study of ethnobotany, native or regional names are collected with their phonetically correct pronunciation known as *transcription*. The native or cultural names are deciphered, etymologically and philologically with the help of local guides or linguists. This adds interesting information about the plant. As an example, in Ladakh, *Erigeron alpinus*, a small herb, grows near the glaciers and is locally known as *Kukling kukling chi bhando*. It is said that a particular type of insect eats only this plant. An interesting folk tale is attributed to the naming of this plant. Once, the insect that eats it did not get this plant, and when he was coming back after the day's toil, another insect asked him whether he got his favourite plant to eat. He replied, "Kukling kukling chi bhando" (Yes I got it but it was too bitter) (Shah 1994a). The botanical names of the plants, with their synonymy and family, habit and habitat, distribution within the region, and phenology (time of flowering and fruiting), are usually given.

Ethnobotany in India started when the British botanists came to India and searched for plants to study and also noted the native uses of the plants. Roxburgh (1832) described the use, the vernacular names, and the botanical identification of plants. Describing the use of *Tylophora asthemetica* leaves for asthma and their roots for dysentery are part of his ethnobotanical contributions (Shah and Kapoor 1976).

In 1873, Sir George Watt studied the economic plants of the Manipur and Burma (Myanmar) border for 10 years. In 1883 he was put in charge of an exhibition on Indian economic products sponsored by the then government of Bengal (now West Bengal and Bangladesh). Plant exhibits from all parts of the country were obtained and, after he obtained proper botanical identification, vernacular names and information on various uses, they were exhibited in Calcutta. This was the first workshop on Indian ethnobotany. Sir Watt published, with the help of the material from the exhibits, his monumental work, *Dictionary of the Economic Products of India*, with an index of 3,000 vernacular names and various uses from different parts of India. He also supplied the plant product names in different languages including Arabic, Persian, Sanskrit, Hindi, Bengali, and the South Indian and tribal languages and dialects such as Bhils, Gonds, Nagas, Santals, and Bhotias. In his publication he reported various uses of plants such as indigenous dye plants, such as *Indigofera tinctoria* (Neel), *Saccharum officinarum* (Ganna or cane sugar), and 190 plants as indigenous detergents and substitutes for soap, as well as 500 fodder plants from different parts of the country. He also mentioned sacred and traditional uses of plants, which had no economic significance. He listed *Butea frondosa*, describing its traditional and medicinal uses, the use of its wood and twigs in *Homa* or sacrificial fire and its leaves as plates in the Hindu thread ceremony for eating (Watt 1889–1896). His work is the first true collection of ethnobotany in India.

Actual study on ethnobotany was initiated by Dr. S. K. Jain, who conducted ethnobotanical surveys in Madhya Pradesh and reported various uses of plants (Jain 1963a): as medicine and food (Jain 1965a); for making musical instruments by the Gonds tribe of Central India (Jain 1965b), and in magico-religious rites, taboos, and beliefs among the Adivasi of Bastar in Madhya Pradesh (Jain 1963b, 1964).

Thereafter, there were a number of sporadic studies (Jain and Tarafder 1970; Shah and Joshi 1971). In the first work, the use of medicinal plants by the Santal people, earlier reported by Bodding (1925, 1926), was explained. In the second work, the ethnobotany of the Kumaon Himalayas was reported with various uses of plants, such as for medicines, food, condiments, or incense, along with the etymology and philology of the vernacular names and a brief introduction to the tribal people and their communities.

The subject of ethnobotany was made official in 1982 after the establishment of the Society of Ethnobotanists. A newsletter was brought out and seminars, symposia, training courses, and workshops were held. Later on, in 1990, a journal *Ethnobotany* was published. In 1983 an All India Coordinated Research Project on Ethnobiology was initiated at the Regional Research Laboratory in Jammu. It was a multi-disciplinary, multi-institutional, and action-oriented research program for generating and documenting the multi-dimensional perspectives of the culture, traditions, and knowledge of tribal life.

Work on the ethnobotany of different regions and tribes was published for Central India, Madhya Pradesh, Bihar, Orissa, North Eastern India, Arunachal Pradesh, Assam, Meghalaya, Maharashtra, Nilgiris, etc., in the proceedings of seminars and training courses and in other compilations (Jain 1981, 1987, 1990). The work was summarized by Binu et al. (1992), Maheshwari (1996), and Jain (2001). There are a number of institutions and universities where ethnobotanical field work was conducted: Botanical Survey of India, Howrah; Regional Research Laboratory, Jammu; National Botanical Research Institute, Central Institute of Medicinal and Aromatic Plants and Central Drug Research Institute at Lucknow; Tropical Botanical Garden and Research Institute, Trivandrum. Many Ph.D. theses were awarded in ethnobotany at a number of universities such as University of Calcutta, University of Kumaon, and University of Rajasthan.

Ethnobotany in India can be explained under the following headings.

Food Plants

Three species of *Amaranthus*, *A. caudatus*, *A. hybridus* ssp. *hybridus* and ssp. *cruentus* are cultivated for their seeds. They have been grown along the whole length of the Himalayas, from Kashmir to Bhutan above 1,500–3,000 m and also on the South Indian hills. Amaranths are fast-growing, cereal-like plants that produce high-protein grains in large, sorghum-like seed heads. The origin of *A. caudatus* is the Andes in South America and of *A. hybridus* is Mexico and Central America. However, the crop has declined to almost a vanishing relic in its homeland, and more Amaranth grain is now produced in Asia especially the hill regions of India, Nepal, and Bhutan than in America (Shah 1987).

The young leaves and seeds are used as food. These are called *Marca*, *Scu* or *Cu* or *Kedari-cua* (Himachal Pradesh and Uttaranchal), *Bustanfroz* (Kashmir), or *Ramdana* (Hindi). The etymology of *Scu* and *Cu* is obscure, *Kedari-cua* meaning *cua* of Kedarnath, *Marca* possibly after the name of Marca, a Bhotia tribe. However, it is interesting to note that *Amaranthus* sp. is called *scul* in Mexico (Berlin et al. 1974: 158), which is phonetically very near to the local names *Scu* or *Cu*. In the Himalayas the seeds are parched and then made into flour for making bread or *capati* and the young leaves are used as vegetables. It is one of the commodities Hindus use for breaking the day's fast in Uttaranchal and other parts of the country, and it treated as sacred (Shah 1987).

Fagopyrum tataricum is cultivated in higher altitudes, from 2,500 to 3,500 m, throughout the Himalayan region. Known as *Fafar* (Bhotia) *Fagopyrum esculentum* is cultivated from 1,500 to 2,500 m throughout the Himalayan region and in the Nilgiri hills. The leafy vegetable is known as *Oogal*; the seed grains are known as *Kotu* (Kumaoni), *Kannuja*, *Palti* (Garhwal and Bhotia), *kotu* (Trade name), and buckwheat (English). Its flour is used by the Bhotias in various sacred functions and ceremonies. They believe that it warms the body. The nuts are also used for making local drinks and are also traded to people in the plains. They have a high commercial value as the flour is baked or fried into bread and eaten by Hindus to break their fast (Shah 1987).

Tribal communities throughout the world use yams, *Dioscorea* spp. In the Kumaon region, the bulbils and root tubers of *Dioscorea bulbifera* (Gethi) are used as food. There is a Kumaoni saying, "Khaunhi ne gethi kamar bandhi peti" ("Dioscorea is not available in his house to eat and even then the person poses himself as a big guy"; Pandey and Pande (1999).

Another species, *Dioscorea melanophyma* known as *Tarur* or *Tikhun* (Kumaoni), is the staple food of the Rajis. This tribe is apparently of non-Aryan affinities and is commonly known as Ban Raut, Ban-Manus. Earlier they were known as cave dwellers, but they now live in well-built houses in the Pithoragarh district, Uttaranchal. The present population of the tribe (in 1993) is 556.

The Rajis are known for their craftsmanship in making wooden utensils (bowls) from the wood of a small tree, *Boehmeria rugulosa* (Genthi). Net bags are made for collecting the wild growing root tubers of *Dioscorea* from the fibres of *Boehmeria macrophylla* (syn. *B. platyphylla*), known as *Gargilla*, with a special digging tool known as *Bheku* (Figs. 1 and 2). The Rajis believe that eating *Tarur* rhizomes alleviates hunger (Shah 1987, 1994b). In Uttaranchal and other parts of the Indian Himalayas, another crop which is cultivated on non-irrigated land is *Eleusine coracana*, commonly known as *Ragi* or *Madua* (finger millet). In Uttaranchal, also growing in the wild, are *Urtica parviflora* and *U. dioeca*, Himalayan stinging nettle and stinging nettle, which are collected along with other fodder grasses and locally called *Shishuna* (Kumaoni) and *Kaldiya* (Gahwali). Its young offshoots are used as a vegetable. The Himalayan stinging nettle and finger millet are both designated as poor man's food.

There is a saying in the Kumaoni language, "Madua ka roti shishona ka sag, Khale rankara yo tero bhag" (O lad! what a pity on your poor fate that you have to eat the cooked vegetable of stinging nettle with a bread of finger millet). *Shishuna* tastes like spinach. Another interesting seed crop, which is cultivated throughout the Kumaon region, is *Glycine max*, locally known as *Bhat mas* or *Bhat*, black soy or black bean. This is a most interesting crop, introduced from China as the

Ethnobotany in India. Fig. 1 A Raji boy showing *Japi*, a net bag made up of fibre from *Gargilla* (*Boemehria platiphylla*) and also holding *Bheku* a digging tool for *Dioscorea* spp. (photo by N. C. Shah).

Ethnobotany in India. Fig. 2 A Raji girl stripping fibres from *Gargilla* (*Boemehria platiphylla*) to be used for knitting a net bag known as *Japi* (photo by N. C. Shah).

wild Soya bean, *G. soya*. It is found only in China from Heilong to Taiwan to Tibet, Japan, Korea, and Russia (Shah 2002 and 2006).

The local name was possibly coined because of the sound, Bh..a..tt, which emerges when the black bean is parched (Shah 1987).Various recipes are prepared, such as *thatwani* or *rasa*, *dubka*, *curkani*, and *jaula*. They are prepared in an iron bowl known as *karahi*. These recipes are very nutritious and they are prepared in every house of Kumaon (Shah 2002 and 2006). Hymnowitz (1969) conducted a survey in Kumaon to collect a germplasm of the species, when he noted that kwashiorkor, a disease caused by protein deficiency, was not found amongst the children of the Kumaon hills.

Incense, Condiments, Seasonings, and Narcotics

Burning of incense has long been part of Indian culture. It is not clear why the incense is burned. *Aquillaria malaccensis* (*A. agallocha*) is a tree found in Arunachal Pradesh and Assam. The fungal-infected highly aromatic wood is used as incense and known as *Agru* after which the common Indian name *Agar batti* (incense stick) was coined. In ancient times, it was an important commodity of export from India and it is the costliest aromatic wood in the world. The current rate for the wood is ca. US $2,000 per kg, and now it is banned both for collection and export.

Nardostachys jatamansi, *Jatamansi*, or spikenard, was known not only in India, but also in Assyria, Egypt, Greece, Rome, and Arab countries as an important import from India. It was known for its various uses such as incense, a nerve tonic and for its use in hysteria, epileptic fits, heart palpitations, etc. The rhizome of *Nardostachys jatamansi* grows in the high Himalayas in Uttaranchal, Nepal, Bhutan, South China, and Tibet. It is used by the Bhotias as incense and for medicinal use. It has religious as well as cultural sanctity. In Kumaon a song is sung in its praise usually in fairs and festivals (Shah 1987, 1994d). In Mesopotamia, it has been recorded in cuneiform-shaped script (Speiser 1951). Its association with Alexander the Great has also been established (Rücker and Glauch 1967), and it was mentioned in the holy Bible (Modenke 1954). Akbar the Great used it as a royal perfume (Jarett 1948), and the Monpas (Arunachal Pradesh) (Dam and Hajra 1981), Santals and other tribals of South India also recorded using it (Jain and Tarafder 1970).

Jurinea dolominaea (syn. *J. macrocephala*) is locally known as *Dhup* in Kashmir and the Punjab Himalayas and *Guggul* in the Kumaon Himalayas. *Dhup* means incense. The rhizomes and roots are collected and traded, to be used mostly in sacrificial fire or *homa*. The herb was also used in royal cosmetic preparations during the reign of Akbar the Great (Shah 1994a).

Cannabis sativa is commonly known as *Bhangãlu*, *Bhangãu* (Kumaoni), *bhangah*, *gangika* (Sanskrit), hemp or marijuana (English). *Bhangãu* or *Bhangãlu* are derived from the Sanskrit word *Bhang*. The root of these words, “ang” or “an”, recurs in all Indo-European and modern Semitic languages (De Candolle 1886: 148). In Uttaranchal, local people recognize two types of *C. sativa*: the cultivated one, known as *Ghar-bhangau*; and the wild one, *Kath-Bhangau*, which usually grows near habitations, mostly near cattle sheds known as *khattas*. *Kath* and *Ghar* mean wild and domestic. *Ghar Bhangau* are cultivated tall plants, 1.5–4 m high, grown mainly to procure edible seeds and fibre; *Kath Bhangau* are wild, comparatively short, 0.5–1.5 m, and are used to collect hashish and crude resin. In Uttaranchal, their seeds, seed oil, stems, fibre, leaves, inflorescence, and resin are used (Shah and Jain 1988). The fibre is used for making cordage or ropes and the pith of the stem is used as torchwood. The seeds are used as food (Shah 1997a, 2001).

The plant is also used as a narcotic. The plant produces three types of narcotics. (1) Hashish (*bhang*) consists of the dried leaves and flowers of male and female shoots. In the northern plains, a preparation of *bhang* is used as a beverage and sold Varanasi, Lucknow, and Allahabad. (2) *Ganja* consists of dried inflorescence specially from female plants without any leaves. (3) *Attar* or *charas* is the crude resin, which appears on the stem and inflorescence and is the strongest part. Cannabis is often seen growing around abandoned and dilapidated houses and is used abusively. When the Kumaoni people want to curse someone, they say, “Teri kuri bhangau jam jo”, which means, “May hemp grow in your house”, i.e. “May your house be ruined and damaged to such an extent that Cannabis will grow there”. People of Garhwal also name their male children after the intoxicant resin, *attar* obtained from the plant such as *Attar Singh* (Shah 1997a).

Liquor Producing Plants

There are a number of cereals which are used for producing liquor with or without fermentation in the Himalayas and other parts of the country. Some are *Hordeum vulgare*, *Juar*, or barley; *Eleusine coracana*, *Madua*, *Ragi*, or finger millet; *Echinocloa frumentacea*, *Jhungra*, *Madira*, or Japanese barnyard millet; and *Panicum miliaceum*, *Ceena* (*Kangi*), or common millet.

There are also trees from which liquor is produced. Most important among them is *Madhuca India*, commonly known as *mahua*. The fleshy pericarp is fermented and liquor is produced by fermentation. This is a common practice in central parts of India among the tribal and village people. The dried fleshy pericarp is ground to produce flour and bread is produced. The seed of this plant is used to produce edible oil.

Another tree is *Caryota urens*, known as *Mari*. The sap is collected in a pot which is hung and tied to an incised tree. The sap so collected is known as *Toddy*. It is used like a beer or it is fermented and then distilled to yield an alcoholic liquor.

Medicinal Plants

Rauvolfia serpentina is generally known as *Sarpagandha*, the local people used the roots in folk medicine in snakebite and to calm troubled people, in Bihar it was called *Pagal ki Dawa* (“the medicine of the insane”). The drug was adopted first in the Unani system of medicine and consequently in Ayurveda. Because of the alkaloid reserpine found in the root, antipsychotic and hypertensive properties are attributed to it, and it was included in modern medicine in the early 1950s (Shah 1995).

Recently, scientists at the Tropical Botanical Garden and Research Institute (TBGRI) found that the Kani tribes of Kerala use *Trichopus zeylanicus* ssp. *travancoricus* (*Trichopodaceae*), locally known as *Arogyapacha*. It is used as a health food to maintain vitality and as an immunomodulator to increase resistance against diseases in the body, as is ginseng. The extract of the leaves was commercialized by a pharmaceutical company and exported to Japan, Germany, Malaysia, and Indonesia. From the net profit obtained from the sale, 2% was shared between TBGRI and the Kani tribes of the region. It was the first model in the world of recognition of an Intellectual Property Right (IPR) pertaining to ethnobotanical and medicinal plant knowledge (Bagla 1999).

Socio-Religious and Socio-Cultural Plants

Plants have so deeply influenced the life and culture of the people of the Indian subcontinent that a number of plants are worshipped like deities (Gupta 1971; Gandhi 1989). In India, there are two kinds of worship: *Havan* or sacred fire, which means the act of oblation and sacrificial offering to Gods and Goddesses through fire. The Aryans used to offer their deities animals, butter and milk, cakes of barley, and the Soma plant, a divine plant not yet convincingly identified. A number of plants have been considered, such as Ephedra, Sarcostemma, Cannabis and Amanita muscaria, the fly agaric mushroom. (Mehdihasan 1963; Shah and Badola 1977 and Shah 2005). The latest speculation points more clearly to Ephedra as the likely species. People now usually use *Ephedra* species. There are a number of plant materials which are used in the oblation. These are cereals, sugar, raisins, dates, coconut, sesame (*Sesamum indicum*), and a number of medicinal and aromatic plants. *Puja* is a pre-Aryan practice and ritual, in which cooked food, vestments, ornaments and other materials like flowers, leaves, and water are offered to deities. The people burn incense and wave light in front of an idol, e.g. Arti. They also chant mantras. The word

Puja is derived from the Dravidian word *pu* meaning, flower, and *ja* meaning, "to do", so it is a flower ritual or *pushpakarma* (Shah 1994c).

There are many plants worshipped by the Hindus in India. *Ficus religiosa*, commonly known as *Peepal* (sacred banyan), is worshipped on every Sunday on every Somvati Amavasya of the year that is on the non-lunar day of the Hindu month known as Shravan, usually falling in July or August. Each part of this tree is considered sacred. In most Hindu and tribal communities, the bride is first married to a tree and then to the bridegroom. A Hindu never cuts the tree and cutting is equated with killing a Brahmin (Dube 1995). Every part of the plant is also considered medicinal, and Santals. Bodding et al. reported 16 therapeutic uses of the plant parts (Jain and Tarafder 1970).

In the month of Jeth (May–June), on a day with a full moon, the *F. benghalensis*, commonly known as *Vat* (banyanan tree), is worshipped. In Bhado (August–September) on Durva-ashtimi day, *Cynodon dactylon*, Hindu women worship the *Doob* grass and they also fast on that day. Doob grass is always used in performing *Pooja*. *Ocimum sanctum*, *Tulsi* (holy basil), is the highest venerated plant among the Hindus; it is believed to be an incarnation of a Goddess. It is always kept in every house and worshipped daily. It is used in cough and cold and fever as a household remedy. Some claim that it can cure cancer. *Curcuma longa*, *Haldi* (turmeric), is used as an important condiment in every house and in various religious ceremonies. It has a number of therapeutic properties, some of which have undergone scientific studies (Shah 1997b). There was a lot of hue and cry when some NRI Americans (Non-Resident Indians living in the United States) patented the use of turmeric for healing fresh wounds, which is quite a common use in India. After a long fight in the American courts, the Council of Scientific and Industrial Research (CSIR), New Delhi won the case after they presented documentary proofs of its uses in fresh wounds from old medical treatises. Last, but not least is *Azadirachta indica*, the Neem tree. All parts are regarded as medicinal for day-to-day ailments and diseases. It is sometimes called a "home tree doctor". It is not worshipped, but it has socio-cultural significance. On the first day of the Hindu calendar year known as *Samvatsar*, which is a festival usually falling in March, early in the morning a few leaves of Neem are eaten with a belief that the person will remain healthy throughout the year (Dube 1996).

The Indian subcontinent consists of separate linguistic communities each of which share a common language, traditions, and culture. If we want to learn the use of plants by a community, then we have to probe through their language as a tool.

A. Barrea, one of the first promoters of ethnobotany in Mexico, states:

> The best ethnobotanist would be a member of an ethnic minority who, trained in both botany and anthropology, would study the traditional knowledge, cultural significance, and the management and uses of the flora. And it would be even better for him and his people if his study could result in economic and cultural benefits for his own community (Martin 1995).

Ethnobotany: Malay Ethnobotany

ROHANI LONGUET

Is There Such a Thing as Malay Ethnobotany?

It is surprising that in a country as rich in floral species and knowledge as Malaysia, Malay ethnobotany – the knowledge that the indigenous Malays have of their flora – has not been studied as such. Lists of plants and their uses have been compiled, but not many systematic approaches on the perception of the flora by the local inhabitants have been made. That is probably because of the diversity of influences to which the country has been submitted through history. Complexity may be perceived as a lack of unity.

One must distinguish between the Malays living in Malaysia and the rest of the "Malay peoples" who have inhabited not only the Indonesian archipelago, but also areas from the Pacific to the Indian Ocean, from Madagascar to New Zealand and Taiwan. It is possible to cover the subject by considering the particular heritage of the Malays that are presently living in Malaysia. These Malay groups have developed a common indigenous system of botanical knowledge. Their system refers to a worldview and a perception of nature that is steeped in the great Asian traditions, but has a particular local terminology and an indigenous use of native – or imported – species. Such an enterprise is useful because, together with the other Malaysian citizens of various ethnic origins, the Malays of that country have to face the problem of the possible disappearance of their natural and cultural heritage.

Malaysia's Botanical Richness

Malaysia is located at the heart of the Indo-Malesian system, one of the biggest rainforest systems on the planet. Rainforests are defined as "evergreen, hygrophilous (living or growing in moist places) in character, at least 30 m high, but usually much taller, rich in thick-stemmed lianas and in woody as well as herbaceous epiphytes[1]" (Shimper 1903, in Dunn 1975). Diversity, splendour and luxuriance characterize the original flora of the country.

Malaysia itself is divided into two parts separated by a shallow sea. The West part comprises the Southern Malay Peninsula, and the East part comprises the Northwestern part of the island of Borneo. Almost 95% of the plants present in Borneo and Sumatra – which belong to the same geological area – are present in the Peninsula, a significant feature for the permanence of botanical knowledge among migrating peoples.

Both parts of the country have a "main range", a series of hills culminating at 2,187 m in Gunong Tahan for the Peninsula and 4,094 m in Mount Kinabalu for Borneo. From the hills, streams run down on limestone boulders to merge in majestic rivers that end in large estuaries where villages have settled. Up until the 1960s, forest covered 85% of the soil (Polunin 1988). A relatively small country, Malaysia has a rich density of species: 8,000–10,000 (compared to, say, 11,000 in India). Botanist Keng calculated that the Malaysian flora has 2.96% of the gymnosperms and 2.79% of the angiosperms of the world.

Three factors have contributed to the floral richness (Deverre 1985).

The climate, which is hot and humid, with rain all year round;

Geological stability from the beginning of the tertiary; and

The encounter and interpenetration, in the Peninsula, of two kinds of flora, from the Asiatic continent in the North and Malesian flora from the South.

Various floral landscapes create a rich pool of environmental resources for the inhabitants to draw from. There are mountains, hill forests, lowland forest, fresh water swamps, coastal beaches, saltwater swamps and agricultural lands.

The major botanical families are

1. The Dipterocarps. They are so large that a *cengal* tree in the state of Terengganu needed eleven men to circle its girth.
2. Palms. There are five times the number of native palms than in all of Africa.
3. Eugenias. They align the hill slopes with the bright red of their young leaves
4. Tall gingers, mostly strongly scented.

Malaysia is also home to half of the world species of Nepenthes, who digest insects in their receptacles, and to other botanical stars like the *Raflesia Tuan Muda*, the world's biggest flower, many species of orchids and prehistoric species like the *Gnetum gnemon* and the giant fern-looking *Cycas*.

[1] Epiphytes are plants that grow on other plants mainly for support. Examples of these in tropical rainforests are orchids and ferns. Epiphytes are sometimes also known as "air plants".

The Geographical and Historical Components of the Malay Knowledge of Plants

The botanical lore of the Malays reflects the Peninsula and Borneo's floral composition. But Malaysia was at a crossroads of maritime routes that brought in science and culture from three great civilizations: India, China and the Arab world.

First were the years of early trade. The people of the Peninsula collected and sold the fragrant *gaharu* (*Aquilaria Agallocha*), dammars (from various *Dipterocarpacea*) and camphor (from *Dryobalanocarpus camphora*); this trade was recorded in the Chinese chronicles (Weatley 1980). The Peninsula remained for centuries within the sphere of influence of the Indianized empires, Funan, Sri Vijaya and Majapahit. Its inhabitants may have benefited from early initiation to Ayurvedic botanical knowledge. Some common village native plants like *gandarussa* (*Justicia gandarussa*) and *patarwali* (*Tinospora crispa*) still bear Sanskrit names.

From China came Buddhist scholars. In the wake of Admiral Cheng Ho, a Chinese community settled in Malacca. Chinese *sen seh* and settlers established medicinal gardens around temples and houses, sharing knowledge on small tropical herbs such as the *empedu bumi* (*Andrographis paniculata*) (also an Indian plant) *getang* (*Spilanthes acmella*), and the *pegaga* (*Centella asiatica*).

Malays have also benefited from Arabo-Persian medicinal and botanical knowledge that included the value of spices as medicine as well as food flavouring and preservatives. They brought in plants names such as *limun*, *henna* and *halba*.

There was a permanent influx of visitors and settlers: from the South – Achenese, Minangkabau, Javanese, and Bugis; from the North – Pattani Malays and Chams, carrying Chinese, Vietnamese and Cambodian knowledge. For instance, Mohammed Yusoh is a well-known roots and leaves seller from the East Coast of the Peninsula. He claimed to have had Arabic, Javanese and Chinese "gurus". He was also so familiar with some aboriginal tribes that he was dubbed "Mat Sakai" (Mat of the aborigines). The term *Sakai* has since become derogative, and is now replaced by *Orang asli*, literally the "original people". The life source of the *orang asli* tribes is the forest. They are the ones who would have transmitted knowledge on dangerous species like the Antiaris dart poison, the *tuba* Derris to kill fish or the *susu harimau*, a contraceptive mushroom.

Like pharmacists, aboriginal people provided the medicines; like medical doctors, Malay *bomoh* or traditional healers would tune the prescriptions to their patients. Some Malay peoples – proto – or deutero – Malays like the Jakun – belong to the *orang asli* group. However, generally for the Malays, the forest is considered dangerous. It is a vast, inexhaustible store of resources to be exploited. Villagers on the forest fringes, hunters, martial art gurus, herbalists and animal traders make expeditions in the forest from the base of their village.

One difference between the forest dwellers and the Malay settlers is the level of intervention that the Malays have introduced in nature. They tended to select and "grow" their natural environment in settled villages while aboriginals made use of everything they needed on the large tracks of forest they knew, without changing the natural composition of species. Malay villagers encouraged the growth of *nipah, nibong, pinang* and coconut palms. They planted crops on the outskirts of their villages and fruit trees around their houses.

Another example of a transmitter of botanical knowledge is Tuk Ku Paloh – Syed Abdul Rahman (1818–1918), a religious teacher of Arabic lineage and a political advisor to three successive sultans of Terengganu. He planted orchards of *jambu* (*Eugenia* sp.) and *rambutan* (*Nephelium* sp.) fruit trees in his vast ashram-like compound. He even created a spice garden for medicinal use.

Species native to drier and cooler regions were acclimated. In the Northern states, a *Zyziphus* (*bidara*) used in religious rites (also belonging to the Chinese materia medica) is planted around mosques and cemeteries. The pomegranate, dear to Arabo-Islamic tradition and a symbol of fertility for the Chinese, is grown in some Malay gardens against climatic odds.

Concepts and Philosophy of Malay Ethnobotany

Researchers have been puzzled by the apparent contradictory and overlapping beliefs of the Malays. A traditional healer would summon spirits from the animist past, chant a Hindu *mantra*, wrap up the incantation in a Muslim *doa* prayer and prescribe a plant preparation. The Malays do not seem to have perceived a contradiction in their multi-layered spiritual interpretations of the relationship of man with nature.

Mohd (1995), writing about the passage from animism to Hinduism, suggests that the Malays "merely transferred their beliefs in spirits and in nature to the various Hindu gods." Subsequently, one could surmise that the belief in Shiva, a Hindu creator god, introduced the concept of a unique force behind nature, separate and above it, perhaps preparing for the Muslim concept of *tawḥīd:* the oneness of God.

During the nineteenth century, compilations of medicinal and botanical knowledge were made in *jawi* script or translated, giving lists of therapeutic plants. These, like the *Tajul Mulu"* (Medical Book of Malayan Medicine) or the *Ilmu Tabib* contain lists of charms and references that place them in traditional healing systems. The role and the effect of the plants were described according to their relation with the balance between the four elements, the humours and "hot or cold" or "wet or dry" states. Studies are still needed to identify to which tradition(s) they actually owe their formulas.

Today, the idea of an indigenous perception of nature – how the Malay villagers see themselves in relation to the plant world – can be found in interviews with villagers and forest workers, especially in remote areas. They have a strong sense of a reciprocal link between all living things as *insan* (creatures of God). "The growth of trees toward the sky is their prayer to God," explained an elderly lady. Plant collectors in the forest believe in the "signature doctrine". Just like the *Qurʿān* Holy Book, nature is knowledge revealed (*ilmu naqli*).

Villagers have long maintained a symbiotic relationship with nature. Plants are found everywhere in art and crafts; twirling *Cucurbitacea* and Ipomeas are found on carvings on *cenggal* wood verandahs (Said 2000). Flowers enliven the batik sarongs worn by the villagers. In *pantun* poems (Daille 1990), fragrant flowers of jasmine and *Michelia cempaka* decorate love promises. In cemeteries sweet smelling Plumeria species alleviate sadness. The Muslim paradise is pictured as a garden, so gardens also have religious significance. Even today, the Malays try to arrange some flowers to compose a welcoming entrance to their house (Nor 2003).

Malay Classification and Exploitation of Botanical Materials

In the vernacular system, plants in general – herbs, shrubs, climbers and epiphytes – are *pokok* (which means "tree" – in lay language). The "trees" are subdivided into *akar*, which means roots and climbers, *rumput* (herbs) and *paku pakis* – "nails" – for ferns.

The Malay floral nomenclature is pragmatic and empiric. It does not refer to a phylogenic organization of the floral kingdom; nor does it refer to Arab, Indian or Chinese classifications. Plant species receive their names by reference to their aspect (morphology) or their use (ergology/phytopharmacology) (Table 1).

A name sometimes evokes both aspect and use. *Tongkat* is "cane". In *Tongkat Ali*, it refers to the aspect of the straight growing *Eurycoma*, a shrub with a deep, hard-to-dig root. The word indicates the use: like a cane, it supports failing strength. *Putar* means "to turn" in Malay and Sanskrit. *Patarwali* (*Tinospora Crispa*) is

Ethnobotany: Malay Ethnobotany. Table 1 Examples of forest species familiar to the Malays and their vernacular names

Malay names	Translation	Botanical name	Reputed traditional use
Gajah beranak	Elephant giving birth	Goniothalamus	Post partum decoctions
Penawar hitam	Black medicine	Schortechinii	
Tongkat Ali	Ali's staff, sky pointer	Eurycoma longifolia	Febrifuge, sexual tonic
Teja lawang	Specific name	Cinnmonum	All medicinal decoctions
Aji Samat	Haji Samad	Jackia ornate	Tonic
Tengkok biawak	Neck of monitor lizard		
Betek hutan	Forest papaya	Renellia sp.	Nasal and sinus troubles
Setawar hutan	Forest antidote	Costus speciosus	Mostly decoration
Dedawai	Wiry one	Smilax callophyllum	Tonic, diuretic
Tongkat Ali	Ali's staff		
Kacip Fatimah	Fatimah's scissors	Labisia pointiana	Feminine health
Kerbau melawan	Fighting buffalo	Shefflera sp.	Sexual tonic
Gajah tarik	Pulling elephant	Strychnos intai	Tonic, hypotensor
Hujung atap	Tips of roof thatch	Baekia fructexcens	Postpartum
Mas secotet,	A spot of gold	Ficus deltoidea	Tonic for women
Telinga kera	Monkey's ear		
Tonkat Ali biru	Blue Ali's staff	Polyaltia bullata	Heart tonic
Cengal	Specific name	Neo balanocarpus heimii	Mostly building material
Resdong	Nose inflammation	Ervatamia	Nasal and sinus troubles
Telinga beruk	Bear's ear	Thothea	Diarrhea, colic
Mengkudu bukit	Hill Morinda,	Renellia speciosa	In medicinal decoctions
Ginseng Melayu	Malay ginseng		
Akar sarsi	Sarsaparilla	Cinnamonum ebracteum	Fragrant, diuretic

a spiralling climber. That name is also pronounced *putrawali*. *Putra* means "son"; *wali* is "representative". So the *Tinospora* in Malay is "the whirling plant that helps to get a male descendant". The pretty Tetracera climber is called *mempelas* – sandpaper – as its rough leaves are used to polish wood and metallic surfaces.

There are also specific species names, sometimes derived from the ancient Malay or Melano-Polynesian vocabulary. For instance, the sea Hibiscus is *Bebaru* from the island of Madagascar.

Composite plant names are formed by adding a qualificative identifying the individual species within the vernacular genus: *Limau* is for citrus, *limau purut* is *Citrus hystrix* and *limau nipis* is *Citrus aurantifolia*. A qualificative may indicate the degree of effectiveness of the material, either as a timber or medicine. *Tongkat Ali* is "Ali's own cane". Ali's name, the Prophet Muhammad's cousin, carries a connotation of effectiveness and strength. Other tonics for men are associated with Ali. Plants good for women refer to Fatimah, the Prophet's daughter.

Evocative qualificatives are drawn from the animal kingdom: elephants, bear, tigers, monkeys and buffaloes help characterize plants. The aerial *Paku langsuiyr* is the "vampire fern" – an *Asplenium* which hangs its large and long dishevelled leaves on the fruit trees at the back of a house. Information on location, origin or gender is frequent: "Female" often means a large variety and "male" a smaller one (noted by British forester Watson as early as 1928).

Like the *limau*, some plants names correspond a to modern botanic genus: *Uncarias* are *kekait*, some *Eugenias* are *kelat*, a word referring to the tart taste of their wood. The edible Eugenia are *jambu. Cinnamonun* species are known as *teja* with various qualificatives: *jantan* (male), *bulu* (hairy). The more poisonous ones are often called *medan* and may be used as insecticides. Misleading appearances or similarities are signalled by a repetition: *Annonacea* are *pisang pisang* – false bananas or the qualificative *hantu* (ghost).

Some plants are so specific to some ailments that they are called by the name of what they cure: there is "ring worm medicine" (*Cassia alata*) and the "sinusite trees" (*Ervatamias*). Or they may be known by the illness they cause. *Excoecaria agallocha (bebuta)* is the "blinding" or "blind one" because of its latex, which is harmful for the eyes.

Plant collectors and healers are familiar with the principal names and the alternative names of the most famous floral species. The confusion of species perceived by botanists as they noted the existence of synonyms and substitutes is not relevant within the pragmatic system that gives priority to the use of the plants. Plants that share the same use and same look will be designated with the same names. For instance, leaves from the *Leucopogon Malayanus* – an

Epacridacea – may conveniently replace the other similar looking *Cucur atap* (roof leaves) species, *Baeckia* and *Leptospermum*, in the herbalist post-delivery tea (Yusof 1985).

As the main criteria for designating plants is their use, a few very useful and well-known species change names. *Oriza sativa* is rice *(nasi)* in the plate, *beras* in the shop and *padi* in the field. *Aquilaria Agalocha* is the *tengkaras* timber of the foresters, the *chandan* tree of collectors and becomes *gaharu* when the precious fragrant wood is found in the tree.

The vast range of use of plants in Malay ethnobotany run from the rites accompanying protection ceremonies to the criminal use by thieves sending *Datura* smoke through the floor boards of houses on stilts. There are building materials, dyes, mats, food, flavourings, wrappings and cosmetic, soaps, talcum, perfumes – a complete shopping mall (Table 2).

Coherent, pragmatic and didactic, the Malay system of vernacular botany was based on the villagers' needs. About 20 years ago Malay gardens in villages were good illustrations of the familiarity of their owners with the local flora. (See Extra: "Plants on a Day in a Village 20 years ago")

The Future of Malay Ethnobotany

Today, Malay vernacular botany shares the fate of other ancient knowledge in the world. It vanishes because it is written on vanishing material supports. One of these supports is the memory of the elders. Records have been made and translated into modern Malay and scientific botanical terminology; the most recent are those of Pr. Kamarudin Mat Salleh at the University Kebangsaan Malaysia and of Pr. Roland Werner at the University Malaya). However, behind the names, has the frame of mind and the worldview of the indigenous botanists been documented enough? Can translation render the esoteric yet powerfully suggestive context? The second support of botanical knowledge is the flora of Malaysia. In the process of development, the diversity and quantity of plants species are reduced. In consequence "hands on" knowledge of species which were previously common is on the way to being lost.

On the other hand, the relationship of the Malays with the world of plants still runs deep. Beyond the country's political and scientific interest for biotechnology (see Extra "Three Malaysian Plants in the Hall of Fame"), it has been found (Said 2000; Nor 2003) that modern Malays grow species from their past in the small gardens of their suburban terrace houses. They have a desire to continue combining esthetics, ethnic heritage and function, in the plants they display in their new environment.

Extra: Plants on a Day in the Village, Twenty Years Ago

In the Malay village, a young mother woke up on her mat made of Pandanus, with the smell of the Euphorbia ambers still warm under her special post-delivery sleeping platform. There was a light fragrance from the surrounding *belukar* secondary forest: the astringent *Rutacea Glycosmis*, frothing *Cinnamonum* and camphor. These contained plants prepared for her morning bath. Her newborn had his umbilical cord cut with a bamboo *sembilu* and later he would be circumcised with same type of disposable knife.

The mother is having a breakfast of sweet potatoes sprinkled with grated coconut. She will take a tonic *majun* pill made mostly of spices and ginger (*rempah ratus*) mixed with honey collected from nests on the gigantic forest Compassia tree. She set aside a large basin of *ubat periok,* a decoction based on *akar kayu* (jungle roots and trees) bought from herbalists at the market (*Annonacea*, *Cinnamoum*, a bitter *Eurycoma*, the slim leaves of *Baekia fructescens*, and a modest beach creeper, *Vitex trifolia*).

The forest smell pervades the house built in cool timber (*seraya or cengal* Dipterocarps) with a *nipah*-thatched roof. The midwife performs a thorough massage of the young mother with coconut oil, applying lime juice on her stomach, wrapping her in a tight batik (dyed cloth) corset and finally applying the heat of stones wrapped in large *Morinda* leaves to help the recovery process.

Meanwhile, the men are at sea on a *chengal* made boat. The sails are made of *sekecut* sedge from the paddy fields mounted on bamboo battens from the *belukar*. They pull ropes made of coconut husks and prepare a *gala gala* caulking made of jungle resin and *minyal kuin* oil in case the deck needed it. The seams on the flanks of the boast rarely leak as they are built with strips of the bark of tannin rich *gelam Melaleuca leucadendron* (from the swamps) fixed during the construction on the *pasak* "nails" *Mesua ferrea* (from the forest) that join the planks of the boat. If a new crew member became seasick, he could use an oil distilled from the leaves of the same *gelam* tree.

In the village, in the afternoon, sitting on a platform in the garden, the great grand mother is sewing a pillow stuffed with floss from the *kekabu* tree. Her daughter gathers *ulam* greens and *daun serai* (*Cymbopogon*) to perfume the sauces for the next meals. A group of young girls ask permission to take some *inai* leaves from the Henna tree for an elder sister who is going to be married soon. She may look at the *bidara* (*Zyziphus*) and the cotton tree which are used during the funeral rites. A small *jambu* (*Eugenia*) has been planted where foetal membranes of the new grandson are buried. Life stages are written in the garden around the elderly lady. The presence of the plants helps preserve practical knowledge as well as spiritual beliefs. The next generation naturally learns from them.

Extra: Three Malaysian Plant Species in the Hall of Fame

A Criminal Tree?

Recently, for as long as six weeks, a battle was fought in the news (*Utusan Malaysia* November and December 2004) around a *Rubiacea* species, the *Mytragyna speciosa* (*ketum* in Malay). Journalists reported that police officers had felled an old *ketum* tree in Perak, causing a stir among nature lovers. The police explained that villagers had called them as the tree attracted drug addicts to the area. In fact, the police in Terengganu had previously felled hundreds of them. Addicts use the leaves of ketum to calm the effects of their drug craving, as it was explained in other articles. The tree is placed, just as in Thailand, on the list of forbidden substances.

The ketum or biak, endemic to Northern Malaysia and Southern Thailand, was traditionally used by villagers in post-partum teas to ease afterbirth pains and by workers who faced long hours of work in

W = Wild, P = Planted, F = favoured (refers to how villagers find the species and not to an imported or native botanical status).

E

the forest. A few times in the past, it had received attention from researchers in Malaysia and abroad. Other species of Mytragyna grow in Africa; they have been studied for their alkaloid contents and are used there in traditional compound medicine for mental illness. Malaysian scientists agreed that the plant did have a potential as a methadone substitute and that it had a mild analgesic effect. It acts on opiate sensitive receptors in the brain.

Researchers at Chiba University in Japan (Journal of the Pharmaceutical Society of Japan Oct. 2003) have published analyses on plants gathered in Malaysia and Thailand. Among the newly identified compounds, one of them, a mytragynine pseudoindoxyl, was found to be much more effective than the same amount of morphine.

Tongkat Ali, the "Malay Viagra"?

This shrub or small tree with a particularly thick, deep and straight root is not easy to collect. It used to be very common on the slopes of forest hills in Malaysia. It is also found in Indochina and Indonesia. But now it is becoming rare, and forest officers mark trees because their fame as a source for a sexual tonic has triggered harvests of commercial proportions.

The bitter tongkat or Eurycoma longifolia was studied at Malaysian universities and found to be effective, as traditionally claimed, as a febrifuge (a substance that lowers fever) and anti-diabetic. It has a testosterone-like effect on mice, which produce a plethora of male progeny. It does not seem to have harmful secondary effects. Under Malaysian law, it is on the list of protected and non-exportable species.

With academic endorsement, and following Good Manufacturing Procedure (GMP), entrepreneurs in the country are now using extracts of tongkat Ali in very successful "power" drinks together with coffee and ginseng. To face the oncoming shortage of wild material, the Eurycoma is now grown commercially.

Sarawak Tree in the Race to Find a Medicine for AIDS

During pharmacological screenings for anti-cancer activity of medicinal plants from Malaysia, a team of US scientists identified an interesting substance in a species of Calophyllum (bintangor in Malay). It had prospects as an immune system booster and even as a treatment for AIDS patients. The scientists formed a research company and entered into a partnership with the state of Sarawak to create a drug from the particular variety of Calophyllum that had been collected and is not very common. The Government participated in funding the first stage of the research in exchange for returns on the sales of the end product medicine for AIDS.

Calanolide – and other compounds from Calophyllum species – have passed the tests on their effects on the HIV virus, and calanolide is at the clinical phase. But the competition is fierce and it has to be shown to be better than other candidates supported with equally motivated teams. More information is available at ►http://www.forestry.sarawak.gov.my/forweb/research/fr/ip/eco/calophys.htm, "The Calophyllum Story".

Ethnobotany in Mesoamerica

RICHARD EVANS SCHULTES

The ethnobotany of Mesoamerica is extremely rich. The region is the original home of many useful plants. Amongst the numerous species, maize (*Zea mays*), avocado (*Persea americana*), henequen (*Agave fourcroydes*), maguey (*Agave cantala*), and chili pepper (*Capsicum frutescens*) immediately come to mind. All of these are inherited from aboriginal peoples who domesticated them long before the arrival of Europeans.

Perhaps the ethnobotanical aspect most typical of the region was the medicinal and ceremonial use of psychoactive or hallucinogenic plants. The Indian populations of Mesoamerica discovered and still employ in their magic and medicine many species with psychophysical properties. Even more significant is the evidence that from ancient times these plants have been considered sacred. That explained why the few plants with these unworldly effects amongst the half-million species in the world have such weird effects when ingested; they must be endowed with spiritual power, according to the belief of the aboriginal people. They are capable, through visual, auditory, or other hallucinations and related bioactivity, of allowing the medicine men or even ordinary individuals to communicate with ancestors or the spiritual forces who govern the affairs of the world below and who are able, if not propitiated, to inflect sickness, suffering, death, or calamities on people or on whole tribal groups.

We know much today about the use of bioactive plants for magico-religious and medicinal purposes from archaeological finds, ancient monuments, petroglyphs, codices, missionary reports, and other early publications. It is obvious from all of these and other sources that the use of plants capable of producing physiological and psychological alterations has had deep significance amongst native peoples in many parts of the world, especially in Mesoamerica.

In view of the great importance of psychoactive plants in the life of Indians of Mesoamerica, a brief discussion of the cultural importance of several of the numerous psychoactive plants employed by the Indians of Mexico and Guatemala in ancient and modern times will best indicate this particularly significant aspect of Mesoamerican civilizations.

E

Peyote (*Lophophora williamsii*)

The hallucinogenic peyote cactus has a long history in Mexico as a sacred plant employed in numerous medicinal and ceremonial ways. Peyote is a low, spineless cactus. It is still used ceremonially by Indians in central and northern Mexico, particularly the Huichol, Tarahumare, and Cora. The Huichols each year make a sacred pilgrimage to the peyote deserts and cut off the tops of the peyote plants, leaving the roots in the ground to regenerate tops. The tops are dried and taken back for use throughout the year. It is the dried top, known as the "peyote button" that is eaten during their ceremonies and dances.

Early reports, mostly by post-Conquest ecclesiastical writers, usually condemned the use of this innocuous hallucinogen as the work of the devil, and they tried, unsuccessfully, to exterminate this pagan religious ceremony. One report equated the eating of peyote to cannibalism. One of the early writers intimated that the Chichimecas and Toltecs were acquainted with peyote as early as 300 BCE, but the accuracy of this dating depends on interpretation of native calendars.

Recently, however, excellently preserved archaeological findings in Trans-Pecos, Texas, and Coahuila, Mexico, have confirmed ceremonial use of peyote. Identifiable remains of peyote buttons in great abundance and in a context suggestive of ritual use have been dated by Carbon 14, and they span 8,000 years of intermittent human occupation. In Coahuila, ceramic bowls dated from 100 BCE to AD 200–300 depict significant use of peyote; four peyote-like ornaments and a hunch-backed man holding a pair of peyotes are depicted in these bowls. There can be little doubt that peyote is the most important psychoactive plant still utilized in the dry regions of Mexico.

Of the many alkaloids (30 or more) in the peyote cactus, only one, mescaline, is responsible for the richly colored, kaleidoscopically moving visions induced when peyote buttons are ingested.

Red Bean or Mescal Bean (*Sophora secundiflora*)

Together with the archaeological cache of peyote in Texas, two other plants were discovered. One is the red bean or coral been (*Sophora secundiflora*); the other is a suspected psychotropic plant known today as the Mexican buckeye (*Ungnadia speciosa*).

An early Spanish explorer of Texas, Cabeza de Vaca, mentioned mescal beans as an article of trade amongst Indians of the southern regions of North America in 1539.

Sophora secundiflora was employed in northern Mexico until recently in certain ceremonies, but, as in the southwestern United States its use as an intoxicant has disappeared. According to the Stephen Long expedition of 1820, the Arapaho and Iowa tribes were using the large red beans as medicine and a narcotic. A well-developed mescal bean cult existed amongst at least 12 tribes of the United States. There are so many parallels between the peyote cult and the former Red Bean Dance that the origin of the ceremony must have had a southern or Mexican origin.

The active principal of *S. secundiflora* is cytisine which is common in the legume family. This alkaloid belongs to the same group as nicotine; it is a strong poison, attacking the phrenic nerve controlling the diaphragm. Death can occur from asphyxiation. It may possibly be because of the great danger in cases of overdosing with the red bean that its ceremonial use has disappeared. It is of interest, however, that the "road-man" or leader of the peyote ceremony today always wears a necklace of the red beans during the peyote ceremony, undoubtedly as a reminder of a once sacred plant.

Ololiuqui and Badoh Negro (*Turbina corymbosa* and *Ipomoea violacea*)

Early Spanish ecclesiastical chroniclers, writing at the time of the conquest of Mexico or slightly later, described the medico-religious use of a brown lentil-like seed which the Aztecs called *ololiuqui*, coming from a plant known as *coatlxoxouhqui* (snake plant), indicating a vine with heart-shaped leaves and a tuberous root, clearly a member of the Morning Glory family. Its present botanical name is *Turbina corymbosa*, but it has also been known as *Ipomoea sidaefolia* and *Rivea corymbosa*.

We know much about the preconquest use of this hallucinogenic plant. Furthermore, there are clear, although crude, illustrations of ololiuqui in the codices. The plant is depicted in mural paintings showing the water goddess with a stylized vine reminiscent of this sacred vine.

But even more scientifically meaningful is the report and illustration of ololiuqui in a most extraordinary book: *Rerum Medicarum Novae Hispaniae Thesaurus, seu Plantarum Animalium, Mineralium Mexicanorum Historia* (Medical Thesaurus of New Spain or the Story of the Plants, Animals, and Minerals of Mexico). Shortly following the conquest, the King of Spain sent his personal physician, Dr. Francisco Hernández, to live with the Aztecs and study their medicines. His notes did not appear as a book, however, until 1651, although some of Hernández' notes were published as early as 1615 by Ximénez, who wrote of ololiuqui, without identifying it, because, he stated "it will not be wrong to refrain from telling where it grows, for it matters little that this plant be here described or that Spaniards be made acquainted with it." Another report, dated 1629, stated that "…when drunk, the seed deprives of his senses him who has taken it, for it is very powerful." Still another source said that "it deprives those who use it of their reason… The natives communicate with the devil… and they are deceived by the various hallucinations which they attribute to the deity which they say resides in the seeds" (Ruiz de Alarcón 1629).

Besides being a hallucinogen, ololiuqui was used as a magic potion with reputedly analgesic properties. Aztec priests, before making human sacrifices, rubbed the victims with an ointment of the ashes of insects, tobacco, and ololiuqui to benumb the flesh and lose all fear. The seeds were venerated and placed in idols of the ancestors.

Mexican botanists identified ololiuqui correctly in the last century, but doubts arose, since intoxicating chemical constituents were unknown in the morning glory family. In 1911, a German specialist, Christian Hartwich, suggested that ololiuqui might be a species of the Solanaceae, and in 1915, an American ethnobotanist, William Safford, assuming that the chroniclers had been misled by the Indians, definitely identified it as a species of the solanaceous genus *Datura*. There were voices of protest. Not until 1939, however, were actual specimens collected in Oaxaca and used in Mazatec rituals.

It is now employed by more than six tribes and in many Oaxacan villages the morning glory is planted "as an ever present help in time of trouble." When employed ceremonially as a medicine, the patient must himself collect the seeds, and they are ground and made into a beverage by a virgin, usually a child.

In 1960, the seeds of another morning glory, *Ipomoea violacea* (formerly called *I. tricolor*), was identified as a sacred hallucinogen amongst the Zapotecs of Oaxaca. These seeds are black – thus the local name *badoh negro* – and larger than those of *T. corymbosa*, with which the badoh negro, usually employed alone, may be mixed. It has been suggested that these black seeds represent the ancient Aztec narcotic seed called *tlitliltzin*, a term in Nahuatl derived from the word for black with a reverential suffix. An early chronicler, Pedro Ponce, had written of "ololiuqui, peyote, and tlitliltzin," indicating that three different inebriating agents were represented (Wasson 1963).

The seeds of both ololiuqui and badoh negro contain a number of ergoline alkaloids, chemically related to the synthetic D-lysergic acid diethylamide (LSD).

Toloache (*Datura inoxia, D. discolor, D. Wrightii, D. kymatocarpa, D. ceratocaula*)

Species of *Datura* have a long history in both hemispheres as a genus valued as medicines and hallucinogens. The main center of ceremonial use of *Datura*, however, lies in the Southwest of the United States and Mexico where a number of species are employed. All are known as toloache in Mexico (Fig. 1).

Today, many Indians believe that they can acquire supernatural helpers through the drug, and much secret knowledge is thought to be gained during the ceremonial intoxication. In tribes of northern Mexico boys who are studying to be medicine men must undergo *Datura* intoxication once a year. Modern Tarahumare add *D. inoxia* to *tesquino* (a drink prepared from maize) to make it strong and to induce visions. Some Mexican Indians consider toloache an hallucinogen inhabited by a malevolent spirit, unlike peyote.

All species of *Datura* owe their activity mainly to their active constituent scopolamine.

Puffballs (*Lycoperdon marginatum, L. mixtecorum*)

More ethnobotanical research must be carried out on the use of two species of puffballs amongst the Mixtec Indians of Oaxaca. The first of these two species is known by the Mixtec name *gi-i-wa* (fungus of first quality), the second as *gi-i-sa-wa* (fungus of second quality).

Lycoperdon mixtecorum causes a state of half sleep in which voices and echoes are heard and, according to the natives, voices respond to questions posed to the spirits.

Ethnobotany in Mesoamerica. Fig. 1 Two species of *Datura*: *D. Inoxia* and *D. ceratocaula*. From *The Badianus Manuscript; an Aztec Herbal of 1552*. Edited and translated by Emily Walcott Emmart, 1940. Reprinted by permission of the Johns Hopkins University Press.

There is a puffball, still unidentified, reportedly employed by the shamans amongst the Tarahumare.

The active chemical in these fungi with auditory activity has not been identified. There are, however, medical records attesting to this physiological activity amongst patients who ate puffballs in North America and were rushed to hospitals hearing voices.

Mushrooms (Teonanacatl) (Conocybe, Panaeolus, Psilocybe, and Stropharia species)

Undoubtedly the most important hallucinogenic plants employed from ancient to modern times from central and southern Mexico and Guatemala involve a number of species of several genera of mushrooms.

The Spanish conquerors of Mexico were disturbed by the religious and ceremonial use of "diabolic mushrooms" known by the Nahuatl name *teonanacatl* (divine flesh). As with other native religious rites, the early clerics tried to stamp out such a loathsome religion that venerated mushrooms. It has been said that there was little that Christianity could offer comparable to the supernatural power of teonanacatl. One of the early Spanish writers reported: "They possessed another method of intoxication which sharpened their cruelty; for it they used certain small toadstools… they would see a thousand visions and especially snakes… and in this wise with that bitter victual by their cruel god were they hassled" (Sahagun 1829). The King of Spain's personal physician, who studied the medicines of the Aztecs shortly after the conquest, reported in a more scientific vein three intoxicating mushrooms that "cause not death but madness that occasionally is lasting, of which the symptom is uncontrolled laughter… There are others which, without inducing laughter, bring before the eyes all kinds of things, such as wars and the likeness of demons."

There is plentiful archaeological evidence indicating a long use of teonanacatl. Frescoes from central Mexico made at least 1,700 years ago unmistakenly refer to these intoxicating mushrooms (Fig. 2). Clay figurines from Jalisco about 1,800 years old have mushroom effigy "horns." In Colima, a clay artifact dated between AD 100 and 300 illustrates figures dancing around a mushroom. Stylish mushrooms decorate the pedestal of the statue of Xochipili, the Aztec god of sacred flowers whose body is decorated with a number of intoxicating plants. This statue was discovered on Mt. Popocatepetl and dated about AD 1450.

In Guatemala, however, the deep roots of mushroom use in ceremony go back to the famous "mushroom stones" dated between 300 and 900 BCE. Consisting of an upright stem with either an anthropomorphic or animal figure and crowned with an umbrella-like top,

Ethnobotany in Mesoamerica. Fig. 2 Teonanacatl ("flesh of the gods"): the Aztec sacred, hallucinogenic mushrooms. Painting by a Mexican artist of the sixteenth century, showing an Aztec-looking devil encouraging an Indian to eat the fungus. From the *Magliabecchiano Codex*, Biblioteca Nazionale di Firenze, Italy. Used with permission.

they are now thought to have been associated with the sacred Mesoamerican ball game ritual (Fig. 3).

It was nearly five centuries after the arrival of Europeans that serious ethnobotanical research on the sacred mushrooms of Mexico began. Since in this period of time the ceremonial use of these fungi had not been seen, W.E. Safford, an American ethnobotanist suggested, in 1915, that the Aztecs had misled the chroniclers and that, since he assumed that the dry brown top of the peyote cactus superficially resembled dried mushrooms that *teonanacatl* and *peyote* were synonymous and referred to the same plant. Unfortunately, this "identification" received some acceptance, despite voices of protest. It was not until specimens of the mushrooms were collected in the Mazatec country of Oaxaca that the first of many species – *Panaeolus sphinctrinus* – was botanically identified. Later ethnobotanical and anthropological research in a series of expeditions to the same region has led to the identification of more than 30 species of Psilocybe, Stropharia, and Conocybe ceremonially employed by at least nine tribes in southern Mexico.

Intensive research on these fungi has led to a tremendous increase in ethnobotanical, mycological, chemical, and anthropological knowledge and to an extensive bibliography. Not only have many new species of mushrooms been described, but also chemical investigation of these plants has led to the discovery of the active alkaloids, psilocybine, and psilocine.

This relatively recent discovery and research on what perhaps is a most significant aspect of Mesoamerican ethnobotany has been certainly an important factor in stimulating ethnomycological and even general ethnobotanical investigation in Mesoamerica as well as in other areas in both hemispheres.

Ethnobotany in Native North America

Daniel E. Moerman

Native American peoples developed a sophisticated plant-based medical system in the ten millennia before the European conquest of America. Although there were significant differences between the systems developed by the many native groups, about which many fine works have been written, there were also many broad similarities which will be detailed here. There are approximately 28,000 species of plants in North America. Native Americans used about 2,500 of them medicinally (Moerman 1996, 1998); a convenient database of all of these plant uses is available at ►http://www.herb.umd.umich.edu. The utilized portion (the medicinal flora) is a distinctly nonrandom assortment of the plants available. The richest sources of medicines are the sunflower family (*Asteraceae*), the rose family (*Rosaceae*) and the mint family (*Menthaceae*). By contrast, the grass family (*Poaceae*) and the rush family (*Juncaceae*) produce practically no medicinal species. This remarkable volume and extraordinary selectivity demonstrate without any doubt the falseness of demeaning claims which suggest that native American medicines were chosen at random, that they "just used everything and stumbled on something useful once in a while."

Health and Disease

To understand the character and effectiveness of a medical system, one must understand the health status of the people who use it. Native American peoples generally did not suffer from the heart and circulatory diseases of modern times; their diets were rich in fiber and carbohydrates and low in fats. They lived vigorous lives which provided hearty exercise on a daily basis. They experienced little cancer. Cancer is largely a disease of modern civilization. Although the situation is obviously very complex, an apparently necessary condition for cancer is carcinogens which are largely products manufactured by industrial societies (organic chemicals and dyes, nuclear radiation, etc.). Even into the current day there is evidence that the Navajo have lower rates of cancer than surrounding people (Csordas 1989).

In addition, they suffered little from the classic infectious diseases which ravaged European society over the past two millennia. In large part, this seems to be due to the fact that most such diseases (plague, typhoid, smallpox, cholera, etc.) are zoonoses, diseases of animals which, under conditions of domestication, underwent massive evolutionary change and subsequently affected the human keepers of these animals. Native Americans never domesticated animals to any significant degree (the guinea-pig and llama of Peru were apparently only coming under domestication in the few hundred years before European contact). Once these diseases were introduced into North America, they devastated native populations which had no immunity to them. However, until the sixteenth century, while Europeans underwent successive epidemics which regularly killed a quarter or half of the population, native Americans were spared this devastation.

What medical problems *did* native Americans face? In the southeast and southwest, there is evidence of a decline in health status after the invention of agriculture when the diet became simpler, which apparently led to some deficiency diseases. Hunting and gathering peoples avoided that problem, but they, like Europeans, may have experienced some zoonotic infections particularly from beaver, and some trichinosis from bears. These would have been direct zoonoses which individuals contracted directly from the infected animal, not remote zoonoses which, once passed to one human being, were subsequently passed from person to person. Like rabies, a terrible disease for the individual who contracts it, these direct zoonoses are not serious threats to a whole society because they are not contagious in the ordinary sense of the term.

Native Americans probably paid a price for the vigorous life they led. Accidents, sprains, broken bones, cuts, lacerations and the like were common. There was a range of arthritic conditions, some probably the result of injury like those just mentioned, and perhaps some similar to rheumatoid arthritis. There is ample evidence that native peoples engaged in warfare; this would have been a source of serious medical problems. There was a range of occasional problems associated with menstruation, pregnancy, childbirth, and lactation which required attention. Living in smoky houses, it is not surprising that they had a broad range of treatments for irritated eyes: they also treated colds, headaches, cold sores and bruises, the normal insults of daily life everywhere (Vogel 1970).

Drugs

To address this range of problems, native Americans inevitably resorted to drugs based on various plants. There were some nonplant substances used medicinally. *Castorecum* from beaver was utilized for various conditions, and some minerals and clays were used as well, but by far the preponderance of medicinal substances came from plants. Every native American group for which we have any information had a botanical pharmacy. While some were quite small (the Inuit had few plant resources on which to rely) most were quite elaborate with hundreds of plant drugs used for a broad range of conditions.

This straightforward proposition raises a number of much more challenging questions. Native American healers, even into the early twentieth century, regularly knew the identity of 200 or 300 medicinal plants which they could readily distinguish from the 3,000 to 5,000 species which grow in any particular area. Among 100 sophisticated and well-educated modern Americans, it seems unlikely that very many could identify 200 species of plants of any kind unless they were professional botanists (or perhaps gardeners). How did nonliterate people, without reference to botanical keys or floras compiled by professionals, maintain this extraordinary amount of knowledge (Berlin 1992)?

Another challenging question is this: Why is it that plants might be of medicinal value in any case? Why do poppies (*Papaver*) (Fig. 1) or nightshade (*Solanum*) (Fig. 2) induce unconsciousness? Why does willow (*Salix*) bark tea relieve headaches? Why does wormseed (*Chenopodium*) kill intestinal parasites? Why does milkweed (*Asclepias*) (Fig. 3) cause vomiting? Although there are many obstinate details yet to understand, the broad outlines of an answer to this question may be sketched. Plants often produce substances of a variety of sorts to protect themselves against browsers (most often insects or worms, but also vertebrates), to defend their space against other plant competitors, or for a wide variety of other particular purposes. These substances share one character: they are somehow biologically active. In using them as medicine, people appropriate these (usually) defensive chemicals to induce reactions which they desire. They are usually toxic; they are therefore customarily used in moderation (for example, by "prescription").

Ethnobotany in Native North America. Fig. 1 Poppy, *Papaver somniferum*.

Sometimes the answer to particular questions seems fairly straightforward: the toxic cardiac glycosides in milkweeds (*Asclepias* spp.) discourage browsing by insects, worms, deer, or other vertebrates. However, for people who want to induce vomiting, to clear their systems of foul humors or the like, such plants are ideal medicines. Similarly, the substances in wormseed which deter various worms from eating the roots also kill intestinal parasites in human beings. There are nonhuman analogues to these uses of drugs which are of great interest. In the case of milkweeds, an insect, the monarch butterfly, might be said to use the plant medicinally as well. By virtue of a complex evolutionary adaptation, they manage to tolerate the milkweed toxins, sequestering them throughout their bodies, making themselves in turn unpalatable to predatory birds, notably blue jays (Brower and Glazier 1975). In a case similar to the human use of goosefoot as an anthelmintic, there is evidence to indicate that occasionally chimpanzees, when they appear not to feel well, seek out the leaves of a particular species of *Aspillia* which has anthelmintic properties. Otherwise, the species is ignored (Wrangham and Goodall 1989).

Some cases are less clear-cut. Salicin is a substance found in the leaves of most species of willow; the chemical is named after *Salix*, the genus of willows. This water-soluble substance washes off the leaves during rain, and acts as an herbicide on plants growing around the tree. It is also the chemical precursor of acetylsalicylic acid, a synthetic drug which we know

Ethnobotany in Native North America. Fig. 2 Nightshade. *Solanum americanum*.

Ethnobotany in Native North America. Fig. 3 Milkweed or Butterfly weed, *Asclepias tuberosa*.

as aspirin. Various naturally occurring salicylates (also found in certain birches, in the common ornamental *Spiraea*, and in wintergreen) have the same general biological effects as aspirin (named after *Spiraea*) relieving headache and reducing inflammation and fever. The advantage of aspirin is that it is less toxic than the natural chemicals. All of the salicylates seem to work as a result of their inhibiting effect on a class of substances known as the prostaglandins which are involved in all these biological processes. The prostaglandins are also involved in the maintenance of the mucous layer in the stomach and intestine; this is why aspirin (and the other salicylates) can cause stomach upset. What is not clear is why a herbicide should have this effect on mammalian biochemistry. Many similar cases remain to be understood.

Psychological Drugs

There is little evidence of native American use of drugs for recreational purposes. In addition, there is only very little evidence indicating the use of drugs in religious or other ritual. This differentiates native North American peoples from indigenous peoples of Mexico, Central and South America, and many other places as well. The one significant native American use of a consciousness altering substance involves peyote in the Native American Church. This, however, is a recent development of the twentieth century with no obvious precursors. There are a number of highly active drugs available for such uses, among them various members of the Solanaceae family (particularly nightshade and jimsonweed), as well as a number of hallucinogenic mushrooms, most notably *Amanita muscaria*. The one drug of this sort which was widely used was tobacco (*Nicotinia* spp.). Uncured native tobacco is a much more powerful drug than the highly processed modern variation. In Mexico, powerful tobacco concoctions were ingested in a number of ways to induce substantial transformations of consciousness. This seems not to have happened north of the Rio Grande. All accounts of its use in North America indicate that it was utilized very sparingly: individuals sat in a circle and shared the smoke from an ounce or so of tobacco. Its function was clearly more symbolic than biological. There may be a few exceptions to this generalization, but they are all either controversial or very poorly documented. When native American peoples wanted to transform consciousness – in the vision quest, for example – they did so with disciplines like starvation, concentration, isolation, and sleep deprivation.

Some Interesting Medicinal Plants

Here are some notes on several interesting plants used medicinally by native peoples of north America. St John's Wort, *Hypericum hypericoides*, (Figs. 4 and 5) is a very useful plant. Recently, a number of double blind controlled trials have shown that several substances in the plant work to reduce mild to moderate depression. There is little evidence to indicate that native peoples suffered from this common modern scourge; Vogel's authoritative account, *American Indian Medicine*, never mentions it except as a possible effect of European *Arnica montana* taken internally (Vogel 1970: 261). Instead, it was used, primarily by peoples of what is now the southeastern United States (Alabama, Cherokee, Choctaw, Houma, Natchez) for a variety of purposes: an infusion of the whole plant taken for dysentery; decoction of the root taken for severe pain especially in childbirth; an infusion of the leaves used as a wash for sore eyes.

Another important plant is yarrow, *Achillea millefolium* (Figs. 6 and 7). With 258 recorded uses as a drug (Moerman 1998), it is the most utilized of all native American medicinal plants (second: *Acorus calamus*, sweetflag, with 219 uses; third: *Artemisia tridentata* ssp. *tridentata*, basin big sagebrush, with 166). Yarrow is one of the most widespread plants in

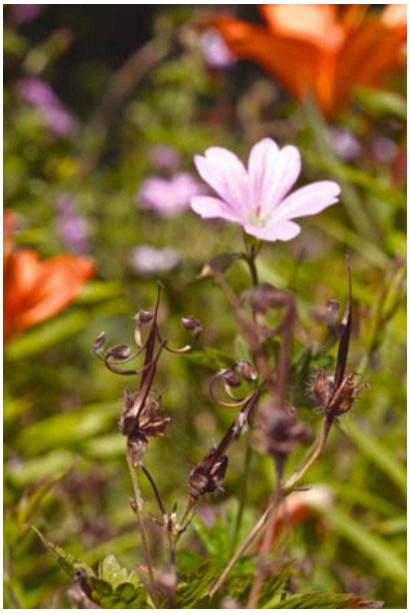
the world, found over most of the northern hemisphere, and in temperate regions of the southern hemisphere as far south as Peru and Tanzania. Wherever it grows, it is used to treat wounds, infections, burns, swellings, sores, pimples, insect bites, and other problems of the skin. The ancient Greeks attributed the discovery of the virtues of *Achillea* to Achilles after whom it is named. He, trained in the arts of medicine, war, and diplomacy by his tutor, Chiron the Centaur, used it to heal a festering wound in an old enemy to establish an alliance against the Trojans. Native Americans also used it internally for a range of conditions: as a diuretic, for fevers, colds, coughs, internal pains, and for diarrhea, among others.

Finally, among the 49 American species of crane's-bill, or wild or hardy geranium, the one most favored as a medicine by native peoples was *Geranium maculatum*, the spotted crane's-bill (Fig. 8). A favorite of a number of Midwestern tribes – Menominee, Meskwaki, and Ojibwa used it for diarrhea, sore gums and toothache – its use by the Iroquois can show us some



Ethnobotany in Native North America. Fig. 9 Cranesbill or Wild Geranium, *Geranium maculatum*; hooked seeds. Copyright D. Moerman.

important elements in the medical thinking of non-western peoples (Herrick and Snow 1995). As it goes to seed, *Geranium maculatum* develops a series of very distinctive hooks from its peduncle which hold newly formed seeds (Fig. 9). These hooks, for the Iroquois, were distinctive and important, putting it in a special category of plants with "hook-like or ensnaring features," along with a number of other plants like the Canadian anemone, *Anemone canadensis* which has spiky hooks on its seeds, as does the purple avens, *Geum rivale*, and a number of other species. The Iroquois utilize most of these for conditions of eversion, or looseness, or escape, like cold sores, or diarrhea. The idea is that the hook-like, ensnaring quality of the plant will engage, or grab, or capture the looseness and pull it back, and so a tea of the roots is used to wash a chancre sore, and a poultice of dried root is applied to the unhealed navel of an infant. And so the ethnopharmacologists are happy when they find that the geranium root contains substantial quantities of tannin which is a strong astringent, hence "validating" this usage. But the wild geranium has more uses than that. Suppose one suspected that his wife were having a flirtation with another man. Putting a bit of geranium root or flower in her food or drink might capture her, and bring her back. Likewise if you are trying to sell some baskets, you could sprinkle them with geranium root tea to ensnare a buyer (and I can attest that books with drawings of wild geraniums included in them sell better than ones that don't). There is more to medicine than chemistry (Moerman 2002). In addition, no garden is complete without an assortment of wild geraniums (Figs. 10–14) .

The medicinal knowledge of native North American peoples is extraordinary. Just how this knowledge was developed remains a mystery. Native American peoples came from Asia; the flora of Asia is in many ways similar to that of North America (Duke and Ayensu 1985). It is quite likely that the first migrants to the New World brought with them detailed knowledge of medical botany, much of which was applicable to this new flora.

Most remarkable, however, may be this: I am unaware of any significant medicinal use of any indigenous American plant species which was not used medicinally by one or another native American group. An interesting example involves recent research on taxol, a substance of great medical value found in the common yew, *Taxus brevifolia*, and the Canadian yew, *Taxus canadensis*. Taxol has shown substantial effect in the destruction of tumors in a number of forms of cancer, particularly ovarian cancer, until now a highly refractory form of the disease. Native Americans did not use yew to treat cancer (see above), but they did use it for a variety of other conditions, among them skin problems, wounds, rheumatism, and colds.

Ethnobotany in Native North America. Fig. 14 Spring garden dominated by Horticultural Hardy Geraniums; also columbines, *Aquilegia canadensis*, and poppies, *Papaver somniferum*.

In general, if one were interested in finding potentially useful botanical chemicals from the North American flora, it would clearly be wise to focus first on that portion of the flora which had been used by native Americans. Their experience and knowledge can yet guide our scientific efforts to enhance human health.

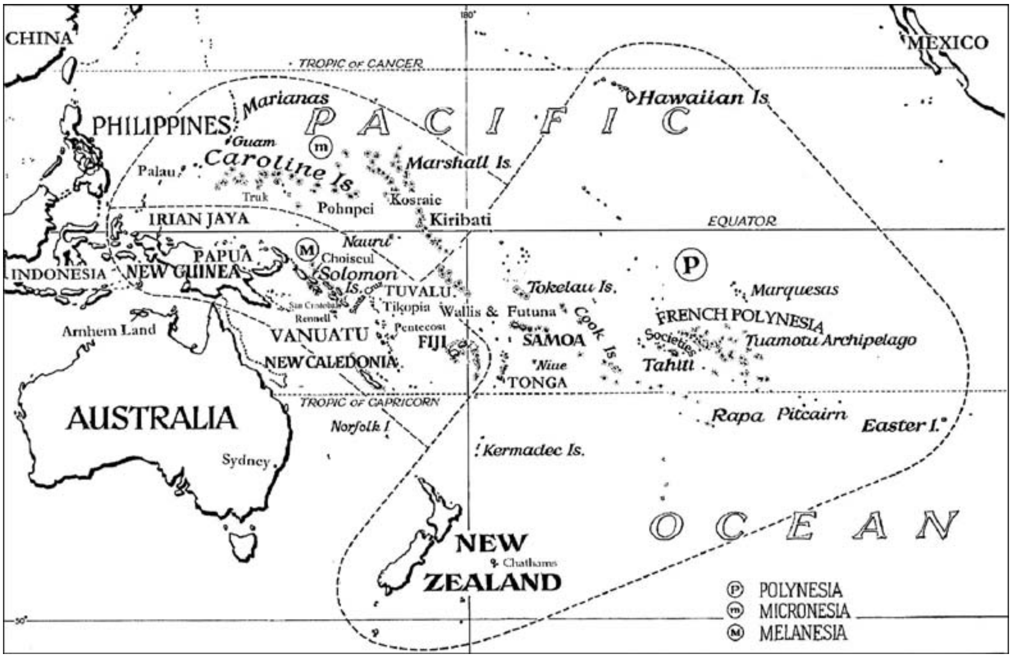
Ethnobotany in the Pacific

YADHU N. SINGH

The island communities of the Pacific, sometimes collectively known as Oceania, are inhabited by indigenous peoples from three major cultural or ethnic regions: Polynesia, Melanesia, and Micronesia (Fig. 1).

Because they lacked a written language of their own at the time of first contact with Europeans in the eighteenth century, much of the earlier information on the ethnobotany of the area has been constructed from the journals and other records of explorers, missionaries, and anthropologists. The increasing westernization of the islands has led to a greater reliance on imported food, clothing, fibers, and other materials, resulting in a decline in the use and specialized knowledge of native plants and agriculture. Fortunately, this influence is greatest in the urban areas and many of the traditional practices continue to flourish in the more rural and isolated communities. Some practices or items of material culture have lost their original roles, but instead have since acquired social, cultural, or historical significance, and consequently are being perpetuated by the present generations. A considerable body of plant lore still exists among the aged chiefs and inhabitants, and several anthropologists and ethnobotanists have strived to document this information. Because of space shortage, only a brief synopsis is presented and the reader is directed to the bibliography for a more complete treatment.

One popular theory on the origins of the Pacific islanders contends that their navigator ancestors migrated eastward from the Indo-Malay area, carrying with them from island to island the plants they needed for food, social, and cultural purposes. The food plants include all of the starchy perennial plants which are propagated vegetatively, including the taro, *Colocasia esculenta* (Fig. 2) and other nourishing *Araceae* of the genera *Alocasia, Amorphophallus*, and *Cyrtosperma*; the various yams, *Dioscorea* spp., whose numbers of cultivated species decrease from west to east; the breadfruit, *Artocarpus altilis*, (Fig. 3) of Captain Bligh and the mutiny on HMS *Bounty* (Fig. 4) fame, and for



Ethnobotany in the Pacific. Fig. 1 Map of the Pacific Ocean showing the three cultural regions of Melanesia, Micronesia and Polynesia. Modified from *Fiji in Color* by Jim Siers, and reproduced with permission from the author.

Ethnobotany in the Pacific. Fig. 2 Taro (*Colocasia esculenta*) plants and tubers.

Ethnobotany in the Pacific. Fig. 3 Breadfruit (*Artocarpus altilis*).

which the greatest number of cultivated varieties are found in eastern Polynesia; the principal bananas, *Musa* spp. (Fig. 5); also sugar cane, *Saccharum officinarum* (Fig. 6), which provides a nourishing drink; and the kava plant, *Piper methysticum* (Fig. 7), the source of the kava beverage which is used for many different activities in the islands.

Throughout its long history, the Pacific most certainly witnessed modification of its vegetation as its inhabitants adapted to the new environment and improved their techniques, and as waves of new migrations of humans arrived with new methods, ideas, and plants. Two important plants which fall into this category are the sweet potato, *Ipomoea batatas*, and the manioc or cassava, *Manihot esculenta* (Fig. 9), being cultigens which were introduced from the American

tropics in the last century, and which have become important components of the local diet.

The most widely reported uses of plants in the Pacific are for food and utensils, medicine, ceremony and rituals, general construction, fuelwood, boat and canoe building, cordage and fiber, fish poisons, woodcarving, tools, weapons and traps, mats, clothing, dyes and pigments, and perfumes and oils.

The dominant food economy is based on the cultivation of the small number of starchy perennial plants mentioned above, which are propagated by vegetative means and which provide tubers and starchy fruits. They are usually embellished for taste, flavor, and variety by various condiments and complimented by seafoods and other plants and shrubs. They include the coconut tree, *Cocos nucifera*, which is unquestionably the most utilized of all plants in the Pacific (Fig. 10).

By one count as many as 125 different uses have been reported. Food uses include eating the soft flesh of immature nuts as an important weaning and adult food; drinking the juice of immature nuts as a nutritious and refreshing local beverage which is often sold and is considered a sacred offering to visitors in Kiribati; using the kernel of the endosperm of the mature nut raw, cooked, or fermented in a variety of ways as a staple food and as a major food for chickens and pigs, as well as an ingredient in locally produced commercial livestock feeds. It is also used for fish and rat bait. The kernel is dried to make copra from which coconut oil is obtained for use in cooking, soap making, as scented oil and in perfumery, and in medicinal potions. The sap from the flower spathe is used to make fermented and unfermented toddy and syrup, which are of considerable nutritional importance in Micronesia and on the atolls. Also, the husks of some cultivars of green nuts are eaten in atoll Polynesia and Micronesia. Other parts of the plant serve as a major source of fuel, for construction and fiber and cordage (Fig. 11), Recently, the fibers from the tree trunk have been pressed into materials suitable for making furniture (Fig. 12).

Young and mature leaves are used for weaving baskets, food containers and parcels, table mats for

Ethnobotany in the Pacific. Fig. 8 *Cordia subcordata* habit, leaves and flowers.

Ethnobotany in the Pacific. Fig. 9 Cassava (*Manihot esculenta*) plants and crop.

feasts, to beat water during fish drives, and for pounding and stabilizing banks of taro beds. The shells are used to make drinking cups for water and kava (Fig. 13).

Small bowls, cooking vessels, funnels, storage utensils, fish hooks and lures, and various types of body ornaments were also made of shells. Other supplementary food sources include using the pith of the trunk of the sago palm, *Metroxylon* spp., Polynesian arrowroot, *Tacca leontopetaloides*, mature seeds or drupes, aerial root tips, and hearts of meristem of the screwpine, *Pandanus* spp. (Fig. 14), seeds and flesh of ripe fruit of the tropical or beach almond, *Terminalia catappa* (Fig. 15), seeds of the cycad, *Cycas circinalis* (Fig. 16), and the young fronds of many ferns and tender shoots of a wide range of species.

The beverage called kava, prepared as an infusion from macerated stems and rhizomes of the kava plant, *Piper methysticum*, is probably the best known and most distinctive item of the material culture of the Pacific. It continues to occupy a central place in everyday life in the islands, although its role has been somewhat diminished by time and outside influences. Besides being the social beverage of chiefs, noblemen, and more recently of commoners, it has also been used to welcome distinguished visitors at formal gatherings, at initiation

and completion of work, in reconciling with enemies, in preparing for a journey or an ocean voyage, for installation in office, validation of titles, ratification of agreements, celebration of important births, marriages, and deaths, as a libation to the gods, to cure illnesses and to remove curses, as a prelude to tribal wars – in fact, in almost all phases of life in the islands.

Despite the gradually declining reliance on traditional medicine, over 120 different plant species are

Ethnobotany in the Pacific. Fig. 13 Picture of coconut shell kava cups. Photograph courtesy of *Kava Kauai*.

reportedly used for medicinal purposes. Herbal preparations and potions are used to treat a wide variety of ailments, although not always identified with the equivalent Western disease names. Some of these ailments are shown in Table 1. Among the plant species of most widespread medicinal importance are the beach almond, coconut, pandanus, *Vigna marina, Centella asiatica* (Fig. 17), *Premna taitensis, Ageratum conyzoides, Hernandia nymphaeifolia, Entada phaseoloides, Triumfetta procumbens, Morinda citrifolia* (Fig. 18), *Guettarda speciosa*, and *Terminalia catappa*.

Traditional practitioners and midwives continue to play an important role in healthcare delivery and, with the rapidly rising costs of Western medicine, there is renewed interest in herbal cures and practices. Presently, an extensive literature on the past and current medicinal practices is being assembled by anthropologists and ethnobotanists. However, the active chemical components have been identified for only a small number of the herbal potions.

Also of medicinal value are species used as fumigants or insect repellants, soap substitutes, shampoos or hair

Ethnobotany in the Pacific. Fig. 14 Screwpine (*Pandanus tectorius*). The hearts of the ripe meristem (right) are savored by many communities. Pictures courtesy of University of Hawaii Botany Department.

conditioners, and antitoxins. Of the soap substitutes, *Colubrina asiatica* is used almost universally for this purpose. Among those used as antitoxins, or to treat puncture wounds from marine animals or jellyfish stings are *Avicenna maritima, Cassytha filiformis, Excoecaria agallocha, Sophora tomentosa*, and *Tournefortia argentea*. The seeds of *Calophyllum inophyllum*, the heartwood of *Santalum yasi*, and the leaves of *Vitex* spp. are burned as mosquito repellants.

Tree trunks and timber from about eighty different species have found multiple uses, including for house, canoe, and boat building, tool and weapon making, woodcarving, fishing equipment, food utensils, furniture, games, toys, and musical instruments.

Various items for the tourist industry made from wood and plant materials. From left: warclub, comb, cannibal fork, box and fan.

General construction purposes utilize sawn or hewn timber for house poles, beams, rafters, flooring, walls, pilings, bridges, wharves, etc. Some of the more commonly used species include *Bruguiera gymnorhiza, Calophyllum inophyllum* (Fig. 19), *Casuarina equisetifolia, Cocos nucifera, Guettarda speciosa, Hibiscus tiliaceus, Inocarpus fagifer, Intsia bijuga, Pandanus tectorius, Rhizophora* spp. (Fig. 20), *Terminalia catappa*, and *Thespesia populnea*. For thatching purposes, various grasses, and the leaves and fronds of coconut palms and pandanus are extensively used.

Ethnobotany in the Pacific. Fig. 20 Red mangrove (*Rhizophora mangle*).

Ethnobotany in the Pacific. Fig. 21 Coconut fiber coir cord and wooden fishing hook. Photograph courtesy of Fiji Museum.

The timber and woody parts of many of the same species are used to construct warclubs, spears and spearpoints, bows and arrows, fishing poles, fish traps, fish hooks (Fig. 21), floats, paddles, digging sticks, needles and awls, adzes and tool handles, tapa cloth beaters, bowls, including kava bowls, ladles, spoons, stirrers, mortars and pestles, coconut huskers, bread-fruit splitters, and food containers.

For toys and games, the seeds or fruit of *Abrus precatorius, Barringtonia asiatica, Caesalpinia bonduc, Erythrina variegata*, and others, are used for small balls, marbles and lagging pieces, while the wood of *Gardenia taitensis* is carved into marbles and cricket balls in some Polynesian islands. Pandanus leaves are made into kites and whistles while parts of the coconut palm are made into toy windmills, toy boats, rattles, sledges and clappers. The thin epidermis of pandanus leaves serves as a substitute for cigarette paper for handrolled cigarettes.

A basket and a mat made using dried pandanus leaves.

Musical drums (like the *lali* of Fiji) and the slit-gongs (of Vanuatu) (Fig. 22), beside being musical instruments, are still extensively used for summoning people to village meetings or to church services, the most favored species for this purpose being *Cocos nucifera, Guettarda speciosa, Pemphis acidula, Terminalia catappa*, and *Thespesia populnea*.

Ocean going crafts of diverse structures and sophistication were developed to serve specific functions such as for transportation between the islands, for fishing, as racing outrigger or war canoes, and chiefly for voyaging. The components of such crafts, most of which were obtained from plants, include hulls, keel and prow pieces, outriggers (Fig. 23) floats, booms, ribs and spreaders, planking, platforms, shelters, masts and mastheads, paddles, steering oars, and sails, bound together with fiber cordage.

Ethnobotany in the Pacific. Fig. 22 A lali (arrow, and sculpture, left picture) and a slit-gong from Vanuatu located on the Suva (Fiji) campus of the University of the South Pacific.

The hull and keel pieces were composed of extremely strong and durable timber. *Calophyllum inophyllum* has been favored for the hulls of the larger Polynesian and voyaging canoes. Other species also used for this purpose include *Cordia subcordata, Intsia bijuga*, and *Hernandia nymphaeifolia*. Sails were plaited together from pandanus or coconut leaves and other species were used as adhesives and for caulking. Cordage and fiber for lashings on crafts, housing, weapons, fishing lines, stringing fish nets, and in various handicrafts are obtained from the husk fiber or coir of the coconut (Fig. 24), the bast fiber of *Hibiscus tiliaceus* (Fig. 25), and the leaves of the pandanus. These three materials are also used for straining coconut cream, kava, and other liquids, and for stuffing and caulking. The dried fibrous pandanus drupes, coconut coir and *Hibiscus tiliaceus* bast fiber are used as brushes for painting the tapa cloth, other ceremonial clothing, and handicrafts.

Ethnobotany in the Pacific. Fig. 23 Outrigger canoes used in the tourism industry.

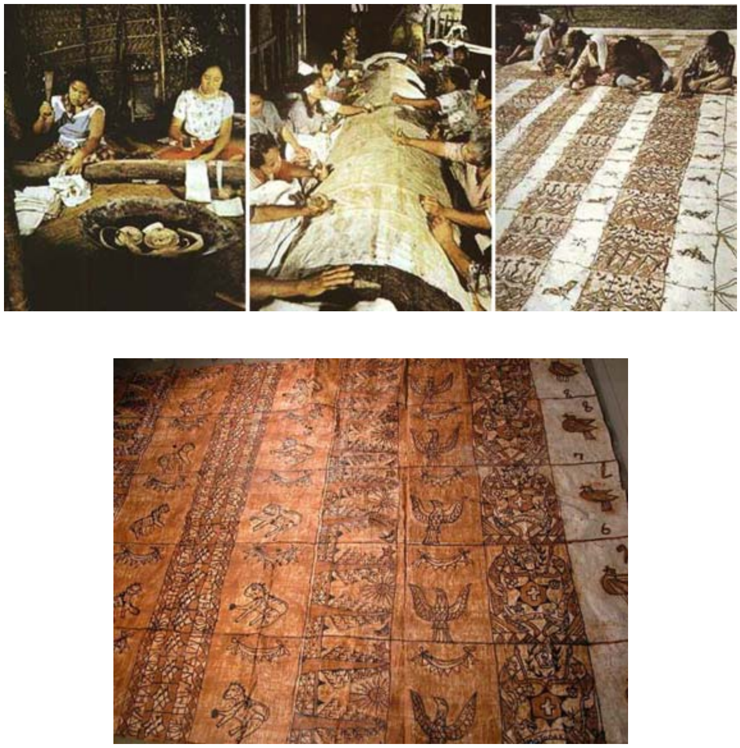
Ethnobotany in the Pacific. Fig. 24 Coconut fiber coir.

Of the various species used in the production of clothing and handicrafts, the most important are the coconut palm, pandanus, breadfruit tree, *Hibiscus tiliaceus*, and the paper mulberry, *Broussonetia papyrifera* (Fig. 26). The leaves of the first two and the bast fiber of *Hibiscus tiliaceus* are used throughout the Pacific for making hats, ordinary and ceremonial mats and garments, fans, and a wide array of handicrafts. The bark of *Broussonetia papyrifera* and the breadfruit tree are processed to make the cloth called tapa which is best known in Fiji, Tonga, and Samoa (Fig. 27). Dyes, pigments, and preservatives, obtained from a number of species, in particular *Ficus tinctoria, Bruguiera gymnorrhiza, Morinda citrifolia* and *Rhizophora* spp., are used for dyeing, painting, or strengthening and preserving bark cloth, mats, baskets, and other plaited ware, hats, breechcloths, grass skirts, canoe sails, and for decorating parts of the human body on ceremonial occasions. The dyes and pigments are obtained from the bark and, less commonly, from leaves, roots, flowers, sap, fruit, and seeds.

Although most wood species are used as firewood, some are particularly favored because of their high heat

Ethnobotany in the Pacific. Fig. 26 Paper mulberry (*Broussonetia papyrifera*) habit and tree trunk.

Ethnobotany in the Pacific. Fig. 25 Beach hibiscus (*Hibiscus tiliaceus*) habit, flower, and strainer from the bark in use for kava making.



Ethnobotany in the Pacific. Fig. 27 (a) Tapa making in Tonga. Most commonly the bark of the paper mulberry or breadfruit tree is used. The bark is stripped from young saplings, and the white inner layers are peeled off for the tapa. These narrow strips are soaked in water until softened (in the bowl in the foreground), then they are pounded with grooved mallets, which spreads the bark into increasingly wider strips until they are about ten inches wide. The edges are then overlapped and glued with cassava root juice, breadfruit, or arrowroot starch to make wide sheets. Then, on a long log, the tapa is stretched over a series of these design plates, and the tapa is rubbed with dye to stain the surface in areas where the design is raised (middle picture). Finally, after the tapa has dried, dark outlines and details are hand painted, using crude brushes made from sticks with frayed ends. A variety of natural plant dyes are used (right). Natural brown dyes, for example, have been made from clay and tree sap. (b) The finished tapa cloth. Photographs courtesy of the Government of Tonga.

Ethnobotany in the Pacific. Fig. 28 *Derris elliptica* leaves and vines.

content (*Pemphis acidula, Suriana maritima, Premna serratifolia*), ability to cook slowly and produce slow-burning charcoal (*Bruguiera gymnorhiza, Rhizophora* spp., *Casuarina equisetifolia*, coconut shells), or provide a desired taste to foods. All parts of the coconut palm are used for fuel, and it is by far the main source of fuel in the atoll countries, as well as in some of the larger low-lying islands.

Sophisticated fishing gear used by coastal communities has been complemented by fish poisons or stupificants, with some ten species being used for this purpose. The fruits, roots, or vines are pounded and the juice is scattered in a tidal pool or the lagoon. The suffocated fish rise to the surface and are gathered in baskets woven from coconut leaves. The poisons do not affect the edibility of the fish. The most commonly used species are *Barringtonia asiatica* (fruits), *Tephrosia piscatoria* (roots), and *Derris* spp. (roots and vines) (Fig. 28). The use of these fish poisons has recently been outlawed in many countries.

Ethnobotany in Pakistan

Zabta K. Shinwar, Anwar Nasim

Ethnobotany is a very broad discipline and covers all types of human–plant interactions. It is the study of how the people of a particular culture and region make use of plants. However, there are also other definitions, such as the use of plants in early societies.

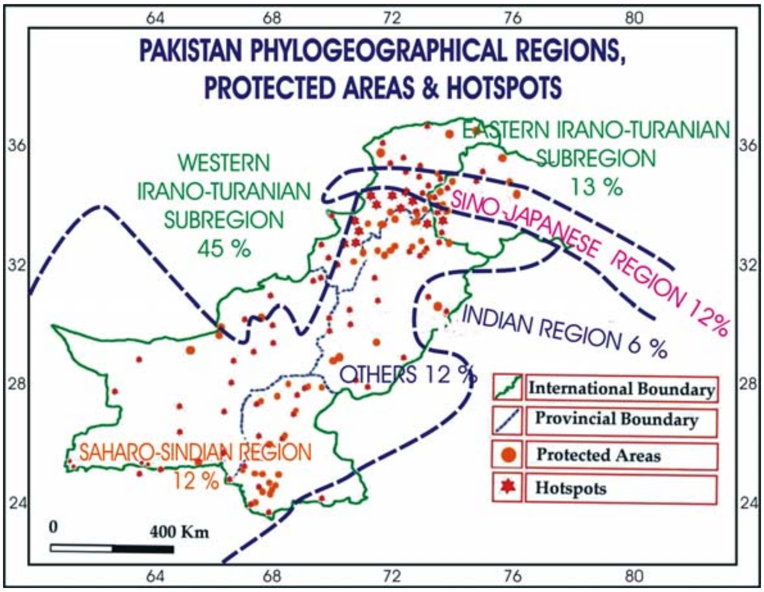
One cannot separate poverty from threats to biodiversity conservation. Pakistan is a developing country with 150 million people. Each child born inherits an average debt of Rs. 4,400 (US $80). About 32% of Pakistan's population has a monthly income of Rs. 650 (US $11). Infant mortality is 83.3 per thousand (compared to Thailand's 28, Indonesia's 41, Bangladesh's 60). Global borrowing, shrinking incomes, diseases, lower average ages, and greater mortality are all moving the majority of the world's population to desperation.

Pakistan has varied climatic and ecological zones and topography along with vast floral diversity. It contains nearly 6,000 species of flowering plants of which 70% are uniregional. Pakistan has four phytogeographical regions (1) Irano-Turanian (46% of species confined to Pakistan), (2) Sino-Himalayan (10%), (3) Saharo-Sindian (9.5%), and (4) Indian element (4.5%). Despite the Saharo-Sindian Region being the biggest area, the diversity of species confined to this area is lowest for any phytogeographical region (Ali and Qaiser 1986) (Fig. 1).

Ethnobotanical plant resources can be divided into two broad categories:

1. Ethnobotanical resources: plants used directly by local communities for food, forage, fiber, timber, medicine, ceremony, symbol, or income.
2. Phytogenetic resources: plants processed or manipulated to extract genes or DNA for crop improvement, cells for tissue culture, or chemicals as precursors of pharmaceuticals.

Local communities in different regions of Pakistan have centuries old knowledge concerning traditional uses of



Ethnobotany in Pakistan. Fig. 1 Pakistan phylogeographical regions, protected areas and hotspots.

most of the plants in their areas. Some of the important plants are commercially harvested for the extraction of various types of active ingredients. Even though the systems of *Unani* and *Ayurvedic* medicines are largely based on plants, the precious wealth of indigenous knowledge is in danger of being lost. The use of traditional knowledge must also reflect the values embedded in the traditions upheld by elders, especially with regard to medicine. Practitioners know that respecting plants is essential to the efficacy of medicines, which should be seen as having curative energy that draws its medicinal qualities from a relationship between the plants and the people (Juden 2003).

Overharvesting of medicinal plants for commercial purposes has threatened their abundance, and even their occurrence. Detailed surveys were conducted to document species of priority for commercial harvesting. Priority species chosen by the Ministry of Food, Agriculture, and Livestock (MINFAL), and two major herbal facilities in Pakistan (Hamdard and Qarshi) are listed in Tables 1–3.

The plant hotspots of Pakistan are spread over 13 natural regions from alpine pastures to mangrove forest. More than 10% of the flora is endangered (Shinwari et al. 2000, 2002) (Fig. 2). This is because of environmental problems including population pressure, poverty, and poor quality of the natural resource base, breakdown of social institutions, lack of land-use plans, and lack of enforcement of existing rules.

Global efforts to conserve and protect the natural environment are a recent phenomenon, though efforts to conserve economically important natural resources have a long history. Ethnobotany and conservation are inseparable and conservation is one of the most-valued tasks of ethnobotanists. In addition to conservation techniques, communities also need to be educated on the importance of conservation of local ecosystems, and with that, their socioeconomic conditions.

There is a rising trend to shift resources from allopathic to traditional healthcare systems. For example in Japan, a Society of Oriental Medicine Studies was established by 98 members interested in Kampo (traditional Japanese medicine). Today, it has about 10,000 members of whom 80% are allopathic doctors. Back in 1967, health insurance companies approved only four Kampo prescriptions. Today, there are more than 200 approved prescriptions.

There is a need to cultivate medicinal plants (MPs). In Lucknow (India), medicinal plants worth Rs. 90 million are grown annually. In China, in the year 2000, the total output value of the pharmaceutical industry was 233 billion yuan (US $28 billion). By the year 2010, the share of traditional Chinese medicine in the international market is projected to improve from 3 to 15%.

Ethnobotany in Pakistan. Table 1 Priority species by MINFAL

Scientific name	Local name
Apium graveolens	Ajmood
Carum copticum	Ajwain
Cassia angustifolia	Sana-maki
Cassia senna	Sana-Makki
Curcuma zeodaria	Aania Haldi
Foeniculum vulgare	Sonf
Hyocyamus niger	Ajwain Khurasani
Lawsonia inermis/alba	Barg-e-Hina
Matricaria chamomilla	Gul-e-Baboona
Nigella sativa	Kalonji
Rosa damasena	Gul-e-Surkh

Major Issues Pertaining to Medicinal Plant Cultivation, Conservation, and Income-Generation in Pakistan

Following are the major issues concerning medicinal plants in Pakistan:

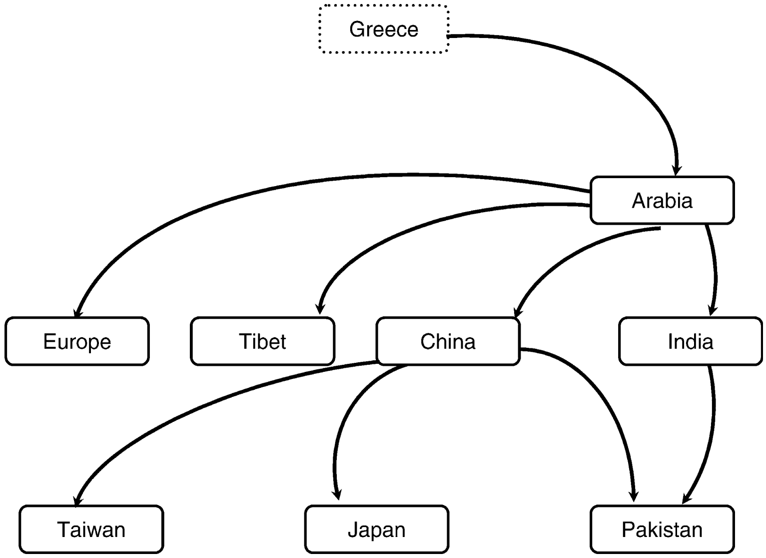
- Potential of medicinal plants: commercialization, economic growth, and prosperity
- Increasing demand of herbal medicines globally
- Illegal collection/extraction from wild populations with the reduction of many valuable species
- Traditional healthcare system and extinction scenario
- Policy issues relating to promoting large-scale cultivation and conservation

Ethnobotany in Pakistan. Table 2 Species, prices, quantities, and values of medicinal plants (Hamdard Laboratories (Waqf), Pakistan)

Scientific name	Common name	Average price (Rs. per kg)	Quantity collected (kg)
Lavandula officinalis	Ustukhuddus	320	3,000
Achillea millefolium	Baranjasif	285	6,000
Viola odorata	Gul-e-Banafsha	550	2,000
Carum carvi	Zeera siya	495	2,500
Onosma bracteatum	Gul-e-Gaozaban	290	1,500
Berberis aristata	Zarishk	238	2,000
Polypodium vulgare	Bisfaij	250	4,000

Ethnobotany in Pakistan. Table 3 Species, prices, quantities and value of medicinal plants (Qarshi Industries (P) Limited, Pakistan)

Scientific name	Common name	Average price (Rs. per kg)	Quantity collected (kg)
Plantago ovata	Ispaghol Musallam	225	2,300
Achillea millefolium	Saffron	30,000	5
Viola odorata	Gul-e-Banafsha	550	2,000
Carum carvi	Zeera siyah	400	2,500
Lavandula officinalis	Ustukhuddus	320	3,000
Onosma bracteatum	Gul-e-Gaozaban	290	1,500
Berberis aristata	Zarishk	238	2,000
Polypodium vulgare	Bisfaij	250	4,000



Ethnobotany in Pakistan. Fig. 2 Trade chain of medicinal plants showing its possible origin from Greece.

Ethnobotany in Pakistan. Table 4 Medicinal plants of Pakistan

Total species of higher plants (medicinal and nonmedicinal)	About 6,000
Species used as medicine	(10%) > 600
Species available in the market	>300
Wastage from collector to consumer	>50%
Price difference from collector to consumer	>100%
Availability of quality material	Questionable
Trained collectors	None

Twelve percent of Pakistani flora is used in medicines, and more than 300 medicinal plants are traded (Table 4). The ten leading Dawakhanas (herbal manufacturers) of Pakistan annually consume more than 2 million kg of 200 medicinal plants (Table 5). Some of the medicinal plants in the Unani system seem to have originated in the medicine of ancient Greece (Fig. 2).

Almost all medicinal plants in Pakistan are wild. Local collectors are sometimes unaware of the best collection procedures. Medicinal plants from the sites of collection to the national and international markets pass through various middlemen. Consequently, the prices of the crude drugs increase more than 100% along the trade chain. The flora of Pakistan is also threatened because of rapid infrastructural development (roads, building construction), population explosion, spread of irrigation systems, and pollution.

Twenty-two species of medicinal plants worth Rs. 14.733 million were traded in 1990; in 2002, this value rose to more than Rs. 122 million. In 1990, 95 species were consumed worth Rs. 36 million while in 2002, medicinal plants worth Rs. 218 million were consumed (Shinwari et al. 2002).

Ethnobotany in Pakistan. Table 5 Annual consumption of important medicinal plants used by ten leading Dawakhanas (data from 1990, published by NIH-Pakistan)

Category	Average consumption (million kg)	Total value (million Rs.)
20 species used >10,000 kg year^{-1}	0.33	5.6
80 species used >1,000 kg	0.26	8.2
100 species used <1,000 kg	0.05	1.4
Total 200 species	0.63	15.2
Estimated production 4–2 million kg	1.27	30.4

E

Ethnobotany in Pakistan. Table 6 Total flora and medicinal plants of the hotspots of Pakistan and their current status

Region	Size of flora (number of species)	Total number of medicinally important species	Threatened flora (number of species)
Chitral	±1,600	800	150
Kashmir	1,500	900	200
S. Waziristan	425	323	??
Sindh	1,185	700	100
Hazara	1,759	>1,000	??
Swat	1,550	500	87
Balochistan	1,330	700	>150
Kurram Agency	1,200	>600	>100

Deforestation in the Himalayas is generally attributed to demographic pressure and other related effects (1) increase in demand for land for cultivation, (2) livestock population, and (3) use of the remaining forest to meet growing needs for fodder, fuelwood, and timber. On the other hand, social issues, such as social relationships, perceptions and values about natural resources as seen by different social groups, issues of access to and control over resources, and issues of power in relation to deforestation, have rarely been discussed in current literature as possible driving forces to deforestation (Saxena et al. 2001).

Thousands of Afghan refugees have taken shelter in Pakistan. They are dependent on plants for their daily domestic needs. The Ghamkol Area, Peshawar Road in Kohat, for example, was rich in *Berberis lycium* and *Delphinium kohatense*. The Ghamkol Refugees Camp was established in the early 1980s. Today, *Berberis lycium* and *Delphinium kohatense* are lost from the area (Shinwari et al. 2002). Because of such trends, many of the species, especially those having medicinal values, are becoming threatened (Table 6).

According to Chaudheri and Qureshi (1991), nearly 37% (266 species) of the total of 709 endangered species are endemic to Pakistan. A recent study has revealed that there are over 600 endemic species of Indo-Pakistan (Shinwari et al. 2002) (Table 7). The center of evolutionary radiation is Kashmir, northern Balochistan and Chitral (northern Pakistan).

Ethnobotany in Pakistan. Table 7 Endemic plants of Pakistan (Modified from Ali and Qaiser 1986)

Area	Number (%)
Endemic in Kashmir (both the sides of the divide)	Over 600 (37%)
Endemic in Alpine-Hindukush	76 (20%)
Endemic species in Pakistan	Over 400
Bi- or triregional	Over 100
Uniregional	Over 300
Irano-Turanian	125
Sino-Himalayan	115
Saharo-Sindian	60
Mountainous areas	78%
Other regions	22%

The rapid loss of floral and cultural diversity and the poverty of 30% of the people in Pakistan make it urgent that we find solutions to their problems and to take active roles in making decisions about the management of natural resources and about the legal status of their traditions and knowledge.

WWF-Pakistan is playing a leading role toward conservation and sustainable management of plant resources. Keeping in view the floristic richness, local uses, danger of loss of knowledge, conservation status, and endemism, the Ethnobotany Project (then headed by one of the authors of this report), introduced Ethnobotany as a subject at M.Sc., M.Phil., and Ph.D. level in various universities.

A project initiated in 1997 as a collaborative effort between WWF-Pakistan and the People and Plants joint program of UNESCO, WWF, and the Royal Botanical Gardens Kew had the aim of developing an applied ethnobotany project to investigate the status of fodder and fuelwood management at Ayubia National Park (ANP) and in its periphery. The project, currently known as Ayubia Ethnobotany Project, also aimed at providing recommendations for improvement of fodder and fuelwood management systems, as well as implementing some activities to contribute toward greater sustainability of plant resources at ANP and in the surrounding forests. The overall objectives of the People and Plants program in Pakistan were to (1) strengthen the capacity for work in applied ethnobotany in Pakistan through a program of training of young professionals and students, and (2) achieve better integration between conservation and development at selected field sites.

The work conducted at ANP and in the surrounding forests was thus developed in order to provide a model, where the aim is to improve the management of forests including fuelwood and fodder resources outside the National Park. The aim was also to encourage agreements between communities from local villages and the Forest Department for joint management of forests in which communities have certain rights of use. This would reduce pressure on plant resources in the National Park.

Major Developmental Issues in Pakistan

Pakistan is the tenth most populated country in the world with 144 million people. Major national developmental issues are to alleviate poverty through increasing agricultural productivity and through improvement of other sectors such as industrial development and trade and tourism (UNEP and WTO 1998). In the forestry sector, programs of afforestation have been implemented to try and meet the country's timber and fuelwood needs. Timber harvesting through (unsustainable) logging is threatening environmental quality including supplies of some resources required by local communities (WWF-Pakistan 2000). Local cultural and social systems are progressively fading and, with them, local knowledge of resource management (Shinwari et al. 1996). National healthcare support at the village level is poor due to lack of facilities and qualified staff. The use of medicinal plants is therefore a necessity in many rural areas.

Women are usually responsible for fuelwood, fodder collection, and water carriage besides a host of agricultural activities. Access to fuelwood and fodder and other nontimber forest products (NTFPs) is also decreasing due to decreases in forest cover and also mismanagement of existing forests. Besides being overwhelmed by fuelwood and fodder collection tasks, education of young girls is also affected by lack of schools for girls. As is generally recognized in South Asia (Gururani 2002) and based on our own assessment of the situation at ANP, the link between women and resource management requires particular attention (Aumeeruddy 1996).

Conservation Priorities

Forest cover represents only 5.2% (4.58 million ha) of the country's area, but the country is highly dependent on trees as well as on NTFPs (Shinwari and Khan 2001). Scarcity of biological resources is a major concern because it represents the livelihood for a large portion of the population. Biodiversity is endangered through increase in population, timber harvesting beyond the productive potential, overgrazing in forest undergrowth as well as in pastures, unsustainable collection of NTFPs such as medicinal plants, for trade, and unsustainable collection of fuelwood (Government of Pakistan 1998). Fuelwood is still the main source of energy in Pakistan with 90% of the rural population and 50% of the urban population mainly relying on it.

International NGOs such as IUCN and WWF are working on natural resource management with a strong emphasis on the role of local communities. IUCN has been involved in recording traditional management of medicinal plants in Bomberet Valley in Chitral (Ali and Khuwaja 2003). Among local NGOs, the Agha Khan Rural Support Program is regionally recognized for its experience related to natural resource management involving local populations in afforestation programs, cultivation of medicinal plants, and social forestry. International agencies such as the European Union (EU) and a German aid agency (GTZ) are also involved in major projects in close collaboration with the Forest Department: the European Union project "Environmental Rehabilitation in NWFP and Punjab" and GTZ Joint Forest Management project in Mansehra (NWFP).

Priorities for Capacity Building in Ethnobotany

Ethnobotany is a multidisciplinary science encompassing botany, anthropology, economics, and linguistics that studies the way in which a society relates to its environment and particularly to the plant world. These relationships can be social, economic, symbolic, religious, ritualistic, commercial, or artistic (Aumeeruddy-Thomas and Pei Shengji 2003). In the early 1980s, there was an increased focus on local management practices by ethnobotanists as a result of greater global concerns about the environmental crisis. A great number of ethnobotanists were then engaged in studies to understand the rationale for such practices, the functioning of local institutions relating to management practices, as well as their impact on the conservation of biodiversity (Aumeeruddy-Thomas 2004).

An introductory workshop was organized in September 1996 that showed that ethnobotany in Pakistan had mainly focused on people's use of medicinal plants with relatively little concern for other plant resources. However, the practicalities related to resource management, aspects related to tenure, ownership, rights of access, methods of harvesting had not yet been investigated. Consultation during the workshop with conservation managers, academics, NGO representatives, and practitioners such as *hakeems* (traditional doctors) showed that there is much interest in using ethnobotany as a tool to learn more about people's needs and perceptions, in order to design better conservation approaches.

Ayubia National Park: An Example

ANP was chosen for the project in applied ethnobotany because it is representative of many situations encountered in other forested areas in NWFP—high pressure on resources due to high energy needs (because of prolonged winters and nonavailability/scarcity of alternate sources), mismanagement due to unclear access and tenure regimes, and a high level of conflict between local communities and the Wildlife and the Forest Departments.

Most of the vegetation in and around the Park is heavily influenced by people. The vegetation of ANP, which seems fairly well preserved in places, is dominated by coniferous species principally Blue pine (*Pinus wallichiana*) and Spruce (*Abies pindrow*) mixed with scattered broad-leaved tree species such as Oak (*Quercus dilatata*), *Aesculus indica*, Elm (*Ulmus wallichiana*), *Prunus padus*, etc. Populations of broad-leaved trees have declined. Blue pine and fir have colonized large areas, leaving seemingly little space for broad-leaved species to grow and relatively poor vegetation in the understorey. Outside the Park, forested areas are almost entirely composed of fir in the northern aspects and blue pine elsewhere.

Conservation and Developmental Issues at ANP

Forests are important in the Himalayan foothills for catchment's protection. At present, poorly regulated collection is leading to degradation of the resource base, both within and outside the Park. Tree populations are decimated and regeneration is highly affected. Women have to walk very long distances to collect fuelwood and fodder, and a situation of conflict persists between the women and the Park guards. Guzara forests (outside the Park) do not have a clear tenure regime and wild plant resources have greatly declined due to mismanagement, the absence of clear rules of control and access to resource. A critical social issue at Ayubia is that women are the main harvesters and users of natural resources but are also the least represented in decision-making processes. It is men who control the influential networks taking decisions regarding access to resources, tree planting, or timber harvesting.

Unlike in many other traditional societies, there is no well-developed classification or folk taxonomy. Moreover, knowledge and practices especially relating to fodder and fuelwood are not linked to cosmology or larger cultural beliefs. Beyond ethnobotanical knowledge, they also have some ethnoecological expertise, such as knowledge of bird nesting or over-flying the area, and habits and habitats.

E

Wild Vegetable and Mushroom Collection in the National Park

Types of mushroom collected were mainly different species of morels, locally known as *Kali* (black) and *Surkh* (red) Guchi (*Morchella esculenta*), Narela, Begar Guchi (*Morchella* sp.). Kali and Surkh are phenotypic variations of *M. esculenta*, the only mushroom collected for sale. For women, collection is associated with fodder or fuelwood collection trips.

The main vegetables collected are *Kunji* (*Dryopteris stewartii*), *Mushkana* (*Nepeta laevigata*), *Kandhor* (*Dryopteris blanfordii*), *Mirchi* (*Solanum nigra*), and *Tandi* (*Dipsacus inermis*). Parts collected are young leaves for all species. The most collected vegetables are the two *Dryopteris* species, followed by *N. laevigata*. It should be noted that two of these three species are ferns. Collection season for wild vegetables is between April and the end of June (Aumeeruddy et al. 2004).

Conservation Practices

Conservation of plants involves more than plant protection and controlling access to plant resources. Conservation also demands collection of baseline data on social, economic, and ecological parameters, to be incorporated into a comprehensive management strategy. Effective conservation also requires extension activities and education about the importance of plants as well as strategic cultivation initiatives. Moreover, conservation requires the involvement and support of the communities that ultimately depend on these plant resources.

A notable lack of available information on propagation and management of important species limits the increased cultivation of plants. This lack of information is exacerbated by a paucity of quality planting materials. By increasing both the amount of available information and the quantity of local nursery-based stocks, the project hopes to leverage a substantial reduction in the pressure on wild populations of plants. Whatever information exists on the cultivation of plants is not readily available to the farmers who actually could use it.

Selection of species for study must be based on several criteria: degree of endangerment in the wild, actual or potential market value, and the availability of existing information. To harvest medicinal plants sustainably, training of collectors, training in nursery techniques, and removal of some of the middlemen from the trading chain are essential.

Ethnobotany in South America

Ingrid Roth

Historic Considerations

Ethnobotanical investigation started in Venezuela with the first description of useful plants by Humboldt and Bonplan (1799–1804).

The original population of South America, the Indians, came from Asia about 23,000–10,000 years ago. Today, hundreds of Indian tribes still exist, each comprising a 1,000 people or less and each with its own language or dialect. They accumulated a knowledge of the native flora over centuries or even thousands of years. Almost every primitive society has its own pharmacopoeia. The Amazon area, extending over Colombia, Ecuador, Brazil, Perú, and Venezuelan Guiana (Schultes and Raffauf 1990), supports the most extensive tropical rainforest in the world, and rainforests are ecosystems with the greatest wealth of plant species.

The Indians searched mainly for medicinal plants which cured stomach and intestinal problems, inflammations, skin diseases, intoxications, gynecological disorders and parasites. For about 5,000 years, the Indians searched for useful plants and cultivated a large number of them. The most ancient archeological findings of plants used by Indians are Cucurbit seeds about 14,000 years old, and avocados about 10,000 years old. Cultivation of plants and agriculture were started, at the latest, about 5,000 years ago (Brücher 1989). South and Central American Indian tribes improved the yield and quality of numerous crop plants which today enrich our daily diet. Indians carried out experiments for possibly hundreds of years, but they may also have been accustomed to certain poisonous substances or more resistant to local drugs.

Indians not only supplied us with valuable goods, but also transmitted their language.

On the Origin of Common and Some Latin Plant Names

In tropical regions, plant identification is most difficult. Most of the plant families have their own specialist somewhere in the States, in the Netherlands, or in other countries so that the material has to be sent to them where it may rest for years or decades until identification is settled and sanctioned. In the meantime, one is dependent on the local and common names which – in many cases – are very useful and unmistakable. In Venezuelan Guyana, there was a peasant without any scientific training who could distinguish most of the 280 collected specimens, even separating the species from one another, relying thus only on common names. A binary nomenclature is frequently used so that sometimes a perfect correspondence between scientific and common names is maintained: *Guamo*, for example, corresponds to the genus *Inga*; and each species also has a species name. *Inga alba* carries the vernacular species name *colorado,* which means colored (*Guamo colorado*). *Inga capitata* is called *Guamo negro* (black Guamo), *Inga rubiginosa* corresponds to *Guamo terciopelo* (velvety Guamo), and so on. The complication which arises from this nomenclature is its regional restriction, so that a species called *Guamo colorado* in Venezuelan Guyana may have a completely different name in other parts of Venezuela. Also, the name *Guamo colorado* may be applied for two completely different species belonging to different families in geographically different regions. Great caution in the application of these names is therefore indicated, and information about the geographical origin of the species in question is indispensable.

Within the mixed-up jungle of common names, this author made the observation that some words were obviously of Spanish origin while others had an Indian sound. After the conquistadores had entered the country, many of the original Indian plant names were altered. A *palo de Maria* (*palo* = pole, stem; in Venezuelan Spanish, it is a tree) corresponding to *Tachiglia paniculata,* or Santa Maria (*Triplaris surinamensis*), San Jose (Saint Joseph = *Jacaranda obtusifolia*), or Nazareno (from *Nazareth* = *Peltogyne pubescens*) certainly resulted from attempts to Christianize the Indian world. A great part of the common names are thus of Spanish origin, created soon after the colonizers arrived. Names were given by using personal names such as Don Juan, or recognizing special characteristics of the plants such as *azucarito* (sugary) or *espina de erizo* (spine of the hedgehog). The Spanish name *sangrito* (bloody, bleeding) for *Pterocarpus* refers to the red secretion from the bark; *cenizero* (ashtray) relates to the old powdery bark; the name *jabón* (soap) comes from the smell of the fresh bark. The name *kerosen* indicates the propensity of the cork to catch fire when lit with a match; the *zapatero* (shoemaker) has a fruit in the shape of the sole of a shoe. Other names refer to characteristic colors, geographical origin (*montanero* = from the mountains, *sabanero* = from the savanna), to similarities and comparisons with animals (*pata de zamuro* = claw of the vulture; *burro muerto* = dead donkey; *cabeza de mono* = head of the monkey); and many other designations which are more remarkable for their oddity than their characterization of the plant. Some names, however, such as *conserva* (canned food), certainly a very recently applied name, have little or nothing to do with the appearance of the plant. Many species, on the other hand, were compared with the indigenous European plants and some of them recognized more or less correctly by the Spanish colonizers, such as certain Lauraceae of the genera *Aniba*, *Endlicheria*, *Ocotea*, and *Nectandra* which received the generic name Laurel (for example: yellow Laurel, black Laurel). However, it may be possible that some of these names were given relatively recently by people already trained in Botany. Rollet's Laurel, certainly, is a very recent creation in honor of Dr Rollet. *Higuerón* (fig) for *Ficus* is also correct. Most of the comparisons with the indigenous European plant species, however, are very unsuccessful falsifications which have nothing to do with the European genera or species after which they were named. *Cedro dulce* (the sweet cedar) is *Eriotheca*, Bombacaceae; *Crudia*, Caesalpiniaceae, is called *algarrobo* (carob); *Caryocar nuciferum*, Caryocaraceae, became an almond (*almendra*); *Platymiscium*, Papilionaceae, was made an oak (*roble*); and *Swartzia schomburgkii*, Papilionaceae, was transformed into an olive tree (*olivero*). The name *uvero* (grapevine) for *Coccoloba,* Polygonaceae, refers to the clustered grape-like infrutescence of this tree. *Touroulia guianensis*, Quiinaceae, is called *palmito*, but it has nothing to do with palm trees, and *helecho* (fern) corresponds to *Dilodendron,* Sapindaceae, which has no relationship with ferns.

As mentioned above, in many cases we can only guess in which historical period names were given, whether soon after the conquistadores had entered the country (Christian names) or only recently by botanically trained people (as Laurel Rollet). Some species of *Sapium,* Euphorbiaceae, are, for example, designated as *caucho* (rubber), probably a name of Indian origin.

Many of the originally applied Indian names may have been much more meaningful than the later Spanish names. In the jungle of names even some of

Arabic origin appear; these were first assimilated from the Arabs by the Spanish people and came from Spain via the conquistadores to South America. *Jebe* (*Lonchocarpus sericeus,* Papilionaceae) is an Arabic name. Checking a complete plant list with over 270 species the author found that about 50% were of Indian origin. But it is very difficult to find them out. Not all names which mean nothing in Spanish are Indian names.

Within the approximately 370 known Indian tribes, 125 different language families are distinguished, not counting dialects and individual languages. The fact that no fundamental language type unites all these different tongues complicates any investigation. Best studied are probably the Mexican Indian languages. Indian plant names from Mexico sound different from Venezuelan names. In Venezuela, however, philological studies of Indian languages are hardly cultivated. Checking a dictionary of Yanomami, no word referring to a plant name could be found. However, some names of very different Indian origin, such as Chibchua, Quechua, Náhuatl, Taino, Caraibic, Guarani, Araucanic, Tupi, or Guaicurü (from Mexico, Brazil, Peru, Chile, and the Caribbean) were adopted in other South or Middle American countries and are now known all over the world. From the Taino came such common words as *maiz*, *tabaco*, and *sabana*. From Náhuatl (Mexico) we have *aguacate* (avocado), *cacao*, chocolate, tomato, potato, and chicle. *Colibri* (a bird) comes from the Caraibic (or Caribic); *ananas* is from the Guarani. Quechua has contributed the words quinine and cocoa, while petunia comes from Tupi.

Some Indian words may easily be recognized by their prefixes or suffixes. The prefix *gua-* always indicates Indian origin, as in *guamo, guatacare, guacharaco* or *guaraunera*; Guatemala is also an Indian name). -*Gua* also appears at the end of the word in *majagua*, or in the middle of the word, as in *masaguaro*. The suffix -*cua* in Nicua or -*guo-* in Purguo is used frequently. -*Guay-* or -*guaya-* in *guayaba* and *guayabito* are other forms of Indian vocal music rich in vowels. Double vowels like ua, ue, and uo are frequently represented in Indian words such as *carruache, arahueque,* and *bocsuo* or *merguo*. The *puig* rich in vowels may be a creation of the Caribbean area, being used in Northern South America and the Caribbean Islands. In some words one may perceive the Indian onomatopoeia as in *paují*, a bird name. Double vowels are also characteristic of such words as *copey* (the Christian-Social party of Venezuela has chosen this as its party name which is adopted from the copey tree, a *Clusia), cozoiba, cacaito,* or *yigüire*. The ending –*mán* is frequently found in such Indian words as *baramán, cajimán, samán*. The suffix –*i*, otherwise frequent in certain Indian languages, is seldom found in Venezuelan Indian names. However, the accentuated ú is not infrequent, as in *cacú*. The ending -*ey* as in *araguaney* and *merey* also indicates Indian origin. The ending -*tl*, on the other hand, as frequently found in Mexican Indian (Náhuatl, for example), seems to be missing in Venezuelan Indian. A repetition of a word, a twin word, is usually a reference to the Indian in such word compositions as *sun sun, marimari*, or *yarayara*; in Yanomami Yare means "gone with the wind" and may be the origin of the name *yarayara*, eventually referring to seed dispersal. Some of the Indian names became part of the scientific nomenclature. Examples are *samán (Samanea saman), ceiba, simarouba,* Cacao *(Theobroma cacao),* and many others. The meanings of the Indian names are unknown. For some cultivated plants or plants of high economic value, however, the significance of the names is known. The name caucho or *caoutchouc* (*rubber*), in Indian *cau-uchu*, means the weeping tree which sheds tears of latex. Dozens of English words thus have their origin in one or another Indian language.

Transmission of Information

Botanical knowledge was transmitted to the present population mainly orally. It is based on the experience and experiments of Indians for hundreds or even thousands of years. It is estimated that at least 20 alimentary plant species were cultivated on the continent by Indians before the arrival of Columbus in 1492. The Andean Incas trained pharmacognosts specialized in the search for new natural drugs. In the Maya culture, illustrated books called codices were elaborated in which preparations of medical plants are described. The oldest book dates back as far as the tenth century. Dr M. de Cruz had already described 250 curative plants in 1552. The Incas, however, unfortunately did not draw the plants.

Inca Medicine

Inca medicine was divided into a magic-religious branch administered by the priest of the Temple of the Gods and an empirical branch practiced by the *curanderos* (healers) (*Primera nueva cronica y buen gobierno* of Felipe Poma de Ayala in 1613) (Albornoz 1993).

Illness and death were connected with religion and mysticism. Indians believed that they were caused by magical sources. Consequently, shamanistic use of hallucinogenic plants was well developed. Healing was accompanied by ritual dances, dances imitating animals, black magic, exorcism, faith healing and the use of amulets. Astrology was integrated into the healing methods of the ancient Indians. Medicine men collected roots and other vegetable parts in the woods while singing and praying. They applied the theory of signatures, just as Paracelsus did in the sixteenth century, suggesting that each plant resembled the part of the human body which it could cure (Albornoz 1993).

Sick people were cured with massages, suction, vapor blowing, or cataplasms. Shamans acted as intermediates between people and the gods. The Indians used plants in rites and religious ceremonies; the plants are important as they open the entrance to the spiritual world and enable the person to communicate with ghosts and gods and to develop spiritual power (Fig. 1). Species of *Nicotiana* (tobacco) were used to prepare stimulants and narcotics, as well as for medicinal, ritualistic, and hedonistic purposes. Shamans and priests employed nicotine to enter into ecstatic trances. Today, nicotine is also used as an insecticide.

Hallucinogenics of *Ebena* were smoked with blowpipes. The action of the active alkaloids started only a few minutes later, when the spirit abandoned the body to enter the world of ghosts. In this way, shamans expelled the bad ghosts from the body of the patient. *Ayahuasca* (*Banisteropsis*) alkaloids enable telepathy and prophecy. Pictures painted under the influence of ayahuasca are rich in vivid and bright colors, in symbolism and details.

Cacao was called the Food of the Gods (Figs. 2 and 3). The Indians have domesticated it since 2,000 years ago. They developed the art of planting and selecting cacao. The Indian emperor Moctezuma (Montezuma) is said to have drunk 400 cups of hot xocolatl (chocolate) a day. Cacao contains stimulating alkaloids.

Cocaine (*Erythroxylum coca*) has been cultivated in the Andes since 7000 years BCE The coca shrub contains the alkaloid cocaine, used as a remedy for hunger and fatigue. Indians masticate the leaves. The hydrochloride of cocaine is used as a local anesthetic. The function of the brain is altered by the use of psychoactive plants. The use of drugs is, however, prescribed by religious instructions of the tribe.

The native population can utilize almost every plant growing in their environment. The discovery of South America brought a large number of new plant species to Europe and in this way profoundly altered European habits. As a consequence of the discovery of America, such products as maize, cocoa, potato,

tobacco, and beautiful orchids improved the European standard of living. *Hevea brasiliensis* supplied the latex rubber.

Utility of South American Plants

Indians used plants to make fermented drinks, syrup, jam, and marmalade from fruits, baskets and cloth from fibers, vessels from calabashes, and housing, canoes, musical instruments, arrows, and bows, furniture and carved objects from timber. For hunting, they used fish and arrow poisons extracted from plants (curare). Timbers resistant to termites were particularly useful. Some plants supply perfumes or even insecticides. Oils, resins and balsams, wax, cork, gum and rubber, glycosides, saponins, alkaloids, flavonoids, coumarin, tannins, carbohydrates, pectins, lipoids, and tars are found in South American plants. Enzymes, lectins, vitamins, vegetable sweeteners, antidotes, antibiotics, cytostatics, immunostimulants, immunosuppressives, antiallergens, and laxatives may be extracted from many plants, as well as antimicrobial substances, antioxidants, cholesterol-reducing and glucose regulating or anti-inflammatory and antiphlogistic substances. Some plants not only contain a single substance, but some contain as many as 70 different alkaloids or dozens of active substances with similar effects.

A large number of tropical plants have a variety of uses. Most medicinal plants cure quite a few diseases. These plants may also have other uses.

Other not-curative substances obtained from plants are edible plant parts, cloth, material for construction and transportation, condiments, perfumes, soap, stimulants, fibers, cork, tannins, timber, and natural dyes. The Indians also used these dyes to paint their bodies (e.g. red with *Bixa orellana*) and were consequently called red skinned people. Seeds of the cacao tree were used by Indians as currency: with 100 beans one could buy a slave. Further objects of exchange were condiments, timber, and textiles (Figs. 4–22).

Preparation of Herbal Drugs

Natives frequently use crude herbs. They put fresh leaves on wounds for disinfection or on the forehead to soothe headaches. Fresh fruits, seeds, and leaves may be eaten raw or plant parts may be cut to pieces, broken, shredded, crushed, ground, or pulverized. For external use, cataplasms are prepared by crushing and grinding.

knowledge on to their daughters. Many useful plants are cultivated by women in special house gardens around the house (Silva 1999). Women likewise play their part in agriculture and are aware of the biological diversity of plants. In many places they maintain the agricultural system called *conuco* carried out in the form of small plantations (Royero et al. 1999).

Actual Use of Medicinal Plants

In 1884, the first school of pharmaceutical studies was founded in Venezuela. Although in the twentieth century interest in natural medicine declined abruptly, due to the development of chemotherapy and synthetic products, native people who live far away from urban centers, e.g., in the Orinoco delta or in large forests where no public transportation is available, plants are still the best and the most inexpensive medicine available for everybody all the time. In underdeveloped countries, 3.5 million people depend on phytopharmacy. Natural medicines also have the advantage of having been tested by Indians for hundreds of years.

Further Possible Investigation and Recommended Bibliography

The first place to find information about medicinal plants would be the *herbolarios*, open stands where healing plants are offered. They are scattered all over

Ethnobotany in South America. Fig. 19 Woodcarving representing a llama with its shepherd (original).

the country and staffed by native experts on healing plants. These people preserve the knowledge of useful plants transmitted to them by their ancestors. They know exactly the right plant species, the organs which have to be used, the methods to prepare the drugs and the way to administer the medicine. They also are informed if the plant was collected wild or whether it was cultivated, and they know their vernacular and local names. Drugs of this kind have to be handled with care. Native people are accustomed to these drugs over as many as hundreds of years; other people may react in very different ways. Caution is advisable. The *herbolarios* are often found along highways or at local markets. Perhaps the most authentic information is found with the living Indian tribes, who know not only healing plants, but also narcotics (Schultes and Raffauf 1990).

In most cases, healing substances are only found in one or another organ, or are enriched in determined organs. When buying drugs at the pharmacological stalls, only plant parts or organs are handed over to the buyer, who then has to find out which plant species is the donor and which taxonomic name the plant has, as plants are usually sold by their vernacular names.

The collection of SECAB is one of the most valuable compilations of medicinal plants which includes the flora of Bolivia, Colombia, Chile, Ecuador, Panama, Peru, and Venezuela. Pittier (1926) contributed a great deal to the knowledge of the useful Venezuelan plants. Gupta (1995) studied 270 Ibero-American medicinal

plants. Schultes and Raffauf (1990) deal with the healing forest of the northwest Amazon region. Brücher (1989) treated the genetics of neotropical useful plants. Interest in tropical useful plants has been growing steadily, so that several books dealing with taxonomic description, chemical contents, pharmacology, use (including recipes), ecological requirements and cultivation of medicinal plants have appeared, written by native botanists, pharmacists, experts on human nutrition, chemists, etc. Uphof provides a good survey of useful and medicinal plants of the world up to 1968. Exhaustive information on South American medicinal and useful plants can be found in Roth and Lindorf 2002.

Ethnomathematics

Marcia Ascher

Ethnomathematics, as a field of inquiry, began in about 1970, although the term itself did not come into use until about 10 years later. Its basic tenet is that mathematical ideas are cultural expressions embedded within cultural contexts. The emergence or elaboration of mathematical ideas follows no necessary or universal path. The ideas that are stressed, their expressions, and their applications vary depending on the culture. Whether an idea arises within a culture or is stimulated by contact with another culture, it becomes enmeshed in the complex of ideas particular to the culture. This perspective is of particular importance because mathematics had long been viewed as culture-free or culture-neutral.

Ethnomathematics calls for a definition of mathematical ideas that is broader in scope than just those associated with modern mathematics. By modern mathematics we mean the category so designated by professional mathematicians worldwide and spread through Western-style schooling. Modern mathematics itself is the confluence of ideas from people in many cultures which became merged through translation, media, and standardization of expression. Mathematical ideas, however, whether or not they fed this stream, are those ideas involving number, logic, spatial configuration, and more important, the organization of these into systems and structures. To fully appreciate the ideas, they must be viewed in their cultural and ideational contexts.

The number of different cultures existing during the past 300 years, using the criterion of mutually exclusive speech communities, is in the range of 5,000–6,000. Although today there is an overlay of a few dominant cultures, traditional cultures still exist, in some cases blended with, or within, the dominant cultures. Moreover, there are, particularly within large or small industrialized nation-states, subcultures, part cultures, and composite cultures which have developed shared ideas and particular ways of doing things. To learn about the mathematical ideas of cultures that had no writing systems or whose traditions are no longer extant, we must depend on information that can be gleaned from artifacts or from reports of observations left by others. Even where the ideas are current, they are often implicit rather than explicit, and so must be obtained through the interpretation of observations and conversations. Thus, the study of mathematical ideas in their cultural contexts often interacts with or draws upon such fields as archaeology, ethnology, linguistics, culture history, and cognitive studies.

For some, the primary goal of ethnomathematics is to broaden the history of mathematics to one that is global and humanistic. For others, the pedagogical implications and uses are paramount.

Through a discussion of planar graphs and concepts of space/time, the sense and perspective of ethnomathematics will be made more specific.

Planar Graphs

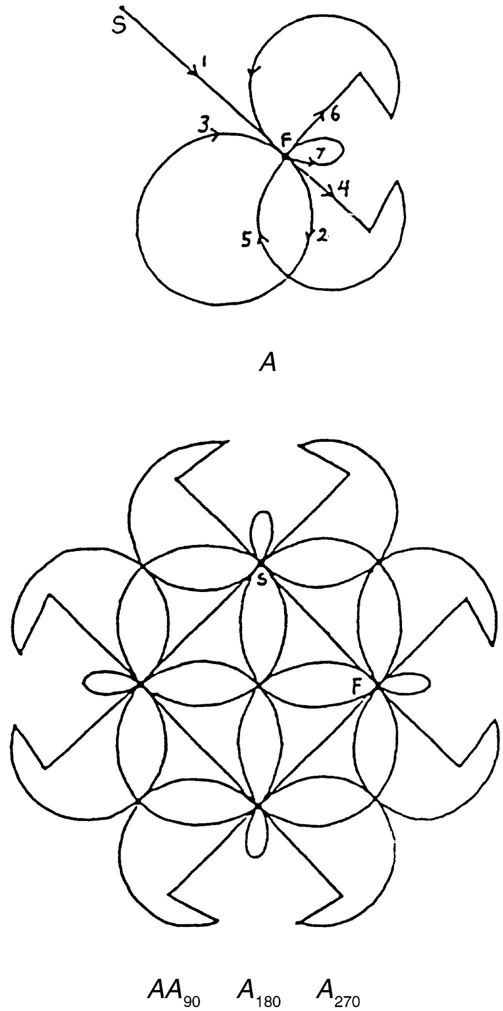
The mathematical idea of tracing figures continuously is found in several diverse cultures. Just as the contexts for the tracings differ from culture to culture, so do the associated geometric or topological ideas.

In modern mathematics, the concept of continuous figure tracing falls within graph theory. Described geometrically, graph theory is concerned with arrays of points (called vertices) interconnected by lines (called edges). The question said to have inspired the founding of graph theory by the mathematician Euler was: "For a graph, can a continuous path be found that covers every edge once and only once? Also, if such a path exists, can the path end at the point it started?" According to the story, there were seven bridges in Königsberg, Prussia where Euler lived. The townspeople wondered if, on their Sunday walks, they could start from home, cross each bridge once and only once, and end at home. Between Euler in 1736 and Hierholzer some 130 years later, a complete answer was found. The answer depends on the degrees of the vertices – the degree of a vertex is the number of edges emanating from it. First of all, not all graphs can be traced continuously covering every edge once and only once. Such a path exists if the graph has one pair of vertices of odd degree, provided that you start at one of them and end at the other. Also, if all vertices have even degree, such a path can be traced starting anywhere and ending where you began. There can be no such path when a graph has more than one pair of vertices of odd degree.

Much the same question was of concern to the Malekula who live in Oceania in what is now the Republic of Vanuatu. There, however, the issue is getting to the Land of the Dead. According to the Malekula, when a man dies, in order to get to the Land of the Dead, his ghost must pass a spider-like ogre who challenges him to trace a figure in the sand. He must trace the entire figure without lifting his finger or backtracking and, if possible, ending at the point he started. If he cannot meet the challenge, he cannot proceed to the Land of the Dead.

From the ethnographic literature about 100 figures and the exact tracing paths used by the Malekula are known. Analysis of the tracing courses corroborate the Malekula's concern for the problem and their adherence to its stipulations and solution. However, in addition, the tracing courses demonstrate the use of systematic procedures involving general systems that extended beyond individual figures to groups of figures. There are three or four of these extended systems, one of which is briefly described here.

For each figure in the group, there is an initial procedure, namely some ordered sequence of motions (call it A). This is followed by the same procedure modified by formal transformations. Call a transformed procedure A_T. For the group of figures, only a particular set of transformations is used: rotation through 90°, 180°, 270°; horizontal reflection; vertical reflection; each alone or in combination with inversion. Inversion is the reversal of the order of the procedure. One figure and its initial procedure, A, are shown in Fig. 1.



Ethnomathematics. Fig. 1 A Malekula sand tracing. Top: A; bottom: $AA_{90}\ A_{180}\ A_{270}$.

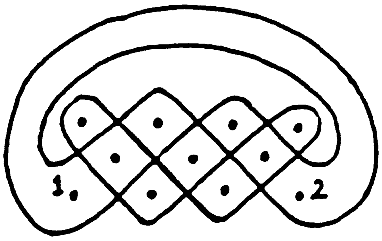
In terms of A, the figure can be succinctly described as $AA_{90}\ A_{180}\ A_{270}$.

The figure exemplifies the Malekula interest in symmetry combined with graph theoretic constraints and formal, systematized tracing processes.

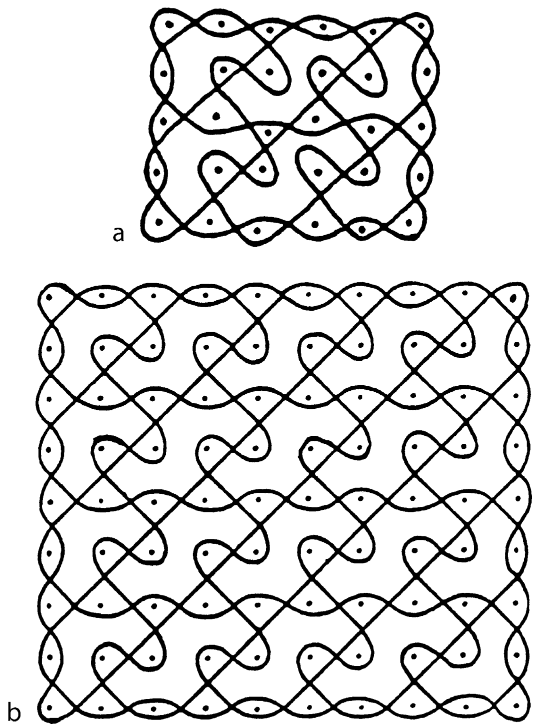
The study of the mathematical ideas embedded in the Malekula sand tracing tradition leads to an appreciation of this as an intellectual endeavor. However, the global history of mathematics is also enriched. The question of continuous figure tracing is seen as one that arises in different human settings and that has intrigued and challenged quite diverse people. As such, it has been used in the teaching of modern mathematics to create a more inclusive and humanistic view of mathematics.

Another, quite different, sand tracing tradition is found among the Tshokwe of what is now the Angola/Zaire region of Africa. In this tradition, a rectangular array of dots is first constructed. Then a skilful storyteller intrigues his audience by drawing a continuous figure around the dots as the story related to the figure emerges. Some of the stories highlight the topological fact that the resultant figure defines regions in which certain dots are isolated from others.

In Fig. 2, for example, dots 1 and 2 represent a husband and wife; the other dots are their neighbors. The husband built barriers to keep his wife from the neighbors so that she would attend to her chores instead



Ethnomathematics. Fig. 2 A Tshokwe sand tracing.



Ethnomathematics. Fig. 3 Tshokwe sand tracings. (a) *Top*; (b) *bottom*.

of visiting. A large collection of these figures and their stories have been made during the past 50 years. The collection is rich and varied. There are, for example, sets of figures sharing general characteristics of shape but differing in a construction parameter. For example, compare Fig. 3a, b.

Again, exploration of this tradition has increased our appreciation and enriched the global history of mathematics. In addition, however, now having several instances of continuous figure tracing, we see that a particular mathematical idea can lead to different elaborations through combination with a different assortment of mathematical ideas.

Concepts of Space/Time

All cultures define time and the space around them by the physical and mental imposition of order. Because these orderings play such a significant role in how experience is perceived and interpreted, it is extremely difficult to comprehend that others may define them differently. Western concepts of time and space are an intimate part of modern mathematics. We briefly describe another view, that of the Navajo of North America, with particular emphasis on points of contrast with the Western view.

In Western culture, until the late nineteenth century, Euclidean geometry was believed to describe truths about the physical world. Basic to Euclidean geometry are points, lines, surfaces, and solids, and the belief that they can be used to separate space into parts. For example, a line can be separated into two parts by a point, or a surface can be separated into parts by lines. It is also assumed that space has three dimensions, it has no gaps (continuous), it extends in all directions without bound (infinite), it has zero curvature, and neither size nor shape are changed if something is in one place rather than another (uniform). At the end of the seventeenth century – particularly because of the work of Isaac Newton – the three spatial dimensions were augmented by time as a fourth. This time dimension, however, is distinct from the space dimensions. That is, a configuration in space may change with the passage of time but spatial properties are absolute and not affected by time. Mathematicians now understand that Euclidean geometry is a mental construct and that, under other assumptions, there are other geometries. Also, for the physical universe, time and space have become interrelated by Einstein's theories of relativity and by the cosmological theory that space itself has been undergoing expansion since the universe began as a single point. Nevertheless, the Euclidean model (with an augmented time dimension) still underpins the worldview incorporated in modern mathematics and science.

For the Navajo, space and time are so inextricably interwoven that one cannot be discussed without the other. They see the universe as dynamic, made up of processes rather than objects and situations. They do not conceptualize things as wholes made up of clearly distinguishable static parts. We, for example, see the body as a physical unit which has distinct parts with specific locations and specific boundaries. For us, arms, legs, teeth, and eyes are part of the body but, say blood pressure, is not. To the Navajo, on the other hand, the body is a dynamic whole, that is, a *system* of interrelated parts. To be a part of the body means to be involved in making the body work. Blood pressure then, without a static specific place, is as much a part of the body as an arm or leg.

For the Navajo, of course, specific locations and spatial boundaries do exist. However, while we view a location as where something *is*, the Navajo view it in terms of process – an object is in process of being in a specific place as the result of the withdrawal of motion. Spatial boundaries, as well, have dynamic components: some interrupt action but the action can continue once the boundary is surmounted; others require that actions be modified.

Another contrast is the description of two overlapping surfaces. We see as significant that the surfaces have a region in common. Since our focus is on the region as a set of spatial points, we can describe the region with no concern for time or motion. The Navajo see the overlap as part of an active, ongoing process. What is of primary significance is whether the same or different elements are in contact and, hence, are defining the region. If, for example, the surfaces that overlap are a snake and a rock, the overlap is different in kind if the snake is sleeping on the rock or if the snake is slithering over the rock.

As contrasted to focusing on when and where something is, the Navajo focus on its motion – whether it is coming or going, getting faster or slower, or moving purposefully or aimlessly. Distance, too, is conceptualized in terms of movement with respect to markers.

In the Navajo worldview, space is continuous, has three dimensions, and is finite in that the universe is expanding outward but will eventually shrink back to its starting point. However, above all, interrelatedness and motion are ever present, incorporating and subsuming both space and time.

Differences in worldview have ramifications for approaches to solutions of problems as well as to their contents. The analytic approach is fundamental to mathematics and its teaching. Problems are broken up into subparts in the belief that the solution is the sum of the solutions of the subparts. Furthermore, the steps used in mathematical problem solving superimpose processes on what are viewed as static entities and fixed relationships, in the belief that these processes have no effects on the entities or relationships. By contrast, Navajo problem solving is holistic and focuses on the problems' dynamic interrelationships.

Ethnologists and linguists in the first half of the twentieth century discussed the Navajo culture and worldview. However, only much more recently have studies concentrated on their mathematical ideas and on the ramifications of their worldview for school learning of mathematics (Moore 1993; Pinxten 1983). From these studies we have gained insight into how very deeply mathematical ideas are embedded in culture. The ethnomathematical perspective, which views mathematical ideas as cultural products, provides an enlarged framework within which there can be more than one worldview, making clearer contrasting underlying assumptions and enabling diverse contributions.

The ethnomathematics endeavor has drawn together researchers and educators from many parts of the world. For example, Claudia Zaslavsky's seminal book on African mathematical ideas and practices inspired further investigations by many African scholars. Notices of their work appear in an ongoing newsletter published by the African Mathematical Union's Commission on the History of Mathematics in Africa. The newsletter is available at ►http://www.math.buffalo.edu/mad/AMU/amuchma_online.html.

And, in Mozambique, Paulus Gerdes, a mathematics educator, has made extensive use of the Tshokwe figures discussed earlier, using them as a basis for introducing students to a variety of numerical, topological, and algorithmic ideas. The association of these and other ideas with indigenous traditions is being used by him (Gerdes 1993, 1999) to underscore the premise that mathematics is not the exclusive product or province of an outside, dominant culture. More anthropologically based studies continue to enlarge the global history of mathematics and mathematical ideas. See, for example, Ascher (1991, 2002), Washburn and Crowe (1988) and Frank (1992, 1999). The intimate relationship between language, cognition, and mathematical ideas continues to be explored. A thoughtful overview and discussion of this can be found in Barton and Frank (2001).

The International Study Group on Ethnomathematics serves as a focal point for those primarily concerned with the pedagogical implications of ethnomathematics. It has a large international membership primarily made up of elementary mathematics educators who teach in non-Western settings. Reports of activities and projects of the organization and its members can be found in their newsletters, which are available through their website ►http://www.rpi.edu/~eglash/isgem.htm.

Ethnomathematics of the Inkas

Thomas E. Gilsdorf

Under the shade of a tree some women are sitting. They are watching over several children, but at the same time their bodies are subtly swaying and their hands are busy moving threads. These women are weaving. As they talk among themselves, calculations are occurring: 40 × 2, 20 × 2, 10 × 2, etc. On their weaving tools symmetric patterns of geometric and animal figures are slowing emerging, produced from years of experience in counting and understanding symmetric properties. The procedures they follow have been instructed to them verbally as has been done for thousands of years, and they follow it precisely, almost subconsciously. In fact, these women are doing *mathematics*. They are calculating pairs of threads in blocks of tens (10, 20, and so on) and determining which colors of threads must go in which places so that half of emerging figures will be exactly copied across an axis of symmetry. These women, and likely some girls who are learning from them, are not writing down equations or scratching out the calculations on a notepad. Remarkably, the weaving is done from memory.

Weaving has existed in most cultures around the world, so the events and hence the mathematics in the previous paragraph could occur almost anywhere. In our case, we are going to consider the mathematics of the South American cultural group of the Quechua-speaking Inkas (Incas). As with weaving, we will see that Inka mathematics is intimately tangled with Inka culture.

Before we can jump into the details of their mathematics, we must take some time to understand who the Inkas were, and some small picture of what their culture was like. Backing up even further, the first term we must clarify is "Inka," by which we refer to a collection of many groups who had a common government, religion and language, but were of distinct cultural origins. When we speak of the "Inka Empire," we refer to the territory controlled by the Inka from about 1400 to 1560 (CE). The first Inkas started near Cuzco in present-day Peru and persistently moved on neighboring groups, forming an enormous empire that included part or all of Peru, Ecuador, Bolivia, Chile, Argentina, and southern Colombia (Fig. 1).

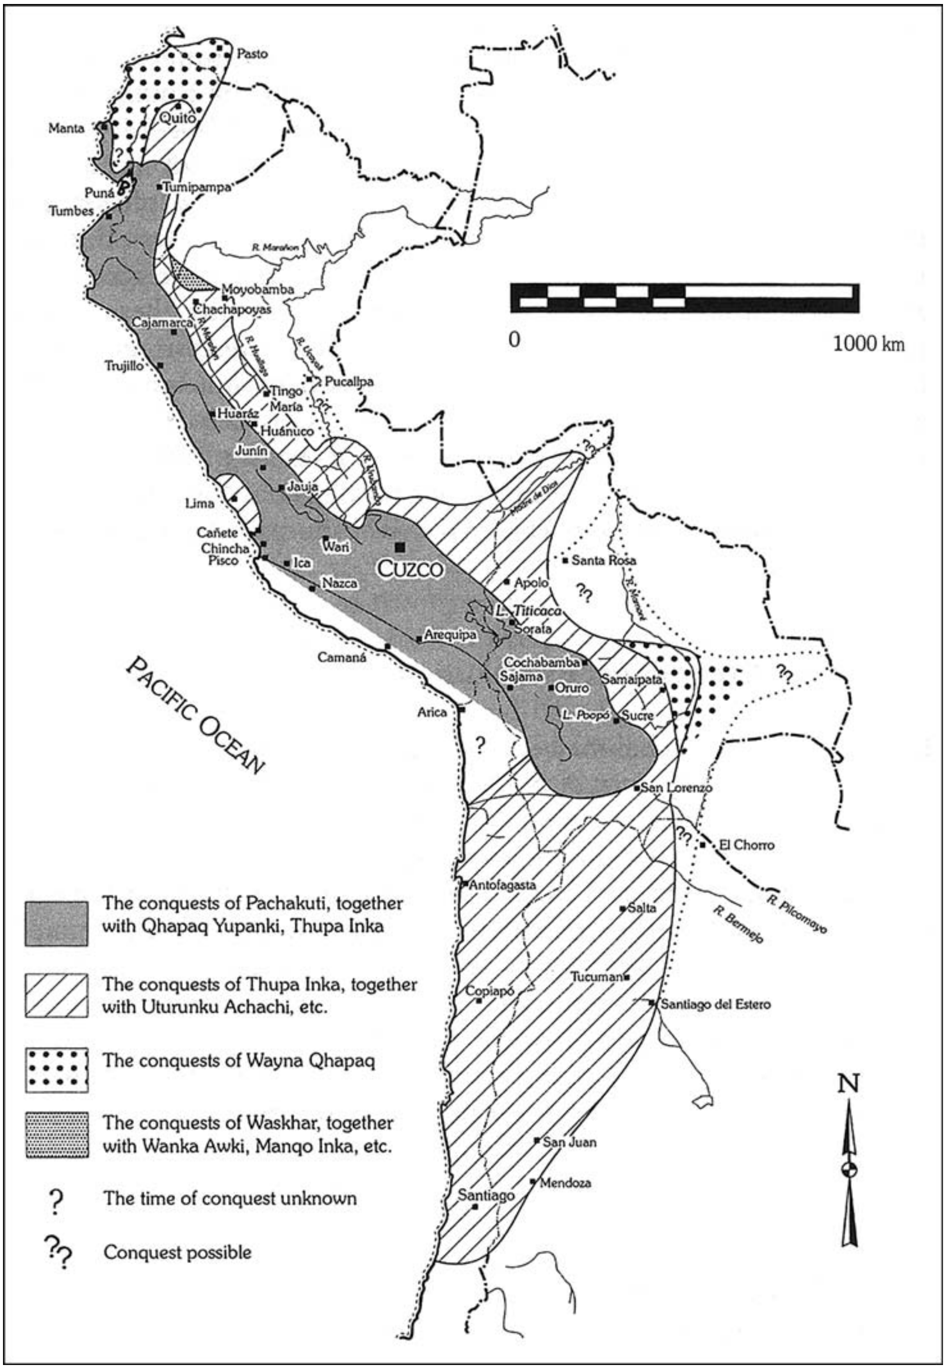
We have seen that there is mathematical thought occurring in weaving, but as we proceed, we can also observe factors such as geography that may have influenced the development of Inka mathematics.

Geographic, Climatic, and Environmental Aspects of Inka Mathematics

The Inka territory included regions of widely varying geography: coastal desert, high rugged Andes, the Lake Titicaca inter-mountain area, seacoast along the Pacific, and jungle on the eastern edge of the Andes as they descend into the vast Amazon basin. From pages 24–32 of D'Altroy (2003), we can get a glimpse of the situation, by noting that a 200 km trip by air from ocean to forest in central Peru would cross 20 of the world's 34 major life zones. In addition, the Andes range contains many areas that are rugged enough to be inaccessible even by horseback.

In terms of weather, there are numerous, unstable climate and geological patterns such as earthquakes, droughts, floods and the corresponding effects of periodic occurrences of el Niño.

These geographical aspects indicate several needs for mathematics. For example, all successful groups in the dry regions had to have some kind of effective water control in the form of irrigation and aqueducts. Next,



Ethnomathematics of the Inkas. Fig. 1 The Inka Empire. From D’Altroy, *The Incas*. Oxford: Blackwell Publishing, 2003: 66. Used with their kind permission.

those in the high altitudes had to have some form of flexible mountain agriculture, such as terrace farming. Moreover, in many parts of the Inka territory, the groups there had to construct bridges to cross deep canyons and difficult mountain areas. In effect, civil, and agricultural engineering were crucial elements of survival. Finally, as in almost any cultural group, knowledge of astronomy is important in terms of predicting planting and harvesting seasons, approximating weather changes, and general time keeping. Mathematics is, of course, necessary for all of these activities.

A Few Relevant Cultural Groups

As alluded to previously, there were many groups that formed what we are calling the Inkas, and we would like to mention just a few of them. The relevance is that these groups had their own mathematical concepts and practices, and as the Inkas absorbed these groups into their system, they almost certainly made use of some of that mathematical knowledge. A quite complete general reference on the various groups and their interactions with the Inka is in Moseley (1992).

Of the many competing cultural groups in what became Inka territory, we can first mention the Moche of the northern Peruvian coast, from about 100 to 700 CE. Later, in old Moche territory a substantial group called the Chimú arose, forming the Chimor Empire with its capital city of Chan Chan. The Moche-Chimú group was the largest Inka rival, and they inhabited the northern Peruvian coast during the Early Intermediate period to the Late Intermediate period (about CE 0–1470). They practiced river valley agriculture along several of the rivers that descend from the Andes to the Pacific, including the Moche River. They were not overcome by the Inkas until 1470.

Another group is the Huari of the central Andean highlands of Peru during the Early Intermediate and Middle Horizon periods (about CE 600–1000). The Huari engaged in advanced irrigated terrace farming and had quite mathematical artwork.

Next, we can mention the Aymara kingdoms of the Lake Titicaca region of the Late Intermediate period (about CE 1000–1400). The Aymara themselves consisted of several groups, e.g., the Colla and Lupaqa groups. Also, the Aymara had their own language group, and some dialects of Aymara are still spoken today. The Aymara also had extensive terrace agriculture as well as domesticated llamas and alpacas.

The last of this sampling of groups that we mention is the Nazca of the southern Peruvian coast of the Early Intermediate period (about BCE 400–CE 500). Some indication of Nazca understanding of geometry and astronomy can be seen in the lines and figures they created in the desert. It is still not clear what the lines represent, but there are connections between many of the lines and both astronomy and ritual of the Nazca. The interested reader can get some idea of this topic in the book edited by Aveni et al. (1990) and in the article on Nazca lines in this encyclopaedia. Of course, we cannot exit the Nazca topic without mentioning in passing the inspiration to mathematics teachers in the name of Maria Reiche (1903–1998). Reiche was a German-born teacher who made a daring career move in 1932 by moving to Peru. By the end of her career, she had played a crucial role in the preservation and study of the Nazca culture and lines. See her collected works in Reiche (1993) for more details.

All of the above groups had some knowledge of mathematical ideas. The *khipu* that Marcia Ascher will discuss in detail elsewhere in the encyclopedia existed long before the rise of the Inkas and was known for example, to the Huari and Aymara; see Chap. 10 of Quilter and Urton (2002). As the Inkas grew to control territory, their control and/or interaction with these groups must have played into their own mathematical understanding and development. We could even go much farther and say that this little piece on Inka ethnomathematics is only a peek into the larger realm of mathematical interaction, history, and culture of Andean societies, most of which has yet to be carefully researched.

Understanding Preconquest Inka Culture

Tahuantinsuyu, "Land of the Four Quarters," is the word the Inka used to describe their territory. We would like to know a little about what Inka culture was like before the arrival of the Spanish in 1532. However, it turns out that it is not so easy to reconstruct an ancient culture.

First, although the Inkas were indisputably advanced in many regards, they did not use a writing system as we know it. In fact, the subject of how the Inkas created and maintained complexity in terms of society, government, and economy without communication through what we would consider a writing system is one of active debate. The khipu represents a mathematically based system of information keeping that could well have served in place of writing. Meanwhile, however, it is also the case that the Inka groups made use of oral tradition, whereby information, history, and social practices are passed along via oral descriptions. See Schneider (1994) for a general description of oral tradition. Also, an interesting description of Inka culture and literature can be seen in Lara (1960).

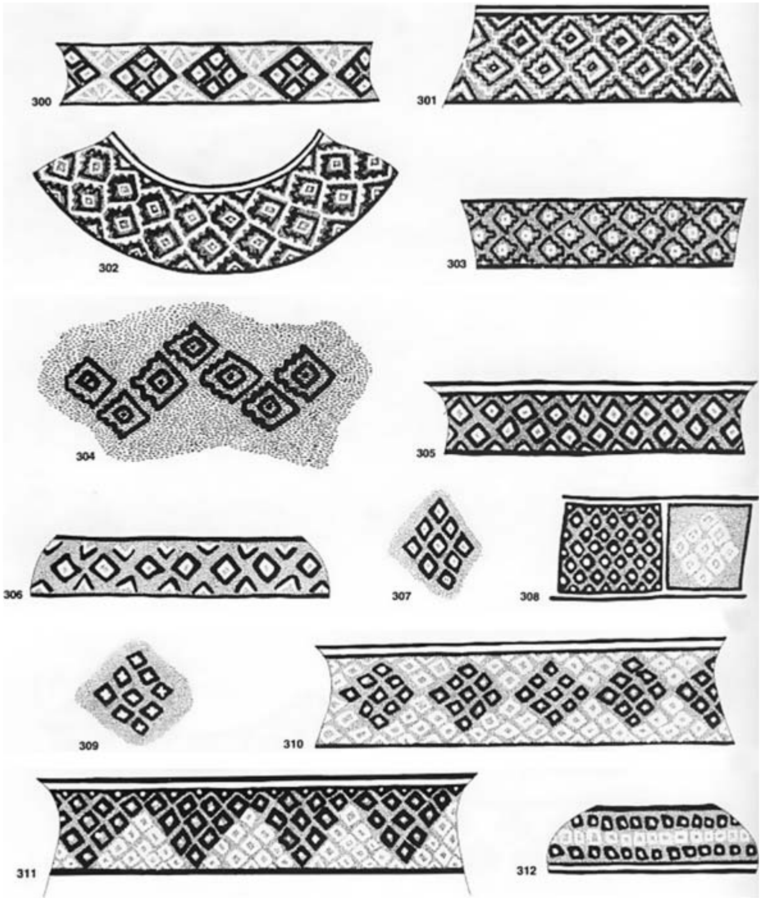
Next, there are problems with accuracy of information on the history of the Inkas. Because the only studies of Inka culture took place after the Spanish conquest, information about the Inkas is either substantially culturally biased, as in the case of most Spanish chroniclers, or is a study of a group that has changed significantly in nature, as is the case in studying present-day descendants of the Inkas. Thus, accurate information is difficult to obtain. For our purposes, two sources considered to be relatively accurate are those of Pedro Cieza de León and Felipe Guaman Poma de Ayala. In Ascher and Ascher (1981: 3), the reader may find a detailed description of original works and translations of Cieza de León's work, and in the bibliography here we have listed a reference to the works of Guaman Poma (1936). Guaman Poma is particularly known for the many drawings of Inka culture that he made, a few of which are presented in Fig. 19. From sources such as

Ethnomathematics of the Inkas. Fig. 2 (a) Bolivian textile pattern. From Tamara E. Wasserman and Jonathan S. Hill, *Bolivian Indian Textiles, Traditional Designs and Costumes*. New York: Dover Publications, 1981, Plate 11. (b) Bolivian textile pattern. From Tamara E. Wasserman and Jonathan S. Hill, *Bolivian Indian Textiles, Traditional Designs and Costumes*. New York: Dover Publications, 1981, Plate 13.

these, we can explain a few aspects of Inka culture that are relevant to our theme of mathematics.

One feature of the Inkas worth mentioning is that as they expanded into regions of other groups, they allowed those groups a certain amount of local control. There are two advantages to this attitude. One is that the subjugated groups would not be as likely to reject Inka rule. The other, relevant to our theme of mathematics, is that by allowing the conquered groups to retain some original culture, the Inkas could use and improve mathematical and engineering ideas of those groups, such as astronomy and agriculture. This last comment implies that some of the mathematics of the Inkas was probably diffused from other groups.

Also relevant to the development of mathematics in the Inka region is that of economy. Starting with very



Ethnomathematics of the Inkas. Fig. 3 Ica design patterns. From Dorothy Menzel, *Pottery Style and Society in Ancient Peru*. Berkeley: University of California Press, 1976, Plate 26. Used with their kind permission.

early organized groups and extending even to the present, trade has been an important factor in the societies in the Inka region. In addition, the Inka economy included an extensive taxation system. Later, we will see that this taxation, among other activities, could be recorded on the Inkas' khipus. A good reference to the ideas of trade and interaction of the various groups can be found in Moseley (1992).

Quechua Number Words

Our first mathematically close look at the Inkas comes by way of discussing Quechua number words, which reflect Inka numeration. In a study of numbers in cultural mathematics, there are two distinct aspects that we must consider: Number words and number symbols (representation). These two concepts are not the same.

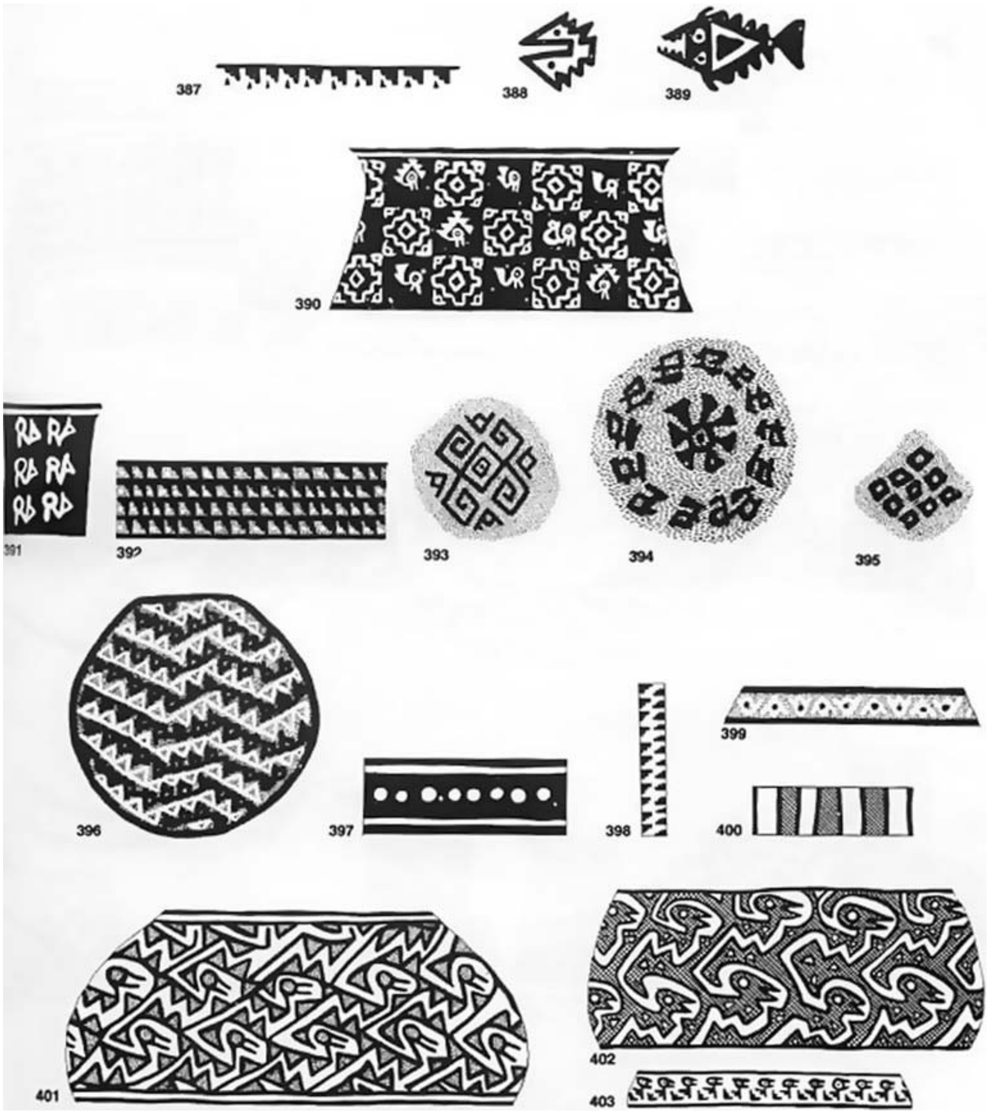
The first things we must clarify have to do with Quechua, the language used by the Inka. Until the 1960s, it was commonly thought that Quechua originated and spread with Inka expansion. In Mannheim (1985), Mannheim (1991), Stark (1985), Urton (1997), and Weber (1989), the reader may find explanations and references indicating that Quechua in fact originated in northern central Peru and later split into essentially two branches. For our intentions, we take as our model Weber's description of Huallaga (Huánuco) Quechua, which is often referred to as *Quechua I* or *Quechua B* in the references. As Weber indicates on, Huallaga Quechua seems to have suffered fewer changes than some other Quechua dialects, which implies that our discussion here of number words should have some accuracy.

Here is a short list of number words from Huallaga Quechua:

huk – 1, *ishkay* – 2, *kimsa* – 3, *chuska* – 4, *pichqa* – 5, *soqta* – 6, *qanchis* – 7, *pusaq* – 8, *isqon* – 9; *chunka* – 10, *pachak* – 100, *waranqa* – 1000.

The format of more complex number words is the following:

[multiplier] {nucleus} (adder).



Ethnomathematics of the Inkas. Fig. 4 Ica design patterns. From Dorothy Menzel, *Pottery Style and Society in Ancient Peru*. Berkeley: University of California Press, 1976, Plate 31. Used with their kind permission.

The nucleus is always a power of ten. For the examples that follow below, we will employ the above notation, namely, multipliers – [], nuclei – {} and adders – ().

Example 1: *isqon pachak*: [9] {100} = 9 ¥ 100 = 900.

Example 2: *qanchis chunka pichqa*: [7] {10} + (5) = 75

Example 3: 347,002: [[3] {100} ([4] {10} (7))] {1000} (2).

kimsa pachak chuska chunka qanchis waranqa ishkay.

From the number words and the examples above, we can deduce that the Inkas counted in base ten; i.e., they used a decimal system.

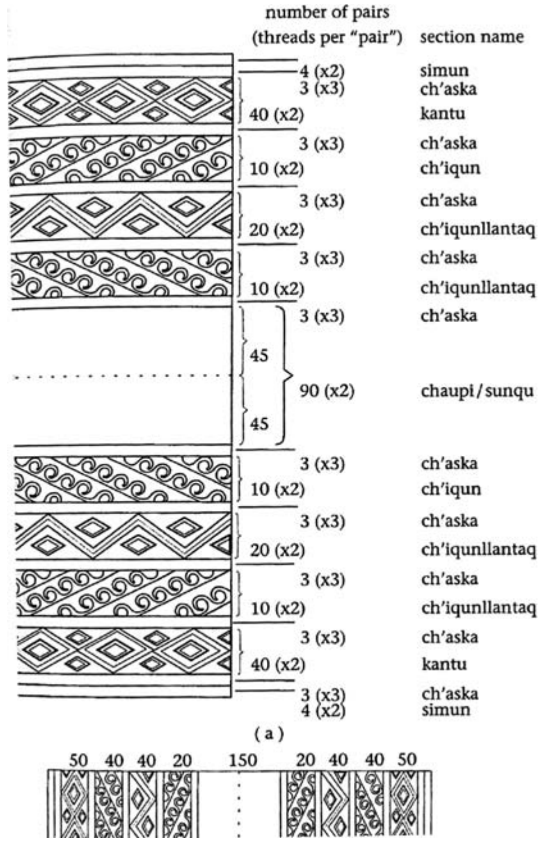
Looking Deeper: Weaving, Symmetry, and Counting

The previous section describes some basic facts about number words of the Inkas. However, that information tells us little about the cultural context of Inka mathematics. Such contexts between mathematics and culture pull us into the field of ethnomathematics. Good places to start in the study of ethnomathematics in general are with Selin (2000), Ascher, (2002), Closs (1986), Pacheco (1998), Urton (1997), and Zaslavsky (1973). What comes out of ethnomathematical considerations is the understanding of how a particular culture perceives and interprets mathematics. It is often surprising to learn that some cultural activity of a particular group

Ethnomathematics of the Inkas. Fig. 5 Ica design patterns. From Dorothy Menzel, *Pottery Style and Society in Ancient Peru*. Berkeley: University of California Press, 1976, Plate 45. Used with their kind permission.

involves elegant mathematics that are not easy to see until we look closely and think differently. Moreover, although modern Western mathematical notation of the mathematics being used may not make sense to people of the group, it becomes clear that they nevertheless understand the concepts. The interesting part is that the Western and non-Western interpretations can be dramatically different. We will next examine some such activities for the case of the Quechua-speaking Inkas.

Let us look more carefully at the situation of the women who were weaving, described at the beginning. The first mathematical observation we can make is to notice the symmetry patterns that evolve from the weaving process. In chapter six of Ascher (1991), we find a careful discussion of decoration and various translations, reflections and rotations that reveal a cultural emphasis of the Inkas on formality, precision, and repetition. Fig. 2a–d show some examples of weaving patterns of the Inka and some other cultural groups eventually controlled by the Inkas. In Fig. 2a for example, we can observe many types of symmetry. One such symmetry is horizontal: Imagine a horizontal line drawn halfway through the figure. Then we see that the pattern in the upper half is exactly repeated in the lower half. Similarly, if we draw a vertical line down the middle of the figure, then the pattern on the left half is exactly repeated on the right half, so the figure has vertical symmetry. Now let us look at Fig. 2b. Except for slight displacements of some of the smaller parts of the figure, it has horizontal symmetry. It does not have vertical symmetry, however: Observe that if we draw a vertical line through the middle of the rectangular spirals part of the figure and reflect the figure across that line, then the spirals will appear in a different orientation; that is, we will not see the same pattern repeated. On the other hand, the rectangular spirals pattern appears again in Fig. 2c, which although it does not have vertical symmetry, has rotational symmetry: Imagine putting a tack in the middle of the strip pattern and rotating the figure 180°. The rectangular spirals then appear in the same orientation as in the original unrotated figure. Now let us look at ceramics, namely the item marked "300" from Fig. 3. It has several symmetry properties including vertical, horizontal, and rotational symmetry. On the other hand, item 311 of



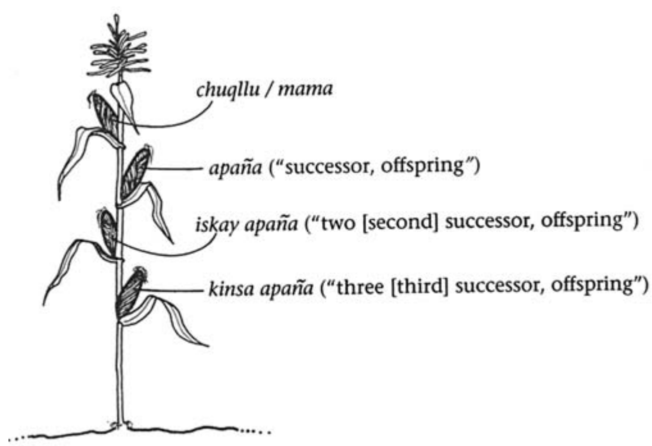
Ethnomathematics of the Inkas. Fig. 6 Warp counts on two axsus from Candelaria. From Fig. 4.6, pg. 121 of the *Social Life of Numbers: A Quechua Ontology of Numbers and Philosophy of Arithmetic*, by Gary Urton with the collaboration of Primitivo Nina Llanos, @1997. By permission of the University of Texas Press.

Fig. 3 only has vertical and translational symmetry (translational symmetry means the pattern is repeated if we slide the figure to the right or to the left). Next, item "401" of Fig. 4 only has translational symmetry.

Furthermore, symmetry can appear in contexts other than weaving. Go get yourself a snack or something refreshing to drink while you ponder the symmetry properties in Figs. 3–5. If you want to look even deeper into more types of symmetry properties, you can read Ascher (1991), Chapt. 6.

The above is good practice for learning about symmetry patterns in general, but we must get back to the cultural part of this. We can ask questions like: What can we deduce from the symmetry properties used in a particular cultural group? In the case of the Inkas, we see the repeated preference for a lot of symmetry. This preference indicates a strong sense of order and precision in Inka culture and mathematics. This corresponds with our general knowledge of the Inkas as being a culture that kept careful records via their *khipus.*

Here is another question: how do the weavers know how to construct the patterns in order that they have such symmetry? Even in the case of what at first appears to be a simple shawl having several stripes of varying widths, we can ask as to how the weaver knew how to obtain the widths from the threads. Look at Fig. 2a again. In these questions we are in fact asking about mathematics. The people (mainly women) who weave such items must in fact count (*yupa*: "to count or account") threads. For the case of stripes, the number of say, red threads for the first stripe must correspond in some way to the number of red threads that might appear later in the pattern, so that the two red stripes have the



Ethnomathematics of the Inkas. Fig. 7 The 'birth order' and naming of ears of corn. Ethnomathematics of the Inkas. Fig. 8 Cuzco's ceque system. From Terence D'Altroy, *The Incas*. Oxford: Blackwell Publishing, 2003. Fig. 7.1, page 160. Used with their kind permission.

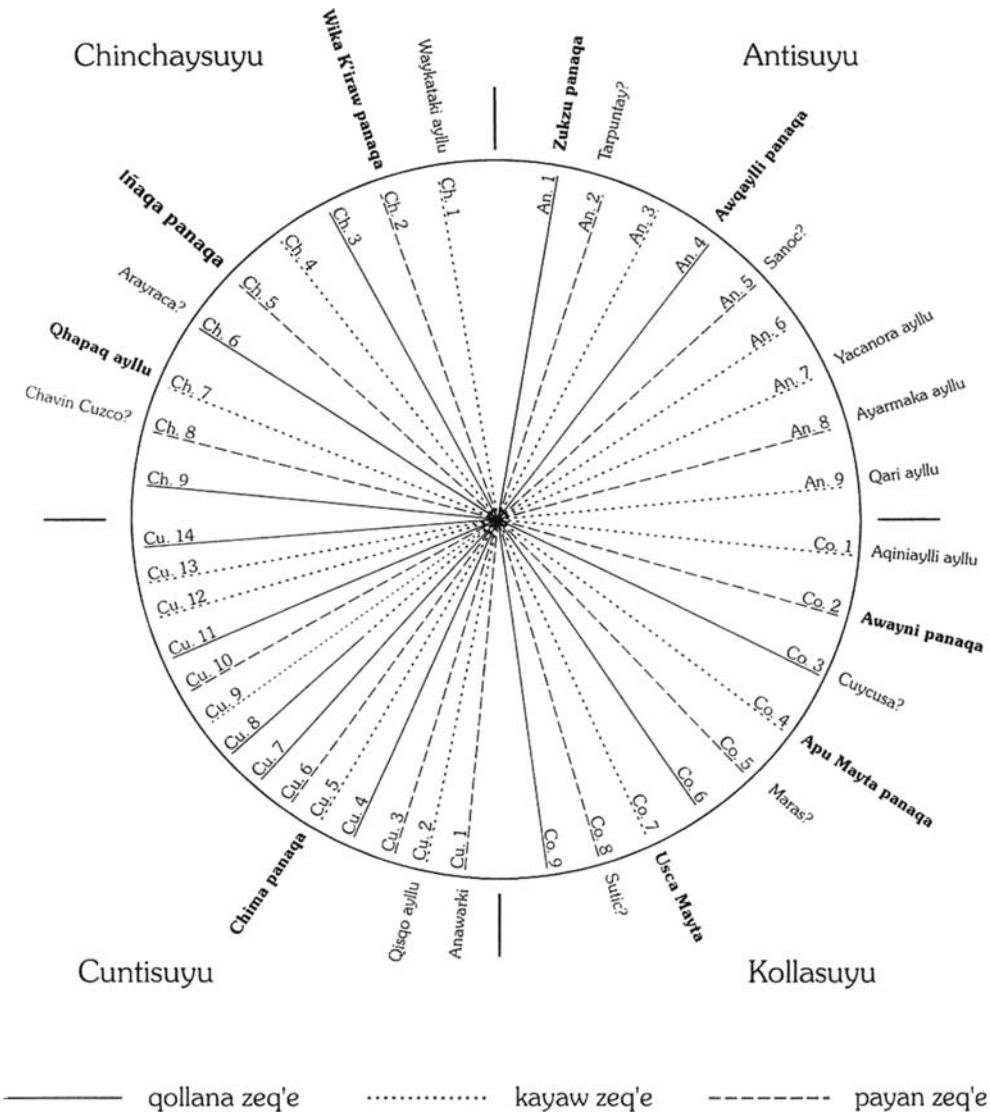
same width. The numbers of threads to be counted in each step of a weaving process is often complicated, and must be decided upon ahead of time. Indeed, the weaver must know in advance what the entire pattern will look like. Once the process starts, what is remarkable is that the weaver does the counting of threads mentally. A detailed discussion of how groups of threads are counted by Inka (Quechua) weavers can be found in Chapter four of Urton (1997). In our context of ethnomathematics, we can observe some mathematical properties in Inka weaving. One such property described in Urton (1997) (see Fig. 6) is that thread counts are usually done in blocks of 10 and 20, and that in general what is being counted are values of pairs of numbers of threads. Notice the influence of the decimal system. The complex geometric or animal motifs are created by a process called *pallay*- "to pick up."

It is worth mentioning that the master weavers or *Mamas* are women who most likely started weaving when they were girls and reached a high level of expertise. They were treated with special respect. Their abilities in counting, understanding patterns of symmetry, and in geometry were part of that expertise. The ethnomathematical aspect of this situation is this: if we asked one of these women to explain geometric or symmetry properties in terms of lines, rotations, polygons, and so forth, they probably would not be able to explain them. Yet, they clearly understand these mathematical concepts; the difference is that their understanding comes from the perspective of a weaver who must create a pattern.

A Bit More About Counting, Pairs, and Even Numbers

In Quechua culture, counting is closely tied to important cultural aspects. Kinship and social organization, as explained by Urton (1997), represent one such aspect. On page 85 for example, he tells us that ears of corn on a stalk are carefully named in the order in which they appear, with the first representing the "mother" and others being defined in accordance to the first as offspring of the mother (Fig. 7).

Note that the order of the counting is as important as the counting itself. As for the subject of pairs, it turns out that the Inkas view the property of being even in a count as extremely important. In fact, we could go so far as to say that odd numbers are considered as incomplete pairs. We saw above that the counting of threads in the weaving process is done in pairs of threads. There are many more instances in which one counts pairs in Quechua society. The perception of even versus odd numbers is in fact one of the main themes of Urton's (1997) book. The cultural impetus



Ethnomathematics of the Inkas. Fig. 9 Schematic diagram of Cuzco's ceque system. From Terence D'Altroy, *The Incas*. Oxford: Blackwell Publishing, 2003. Figure 7.2, page 161. Used with their kind permission.

for this viewpoint is that the Inkas constantly strive to have proper order in their world. Such order even extends to contexts like social situations. If a person has done something inappropriate, then something must be done by him or by the community so that proper social order is regained. This can be thought of as completing an incomplete pair. By the way, notice that this persistence of order and proper organization appeared in the symmetry patterns, too.

A Few Remarks About Astronomy

Inkan astronomers knew about the solar, lunar, and Venusian cycles. They had a solar calendar and festival calendar based on 12 lunar cycles, plus adjustments to account for the difference necessary to make a full 365 day year.

Throughout the city of Cuzco there are remains of some of about 400 markers, called *huacas,* along imaginary lines called *ceques* (also *zeq'e*). These lines originate from the center of Cuzco. Figs. 8 and 9 show some details of the system, though you will have to read Chapt. 7 of D'Altroy (2002) to fully understand the figures. These huacas had ritual and social significance. Some had connections with astronomy, hence mathematics. In particular, the Inka used several of the ceque lines as part of astronomical observations such as the June solstice. Furthermore, the ceques and huacas were crucial components of the Inkan religious ceremonies and in fact the huacas are more accurately described as sacred shrines. For more details about Inkan astronomy and the ceque lines, see for example, Moseley (1992), pages 78–79, Chapt. 7 of D'Altroy (2002), or Urton (1981), and the article on Quipus in this encyclopaedia.

Astronomy and culture quickly become intimately involved with each other. We know that astronomy and mathematics also have a close relationship, so we can conclude here that astronomy, culture, and mathematics of the Inkas are intertwined.

Yupana

The Inka performed rather complicated computations. The khipu was a record keeping device not used for calculating. In fact, most of the knots on known khipus are tight, implying that the values on them were usually intended to be fixed. This leads us to ask the question: How did they make the computations? The answer to this question is still not completely understood. One possibility arises in the first of the drawings of khipus made by Guaman Poma. (See Ascher's article on the Quipu.)

The rectangular grid of solid and unfilled dots appears to be a kind of counting board; however, Guaman Poma gives no explanation of the grid. Certainly there would be reason to believe that the grid has mathematical meaning because of its appearance with a khipu. A curious aspect of the grid is that each row contains 11 dots, something that obviously does not coincide with a decimal counting system. In addition, because Guaman Poma's work occurred after the Spanish conquest of Peru, the grid does not necessarily represent a device of the Inka.

On the other hand, proposals of mathematical uses of the grid have been given, with the term *yupana* (Quechua for the verb to count) used to denote it, such as appears in Mackey et al (1990), Higuera (1994), and Burns Glynn (1981, 1990).

The mathematical methods for counting that are presented make logical sense, such as filling the 11th dot as a placeholders for powers of ten. Included are photos of three-level rectangular stone figures that resemble counting grids in some ways that could have served as abaci for counting. There are descriptions by Spanish chroniclers of observations of Inkas counting on these rectangular forms, but here we encounter the problem of accuracy. A conclusive explanation of the grids and rectangular forms still has not been given. However the works cited here point toward possible patterns of counting or symbols.

Faience in Ancient South Asia

Blythe McCarthy

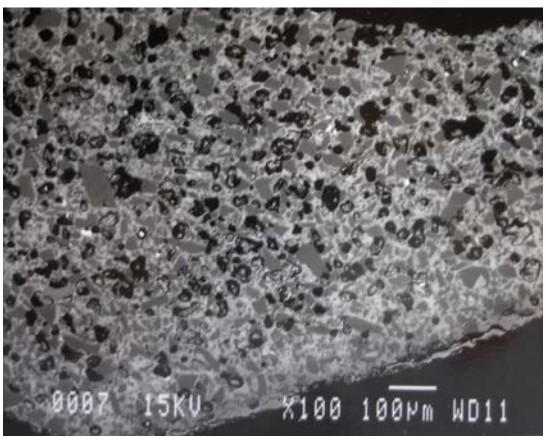
The term faience when refering to ancient materials describes a man-made material of mineral grains, generally quartz or sand, that are bound together by varying amounts of glass, often with a layer of glass (a glaze) on the surface. The material can be very friable and crumble easily or can be hard and dense, depending on the amount of glass present. Several terms have been used to describe this material including glazed quartz frit, glazed paste, glazed composite bodies, blue-glazed whiteware, fritware, and siliceous paste. Faience is however the term most commonly used. Although faience is most often associated with ancient Egypt there was also a well-developed faience industry in the Indus Valley as well as in ancient Mesopotamia. The faience industry in South Asia dates to the third millennium BCE while that from Egypt dates to the first half of the fourth millennium BCE and Mesopotamia from the late fifth millennium BCE (Stone and Thomas 1956; Moorey 1985).

Faience using quartz for the mineral grains first appeared in South Asia during the Kot Diji phase (2800–2600 BCE or Nausharo I). It is seen at Nausharo and Mudigak in the form of beads (Barthélemy de Saizieu and Bouquillon 1997). Beads were primarily small in size and shaped as cylindrical rings during the early Harappan period, Kot Diji phase; however small tubular, spherical and diamond shaped beads have also been found. There are also beads, lenticular and biconical in shape, from this period at Harappa (Kenoyer 2000). Some of the faience from the end of this phase appears similar to compact faience seen in the later mature Harappan phase. Beads continue to constitute a large proportion of the faience into the mature Harappan phase (►http://www.harappa.com/indus2/174.html). There is a concentration of ellipsoidal beads, but larger and more complex beads, such as segmented and multicolor beads, are present as well. Faience beads form a small part of the bead corpus with steatite beads accounting for the majority. At the site of Nausharo only faience beads and small amulets made of faience have been found. In addition to beads, bracelets, buttons, spindle-whorls, gamesmen, animal figures, and small jars made of faience have been found at the sites of Harrappa, Chanhudaro, Lothal, and Mohenjodaro among others. Fig. 1 shows some fragments of bangle bracelets of varying diameter, as well as vessel fragments. Small faience jars have been found in all faience containing strata at Harappa. Several of the vessels have textile impressions (Kenoyer 1998: 159).

Faience is occasionally found in sites of periods later than the Harrappan period. A microbead hoard was found in a black slipped ceramic at the site of Agiabir (Mirzapur), Uttar Pradesh (Singh 2002) dated to the Northern Black Polished Ware (NBP) culture (600–200 BCE). Occasional faience beads were recovered in two earlier periods at the site, that of the Narhan culture (1300–900 BCE) and Pre-NBP with Iron (900–600 BCE). Singh states that it was similar to the high strength faience of the Indus Valley civilization. Faience bangles also continue after the Harappan period and may lead to the introduction of glass bangle technology in the early historic period (600 BCE) (Kenoyer 1994).

Two types of quartz faience have been identified for the Indus Valley Civilization. One, coarse with 50–100 μm quartz grains, is speckled in appearance, with a glass binder and colorant. This material was used for beads and small tokens (Barthélemy de Saizieu and Bouquillon 1997). A second type is fine with a compact structure, evenly colored with quartz grains less than 30 μm in diameter. This dense, homogeneous form of faience was determined to have been formed by multiple cycles of heating, to a temperature between 1,000 and 1,100°C, and grinding an initial mixture of alkalies (salts), clay, and quartz. This produced faience of uniform color due to a very homogeneous glass phase and very small quartz crystals as seen in Fig. 2. The addition of alkalies in the final step where the objects were fashioned resulted in a thin surface glaze through an efflorescence glazing process (McCarthy and Vandiver 1990). In this process, the alkalies migrate to the surface during drying, react with the quartz particles at the surface and form a glass (►http://www.harappa.com/indus3/255.html). This type of faience manufacturing results in a material of higher strength than other forms which may account for its use in bangle bracelets and vessels unlike the other forms of

Faience in Ancient South Asia. Fig. 1 Compact faience bangle bracelet and vessel fragments from the site of Harappa.



Faience in Ancient South Asia. Fig. 2 Backscattered electron image from a scanning electron microscope of a cross section of a faience bangle bracelet from Harappa. The dark gray grains are quartz, the light gray matrix is the glass phase. The exterior of the bangle runs along the lower edge of the photomicrograph and a thin glaze layer is visible along part of the length at the lower right.

Indus valley faience which are primarily used for beads. Faience can be manufactured in this manner without the addition of glass, i.e., with only salts and sand; however, this forms a glazed material with a very friable interior.

A workshop was found at the site of Harappa in 2001 (Kenoyer 2003) that included debris from faience manufacture (►http://www.harappa.com/indus3/246.html). Steatite tablet molds, carved in reverse, were uncovered as were firing containers, kiln supports and a yellow green slag. The clay containers were lined with crushed bone and steatite. (See slides 250–253 at ►http://www.harappa.com/indus3/slideindex.html.)

To date, no traditional kilns have been found that can be linked to faience manufacture. Recent experiments have resulted in a plausible method for the firing of the small faience objects found in the Indus Valley culture. Replication of the containers, setters and faience material similar to that found in the workshop were made and used to fire faience and steatite. The filled containers were set in a bonfire. The temperature in the containers reached 935°C and glazed faience resulted. (See slides 254–257 at ►http://www.harappa.com/indus3/slideindex.html.)

The color of South Asian faience varies. When a pure quartz mineral is used for the grains and there is no colorant in the glass phase a white material results. This may have a colored glaze layer and so appear colored if not broken. If a colorant is present in the glass binding material, such as copper that produces a blue color, or iron oxide particles, that produce a red color, the interior of the faience has that color. When weathered, faience appears similar to weathered glass and the two materials can be easily confused. Colors include white (colored by high calcium), black (colored by manganese), deep blue (colored by copper or cobalt and manganese), yellow, brown and red-brown (colored by iron), and brilliant red. Faience with multiple colors has been used to imitate banded agate and agate or carnelian eyebeads, white with brown, black or red-brown (Kenoyer 1998; Barthélemy de Saizieu and Bouquillon 1994). Lead has been found in the glazes of two Indus period faience beads from Nausharo (Barthélemy de Saizieu and Bouquillon 1995). This is 1,000 years before the earliest known lead glazes, but the small number of beads containing lead may indicate that it was an experiment.

Dayton theorized that spent metallurgical molds made of steatite were used to form the first faience (Dayton 1989). Bouquillon and Barthélemy de Saizieu identified such steatite faience in four cylindrical beads from the pre-Indus period at Mehrgahr dated to around 3000–2800 BCE where a steatite glazing tradition was in place as early as the Chalcolithic period (Barthélemy de Saizieu and Bouquillon 1995). This date places the manufacture and use of this material earlier than siliceous faience in South Asia. In this form of faience, ground steatite is used for the mineral grains. The steatite faience makes up less than 1% of the steatite objects recovered from the site. The compositions of the glazes on the steatite faience are similar to those found for glazed steatite from the pre-Indus period.

The development of faience occupies an intermediate step in the technological progression that led to glassmaking in South Asia. The earliest step was that of heating and glazing of stones (steatite), followed by manufacture of faience, first one of crushed steatite, then of quartz grains, progressing finally to glass manufacture.

Fengshui

GRAHAM PARKES

Along with acupuncture, the best known representative of Chinese science in the West today is *fengshui*. The term is often translated as "geomancy," though the two graphs that comprise the term simply mean "wind" and "water." The practices associated with *fengshui* have been informed by ambiguity since their early beginnings – between a practice encouraging charlatanry based on mystification and a set of practical recommendations grounded in sensitivity to the natural environment. This article will ignore the mantic and divinatory aspects of *fengshui*, and the associated panoply of arcane symbolism of colors and animals and planets and stars, all of which distract from its more down-to-earth applications.[1]

It was not until the 1950s that Western scholars began serious investigation of Chinese sciences, as signaled by the first volumes of Joseph Needham's monumental *Science and Civilization in China*. Needham devotes large sections of his second volume to the philosophies of nature found in Daoism and "the school of Naturalists" (the so-called *Yin-Yang* thinkers), the theory of the five elements (*wuxing:* better translated as "five phases of transformation"), symbolic correlations and correlative thinking, and the system of the *Yijing* (Book of Changes).

We have here for the first time a comprehensive, scholarly, and open-minded account of the philosophical and scientific background from which *fengshui* emerged. The practice of "geomancy" itself, however, Needham relegates to a chapter on "the Pseudo-Sciences," considering it under the heading "Divination" along with such practices as scapulimancy (prediction of good or bad fortune on the basis of the behavior of ox and deer shoulder-blades when subjected to heat), astrology, chronomancy, cheiromancy, and the

[1] For a more detailed treatment of *fengshui* is its broader context, see Parkes (2003) and see Geomancy in China in this Encyclopaedia.

like. Operating on the straightforward definition of *fengshui* as "the art of adapting the residences of the living and the dead so as to cooperate and harmonize with the local currents of the cosmic breath [*qi*/*ch'i*]," he devotes four pages to a brief history and description of the practice.[2] After remarking on its advantages and drawbacks, he concludes that "all through, [*fengshui*] embodied a marked aesthetic component, which accounts for the great beauty of the siting of so many farms, houses and villages throughout China" (Needham 1956: 2:361).

But if one considers the continuities between the basic features of the Chinese worldviews from which *fengshui* arose – the understanding of the world as a dynamic play of forces, or *qi* energies, rather than an aggregate of material things, with a corresponding emphasis on *becoming* over being, or *process* rather than substance – the scientific components of the practice will become as apparent as the aesthetic aspects.

The historical beginnings of *fengshui* are shrouded – appropriately for such an enigmatic science – in mystery. Marcel Granet cites as perhaps "the first mention of beliefs that are at the origin of geomancy" a passage in the *Book of Songs* (Shijing; ninth to fifth centuries BCE) where the founder of a town is said to have observed "the shadows" (which would indicated south) and also "the surrounding yin and yang." Feuchtwang remarks in this connection that the application of *fengshui* principles to the layout of towns and cities is apparently much earlier than to houses and graves (Feuchtwang 1974).

Another indication of an awareness of *fengshui* principles comes from a story concerning Meng Tian, the Qin Dynasty general who supervised the building of the first part of the Great Wall. Construction was begun in 221 BCE: "He… built a Great Wall, constructing its defiles and passes in accordance with the configurations of the terrain. It started at Lin-t'ao and extended to Liao-tung, reaching a distance of more than ten thousand li."[3] Thanks to its following the contours of the land, the Wall is traditionally seen as resembling a great dragon, which is an image that comes to refer in *fengshui* to any important topographical formation. Meng Tian is also credited with the invention of the camelhair writing brush, which eventually revolutionized the writing of Chinese characters. Thus in addition to being responsible for a good part of a 2,000-mile long "dragon" in the form of the Great Wall, he facilitated the production of countless smaller dragons – the image that characterizes calligraphy executed with especially vital energy – in the centuries since his death.

In 210 BCE, upon the death of his patron the first Qin Dynasty emperor, Meng fell victim to a dastardly political plot and was ordered to commit suicide. On hearing the news, he is said to have cried out in uncomprehending lamentation over this cruel stroke of fate. Then, on reflection, he said gravely: "I am guilty, and assuredly should die… A moated wall of more than 10,000 li; in the course of this work I cannot have avoided cutting through the earth's veins [*di mo*]: this is my guilt." He thereupon swallowed a lethal dose of poison (March 1968: 260–261). The *mo* of *di mo* ("earth's veins") corresponds to something in the human body like veins, or arteries, or pulses, but more closely to the acupuncture meridians, since no physical "envelope" for the flow is perceptible.

In a survey of the history of *fengshui* the Ming Dynasty author Wang Wei writes: "The theories of the geomancers have their sources in the ancient Yin-Yang school. Although the ancients in establishing their cities and erecting their buildings always selected the sites (geomantically), the art of selecting burial sites originated with the *Burial Book* [Zangshu] in 20 parts, written by Guo Pu [276–324] of the Qin Dynasty" (cited in March 1968: 261). Central to the *Zangshu*, also known as the *Book of Funerals*, is the idea that certain sites are blessed with flows of especially vitalizing energy known as *shengqi* ("vital breath," "life energy"), which is a phase of the larger circulation of cosmic energies: "When the *qi* of yin and yang breathes out it is wind. When it ascends it constitutes the clouds, and when it falls it is rain. It travels on and in the ground and becomes vital *qi*. Vital *qi* travels on and in the ground and engenders the myriad things." Vital *qi* is further subject to the forces of wind and water: "The [*Burial*] *classic* says that *qi* rides the wind and disperses. When bounded by water, it halts" (*Zangshu*, cited in Bennett 1978: 9–10). With respect to a place characterized by multiply dividing streams, the *Shuilongjing* (Water dragon classic) says: "If the wind shakes the willow branches, or if the wind bends the grass whether passing over the position or not, it will mean trouble, and even meandering water will not justify the site. It will bring decay and sickness" (Feuchtwang 1974: 139).

Water molds the natural environs from the outside in obvious ways, primarily through watercourses' cutting into the earth, but also through precipitation's sculpting over time the shapes of mountains. Winds, too, move earth, if not mountains, over the long term – in ways less obvious than waters since the movement of air is itself invisible, becoming perceptible only through its effects on water, vegetation, and loose soil. But *fengshui* is concerned with winds and waters in a deeper sense too: with the invisible "breath of the earth" discussed above,

[2] The quote is cited from the article by H. Chatley in Samuel Couling's *Encyclopaedia Sinica* (1917).

[3] Cited from the *Shiji* (Records of the Historian), in the *Cambridge History of China* 1: 62.

and with the "flows" of *qi* beneath the earth that were thought to be responsible for the formation of minerals (Needham 1970: 3:637, 650).

The art of proper burial consists in choosing a site with favorable life-breath. Guo Pu puts it succinctly by saying: *cheng shengqi*, "burying [is a matter of catching] life-breath" (cited in March 1968: 256). The understanding of *qi* expressed in the *Zangshu* has been aptly characterized as:

> "the breath at the origin of things, forever circulating," which flows through the whole of space, endlessly engendering all existing things, "deploying itself continuously in the great process of the coming-to-be and transformation of the world" and "filling every individual species through and through" (Jullien 1995: 91–2).

The quality of a place, according to Guo Pu, depends on the local *shi*, meaning configurations of earth-energy (which François Jullien translates in this context as "lifelines"): "The vital breath circulates along the lifelines of the terrain and is concentrated at the points where they come to an end." John Hay draws a helpful distinction between *shi* as "dynamic configuration" and *xing* as "form" or "shape" of concreted objects: "It is the changefulness of *shi* that is lasting, whilst the fixedness of *xing* is transient" (Hay 1985: 53). On the *fengshui* understanding of a landscape, *shi* refers to both the "veins" of earth through which the *qi* flows and also the "skeletal structure" or "spinal column" of the terrain. In order to perceive the dynamic configurations of a landscape, it is necessary to gain some distance for a broader perspective: "The lifelines are visible from a thousand feet away, the particular configurations of the terrain from a distance of one hundred feet" (*Zangshu*, as cited in Jullien 1995: 93). Another way, as Jullien suggests, is to consult an appropriate masterpiece of Chinese landscape painting, the primary principle for which was to "achieve the *shi*" of the landscape (99).

Another important source of ideas behind *fengshui* is the *Huangdi zhaijing* (The Yellow Emperor's Siting Classic), attributed to the fifth-century thinker Wang Wei. As the title leads one to expect, a central idea in this text is that of *zhai*, meaning "site/siting" or "place/placing": "All human dwellings are at sites… sites are the foundation of human existence" (cited in Bennett 1978: 5). A *zhai* is therefore not merely some location in abstract space, but rather a place as defined both by a particular topography and by the kinds of human activities that take place in it.[4] Since an inhabited place is a dynamic locus of flowing energies, the *Siting Classic* addresses the temporal as well as the spatial aspects of *fengshui* practice: "Every year has twelve months, and each month has positions in time and space of vital and torpid *ch'i* [*shengqi* and *siqi*]" (Bennett 1978: 7). Human activities undertaken at times of vital *qi* are more likely to be successful than at times when the *qi* is torpid. The quality of *qi* also varies within smaller cycles, such as the diurnal: Manfred Porkert characterizes *shengqi* as "the quality of energy during the *yang* hours of the rising sun (midnight to noon)… [which has] a quickening and invigorating effect on active enterprises," and the opposite for the yin hours from noon to midnight (Porkert 1974: 172–73). The *Siting Classic* also asserts an isomorphism between a *zhai* and a human body, a correlation that is central to Daoist thinking about the relations of the human being to the landscape: "The forms and configurations are considered to be the body; water and underground springs are the blood and veins; the earth is the skin; foliage is the hair; dwellings are the clothes; door and gate are the hat and belt" (Bennett 1978: 13).

In spite of the prevalence of all these ideas, it was not until the Tang dynasty (618–906) that *fengshui* theories and practices began to be synthesized and formalized into a distinct school named as such.[5] Wang Wei's historical survey distinguishes two schools, one using the "Kiangsi [Jiangxi] method" and the other the "Ancestral Hall" or "Fukien [Fujian] method," both of which he claims are derived from Guo Pu (March 1968: 261). The latter (founded a century or two later) is also known as the "Compass School" and it emphasizes the importance of the Eight Trigrams of the *Yijing* and the Five Planets, as well as the indispensability of the geomantic compass. Since this school's methods are more abstract and less scientific, it seems to have been infected by more charlatanry than its counterpart.[6]

The school employing the Jiangxi method is also known as the "Form and Configuration" (*xing shi*) School, because of its concern with intuiting the configurations (*shi*) of *qi* from the shapes or forms (*xing*) of the landscape. It was apparently founded by an imperial *fengshui* master by the name of Yang Yunsong (c. 840–888). In its consideration of mountains and watercourses the Form and Configuration School lays particular emphasis on the motif of the dragon as a pattern to be found in "all topographical formations" (Feuchtwang 1974: 141), as indicated by the

F

[4] Western philosophy has generally devoted far more thought to abstract space than to live place: for a judicious restoration of this imbalance, see Casey (1997).

[5] For example, the *Guanshi dili zhimeng* (Mr. Guan's Geographical Indicator) attributed to the third-century author Guan Lo, the *Zhangshu* (Book of Funerals) attributed to Guo Pu, and Wang Wei's *Huangdi zhaijing* (The Yellow Emperor's Siting Classic); see Needham (1956: 360).

[6] A comprehensive account of the practices of the Fujian School, with fascinating descriptions of the geomancer's compass, is to be found in Feuchtwang (1974: 18–95).

titles of such important treatises by the founder as the *Hanlongjing* (Classic on Arousing the Dragon) and the *Yilongjing* (Classic on Approximating the Dragon).

The dragon is best understood as an image for all vital topographical formations, since some places may simply be "dead" in terms of the flows of *qi*. As a later author, Shen Hao (seventeenth century), puts it:

> Surely nothing but the writings of the magic dragon is an adequate figure of the mountain-ridges' permutations. What does not resemble the permutations of the magic dragon does not realize the subtle geomantic essence. Therefore it is said: if it has permutations, call it dragon; if it has none, call it barren mountain. (cited in March 1968: 256–57).

This is not the Azure Dragon as an image for one of the four directions, which is culturally and geographically specific to China, but "a universal symbol of the powers of nature" and especially of "the power of [self-]transformation."[7] Since Chinese culture is based on the premise that all events in the world are continually transforming themselves, the dragon is its perfect emblem. It is also an archetypal image common to a wide range of cultures and mythologies, in some of which its meaning is negative by contrast with its generally auspicious quality in China.

General Meng Tian's concern for respecting the earth is often echoed in the Ming period, which also saw a special flourishing of the art of garden making in China. Fear of damaging the "earth's veins" fueled opposition to gypsum mining in Taihe county in the fourteenth century, and the government prohibited the digging of ponds in Nanjing "lest they damage the *qi* of the earth in the imperial capital" (Clunas 1996: 181). The sixteenth-century author of the *Nongshuo* (Talks on Farming) writes eloquently of "energy arteries running within the earth" and how "earth and bone are like the arterial system of the human body which carries the energy-blood" (cited in Hay 1985: 42). When the body is understood as an organism situated within the larger organism of the environment, its various energetic pulses (*mo*) correspond to the dynamic configurations referred to earlier as the earth's "lifelines" (*shi*).

To fully appreciate sciences based on becoming rather than being, on energy rather than matter, we need to reorient our ways of perceiving our environment. In introducing his discussion of the notion of *shi* as "lifelines" in the earth, François Jullien recommends that we stop regarding nature as "an object of science" in the Western sense: "Rather, we should here perceive nature intuitively, through the sensibility of our bodies and their activity, as the single common principle within and outside us that operates throughout reality and explains how the world is animated and functions. Let us imagine a new 'physics' and stop thinking of nature abstractly" (Jullien 1995: 91). If this idea seems too exotic – a physics associated with a transformation in our experience – we might recall that there exists something similar in the Western tradition, with the Hellenistic philosophies of the Stoics and Epicureans. As Pierre Hadot puts it: "Contemplation of the physical world and imagination of the infinite are important elements of Epicurean physics. Both can bring about a complete change in our way of looking at things. The closed universe is infinitely dilated, and we derive from this spectacle a unique spiritual pleasure" (Hadot 1995: 87–8).

Just as the breath that animates the human body through bringing oxygen to the blood is invisible (the misty exhalations in cold weather being water vapor rather than air), so the cosmic breath animating the body of the earth cannot be seen, though it can be felt or otherwise sensed. The science of acupuncture, which is closely related to *fengshui*, has been slow to gain acceptance by practitioners of Western medicine. The main reason is that its background assumptions are so different, and there is also that fact that the meridians (*jingluo*) through which the currents of *qi* flow through the human body are invisible, and Western researchers were looking for literal conduits such as veins or nerves.

Corresponding difficulties arise with the idea of energies flowing through the earth (in the broad sense, including watercourses, vegetation, and the other processes of metal and fire) along "lifelines" that are invisible to the eye but can be intuitively discerned by the well-trained practitioner. This notion should, however, be less mysterious to Western physicists since the discovery of the earth's magnetic field (the magnetosphere), whose energies flow along lines that are similarly invisible. Indeed the Chinese appear to have been the first to understand the phenomenon of magnetism, and texts referring to the "south-controlling spoon" – a piece of lodestone carved into the shape of the Northern Dipper (Ursa Major) – appear in China over a 1,000 years earlier than the first European references to the magnetic compass. These Chinese discoveries naturally took place within the context of *fengshui* (Needham 1969: 71ff; 1962: 4/1, 229–334).

In conclusion, a brief look at three Chinese arts will help further our understanding of *fengshui*, especially along the experiential dimension: landscape painting, garden making, and the martial arts and their derivatives.

We saw that Guo Pu understood the lifelines of the land as both its "skeletal structure" and its "veins," and when the Form and Configuration School of *fengshui* applied the image of the dragon to any important topographical formation, it was on the assumption that the dragon was animated by *qi* flowing through its

[7] Feuchtwang (1974: 149–150). See also the chapter entitled "The Dragon Motif" in Jullien (1995: 151–161).

bones as well as its veins. This idea is associated with the distinction between the "mountain" (*shan*) and "waters" (*shui*) *qi* animating a landscape (*shanshui*), with peaks and ridges as skeletal structure and watercourses as veins, and it is also exemplified in one of China's greatest contributions to the world's art, landscape painting (Feuchtwang 1974: 141–48). François Jullien quotes and comments upon the tenth-century aesthetician Jing Hao on this topic:

> Under the painter's brush, as in nature, "the aspects of mountains and waters are born from the interaction of vital breath and the given layout to which that force imparts dynamism." In China, the purpose of painting is to rediscover the elemental and continuous course of the cosmic pulsation through the figurative representation of a landscape. (Jullien 1995: 94).

Thus an excellent way of learning to discern the lifelines in a landscape is to study Chinese landscape paintings, which is in itself one of life's great pleasures.

Another great Chinese contribution to the world of the arts, again associated with *fengshui,* is the art of the garden. We saw earlier that *fengshui* allows for certain kinds of human intervention in order to improve, when necessary, the conditions of a particular site – though the tragic figure of Meng Tian stands as a constant reminder of the dangers of too deep an intervention. As an important adjunct to the dwellings of the living in China – of the well-to-do in particular – the garden provides an opportunity to put the principles of *fengshui* into practice from the ground up, as it were.

The classic garden manual, the seventeenth-century *Yuanye* (Craft of Gardens) by Ji Cheng, talks of the way a well constructed garden, where one has "visualized the balustrades as if they were in a painting", can "flood the heart with intoxication" and create "a pure atmosphere around our tables and seats [so that] the common dust of the world is far from our souls" (Ji 1988: 43–44). Chinese gardens would often be laid out in such a way as to "borrow" features of the neighboring landscape, by offering views from within the garden of a local mountain or lake. A basic premise of the Chinese garden is the microcosm/macrocosm correlation between the human body and the physical environment: the well designed garden sets up a pattern of energies that corresponds to the dynamic configurations of a larger landscape – and indeed energies just as powerful thanks to the amplifying effect of miniaturization.[8]

[8] The classic work on this topic is Stein (1990): see, especially, part one: "Trees, Stones, and Landscapes in Containers," and "Survey of Themes." For a brief history of the remarkable lithophilia (or petromania?) that has characterized the Chinese tradition, see Parkes (2005).

For those of us unable to afford the luxury of a garden, there are other ways of cultivating an appreciation for the relations between the body's energy configurations and those of the environment – through practices such as *qigong* (literally, "energy work") and *taiji quan* ("Great Ultimate bare-hands-combat-technique"), one of the "softer" martial arts to have been developed in China. Anyone who is skeptical about the existence of the *qi* that flows through and energizes the body need only try some *qigong* exercises (for example, the set known as the "eight sections of brocade," often used as a warm-up for *taiji* practice) in order to experience the flow of *qi* in his or her own person. As with yoga, the breath is central to *taiji* practice, insofar as breathing is a manifestation of the cosmic breath in the human body.

Taiji practice brings about precisely what *fengshui* encourages: a greater awareness of the relations between one's activities and the configurations of the surroundings, whether natural or built. Unless one has the luxury of choosing a place to live and building a dwelling there, there is no opportunity for engaging in the practice of *fengshui* as "siting" and participating in the architect's decisions concerning the orientation of the house in relation to prevailing sun, wind, rain, and terrain. But one can always change the ways one's living space is configured in a residence already built, by the simple expedient of becoming more aware of one's activities in relation to the surroundings. It is quite possible thereby to improve the positioning of one's furniture and personal effects without going to the expense of hiring an "expert" consultant. A little common sense combined with heightened sensitivity to one's environment goes a long way. Opportunities to set up one's workspace will generally be more limited than in the home, but improvement is usually possible nonetheless.

One might take encouragement from those writers on *fengshui* like Shen Hao who emphasize intuition. Coming upon a place that is right, he writes,

> One's eyes are opened; if one sits or lies, one's heart is joyful. Here the breath gathers, and the essence collects. Light shines in the middle, and the magic goes out on all sides. Above or below, to right or left, it is not like this… Try to understand! it is hard to describe (cited in March 1968: 259).

Among contemporary scholars, no one has put it better than François Jullien, who paraphrases Guo Pu as follows:

> Not only my own being, as I experience it intuitively, but the entire landscape that surrounds me as well, is continuously flooded by subterranean circulating energy… The most glorious sites will be those where it is most densely accumulated,

F

where the circulation of the breath is most intense, its transformations most profound… By rooting one's dwelling here rather than elsewhere, one locks into the very vitality of the world, taps the energy of things more directly (Jullien 1995: 92).

If in response to such an expression of the more sensible tenets of *fengshui* we could become skeptical concerning the modern conceit that we can be at home anywhere, no matter where, and instead practice some environmental science at the personal level, we would surely witness a greater flourishing on the part of human beings and the natural environment on which we depend.

Fishing in Ancient Egypt

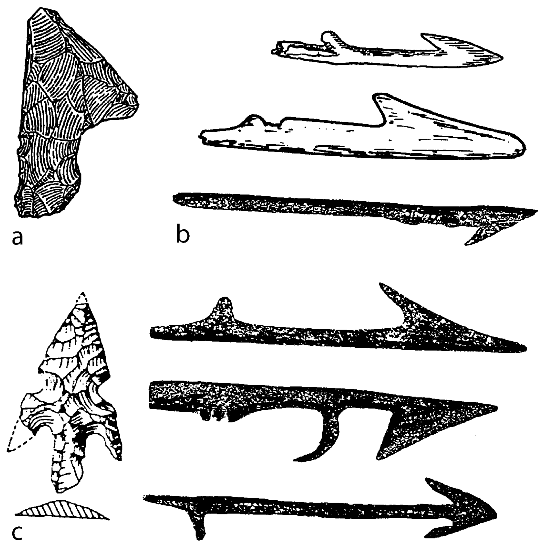
Dietrich Sahrhage

Early civilization in the Nile valley developed mainly because of heavy summer rains in the highlands of Ethiopia and around the East African lakes. Every year a huge flood reached Egypt around mid July, carrying to the lower parts of the Nile enormous quantities of fertile silt. This settled as soil especially suitable for agriculture and filled up the Delta, originally a bay of the Mediterranean Sea. The timing and intensity of the floods determined whether people would have wealth or famine, depending on the water supply and agricultural production.

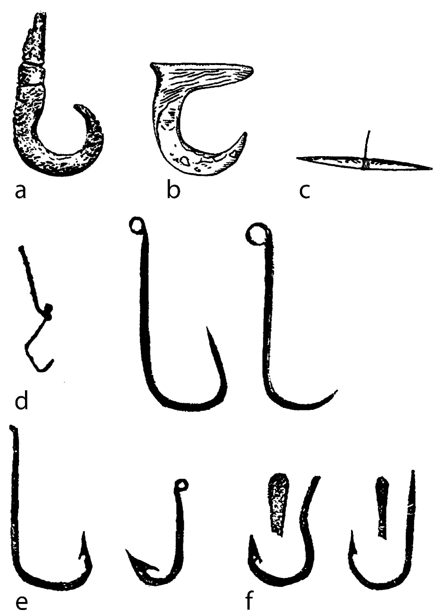
The waters of the Nile, the floodplains, and many pools that remained when water receded or evaporated in autumn, as well as the coastal lagoons of the Delta, contained rich resources of fishes and other aquatic animals which were utilized since prehistoric times. There is much evidence for this from archaeological finds, well preserved in the desert, engravings and wall paintings in tombs and temples, and from hieroglyphic inscriptions.

As indicated by bone and shell remains at Kom Ombo near Aswan, hunter-gatherers already fished during the Late Palaeolithic around 15000 BCE for Nile perch, catfishes and barbels, and they collected Nile oysters and African softshell turtles. Some flint tools have been interpreted as points of lances. After 10000 BCE, as North African savannas deteriorated to deserts due to climatic changes, game became rare, and hunters turned increasingly to fishing, employing gear like spears with stone or bone points, harpoons, and curved fishhooks and gorges made of bone or antlers (Figs. 1 and 2). Hippopotamuses and crocodiles were also harpooned or caught in traps (Fig. 3). The development intensified during the Neolithic (5500–4000 BCE), when Lake Quarun in the Faiyum Depression filled with water and became an important fishing area like the Delta. Around 3500 BCE the first fishhooks of copper appeared and increasingly replaced the stone and bone tools.

The unification of Upper and Lower Egypt around 3000 BCE led to the formation of the Old Kingdom (ca. 2600–2150 BCE) with powerful rulers and an efficient administration, promoting the construction of pyramids and hydraulic engineering for drainage and irrigation to improve agriculture, fishing and transport.

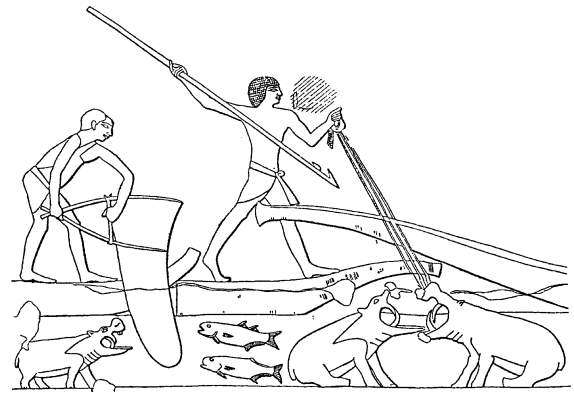


Fishing in Ancient Egypt. Fig. 1 Ancient gear: (a) points of lances and spears made of flint stone; (b) prehistoric harpoon points made of bone; (c) points of copper harpoons (after Petrie 1920; Brewer and Friedman 1989).



Fishing in Ancient Egypt. Fig. 2 Hooks for line fishing: (a) bone; (b) antler; (c) gorge; (d) copper hooks, Old Kingdom; (e) barbless copper hooks, Middle Kingdom; (f) barbed copper hooks with plate for fixing a line, New Kingdom (after Eiwanger 1992; Debono and Mortensen 1990; von Brandt 1975; Petrie 1917; Brewer and Friedman 1989).

During this epoch artists created very realistic images of fish species and fishing methods in reliefs and wall paintings on tombs, mainly at Saqqara, the necropolis of Memphis (*Mennofer*), the old capital



Fishing in Ancient Egypt. Fig. 3 Harpooning hippopotamus and fishing with hand net. Relief in tomb of Princess Idout at Saqqara, Old Kingdom. The harpoon head was attached to a retrieving line (Macramallah 1935).

Fishing in Ancient Egypt. Fig. 4 Fishing with multiple hook and line and with hand net. Relief in tomb of Kagemni at Saqqara, ca. 2280 BCE (von Bissing 1905).

(Fig. 4). The fishes frequently depicted are Nile perch, Nile tilapia, various species of catfishes and elephant-fishes, barbels, mullets and eels (Fig. 5). Modern studies revealed about 65 fish species in the Nile waters; some 30 of them can be recognized in ancient images. Presentations of fish and fishing had revivals during the Middle and New Kingdoms (ca. 2000–1780 and 1550–1070 BCE), particularly at Thebes, west of Luxor, and elsewhere. A considerable number of marine species from the Red Sea/Indian Ocean are depicted under ships of the expedition to Punt in reliefs of the mortuary temple of Queen Hatshepsut at Deir el-Bahri.

Famous pictures in tombs show the deceased spearing fish, usually Nile perch and tilapia, in the papyrus swamps (Fig. 6). Many images illustrate the use of weir baskets (Fig. 7) and of nets, mostly small hand nets and seines, operated both from the beach and from boats (Figs. 8 and 9). Fishermen made and repaired seine nets of flax or other natural fibres (Fig. 10) which were kept vertical in water by floats

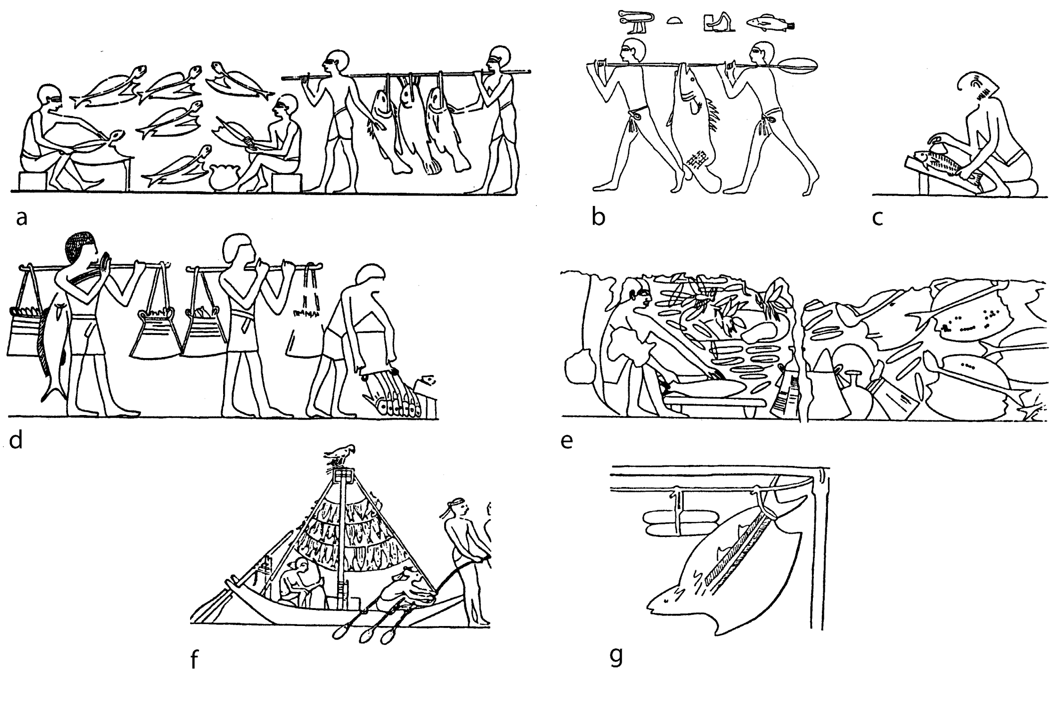
Fishing in Ancient Egypt. and sinkers. Trawls pulled between two boats may even have been used (Fig. 11). Cast nets appear in the Late Period. Fishing vessels were papyrus rafts and boats constructed from blocks of wood, since large trunks were scarce (Fig. 12).

As shown in wall pictures, fishes, mainly Nile tilapia, were kept in basins, apparently mostly waters belonging to palaces or temples. A few presentations seem to indicate that fish were also kept in natural ponds, perhaps as storage of living food (Fig. 13).

Fish were gutted and eaten raw or grilled. Large quantities were clipped and dried in the sun, often hanging on lines. Salted fish also had a wide market both in Egypt and for export (Fig. 14). Some sort of

Fishing in Ancient Egypt. Fig. 13 Miniature from the neck of a silver can found at Bubastis, showing a fish pond (after Vandersleyen 1975).



Fishing in Ancient Egypt. Fig. 14 Fish processing: (a) transport and clipping; (b) carrying a large Nile perch; (c) removing the fish spine; (d) baskets full of fish for processing; (e) gutting (insects are shown infesting the meat); (f) fish hanging in ship's rigging for drying; (g) clipped mullet and its roe hanged for drying (Épron and Daumas 1939; Petrie 1892; Taylor and Griffith 1894; Moussa and Altenmüller 1977; Wreszinski 1914; Keimer 1939).

caviar was prepared from mullet roe. It seems that fish for food consisted almost exclusively of freshwater species.

The profession of fishermen was regarded socially as only of a low level. Various images show how they participated in coarse games, knocking each other from the boats with long poles.

Catches usually had to be delivered to palaces or lords of the manor, and fish were often used, jointly with other natural products, as payment in kind for labour. Catches were subject to taxation, and fees had to be paid for fishing rights.

Also well documented is the important role of fishes and other aquatic animals in religion, mythology and medicine. In many provinces different fish species were adored as representing gods, e.g. African butter catfish (*Schilbe mystus*) as a symbol of Hatmehit at Mendes in the Delta, Nile tilapia as a symbol of fertility and rebirth, elephantfish as a symbol of Hathor at Oxyrhynchus and other places, Lepidotos (*Barbus bynni*) at Lepidopolis near Abydos, Phagros (mullet?) and puffer fish at Aswan, and Latos (*Lates niloticus*) at Esna. Devotion to fish was often combined with a ban on the consumption of certain fish species at certain times in certain areas, especially by priests in temples. Mainly during the New Kingdom and Late Period thousands of fishes were mummified and buried in large animal cemeteries. Fishes were found as gifts to the deceased in graves, and fish offerings were portrayed on tomb walls, although infrequently.

As described in papyri, extracts from various parts of fish were used as drugs for medical purposes. For curing gout, live electric catfish (*Malapterurus electricus*) were placed under the feet of patients.

Fishing in the Indus Valley

Dietrich Sahrhage

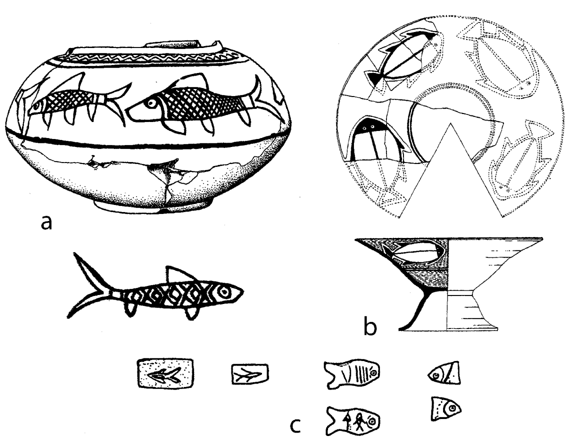
The ancient civilization in the region of the Indus valley reached its zenith around 2600–1900 BCE. It was characterized by cities like Harappa, Mohenjodaro, and many urban sites which have been excavated or identified by archaeologists in what is now Pakistan and Western India.

It was the regular supply of water that allowed the early development of agriculture and hence the growth of the human population. The main sources were the rainfalls and melting snow from the Hindukush and Karakoram Mountains in the north and monsoon rains from the west. This resulted annually in mighty, though very variable, floods in the River Indus and its effluents with a peak in July and August. The water carried enormous quantities of very fertile soil to the south, which filled the riverbeds and forced streams to change their channels frequently, inundating large areas.

The rivers, numberless lakes and pools, often arising and vanishing, and the waters of the Arabian Sea along the Makran coast were the home for large resources of fish, crustaceans and molluscs. These animals formed a significant element in the diet of people and of the trade in the region.

Since the Indus script and language have not yet been deciphered, and there seem to be no reliefs or wallpaintings in temples or palaces, we depend mainly on archaeological finds and on the observation of apparently old practices today for information on fishing and other activities in ancient times.

Fishing in the Indus Valley. Fig. 1 Steatite stamp seal from Mohenjodaro with pictogram of fish in the script line on top, 3.5 × 3.5 cm. National Museum Delhi (from Jansen 1986, drawing Bunse, Aachen). Used with their permission.



Fishing in the Indus Valley. Fig. 2 Fish images on pottery and in figurines: (a) red/black ceramic vessel from prehistoric cemetery at Nal (Baluchistan). Used with their permission, (b) painted dish on stand with fish from Lewan, ca. 3000 BCE (Allchin 1982/1993), (c) zoomorph figurines with fish design.

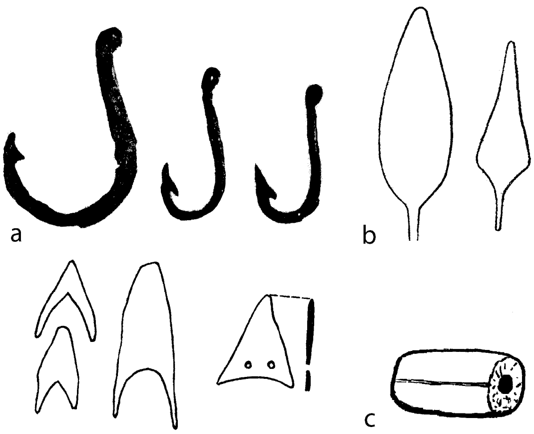
Fishing in the Indus Valley. Fig. 3 Potsherd from Harappa with painted men fishing with baskets, in front probably seine net (after Vats 1940 from Jansen 1986). Used with their permission.

Fishing in the Indus Valley. Fig. 4 Remains of a fishing net, discovered near Shahr-i-Sokhta in the swamps of the Seistan Depression, third millennium BCE. Netting knitted with reef knots, square mesh 4 cm on average, finely woven fibre, possibly wool (Istituto Italiano per l'Africa e l'Oriente, Rome. Photo: Bonardi). Used with their permission.

The importance of fishes in the Indus civilization is evident in many typical seals with a pictogram of fish (Fig. 1). Presentations of fish and fishing also appear on pottery and in the form of small zoomorph ceramic figurines (Fig. 2). Most interesting is a potsherd, discovered at Harappa, with the drawing of men obviously fishing with baskets (Fig. 3). In the foreground one sees netting which could be interpreted as part of a seine. The existence of such nets is revealed by a great number of typical sinkers, mostly of limestone. Pakistani fishermen still use the same type today. Direct evidence for net fishing is provided by remains of an almost 5,000 year old net discovered in 1972 by an Italian mission at Shahr-i-Sokhta in the Seistan Depression, today in Iran near the border with Afghanistan (Fig. 4) .

Finds of ancient fishing gear consisted mostly of spear points, arrowheads and a limited number of fishhooks (Fig. 5). Spears and arrows were certainly also used for hunting. With the development of metallurgy since the fifth millennium BCE, artefacts were made of copper. Fishhooks discovered at Mohenjodaro, Chanhudaro and Harappa were 1–10 cm long. The longest must have been employed in fishing for very large fishes. Hooks were mostly barbed, but barbless hooks were also found. From investigations it appears that copper was imported from Baluchistan, Rajasthan (Khetri) and overseas from Muscat and Oman (Magan).

In the absence of ancient fish images, skeletal remains are of utmost importance for identifying fish species caught in ancient times. From fish bones unearthed in Mohenjodaro, Harappa and elsewhere it is indicated that catches in freshwaters consisted mainly of carp-like fishes, particularly the large barbels *Catla catla*, Mahseer (*Tor tor*) and the Rohu (*Labeo rohita*), which grow to lengths of over 2 m, and also various species of small barbels which nevertheless are important due to their biomass. Also the large catfish *Wallago attu* was a major food fish.

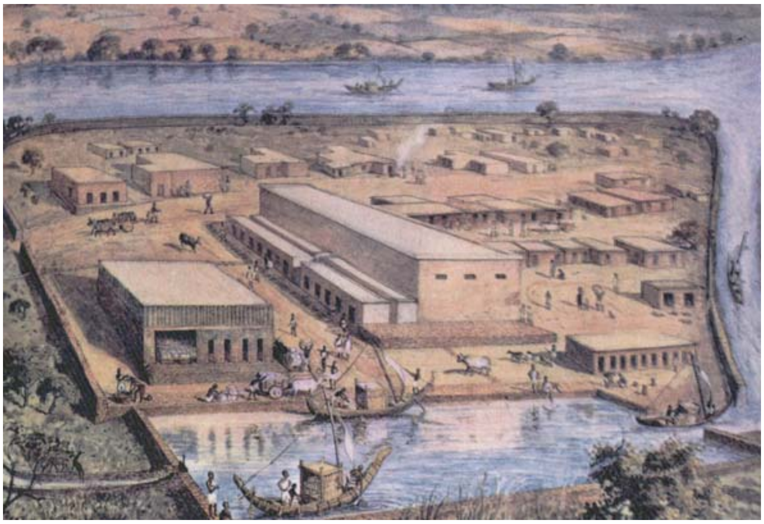


Fishing in the Indus Valley. Fig. 5 Fishing gear in the Indus civilization: (a) Copper fishhooks from Mohenjodaro (Sarkar 1953); (b) spearpoints and arrowheads (Agrawala/Kumar 1993); (c) net sinker of limestone discovered at Mohenjodaro (Marshall 1931/1973).

The coastal waters of the Arabian Sea provided good catches mostly of giant seacatfishes (*Arius thalassinus*), croakers, grunts, skates and small sharks. This was discovered when a French team with Desse and Desse-Berset in 1989 found thousands of fish bones, together with shells and Harappan potsherds, lying on the Prahag beach near Pasni. Finds of such bones at Miri Qalat, 120 km north of Prahag, and even at Harappa, some 900 km further north, prove that fish had been transported far inland.

In a region with a hot climate this would have been impossible without proper conservation of the catches near the coast. The bone remains on the beach of Prahag gave a hint: they were placed in a number of circles 5–8 m in diameter. It seems that the fishes had been put into round pitches in the sand for salting. In fact, this method is being used by present-day Baluchi fishermen, as Belcher observed at Balakot near Karachi. The fish, mostly silver grunt (*Pomadasys hasta*), are beheaded, clipped, the halves put into brine for 2–3 days and exposed to wind and sun for drying.

Rivers, lakes, and the Indian Ocean offered good opportunities to catch crustaceans and to collect mussels and gastropods. Whereas the crustaceans remains decayed, the mollusc shells lasted over thousands of years. Already during the Stone Age they were worked into ornaments, amulets and objects of daily life like vessels and spoons. Workshops existed in many Harappan cities, where craftsmen produced highly artistic objects with fairly uniform techniques and styles. Like precious stone products, mollusc shell products were also traded in the Indus region and far beyond (Kenoyer 1984).



Fishing in the Indus Valley. Fig. 6 Reconstruction of the city of Lothal with harbour basin, wharf and store. Large central building (“acropolis”) on platform of loam bricks. In the back living quarters and workshops for copper, marine shells, lapidary and semi-precious stone working industries (Rao 1973).

The central part (columella) of sacred conch (*Turbinella pyrum*) was used to produce hollow cylinders for seals which were exported to Oman and Mesopotamia. Finds of such cylinders, and of Indus stamp seals, in Mesopotamia prove trade connections between Meluhha (as the Indus region was named) and the cities on the rivers Euphrates and Tigris. Cuneiform scripts on clay tablets from Mesopotamia tell that King Sargon I, around 2300 BCE, ordered that ships from Meluhha sail upstream on the Euphrates beyond Ur to reach his capital Akkad for unloading their cargo. After the Akkad period direct connections were discontinued but indirect links via Dilmun on the Bahrain Islands and Oman lasted for many years.

One of the ports for trade overseas was Lothal on the Bay of Cambay, where a basin and likely harbour installations and workshops have been excavated (Fig. 6).

The Indus civilization perished around 1700 BCE for unknown reasons. Possible explanations include climatic changes, tectonic activities with earthquakes, and socio-economic influences like overgrazing, burning of grassland and forests, and the impossibility for rural people to feed the increasing urban population.

Fishing in Mesopotamia

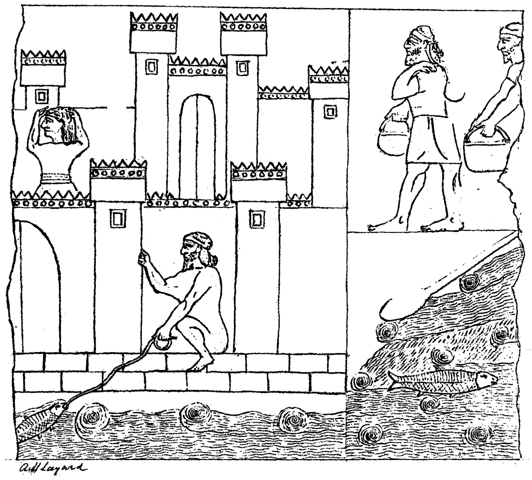
Dietrich Sahrhage

In Mesopotamia, the region of the rivers Euphrates and Tigris and their tributaries, the formation of old civilizations depended on water for drinking, agriculture, traffic and trade. Living aquatic resources like fish, crustacea, molluscs and turtles contributed substantially to feeding the growing human population.

Annual floods, originating from rainfall and meltwater in the highlands of Anatolia and the Zagros Mountains, transported large amounts of pebble and fertile silt downstream; rivers frequently changed their channels, often with catastrophic consequences. During highest water-levels (April–June) wide areas were flooded until water ran off or evaporated in the hot climate. Swamps with reed thickets and lakes (Hors) developed in the depressions. Floods became less dangerous when rivers were regulated with dams and canals, and when irrigation was implemented in the south, from at least 5000 BCE. The many waters were productive areas for fishing.

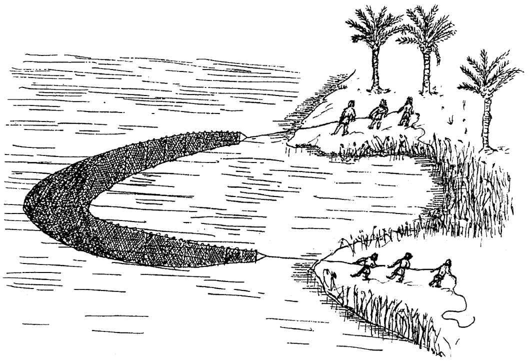
Investigations have shown that Neanderthals lived in northern Mesopotamia as nomads at least 100,000 years ago. During the Neolithic, after 10,000 BCE, the people formed settlements and developed farming and animal husbandry. The oldest evidence for fishing activities are points of spears and arrows of flint and obsidian, fish bones and shells of river mussels (*Unio tigridis*) from around 5500 BCE.

Reports on clay tablets seem to indicate that fish-hedges, traps and baskets were widely used; however any evidence we have has decayed long ago. Fishhooks of stone have only occasionally been discovered, but hooks became more numerous after the implementation of tools of copper around 4500 BCE and bronze (copper–tin alloy) around 3000 BCE. Hook and line fishing is represented in many reliefs (Figs. 1 and 2). According to texts in cuneiform characters, net fishing was frequently used. Stationary nets were set between stakes and seine nets used from the beach, probably also from reed rafts and boats, to encircle fish shoals



Fishing in Mesopotamia. Fig. 1 Fishing with hook and line on the river banks. Drawing after a relief in the Southwest Palace of King Ashurnasirpal II (883–859 BCE) at Nimrud (Layard 1853).

Fishing in Mesopotamia. Fig. 2 Fishing with rod and line. Quare stone of basalt from Tell Halaf, Syria. Height 47 cm (Staatliche Museen zu Berlin-Preussischer Kulturbesitz, Vorderasiatisches Museum). Used with their permission.



Fishing in Mesopotamia. Fig. 3 Hauling a seine net (after Salonen 1970).

Fishing in Mesopotamia. Fig. 4 Impressions from cylinder seals showing fishing activities. (e) and (f) may depict traps, (g) and (h) fishes in front of nets (after Amiet 1972/80; Legrain 1936; Lenzen 1960; Van Buren 1948/49).

(Fig. 3). Cast nets were also known. Impressions of cylinder seals often show fishing activities (Fig. 4).

Mesopotamian graves are much simpler than Egyptian tombs, where fish images, particularly from the Old Kingdom, are presented naturalistically. In contrast, Mesopotamian reliefs, sculptures and cylinder seals show such pictures, but they are fairly stylized. However, rich finds of ancient fish bones from food remains on many sites provide the possibility of identifying a great number of fish species by comparing them with skeletons of modern fishes. Such investigations revealed that various species of barbels, some of very large size (Fig. 5), catfishes and mullets formed the bulk of catches in freshwater areas, whereas sea breams, grunts, croakers, groupers, and many other marine fishes were caught along the coasts of the Arabian/Persian Gulf. Frequent finds of marine fish

remains far inland prove that these animals were traded over long distances. The same holds true for marine mussels and gastropods, which were converted into ornaments, inlaid work and objects of daily life.

Texts on thousands of clay tablets with writing in cuneiform characters permit a deep insight into many aspects of Mesopotamian matters, especially in the fields of economics, legal affairs, medicine, religion and literature. From these scripts it can be seen what names in Sumerian and Akkadic languages people used

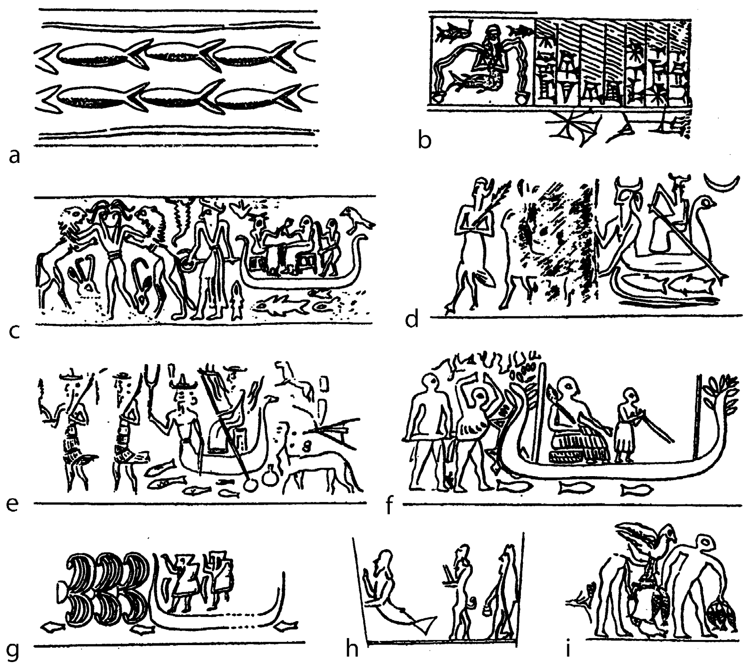
Fishing in Mesopotamia. Fig. 9 Mixed figures in Mesopotamian mythology: (a–c) goat-fish; (d) dragon and birdlike beings with fish tail; (e) fish-man and fish-woman; (f) and (g) Apkallu (after Legrain 1936; Potraz 1961; Scheil 1918; Thureau-Dangin/Durand 1936).

Fishing in Mesopotamia. Fig. 10 Fish-man on quare stone from Tell Halaf, Syria, ca. 900 BCE. Limestone, ca. 40 × 60 cm (Staatliche Museen zu Berlin-Preussischer Kulturbesitz, Vorderasiatisches Museum). Used with their permission.

for various species of fish. Most of the 324 names collected could not be attached to a certain fish species, but some could, like *kusu* for the dangerous Ganges shark (*Glyphis gangeticus*) which migrates upstream from the Gulf to the north of Baghdad.

The texts also provide information on the organization of fishing, commitments and wages of fishermen, as well as facilities for the delivery and distribution of catches. Regulations were most rigid around 2300–1600 BCE, when palaces and temples played a central role for the public production, storage and distribution of foodstuffs and commodities. Detailed statistics were collected regarding the deliveries of fish (Fig. 6). Sometimes temples let out fishing rights to independent fishermen who paid a fee in the form of fish and delivered the rest to trade agents who organized the barter on the basis of silver equivalents for natural goods.

In the vicinity of rivers, lakes and the Gulf, fish were mainly consumed fresh. Because of the hot climate and because fish are perishable, large parts of the catches had to be processed. The fish were gutted, and the marine fish were mostly clipped, dried in the sun, crushed and pressed to blocks suitable for

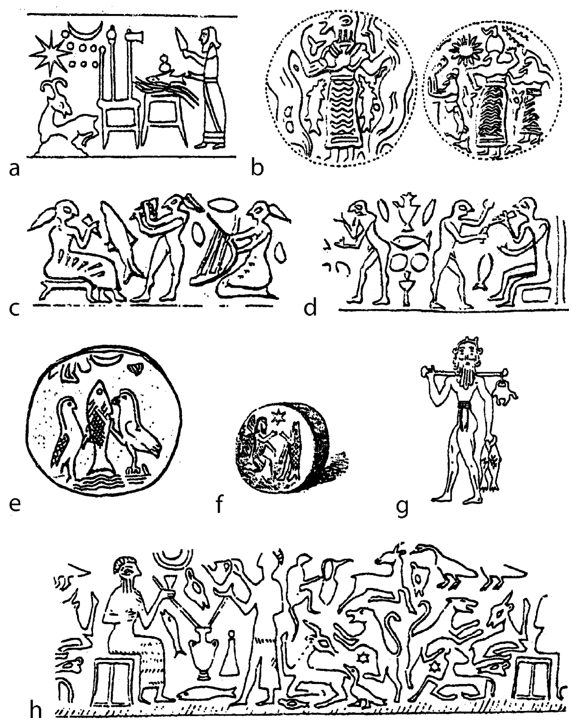


Fishing in Mesopotamia. Fig. 11 Impressions from cylinder seals with mythological scenes related to fishing (after Amiet 1972/80; Orthmann 1975; Weber 1920).

transport over long distances. Freshwater fishes were dried for longer times in the shade. Salting seems to have been less important, but many fish were put into brine prepared from fish guts and crustacea, possibly a forerunner of garum in Greek and Roman times.

Texts on clay tablets also describe medical prescriptions against various diseases in which substances from fish, turtles and seaweeds were considered helpful. Doctors and priests collaborated closely during magic exorcism.

Fish were an important element in Mesopotamian religion and mythology. From the many gods of the Mesopotamian pantheon it was particularly Enki (Ea in Akkadic), the creator of man and god of wisdom, who was adored as the donor of water and fertility. Usually he was depicted carrying a vase through which water from heaven flowed down to earth (Figs. 7 and 8), while fishes, as symbols of life and fertility, swam upwards in the running water. Enki's attributes were goat-fish and fish-man (Figs. 9 and 10). Frequent figures related to Enki are also men, dressed in the skin of a large fish, probably a barbel (*Barbus esocinus*) (Fig. 5). These figures (priests?) presented in cylinder seals, sculptures and many reliefs, are called Apkallu, which means sage. A great number of cylinder seals show scenes with fishing, boats, fish offering and libation ceremonies (Figs. 11 and 12).



Fishing in Mesopotamia. Fig. 12 Impressions from cylinder seals with scenes of fish offerings and libation ceremonies (after Amiet 1972/80; Buchanan 1966; Heuzey, Legrain 1936; Perrot/Chipiez 1884; Weber 1920).

Fishing in the Stone Age

DIETRICH SAHRHAGE

Fishing is one of the oldest activities of man. The hunter-gatherers of the Stone Age not only fed on game and plants but also on fish and other aquatic animals. Living as nomads, they were bound to the neighbourhood of springs, rivers and lakes for drinking water, hunting game at the watering places and using the dense vegetation. No wonder that they soon discovered rich aquatic resources for their food. Also in coastal areas, preferred as migratory routes, they were able to collect and catch many fishes, crustacea and molluscs.

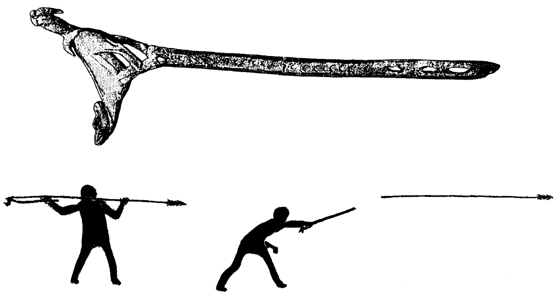
It is striking that fishing gear was developed in different regions of the world to rather similar, sometimes almost identical, forms, although the globe was still only thinly populated. Whether the various techniques were invented independently in different civilizations since human intelligence led to similar solutions (convergence), or whether the experience was distributed by migrations and cultural exchange (diffusion), is an open question.

The oldest indications of fishing, about 2 million years old, are bones of Tilapia and shells of molluscs together with simple pebble tools and human bones left by *Homo habilis* in the Olduvai Gorge in Tanzania, but no fishing gear was found.

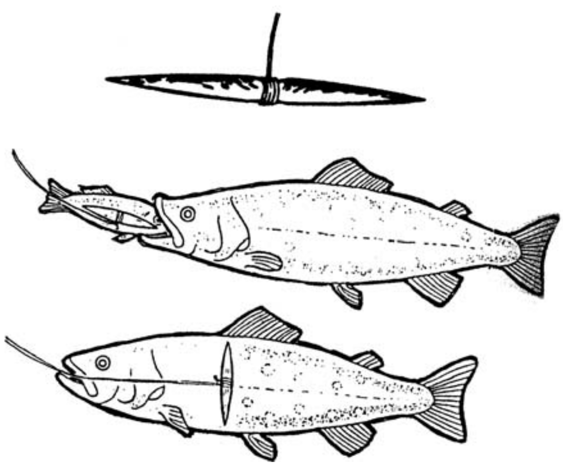
It may, however, be assumed that already during the Palaeolithic times humans were able to develop a palette of simple techniques to reach their goal. Men went hunting for fish with the same gear used for small game, particularly with wooden lances equipped with stone points (Fig. 1). Women and children collected crustacea and molluscs in shallow waters. People soon managed to catch fish with their bare hands and to build stone walls and wooden hedges to improve fishing

Fishing in the Stone Age. Fig. 1 Group of Bushmen hunting fish with lances. Drawing after prehistoric rock painting at the Tsielike River, South Africa (Battiss 1945).

Fishing in the Stone Age. Fig. 2 Harpoon of prehistoric fishermen on the coast of southern Peru used for hunting seals and possibly sharks. The harpoon consists of seal bone with a flint point and ligature of leather or sinew. Shaft is of wood, retrieving line of plant fibre (Lavallée, *Pour La Science* 2001). Used with the permission of *Pour La Science*.



Fishing in the Stone Age. Fig. 3 Atlatl, spear throwing sling from the cave of Mas-d'Azil, Ariège, southern France, about 20,000 years old (after Stodiek and Paulsen 1996). The 32 cm long stick is decorated at the end with a highly artistic sculpture of a fawn and a bird. The end of a spear is put against a spur of the sling, and – as with a catapult – the hunter can propel the spear with a force much greater than that of a hand-thrown spear.

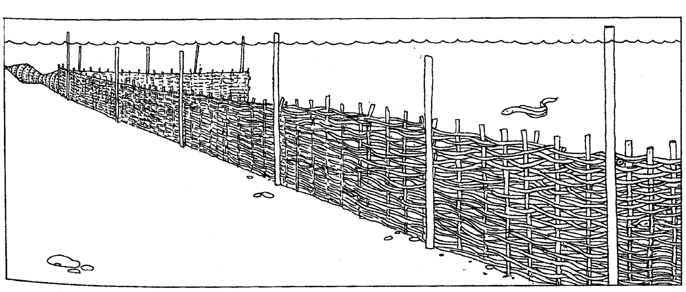


Fishing in the Stone Age. Fig. 4 The gorge, probably the oldest angling tackle. In Europe it has been used since the Magdalenian, about 16,000 years ago. The stick is put into the bait. When the prey snaps at the bait, the gorge turns transverse as the line gets tight (Evers, Franz Steiner Verlag Stuttgart 1988). Used with their kind permission.

possibilities. Branches of bushes were stuck into the ground in waters where fishes concentrated to shelter. The hunters also discovered that fish were attracted by light from fire. Most likely they built fish traps similar to those used for game, but any material evidence decayed long ago.

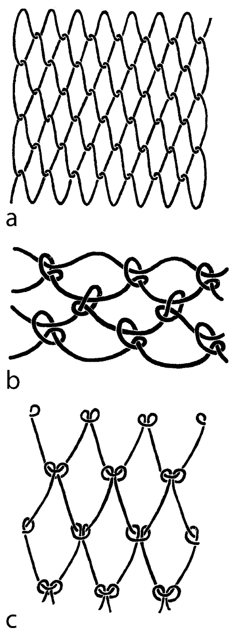
A great step was the invention of the javelin. This tackle was used by *Homo erectus* some 400,000 years ago, as proved by finds in Lower Saxonia, Germany.

Fishing in the Stone Age. Fig. 5 Above: Curved fishhooks from the Mesolithic period found at various sites in Denmark (The National Museum of Denmark, Copenhagen). Used with their permission; Below: Compound fishhook of seal bone with mussel shell barb from Quebrada de los Burros on the coast of southern Peru, about 8,000 years old (Lavallée, *Pour la Science* 2001, drawing by Bailly). Used with the permission of *Pour La Science*.



Fishing in the Stone Age. Fig. 6 Reconstruction of a fish hedge with trap from Oleslyst, Denmark, about 4,500 years old. Hazel stakes in the sea bottom held wickerwork panels over a length of about 45 m. Fish, mostly eels, swam along the hedge to deeper water and were caught in a weir at the end (Pedersen 1997; drawing Petersen, Kalundborg Regional Museum). Used with their permission.

Fishing in the Stone Age. Fig. 7 Hugh mounds of shell middens were left over from meals of Stone Age people in many places of the world, as here in Otuma on the coast of Peru (photo: Tulio Cusman, Lima).



Fishing in the Stone Age. Fig. 8 Fish nets with different kinds of knots to produce meshes: (a) knotless nets with simple hanging in; (b) nets knitted with "lake-dweller knots," (c) nets knitted with "Peru knots" (von Brandt 1984).

Fishing in the Stone Age. Fig. 9 Rock painting of a flatfish (flounder?) in the cave of La Pileta near Ronda in Andalusia, Spain, around 20,000 years old, length 1.5 m (photo: José Bullón Giménez ►http://www.cuevadelapileta.org). Used with permission.

Fishing in the Stone Age. Fig. 10 Barramundi fish (*Lates calcarifer*) painted by Australian aborigines about 2–3,000 years ago in "Roentgen" (X-ray) style in the Cockatoo National Park, western Arnhemland (photo: Tacon, The Australian Museum, Sydney. Used with their kind permission).

Neanderthals (*Homo sapiens neanderthalensis*), living in Europe and the Near East some 200–30,000 years ago, fed mainly on meat, as indicated by their petrified excrements, but fish also played an important role. This was shown by bone remains of trout and salmon on their resting places along rivers in France and Spain.

Much progress was achieved after modern man (*Homo sapiens sapiens*) originated. This began about 150,000 years ago somewhere in southeastern Africa and spread out over the globe, reaching Australia around 40,000 BCE and the American continents via the Bering Straits about 15,000 BCE, perhaps earlier. Now more delicate spear points, blades and scrapers of stone, were produced, and later tools of bone and antler.

Modern humans invented the harpoon, a sharp barbed piece of bone, detachable from the spear shaft, which kept the prey (game or fish) on a retrieving line when it stuck in the body of the animal (Fig. 2). Such gear was found on many locations in the world and has been used frequently up to the present. The oldest harpoon head, found in East Africa, is about 90,000 years old.

Another ingenious invention was a spear-throwing instrument, later called *atlatl* by the Aztec of Mexico, which was distributed widely over all continents (Fig. 3). The oldest known atlatl was used in northwestern Africa 25,000 years ago; Australian aborigines still hunt with similar tools today. The atlatl was increasingly replaced by bows and arrows, known in Europe since 25,000 BCE, and in America since about 2,500 years ago. Many native people even today fish with this technique.

Angling may have started during the latest glacial epoch with the gorge, a little wooden stick, pointed at both ends, with a ring furrow for fixing a line (Fig. 4). Curved fishhooks seem to appear only after the Ice Age in the subarctic hunter civilizations of northern Eurasia from where this method spread out to Europe and to the Far East and America (Fig. 5).

With major climatic changes around 12,000 BCE, large parts of the ice cover melted and the sea level rose in all the oceans. Wide coastal areas were flooded and many valleys and depressions filled with water. People changed their activities increasingly from hunting to fishing with subsequent improvements in catching techniques (Fig. 6). Temporary, and later permanent, settlements on rivers, lakes and the seaside developed where fishing possibilities proved favourable. Dense concentrations of prehistoric fish, seal and whale remains, and huge heaps of shell middens in many places of the world indicate the great importance of aquatic fauna as human food (Fig. 7).

Remains of fishnets lasted only under special conditions in swamps and arid deserts. Knowing how to knit netting marked a major form of progress (Fig. 8). The oldest nets, excavated in Finland and Peru, are 9–10,000 years old, but the history of nets may go back far earlier. In the Czech Republic 27,000 year-old impressions in clay were found which seem to originate from net meshes.

Fishing in the Stone Age. Fig. 11 Fishing with tamed cormorants. *Above*: An old method used in China (Dabry de Thiersant 1872); *Below*: Drawing from a ceramic receptacle from the Moche culture, 100 BCE–700 AD in Peru, exhibited in the Museo Amano, Lima (drawing Sahrhage).

Fishing in the Stone Age. Fig. 12 Prehistoric dugout canoe, about 8,000 years old, being excavated near Dufuna in northern Nigeria (photo: Breunig). Used with permission.

Many rock paintings and engravings certify the role of fish in the spiritual life of Stone Age people, possibly during magic rites in shamanism (Fig. 9). This is evident also from X-ray images found in Europe, northern Asia, America and Australia, showing the inner organs of the animals (Fig. 10).

A sophisticated technique of fishing developed in China, Japan and Peru, where cormorants were tamed to deliver their fish prey to the fisherman who took care of the birds (Fig. 11).

Probably rather early, people started to build vessels for crossing the waters and reaching aquatic resources in deeper areas. For this they used the materials locally available to produce, for example, reed rafts in swamps, dugout canoes in forest regions (Fig. 12), and boats with skin hulls stabilized by wooden sticks.

Various methods of fish preservation were also developed during the Stone Age: drying over the fire or in the wind and sun to produce stable food for the long winter periods passed mostly in caves, and for migrations, as well as salting and pickling.

Most of the basic types of fishing techniques originated in the Stone Age. They are still widely applied.

Five Phases (*Wuxing*)

Ang Tian Se

Five phases, or *Wuxing*, is one of the basic concepts used by the ancient Chinese along with *Qi*, *Yin*, and *Yang*, to explain natural phenomena. The term *Wuxing*, formerly translated as "Five Elements" is now rendered as "Five Phases". The reason for such a rendering is simply that the term *Wuxing* in Chinese did not necessarily mean "Five Elements" as we understand them today but is a term which implies something dynamic, ever moving, and transforming in a regular pattern through the operation of *Qi* in nature.

F

Before we trace the origins and development of the *Wuxing* concept, we should bear in mind that early Chinese thought was perennially involved with the relationship of humanity and nature. Humans were seen to hold an integral but not an assertive place in nature. They had to understand nature and live harmoniously with it. To provide a rationale for it, *Zou Zhuan* (Master Zou's Enlargement of the Spring and Autumn Annals) of the fifth century BCE says:

> There are Six *Qi* in nature. When they descend, they give rise to the Five Tastes; display themselves in the Five Colors, and are evidenced by the Five Sounds. When they are in excess, they generate the Six Diseases. The Six *Qi* are *yin* and *yang*, wind and rain, dark and light. They divide to form the Four Seasons, showing the Five Periods in sequence. When they are in excess, they bring about calamities. Excess in *yin* results in cold diseases; excess in *yang*, hot diseases; excess in wind, the diseases of the extremities; excess in rain, the diseases of the stomach; excess in dark, delusions; excess in light, diseases of the heart.

Realizing that nature is vicissitudinary, the early Chinese classified, through their observations and experiences, all the natural phenomena as well as mundane affairs in groups of fives. Classification as such was based on their perception of nature and the society in which they lived. Hence, in several pre-Qin (third century BCE) texts we come across such terms as *Wufang* (Five Directions), *Wushi* or *Wuchen* (Five Periods/Seasons), *Wude* (Five Powers), *Wucai* (Five Materials), and other fivefold categorizations. The oldest reference to the term *Wuxing* without the nomenclature for the set of five is found in the *Guo Yu* (Discussion on the Ancient Feudal States) of Western Zhou in the eighth century BCE.

The person purported to have systematized and stabilized these ideas of categorization was Zou Yan who flourished between 350 and 270 BCE. He referred to the set of Water, Fire, Metal, Wood, and Earth as "Five Powers". He cited the rise and fall of past dynasties to put forward a cosmological theory of monarchy. As a reflection of the order on Nature, the political order was subject to the Five Powers which conquer each other. This sequence later came to be known as the Mutual Conquest Order (*Xiang Ke* or *Xiang Sheng*), wherein Water conquers Fire by extinguishing it, Fire conquers Metal by melting it, Metal conquers Wood by cutting and carving it. Wood conquers Earth either by digging it up or growing out of it, and Earth conquers Water by damming it up and constraining it. Because the Five Powers dominate alternately, it is seen that the process of domination is itself "controlled" by the Power which conquers the conqueror. For example, Wood conquers Earth, but Metal controls the process. There is yet another sequence which is found in the *Chun Qiu Fan Lu* (String of Pearls on the Spring and Autumn Annals) by Dong Zhongshu of the second century BCE. The sequence gives rise to the Mutual Production Order (*Xiang Sheng*), in which the Five Powers generate each other. The sequence begins with Wood which produces Fire (being consumed as fuel). Fire produces Earth (by forming ash), Earth produces Metal (by fostering the formation of metallic ores), Metal produces Water (by liquefying itself when heated), and Water produces Wood (by nourishing the plants). If both the orders of Mutual Conquest and Mutual Production are taken together, it is seen that in the process of destruction of one Power by another, the process of change is somehow "masked" by some other process which produces more of the substrate, or produces it faster than it can be destroyed by the primary process.

Another *locus classicus* of the pre-Qin period which describes the Five Powers as Five Processes is found in the *Hong Fan* (Great Plan) chapter of the *Shu Jing* (Historical Classic). The text gives the names of *Wuxing* in numerical order, followed immediately by their respective descriptions. Thus, we have:

- Water: wetting, descending
- Fire: flaming, ascending
- Wood: (allowing to be) carved, straightened
- Metal: (allowing to be) molded
- Earth: sowing and harvesting

The description suggests five sorts of fundamental processes characterized by their respective quality in nature.

In their effort to understand the physical changes in Nature, the early Chinese tried to establish a viable system in terms of abstract ideas. In the *Wuxing* chapter of *Guan Zi* of the late fourth century BCE, the set of Wood, Fire, Earth, Metal, and Water is fitted to 72-day divisions to the 360-day year in order to show the change of seasons in an evolving manner. The set of five is associated with five types of *Qi* that bring about changes in nature. Then, in another *Wuxing* chapter in *Bai Hu Tong* (Comprehensive Discussion in the White Tiger Hall) of the first century, the word *Xing* is specially used to mean "the activity of *Qi* by the natural order." In the *Chun Qiu Fan Lu*, too, *Xing* means "activity". It is clear that *Wuxing* is no longer seen as a set of chemically or physically distinct substances, nor is it a force itself which is capable of performing actions. The *Wuxing*, then, are phases of change brought about by *Qi* in Nature.

Food Technology in Africa

RICHARD NNAMDI OKAGBUE

Food processing embodies all treatments applied to foodstuffs after harvest, capture, or slaughter to prepare them for consumption or preservation. Treatments may be single or suitably combined physical, mechanical, chemical, and biological procedures which modify foodstuffs aesthetically, nutritionally, texturally, and organoleptically.

In traditional Africa, food processing is a daily domestic or village-level activity. Women constitute the main workforce and appropriate skills are acquired informally during the process of acculturation. Male professional blacksmiths, stone-cutters and wood carvers, basket makers, and others produce the grindstones, earthenware pots, pans and plates, wooden pestles, mortars and spoons, baskets, knives, calabashes, and gourds used in the processing.

In addition to familiar food plants and animal resources some uncommon products have food uses in certain areas of Africa, depending on their availability and on the prevailing culture and religion. For example, toxic castor oilseeds (*Ricinus communis*) and leaves of the toxic legume *Cassia obtusifolia* are processed into food condiments in Nigeria and Sudan, respectively. *Spirulina*, a "vegetable" microbe, is consumed in Chad, and caterpillars called mopane worms constitute human food in Zimbabwe. Other items include dog meat, cow and goat blood in parts of Nigeria, Kenya, and Zimbabwe, and gall bladder juice, hides, and skins in Sudan and Nigeria, respectively.

First-stage processing is a preliminary treatment used to release valuable seeds and fruits from heavy pods, heads, or husks. Melon pods (*Citrullus vulgaris*), breadfruit heads (*Treculia africana*), and oil palm husks (*Elaeis guineense*) are examples, and they are generally allowed to ret or soften over a period of time. The process may occur in the farm or bush to circumvent transportation and pollution problems.

Retting occurs naturally, but it is aided traditionally by hitting the structure on a hard surface or with a machete in order to rupture it. After about a week, the rotten seed-containing pulp is scooped into a basket. Loose material leaches out, leaving the seeds which are washed and sun-dried.

Sundrying precedes other steps for treating cereal heads to release grains and for shelling legumes and other fruits like the castor seed. Dried millet, sorghum, and rice heads or husks are threshed on hard ground or pounded lightly in a mortar to detach the grains; rice is invariably pounded. Mixtures of grains or seeds are winnowed with flat winnowing baskets. Then manual screening separates the food material from the chaff.

On a large-scale sun-dried pods of legumes such as the cowpea (*Vigna* sp.) are packed in jute bags, and then shelled by being beaten by sticks or trampled upon. One method of separating mixtures of seeds and chaffs is to spread them on a mat across a distance of 4–5 m. The lighter chaffs fall-off during the throwing, and denser seeds are retained on the mat.

Overall, first-stage processing eliminates bulky wastes from harvests and prepares foodstuffs for markets and for further processing. The products mostly remain inedible or unpalatable.

In second-stage processing, foodstuffs undergo textural and organoleptic modification to yield palatable products or flours and oils. Two categories of second-stage processing will be treated—those not involving fermentation and those which are fermented.

Cooking with water, frying in oil, and roasting are commonly used methods. Individual cooked items or suitable mixtures may be pounded into sticky doughs and eaten with relishes. Pounded yam is popular in West Africa, and small amounts are also used for thickening soups or relishes. Ordinary cooking suffices for preparing some cocoyam (*Colocasia esculenta*) varieties but at least one toxic variety is detoxified by prolonged boiling.

Leguminous seeds are generally cooked and consumed with their skins (testas). However, groundnuts (*Arachis hypogaea*) and the bambara nuts (*Voandzeia subterranea*) are often cooked in the pod and later extracted manually.

Smoking is rarely used for preserving plant-based unfermented foods. In contrast, sundrying is widely practiced. Raw or lightly cooked thin slices of sweet potatoes may be so preserved in Zimbabwe, but thinly-sliced cassava is cooked and washed throughly before sundrying, to remove the cyanide and guarantee a safe product. In the Chad Republic, mats of *Spirulina*, a microscopic alga which grows in ponds around Lake Chad, are sun-dried for use as a vegetable in local sauces.

Roasting is traditionally carried out with a burning or glowing fire and is commonly applied to tubers and plantains. Among the legumes, only groundnut seeds are roasted. Cowpea seeds are dehulled, without roasting, by first soaking them in water overnight. Placing the container on the surface of water in a deep bucket or pan makes the testas float, and they are skimmed off. Wet dehulled cowpea seeds are pounded further and ground into a slurry which is seasoned and fried in hot palm oil to form palatable balls called *akara* in Nigeria.

Many kinds of dried foodstuffs are processed into flours. In Southern and Eastern Africa, flours from grains are called meals, as in maize meal, and production begins with pounding and winnowing to remove coarse chaffs. The grains or the mortar are then moistened to prevent scattering during a second pounding. The material is then sun-dried for a few hours and finally ground on a grindstone. The finished meal is sun-dried on a mat before storage or use.

Yam and sweet potato tubers are peeled, chipped, and blanched by soaking the chips overnight in hot water before sundrying, pounding, and grinding. In processing cassava flour, chips of peeled and sun-dried tubers are ground.

Many other types of foodstuffs are processed into flour. Shelled groundnuts are roasted and ground for meat seasoning in Nigeria and as a source of butter in

Zimbabwe. Various dried spices are also processed into powders.

Cooking oil is extracted from raw or cooked palm fruits and from roasted groundnut seeds. By pounding oil palm fruits in a deep mortar the oil-laden fibrous pericarps are abraded from the kernels which are sorted manually. Batches of the fibrous mass are subsequently warmed in a wide-mouthed earthenware pot to melt the oil. Then suitable portions are pressed between the palms of the hands and the oil flows into a bowl or other container.

Food processing by fermentation is widespread in Africa and various cultures have developed methods of fermenting selected food resources for different purposes. Virtually every kind of foodstuff can be fermented, and suitable processes produce heavy main course meals, condiments, and flavor enhancers, nonalcoholic and alcoholic beverages, meat substitutes, and foods for the elderly, infants, and the convalescent.

Cassava tuber is processed mainly by fermentation to detoxify it by eliminating the cyanogenic glucosides linamarin and lotaustralin and to impart desirable flavors. Important fermented products from grated material include *gari* (West Africa), *attieke* and *plakali* (Ivory Coast), and *oyoko* (Zaire).

Major products of fermenting cassava are *chikwange* (Central Africa), *ntuka* (Zaire), and *fufu* (Zaire and Nigeria). The fermentations are retting processes because they soften the tubers. For *chikwange* and one form of Nigerian *fufu* the fermented pulp is mashed and sieved through a basket into a cloth bag; the solids are concentrated by pressing the water out. Meals are prepared by steaming portions of the processed material, and then kneading, boiling, and pounding into a gel. In Zaire the fermented pulp is steamed (*ntuka*), or sun-dried, milled, and cooked (*fufu*).

African cereal-based fermentations result in diverse foods and beverages which satisfy different nutritional needs. Maize (*Zea mays*), sorghum (*sorghum bicolor*), and various millets – pearl millet (*Pennisetum glaucum*) and finger millet (*Eleusine coracana*) – are the fermentation substrates and products include acidic porridges, nonalcoholic beverages, and opaque beers.

The first step in preparation of acidic nonalcoholic beverages and porridges is soaking the cereals. Subsequent sieving, sedimentation of solids, and decantation of liquor leaves a product which can be molded into various sizes for sale. They are particularly useful for infant weaning and convalescent feeding.

Examples of acidic nonalcoholic drinks are Southern African *mahewu*, Nigerian *kununzaki*, and Sudanese *hulumur*. In *mahewu* preparation, a suspension of maize meal in boiled water (1:9) is cooked and cooled. Some wheat flour is added and the drink is ready after a day's fermentation. Nigerian *kununzaki* uses flour produced by grinding grains soaked in water for 1 or 2 days. Sudanese *hulumur* is prepared by flavoring cold water with flat sheets of fermented and baked sorghum dough prepared with equal amounts of flours from malted and unmalted sorghum.

African acidic alcoholic beverages are produced from malted grains. Malting involves germination of the appropriate grain followed by malt grinding and mashing in warm water to saccharify the malt. Unmalted grain or another carbohydrate source may be added to the mash before fermentation, which may proceed naturally or by induction with a starter from a previous brew.

Clear beers are relatively rare in Africa. Nigerian *otika*, Cameroonian *amgba*, and Sudanese *assaliya* are exceptions. *Talla* is an Ethiopian home-brewed beer which differs from the others in some respects. First, it is brewed with barley or wheat, hops, or spices. Secondly, it has a smokey flavor due to the addition of bread darkened by baking and use of a fermentation vessel which has been smoked by inversion over smoldering wood.

Sugary plant juices and saps and honey are the substrates for wine and spirit production. West African palm wines are produced by fermenting saps from oil palm trees (*E. guineense*) and from Raphia palm trees (*Raphia* spp.). In Zimbabwe sap from the ilala palm tree (*Hyphaene benguel-lensis*) is fermented into wine, while in Northwest Africa a wine called *lagmi* is produced from the sap of the date palm. Over-ripe bananas and plantains are also used for wine production in Southwestern Nigeria. For West African palm wines, the best known, fresh juice tapped into gourds contains up to 10% sugar and has a neutral pH. The fermentation occurs naturally and in 24 hours lowers the sugar content considerably, acidity develops, and alcohol builds up so that the wine becomes intoxicating.

Spirits are processed in Africa by distillation of fermented sugary substrates. Zimbabwean *uchema*, Nigerian *ogogoro*, and Ghanaian *ekpeteshi* are distilled from Zimbabwean ilala palm wine and from West African palm wines. Kenyan *chang'aa* and *Nigerian kai–kai* are distilled from fermented cane sugar juice. Generally the alcoholic content of African spirits ranges from 20 to 30%.

Food fermentations based on oilseed and leguminous seeds are sometimes called vegetable protein fermentations. West African *iru* or *dawadawa* (from locust bean), *ugba* (from oil bean), various *ogiris* (from melon, fluted pumpkin, *Telfaria occidentals*, castor bean and sesame), and Sudanese *sigda* (from sesame oilseed press cake) are fermented vegetable protein foods, and they are flavor enhancers.

Sudanese *kawal* produced by fermentations of leaves of a toxic legume *C. obtusifolia* and Nigerian *ule* are examples of African food products of leaf fermentation. *Kawal* and *ule* are flavoring materials for stews and other relishes.

Meat fermentation is uncommon in West Africa. However in Sudan virtually every part of a carcass including bones, hide, and gall bladder juice is fermented for food purposes. Fermented gall bladder juice is called *itaga*. It is prepared by adding some sorghum flour or grains to the juice which is then hung up to dry slowly. *Itaga* is pounded and used as a kind of spice for fatty meat dishes.

Fish is processed like meat, and fermentation is also uncommon. It appears to be a last resort for preserving a day's unsold catch. *Bonome* and *guedj* are fermented dried products of Ghana and Senegal, respectively. Fresh fish is allowed to undergo putrefactive fermentation in the open air for 20 hours. It is then eviscerated, soaked in salty sea water, and dried in the sun for 2–4 days with or without filleting. Sudan has a variety of fermented fish products including pastes and sauces prepared from fresh water Nile fish.

Many insects, especially gregarious and seasonal types, were traditionally acceptable as food in Africa. Examples are locusts, swarming winged reproductive termites, the large cricket (*Brachytrypes*), and caterpillars of the African silkworm (*Anaphe* spp.). Traditional processing of insects included cleaning and salting, then roasting or tying in parcels and boiling. Although the practice is now restricted to isolated areas of the continent it is noteworthy that in Zimbabwe the commercial product *madora*, also called mopane worms, consists of edible caterpillars. *Madora* is available in markets or in supermarkets. The caterpillars are generally squeezed after capture to press out the digestive fluid, then salted and preserved by sundrying.

The art of fermenting milk is widespread in Africa. Cattle and camels are important dairy animals, and milk fermentation products vary widely. For example, *jben* and *ayib* are Moroccan and Ethiopian cheeses, *nono* is a Nigerian yoghurt-like product, and Zimbabwe and Sudan also have fermented milk products. African milk fermentations occur naturally with attendant souring or coagulation, the milk having usually been collected into clay or earthenware pots or animal skin bags, gourds, or calabashes. They are often churned to produce butter. Moroccan *jben* is prepared by placing the coagulated milk (*raib*) in a cloth at room temperature and draining the whey. In Kenya various additives such as wood ash, animal blood, urine, and sometimes leafy vegetables may be added to preserve a fermented sour milk called *maziwa lala*.

Scientific Bases of Some Traditional Practices

African traditional food processing is a cultural activity which evolved independently from modern science and technology. Nevertheless valid scientific explanations can be offered for many food practices.

In many traditional fermentations, starters consisting of small amounts of previously fermented materials are introduced into new processes. Scientifically speaking, the starter contains a dense population of relevant microbes which accelerate the new process. Also, most fermentations are carried out in warm conditions, or fermentation time is prolonged in cold weather; these practices are consistent with scientific knowledge of beneficial and adverse effects of warmth and cold on the growth and activities of microbes.

Traditional food preservation with plant extracts is exemplified in the processing of Nigerian palm wine and *nono* with *nche* and *kuka*. Both preservatives inhibit spoilage microorganisms by means of chemicals: *nche* contains phenolics and alkaloids, and *kuka* contains tartarates. Again, the use of small amounts of urine, among other things, for improving the shelf life of Kenyan sour milk has been explained in the context of the lactoperoxidase system which inhibits Gram negative, catalase positive bacteria in milk. Traces of hydrogen peroxide and thiocyanate are known to be present in urine and these may exhibit antimicrobial effects together with lactoperoxidase which normally occurs in bovine milk.

Traditional food softening or flavoring with extracts from ashed monocot heads or husks is exemplified by the use of Sudanese *kambo* from sorghum, Nigerian *ngu* from palm oil husk, and Zimbabwean products from yellow nut grass (*Cyperus esculentus*) and maize cobs. Ashing concentrates inorganic elements, and high levels of potash in the leachates influence flavor and soften foods by hydrolysis.

African traditional food processing involves diverse food resources, equipment, practices, and products. Productivity is low, and final products often lack good hygienic quality, uniform composition, and predictable shelflives.

Research efforts to modernize food-processing systems have been intensified in African institutions. Production of Southern African opaque beers and *mahewu*, Nigerian *gari*, *dawadawa*, and *poundo* yam have become industrialized, and microbiologically safe processes have been developed for production of Moroccan and Ethiopian dairy products. These developments are encouraging and continuing research efforts will probably assist future generations in preserving Africa's rich traditional food heritage.

Food Technology in China

H. T. Huang

Agriculture started in China with the domestication of rice in the middle reaches of the Yangtze Valley at about 8000 BCE. Rice was followed by millet (at about 5000 BCE), wheat and barley (1500 BCE) and soybean (1000 BCE). In the classical period (1000–200 BCE), the principal grains of the realm were millet (both panicum and setaria), rice, wheat, barley, and soybean. Much ingenuity was expended by the Chinese to develop methods for processing these crops into attractive and nutritious articles of food and drink.

The kernels of both rice and millet are relatively soft. They were steamed to produce tender, palatable granules called *fan*. Pottery steamers of great antiquity (4000–5000 BCE) have been found in the neolithic sites in Banpo near Xian in the north, and at Hemudu near Hangzhou in the Yangzi delta. It was probably the use of steaming that fortuitously led to the discovery of a distinctive technology for the conversion of cereal grains into alcoholic drinks.

The Discovery of *Qu* (Chinese Ferment)

The fragrant, fluffy *fan* granules obtained by steaming rice grains were not only appetizing to humans, but also highly attractive as a medium for the growth of airborne fungi, such as those of the genus *Aspergillus*, *Rhizopus*, or *Mucor*. As these fungi proliferate they produce enzymes which hydrolyze the starch in the granules into fermentable sugars. Yeasts then multiply on the hydrolyzed granules and convert the sugars to alcohol. This mixed culture of fungi could be used to inoculate larger amounts of *fan* to produce an alcoholic drink, or dried and stored as a stable solid product known as *qu* (translated as *ferment*) for use in future fermentations. As we shall see, in addition to its role in alcoholic fermentations, *qu* ferment was the foundation upon which a rich array of fermented foods were later developed.

Alcoholic Drinks

The use of *qu* to make an alcoholic drink or wine called *jiu* was probably practiced in China as early as 2000 BCE. The technology for *qu* and *jiu* reached a mature level by the Han Dynasty (206 BCE–AD 220). Extensive recipes for preparing varieties of *qu* and *jiu* (as well as vinegar from it) are given in the *Qimin yaoshu* (Important Arts for the Peoples' Welfare), of AD 544. In making wine, *fan* (steamed millet or rice) was mixed with *qu* and the semisolid medium allowed to ferment until the substrate was depleted. The semisolid mash was then pressed and clarified to give the finished wine. One interesting innovation was the cumulative addition of fresh *fan* to the medium before the substrate was spent. This technique made it possible for skilled brewers in the sixth century to produce wines with alcoholic contents that were comparable or even superior to those of grape wines in the West.

During the Song Dynasty (AD 960–1280) the art of heating the wine before storage, later called pasteurization, was introduced; a red *qu* based on strains of *Monascus* sp. was developed, leading to the production of the so-called yellow or red wine. Although bronze stills were known as early as the Han, distilled spirit did not become commercial until after the Song dynasty. The fermented mash was placed directly on a grid in a boiler and the alcohol carried over by steam distillation. The result was a spirit with a strikingly rich flavor and an alcohol content of greater than 50%.

Malt Sugar

Sprouted rice or millet, *nie*, was of equal antiquity as *qu* in China and it has been suggested that some of the earliest wines might have been made with *nie* as the saccharifying agent. But soon *qu* displaced *nie*, and the *nie*-based fermentation died out. *Nie* from wheat or barley, however, lived on as the agent for converting steamed millet or rice into malt sugar, the most important sweetener in ancient China. Although its importance declined somewhat when the refining of sugar from sugar canes was introduced from India in the Tang Dynasty (AD 618–905) malt sugar continued to be a popular treat in the Chinese diet until the present day.

Products from Wheat Flour

Since the kernels of wheat are hard, they cannot readily be made palatable by boiling and steaming. Thus, wheat was less popular than millet or rice in ancient China. However, the situation changed during the Han when mills for grinding wheat into flour or *mian* became widely available. The dough made from *mian* could be processed into a dazzling variety of delicious pastas, cakes and breads (including leavened breads). Most of these products were cooked by steaming or boiling. As a result, wheat flour soon became the staple food in the North while rice remained the staple food in the South.

Probably the best known Chinese food processed from wheat flour is the filamentous noodle, *mian tiao*, which was first made in the second century AD. There is, however, no evidence that Marco Polo ever brought filamentous noodles from China to Italy. Filamentous pasta was already known in Italy before Marco Polo was born. It appears likely that the concept of filamentous noodles had traveled from China to Italy by transfusion along the Silk Road in the tenth to twelfth centuries.

Another important product processed from flour is wheat gluten *mian jin*, an valuable source of protein for vegetarians. It is obtained by the continuous washing of wheat dough with water. The phenomenon was first described in the *Qimin yaoshu* (AD 544), but gluten did not become a popular component of Chinese foods until the Song.

Soybean Processing

Although soybean is an excellent source of protein, it is hard to cook and difficult to digest. Three methods have been developed to process soybeans into wholesome, attractive, and nutritious products. The first is simply to allow the beans to sprout in the dark. Soybean sprouts were known before the Han as a medicament; they did not become popular as food until the Song. Since then sprouts from both soybean and mung bean have remained standard fare in the Chinese diet.

The second method is to process the beans into *doufu* (bean curd). The steps involved are: (1) soaking the beans in water overnight, (2) grinding the beans to a puree, (3) filtering the puree through cloth, (4) heating the milk to near boiling, (5) adding a coagulant, such as bittern, to the cooled milk, and (6) pressing the soft curd in a wooden frame. The procedure is depicted in a mural in a late Han tomb (second century AD), although the product did not become commercialized until the late Tang. Since then *doufu* has been the most important vegetarian source of protein in the Chinese food system. Soymilk, however, was not accepted as a food until the eighteenth century.

The third method is to ferment the cooked beans with *qu* in a high salt medium to give a triad of relishes and condiments; they are *shi*, fermented bean relish, *jiang*, fermented bean paste, and *jiang you*, soy sauce, probably the best known processed soybean product in the West. When cooked soybeans were incubated with *qu* and salt, the product was *shi*. When they were incubated with *qu*, wheat flour and salt, the product was *jiang*. Both *shi* and *jiang* were already made on a large scale in early Han. Recipes for their preparation can be found in the *Qimin Yaoshu*. Soy sauce was simply the liquid drained from *shi* or *jiang*. It was known during the late Han, but the name *jiang you* did not come into common usage until the Song.

Much of this distinctive food technology was transmitted to Japan during the Tang and later dynasties. Thus, *qu* and *jiu* are known as *koji* and saké in Japan; *shi*, *jiang* and *jiang you* evolve into *natto*, *miso* and *shoyu*; while *doufu* remains as *tofu*. All these products have become integral parts of the food system in Japan, Korea, and Vietnam. They are now gaining acceptance in the West.

However, the best known dietary product from China is actually a drink. Tea was first prepared by steaming, crushing, and drying the leaves of *Camellia sinensis* during the Han. It became widely popular during the Tang, and was disseminated to the West in the seventeenth century. Tea and coffee are now the two major beverages consumed throughout the world.

Food Technology in Latin America

Judith Vidal

About 5000 years BCE, native populations in the Caribbean and Latin America developed food technologies which enabled them to exploit their natural biota and become settled. By the time of the Columbian encounter, Indians had evolved unique agricultural techniques suitable for efficient food production in various terrains and climates. Their indigenous staples were cassava (*Manihot esculenta*), maize (*Zea mays*), potatoes (*Solanum tuberosum*), and yams (*Ipomea batatas*), beans, and squash supplemented by fruits and vegetables, fish, turkey, deer, dogmeat, and guinea-pigs, as well as assorted beverages and flavorants.

Food technology began with soil preparation and with the selection of seeds, roots, tubers, or cuttings. The ground was cleared through slash-and-burn and girdling, which is removing a ring of tree bark. Farmers then worked the earth into numerous knee-high mounds several feet in diameter (*montones*), collectively called *conucos*, among the stumps in irregularly shaped fields, or *milpas*, fertilized by ashes and decaying vegetation. These mounds produced less water runoff, and hence less erosion, than traditional European fields plowed in rows.

In the Caribbean, Middle America, and South America, *conucos* were planted with bitter cassava, with a vegetable triad such as maize–beans–squash, or with potatoes in the Andean highlands. In the lake regions of Mexico, floating garden islets (*chinampas*) formed of dense intertwining roots covered with soil and plants could be paddled over the water. In the Andes, irrigated stone-walled terraces (*andenes*) allowed farming steep grades in narrow strips at higher altitudes dominated by llamas, quinoa, and potatoes, descending in ever broadening tiers to cacao, cacti, and tropical fruits at lower levels, each with its own biota, creating a diverse diet in a small vertical space. Where the parched soil of valleys was unyielding, natives removed the earth's surface in expanses as large as an acre to form *hoyas* (pits) which reached natural moisture and permitted cultivation.

Indians learned to cultivate strains of indigenous flora by taking cuttings, by planting tubers, or by carefully selecting seeds which they planted individually in small holes poked by a planting stick called a *macana* in the Caribbean and a *taclla* in the Andes. These methods produced more uniform quality than European broadcast seeding and resulted in higher caloric production per acre than Old World counterparts of wheat, rice, millet, and barley.

The bitter cassava (also known as *yuca brava*, manioc, mandioca, tapioca, and *farinha*) roots from 2 to 6 in. in diameter were dug up, peeled, and grated. The wet pulp was then stuffed into long mesh baskets and hung from a beam which allowed for twisting to express the poisonous prussic acid. When the toxic juice was removed, the pulp was forced through basket sieves or pounded, and the resulting flour was spread in flat three-foot cakes on hot stone grills or dried and stored for later use. The poisonous liquid was safe to drink after boiling. From Colombia southward down the Pacific coast of South America, a nontoxic sweet cassava was similarly processed and often made into preserves.

The true staff of life for most of Latin America was maize. This Indian corn occurred in hundreds of varieties and colors. Indigenous cultures hybridized the silky tassels by hand to breed the most desired traits. Some kernels were so hard they had to be soaked or chewed before boiling gruels. Women pounded grilled kernels with stones to produce a flour meal for tortillas or other dishes. Dried grain was also stored indefinitely in elevated, aerated storage silos.

Indians of the upper Andes invented freeze-dried potatoes by alternately exposing the tubers to night frost and sunshine. Within a few days all the water was removed, leaving a potato preserve called *chuñu* which could be further whitened or reconstituted by steeping in water. Lightweight and easily transported, the *chuñu* could be preserved indefinitely like cassava or maize. There were over 3,000 types of potatoes, sweet potatoes, ocas, and other tubers. Bean and seed pulses were also important foods throughout Latin America. They too were dried for preservation if not cooked immediately.

In addition to drying, there were several other technologies for preserving foods. These included salting, pickling, fermenting, toasting, and ensiling. Fish was salted as was meat cut into strips. Brine solutions and lime mixtures were also used. Vegetables and fruits were pickled in a variety of herbal vinaigrettes. Fruit and vegetable juices were fermented and distilled into alcoholic beverages which were also used as preserving agents.

Among native beverages, cacao (*Theobroma cacaoyer*) was the most lucrative exchange commodity in New Spain and parts of Peru. Cacao trees were grown by Indians in orchards shaded by large "mother" trees. When the large red pods ripened, they were picked, and hundreds of bitter-tasting seeds were removed by chewing the luscious fruit. The sun-dried seeds were used as money or ground and roasted for a bitter brew restricted to nobles and ceremonial rites. Under Spanish colonization, the chocolate beverage gained widespread popularity in Mesoamerica.

In the Pampas, another stimulating beverage came from a native tea known as *maté*, steeped in boiling water like East Indian varieties. When coffee was introduced to tropical Latin America, it was prepared much like cacao and was widely consumed. All three of these nonalcoholic beverages grew in popularity with the increasing availability of sugar and vanilla which replaced pepper as the preferred seasoning.

In addition to flavor enhancement, many herbs and spices were used to preserve foods and to add medicinal benefits. Seaweed supplemented natural salt sources in Andean diets to protect natives from goiter. Tropical fruits added vitamin C. Cinnamon, cloves, and capsicum peppers preserved as well as flavored foods. Sarsaparilla was a refreshing beverage which soothed gastrointestinal ailments. Another vegetable product, *guayacán* treated syphyllis while *cuasi*, a valuable insecticide, also eased fever symptoms. The most important treatment for malaria came from quinine or *chinchona* which remains a viable cure as well as a popular tonic water.

Alcoholic beverages were consumed in moderation before conquest. In Mexico, the agave or maguey was fermented and distilled into pulque, mezeal, and tequila. Maize was fermented into a beer-like beverage called *chicha* which was popular throughout Middle America and the Andes. *Chicha* could also be fermented from a variety of fruits. Other alcoholic beverages came from fermentation of potatoes, cassava, and tropical fruits such as pineapples and bananas. These were sometimes mixed into brandy called *aguardiente*. None of these beverages became popular in Europe, but rum – fermented from cane sugar – became commercially successful throughout North America and Europe.

Prior to European contact, indigenous populations had few meat sources and no beasts of burden other than the llama and the dog. With the introduction of horses, cattle, oxen, sheep, swine, goats, mules, and donkeys, they gained transportation, meat, and power to plow, haul, and operate mills. They also received protein-rich meat and dairy supplements to their diets. By-products from domesticated and feral herds included fibers, leather, tallow, bones, and horns.

Among the food cultigens brought to the New World, the grape–grain–olive culture remained heavily European. Sugarcane and coffee, however, dominated enormous regions where native labor consumed the stimulants while working plantations. Both commodities were labor-intensive requiring hand planting and harvesting. Sugar works (*trapiches* or *engenhos*) used human, animal, or water power for the crushing mills which released the sugary syrup. Slaves operated a train of boiling vats to purify and clarify the liquid for evaporation. The resulting muscovado sugar was 96% pure and was packaged in cones or loaves for shipment to European refineries. Hand-picked coffee beans were spread on patios to dry before roasting and shipping.

Many of the technologies used by indigenous populations are practiced today throughout rural areas of Latin America. Scientists are studying their techniques and lore for insights into environmental protection, expanded food production, and medicinal applications. Global dietary diversity has been accompanied by language enrichment as a result of food exchange. As a result of Latin American food technology, words such as barbecue, olla, mezquite, cassava, tapioca, quinine, banana, palm, tomato, etc. have joined the alimentary menu.

The Indians practiced ecological efficiency and perspicacity unrivaled by the colonial powers who imposed a wheat–wine–oil–meat agriculture in lands more suited to manioc, maize, and potatoes. None the less, dietary diversity has been enhanced throughout the world as a result of native Latin American technologies which first unlocked the secrets of preparing and preserving exotic New World foods which have become staples for subsistence.

Food Technology in the Pacific Islands

Richard Beyer

The range, variety and sophistication of food preserving and commercialisation activities throughout the Pacific Island Nations (PINs) are as varied as the climate, agricultural framework and culture. The techniques so necessary for basic survival have been the foundation of food preservation but the practises have been refined and expanded since European arrival. Countries such as Fiji and the Marshall Islands are now home to highly sophisticated food processing operations sponsored by multinational companies that have been attracted by tax incentives and relatively low wage rates. The ethos of food processing and food exploitation has infiltrated wider communities as the international food standards defined by Codex Alimentarius have been adopted by *inter alia* Vanuatu, Samoa, Tonga, the Cook Islands and Fiji. Countries such as Kiribati and the Federated States of Micronesia remain at the other end of the spectrum but the importance of maintaining food quality has been strengthened by the mandatory conformance to the hazard analysis and critical control points (HACCP) system of quality maintenance for economically important fish exports to the US and EU markets (Beyer 2000, 2003a,b,c). The welfare of the people of the Pacific nations is nevertheless highly dependent on subsistence farming and traditional preserving techniques (Laban and Swain 1999) particularly of fish and starchy staples – cassava, taro, plantain, yam, breadfruit and sweet potato (Bradbury 1987).

Traditional Preserving Techniques

Historically, processing has been confined to practises that will preserve foods to reduce waste and to extend availability, particularly for foods with very short seasons (Greenwell 1947; Parker 1967; Root Crops Development Newsletter 1982; Kwatia 1986a,b, 1988; Atkinson 1990; Kordylas 1991; Root Crops Processing 1993; Beyer 2001). Traditionally, foods have been preserved using techniques that exploit environmental factors (Atchley and Cox 1985; Atkinson 1990). Sun drying has been used extensively as a means of extending shelf life because of the high ambient temperatures prevalent in the tropics. The process is benign – fish, occasionally pork, vegetables and fruits are merely sliced and laid on racks to dry. If prevailing conditions permit, the foods reach a final moisture content that will inhibit mould growth and the products are edible although not always appetising. In many cases vegetables turn brown, mould may grow before the drying process is completed – or occasionally later if the dried food reabsorbs water as a result of increases in relative humidity during storage. Other products may bleach and become tough.

A number of readily available chemicals have been used to stabilise foods. Salt obtained by sun-evaporation of seawater has been smeared onto root crops to prevent bacterial and mould growth. In other cases, the vegetables are dipped in seawater prior to drying and the salt concentrates during the drying process. Sun-dried lime segments and evaporated lime juice have been used to increase the shelf lives of some root crops and bananas – the vitamin C and the low pH (citric acid) both act as preservatives. Dusting with wood fire ash has been used to prolong the shelf life of breadfruit and yams. In this case, the high pH is hostile to moulds and other bacteria.

Many of these traditional preserving techniques continue to be appropriate for the preservation of root crops in the rural areas. Political upheaval in countries throughout the region has retarded economic progress, and economic empowerment has proceeded at rates below aspirations. Traditional food preservation techniques remain relevant but the end products enjoy declining popularity – particularly among the young. Some of these traditional products continue to appeal to older members of the community and to older expatriates now living in Australia, New Zealand, Canada and the USA. As a natural evolution, there are isolated instances where those products have formed the basis of export industries. Where markets have persisted for traditionally preserved foods, processes have been standardised with conformity in manufacturing techniques.

Nutritional surveys around the region however indicate that the consumption of traditional foods is decreasing. Such industries as the garment industry and tourism have provided increasing employment for women. As their time for food preparation has become eroded, they have become less tolerant of traditional foods such as yams, cassava and taro in favour of more convenient (often cheaper and lighter) alternatives such as rice and flavoured noodles (FNFC 1997; Hodge et al. 1997; Food Security: The New Millennium 1999; Paterson and Crossland 1999; FNFC 2000).

Travel, tourism urban drift television and other lifestyle changes have transformed food choices in the PINs. Although much of the food is imported, local entrepreneurs have copied and modified a number of these imports and form the basis of a wide range of small scale processing operations (Beyer 2001).

Conventional Preserving Techniques

Dehydrated Products

The cost of removing moisture from foods rises exponentially as the moisture content drops (Brennan 1994). Thus it is in the processors' interest to remove only that proportion of water that impinges on the keeping quality of the finished product. Not only are processing costs reduced to a minimum but also the product retains some water, which adds to the weight. Unfortunately, intermediate moisture foods (a_w values between 0.35 and 0.6) deteriorate unless they are protected with preservatives, humectants or antioxidants. Only at very low moisture contents (a_w values < 0.3) is deterioration kept to a minimum. The exceptions are non-hydrolytic reactions, which usually take place in fats and oils. Rancidity will continue in low moisture foods and may occur even faster than in moist foods because thereactants are very concentrated by the lack of moisture. It is important therefore that low moisture foods are protected with antioxidants. Antioxidants such as butylated-hydroxy-toluene (BHT) and butylated-hydroxy-anisole (BHA) and even ascorbic acid can be used.

Recent innovations in dehydration and drying are directed towards reducing the relative humidity of the air used for drying by removing the water vapour rather increasing its temperature. So-called heat pump dryers pass heated air, which has previously been used for drying, over cooling coils. The water vapour in the drying air condenses on the cooling coils and thus the relative humidity is reduced. The same air is used repeatedly on this drying cycle. The low temperatures used in this technique cause less oxidative damage and food dried by this means is usually much higher quality. The heat pump dryers are used in some PINs for products where ultimate retail price advantage justifies the capital expenditure and the running costs, which in turn depends on the cost of electricity.

Throughout the PINs some success has been achieved in early trials using secondary air dryers. Secondary air dryers rely on drying an intermediary component – commonly coconut husk using wood-fired drying kilns. Ambient air is then circulated around the pre-dried coconut husk, which removes the water vapour. This reduces relative humidity of the air that is then passed over the food. The food – particularly in the latter stages of drying – is not subjected to high temperatures and therefore suffers less deterioration.

Modern processing techniques have been applied to a number of products including dried cassava dalo, fruit slices and some thinly sliced fish. The sliced product is immersed in a solution containing 150 ppm of sodium metabisulphite (or 200 ppm ascorbic acid). For vegetables they use 1–3% w/v of sodium chloride (soy sauce is used sometimes especially with fish). The slices are then dried on racks in a heat pump drier. The maximum outlet temperature of the drying air is 55°C, which is sufficiently low to prevent browning due to caramellisation of the simple sugars. The relative humidity of the outlet air is 55%, which gives a value for water activity of a_w of 0.55. Some sulphite is lost during the later stages of drying as sulphur dioxide.

These products are then shelf stable and do not brown on storage. Residual polyphenolase activity is inhibited by sulphite or ascorbic acid.

Dried granules from the starchy staples have also been developed as the raw material for extrusion. Extrusion technology has been applied to corn and rice starch and combinations of them. During extrusion, granules are forced at high pressure through a heated die. At the very high temperatures and pressures, the starch molecules align in the direction of shear and superheated water boils off rapidly as the pressure on the mass is released. This opens out the matrix to give the familiar honeycomb texture, which is a characteristic of puffed snack foods. Cassava granules in particular perform very well using this technology and preliminary trials have indicated that cassava is a likely candidate for future research and development (R&D) programmes.

Canning

Dalo, cassava, breadfruit and some local vegetables (e.g. *duruka*) and fruits have been canned and exported for some 12 years. The very high temperatures used in canning are responsible for significant damage to the texture and flavour of fruits and vegetables. The products have very soft textures and the heating regimen results in warmed over flavours characteristics of Amadori compounds. These quality characteristics are thus significantly different from fresh items. The market is somewhat resistant to such quality features and sales are consistent but small. Similar products canned in coconut milk are marginally better and sales figures are higher but coconut milk supplies are inconsistent.

Fruit and vegetables processed in retortable pouches (polypropylene/aluminium/foil/nylon/polyethylene laminate) have better quality characteristics because the heat penetrates to the centre of the pouch faster, but the technology is not readily available in the Pacific region (overpressure retort).

Conventionally canned fish (tuna) is the largest single item of canned food produced and exported from the Pacific region with very large factories in Fiji, American Samoa and the Marshall Islands and smaller factories located in Tonga and Manu Samoa.

An alternative technique (Beyer 1998) is a multiple pasteurisation technique. Foods are packed in polyethylene/nylon bags and vacuum-sealed in such a layout that the products are not touching and that heat can reach every food surface. They are then immersed in boiling water for sufficient time for the heat to penetrate through the bags so that the surfaces of the foods reach at least 80°C for 15 s. The pouches are then cooled using cold water to prevent over cooking.

In low acid foods, this is sufficient to destroy the vegetative cells of bacteria but not the spores of thermophilic organisms. However the heat shock is sufficient to encourage germination of the spores. These are then destroyed by pasteurising again 24 h later by immersion in the boiling water bath for enough time for the temperature at the surface of the vegetable to reach 80°C for 15 s. As an extra insurance measure, the package is heated in the same way on a third day. This is sufficient to destroy surface bacteria. With carefully handled vegetables, the deep tissue will be sterile. Thus this technique should result in pack sterility. In the event that the packs are still not sterile – which would be manifest by blowing – the product can be reheated for a fourth time since the heat penetrates to the same depth each time and damage to the product is still confined to the outer surface. The technique means that relatively little heat is applied to the surface of the vegetable and the damaging effects of the heat penetrate only a short distance into the tissue. The vegetable has the appearance texture and taste of fresh vegetables.

Freezing

In the short period of 30 months preceding May 2000, an export industry in free-flow frozen root crops was established, which peaked in February of 2000. At its maximum volume, 66 tonnes/month of frozen cassava were being exported to Australia (Beyer 2000). Much smaller volumes were destined for New Zealand. Trial shipments were also sent to Japan, but large-scale exports were not possible because of cyanide levels that exceed Japanese standards. An unexpected demand has arisen for frozen root crops however, and production level is well below market demand.

Fry Drying

There is now a plethora of small fried snack root crop and plantain producers throughout the PINs. Products are becoming commonplace and some are emerging as export products. Entrepreneurs are encouraged to use these products as a basis for increasing market depth and width through product development programmes described as more appropriate technology and products. By mixing into dough there are many opportunities to:

- Extend using other ingredients
- Improve acceptability by adding flavours
- Improve nutritional value by adding other ingredients such as carrot and tomato (vitamin A)
- Add improvers to extend shelf life
- Produce more consistent products

The cooking medium can have a significant bearing on the acceptability of the final product. Commonly soya bean oil is used, since it is the cheapest of the frying oils. The viscosity of oils is temperature-dependent. Oil temperature should be high as the product is removed. At high temperature, the oil is mobile and drains from the product easily. At low temperature, the oil adheres to the product, thereby increasing costs (oil is commonly very expensive in the PINs). Fried snack foods with high oil contents are more prone to rancidity during storage, they are nutritionally less desirable and the mouth-feel is poor.

Oils used for cooking should therefore be heated to temperatures a little below the smoke point and relatively small quantities of product added to it, to prevent excessive cooling. Used oil should never be topped up with fresh oil since rancidity is autocatalytic – the products of rancidity catalyse the onset of rancidity. Thus used oil should be stored and allowed to settle. It may be washed with water and the (more dense) water layer drained. It can then be shaken with dried calcium chloride that can be subsequently removed from the oil by filtering (and re-dried for repeated use). The used oil pooled in such a way can be used for several processes after it would normally have been discarded.

Rancidity is accelerated by ultraviolet light, some divalent metals such copper, (cast) iron and zinc and oxygen. Product keeping quality can thus be enhanced by high quality processing equipment fabricated from stainless steel and by using packaging material (usually incorporating foil) which is opaque to ultraviolet light and which prevents the transmission of oxygen. Vacuum packing improves keeping quality even further.

An antioxidant – an agent that captures free radicals – will also protect the product. Oils are frequently sold with antioxidant added. The antioxidants of choice are BHA or BHT. Unfortunately, these antioxidants are volatile and are lost after only two or three frying cycles so that they do not carry over into the final product. This assists the oil manufacturer because oil must be replaced more frequently, but the snack food is not protected to the same degree. A preferred antioxidant is tertiary butyl-hydoxy-quinone (TBHQ), which is not volatile and which carries over to the product for longer period. This affords antioxidant protection after the product is packaged and will assist in prolonging shelf life.

Current Food Activity

Commercial factors have been responsible for shaping the current status of food technology in the Pacific region. Unlike more developed regions of the world however, the strong cultural foundations have enriched the industry with the modernisation of traditional food preserving methods. Liberalisation of migration policies has resulted in alarming population movements from the island nations to Australia, New Zealand and the USA, however these immigrants have become nuclei markets for exported traditional foods. More than that, they have become ambassadors in the role of introducing new foods to their newfound fellow consumers.

Hence the region has a spectrum of food-related activity not only in the degree of sophistication of the technology but also in the demands of the markets.

Forestry in India

Deepa Pande

One of the earliest civilizations of the Indian subcontinent was that of the Indus Valley (third or fourth millennium BCE). It was here that cedar (*Cedrus deodara*) and rosewood (*Dalbergia latifolia*) used for coffins was found. A wooden mortar of ber (*Zizyphus mauritiana*) for pounding grain and charred timber of *Acacia* spp., *Albizzia* spp., teak (*Tectona grandis*), haldu (*Adina cardifolia*), and *Soyamida febrifuge* were also found. This shows that Neolithic people not only made extensive use of wood, but also understood its particular characteristics for different purposes. This concept today is known as forest utilization.

Evidence of tree worship during the Indus Valley civilization is exhibited by various seals of the Harappan culture which depict the pipal (*Ficus*) and weeping willow (*Salix*) trees. Trees were an essential and integral part of the life support system and considered existing agencies of the creator of God.

Just as forests played an important part in Vedic India, tree worship was also practiced by the Aryans. Because of the human dependence on trees, they were venerated and protected by religious injunctions; their planting was encouraged by a promise of eternal bliss in future life. *Ṛgv̄eḍa* and *Aṭharv̄aveḍa*, basic texts of the Vedic period, contain several hymns praising and endowing trees, plants, and vegetation with various divine qualities, highlighting their medicinal significance, and enunciating the policy of conservation or sustainable management. Various *Upaniṣads*, a later group of philosophical treatises that explain the theology of Hinduism, like *Bṛhaḍāruṇyaka*, *Chāndogya*, *Chulikā*, and *Muṇḍakopniṣaḍa*, conclude that trees had life akin to human life. *Maṭsyapurāṇa* and *Varāhapurāṇa* describe the benevolence of trees along with the rituals of tree planting. *Skanḍapurāṇa* contains a long list of trees which should not be cut except for the purpose of *yajnas* (holy rituals). Whereas planting of trees led to heavenly comforts (*Agnipurāṇa*) indiscreet felling of trees meant torture in hell.

Vedas also contain valuable information about various species of birds. In *Ṛgv̄eḍa* for instance there is a mention of *Garuda* (eagle), *Mayūra* (pea fowl) along with various Himalayan pheasants, partridges, and other species of birds. Surprisingly *Ṛgv̄eḍa* also mentions not only anatomical details of some common birds, but also details about their staple food. For example *Vartika* (partridges) are said to have well-developed bills, legs, and rounded wings; their food consisted of grain, grass, weed, seed, tender shoots, insects, and even white ants. These kindled the sparks of wildlife management during the later period of civilization.

Great saints and sages who understood these texts, passed on their knowledge and wisdom to their disciples. Such education was given in the *Gurukuls* (schools) which were located in the forests. The students lived in the forests and continued their studies. Thus a sense of tolerance and coexistence with various forms of plant and animal life was infused in early childhood. This *Aranya* (forest) culture provided early exposure to nature study and ecology, as well as the policy of development without destruction in current parlance. Forest and environment consciousness was thus ingrained into the educational system from the very onset.

Even epics and religious texts written later on describe the protective role of trees and their unlimited usefulness. *Rāmāyaṇa* and *Mahābhārața* describe the rich biodiversity and multiplicity of flora and fauna. In *Bhagwaṭgīṭa* Lord Krishna compared himself to the *Aśvaṭha* (ficus) tree in order to emphasize the importance of trees.

Other religions of that time also mentioned the importance of forests and forestry. According to Lord Buddha it was the obligation of every good Buddhist to plant and nurture at least one tree every 5 years.

Moving along chronologically we find that forest management practices were well documented during the reign of Chandra Gupta Maurya (321–296 BCE). Reliable historical documents, such as the *Indika* of the Greek ambassador Magasthenese, the *Arṭhaśāsṭra* of Kautilya and the *Mudrārākśasa* of Viśākhadaṭṭa vividly depict various aspects of forestry and wildlife. Kautilya's *Arṭhaśāsṭra*, recognized as the pioneer work in economics in India, indicates the existence of a regular Forest Department headed by *Kūpyādhakśa* with definite duties and responsibilities for various officers of the department. Some of the important duties of *Kūpyādhakśa* were to increase the productivity of forests, classification, price fixation, and disposal of various types of forest produce, raising block plantations of important species (e.g., sandalwood), pasture development in saline–alkaline waste lands, and joint management of forests with people dependent on forests.

Forests were legally classified into three main classes: reserved forests, forests donated to eminent Brahmans, and forests for public use. They were classified into six categories on the basis of crown density, luxuriance, growth, and origin. Planted forests were called *Upvana*.

Forest and game laws were stringent and draconian, containing corporal punishment. The death sentence was envisaged for poaching of elephants. Awards were provided to a person who collected elephant tusks from dead elephants and deposited them with government officials. Kautilya's treatise also dealt at great length not only with the use of various trees and shrubs, but also with the specific use of various parts. For example it indicated that flowers of *Palāś*, *Kusuma*, and saffron are used as dyes, *Munja* and *Love* grass are used for making ropes, and fruits of *Aonla*, *Harara*, and *Bahera* are used as medicines.

Emperor Aśoka adopted and improved these practices. Plantation of fruit-bearing shade trees for the benefit of travelers and common people was started on an ambitious scale. Aśoka was the founder of *Abhyāranya*, the *sanctum sanctorum* of wildlife, now known as National Parks and sanctuaries. Aśoka's edicts at Sarnath Varanasi bear ample testimony to the above.

Forestry flourished during the Gupta period (320–800). *Ṣukranīti*, a well-known work of that time, throws light on the improvements in forest management practices. Seeds of "Social Forestry" were sown during this era. *Ṣukranīti* dwells on the concept of village forests, choice of species, afforestation and maintenance techniques, fertilization procedures, irrigation schedules, and measures to increase flowering and fruiting in trees. Names of various multipurpose trees such as *Kadamba*, *Sīśama*, *Peepal*, *Mango*, *Nīm*, *Coconut*, and *Imlī* are listed in this policy document for planting near villages. Incidentally many of these are also listed in the latest ICRAF (International Council for Research in Agroforestry, in Kenya) booklets. This shows the worth of these ancient publications.

It is thus clear that in ancient India trees were the best friend of people in a hostile environment. They were held sacred, worshipped, and studied in great detail for service to humanity. Forestry practices evolved gradually, in a scientific and rational manner, and are important even today, although in the modern parlance new names have been coined for them.

Forestry in Japan

Conrad Totman

Forestry may be defined as "the science and art of forming, caring for, or cultivating forests." Another definition is "the science, the art and practice of managing and using for human benefit the natural resources that occur on and in association with forest lands."[1] The former, dictionary definition, leaves unidentified the interests to be served by this "science or art." The latter, autecological definition, with its explicitly human beneficiary, was propounded by the Society of American Foresters around 1970. It fitted nicely the Japanese approach to woodland for centuries down to about 1980. Since then, however, socioeconomic changes have undermined the established rationale of forest policy, permitting advocates of environmental protection to call for a richer synecological understanding of forestry's proper purpose.

Factors Shaping Japanese Forestry

In Japan, as elsewhere, forestry has been profoundly shaped by its geographical and social contexts.

By global standards the Japanese archipelago is extraordinarily youthful and mountainous. Mostly formed in the past 15 million years, it is characterized by elaborate dendritic systems of acutely upthrust ridges that are covered with thin, immature soils and incised by narrow valleys down which course fast-running streams that eventually debouch onto slender alluvial plains, most of which front the surrounding seas.

Because of the way continental and oceanic weather patterns interact in the northwestern Pacific region, Japan experiences pronounced seasonal differences and a relatively moist climate during most of the year. And its length from north to south assures it substantial variation in mean temperatures, which range from subtropical in the far south to subarctic in the far north. In consequence woodland vegetation is lush everywhere. But it varies from a thin strip of evergreen broadleaf forest along the southern littoral through woodlands of mixed deciduous broadleaf and evergreen firs (which cover most of the realm) to coniferous boreal forest in far northern regions and at high elevations.

Before the introduction of fully fledged horticultural practices some 2,500 years ago, these richly forested islands supported a very modest population of foragers. Once agriculture was introduced, however, the population grew rapidly, and over the course of two millennia cultivators opened much of the archipelago's lowland to cultivation or other human use. In the process, forest was eliminated from most lowlands and lower slopes of hilly terrain, an outcome reflected in the language. Forest of any substantial dimension is called *sanrin*, literally "mountain-forest," while the more basic terms for "woods," *mori* and *hayashi*, which lack reference to mountains, are ordinarily used when talking about small residual groves of trees or parcels of brushwood that have chanced to survive on or near lowland.

Nevertheless, because Japan is so extensively and acutely mountainous, even today about 70% of it still sustains woodland. Part of this is plantation stands and part mixed, natural growth, some subject to management, some not.

Within this physical context, forestry in Japan has moved, as it has elsewhere, through two major phases, from a long era of exploitation forestry to a shorter era of regenerative forestry. The latter runs from the seventeenth century to the present but can be examined in terms of preindustrial and industrial-age segments.

Exploitation Forestry

For millennia residents of the islands utilized their woodland primarily for fuel and food. With the development of agriculture, however, food came more and more from arable land, and the receding forest provided, instead, water and fertilizer materials to grow the food, fodder for beasts of burden, construction timber for buildings and gadgetry, and fuel for cooking and various industrial tasks, notably metallurgy and kiln work.

During the seventh and eighth centuries CE, political consolidation gave Japan grand capital cities that housed a ruling elite of unprecedented power and cultural pretension. They adopted new architectural styles and construction techniques that led to a major increase in the consumption of both timber and fuel wood (see Timber-Handling Technology in Japan). These developments led in central Japan to overcutting that created serious problems – flooding and drought, forest fire, wood and fuel shortages, and intensified competition for control of surviving woodland. On the other hand, because the Japanese did not maintain herds of goats and sheep for milk, meat, or wool, Japan's landscape was spared the devastation they have wrought elsewhere.

In the outcome, although the problems caused by overcutting did gradually become more widespread as Japan's population grew and towns proliferated, it was not until the seventeenth century that broadly effective patterns of remediation began to be devised and

[1] The former definition appears in *Webster's New Collegiate Dictionary* (Springfield, Massachusetts: G. & C. Merriam Co., 1956); the latter in Grant W. Sharpe, et al. *Introduction to Forestry.* 4th ed. New York: McGraw Hill, 1976. 187, quoting the Society of American Foresters.

applied. They emerged then because a sharp increase in wood cutting and another surge in land clearance were having severe downstream consequences during an era when society was well enough organized so that purposeful woodland regulation and management could not only be needed or advocated, but in fact be devised and implemented in a sustained manner.

Regenerative Forestry

Regenerative forestry can be examined in diverse ways. One approach discusses "negative" policies designed to prevent or contain unauthorized exploitation and "positive" policies designed to foster more, better, or different types of forest performance. An overlapping formulation speaks of "protection forestry," which is designed to protect the woodland itself and other areas and affairs vulnerable to damage caused by unwise forest use, and "production forestry," designed to enhance the quality or quantity of woodland yield.

In terms of the former approach, local instances of negative forest policy date from the eighth century, when rulers tried to restrict cutting in select locations. Negative policy became visible again during the 1300s–1400s, when some villages in central Japan began regulating the use of their communal woodland, and during the 1500s, when some regional barons (*daimyō*) tried to protect valued groves and stands from unauthorized harvest.

It was from the 1660s onward, however, that the hegemonial Tokugawa shogunal regime (ruled 1600–1868), the 250-odd daimyo, and villages all across the realm began drafting and enforcing, in woodland within their jurisdiction, regulations to control who might do what, where, when, how, with what tools, and how much yield. Those initiatives developed into a wondrously variegated system of multiple-use rights that allowed diverse people to extract diverse goods from designated parcels of woodland throughout Japan.

Regarding timber specifically – which was of particular concern to the rulers – shogun and daimyo not only regulated the harvest in forests they administered as domanial land, but also began stipulating that no good-quality tree of desirable species was to be injured or felled, save with official permission. And that prohibition applied to all formal categories of land, whether of village, fane, or household, even to include trees standing on a villager's house lot.

To enforce their proliferating rules, shogun, daimyo, and village headmen deployed forest wardens, guards, and patrols to catch rule-breakers. They established fines and other punishments, and they developed and applied adjudication procedures for handling those charged with violation of forest law.

These negative policies, together with vigorous programs of riparian management and repair, did gradually achieve major goals of protection forestry, reducing appreciably the extent of erosion and downstream silting, flooding, and damage. But in terms of production forestry, the rate of harvesting on accessible hillsides was so great that negative policies alone failed to sustain fuel, fodder, fertilizer, and timber supplies at the level of demand. And on numerous lower hillsides, especially those facing the agricultural lowlands of central Japan, overuse gradually destroyed vegetation, creating more and more barren hills and ridges known as *hageyama* or "bald mountains."

Under these circumstances positive policies designed to promote plantation stands, nurture mixed forests, and revitalize *hageyama* began to be advocated by government officials, village leaders, and Confucian scholars of the "practical learning" (*jitsugaku*) orientation. During the eighteenth century, moreover, land-use arrangements were gradually modified, creating forms of rental forestry that assured users long-term control of select parcels and their yield. These modifications encouraged landlords, entrepreneurial lumbermen, villages, and daimyo to invest time and wealth in programs of woodland planting and nurturing, confident that in due time they or their successors would recoup the investment.

As interest in reforestation spread, the body of silvicultural writings grew apace, enriched by the testimony of practicing tree farmers. It provided detail – mostly practical and biologically sound – on the selection, collection, and preservation of seeds and cuttings, on the preparation and use of seedbeds, on the transport and transplantation of seedlings and rooted cuttings, on the suppression of competing vegetation, on pest control, on restocking failed shoots, and on nurturing the growing stand to produce wood (or other) products with the desired qualities. Writers also offered advice on the use of rotation-cutting schemes, on techniques of stand valuation and harvest, and on wood processing and storage.

By the decades around 1800, and on into the nineteenth century, both plantation stands and managed forests of mixed, multiaged new growth were becoming valued sources of timber throughout Japan. They eased the overall timber shortage that had spawned regenerative forestry in the first place. And while *hageyama* were still common and much woodland was still poorly stocked, the humanly fostered forest did, by enhancing Japan's volume of standing timber, help equip the realm to handle the traumatic decades that lay just ahead.

Industrial-Age Forestry

During the 1850s–1860s the global wave of early industrial European imperialism finally reached Japan, where it overwhelmed the decentralized Tokugawa regime in 1868. The new Meiji government saw its primary task as mobilizing sufficient power not only to stay in office, but also to stop further foreign inroads and to repudiate the concessions previously made. Within this new and radically changed context, there were some strong continuities in forestry thought and practice, but the changes seem more noteworthy.

Both protection and production agendas continued to be clearly visible, the balance between them shifting with the ebb and flow of woodland condition and global context. And much of the existing silvicultural knowhow and procedure continued to be applied in planting, nurturing, and harvesting projects.

Even in terms of silvicultural content, however, change gradually occurred. One factor spurring it was new technology, particularly that of the harvest, which placed great new demands on woodland and its handlers (see Timber-Handling Technology in Japan). More strikingly, the practice of forestry became far more systematized. Whereas Tokugawa-era forestry had utilized precedents from China, Meiji leaders took their cues from current practice in industrial societies, Germany most notably. Starting in the 1870s, a number of Japanese studied forestry there and upon their return helped forestry officials develop new policies and launch new programs. By 1883 that government effort had created a school of forestry, a forestry experiment station, a professional association of foresters, and a research bulletin.

In following decades those trends continued: regional forestry associations proliferated, more and more professional meetings were held, technical matters were debated, and new techniques were tried. Students and officials continued going to Germany to study forestry, and German works on the subject were translated into Japanese. New journals appeared; more experiment stations and forestry training programs were established, and the body of trained foresters and published research findings grew apace.

From the outset Meiji leaders had claimed domanial woodland as government forest, and by the 1890s they had created a Forest Agency and subordinate bureaucracy to manage their newly unified system of national forests, which encompassed more than half of all wooded acreage. Later, authorities also developed programs of guidance and assistance for owners, mostly small-scale, of the remaining woodland.

On government woodland foresters developed both overall management plans and local operational plans. Revealing ever more sophistication as decades passed, the overall plans spelled out policies for afforestation, aftercare, harvesting, and the handling of road construction and other forest-engineering projects. They dealt with the technical tasks of mensuration and the fiscal, spatial, and material requirements of projects. They detailed personnel needs, particulars of organizational structure and of research and operations facilities, and estimates of income and expenditures.

Nor was the planning merely a bureaucratic exercise. Research and training in scientific methods did improve. Forest mensuration, one of the world's more arcane arts, made striking advances. The relatively simple task of measuring acreage gained accuracy as more surveyors were trained and deployed and as surveyor's levels and the techniques of triangulation were introduced and mastered. The much more difficult tasks of estimating stumpage volume and predicting timber yield advanced more slowly as "eyeballing" gave way to increasingly refined techniques of estimation, including the use of sample plots. And foresters began developing yield tables for particular species in select localities.

In their research work, professional foresters also undertook studies of specimen growth, soil acidity and its effects, factors affecting seed-germination rates, and other projects designed to improve forest productivity. They also imported and experimented with seed and seedlings of valued foreign species. By the 1920s they were becoming familiar with the concepts of forest succession and continuous forest, and they were beginning to look more skeptically at such recently touted practices as rotation clearcutting, fixed yield rates, and even-aged monocultures.

Behind – and clearly influencing – this story of forestry's development was a less tidy tale of ups and downs in the actual woodland condition. During the decades from about 1870 to 1900, Japan's forests were ravaged by a combination of pushes and pulls that spurred villagers, entrepreneurs, and government loggers to hack down stands, clear land for cultivation, and otherwise misuse it in ways that produced flooding, erosion, and downstream damage. Decades of later-Tokugawa forest recovery were undone. But from about 1900 into the 1930s governments at all levels and private landholders responded by pursuing remedial policies to control flooding, restock forests, and maximize their rate of sustainable production. By the 1930s, these efforts were yielding results all across the realm: reforestation was being pursued widely, flooding problems had abated, *hageyama* were being revitalized, and the volume of standing timber was gradually increasing.

Then, however, during 1937–1950, industrial-age warfare and its consequences undid the gains, stripping the realm of much woodland cover and again producing widespread and destructive erosion, flooding, and damage. That situation precipitated yet another effort at forest rehabilitation, by far the greatest in Japanese history. During the 1950s–1960s countrywide planting restabilized the hillsides, adding thousands of hectares to the country's hand-planted woodland. By 1980 Japan was again a green archipelago, lushly forested from far north to far south. And today about 40% of its forest acreage is in plantation stands, most of it trees 30–50 years old.

That outcome has not, however, proven an unqualified triumph. By 1960 the Japanese lumber industry was becoming enmeshed in the global timber trade, and imported logs and other wood products undersold nearly all the domestic competition. In consequence, by 1970 logging had lost most of its profitability, and reforestation and aftercare had become uneconomic, an investment that carried no promise of eventual return. By then, too, shifts to chemical fertilizers, fossil fuel, and motorized machinery had destroyed the markets for green fertilizer, fuel wood, and fodder for draft animals. Woodland had become useless. It was merely pretty scenery.

Since the early 1970s, therefore, tree planting, stand maintenance, and logging work have all been in sharp and sustained decline. Indeed, logging activity today yields only about a quarter of the peak output of ca. 1940–1960. Instead, intermontane regions depopulate as young people in particular leave to find employment elsewhere. And both plantations and mixed forests simply stand and age, increasingly subject to windthrow and snow breakage and gradually losing their potential economic value (Fig. 1).

Because of these developments, Japanese forestry has recently been facing a crisis of purpose. Government committees and other groups have continually, and especially during the 1990s, drafted and redrafted rules and guidelines, categorizing and recategorizing woodland, giving more emphasis to protection forestry, and formulating purpose one way and another. But at present the basic problem of an uneconomic resource persists, and no coherent and effective policy for addressing it has emerged either within the Forest Agency itself or within government or society more broadly.

So, from a human-centered autecological perspective, Japan's forest affairs currently seem to be in utter disarray. From a broader synecological perspective, of course, it would seem a golden opportunity to encourage the final evacuation of depopulated intermontane regions and their revitalization as more richly diverse biomes. Perhaps even wolves could be reintroduced to manage the population of wild ungulates – deer, wild boar, and serow – that now constitute a widespread nuisance to people. And at the same time, one could pursue at little social cost the gradual, managed restoration of many plantation stands to wildlife-friendly mixed forest.

However, in Japan, as elsewhere, the former perspective – the human-centered autecological assumption that forests exist to serve human purposes and that they do so best when subject to enlightened human management – continues to prevail despite the small voices that fret about biodiversity, species endangerment, and extinctions. And it seems likely that as the twenty-first century advances, global wood scarcities will revive Japan's plantation-based timber industry and revalidate the production-forest priority before a synecological perspective gains effective voice.

Forestry in Japan. Fig. 1 Near Ueda City in Central Japan, March, 1963. By 1950 many of Japan's forests had been stripped of timber, but in following years the hillsides were replanted. By 1980 most of these hillsides again sported rich young timber stands. In foreground terraced rice fields give way to dry fields which ascend the hillsides as far as gradient allows (photograph by the author).

Gaitian

Christopher Cullen

Gaitian is the Chinese name for a scheme of cosmography, i.e., a description of the overall layout of heaven and earth. The term may be interpreted as "umbrella [-like] heaven."

The classical description of the *gaitian* view is found in the *Zhoubi suanjing* (Mathematical Manual of Zhoubi), dating from around the beginning of the Christian era. It seems likely however that it is a systematization of what was the common view of the shape of the heavens at least as early as 250 BCE. Heaven and earth are more or less flat and parallel planes, although they may sometimes be described as gently curved like the cross section of an umbrella. Earth is stationary, while heaven rotates once daily about an imaginary vertical axis through the north celestial pole, carrying the heavenly bodies with it. Day and night occur because this rotation carries the sun beyond the range of the observer's sight and back again. The rising and setting heavenly bodies are an optical illusion. In winter the sun is further away from the celestial pole than in summer, and is hence more distant from the observer and lower in his sky. The *Zhoubi suanjing* gives the height of heaven above earth as 80,000 li. The Chinese observer is said to be 103,000 li from the subpolar point, while the greatest and least radii of the sun's daily orbit round the pole are 119,000 li (summer solstice) and 238,000 li (winter solstice). The scheme gives a fairly good qualitative explanation of obvious phenomena, including the six-month alternation of day and night at the earth's north pole. By the second century AD it becomes clear that mathematical astronomers preferred not to think in *gaitian* terms, but were using the so-called *huntian* (continuous heaven) scheme.

Gan De

Huang Yi-Long

As one of the earliest astronomers in China, Gan De, in the fourth century BCE, made many observations of the heavenly bodies, especially Jupiter, which was then called *Suixing* (the year-star). He wrote two books: *Suixing Jing* (Treatise on Jupiter) and *Tianwen Xingzhan* (Astrological Prognostications). Unfortunately these books were lost long ago, and only some quotations from them are extant in the *Kaiyuan Zhanjing* (The Kaiyuan Treatise on Astrology), compiled between AD 718 and 726.

In the *Kaiyuan Zhanjing*, Gan De is quoted as saying: "Jupiter was very large and bright. Apparently, there was a small reddish star appended to its side. This is called 'an alliance'." Included in the quotation were a date and rough coordinates, both in the ancient Chinese system.

Zezong, of the Institute for the History of Natural Sciences in the Academia Sinica, Beijing, claims that this record is evidence of the earliest discovery of the brightest moon of Jupiter, Ganymede, in the summer of 365 BCE.

Although Ganymede's magnitude of 4.6 is somewhat brighter than that of the naked eye's limit, Jupiter is 760 times brighter and located less than 5.9 arcmin away from this moon. Only people possessing eyes of extraordinary power would be able to see the satellite. Could Gan De have been one of these extraordinary people? We will never know.

Some people claim, on the basis of experiments, that under good observational conditions, the normal naked eye can determine Jupiter and its brighter satellites, especially Ganymede. However, Gan De's reference to the reddish color continues to be mystifying, because Ganymede is too faint for its color to be perceived with the naked eye.

Gardens in Japan

WYBE KUITERT

The Early Centuries

Before a clearly defined native garden art appears in Japan's history somewhere in the eighth century, evidence is found of activities in the field of landscape design. It is mainly through archeology that these early centuries speak to us. At Jo-no-koshi (Mie prefecture) a rather naturalistic arrangement of rocks was unearthed; it was put up along a narrow stream at a point where it divides in two. The arrangement has been dated ca. 500 AD; it resembles a manner of handling rocks seen in a few gardens of the seventh and eighth centuries. Skill in engineering in this early history can be seen in bold burial mounds of advanced design, surrounded by moats. Some square ponds lined with rocks were found, as were quite a few artistic works in carved stone made to have some liquid flow. These were probably used for rituals involving rice wine or water for purification; similar artifacts are known from the continent. A well-known record, dated 612, speaks of a man who came from Paekche, a Korean kingdom; he built a garden arrangement and made a Chinese style bridge in the garden of the emperor. His name was Michi-no-ko Takumi in the Japanese reading of the Chinese characters of his name. It underlines how the early history of landscape design in Japan followed the models of the continent. At the mid-seventh century palace site of Fujiwara-kyo, remains of a winding garden pond have been found. At a slightly later site, parts of an extensive pond garden were unearthed. The pond had rather heavy embankments in piled-up rock, an island and a fountain-like feature. Most likely it had been part of the seventh century imperial Asuka palace of the emperor Tenmu (r. 673–686). Though only partly excavated, and much smaller, this garden arrangement resembles very much, in all its details, the seventh century pond garden Anap-ji in Korea.

The Nara Period (710–784)

Nara was founded as an imperial city in 710 AD; it was planned after Chinese geometrical schemes with streets running in a grid pattern. The imperial palace held a central position in the northern part of the city. It is known from scarce records that there were several gardens. None of these remain, but two extensive gardens were discovered and redone after detailed excavation and research.

Southeast of the main palace compound, a detached palace, To-in, was constructed in the early eighth century. The garden of To-in, or the East Palace Garden, is one of the gardens mentioned in contemporary records. Extensive archeological surveying gave a wealth of added information. The original pond bottom was paved with large flat stones. Like the Asuka pond, the heavy embankment of the East Palace Garden follows a design of simple curves, again similar to the Korean example. Interestingly, the garden had been rebuilt later in the same century, after a covering of the earlier design with soil. The second, younger pond was paved with much smaller pebbles, and the embankment runs in softer, more expressive curves. Rather than embankments, this second pond was contained with shores or beaches covered with smaller stones, the shingles found on Japan's seashore. Here and there at small peninsulas, rock groups suggested weather-beaten sea cliffs in miniature. A group of rather big and craggy stones is set as a decoration in the shore opposite the remains of a hall, traced from remains of foundation pillars. It is this second phase of the East Palace Garden that shows a clear departure from the continental style and the introduction of clearly native landscape motifs; the typical shingle beaches and rocky promontories of Japan's natural sea coast would continue to inspire garden designers for centuries to come. The East Palace Garden has been reconstructed on top of the archeological remains. Buildings, a bridge and planting were remade in a hypothetical reconstruction of what could be guessed from what was found in the soil.

A second garden recovered from eighth century Nara is known as the Imperial Villa Garden, or after its address in the old city of Nara, *Sakyo sanjo nibo rokutsubo kyuseki teien*. The site is not known from records; probably it was a private retreat of some courtly family or the emperor himself. It is in walking distance from the To-in garden. The most distinctive feature of this garden is a double S-curved winding pond, or wide stream bed. The pond was paved with fist-sized stones in the old continental manner, but decorative rock groups at protruding curves and beaches covered with pebbles are completely in the native naturalistic manner. Drawing from a natural river the winding pond has its water running from north to south. It is generally accepted that this pond was used for the so-called winding-stream banquet: guests were sitting along the stream, writing poetry. A poem had to be finished before a cup of wine set on a float would reach the poet. This festivity became famous after the Chinese calligrapher Wang Xizhi (303–379) had invited 41 men for a winding stream banquet on the third day of the third month in 353. Poetry written on the occasion was compiled in the *Records of the Orchid Pavilion*, a Chinese literary classic, well known in eighth century Japan. The garden at Nara's Imperial Villa Garden will also have been used for winding stream banquets. The rockwork excavated was in such perfect condition that it was decided to reconstruct the garden with most of the original stones. Remains of two sets of wooden boxes were found, set among the stones of the pond bottom; these were probably planting boxes for irises. A banquet hall was reconstructed departing from the remains of pillar foundations found. As plant material in these garden reconstructions the Chinese plum (*Prunus mume*) and Japanese pine (*Pinus thunbergii*) are used among other plants.

The Heian Period (794–1185)

In 794 the city of Heiankyo, now Kyoto, was founded as a new capital in a plain surrounded on three sides by hills. The city would remain the most prosperous cultural center for many centuries to come. The site for the new city was well chosen and blessed with a lot of pure water and natural springs, giving great advantage for the household and for garden building. Indeed, natural ponds and streams were used in large palatial gardens. In some cases dams were built to contain more spacious garden ponds. At the back and in between the palace buildings sand was spread out in small court gardens and a little stream ran among flowers, shrubs and bamboo planted as decoration. The old glory is perceived in garden remains in Kyoto such as the one at Shinsen-en or at Saga-in, a place now known as the temple Daikaku-ji. At other places, excavations again revealed garden details. Rocks arranged to make a waterfall were found in some sites. These are never high, as gardens were made in the plain.

Within the city a peculiar architectural style in which the nobility built their palaces became defined. After the main hall, the *Shinden*, it is called the "shinden style," or *shindenzukuri*. In combination with the architecture, the garden also developed into a typical *shindenzukuri* garden style. Of course, each garden was different, but some features appear characteristic. Seen from the main hall, white sand was spread in the front part of the garden; more at the back one found a large pond that could have one or more islands. An arched and a level bridge connected islands and shores. Along the edge of the pond one could find pebble beaches, or standing rocks arranged to suggest a weather-beaten sea cliff. The typical garden stream mostly ran from the northeastern corner through the garden, then among some low garden mounds before emptying into the pond, usually in the southern half of the garden. Hills at the back of the garden provided a background.

But times were changing and the twelfth century brought the nobility an unstable political situation. To counter the increasingly pessimistic worldview that prevailed, they built themselves large temples, with gardens referred to as paradise style gardens. Yorimichi Fujiwara in Uji, for instance, reconstructed his palace and modeled it as a temple named Byodo-in, in a setting of a large pond garden. The still extant Phoenix Hall is shown on the Japanese 10 yen coin. After an archaeologic survey, medieval repairs were removed and the original pebbled beach was repaired. The Paradise style meant to express the ultimate Paradise of Amida Buddhism in this world. Other still extant gardens of the same style are in Hiraizumi, Iwate Prefecture, or the Shiramizu-Amidado in Fukushima Prefecture, and Enjo-ji and Joruri-ji close to Nara. Many elements of the palace style remained to be used in these temple gardens as well; ponds and islands are typical. The garden stream of Motsu-ji in Hiraizumi is extensive and resembles garden streams as represented in paintings of the period. Around this time a nobleman wrote a well-developed manual on garden theory – the eleventh century *Sakuteiki*. It set the tradition for centuries to come. Nameless workers, supervised by noblemen, built gardens in this period; a class of gardening priests soon followed.

The Kamakura Period (1185–1334)

Although a shogun's government of military men was set up in Kamakura, the center of culture remained Heiankyo (modern Kyoto), and all through the Kamakura Period garden art remained under strong influence from the earlier style. Temple gardens built by order of military men followed the pattern of the Paradise style. For instance, Yorimasa Minamoto, after suppressing Hiraizumi in 1189 where he had seen its Paradise temples, was greatly impressed by their magnificence. He started building Eifuku-ji in Kamakura in the same year and in 1192 the ceremonial services for inaugurating the new buildings were performed. At present on the designated historic site the remnants of this garden can be seen.

The gardens at residences of the military class had the same influence, but their scale and their function as a space for ceremony were smaller, leading to more attention being paid to practical use. Also, with a garden space becoming smaller, it became rather a place to look at and enjoy by admiring than a place to enter. Starting from the thirteenth century, garden culture came to receive Chinese influence again, this time, through visiting Zen priests. High-ranking priests of the Chinese Song dynasty, like Rankei Doryu (1213–1278) or Issan Ichinei (1244–1317), given the Japanese pronunciation of their names, were influential cultural leaders of Japan. Many landscape paintings of the Song and Yuan dynasties were imported as gifts and brought a new vision of an imaginary landscape. The Chinese vision of landscape is still profoundly felt in the artistic composition of rocks arranged for garden waterfalls. For example at Tenryu-ji and the Golden Pavilion they probably date to this early period when Chinese priests were around.

The Muromachi Period (1334–1573)

A new ruling class of military men finally replaced the courtly culture of noblemen.

The influence of Chinese culture on garden art was now backed up with a growing trade with China on an unprecedented scale, making a taste for Chinese goods the great fashion. Shogun Yoshimitsu and his palace – of which at present only the Golden Pavilion remains – naturally formed the center of this Chinese fashion. His court was affected by the Chinese mood as can be recognized in the architecture of the Pavilion. The Chinese influence in the fifteenth century shows in the adding of a great variety of pavilions, bridges, and two- or three-storied buildings to the spacious pond gardens of the earlier shindenzukuri-style. The temple Eiho-ji in Tajimi (Gifu-prefecture) is a typical example. Gardens from these days are adorned with Chinese literary phrases. Later, in the days of shogun Yoshimasa around 1500, the fashionable and gorgeous Chinese taste came to an end. Growing power and influence of townspeople mingling with the military rulers led to a less superficial urban culture. A shift toward a more subdued and intellectual expression is seen in a new garden style that came into formation. At present referred to as the "dry landscape style" (*karesansui*), it was called *kazan*, or *kasenzui*, meaning "imaginary landscape" in its time. It strives for an abstraction of landscape by careful placing of rocks. In miniature these can be realistic and suggestive of mountains and waterfalls, employing white sand as an expression of water. Also a quite abstracted placing of just a few rocks was called an imaginary landscape. The textbook examples of the style are now Daisen-in of the Daitoku-ji monastery and the garden in front of the main hall of the temple Ryoan-ji, although this garden was rebuilt in the late eighteenth century. Among the so-called "riverside people" (*kawaramono*) living at the very bottom of the social ladder, skilled gardeners called "landscaping riverside people" (*senzui-kawaramono*) became a group of professional gardeners. They become persons known by name in the records at the end of the Muromachi period. Gardeners living in and around the temple Ninna-ji have left us a detailed hand-written manual on gardening technique (*Sansui narabini yakeizu*) dating from the 1460s.

The Momoyama Period (1573–1603)

The Momoyama period is a period of transition and sudden wealth after the country's unification. On the one hand we see gardens expressed in gorgeous splendor beside the expansive mansions of the powerful military leaders, gardens often employing the ostentatious sago palm tree that was the great fashion of the day. One may visit the garden at the large Reading Hall of the Nishi-Hongan-ji temple in Kyoto, a garden said to have been moved from shogun Hideyoshi's castle at Fushimi to its present site. Another example is the sumptuous garden at Sambo-in of the monastery Daigo-ji, commissioned by the same shogun; it is in fact a lavish display of expensive garden rocks.

On the other hand the subdued taste of the townspeople developed in opposition to the ostentatious manner. Gardens with a romantic vision of landscape were developed around simple grass-thatched huts. These were used for socializing, and in time became associated with the etiquette of drinking tea. These small gardens employed simple stepping-stones, a basin to wash the hands and some rustic stone lanterns. In later history these were classified as tea gardens. Professional gardeners known by name appear as modern tradesmen.

Gardens of the Edo Period (1603–1867)

Two and a half centuries of nationwide peace and stability characterize the Edo period. Garden culture was polished and evolved to an extreme level of contrivance and perfection. In the early Edo Period some fine examples of garden art came about among wealthy members of the imperial court, like the gardens at the detached imperial villas in Kyoto. In contrast with the pond gardens of classical days, garden routes were now intentionally laid out along the shores for the purpose of strolling, as seen in the Katsura Detached Villa, showing scenic techniques taken straight from the tea gardens of earlier days. A garden path of stepping-stones and designed pavements is aligned with tea pavilions and tea huts, or other kinds of garden architecture. Garden mounds, pebble beaches, bridges, stone lanterns, and washing basins were installed to produce scenery that changed with almost every step. This tendency to decorate the garden with numerous details became typical of the later Edo Period garden developed by the *daimyo*, or governors of the provinces.

These daimyo were obliged to live in Edo, currently Tokyo, for six months every year. They had their official residences in the city; some were many hectares large. The other half of the year they lived in their own home province where they constructed their gardens in the same manner. With daimyo challenging each other all over the country, and above all in Edo, the cultural hegemony of Kyoto gardening came to an end. Daimyo gardens first of all served for holding banquets or other garden pleasures, but also signified the birth of a new garden aesthetic. The scale was large and evoked a concern for scenery, thus a more bucolic sense is seen in miniature landscapes reproduced. Some gardens have mini Mount Fujis; others have small tea plantations or rice fields. All over the country daimyo left us with many good examples. In Tokyo, there are Korakuen, Rikugi-en, Shiba-*Rikyu*, and Hama-*Rikyu*. In Okayama one may visit Korakuen, Takamatsu has its Ritsurin-en, Hiroshima Shukkei-en, Mito Kairaku-en, or in Hikone the Genkyu-en garden.

In the course of time well-to-do citizens also came to possess a garden, and gardening became more popular. Popular garden books spread a stylized mannerism, dividing "the" garden in two styles each in three levels of elaboration. The thing to have was for instance an "elaborate hillock-style garden," or an "abbreviated flat garden" as these were shown in the picture books. Gardeners became professional specialists, organizing themselves in houses that would pass on the trade for generations. Propagating and breeding of novel garden plants reached a level matching the modern garden center.

Gardens of the Later Nineteenth and Twentieth Centuries

After the 1860s "the West" was brought to many facets and aspects of Japan's society, but this did not readily reach the garden. Several western-style gardens were built in Tokyo, often with lawns, winding paths, and a look-out on a hill; an extant and successful example is Shinjuku Gyoen. But in face of Japan's century-old tradition these were isolated experiments.

Little by little though, new ideas began to inspire the top end of the garden trade. Among some captains of industry the cramped world of the picture book garden was considered obsolete, and a new taste was required, giving room for a more liberal naturalism. In the course of the 1890s great progress was made again in Kyoto at Murin-an, a garden ordered by a powerful politician Aritomo Yamagata and built by gardener Jihei Ogawa (1860–1933). The garden had meadows of wild flowers set among a pastoral landscape of meandering streams, set before a background of natural hills outside the garden. The meadows and a design of trees and shrubs reflected Japan's agricultural landscape around Tokyo with its coppice woods. Murin-an had many deciduous trees, rather than the eternal pine trees. The experience gained by gardener Ogawa at this job was put into wide practice in many other and larger gardens in the region around the temple Nanzen-ji in Kyoto. These gardens quickly became famous; most are still extant. The garden he designed at the Heian Shrine is open to the public; it is typical of his work and shows us how he interpreted tradition in a contemporary way. Besides Ogawa, we find many other able landscape gardeners. Perhaps Jukki Iida (1890–1977) should be mentioned here, as one of the men important in carrying the traditions over the Second World War, working with a similar feeling for the naturalistic landscape of deciduous trees.

A garden artist negating this style was Mirei Shigemori (1898–1978). He was like a producer, working with gardeners rather than being a gardener himself. Therefore, as he was freer from tradition, he found an appealing new definition of the dry-landscape style, employing coarse white gravel and thick, dark green moss. All over Japan he left us many of his at the time avant-garde gardens, some of them with strong lines and forms expressed in concrete.

The enormous economic expansion of the later decades of the twentieth century brought many commissions and big budgets. Landscaping became a large-scale operation of companies with nameless designers. Experiments with expensive materials such as worked natural stone, often set in concrete, mark this period. Although design was influenced by American plaza design, the tradition remained meaningful. Ogawa's discovery of the deciduous tree and the coppice wood became common in parks, as well as in the private garden. Rock design remained strong, in some cases adding the strong line of the cutter, as can be seen in the Japanese Garden at the Expo site in Osaka.

References

For serious research on the history of Japanese gardens Japanese language sources are required. Sources in Western languages have already made a shift to another mind-set, crossing centuries and cultural borderlines when translating information found in ancient, primary sources. This bibliography has used such sources only if they rely (more or less) on primary, Japanese sources. Western sources on Japanese garden art have, throughout history, always showed interpretations that should be understood in view of the Western context. Some of these are included, as these are of historic interest, having in turn influenced views on Japan's garden art by the Japanese themselves. Some Western sources, as Condor 1893–1912, contain interesting photos illustrating gardens and garden styles that have now disappeared.

Any serious researcher should refer to the volumes of *Zōen zasshi*, continued as *Randosuke-pu kenkyū*, edited by the Nihon Zōen Gakkai (Tokyo) to find updated research results. This journal has a catalogue (searchable with keywords) for the years 1977–1994: *Nihon zōen gakkaishi sōmokuroku*, April 1995. Gas: Exploitation and Use of Natural Gas in Premodern China

Hans Ulrich Vogel

Ancient Chinese sources give many references to strange fiery phenomena burning on water or rising out of the earth. For instance, the *Hanshu* says that in 61 BCE the emperor sacrificed at the “fire well” (*huojing*) of Hongmen (Shaanxi). We do not know the cause of this fiery discharge, but it is clear that this fire well was an object of religious worship, because a fire well temple had been erected there. No mention was made of any use for industrial purposes (Fig. 1).

G

The first reports on the industrial use of a fire well come from the middle and late third century AD. One of these reports state that there is a fire well in Linqiong, Sichuan province. Once Zhuge Liang (181–234), counselor-in-chief of Liu Bei (162–223), came to see it, whereafter the fire turned stronger. People put pans on the well to boil salt. When brands of common hearths were entered into the well, it at once extinguished and did not burn again. Thus, it is clear that the prosperity and decline of the well was seen as corresponding to political developments. Another source, for instance, interpreted the extinction of the well as an omen for the annexation of Shu by Wei.

We cannot ascertain whether the Linqiong fire well was really a natural gas well, because later texts appear to suggest that petroleum was involved. Whatever the case, there is no doubt that it was productive for only a short period. That later authors referred to this well time and again is because it constituted a strange and interesting historical phenomenon. It is therefore hardly justified to speak of the “systematic use” of natural gas for evaporating brine “on an industrial scale” starting in the second or even fourth century BCE, as Joseph Needham claimed. Moreover, Needham also assumed that deep drilling, which was one of the preconditions for a systematic exploitation and use of natural gas, had already been invented during the first century BCE or AD. Recent research showed, however, that deep drilling originated in the middle of the eleventh century.

After the Linqiong fire well had become extinguished, probably in the late third century, Chinese sources do not mention the use of fire wells for industrial purposes until the sixteenth century. Although they still report on the outflow of mist (*yanqi*) and hidden vapors (*yinqi*) from wells, it is clear that these discharges were conceived as threats to well salt production. For instance, in the tenth century explosive “hidden gas” was reported from the Ling well, a shaft well in the Lingjing industrial prefecture. Moreover, it is said that

Gas: Exploitation and Use of Natural Gas in Premodern China. Fig. 1 Fire wells of different quality, as shown on a mid-eighteenth century scroll. The scroll was photographed by Rewy Alley in Beijing in 1954. The location of the original is unknown. Photograph used with the permission of the Needham Research Institute, University of Cambridge.

in the eleventh century, when workers had been let down into the well for repair work, they were killed. Only by the installation of a so-called "rain basin" (*yupan*) over the top of the well could these difficulties be overcome. From the rain basin water sprinkled down like rain, which carried the gas down into the well. This device was derived from the observation that gas discharge was restrained during rainy days.

Systematic use of natural gas began in the sixteenth century. In the beginning, the number and output of industrially used fire wells appear to have been still limited. Until the end of the eighteenth century a fire well usually could supply fuel for only one to four pans, though exceptionally productive wells like the Yongtong well existed, which is said to have fed sixteen pans. A scroll of the mid-eighteenth century shows interesting details of fire wells of differing productivity probably in northern Sichuan.

The standard situation appears to have been that one well was feeding one pan which was placed directly over the well. A bamboo tube inserted into the well served as burner. It was covered by a stone, in case the fire was to be extinguished. The scroll also shows a very productive fire well supplying two pans. The gas distribution device consisted of a large bamboo tube on which a porcelain vessel filled with water was put. The gas was distributed to the pans by two small pipes connecting the burners with the large bamboo tube. Finally, less productive fire wells not only could not feed more than one pan, but had also to be supported with firewood.

The situation changed dramatically with the development of deep drilling techniques in the nineteenth century, when the high pressure gas deposits in the deeper strata of the Ziliujing gas field were tapped. For instance, the French missionary Imbert reported in September of 1827 that a single fire well of Ziliujing could feed more than 300 pans and that the wells were so productive that a part of the gas could not be used and thus had to be burnt off. A new generation of productive fire wells supplying 400–700 pans is mentioned by Li Rong in his famous account of Ziliujing from the end of the nineteenth century. The use of the resources of such highly productive wells necessitated the invention of a number of devices for the control and distribution of the gas flow and for coping with variations in the well's pressure. The utilization of gas was a highly dangerous undertaking which could lead to explosions. That was also the reason why at least in Ziliujing gas was only rarely used for household purposes.

Natural gas was an amazing phenomenon which required explanation. Song Yingxing, in 1637, said that the fire wells contained simply cold water, but not the slightest evidence of the *qi* of fire. One can only see the notion (*yi*) of fire which is bursting forth from the burner's pipe, so that the brine will boil violently. Yet if the bamboo pipelines for conducting the gas are opened and examined, no sign of charring or burning can be seen. "To use the spirit (*shen*) of fire without seeing the solid form (*xing*) of fire – this is indeed one of the strangest things in the world" (Sun and Sun 1966). Later Chinese authors had less strange ideas of the phenomenon of fire wells. For instance, in 1791, Xu Deqing came to the conclusion that the existence of fire and wind in the earth of high-lying terrains should be regarded as something quite normal, similar to the existence of fresh water sources in marshy and low-lying regions.

Ge Hong

Ho Peng Yoke

Ge Hong (ca. 283–ca. 343), alchemist, physician, astronomer, and government officer, was the greatest alchemist and physician in fourth-century China. We also know him under several other names, such as Ge Zhiquan, Zhiquan Zhenren, Baopuzi, and Xiao Ge Xianweng. His exact dates are not known with certainty. Some say that he was born between 280 and 286. Other dates given for his birth are ca. 253, 280, 281, 283, and 284. The year of his death has been variously given as ca. 333, 340, 343, 361, and 364. Chen Guofu's elaborate study suggests the period 283–343 for him. Ge Hong's autobiography is contained in his *Baopuzi waipian* (Exoteric Chapters of the Preservation-of-Solidarity Master), but it says precious little about the author's scientific achievements. His biography is given in the *Jinshu* (Official History of the Jin Dynasty). Since he is regarded by the Daoists as having attained physical immortality, his hagiography is found in abundance in Daoist literature.

When he was young Ge Hong studied alchemy under Zheng Yin and Bao Jing, whose daughter he later married. He also learned much about medicine. He joined the government as an army officer in a military campaign to suppress an uprising in the year 303. After peace was restored he left without seeking reward and traveled widely in search of books. In the year 306 he accepted an invitation from his friend Qi Han to become his military adviser when the latter was appointed Governor of Guangzhou. Qi Han, the author of the *Nanfang caomuzhuang* (Records of Plants and Trees in the Southern Region) was one of the greatest botanists in traditional China, but unfortunately he was soon assassinated. Ge Hong remained for some time in the South and then returned to his place of birth, Nanyang, in Jiangsu province. A belated award came for his past service in the army. He was given the title Marquis of Guannei, and was recommended to the emperor for appointment as a member of the bureau of historiography. He declined the offer, but requested that the emperor make him magistrate of Goulou in South China, which was a rich source of cinnabar that he needed to prepare the elixir of life. Eventually the emperor granted him his wish. Ge Hong then went to live in the Luofoushan Mountain where he carried out his alchemical and protochemical experiments. It was probably there that he completed his famous alchemical work, the *Baopuzi*. Some say that the year was 317.

The *Baopuzi* consists of a *Neipian* (Esoteric Chapters) in 20 chapters and a *Waipian* (Exoteric Chapters) in 32 chapters. Among those in the *Neipian*, chapters 4, 11, and 16 are of special interest to the alchemists, while the other chapters also contain bits of information on alchemy scattered here and there. Chapter 16 specifically describes the transmutation of base metal into gold or silver. Chapter 1 of the *Waipian* contains Ge Hong's autobiography. The rest of the *Waipian* says nothing about science or alchemy. The relevant sections in the *Neipian* contain names of more than 50 elixirs supposed to have various efficacies – some could only prolong the human lifespan, while others could transform the aspirant to a holy immortal varying from 3 days to 3 years depending on the elixir itself. Ge Hong seemed to be successful in aurifiction, the process of imparting an appearance of gold to base metals by artificial means. It is interesting that the attributes of the elixir of being a panacea, of being able to translate base metals into gold or silver by means of projection, and of being able to impart longevity and perpetual youth were already mentioned by Ge Hong in the case of some of the elixirs in his *Baopuzi*. Sulfur and mercury were used in many of his elixir recipes.

Ge Hong was an eminent physician in his own right. His *Baopuzi neipian* describes the medicinal values of many plants and minerals. During his stay at the Luofoushan Mountain he also wrote the *Jingui yaofang* (Prescriptions in the Treasury of Medicine), in 100 chapters. Later he added an abridged version, entitled *Zhouhou jiuzufang* (Handbook of Medicine for Emergencies) in three chapters. Ge Hong's writings contain prescriptions for various types of diseases, including eye trouble, ailments of women and children, and infectious diseases such as smallpox and tuberculosis. They prescribed soya beans, cow's milk and goat's milk for the treatment of beriberi, and for treating bites from mad dogs the recommendation was to apply the brain of the culprit over the wound.

Ge Hong also showed considerable interest in astronomy. The *Jinshu* (Official History of the Jin Dynasty) quotes from a piece of his lost writings on the construction of astronomical instruments by Zhang Heng in the second century. It also narrates Ge Hong's participation in the great cosmological debate of his time. There were then two rival schools, the *Gaitian* (Canopy Heaven) and the *Huntian* (Spherical Heaven). The former was more ancient and pictured a canopy heaven covering a square earth like a tilted umbrella. The latter visualized the earth as the yolk of an egg floating on water at the center of a spherical heaven that was itself supported by water. The argument used against it was that the sun rising from and setting into water would be quenched of its fire and heat. In supporting the *Huntian* theory, Ge Hong skillfully quoted the hexagrams and passages from the *Yijing* (I Ching, Book of Changes) to silence its critics. Ge Hong also observed the effect of the moon on the water in the sea and on the tides. In his *Baopuzi* he referred to the waves of the sea heaving up and down with the waxing and waning of the moon and the increase in magnitude of the tide when the moon was full.

Geodesy

Raymond Mercier

Geodesy, the measurement of the earth, is an essential component of both astronomy and geography. The spherical shape of the earth was a concept developed in the early stages of Greek science, and one finds this concept wherever the legacy of Greek science was taken seriously. Figures for the radius of the earth were reported by Aristotle and a number of other Greek scientists, although a judgment of their accuracy is hindered by our ignorance of an exact measure in modern terms of the units in which the radius was expressed. The coordinates in Ptolemy's geography were fixed by him from various distances measured in terms of *stadia*, converted on the assumption that one degree equaled 500 *stadia*; for Eratosthenes, the degree equaled about 700 *stadia*. On the other hand sources in Latin and Syriac rather later than Ptolemy worked on the assumption that one degree equaled 75 Roman miles, which we can evaluate because the length of the Roman mile is well established, so we know that it is very precise. The radius and circumference of the earth follow immediately from the length of one degree.

In the early stages of Arabic science, especially the work heavily patronized in the early ninth century by the Caliph al-Maʾmūn, various Greek and Syriac sources were consulted with a view to fixing the earth's dimensions. Here the intention was to evaluate the degree in terms of the Arabic mile, which we know to be 4/3 Roman miles, 1,972 m. The Arab scientists of the time, however, were uncertain as to the interpretation of the various figures given in their sources, and they were certainly confused about the true length of the Roman mile. While they were aware that the Roman and Arabic miles were, respectively, 3,000 and 4,000 cubits, they were ready to assume that it was the cubits and not the miles which differed.

Against this background they set about to measure the length of the degree by direct observation of the latitude variations along a north–south traverse in the desert of Iraq. They chose a region south of Sinjār, which is about 100 km west of Mosul. According to extant reports two expeditions were made, one led by al-Marwarrūdhī, the other by ʿAlī ibn ʿIsā al-Asṭurlābī. In one account it is said that they agreed on the ratio 56 miles per degree, but other accounts of the expeditions report 562/3, or 561/4 miles. There is probably a blending here of observation together with a conversion of the late Roman figure of 75, since 3/4 × 75 = 561/4. The accounts are somewhat lacking in circumstantial detail, and probably the methods employed, which must have involved a sufficiently portable quadrant for the measurements of latitude along the route, would not have sufficed to provide more than a rough verification of the received figures, sufficient at least to distinguish between the two different interpretations of the mile.

The great scientist al-Bīrūnī (fl. AD 1030) carried out some work of great value in his determination of a series of longitude differences for stages leading from Baghdad to Ghazna. These were reported in both his treatise on geodesy *Taḥdid nihāyāt al-amākan li-tasḥīḥ masāfāt al-masākin* (The Determination of the Co-ordinates of cities), and in his astronomical treatise the *Qānūn al-Masᶜūdī*. He also reported his own attempt at a determination of the length of the degree. The latter took place in the Punjab, where the plain to the south may be seen from a peak (479 m) in the Salt Range, some 50 km South West of Jhelum. Al-Bīrūnī says that he measured the dip of the distant horizon as 34 min of arc, from which according to his calculation, he finds slightly more than 56 miles to the degree. He considers however that this should be regarded not as a new result but as a confirmation of the earlier result fixed at the time of al-Mamᶜūn. In fact his procedure was flawed in various ways, for his measurement of the height of the mountain was considerably in error, and a correct interpretation would have required that refraction be taken into account. Moreover we may calculate, taking refraction into account, that he would have obtained a dip nearer to 29 min, so that his whole account is quite suspect. The method has been suggested independently by a number of scientists, but even when carried out with the greatest care, it is doomed to failure because the degree of refraction is unpredictable for a ray grazing the earth's surface.

Al-Bīrūnī's determination of the longitude differences was much more successful. The tables of mean motion in his astronomical treatise were referred to the meridian through Ghazna (near Kabul), and he was naturally obliged to determine the time/longitude difference between that place and Baghdad. The primary information available to him, as to Ptolemy before him, was provided by travelers who would have converted a traveler's time to a distance. The region between Baghdad and Ghazna is divided up by al-Bīrūnī into shorter stages along two different routes, one passing North through Rayy and Jurjaniyya, and the other South through Shiraz. For each short stage, he calculated the difference of longitude, given the latitudes at each stage, and the distance from one stage to the next. In every case the travelers' distance is discounted to allow for the fact that the real path deviates from a perfect great circle. The problem of fixing the longitude difference is posed and solved correctly in terms of spherical trigonometry, and he gives all the numerical details, so that one can judge the accuracy of his work. In spite of occasional lapses in the calculation the results represent a very considerable improvement over that available in Ptolemy or al-Khwārizmī; the final longitude difference between Baghdad and Ghazna is only some 15 min of arc short of the true value. People would not be able to improve on that until entirely new methods were discovered in the late seventeenth century, such as the use of Jupiter's satellites.

Geographical Knowledge in Ancient Sri Lanka

P. Wickramagamage

Our knowledge about the early inhabitants who lived prior to the sixth century BCE in Sri Lanka is very limited, but more historical data is available for the period thereafter. Sri Lanka gained a place in the East–West trade and became an important centre in the sea route connecting the Far East and the West. It was known to people outside by several names (Lanka, Serendib, Sihaladeepa, Taprobane, Seylon, Zeylon, Ceylon, etc). Its proximity to the Indian subcontinent meant that people moved back and forth freely in ancient times. The Island has a long history of human habitation from about 130,000 years or more (Deraniyagala 1998).

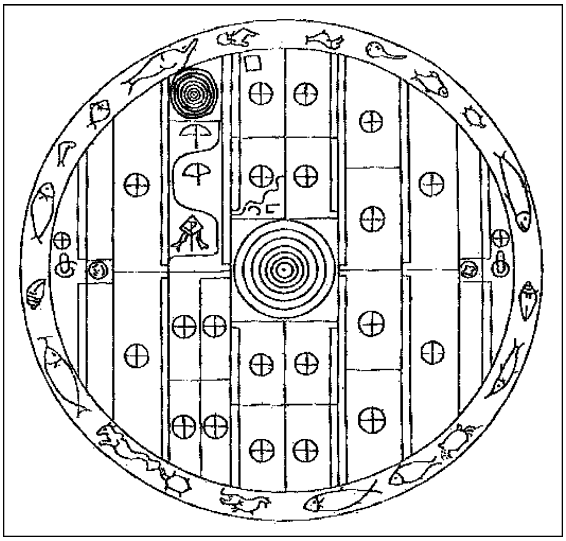
The island is divided into two major climatic zones, dry and wet, with a narrow belt in between with transitional characteristics. The Sinhalese civilization flourished in the Dry Zone, despite a severe water shortage during the long dry season. The highly seasonal rainfall meant rain-fed cultivation was possible only during the wet season. Despite this constraint, the main livelihood of the people was rice cultivation, which required considerably more water than any other crop. The need for artificial irrigation to overcome water deficit was understood from a very early stage, and the technology to develop a complex system of reservoirs and canals seems to have evolved out of this necessity. Development of irrigation demanded a high level of knowledge of the terrain as well as the principles of hydraulic engineering.

Sinhalese Cosmology

The ancient Sinhalese are thought to have known a great deal about the earth, its spherical nature, its position among other planets and the universe at large (Gunawardana 1979). Sinhalese did have close contacts with various parts of India and the Greco-Roman empire, particularly from the first century AD. Both ancient Hindus and Greeks had certain concepts of the earth, solar system, and the stellar constellations. Astrology played an important role in the ancient Sri Lankan and Indian cultures at a very practical level, and knowledge of astronomy was essential to make astrological calculations. It is possible that there was a considerable exchange of astronomical ideas between the east and the west. Verse 29 in *Sūryasiddhāntha* says "This Brahma-egg is hollow; within it is the universe, consisting of earth, sky, etc.; it has the form of a sphere, like a receptacle made of a pair of cauldrons" (Burgess 2000: 285).

Sūryasiddhāntha also places the zero meridian (*madyama-rekha*) over Sri Lanka (Burgess 2000: 362).

There is evidence that *Sūriyasiddāntha* was one of the astronomical/astrological texts taught in the educational institutions of ancient Sri Lanka. *Girasandesaya,* a message poem, composed in the fifteenth century "describes how students at the Vijayaba Pirivena studied the *Sūryasiddhāntha*, plotting the location of various planets by placing sea-shells as markers on a blue board and then moving them in accordance with their calculations" (Gunawardana 1979). The *Vijayaba Pirivena* was one of the foremost educational institutions of Sri Lanka at that time. It is probable that the Indian astronomical texts were in use in Sri Lanka long before that. Further evidence of this can be found in *Sūryasiddhāntha* itself, which speaks about exchange of ideas between students of astronomy in Sri Lanka and elsewhere in South Asia (Gunawardana 1979). At the same time, their links with the Greco-Roman empire means they would have known the ideas of Greco-Roman philosophers. The Sri Lankan ambassadors who visited Rome during the reign of Emperor Claudius are known to have discussed the stellar constellations they observed in Rome and compared them with those observations back in Sri Lanka (Gunawardana 1979).

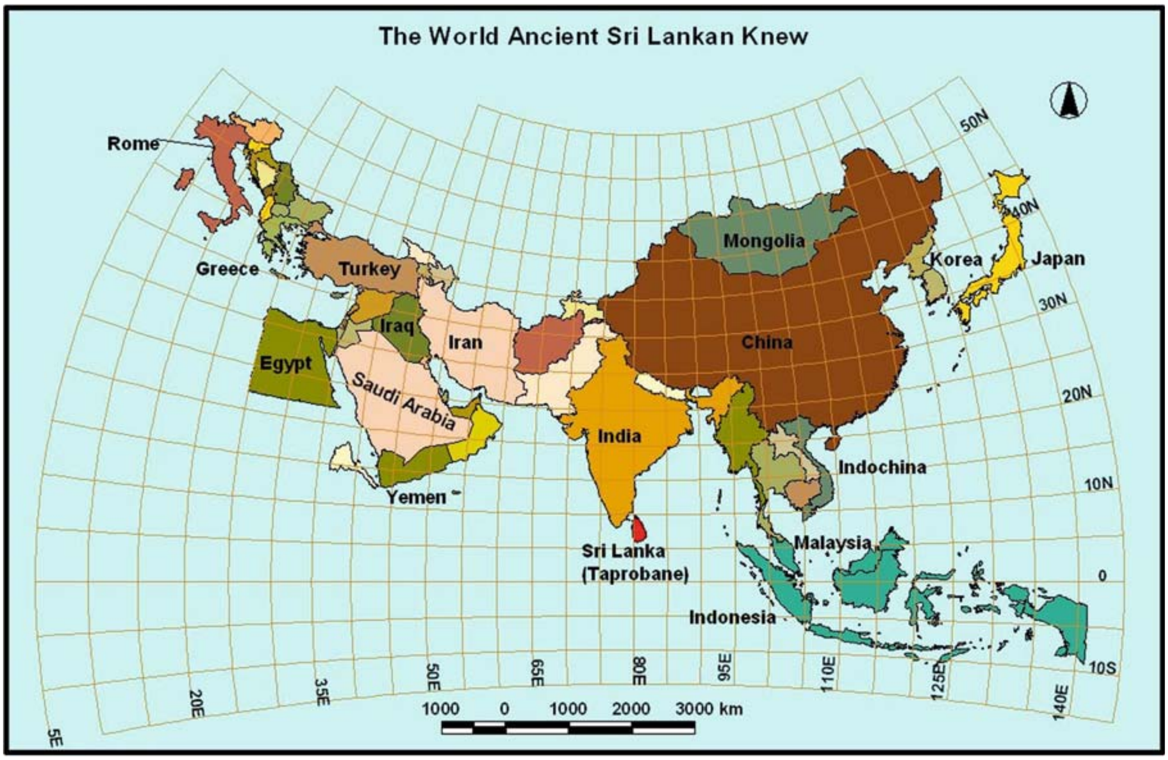


Geographical Knowledge in Ancient Sri Lanka.

Another piece of evidence of the Sinhalese cosmology and the shape of the earth is a carving in a cave in Anuradhapura (Fig. 1), which was discovered by archaeologists at the turn of the twentieth century (Bell 1901), and was named *Sakwala* (earth or universe). It is a circular figure within which numerous symbols are carved and the outermost ring contains aquatic life forms. At the centre of the figure is a carving with seven concentric circles with a dot marking the centre. At this time, there was a belief that this was Mount Meru located at the centre of the world surrounded by seven oceans and four continents. It is possible that the figure with seven concentric circles represent the earth and seven oceans. The same concentric circles occur at the top of the figure as well. The other figures in the interior of the circle have not been identified. Wickramagamage (1995: 54) is of the view that this is a *yanthra* which may have been used for meditation purposes. There is a seat made of stone right in front of this figure.

Ancient World Geography

The ancient Sinhalese maintained relations with countries in South Asia as well as the countries up to Rome in the west, and up to China and beyond in the east. This was facilitated by its strategic position in the east–west sea route. Seafarers from the west and east came to Sri Lanka which acted as a trading post in the ancient world, (Tampoe 1995). Two other ports that participated in this trade are Gokannapatuna (Trincomalee) in the northeast and Magama in the south. Manthai (Near Mannar) functioned as the main harbour and as a great emporium in the ancient South Asia region. Sri Lanka sent its own ships to China (Tampoe 1995).



Geographical Knowledge in Ancient Sri Lanka. Fig. 2 The World Ancient Sri Lankan Knew.

Sri Lankan kings had established links with Greece and Rome as far back as the first century AD. The king of Sri Lanka (Bhatikabaya) explored the possibility of developing direct trade links with Rome. In the year 361 AD, an embassy from Serendivi was received by the Emperor Julian. Similarly, commerce between Sri Lanka and China goes very far back into history. Manthai was involved in transhipment of Chinese goods to the West. China–Sri Lanka trade relations were also reported by the Sinhalese ambassadors to the court of Claudius in the first century AD. Embassies carrying gifts from the Sinhalese king visited China in the first century AD. The relations with China were not confined to trade. There were cultural exchanges between the two countries. The countries with which Sri Lanka maintained relations include Greece, Rome, Egypt, Arabia, Afghanistan, and Persia on the west and China, Korea, Japan, Malay-Indonesian Kingdom in the east (Bandaranayaka 1998). At the same time relations with India remained at a high level. As Weerakkody (1997: 139) has pointed out Sri Lankans themselves had gone to foreign countries on business, and owned ships of considerable size. The Chinese writer, Kien Chang found people from Sri Lanka in Canton. Also a Javanese inscription belonging to the eleventh century mentions Sinhala merchants putting in at ports there (Weerakkody 1997: 139). This evidence indicates that ancient Sinhalese knew a large part of the civilized world. The continents of Americas, Africa, and Australia were not known to them. The world they knew in ancient times is depicted in Fig. 2.

Knowledge of the Island

The dry lowlands of Sri Lanka received early waves of immigrants from India and continued to be the main areas of population concentration up to about twelfth century. Although available evidence shows that the Wet Zone was inhabited since the Stone Age, evidence of major population centres is found only in the western lowlands, where the Kelani Kingdom existed. There are however some references to villages and places of religious importance in the Wet Zone. The Wet Zone highlands were a part of the *Tri Sinhale*, the three provinces the country was divided into. Distribution of stone inscriptions is often taken to indicate the distribution of the ancient settlements in Sri Lanka (Perera 1978). The high concentration of inscriptions in the Dry Zone lowlands can be interpreted as evidence of ancient settlements in that area, and absence or low density of ancient inscriptions in the Wet Zone (both lowlands and highlands) may indicate that these areas were not densely populated at that time.

A number of villages were involved in various crafts and functions, such as industrial, agricultural, King's service, etc. According to Perera (1978) there were four types of settlements in ancient Sri Lanka:

1. *Gama*: Consisting of paddy fields, gardens, and chena. The people belonged to the same caste.
2. *Nigama*: Larger than *Gama* and a market town where traders met.
3. *Patun Gama*: More urbanized than *Nigama*. Both local and foreign merchants traded. These settlements were situated by the shore and usually had a harbour.
4. *Pura* or *Nagara*: Urban settlements, usually seats of government, with streets. Both local and foreign merchants met.

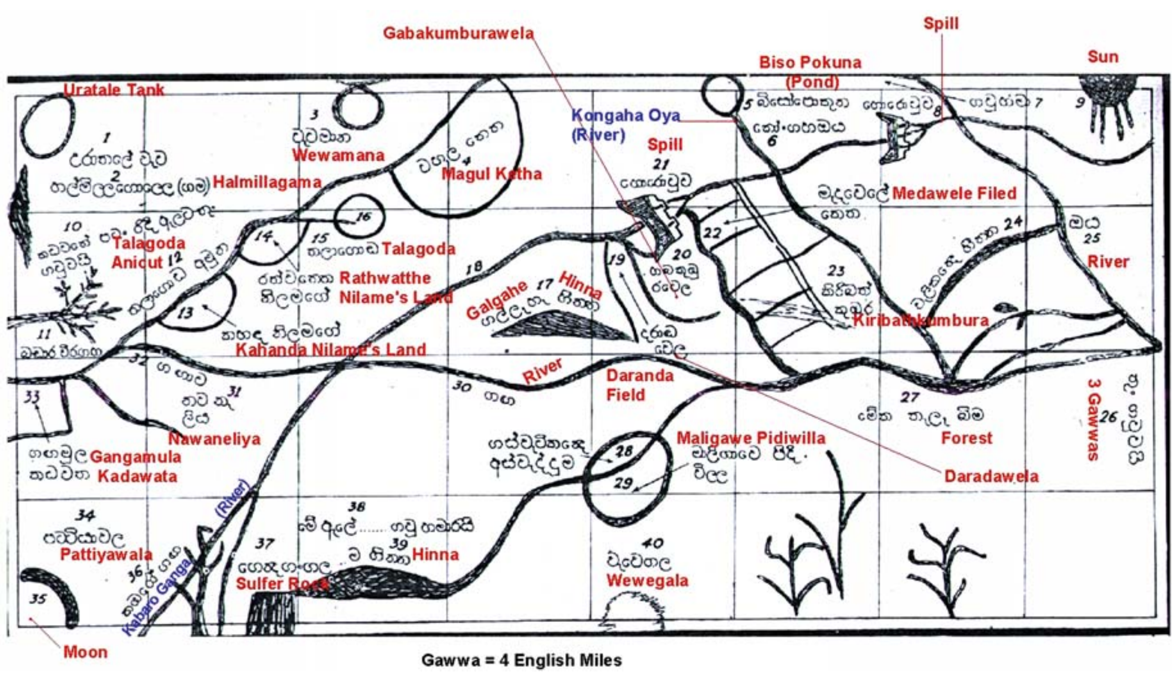
These villages were given names based on a salient characteristic of the village, and it is often its geographic character. There are many village names indicative of land forms, habitats, minerals, or man-made structures such as village tanks. The frequency of a certain name of a landform as a prefix or suffix to the village name indicates the dominance of that landform in the area. For example in the midcountry areas, there are many village names with '*deniya*' which means a valley. This area is characterized by the presence of a ridge and valley topography, and the people have shown a preference to settle in such areas for the reason that they are suitable for paddy cultivation. Some villages are named after a dominant plant or animal species present in the area.

The island has been under one monarch from time to time or split into several kingdoms when there was no strong ruler to unify the country. Unification of the country led to wars which made it essential that the warring armies were acquainted with the terrain. From a very early stage, the different parts of the island were well interconnected by major routes. The chronicles and commentaries speak about five main highways. King Nissankamalla (1187–1196), according to an inscription, fixed *guavas* (2.25 English miles) on the main highways and laid inscribed stone pillars (Nicholas 1959). Buddhist pilgrims from all parts of the island used to visit Adam's Peak (*Sri Pada*) mountain on top of which the foot print of the Buddha is supposed to have been placed. Long distances were covered to reach the *Sri Pada*.

The *Sandesa Kavya* (Message Poems), composed in the Kotte period (fifteenth to sixteenth century), were written to dispatch a bird as a messenger with a message to kings and deities. The route to be taken by the messenger is described in detail in poetry, which contains a geographic description of the landmarks the messenger would encounter in its journey.

Cartography

The oldest known map that has survived goes back to the seventeenth century based on a claim by the person in whose custody it was kept (Fig. 3). This map shows "certain lands and the topography including the



irrigation system in the valley of the Amban-Ganga, near Elehera, in the District of Matale" (Brohier 1951: 192). It has been drawn on a closely woven fabric (40 in. × 80 in.). A reproduction of this map has been published by Brohier (1951) together with the corresponding portion of the one-inch map of the area. The two maps show a remarkable resemblance. The scale of the map appears to be about one inch to a 1/4 mile, but this is not consistent throughout the map. The distances on the map are given in the Sinhala mile of *gauwa* which is about 4 English miles. The relative position of geographic features is accurate. There is no information about authorship of the map, or for what purpose it was produced. The directions are indicated in the map using the rising sun (east) and the waning moon (west). Brohier (1951) is of the opinion that the cartographer of this map was not familiar with the compass. If the author of this map learn the art of mapmaking from the Portuguese who were in the maritime provinces of Sri Lanka since 1505 and the Dutch later, he would have known to determine compass direction. Without more of such evidence, no firm conclusion can be drawn about the history of mapmaking in Sri Lanka. Given the need of such a practice in order to design irrigation canals, paddy lands, and reservoirs, it is conceivable that some form of mapmaking tradition existed in Sri Lanka. Maps may have been drawn on perishable material and therefore no evidence was left for the present generation.

Land Surveying and Design of Irrigation Systems

Without a clear understanding of the characteristics of the topography, construction of large reservoirs, tank cascades, and laying out of canals in an almost flat terrain would not have been possible. These irrigation works and their design can be used as indirect evidence of this knowledge. The early settlers of Sri Lanka chose the dry lowland plains for their settlements despite the severe water shortage during much of the year. This natural constraint was overcome by constructing first what is known as village tanks throughout the settled areas for irrigation as well as domestic use. Later, with an increasing population to be fed, it was discovered that these works were insufficient to last the dry season. This led to the development of large scale irrigation systems such as large reservoirs to store water by damming streams originating in the Wet Zone highlands. To convey water to paddy fields a system of main and distributary canals were constructed. They made decisions on the way canals are constructed, placing of sluices, and constructing dams in an undulating plain taking advantage of the topography. This point can be illustrated using the example of the trans-basin canal, *Yoda Ela* (Giant's Canal), running from *Kala Wewa* reservoir in the *Kala Oya* river basin to the *Tissa Wewa* of *Anuradhapura* (the ancient capital of Sri Lanka) located in the *Malawathu Oya* basin. This canal has a gradient "for the first 17 miles (27 km) of 6 inches" (Brohier 1979: 8). This shows the extent to which the ancient irrigation engineer understood the hydraulic principles and was able to convey water for long distances efficiently in a gently undulating terrain. Further evidence of the knowledge of the ancient Sinhalese engineer can be illustrated by a case where a branch canal from the Yoda Ela constructed by modern engineers some years back was later discovered to have run along the trace of an ancient canal which was used to irrigate the same lands using the water from *Yoda Ela*.

Another example for the extent to which the ancient Sinhalese understood the topography is the construction of village tank cascades in the Dry Zone of Sri Lanka (Fig. 4). "A cascade is a connected series of tanks organized within a micro-catchment of the Dry Zone landscape, storing, conveying and utilizing water from an ephemeral rivulet" (Madduma Bandara 1985). They are constructed taking advantage of the topography along the tributaries of Dry Zone streams. There are 127 tank cascades in an area of 1,225 km^2 covered by the Anuradhapura and Medawachchiya one inch topographic maps alone. This amounts to one cascade per square km. Over 85% of the operational tanks are located in cascades. The tank cascades allowed the optimal utilization of meagre water resources of an area. Each tank is associated with a paddy field, and the excess water from the paddy field returns to the tributary to be input to the tank downstream. The size of the tanks in a cascade tends to increase towards the lower end. The cascade system is reckoned to be one of the most efficient systems of water storage, conveyance and irrigation.

The ancient Sinhalese had a remarkable knowledge of the island as well as the South Asian region, and the countries in the west and the east. Their knowledge was not confined to the knowledge of places, but included such areas as the characteristics of the earth as a planet.

An area that should receive a great deal of attention and in-depth research is the knowledge the ancient Sinhalese had on harnessing water resources of the country. Construction of artificial irrigation systems of colossal magnitude and conveyance systems is a remarkable technological achievement. The most surprising of all is the ability to design these systems with such precision with minimal equipment. They seem to have had an intimate knowledge of the terrain which they utilized to the maximum extent in designing and constructing irrigation systems.

After abandoning these systems for largely unknown reasons, the population moved into the lower parts of the hill country and again used the topography of the terrain to their advantage to protect themselves from enemy attacks. The new settlements were established in the hill country which was completely protected by natural barriers, and entry was possible only through narrow mountain passes which were well guarded.

Although mapmaking would have been an immense help to the designers of irrigation system, no evidence is found on a cartographic tradition in Sri Lanka, except for a Sinhalese map attributed to the seventeenth century. This is surprising given the fact that locating of reservoirs and construction of canals would have to be carefully designed and planed.

A substantial amount of original material is available for careful examination and study. It would be a rewarding exercise which could reveal depth of geographical knowledge of the people who lived in this island for over 3,000 years.

Geographical Knowledge in Non-Western Cultures

NANCY HUDSON-RODD

Cultures differ in their assumptions about the nature of life, the place of their existence, and the place of humanity within their environment. Places, like space and time, are constructed socially and culturally and as such can provide ways to understand the literal and metaphorical geographies of humans. The specificity of place derives from the fact that each place is the focus of unique mixtures of wider and more local relations between social groups, and it is this mixture which accumulates continually to create the distinct place. While distinguishing labels, for people involved in these social relations, such as woman, Canadian, Maori, can be starting points, no one person or one group is exclusively one complete identity, Western, or non-Western, in the end of the twentieth century.

Human cultures are neither essentially coherent nor wholly homogeneous. The borders between nations, classes and cultures have become more fluid. The very notion that the majority of the world's population is defined by not being something (in this case non-Western) infers the continuing power of the past legacy of European and more recently American colonialism or imperialism. The majority of the world's population are non-Western. They did not originate from Europe's colonial expansion into the Americas, Australia and New Zealand.

This geographical inquiry into the historical experience of non-Western cultures is made from the perspective of a Western woman, a cultural/historical geographer, born in Canada, now residing in Australia. A renewed concept of culture refers not to any unified entity. In a post-colonial world, the idea of an authentic culture as an internally coherent world is no longer tenable. Increasing global interdependence has made it clear that neither "we" nor "they", Western nor non-Western cultures, are neatly separated and mutually exclusive. All of us inhabit an interconnected, late twentieth century world, marked by porous national and cultural boundaries that are enmeshed with power, domination and inequality.

It is however, impossible to deny persisting continuities of long standing traditions, literate or oral, sustained habitation and cultural geographies of non-Western traditions. Human history is rooted in the earth. To understand this history, it is necessary to consider human dwelling and also to realize that European expansion meant the taking of land which was already owned by indigenous residents. With the beginning of European expansion in 1500, most indigenous peoples lived on their lands practicing agriculture, hunting and gathering. While all of these people have expanded geographically into adjacent territories, or into lands near where they once lived, there is no comparison with the great spread of people from European nations. It has been this modern colonialism which forced many indigenous peoples off their own land: Aborigines of Australia, Maoris of New Zealand, the indigenous peoples of North and South America. This compulsion of the Western world to explore, conquer, occupy and own other lands has involved such a long continuous process that it has been called the distinctive Western characteristic.

In contrast, a deep sense of belonging to the land, is central to the identity of indigenous peoples throughout the world, as exemplified by this Maori statement, that while "people disappear, land remains; land doesn't belong to the people, people belong to the land" (Yoon, 1986). The names many of these First Peoples call themselves, such as Inuit, Maori, Saami, mean "people" and the names of their places mean "land". They literally know themselves as people of the land. "We have opted to become part of the environment", explains Burnum Burnum of Australia. Although differing widely in their customs, culture, economic status, physical surroundings, and impact on the land, many indigenous societies often share a set of values that are in marked contrast to Western priorities. The Cree of Quebec, San of Kalahari and Tukano of Brazil are all connected through a profound relationship and spiritual attachment with the land.

Human beings have created various cultural space and time systems in order to maintain their unique spiritual relationship with the universe. Before the dominance of Western ideas and colonial empires throughout the world, literate societies of Japan, China and India were eloquent in describing their human relationship with non-human species and their place within the greater environment. Oral traditional societies had highly developed constructions of their environments which were transmitted through stories, dance and by paintings to successive generations. For non-Western peoples, although widely different in customs, culture and impact on the land, there was a shared belief in a deep bond with nature, an awareness that all life, rivers, skies, people, ants and rocks were inseparably interconnected. Physical and spiritual worlds were woven together in one web. Humans were not separate from nature but were a part of the nature of the world. Geographical knowledge concerning human and environmental nature is always socially and culturally construed. Through specific examples from non-Western cultures of both literate and oral traditions, an understanding of the diversity of specific geographical knowledges can be explored.

The Mythic Creation of the World

Each culture possesses creation myths which speak of the creative beginnings, an energetic phase prior to the appearance of physical matter and life. Marriage between the Ancestral couple is common to creation myths of India, Egypt, Mesopotamia, China, Central America and New Zealand. In all these myths, creation is sparked by a cosmic copulation. The intercourse of Geb and Nut in Egyptian mythology and that of Shiva and Paravati in the Indian myth, and Ranginui and Papatuanuku, the primeval pair in Maori myth, reflect creation themes. The vision of the sacred earth as a ledger of cosmology is unique to Australian Aborigines with their creation story written like a book in the earth's topography.

There is evidence of great length and complexity in Australian Aboriginal culture, the oldest continuing society in the world, reaching back to the Pleistocene Age which is based on the remembrance of the origin of life. Aborigines speak of the forces and powers which created their world as Creative Ancestors. During this epoch of world creation called the Dreaming, the Ancestors travelled across a barren flat terrain. Their hunting, loving and fighting shaped the land, deeply marking the surface of the earth and leaving their imprints forming the topographical landscape, making riverbeds and forming rocks and deserts. Before their travels, the Ancestors would sleep and dream the adventures of the following day. In this way, moving from dreaming to action, they had the ability to alternate between pure spiritual powers and an apparition of other forms. In Western scientific language, the earth evolved through a phase of powerful geological and climatic forces which shaped the earth's crust, creating mountains, oceans and rock formations. The main difference between these two myths is that Western scientific description acknowledges only physical forces, while Aboriginal explanation attributes consciousness to the creative forces and to everything created.

The Dreamtime epoch concluded with three fundamental conditions making possible the embodiment of conscious life: the earth's distinct topography, all variety of species of life, and patterns for social relationships. With the completion of this task, the Ancestors grew weary as the world was shaped and filled with species and varieties of ancestral transformations and they retired into the earth, the sky, the clouds and the creatures to exist like a potency within all that they had created. Their journeys were preserved in stories, paintings, ceremonies and patterns of living and extended a universal psychic consciousness to every living being as well as to the earth and the primary forces and elements.

The Western tendency to view land as material object, existing separately from humanity, allowed for it to be bought, sold and exploited. In contrast, Aboriginal culture shared the identity of the forms, principles and activities by which the natural world was created and saw life and sustenance embedded in the landscape which must be cared for as a friend and provider in continuing reciprocity. "With the birds, the fish, the animals, the plants and all of nature we are still Yorro Yorro, standing up in accordance with the blueprint of Creation", explains Mowaljarlai, concerning the role of men in maintaining the connection between cosmic regions and earthly community life in the Kimberley, Western Australia.

Understanding Nature and Humanity

Generally, the Japanese philosophical and religious traditions represent a holistic ecocentric view characterized by an aesthetic and material oneness with all things. In pre-industrial Japan, the intimate relationship between people and their surroundings can be grasped by the Japanese word *fudo*, which translates into the natural environment. While nature and humanity have been viewed as separate but connected in Western thought, fudo refers to the idea that nature and society are inseparable. *Shi-zen* or *Ji-nen* is the Japanese word which most closely corresponds to the European term nature. The connotations of this term signify a concept of nature in which nature is not objectified. Rather, *Shi-zen/Ji-nen* represents the manner of being and becoming of nature, human and environment. *Shi-zen*, originally a Chinese word, was adopted by the Japanese about 1,500 years ago. In ancient Chinese culture, the term had fundamental significance. Lao-Ze wrote: man is based on earth, earth is based on heaven, heaven is based on the Way (*Dao*) and the Way is based on nature (*Zu-ran*, or *Shi-zen* in Japanese).

The contrast between European and Japanese garden design illustrates the difference in perspectives of nature. In the English garden, a person seeks escape from humanity into a natural space free of artificiality. In the Japanese garden, one tries to express, within a defined space, the totality of mountains and rivers. This is an artistic, human act representing the highest meaning of *Shi-zen*. The English garden is a public place, open to all. The Japanese garden is of a private nature created solely for the few who are artistically gifted. Nature relates equally towards all in the English garden. The *Shi-zen* of the Japanese garden requires those who are able to experience *Shi-zen*. This implies that *Shi-zen* can never be separate, but within the person.

It is the same for Ikebana art and the *Shi-zen* of the tea-ceremony. In the Japanese tea-ceremony, the everyday routine becomes an art form. Sitting in a quiet, small room allows for the mind and body to become alert to the slightest sound, movement of the wind, perfume of flowers, changes in the intensity of light. This time passed within a small room heightens the sense of place by creating a moment of spiritual connection with the environment.

Sense of Place

The sense of place exists in the area where nature and humanity interact and shape each other. Within cultures, information concerning the geographical environment is expressed in certain ways, such as the making of maps, conceptualizing landscapes, and giving places names. In the Pintupi language of Central Australia, a place, or a country, or a camp is called *ngurra. Ngurra* signifies both the physical place where people share food, sleep, and dance, and also the metaphysical act of dreaming the country into existence. In this way, the question of Aboriginal identity is obtained by knowing the place. As Kuningga, the ancestral cat, travelled north he crossed plains, identified water sources and, after reaching a ceremonial site, continued north through a gap in the range. Kuningga's dreaming track weaves north, describing the particular geography of the land and of the natural resources contained within through a song cycle. Thus Kuningga's song can be understood as an oral map of the country. Places where significant events happened, where power was stored, or where the Ancestors had retired into the ground and still remain today are known as *Yarta Yarta* or special sites because of their concentrated ancestral potency.

Certain landscapes create a sense of awe by their presence. In Japan, Mt. Fuji, rising 13,000 ft above sea level, has been depicted in poems, paintings and stories from ancient times. The sheer physical presence of mountains which appeared to connect the earth with the sky allowed for them to be considered Japanese shrines. The word *oyama* sometimes means shrine and is derived from *yama* (mountain). Tadahiko Higuchi in his book *The Visual and the Spatial Structure of Landscape*, described seven protoype shapes for shrine and temple complexes which were translated by Kazuo Matsubayashi. They are:

1. Water-distributing: where water flowed out of the mountain creating a perfect rice irrigation place
2. Bowl: a small, peaceful, plain surrounded on all sides by green mountains
3. Lotus Flower Calyx: the site of a mountain temple surrounded by eight other mountains, which resembled the calyx of a lotus
4. Wind and Water (*fusui*): usually having mountains to the north, hills to the east and west, and a sea or river to the south, which was the ideal place to build a city, house or tomb
5. Valley: enclosed by mountains on both sides, which was thought to be the home of the spirits of the dead
6. Thickly forested: a small mountain covered in thick foliage in sharp contrast to its situation near a flat plain, which was believed to be the sacred dwelling of a god
7. Country-viewing: a low hill or mountain standing in the middle of a plain, commanding a view of the surrounding land

The close relationship between the people and their mountainous environment, with each of the types serving a unique purpose, demonstrates the vital reciprocity between humanity and nature.

In Maori tradition, the special relationship between people and their land is revealed, first by the myths explaining the origin of the universe, in which the material world proceeds from the spiritual and the spiritual world interpenetrates the material, physical world of Te Ao Marama, and secondly by the use of dominant landmarks, mountains, or water sources, as symbols of tribal identity. While many indigenous peoples live intimately with nature, the Maori appear to be unique in their formulation of their *pepeha* or popular sayings of tribal identity. Every established Maori community may apply their standard *pepeha* or introduction by naming their mountains, river and tribe at intertribal meetings, now as in the past, actively maintaining the oral tradition and identity of place.

Makeo is the mountain – Ko Makeo te manunga
Waiaua is the river – Ko Waiauna te awa
Tutamure is the Ancestor – Ko Tutamure te tangata

Hong-Key Yoon has described the pattern of structure of these sayings which includes the first two phrases for natural identity in terms of landscape and the third for cultural identity in terms of people. The first phrase mentions the most significant landform, almost always a *Maunga* or mountain followed by the second phrase giving the name of a prominent body of water or *te wai, te awa* or river, *te awauni* or big river, and *te moana* or sea. The third phrase names the tribe, giving social and cultural identity. Maoris associated intense feelings with the mountains, considering them to be the place of buried ancestral bones, while the valleys and rivers, often serving as tribal boundaries, did not assume as intense a sanctity.

These *pepeha* revealed the symbolic relationship of the people within their place and were combined with the functional territorial boundary delineating home territory, while also perpetuating cultural heritage. Today, the Maori traditions of respect for place are represented by the Maori Secretary in the Ministry of the Environment. The name of their movement, *Maruwhenua* comes from the understanding of the human responsibility for protecting the land. Mmaruwhenua reflects the saying, "People perish, but the land endures".

Sustaining Natural and Human Place

Indigenous knowledge of nature has ensured the survival of many peoples living in fragile habitats. For example, the Tuareg of West Africa practice nomadic pastoralism in a land so arid that it cannot sustain continual habitation, and the Inuit of the frigid Arctic regions have traditionally depended on hunting and fishing. Modern hunting and gathering depends on cooperation between group members and the formation and maintenance of economic relations with other groups. In Ituri, the tropical rainforest of northeastern Zaire, a mutually supportive, economic relationship has been created between the Efe, who practice a semi-nomadic lifestyle, and the Lese, who live as shifting cultivators. The Efe trade forest products, nuts, construction materials, meat and fish for produce grown by the Lese, and for their pottery, tools and arrows.

In many areas of the world, indigenous societies have classified soils, climate and animal species. Many of these words and descriptions for insects and plants are yet to be known by botanists or entomologists. The Hanunoo people of the Philippines distinguish 400 more plant species in their forests than the 1,200 ones identified by the scientists working in the same location. The Kayapo of Brazil gather about 250 types of wild fruit, hundreds of tubers, leaves, and nuts, and at least 650 plants which are used for medicinal purposes. This vast, complex, indigenous knowledge is now viewed as being important not only to the sustenance of the traditional owners, but to the very survival of the world.

The human relationship to the natural environment has been conceptualized differently over time and through space. At the end of the twentieth century, understanding of the human experience of nature, from both a Western and non-Western cultural tradition, has become an urgent imperative. The challenge now is to regard humanity and earth in global terms while also seeking an understanding of the social and ecological implications of the whole of humanity planetized. There has been much discussion concerning the damaging perspectives of the Western, anthropocentric approach to nature which has led to actions based on a premise of the separation between mind/body, human/nature and individual/society. This view has been blamed for much of the environmental destruction and exploitation of the world's human and natural resources. At the same time, there have been appeals to consider alternative modes of conceptualizing humanity and nature, such as developing a reverential attitude towards nature and acting in a socially cooperative manner, based on a non-Western, ecocentric perspective.

Cultural expressions, Western or non-Western however, show a universality only at the broad structural level. To go beyond this, it is necessary to explore the specific historical contexts of human habitation in place and through time. Non-Western and Western cultures are historically dynamic. It is important therefore to emphasize the particular and convey the diversity of traditions within and between groups, in order to create mutual understanding.

Geography in China

Mei-Ling Hsu

The term geography (*di li*) which first appeared in Chinese documents during the Spring–Autumn period (770–476 BCE) literally meant the study of the order and morphology of the land. In the beginning the purpose of such a study was for survival; later it was used to facilitate the production of food and gathering materials for shelter. Agriculture was central to the economy, hence information was collected on climate, land, and water supply, and for crop cultivation and water control, e.g., to construct dikes. Because of these needs, studies in "geography of production" increased. Thus the Chinese have accumulated much geographic knowledge since ancient times.

The two frequently cited geographic classics are *Yu Gong* and *Di Li Zhi*. They demonstrate the importance of geography in delineating major regions in the country and in collecting locational information; these geographical applications facilitated the governing of the ancient Chinese empire. Mapping of large regions and local areas followed.

Yu Gong (The Tribute of Yu, who was a semi-legendary emperor) is a short but brilliant work, written in the Warring States period (475–221 BCE). It presents chapters on mountains and rivers, and on two methods of organizing geographical space: delineating nine physical regions, and allocating five political regions in China. Thus this work presents the earliest examples of regional and systematic geographies.

The term geography was first used as a title of a work in *Di Li Zhi* (Treatise of Geography), a chapter in the *Han Shu* (History of Han Dynasty), by Ban Gu (AD 32–92). It includes three sections, of which the first and third were reprints of earlier works, including *Yu Gong*.

The second section is devoted to the geography of 103 prefectures (*jun*/*guo*) and their subunits, the 1,587 counties. Within each administrative unit, some physical, cultural, economic, and demographic features are described. Cities are mentioned. Interestingly, it also describes petroleum as some kind of liquid that can be burnt. However, the major focus of this work is on the history and changes of boundaries of administrative divisions and settlements; such information was important to the governing of a large empire. Unfortunately, too often this particular focus was emphasized at the expense of a more thorough treatment of the physical characteristics of an area, and their effects on the inhabitants and the economy.

The publication of *Di Li Zhi* marked the beginning of a chapter on geography to be included in a dynastic history; this chapter appeared in the second of the 24 such histories. Thus the content and the methodology presented therein became a model that was followed in the later dynastic histories.

Ban Gu's work also planted the seeds of a later development: the publication of local gazetteers (*di fang zhi*) with maps included in these volumes. Beginning in the fifth century, the production of these gazetteers increased in number and gradually became the most prevalent form of geographic writing and compilation in pre-modern China. During the Tang Dynasty (AD 618–907), the scope of some gazetteers began to expand to cover a province and even the whole country; some of these compilations were multi-volume and were really geographical encyclopaedias. Today they constitute a voluminous geographical and historical literature.

Beginning in the Tang Dynasty, field studies became more important. Perhaps, by this time, long distance travel in China had become more manageable. Noted scholars spent many years away from home travelling and studying the country. They left with us their vivid descriptions and insightful interpretations of the geography of China. Among these books, the best known is the *Xu Xiage Yuji* (Dairy of The Travels of Hsu), written in the seventeenth century. Thanks to the efforts of these scholars, accurate geographical knowledge was accumulated, e.g. of the source of the Huang River, the process of erosion, and the retreat of the sea in the area of today's eastern lowlands. The last of these was studied by Shen Gua in the eleventh century; similar observations to that of Shen's were made in Europe by J. Hutton in the nineteenth century.

Despite the richness of the pre-modern literature, geography was not formally included in the civil examination in imperial China. Only during the late nineteenth century, as the modern school system was developed was geography incorporated as an instructional subject in schools. Today, in Taiwan and on the Chinese mainland, geography courses, which vary in area coverage and degree of difficulty, are taught in every grade in the secondary schools. The two major purposes of this instruction are to provide students with basic knowledge of China and of other countries in the world and to foster the spirit of patriotism.

In historical China, geography and cartography played important roles in scientific inquiry and applications. In this century, the subject geography is taught in schools and colleges, and mapping activities are routinely carried out by government agencies and educational institutions.

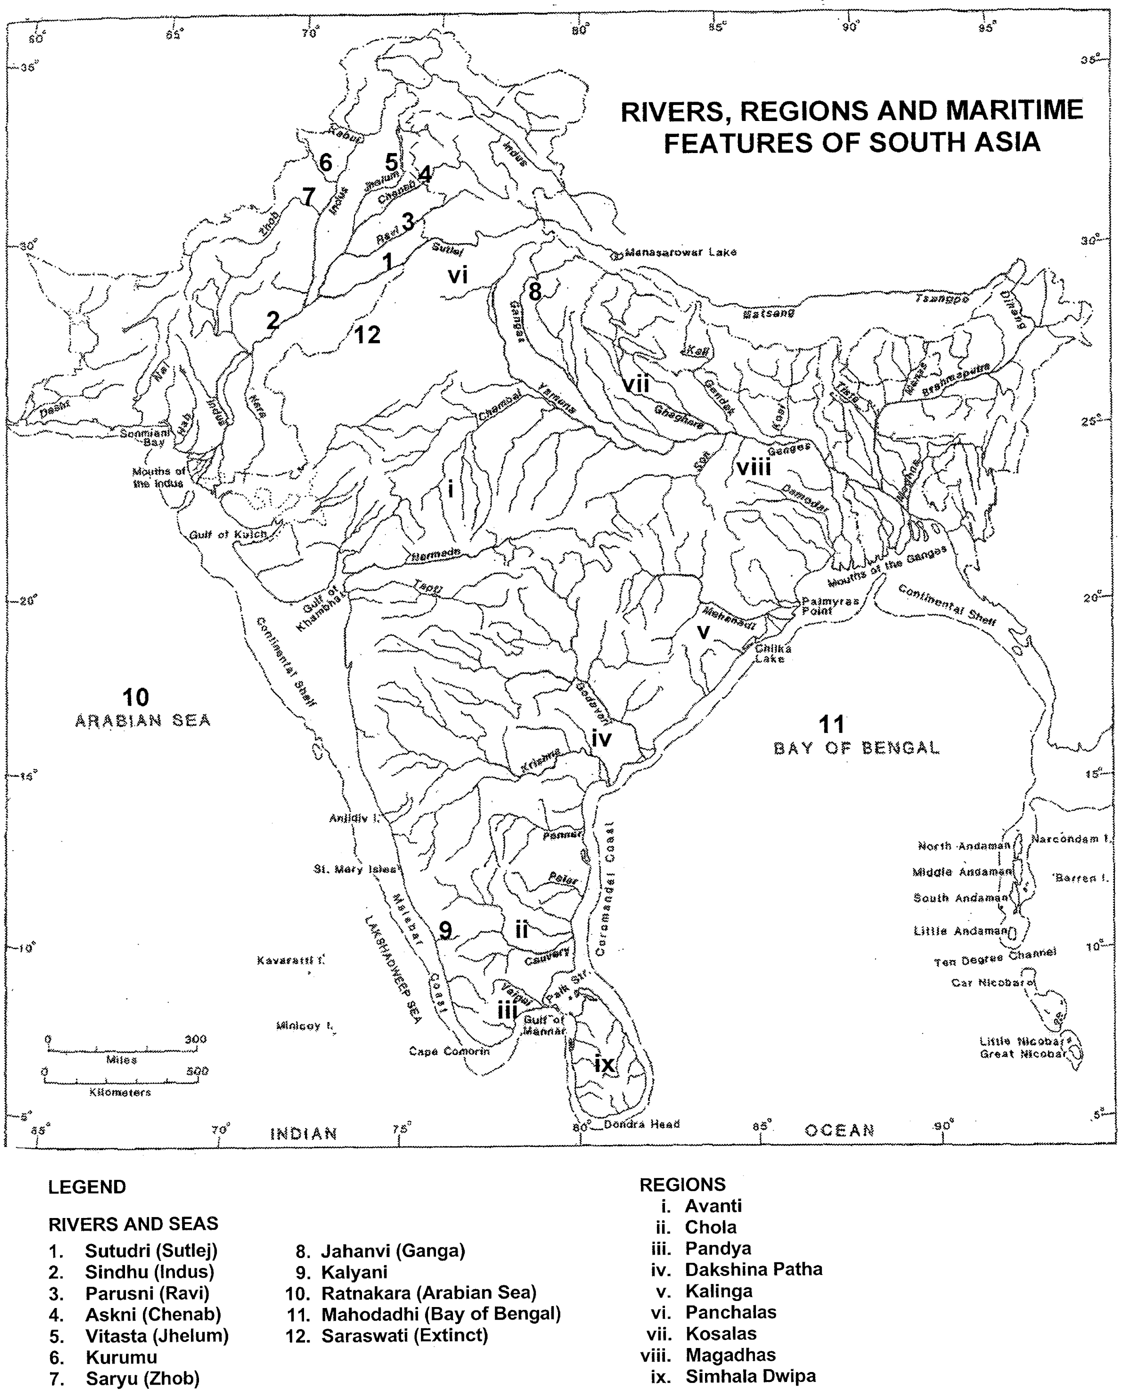
Geography in India

Ashok Dutt, Meera Chatterjee

The study of geography as a systematic science was a significant gap in Indian knowledge during ancient times. However, geographical facts were presented in a nonsystematic manner in the whole range of Sanskrit, Pali, and Prakrit literature. Compositions of a geographical character are often found embedded in the religious, legendary and astrological literature of ancient India. Both religious and secular literature contain numerous isolated references to cities, mountains, rivers, regions, and society, which collectively amount to a considerable addition to geographical knowledge. India is the home of an ancient civilization that originated over 5,000 years ago and attracted many travelers, scholars, ambassadors, and missionaries. Many conveyed impressions back to their compatriots through lively tales, anecdotes, and travel journals. These writings also became important sources of geographical knowledge. The writings of the Chinese, Greek, and Arab geographers are rich sources of information relating to various aspects of geographical science. Various names such as *Bhuvankosa* (Terrestrial Treasure), *Trilokya Darpaṇa* (World's Mirror) and *Kṣetrasamāsa* (Combination of Countries) were used to denote geographic phenomena. Hence, the principal sources of information about the status of geography in ancient India are sketchy because they are obtained from references extracted from nongeographical works, foreign accounts, and inscriptions. The ancient literature developed over the centuries could easily be arranged in a chronological sequence. *Ṛg Veda* (about 1500 BCE) was the first, which was followed by three other Vedas, *Sama, Yajur,* and *Atharva*. The *Upaniṣads, Purāṇas, Jātaka* tales and great epics – *Rāmāyana* and *Mahābhārata* were composed between 1000 and 500 BCE. Kautilaya's *Arthaśāstra* was composed around 300 BCE. Other than these, there are writings of different poets and foreign people that also help us to infer the geography of ancient India.

The *Ṛg Veda* is the earliest Indian literature that has been discovered. It mentions many geographical facts such as tribes, rivers, and mountains. According to Al-Bīrūnī (Alberuni), an Arab traveler in India, "Veda is knowledge of that which was unknown" (Kazmi 1995: 41). These and associated books contain knowledge about philosophy, mathematics, medicines, navigation, music, and dance. The *Upaniṣads* are works on religious meditation (Tamaskar 1985). It is difficult to find any direct description of the earth or the world, but, as in the *Ṛg Veda*, geographical phenomena or features are embodied in them. Like the *Vedas*, the *Purāṇas* also did not deal with geography in a systematic manner; however, they have a lot of geographical facts in them. The scientific material covers a wide range of topics from astronomy, cosmography, and cosmogony to the classical concept of region and regional classification. As defined by Alberuni, *Purāṇa* means "first eternal" and the *Purāṇas* are associated with the names of animal, human or angelic beings. *Purāṇas* not only contain mythical and legendary materials, but also contain scientific information, which is sometimes accurate. Information about astronomical geography can be easily extracted out of the *Purāṇas*. *Jātaka tales* are a huge source of unsystematic geographical information. The legendary stories contained in the *Jātakas* relate the previous lives of Gautama Buddha, the founder of Buddhism. He lived and preached in northeast India between 563 and 483 BCE. As there was no written common language, the stories were memorized and handed down from generation to generation by word of mouth. Several hundred years later they were written down in the Pali language; in the process many facts were exaggerated or lost. The *Jātaka* tales were set in some contemporary kingdoms. Kautilaya's *Arthaśāstra* mentions the names of a few mountains, regions, and tribes. It also provides us with a lot of information about territorial sovereignty and geopolitical principles. The great epics *Rāmāyana* and *Mahābhārata* contain extensive geographical descriptions of north and south India, military geography, family structure and the presence of non–Aryan tribes. (*Mahābhārata* depicts the war that occurred about 900 BCE).

The Aryans, who brought the *Ṛg Veda* from outside the borders of India (possibly from Persia), first settled in northwestern India (Punjab and the Indus plain). They mentioned regional rivers and their branches, such as the Saraswati (extinct), Sutudri (Sutlej), and Sindhu (Indus) (Fig. 1). The rivers, seas and regions had different names in ancient India. A few of them are mentioned in Fig. 1.



Geography in India. Fig. 1 Rivers, regions, and maritime features of South Asia. Base map from Dutt and Geib 1998. Permission obtained from the copyright holders. The authors gathered the information on the names of the ancient rivers from various sources.

According to *Ṛg Veda,* Saraswati was the greatest and most powerful river that flowed from the mountains to the sea. The greatest and the holiest river mentioned was not the Ganges, but the dry Saraswati. The latest studies have shown that the Ṛg Vedic Saraswati was a perennial river. The confluence of the Ganges (Gaṅgā) and its tributary Yamuna are mentioned as the eastern boundary of the Aryan settlement. However the Ganges was mentioned only once, whereas the Saraswati was mentioned many times.

By the beginning of the Christian era, three other Vedas, epics and *Purāṇas* were written, and a more extensive description of Indian geography evolved. The Aryan settlements advanced eastward all the way to Bengal and toward southern India. The latter, though Dravidian in terms of linguistic and physiognomic characteristics, became Hinduized.

Ṛg Veda set the layout of an important aspect of social geography by stratifying Indian society into four different castes. (1) *Brahmins*, who were the interpreters of religious texts and handled all the scholarly literature, (2) *Khasatriyas*, the warriors and the rulers, (3) *Vaiśyas*, the merchants and farmers and (4) *Śūdras,* slaves who did all the hard work including cutting jungles to make land arable. Some of them were designated as untouchables. The following extract is based on *Ṛg Veda* explains the function-based, social hierarchy (four castes).

> The *brahmans* form the highest social order, the literate intelligentsia which gave India its priests, thinkers, law-givers, judges, and ministers of state. The *rajanyas*, later called *khsatriyas* or rulers, were the second social order. The Indian counterpart of feudal nobility: from this class was recruited kings, vassals and warriors. The *vaishyas* formed the class of landowners, merchants, money-lenders, while the *śūdras* originally those people conquered by Aryans, were workers, artisans, or serfs. (*Ṛg Veda*, 10.90, as cited in De Bary 1967: 13–14.)

The caste system still persists among the Hindus. As most of the Muslims and Christians in India are converted from Hinduism, many of them have retained their caste distinction.

Ancient Indians also knew about the land and water ratio on the earth's surface. Though they did not have accurate knowledge of the ratio, they believed that oceans occupied twice as much area as the land surface on the Earth. In the second *Anuwaka* of third *Brāhmana* of III *Adhyaya* of the *Bṛihadāranyaka-Upaniṣad* it is said, "The oceans surround this earth on every side twice as large" (Tamaskar 1985: 7).

The Himalayas were mentioned in *Upaniṣads* as the "White Mountains" because their upper reaches are snow clad year-round. The rivers flow out of this mountain chain in an east and west direction. They have also been referred to as a powerful barrier for invaders, thus acting as natural borders.

The river Ganges is mentioned in the *Vayu-Purāṇa* as a purifier of sinners, passing through thousands of mountains and irrigating hundreds of valleys thus establishing the importance of rivers in the environment. *Matsya-Purāṇa* also mentions the rivers of Jambū-dvīpa (consisting of most of Asia) and Bharatvarsha or India (the southernmost country of Jambū-dvīpa) rising in the ranges of Himavanta (Himalayas). It was in *Kausītaki* that the southern mountain – Vindhyas – was first mentioned, while both *Vasishṭa Dharmasūtra* and the C*ode of Manu* referred to the Vindhyas by name. *Rāmāyana* and *Mahābhārata* give extensive descriptions of geographic features of both north and south India. When King Dasaratha (in *Rāmāyana*), father of Rama, performed an *Aśvamedhayajaña* (Horse Sacrifice) to establish his supremacy over the world, both north and south Indian kings were referred to. In the *Bhīṣmaparva* section of the *Mahābhārata*, Sañjaya, the chariot driver of the blind king Dhṛitarāstra, identified the nations, mountains, and rivers of India. Epics also describe Hastināpur (situated by the side of Ganges), capital of the Kauravas, Indraprastha (situated by the side of Yamuna), capital of Pāṇḍavas, Ayodhyā (in Uttar Pradesh), capital of Rāmā and the city of Mithilā (in Nepal terai). In the *Rāmāyana*, the city of Mithilā, possibly Janakpura in Nepal terai, is referred to as a "city of color and pleasure with people enjoying the business of living." It had "golden turrets and domes, and lofty towers." The book also says that, on the eve of Sītā's *Swayambara* (a ceremony in which the princess selects her groom from among the invited guests), there was a "moat" surrounding (King) Janaka's palace (Narayan 1972).

The *Jātaka* tales were set in some contemporaneous kingdoms. The topographic features are embedded in the tales. The Himalayas were mentioned many times. References to small water bodies (ponds) can also be found. Mostly the stories were woven around animals; this referred to the conservation of wildlife. The tales mentioned the coexistence of carnivores and herbivores, a condition required in nature for a balanced ecology. They frequently refer to thick forests which indicates that the Himalayan and sub-Himalayan zones and parts of the Deccan plateaus were once covered by dense and luxuriant forests. Numerous species of plants and trees were also mentioned. Cultivation and rearing of animals were the principal occupations of the population, although there is a mention of nonprimary activities, such as mining, textiles and trading. The *Ṛg Vedic* literature talks about the abundance of water in North India brought about by melting of ice caps. Present arid regions like Thar and Rajasthan deserts and the deserts of Sind were once fertile and supported agriculture.

Permanent settlements and agriculture led to trade and other occupational differentiation. Aryans after settling in Pañchāla (Punjab and Haryana) started colonizing the central and eastern Ganges plains and advanced to the Ganges delta in Bengal. From east to west there is a progressive diminution of Aryan traits among the population. As the Aryans advanced eastward, more slaves and śūdras (tribals, vanquished people and Dravidians) were used to clear forests in order to make the Ganges and other plains cultivable. The eastward terrain was inhospitable, wet and disease laden and had limited attraction to the Aryans. They employed slaves and śūdras in vast numbers, who performed the most difficult task of land reclamation. As lands along the Ganga (or Ganges) were cleared, the river became a trade route; the numerous settlements on its banks became markets and trading centers. The cities of Varanasi and Pāṭaliputra (Patna) are two important examples. As the majority of the settlements grew up along the river the probability of their being linear was very high. Trade was restricted initially to local areas, and barter was an essential component of trade, cattle being the unit of value in large-scale transactions, which further limited the geographical reach of the trader. Consequently, markets and the trading process were concentrated in some regions. Custom was law, and kings and chief priests were the arbiters, perhaps advised by certain elders of the community. An Aryan *rājā*, (king) was primarily a military leader, who took a share from the booty after successful cattle raids or battles. Although the *rājās* had managed to assert their authority, they scrupulously avoided conflicts with *Brahmin* priests as a group, whose knowledge and austere religious life surpassed others in the community. The priests were the educated group of the society and considered superior to other castes, and they also interpreted religious books.

Kautilaya's *Arthaśāstra* prescribed a state planned colonization policy for undeveloped (primarily natural vegetation covered) areas with people from foreign lands and kingdoms' surplus labor. Each village was to have 500 families, mostly śūdra cultivators or laborers; villages were to be grouped in a hierarchy of settlements of 800, 400, 200, and 10 units with a large town (*sthaniya*), small town (*dronamukha*) smaller town (*karvatika*), and large village (*samgrahara*) to serve each group, respectively.

Beginning with the *Ṛg Veda* through the *Purāṇas*, cosmological and cosmogonic interpretations of the causes of wind, precipitation, day and night, seasons, and the planetary movements were made. A four-way explanation of the origin of the universe was also given: artistic, mechanical, instrumental, and philosophical. First, the artistic origin refers to god as an artist who skillfully constructed the universe. Second, the mechanical origin is conceived as a sacrifice of the *Ādipuruṣa* (primeval body) who not only had the soul and the nucleus of the universe, but also embodied the Supreme spirit, resulting in the formation of the earth, sky, wind, moon, sun, and other terrestrial elements.

> The origin of universe from a primeval sacrifice, in which a cosmic being offers himself as an oblation, is not known in primitive mythological traditions. However, the sacrifice of the male Purusha here is not so much the primordial sacrifice of a world giant or the type *Ur-mensch* found in Norse or Germanic mythology, as it is a cosmogonic idea based on ritual sacrifice itself as the origin of universe. (Based on *Ṛg Veda* 10.90, as cited in De Bary 1967: 13.)

Third, the philosophical concept considered the beginning as an empty space with no atmosphere or sky. The universe was born out of its own nature, possibly by its own inherent heat. The *Ṛg Veda* also attempted to provide a scientific explanation of the mystery of the origin of the universe. Accordingly, the "creation of universe has started with the origin of water and the cosmic golden egg [embryo, *Hiraṇyagarbh*] which very well fits in the geological and biological evolution of the earth with the water age, origin of Zoophytes, primeval fishes, reptiles, invertebrates, vertebrates, and mammals"(Tripathi 1969: 3). It also said that water pervaded the whole universe which held fire in its womb. This indicates that during the Vedic age, the civilization was aware of the fact that the interior of the earth was very hot. The fire probably refers to the rising temperature beneath the surface. The importance and dominance of the water were also realized. The *Māhāpurāṇa* further crystallizes the idea that the world endures under its own nature and is divided into hell, earth and heaven.

Fourth, the instrumental origin idea is reflected in the union of heaven and earth caused by the action of different gods, such as fire (*Agni*), sun (*Sūrya*), and *Indra*. "The central idea of various cosmogonic theories of the vedic and postvedic period appears to be (1) existence of the water in the beginning, and (2) creation of the cosmic nucleus – *Prajāpati*" (Ali 1966). *Prajāpati* is an embodiment of propagation and hence maker of universe. In this concept, they also recognize the supportless movement of the heavenly bodies as iron pieces around a magnet in the sky. Puranic literature mentions solar and lunar eclipses several times although their true mathematical theory was not known. Therefore mystical explanations were advanced.

> The demon will obscure the moon and the sun at the end of the dark fortnight and the full moon. Entering the shadow of earth and moon, the swarthy-figured concealed demon will bring adversity to the moon and sun respectively (Tripathi 1969: 39).

The *Upaniṣads* spoke indirectly about the spheroidicity of the earth. The description of the rising and setting sun is mentioned in *Prapathaka III, Khanda* 6–10 to the *Chandogya-Upaniṣad*: "So long as the Sun rises in the east and sets in the west" (sixth *Khanda*) (Maxmuller 1900). The concept of the rising and setting of the sun was directly related to the shape of the earth. It has been

G

suggested that the sun's rays did not spread over the earth at the same time, but that they fell by slow degrees, suggesting that the earth was a sphere.

Jātaka tales also mention the rising and setting sun. The whole society seemed to try to have a proper balance with the environment. They frequently referred to the laws of nature which were important for their survival.

> The sun gets up each morning
> (And the sun is free)
> It goes to bed each night,
> Why not we?
> The clouds, the rain, the earth,
> This very Banyan tree,
> Obey the laws of nature.
> So do we!"
> ("The Oldest of the Three" DeRoin 1975)

There were six seasons: *Vasanta* (spring), *Grishma* (summer), *Varsha* (rains), *Hemanta* (early fall), *Sisira* (late fall) and *Seet* (winter) are recognized in Vedic literature. Seasons are also discussed in the *Upaniṣads,* but they identified only five, as *Hemanta* and *Sisira* were merged. In the region where the *Upaniṣads* were composed (Punjab Plains) it was difficult to differentiate between the two. The year began with *Grishma* (summer) and concluded with *Vasanta* (spring). Wherever it rained sufficiently, crops were produced; this implied regional variation in rainfall. Punjab, where Aryans settled first, is drier than the east (Bihar and Bengal). With the spread of Aryan colonies from west to east, it was possible to draw a comparative picture of rainfall. The correlation between availability of rain water and food production has also been established in the ancient documents, pointing to the absence of irrigation.

The ancient literature also described the racial composition of the population and their geographical distribution. The *Ṛg Veda* also mentions non-Aryan tribes. It talks about *Dasyus* (Dravidians) not tamed by Aryans, who were considered civilized and supported a matriarchal family system as opposed to the Aryan patriarchal family. The *Ṛg Veda* also mentions *Rakshasas* (demons), who were short, dark, thick lipped, fierce in appearance, curly haired and possibly of Negroid origin. They were considered hostile to Aryans. They did not worship fire. *Rakshasas* were engaged in guerilla warfare, attacking Aryans at night and stealing their cattle. Another tribe mentioned in the *Ṛg Veda* is *Paishachas*, who were ruddy in appearance.

The ancient literature discussed a cyclical human development on the earth. The Hindu view expressed in the *Laws of Manu*, speaks of four ages – *Kṛita, Tritā, Dvāpara,* and *Kali* with a sharp break at the end of each age. Physical and spiritual deterioration occurs at the completion of the four-age period with the universe coming to an end and then beginning a new cycle. The *Laws of Manu* also stated that the age of Gods starts with the *Kṛita* (Winning Age).

> In the Winning Age [*Kṛita*], religion is entire, standing on all four feet, and so is truth; and men do not acquire any gain through irreligion. But in the other [ages], through [such wrong] gains, religion is brought down foot by foot; and because of theft, lying and deceit, religion goes away foot by foot. In the Winning Age people are free from sickness, achieve all their goals, and [have] a lifespan of four hundred years; but in the ages that begin with the age of Treta, their lifespan grows smaller foot by foot" (*Laws of Manu* 1991).

Jainism adheres to the teachings of Mahāvīra who died in 468 BCE. He was a contemporary of Buddha. The Jains also believed in the cosmic cycles, but unlike Hindus they did not foresee any sharp end at the end of the periods (ages). The Jains divided a full cycle into six periods, each with ascending and descending halves. At the end of the sixth period, designated as "very wretched," human deterioration reaches its peak with a fierce storm wiping out almost all inhabitants. After this a new six-cycle period starts.

As discussed by Tripathi, *Vrhannardiya Purāṇa* provides valuable information on mathematical geography. It gives the radius of the earth as 800 *Yojanas* or 4,000 miles (1 *Yojan* = 5 miles). The diameter was calculated as 1,600 *Yojanas* and circumference as 1,600/10 or 1,600 × 3.162 *Yojanas.* It provided a formula for calculating the circumference of any latitude parallel to the equator. These facts show that ancient Indian society was indirectly aware of geographical facts and they also made an effort to work on it scientifically (Tripathi 1969: 40).

A section of *Atharva Veda* and the *Aitareya Brāhmana* refers to five geographical divisions of India, which remains valid today. Further details of the divisions are given in the two great epics *(Rāmāyana and Mahabharta)* and the *Purāṇas.* They contain some chapters giving a fairly good account of not only the different territorial divisions of India, but also rivers, mountains, lakes, forests, deserts, towns, countries, and people (Gupta 1973). India, as mentioned in the *Purāṇa,* is bordered by Himavat or the Himalayas in the north and by the seas in the south, but Puranic *Bhāratvarsha* stretched from the Himalayas in the north to the Southeast Asian archipelago.

The authors of the *Purāṇa* seem to have been acquainted directly or indirectly with the major portion of India. The concept of Hell as described in the Puranic literature covers a geographical region, which is inhospitable and uninhabitable. The road leading to Hell had extreme weather conditions (arid and devoid of water), marshy and swampy land, and very dense forest infested by dangerous animals. They knew that the planet earth had regions which were not conducive for human habitation. So the importance of a favorable environment to survive was known to the people. Living in unfavorable and dull conditions was equivalent to living in "hell." The *Purāṇa* also mentioned favorable sites for human settlements. Availability of water was the decisive factor. According to Tamaskar, sites of settlements during the Puranic age were associated with escarpments, summits of mountains or hills, riverbanks, situation near lakes or tanks, islands, seacoast and forests. Riverbanks were the most important of all the sites. In addition to providing water, they also served as a means of transportation for goods and humans. Modern settlement geography also finds the wet-point-sites as the most favorable for human settlement.

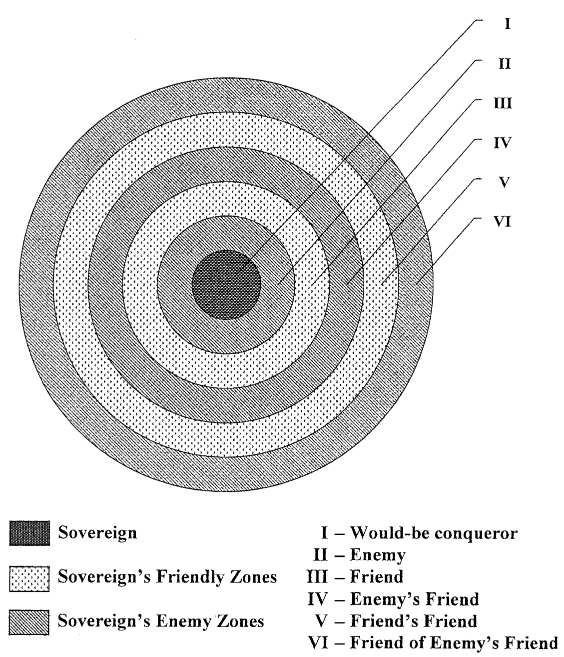
Different geomorphologic features were discussed in the *Rāmāyana*, such as mountains, plateaus, disintegrated rocks, cascades and falls, caves, etc. The mighty Himalayas were divided into three regions – the outer, the lesser, and the interior conforming to the present day classification. The *Rāmāyana* indirectly deals with economic and commercial geography. It mentions the trading relations between different regions, trading items such as horses of Kāmboja (Cambodia), silk goods and silver in the neighboring islands of Java, gold mines in the west and so on. The epic also provides information regarding prevailing weather conditions.

> Mist and its disappearance through diurnal rise of temperature, mist and severe cold, cold western wind, water vapor hanging on the surface of the river, dew formation on the sandy margin of the bank and snowfall give a very good description of winter season with some of its geographic paraphernalia. Mountain winds or wind of mountain valleys are also spoken of" (Tripathi 1969: 103–104).

The *Rāmāyana* indirectly explains the hydrological cycle in its simplest form. It relates solar heating of the ocean, evaporation and cloud formation. It narrates the physical movement of people in different directions. This implies that the transportation and communication system were in a developed stage. There is mention of five types of roads – lanes (*Vithi*), streets (*Rathya*), by-roads (*Uprathya*), roads (*Mahapath*), and National Highways (*Rajmarg*) (Tripathi 1969: 166).

The *Mahābhārata* gives a good account of topography, crops, people's occupations and their political and legal institutions. During that period, India had flourishing international trade with central Asia. This points to the fact that ancient Indians had enough knowledge about sea and land routes and even knew about the air circulation system and the tides. By the time of the composition of the *Mahābhārata* the idea of seven continents, each surrounded by oceans, was firmly established. Four areas are Jaṃbū (all of Asia minus the east), Kuśa (Middle East), Śālamali (Eastern Africa), and Puskara (Eastern Asia). The southern part of Jaṃbūdwīpa was inhabited by Hindus in the land called Bharata or Bharatvarsha. At the center of the Jaṃbūdwīpa was the Meru, identified with Pamir knots, and at the northern extremity adjoining the Arctic Ocean was the Uttarakaru. Jaṃbūdwīpa was surrounded by an ocean, meaning a physical barrier.

Kautilaya's *Arthaśāstra* discusses the principles of territorial sovereignty and geopolitical principles. According to Kautilaya, the seven elements of the state were the king (*Swāmi*), the minister (*Amātya*), the country (*Janapada*), the fort (*Durga*), the treasury (*Kosa*), the army (*Danda*), and the ally (*Mitra*) (Kangle 1965). *Janapada* meant both the land and the people. The organization of space also extended into the coastal regions and territorial waters. Kautilaya believed that success of any state depended on peace which could be affected by the internal and external forces reflecting centripetal and centrifugal forces of modern political geography, discouraging disintegration and encouraging integration of the state. Kautilaya's sixfold policy dealt with the internal and external problems of the state directly, and the policy revolved around peace, war, preparation for war, neutrality, seeking shelter and dual political policies. On the basis of political attitudes the neighboring states at the periphery or beyond were conceived as geopolitical zones of enemy, friend, enemy's friend, friend's friend, or friend of enemy's friend with increasing distance (Fig. 2).



Geography in India. Fig. 2 Geo-political zones of Kautiliya (Modified from Tamaskar 1985).

G

According to Kautilaya, "place means earth. In that the region of the sovereign ruler extends northwards between Himavat and the sea, 1,000 yojanas in extent" (Tamaskar 1985: 96). This implies that the natural boundaries for the states were considered important. The right location of the capital within the boundary manifested geographical consideration. Kautilaya emphasized the importance of the strategic location of the capital.

> …The king may have his fortified capital, as the seat of his sovereignty (*Somudayasthanam*) in the center of his kingdom in a locality naturally best fitted for the purpose, such as the bank of the confluence of the rivers, a deep pool perennial water, or of a lake or a tank, a fort, a circular, rectangular or square in form, surrounded with an artificial canal of water, and connected with both land and water paths (Kangle 1965).

The *Arthaśāstra* also mentioned the importance of developing means of transportation and communication in order to have political unity within the state. Developed transportation would serve as channels for the army to reach at a time of crisis. In addition to defense it would also help to promote trade and commerce, serving as a lifeline for the state.

The great verse writer, Kalidasa, (designated the "Shakespeare of India"), created *Meghadūtam* and *Raghuvaṁśa.* They showed a detailed knowledge of hills, rivers, plains, and cities. In *Meghadūtam*, Kalidasa's description of the path from Ramagiri to the Himalayan gate in the poetry is no less than a geographer's account. While sending clouds as messengers, the routes, rivers, hills, and cities lying on the way were described. Again, in *Raghuvaṁśa*, the poet showed in-depth knowledge of Indian geography. The kingdoms as described by Kalidasa show that he had some knowledge of the southern countries of Pandya and Kerala.

Greeks and Persians are the earliest foreign people to leave accounts of India. Greek writings indicate that ancient Indians had knowledge of the shape and size of their country. In 320 BCE, Eratosthenes gave India the shape of a rhomboid or unequal quadrilateral which had Indus on the west, the mountains on the north and the sea on the east and south. In 300 BCE, Megasthenes, a Greek ambassador of Seleucus Nicator, visited the court of a north Indian King, Chandragupta, and left an account of India on his return. In the *Mahābhārata*, India is described as an equilateral triangle divided into four smaller equal triangles. The apex of the triangle was Cape Comorin and the base was the Himalayas. Cunningham drew a small equilateral triangle by drawing a line between Dwarka (Gujurat) and Ganjam (Orissa) and repeated the exercise on each of the three sides to obtain four divisions of India in one large equilateral triangle. Varāhamihira identified eight divisions. The central division of Pañchāla (Punjab/Haryana) was surrounded by Maghada (east), Kalinga (southeast), Avanta (south), Sindhu-Sauvīra (west), Anarta (southwest), Madra (further south) and Kauṇḍa (northeast).

In the world map of Ptolemy (second century AD), a Greco-Egyptian geographer–astronomer, the true shape of India was distorted. He ignored the southern peninsula and drew an almost straight line from the Gangetic delta to the Makran coast in Baluchistan.

> The cause of this mistake is partly due to the erroneous value of 500, instead of 600, Olympic stadia, which Ptolemy assigned to an equatorial degree, partly to an overestimate in converting the road distance into map measurement, but chiefly to the excess which he allowed for the distances of land journeys over those of sea voyages" (Cunningham 1979).

Though only the southern part of Jaṃbūdwīpa was considered Bhāratavarsha, the Indians referred to the latter as the whole earth because the landmass of South Asia surrounded by mountains in the north and seas in the south was not only a physical cul-de-sac, secluded from other people, but was so productive and large that to the people of India it constituted the world. Puranic legend claims that King Bhārata, whose name was identified with the country (Bhāratavarsha), ruled the entire earth, meaning all of India. Such was the case with the emperor Aśoka as inscribed in his Fifth Rock Edict declaring that he was ruler of the world.

During the ancient Indian historical period when the country was shedding its narrow tribal characteristics, turning into a consolidated tribal conglomerate of Aryavārta (land of the Aryans), converging into organized states, no systematic study of geography evolved. On the contrary, during the same period, the Greeks and the Romans explored the geographical features of their known and unknown worlds and provided the basis for modern geography.

Geography in the Islamic World

Amriah Buang

Geography is the study of the earth's surface as the space within which the human population lives. The internal logic of this study has tended to split modern geography into two parts: physical and human. Such a division was inapplicable in the geography of the Middle Ages, the golden age of scientific inquiry in Islamic civilization. Nevertheless, if we confine the meaning of science and technology to the natural and exact sciences, then a survey of geography in Islam may be divided into three categories: exploration and navigation, physical geography, and cartography and mathematical geography.

Prompted by the sense of Islamic brotherhood, and the quest for knowledge and piety, Muslim scholars engaged in many exploration and navigational activities between the ninth and twelfth centuries. The journeys were not confined to the political boundaries of the Islamic empire but extended to distant regions such as China, Southeast Asia, Southern Africa, and Russia. In Northern Europe, the extent of the Muslims' travels may be gauged from the fact that some ten million pieces of the Islamic state's coins have been found around the Baltic. In Sweden alone 12,000 such coins were discovered at 169 sites.

From extant documents, it may be deduced that no less than 20 geographers were involved in navigation and exploration, resulting in a massive store of information and descriptions of the terra-cognita. Out of these, five may be regarded as outstanding. These geographers are al-Muqaddasī (b. tenth century), Ibn Jubayr (b. AD 1145), Yāqūt (b. AD 1179), Ibn Baṭṭūṭa (b. AD 1304), and Ibn Mājid (b. AD 1400). The contributions of Ibn Faḍlān (tenth century), Ibn Ḥawqal (tenth century), Masʿūdi (d. AD 456), al-Bīrūnī (b. AD 972), al-Idrīsī (b. AD 1099), Ibn Rushd (AD 1300), Jawainī (ca. AD 1000), Abdur Razzāq (AD 1000), Yaʿqūbī (d. AD 897), al-Marwazī (d. AD 887), Nāṣir-i-Khusraw (b. AD 1003), al-Māzinī (b. AD 1080), al-Maghribī (d. AD 1274), and Ibn Khurdādhbih (ca. AD 900) are also noteworthy.

Al-Muqaddasī or al-Maqdisī spent 20 years travelling the length and breadth of the Islamic empire. He perceived that it was important to be able to substitute hearsay with personal observations, and set out on a series of field trips to gather information and knowledge about places. One of his major works was *Kitāb aḥsan al-taqāsim fī maʿrifat al-aqālīm* (The Best Climatic Divisions), which was regarded as accurately informative of areal differences in climate in the Islamic world. Ibn Jubayr was meticulous in his description of places such as Mecca and Medina in his The Travels of Ibn Jubayr, which became a basis for historical comparison with later writings. Yāqūt 's *Muʿjam al-buldān* (Dictionary of Geography) was another major contribution, and his extensive travelling within the Islamic empire resulted in a vivid account of the Islamic world before its fall to the Mongols. Ibn Baṭṭūṭa certainly stands out as the most seasoned traveller. In 20 years he journeyed as far as 120,675 km (75,000 mile) covering countries like China, Southern Ukraine, Sumatra, the Malay Peninsula, Kampuchea, Maldive and the Volga. His detailed accounts of life in these places contributed further to the geographical preoccupation with different areas. However, Ibn Mājid and Sulaymān al-Mahrī were better informed about the Southeast regions of the world. The former's *Kitāb al-fawāʾid fī uṣūl ʿilm al-baḥr waʾl-qawāʿid* (Principles of Navigation) and the latter's *ʿUmda and Minhāj* became important references for those who wanted first-hand information on the Malay Archipelago.

The fact that collectively the Muslim travellers and navigators covered more than two-thirds of the earth's surface illustrates the Muslim scholars' disdain for armchair scholarship. That distant places were visited for collecting information at a time when vehicles, vessels, and instruments were underdeveloped, and when both land and sea routes were more unsafe than otherwise, serves to prove the inquiring spirit of the Muslim geographers.

In physical geography the contributions made by Muslim geographers in the Middle Ages pertain to their theoretical speculations about the lithosphere, atmosphere, hydrosphere, and biosphere. In cosmology, they came out with new notions regarding the relationship between cosmological cycles and geographic changes. For instance, the Sincere Brotherhood or Brethren of Purity (*Ikhwān al-ṣafā*), an association of scholars whose treatises were considered the standard for scientific knowledge of their day, conceived of the influence of the angle of declination on insolation, the influence of relief on precipitation, and the relationship of precipitation with the origin of streams and springs.

With regard to the lithosphere, the solid part of the earth, Muslim geographers thought of landforms as being the results of erosion, deposition, and tectonic activities. Soils were considered the results of organic decomposition, and winds (gases in modern usage) trapped underground and seeking outlets were held responsible for earthquakes.

Their theories on atmosphere embraced both local atmospheric phenomena and the distribution of macroclimatic elements. Thus, by envisaging atmospheric processes, such as insolation, convection, and evaporation, they were able to account for the formation of clouds, rainfall, snow, fog, and dew as different forms of evaporation due to differences in temperatures. They also divided the world into three climatic zones: hot, cold, and temperate, based on their understanding of the changing positioning of the sun.

In terms of the hydrosphere, most of the Muslim geographers' works were focused on understanding the causes of tides, and the origin of oceans and reasons for their salinity. In accounting for tides, the geographers were divided. Some pointed to the influence of heat generated by the sun and moon; others attributed the tides to the influence of wind on the movement of sea water. Muslim geographers, in general, concurred with their Greek counterparts in thinking the oceans had originated from the remnants of primitive precipitation which did not get dried when matter was formed in the universe. They, however, differed again with respect to marine salinity. Some ascribed it to the transformation of calm water to salty hard water after prolonged gestation.

Regarding the biosphere, geography in the Islamic Middle Ages saw the categorization of flora and fauna according to the grade of their creation. Thus, al-Jāḥiẓ wrote of four classes of animals based on their locomotion: those that creep, walk, swim, and fly.

By contrast, Ibn Maskwaih's division was based on the creatures' stage of evolution, with the lowest stage being occupied by vegetation which did not require seeds to grow, and humans occupying the highest stage of evolution. The categorization by the Ikhwān al-ṣafā was based on senses, whereby creatures with one sense occupied the lowest level and those with five senses the highest. In spite of these differences, the Muslim biogeographers agreed that the spatial distribution of organisms was governed by climate, topography, and soils.

Yaqᶜūbī was noted for his *Kitāb al-buldān* (The Book of Countries) written in AD 891, in which he described in detail the physical characteristics of Baghdad, Samarra, Iran, Turan, and the present Afghanistan. Ibn Rustah discussed the importance of locational and physical environmental factors on the development of cities, such as Medina and Mecca, in the seventh volume of his *al-Aᶜlāq al-nafīsah* (The Book of Precious Things), an encyclopaedia completed in AD 903. Al-Maqdisī described an imperfect spherical earth, the northern hemisphere of which contained more land than water. He also gave a detailed account of the world climate in terms of zones. Yet the most daring speculation may be ascribed to al-Bīrūnī, who theorized that, based on empirical evidence of its physical environment, the Indian subcontinent might have been a continental shelf before depositions raised it into a landmass. Lastly, al-Qazwīnī (b. AD 1203) produced two books: *ᶜAjāʾīb al-buldān* (The Wonders of the Lands, or Geography) and *ᶜAjāʾīb al-makhlūqāt* (The Wonders of Creation, or Cosmology), which were notable for their reference to more than 50 authors. The significance of this fact is that the large number of practicing geographers that were cited indicates how active and prolific physical geography was in the medieval Islamic civilization.

The achievement of Muslim geographers in mathematical geography may be described in various phases of development. An important phase was the establishment of the school of mathematical geography in Shiraz, Persia after AD 950. This school produced important scholars such as ᶜAbd al Raḥmān al-Ṣūfī and Ibn al-Aᶜlam. ᶜAbd al Raḥmān reviewed Ptolemy's *Star Catalogue*, while Ibn al-Aᶜlam compiled an astronomical table which became a main source of reference for centuries. Important developments took place in the school in Cairo towards the end of the tenth century and the early eleventh century. Important scholars from this school included Ibn Yūnus, who prepared astronomical tables and corrected several errors committed by the Greeks Ptolemy and Hipparchus. For instance, according to Ptolemy, the precession of equinoxes occurs at 1° in 100 years, but the correct measure was 1° in 70 years, as calculated by Ibn Yūnus. His book entitled *Al-zīj al-ḥakimī* (Tables of Wisdom) explained, among other mathematical ideas, the method of calculating longitudes and latitudes.

Among the notable works written in Central Asia of this school was al-Bīrūnī's book entitled *Taḥdīd nihāyāt alamākin* (The Determination of the Coordinates of

Cities). Other scholars of high reputation were al-Zarqāllu, Naṣal-Dīn al-Ṭūsī, and Ulugh Beg. Al-Zarqāllu produced several books on astronomy including the *Toledan Tables*. His other work, entitled *Qānūn* (Canon), was used by European scholars during the Renaissance. Al-Ṭūsī is remembered for his book *Zij-i-īlkhānī*, which recorded all the notes and observations he made from the observatory of Maragha. His other important writing was on the astrolabe and the problems related to the measurement of time, celestial altitudes, meridians and the like. Ulugh Beg was a Tartar prince (AD 1393–1449) who was also noted for the observations he conducted from the observatory in Samarkand. He managed to point out several errors committed by Ptolemy in the latter's tables and made new tables of latitudes and longitudes.

With respect to cartography, Muslim scholars followed two schools: one was based on the cartographical method of Ptolemy and the other on that pioneered by al-Balkhī. Ptolemy's teachings were followed by al-Idrīsī, and al-Balkhī's were continued by al-Istakhrī, Ibn Ḥawqal, and al-Maqdisī. The Muslims' maps were drawn and utilized in conjunction with countries and regions. Idrīsī became famous in the West because of his maps and cartographical work. His maps were valued not so much because of their accuracy but because of the symbols he used to distinguish various physical and cultural forms.

A prominent feature of the achievement of Muslim scholars in mathematical geography and cartography was the invention of scientific instruments of measurement. Among these were the *astrolab* (astrolabe), the *ruba* (quadrant), the gnomon, the celestial sphere, the sundial, and the compass. The portable astrolabe was used by navigators for measuring altitudes up to the seventeenth century. The ruba was used for measuring the value of angles. The gnomon was also used for measuring altitudes of the sun and other planets. The use of celestial sphere was to explain celestial movements, the sundial for calculating daily time and the azimuth (compass bearing) of Mecca, and the compass for finding direction during navigation. In human geography the achievement of Muslim geographers during the Middle Ages may be summarised into two main categories (1) works which attempt to explain factors deemed responsible for influencing, or even determining the traits, characteristics or qualitative nature of a population or community; and (2) works which describe basic facts (social, economic, political, and cultural aspects) about a society's or a community's life. Viewed from the perspective of contemporary modern human geography, some of these works coincide with discourses on environmental determinism (the doctrine that human activities are controlled by the environment) and environmental possibilism (the view that the physical environment provides the opportunity for a range of possible responses and that people have considerable discretion to choose between them). Others may be aligned more with traditional regional geography which was heavy in chorography (the study of the areal differentiation of the Earth's surface; i.e. the areal variation of human and physical phenomena as they relate to other spatially proximate and causally linked phenomena) or idiography (a concern with the unique and the particular). Some of the names identifiable with this episode of Islamic human geography were Al-Masudi – for his explication as to how climates differentiate between people of northern and southern hemispheres – and Al-Maqdisi – for his characterisation of settlements based on the temperament of their inhabitants.

Modern human geography has since been dominated by thoughts and works of Western human geographers. So much has happened to the secular epistemological thinking of this sub-discipline of geography, and an Islamic preliminary review of it has been written by Buang (1992) (link to attachment on Buang's article).

Geography in Mesoamerica

Vincent H. Malmström

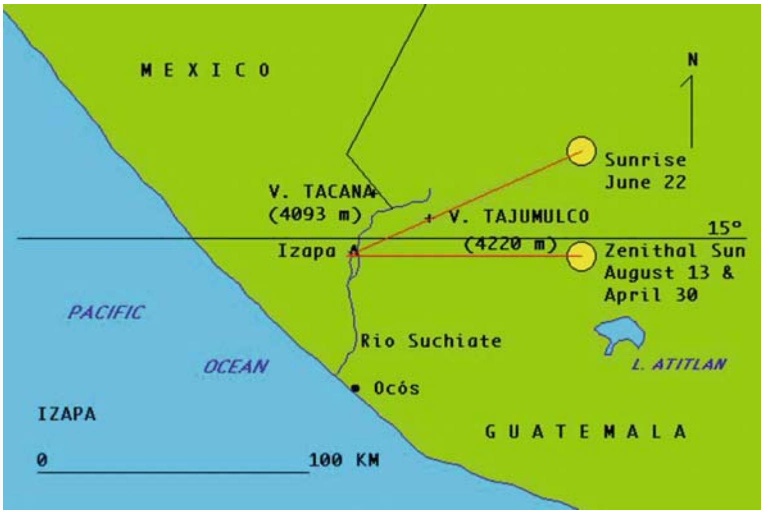
Unlike the ancient Greeks, for whom all knowledge could be categorized according to a tripartite classification – the phenomenon itself, its place in time (history), and its place in space (geography) – the civilizations of pre-Columbian Mesoamerica viewed all knowledge as religion, some aspects of which found their reflection both in time and space. The most original intellectual creation to emanate from Mesoamerica was the 260-day sacred almanac, known variously as the *tzolkin* among the Maya and as the *tonalpohualli* among the Aztecs. Predating the 365-day secular calendar, which these people also developed, it ran concurrently with the latter to produce a never-ending series of 52-year cycles (365 × 52 = 260 × 73 = 18,980 days), giving rise to the Mesoamerican belief that history repeated itself every 52 years.

Though the origin of the 260-day calendar has long been debated, the most convincing explanation for its astronomic underpinnings was first given by Zelia Nuttall in 1928, who argued that it represented the interval between zenithal sun positions at Copán, the major Maya astronomical center located in the mountains of western Honduras. At the latitude of Copán (14.8°N.), the sun passes overhead at noon on August 13 on its apparent southward journey to the Tropic of Capricorn and again on April 30 on its apparent northward journey to the Tropic of Cancer. In 1945, Merrill called attention to the "coincidence" of the August 13 date with the start of the so-called Maya Long Count, which in the Goodman–Martínez–Thompson correlation between the Maya and Christian calendars fixes the beginning of the present cycle of the world as August 13, 3114 BCE. (The Long Count represented a meshing of the 260-day sacred almanac and the 365-day secular calendar in such a way that each day was as uniquely and precisely identified as they are in the Julian Day system employed by modern astronomers.) In 1948 a Guatemalan scholar, Girard, contended that the calendar's birthplace lay along the same parallel of latitude but in the mountains of his country instead. While concurring in the astronomical importance of the 14.8° parallel of latitude, the present writer was forced to reject both Copán and the highlands of Guatemala as the calendar's cradle, for reasons both of history and of geography. No pre-Columbian site situated along that parallel in the highlands of Central America predates the fifth century AD, whereas the sacred calendar is known to have been in use for several centuries BCE. Furthermore, many of the day–names used in the sacred almanac commemorate lowland tropical animals. The only place where the requisite astronomy, history, and geography come together is at Izapa, on the Pacific coastal plain of Mexico, where a large ceremonial center of Formative age (1500 BCE–300 AD) is found amidst a tropical rainforest ecological niche (Fig. 1).

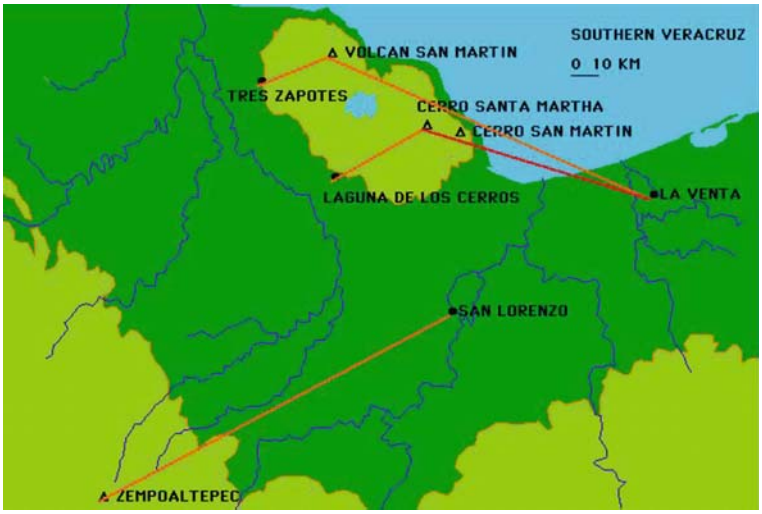
Field work at Izapa in 1974 not only revealed that the entire ceremonial center is oriented to Tacaná, a commanding volcano of 13,428 ft elevation on the northern horizon but also that the highest volcano in Central America, Tajumulco (13,845′) marks the azimuth of the rising sun on the summer solstice (June 22) as seen from Izapa (Fig. 2).

This use of prominent topographic features to serve as calendrical markers was subsequently traced to the oldest so-called Olmec ceremonial centers of San Lorenzo (1200 BCE, oriented to Zempoaltepec (11,138′) at the winter solstice sunset), La Venta (1000 BCE, oriented to Cerro Santa Martha (4,600′) at the summer solstice sunset), and Tres Zapotes (800 BCE, oriented to Cerro San Martín (4,600′) at the summer solstice sunrise), but also to the earliest ceremonial centers of the Mexican plateau, including Cholula, Cuicuilco, Tlatilco, and Tlapacoya (Fig. 3).

Geography in Mesoamerica. Fig. 1 Both Izapa and Copán are situated just south of the 15th parallel of North latitude, the former immediately adjacent to the boundary between Mexico and Guatemala and the latter in the mountains of western Honduras (map by the author).



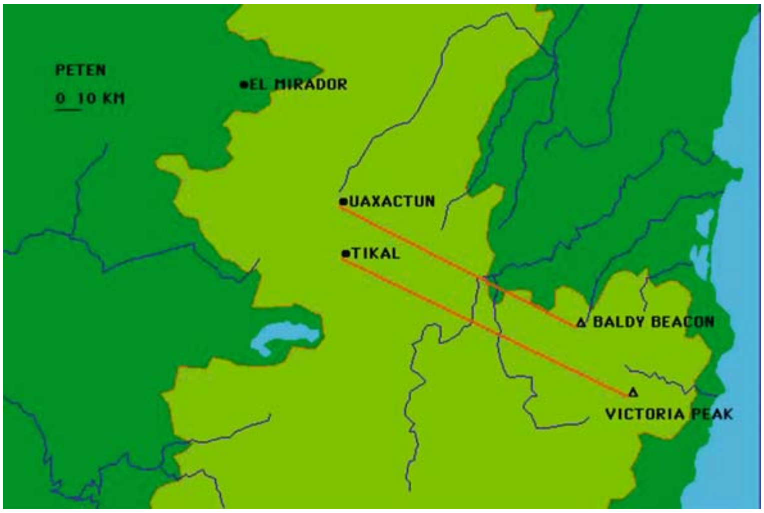
Geography in Mesoamerica. Fig. 2 The unique geographic position of Izapa permitted its priests to calibrate precisely both the length of the 260-day sacred almanac and the 365-day secular calendar – the first by zenithal passages of the sun and the second by measuring the interval between summer solstice sunrises over Central America's loftiest volcano. The sacred almanac had its beginnings about 1320 BCE and the secular calendar was initiated some 34 years later (map by the author).



Geography in Mesoamerica. Fig. 3 Throughout the areas they occupied in present-day Guatemala, El Salvador, and Mexico, the Olmecs continued the precedent of orienting a ceremonial center to a solsticial sunrise or sunset, begun at Izapa. On this and subsequent figures, lines in orange indicate solsticial orientations while those in red mark orientations to the August 13 sunset. Here we see the orientations found at the oldest Olmec sites in southern Veracruz state (map by the author).

Significantly, only two of the earliest Maya sites, Uaxactun and Tikal, have mountains within view, but both of them are likewise oriented to the winter solstice sunrise over the highest peak within sight – the first to Baldy Beacon (3,346′) and the second to Victoria Peak (3,680′). In each instance, the local site-factor which pinpointed the ceremonial center's location was the availability of water, both for domestic uses and, in the early Olmec centers, for transport, but only when the situational factor of the proper solsticial orientation coincided with it (Fig. 4).

Interestingly, where prominent mountains are not visible on the horizon, the early Mesoamericans substituted architectural alignments for solsticial orientations. The greatest of pre-Columbian cities, Teotihuacán, about 30 miles northeast of present-day

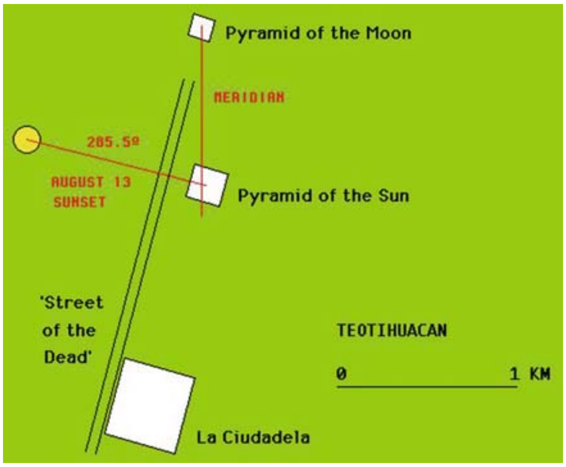


Geography in Mesoamerica. Fig. 4 The flat and relatively featureless peninsula of Yucatán provided the lowland Maya with no mountains with which they could locally calibrate the calendars they had inherited from the Olmecs. However, once within sight of the Maya Mountains of present-day Belize, the practice was revived at two of their most ancient and important sites in the Petén region of Guatemala, Uaxactun, and Tikal (map by the author).

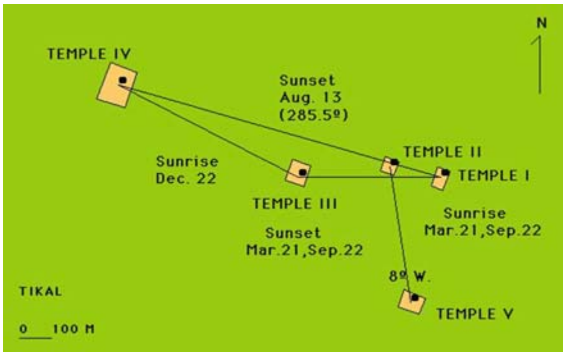
Geography in Mesoamerica. Fig. 5 As the Olmecs carried their calendrical systems onto the plateau of Mexico, they found a plethora of great volcanoes to which they could orient their incipient ceremonial centers. Following the destruction of Cuicuilco about 150 BCE, they founded what was to become the largest urban center in the New World at Teotihuacán and ensured that it was solsticially oriented to Orizaba, the highest mountain in Mexico (map by the author).

Mexico City, combines an intriguing blend of both principles: it is located precisely in line with the winter solstice sunrise over the highest mountain in Mexico – Citlaltépetl, or Orizaba, 18,700′ – but the peak itself is obscured by a low ridge of hills on the southeastern horizon. It would appear that a "relay station" was built there to allow the priests of Teotihuacán to calibrate their calendar with the southernmost position of the sun, whereas the entire city itself was meticulously gridded to the sunset position on August 13 – the day the present cycle of the world was believed to have begun (Figs. 5 and 6).

The commemoration of the August 13 sunset is also found in the layout of other ceremonial centers on the Mexican plateau of later, Toltec vintage, but its most widespread use in city planning was amongst the Maya. The location of the earliest Maya ceremonial center at Edzná (dating to 150 BCE) was primarily dictated by the presence of the largest Aguada, or temporary lake, in all of the Yucatán, but its internal layout clearly



Geography in Mesoamerica. Fig. 6 At least three key astronomical concepts are built into the layout of Teotihuacán, Mesoamerica's greatest pre-Columbian metropolis. Not only it is oriented to the winter solstice sunrise over the highest mountain in Mexico, but its entire internal structure is also aligned to the sunset position on August 13. Furthermore, the location of the Pyramid of the Moon and the Pyramid of the Sun, its two most imposing architectural features, precisely defines the meridian, enabling both noon and midnight to be calibrated as well (photo by author).



Geography in Mesoamerica. Fig. 7 At Tikal, sometimes called "the capital of the Maya," the planning and construction of five "skyscraper" pyramids, all carried out within about a 50 year period in the late eighth century, pointedly demonstrates how the Maya combined the spatial arrangement of their architectural structures with key temporal "landmarks" in their religious year (map by the author).

reflects their religious preoccupation with the August 13 sunset. Similarly, numerous structures throughout the Maya regions of Yucatán and Petén reflect the August 13 alignment, among them the Codz Pop at Kabah, the Pyramid of the Magician at Uxmal, and El Caracol at Chichén Itzá, to name but a few. The crowning blend of celestial mechanics, time, and space is to be found in the Maya capital of Tikal, where five sky-scraper pyramids, all about 200 ft in height and all constructed in the eighth century, mark the alignments of the August 13 sunset (Temple I to Temple IV), the equinoxes (sunrise Temple III to Temple I; sunset Temple I to Temple III), and the winter solstice sunrise (Temple IV to Temple III) in a sophisticated astronomical matrix. Further, an alignment from Temple V to Temple I not only marks a perfect right angle to the August 13 alignment but one from Temple V to Temple II likewise pinpoints the westernmost point in the rotation of Polaris, which at that time was the closest thing to a polestar which existed, even though it was a full 8° away from its present position (Fig. 7). (Clearly, the repeated use in Mesoamerican ceremonial centers of the August 13 sunset orientation not only forcefully argues for the sacred almanac's astronomical origin but it also makes any alternative explanation, such as the length of the human gestation period or the simple permutation of the numbers 13 and 20, untenable.)

In the fifth century, the Mesoamericans appear to have carried out two remarkable geographic expeditions. Although they both had ultimate religious goals in mind, these endeavors probably reflected the closest approach the pre-Columbian civilizations ever made to what we regard as scientific inquiry. The priests of Teotihuacán dispatched an expedition into the northern desert to determine where the "sun stopped" in its annual migration, and in consequence of this, the astronomical center of Chalchihuites was founded on the Tropic of Cancer. Lacking a better means of recording key alignments, they dug trenches through the earth and plastered them with adobe to mark the summer solstice sunrise. (In the tenth century the Toltecs added a trench to mark the beginning of their New Year, February 12.) Perhaps under Teotihuacán's sponsorship, the Maya carried out a similar expedition at about the same time to locate the place where the 260-day sacred almanac could be calibrated. The result of this venture was the founding of Copán, in the western mountains of Honduras, whose oldest recorded Long Count date is 435 AD. Thanks to its key geographic location, Copán was ultimately to become the Mayas' principal center for astronomic studies – the late and distant heir of Izapa where the first intellectual stirrings had begun nearly two millennia earlier.

Geography of the Native North Americans

Martha L. Henderson

Native North Americans sustain sophisticated and complex cultures. What native peoples say about themselves with their own constructs of space and place is essential to understanding native North American populations. This essay attempts to describe geographical data including native spatial organization, relationships with the natural environment, and the location and significance of places. These data and their analysis can shed light on native identity, problems of intercultural relations from a geographic perspective, and the contemporary context of native geography within the pluralistic federal states of Canada and the United States.

North American natives, those living north of the Mexican–United States border, were divided regionally by specific cultural patterns and practices such as language, religion, and relationships with the natural world. Oral traditions and material artifacts about past events provide clues to a native North America. Similar culture groups established territorial boundaries that served to strengthen group identity. Porous boundaries allowed for fluid contact between groups when conditions required. Territories generally conformed to major ecosystems of the continent.

North American ecosystems are roughly divided by landform and vegetation that include a direct reference to climatic conditions of the modern period. The subtropical Southeast extends from the center of the continent at approximately 100° West to the Atlantic coast to its northern limit at approximate 35° North. Corresponding to the west is the Southern Great Plains, Southern Rocky Mountains, and the desert Southwest. Between 35° and approximately 50° North is the temperate zone. In the west, this zone includes the rainy coastal mountain ranges of the Pacific, the cold Rocky Mountains, the dry Central and Northern Great Plains, and the humid Northeast Atlantic region. North of the temperate zone climatic conditions are generally cooler. The northern region was drastically affected by continental glaciations. Except for the Northern Rocky Mountains that extend into Alaska, the northern region has been heavily eroded and generally flattened. Very large lakes and river drainages cut across the rocky surface. Soil development is slowed due to cold temperatures. Trees rarely grow above 55° North. These basic environmental conditions set the framework for native population habitation of the land mass (World Atlas).

Today, the international boundary between Canada and the United States divides federally recognized tribes but not self-identified culture groups. Historic treaty-making and reservation assignments create a federal geography while native populations recognize a cultural geography that reaffirms a traditional past, present, and future in Indian Country.

Traditional Native Geography

Native geography can be described on the basis of creation stories, location, territoriality and boundary making, resource adaptation and interaction with the physical environment, and place-making. Native–land relations are primarily structured around a set of beliefs that recognize Earth as the spiritual and material center of life. Generally, Natives do not divide their world between the real and the spiritual. The world includes every existing entity and those spirits who occupy them. All aspects of nature are sacred; there is no separation between the universal and human actions. For example, the Ojibway of the Upper Great Lakes region view Earth as "spirit garden." Resource adaptation and cultural patterns are closely linked, one sustaining the other. Spiritual, cultural, and physical collaboration established a balance that supported native populations in sustainable, traditional patterns.

Places usually recognize the spiritual integrity of natural objects or events that magnify the wishes of a creator. The Hopi of the American Southwest named each of their mesa homelands with respect to physical features and conditions of Hopi creation beliefs. Hopi place names not only imply the physical, but also the spiritual conditions of existence. Prior to contact with non-Hopi groups, especially non-Indian groups, each mesa was a world unto itself, anchored in a spiritual and material existence. Recent events within Hopi mesas, such as surface coal mining by western industrialists, have wounded this sacred ground.

The White Mountain Apache maintained an oral history by telling each other about specific places. Specific places in traditional territory evoked significant events, lessons of survival, life passages, and mystical events. Without these places, the traditional history of the Apache did not occur. The power associated with each place captures the power of place within many native culture groups (Basso 1996).

Creation Stories

The native populations of the Western Hemisphere constituted a major portion of Earth's human populations prior to European contact during a period of time generally recognized by scholars during the fifteenth century. It is estimated that populations in Central and North America could have been as high as ten million with the same amount in South America. The extent of nonnative knowledge about human habitation in other parts of the world is speculative. It is apparent in some oral traditions that natives knew of white visitors to the Americas prior to the temporal divide of the 1400s.

Northern American natives believe, and continue to believe in, creation stories that do not include a Beringia migration during periods of colder climatic conditions. Recent discoveries in North America of pre-Paleolithic skeletal remains and artifacts stimulate a growing awareness that native occupation is part of a much longer legacy of continental occupation. Native American artifacts have been found across the North American continent in such quantities as to suggest that all parts of the land mass were occupied at the close of the last major glacial period. The post-Pleistocene period is a convenient but tentative temporal divide. Contemporary native peoples are reasserting their own stories of origin, culture, language, and environmental ethics that reset the balance of authority between native peoples, federal governments, and academic researchers.

Location, Territoriality, and Cultural Boundaries

Within each major group were specific groups who established their location around specific physical features at a density that allowed a sustainable population to exist within the entire ecosystem. Local shifts in location, resource acquisition, sacred sites, and interaction zones between groups were not uncommon. These shifts were sanctioned by mutual consent although peaceful readjustments were not always the case. Major stresses such as prolonged drought or loss of a major resource caused location changes and readaptation across ecosystem boundaries.

Natives generally view area based on concepts of territoriality. Territoriality is a common recognition of a physical landscape that supports loosely allied group needs. Acute observation skills, familiarity with local and regional physical characteristics, and recognition of other social groups within the area are consistent attributes of native geography. For example, the Apache utilized an area of the American Southwest generally between the Rio Grande River and the Great Plains. Primarily a mountain people dependent on species found at various elevations during changing seasons, the Mescalero Apache also developed hunting skills that allowed them to take advantage of grasslands species such as buffalo. They shared buffalo hunting with distant Apache relatives. These other Apache groups were permitted to hunt and gather resources in the Mescalero mountain territory when grasslands resources were scarce. The Mescalero Apache held all resources as a common good to be shared when other Apache required assistance.

An important aspect of territoriality is the ability to communicate conditions of space and place. The Inuit are superb cartographers, able to produce maps of territory with accurate scale, a system of symbols, and direction. The maps also convey a sense of space and place where value is placed on animal trails, natural features, and settlement locations. An Inuit map of the north therefore demonstrates Inuit reality as opposed to another culture's maps of northern places.

The continental context of native occupation was well known to native peoples. Means of transportation and navigation technologies existed that allowed for transcontinental exchange as well as regional interaction between groups. Regionally, large game hunting and other resource-sharing opportunities allowed for contact and exchange between groups. Finally, small groups who occupied specific areas achieved a balance between resources and population needs. Expertise in the maximum utilization of all resources supported native populations within a context of spiritual, cultural, and physical balance.

Resource Adaptation

The map of traditional native North America includes recognized areas of group occupation, fluid and sometimes shifting boundaries between groups, and cultural indicators that promoted group identity and survival. Groups of similar culture and subsistence patterns are recognized within each of the major ecosystems of North America. Each major group had unique linguistic, religious, and subsistence patterns. Within each ecosystem were specific groups who maintained their own identity while recognizing their commonalities with similar groups within the ecosystem. Native populations are generally divided into the following large groups: Mississippi temple-mound builders; eastern woodlands hunter-gatherers and cultivators; plains bison hunters; southwest Anasazi; desert hunter-gatherers; west coast foragers, hunters, and fishers; plateau fishers and hunter-gatherers; sub-Arctic forest hunter-gatherers; Arctic marine mammal hunters; and island fishers (Carnegie Museum).

The use of natural resources for survival is generally framed within the context of small Indian populations, exploitation to meet needs, and returning something to nature for the use of an item. Native Americans developed a resource use paradigm that focused on the unity of all beings and their systemic value rather than individual worth. For example, individual animals within a forest ecosystem were recognized in relationship to other plants, soil, water, and air. The use of a specific animal was always observed with respect to other elements of the ecosystem with an attitude of thankfulness and recognition of the animal as a gift. Reliance upon specific species developed over centuries of adaptation. As native groups entered new areas of North America and as North American physical environments were transformed by primarily climatic events, groups had to adjust, migrate, or face decline.

This is not to suggest that specific species were not singularly important to American Indian groups. The buffalo provided nearly all of the needs of plains bison hunters while west coast fishers relied heavily but not exclusively upon salmon. Given the low population numbers of natives, neither species were threatened with extinction due to overkill. It is reasonable to believe that resource demands and human populations would have remained static if European explorers with different technologies and valued resources had not impacted native culture groups (Native North America).

Perhaps the most striking of examples of native cohabitation is found in the cold deserts of the plateau fishers and hunters and gatherers, and the Arctic marine mammal hunters. Using simple technological devices, native peoples occupied and survived in both areas. The Piute established their primary homes along pluvial spring-fed lakes that survived continental warming. These people developed fishing and hunting technologies that allowed them to utilize birds, animals, and fish that inhabited the lakes and marshes of the Great Basin. While large game animals are scarce in the region, small animals such as antelope and rabbits were easily trapped. Plants, whose life cycles were well known to local Piute groups, were readily available. These food resources were abundant to the point that it is estimated that the Piute had more time available for leisure and social activities than any other native group.

Similarly, Eskimo experienced a high amount of time available for artist expression and social activities because they developed sufficient technologies and skills to maintain caloric intake and clothing needs. The Arctic is one of the richest animal and fish ecosystems on Earth. Native fishing, watercraft, celestial navigation, and clothing technologies allowed the Inuit and Eskimo to thrive in the high latitudes.

Oral traditions and present practices indicate that management techniques were utilized to create and sustain certain types of ecosystems. Native use of fire to maintain open fields is apparent across the continent. Native burning may also be the primary force that created the grassland ecosystems of the mid-continent. The eastern woodland natives such as the Iroquois practiced burning of areas, known by European setters as “old fields,” to maintain open areas for large game hunting.

Native cultural ecology places a high degree of respect for living with environmental conditions. The mental constructs of discovery and contact by Europeans overlooked the brilliance of native populations who had, through experimentation and accident, come to live in a state of balance with the physical environment. This balance was radically changed with the permanent migration of Europeans to North America.

Historic Geographies: Cultural Conflict and Emergent Identities

European influences in native North America are generally recognized as beginning in the fifteenth century with earlier contact periods a probability based on archaeological data. Contact between natives and Europeans resulted in major shifts in native geography. European tools, technologies, diseases, and interruption of traditional patterns of resource acquisition and spatial organization altered those natives who experienced direct contact. More importantly, the changes spread within the native population to affect large groups of natives who did not experience direct contact. The presence of English, French, and Scandinavian explorers and their patterns of living spread quickly from the eastern coastal areas inland. Similarly, natives living in the southwest were affected by the presence of Spanish explorers in Central America. The diffusion of European goods, ideas, technologies, and diseases spread quickly across the entire continent.

Once European settlements were established, their demand for resources had an immediate effect on the location and territoriality of native groups. For example, as French fur traders moved into the Great Lakes region, northern Algonquian peoples moved westward into Ojibwa territory. The Ojibwa peoples moved westward into Sioux territory west of Lake Superior. This migration resulted in conflict and warfare between the two native peoples. Eventually the Sioux moved further west and established themselves on the northern Great Plains. When American ethnographers described the Sioux, they called them Plains people who had adapted to living off buffalo, yet this was a very recent location and adaptation for the Sioux.

Spanish *entradas* into the southwest also created a chain reaction of relocation and territorial disputes within native peoples. Coronado's 1540 brutal search for the Seven Cities of Cibola caused Pueblo and Hopi groups to make alliances in order to protect their holdings in the upper Rio Grande valley. In 1598 the Onate and a group of Spanish settlers entered the central Rio Grande valley. Their presence forced Pueblo groups to reestablish themselves in a new configuration of alliance and mutual support.

Some native groups were able to maintain control of their territory and command a more powerful position with colonial and, later, American federal interests. The first treaties between native groups and the Euro-Americans were based on the strengths of two powers entering into treaties as equals. Native peoples agreed to allow Euro-Americans to inhabit certain spaces for mutual protection. In some cases, native treaty-makers did not perceive that what they were agreeing to was conceptualized in a very different way by the Euro-Americans. These natives could not conceive that what the Euro-Americans were doing was acquiring full rights to the land base because the natives did not believe that land was owned or tenured to any one specific group.

Once established, however, Euro-Americans continued to acquire and use land beyond treaty boundaries. This form of disrespect for the treaties caused continue disruption of native use of resources, attempts to live with the new population, and peaceful relations with other native groups. Native peoples also faced disequilibrium as Euro-American settlement spread westward across the continent. Debilitating diseases, alcohol, and physical attacks rapidly reduced native populations.

Native groups in the west, especially the Nez Perce, quickly adapted to the use of horses. The introduction of horses added speed and the ability to cover large distances to these native cultures. By the time the American and Canadian governments made contact with these culture groups, their strength in hunting and raiding proved them to be powerful forces that stood in the way of the federal governments.

By 1830, native groups across the continent were significantly reduced and very strongly affected by the presence of the American and Canadian governments. Population numbers were greatly reduced and in some cases entire culture groups were wiped out. Both governments carried out major campaigns to exterminate native peoples. Those remaining were required to sign treaties that established reservations for native groups. Groups of differing traditional backgrounds were often placed on the same reservations. For example, the Cherokee of the southeast mound-building culture were forced to walk nearly a thousand miles in the winter of 1839 to a reservation established for them in the southern Great Plains. The walk, known as the *Trail of Tears*, resulted in the loss of hundreds of Cherokee lives. Those who survived the walk found themselves in a completely new physical environment for which they were not prepared. They were settled with other native groups with whom they shared little in common. Such conditions continued to undermine natives' ability to maintain cultural identity until the late 1870s. Populations were required to stay on reservations that were inadequate and unable to supply the needs of traditional peoples. Population numbers continued to decline.

Both American and Canadian governments, with the assistance of well-meaning missionary groups, assumed that native peoples would fit into a Euro-American North America if they became farmers. Both governments instituted assistance programs and land tenure policies intended to assist natives into assimilating in the agricultural economies of the United States and Canada. These programs ultimately failed although some natives became farmers. The overall process continued to reduce native populations and open native lands for white settlement.

In a reversal of policy, the federal governments instituted new programs in the mid-twentieth century with the goals of creating tribal governance and business programs for native revenues and protection of native cultures. These new programs assisted native groups in developing tribal resources on tribal lands. Some tribes such as the Mescalero Apache, the Confederated Tribes of the Warm Springs, and the Red Lake Band of the Chippewa developed timber and cattle enterprises. The revenues from these enterprises helped to support native educational, health, and social services needs. However, the revenues were never large enough to fully empower the tribes. Tribes continued to be dependent upon federal programs for basic needs. These programs were unequally and generally poorly funded and administered. The distribution and quality of services on reservations was far from adequate.

The federal governments choose to eliminate many of the native programs at the end of World War II. The American government terminated reservations and treaties in many areas of the United States. All tribes, even those who had created profitable enterprises, were disrupted by these termination policies. At the same time, natives were encouraged to move to urban areas and learn skills that would allow them to find jobs and reside away from rural reservations. As a result of these policies, today the highest population concentrations of native populations in both Canada and the United States are in urban areas.

Contemporary Geographies of Native Peoples

The last decades of the twentieth century saw another policy reversal by both federal governments. Working with native leaders, both governments are now committed to a process of native self-determination. Native groups have recovered some of their powers as established in treaties and have also been able to secure religious, burial, and cultural freedoms through national laws. As natural resources have become scarce in North America, it is increasingly evident that negotiations with native groups are essential in protecting habitats and threatened species, watersheds, major landforms, and critical wetlands. Native peoples continue to develop resources such as fishing and timber to meet their own needs. Native groups have quickly adopted technologies such as geographic information systems to maintain and plan resource management on native lands. Propagation and protection of flora for medicinal purposes have become major foci of native peoples. The Bella Coola and bands of Puget Sound natives have, for example, reclaimed land and protected specific species that play a significant role in cultural identity and health.

Native groups in the United States have exercised the right to develop casinos on native lands. The popularity of gambling and a desire to meet that need with additional casinos has required extensive mapping to identify the exact location of native lands. Revenue from gambling has been invested in resource development and cultural identity programs that support native populations. In some cases, casino revenue has made it possible for native groups to extend financial assistance to other cultural groups including the dominant white culture in local areas. Mutual resource management goals are also being identified and shared by more than one racial and ethnic group.

First Peoples in Canada have recovered major portions of the Northern Territories as part of the new native province of Nunavut (Atlas of Canada). Native peoples who are implementing traditional ideals and ways of knowing administer this province. Place names, the location of sacred places, resource gathering techniques, and social affairs are practices in Inuit traditions. Native groups throughout North America are experiencing a resurgence of cultural identity as the landscape of North American reflects growing acceptance of a plurality of cultures.

Today, the largest growing populations in North America are native. More that half of all native peoples is below the age of 15. This growth rate requires planning and development of tribal resources. This expanding native population is able to access both the traditional knowledge of their cultural past and the freedom to express their native identity. The new emphasis on native knowledge is ultimately changing the power relationship between federal and tribal governments, the rights of native peoples, and the cultural and geographical record of the native populations of North America. With full recognition of native power and self-identification, this short essay is offered as only an introduction to the multidimensional and cultural diversity found among native North Americans.

Geomancy in China

Hong-Key Yoon

The Chinese word for geomancy is *feng-shui*, which means “wind and water” or *ti-li*, which means “the principles (patterns) of the land.” The term *ti-li* is also the Chinese word for geography, which suggests an intimate relationship between Chinese geomancy and geography.

In Chinese geomancy, a place having certain landforms and orientations is believed to be more auspicious than others. An auspicious place is where vital energy (*sheng-ji*) is accumulated and available to humans who occupy the site. The function of vital energy is to give birth to and support all living things, and it is stored in certain places meeting geomantic requirements, blessing the people who use the site in harmony with the surrounding landscape.

The flow of vital energy underground (often through mountain ranges) is analogous to that of blood through the veins of the human body. Therefore, a geomancer’s job is to find a spot where vital energy is accumulated, in a similar way that an acupuncturist finds a critical spot of the body where a needle can be planted.

An auspicious site (geomancy cave) is sometimes compared with a melon on a vine. The nutrients from the soil are taken through the roots, and transported through vines to be stored in the melon before being consumed by humans. In a comparable manner, the vital energy flows underground through the veins and is deposited in the geomancy cave to be available for humans who use the place appropriately by building, for example, a house or a grave.

The most important geomantic condition of an auspicious site is that it be sheltered by a surrounding range of hills on three sides, with one side open. The range on the left (normally East) side is called "azure dragon"; the right (normally West) range, "white tiger"; the hill behind an auspicious site is called the main mountain or "black warrior." A horseshoe shaped basin is an auspicious site. The most desired orientation of the site should face south. The land also needs to have access to a watercourse; the most desirable ones flow slowly with many bends.

In geomancy, the people who occupy auspicious sites are believed to benefit from the land by enjoying longevity, accumulating wealth, or achieving fame in the world. Traditionally, geomancers were normally consulted when cities, temples, graves, and other human settlements were built. Professional geomancers are supposed to know how to choose an auspicious site by applying geomantic principles, and can be seen as the traditional Chinese version of modern geomorphologists, location analysts or landscape, and architectural planning consultants.

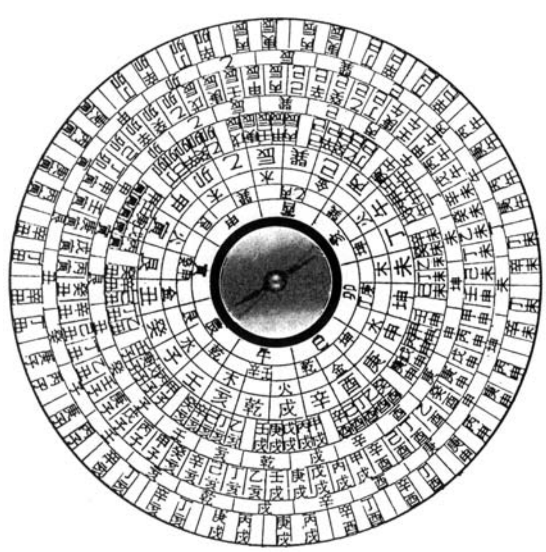
It is virtually impossible to understand the East Asian cultural landscape without having knowledge of geomancy. For instance, important cities like Beijing and Nanjing in China, Seoul and Kaesong in Korea, and Kyoto and Nara in Japan all were chosen and planned geomantically. Thus, Chinese geomancy is defined as "a unique and comprehensive system of conceptualising the physical environment, which regulates human ecology by influencing man to select auspicious environments and to build harmonious structures (i.e., graves, houses, and sites) on them" (Yoon 1976).

In the evaluation of the quality of the landscape (the environment, place) in geomancy, the following three images are important. First, the landscape is perceived as a magical being which can influence people mysteriously, either auspiciously or inauspiciously. An auspicious site can bless people with a happy life, whereas an inauspicious site can cause people to suffer misfortunes, including disease, bankruptcy, death, and infertility.

Secondly, the landscape is personified and regarded as a system of either a living organism or an inanimate object. Either an element of a local landscape such as a hill or stream, or the entire landscape itself may be treated as a functioning system of an object such as a cow, boat, or a flower. Personification of a landscape as a beautiful, balanced, and peaceful object normally indicates an auspicious site, whereas personification as an ugly, dangerous, and unbalanced object suggests an inauspicious site. Depending on how a geomancer perceives a local landscape, it may be compared to (personified as) any object in the world.

Thirdly, the landscape is seen as a vulnerable being, which can easily be hurt or remedied by human interference, because the vital energy that flows beneath the surface is extremely vulnerable. Vital energy is only one particular phase of the *Yinyang* energy according to a geomantic classic called *Zang-shu*. When *Yinyang* energy belches out, it becomes the wind. When the wind ascends, it becomes a cloud. When it descends, it becomes rain. When it flows under the ground, it becomes vital energy, but when it emerges out of the ground, it is no longer vital energy (*Guo Bu*). That is why the vital energy of an auspicious site should be utilized without disturbing it, by building a house or a grave in harmony with the surrounding landscape.

In the history of China, geomancy was often more popular for choosing an auspicious site for a grave rather than for a house, although the same geomantic principles were applied for both cases. All the important principles concerning an auspicious place are in fact about ideal conditions relating to a living person's dwelling site. The analysis of geomantic principles concerning auspicious locations suggests that Chinese geomancy began as an art of selecting a comfortable place to live, and then came to be applied to selecting grave sites as well (Fig. 1).



Geomancy in China. Fig. 1 A geomantic compass currently in use by professional geomancers.

By the sixth and seventh centuries, geomantic principles as we know them today were probably well established in China. Ever since then, geomancy in China has been a powerful part of the art of environmental planning, landscape design, and determining various types of settlement location.

This art was probably diffused to Korea with an early wave of Chinese cultural diffusion. Koreans in turn introduced this art to Japan. Judging from ancient capital sites in Korea and Japan, this art was introduced and practiced in those countries by the seventh century. Geomancy is still practiced in China, Taiwan, Hong Kong, Singapore, Korea, and Japan. In fact, in Hong Kong, Singapore, and Korea, a number of geomantic institutes were established, and professional geomancers practice their art in planning building structures and in the selection of residential and gravesites.

Geomancy has been adapted to the modern urban environment, and even many Chinese living in cities like America apply geomantic principles in selecting their house sites and designing house structures. In city situations the main points of geomantic considerations are in place of the land-form conditions, street patterns, roof lines of neighbors, the shape and situation of a house section, and the floor plan of a house. In some cases, the furniture arrangement inside a house is decided by applying Chinese geomancy to present day city dwellings.

There have been numerous geomantic textbooks and manuals throughout the history of China, and even now there are more than a dozen printed editions of geomantic books are available for purchase in the Chinese language alone.

Geomancy in the Islamic World

Emilie Savage-Smith

The term geomancy comes from the Latin *geomantia*, first used in Spain in the twelfth century as a translation of the Arabic *ʿilm al-raml* (the science of sand), the most common name for this type of divination. The practice is to be distinguished from a totally unrelated Chinese form of prognostication based on land forms, unfortunately also called geomancy in English. The origin of this distinctly Islamic art is a matter of speculation, but it appears to have been a well established practice in North Africa, Egypt, and Syria by the twelfth century.

The divination is accomplished by forming and then interpreting a design, called a geomantic tableau, consisting of 16 positions, each of which is occupied by a geomantic figure. The figures occupying the first four positions are determined by marking 16 horizontal lines of dots on a piece of paper or a dust board. Each row of dots is examined to determine if it is odd or even and is then represented by one or two dots accordingly. Each figure is then formed of a vertical column of four marks, each of which is either one or two dots. The first four figures, generated by lines made while the questioner concentrates upon the question, are placed side by side in a row from right to left. From these four figures the remaining 12 positions in the tableau are produced according to set procedures. Various interpretative methods are advocated by geomancers for reading the tableau, often depending upon the nature of the question asked. The course and seriousness of an illness, the outcome of pregnancy, the location of lost or buried objects, and the fate of a distant relative are among the most popular questions addressed to a geomancer.

The acknowledged master of geomancy was Abū ʿAbdallāh Muḥammad ibn ʿUthmān al-Zanātī, who lived before AD 1230. Virtually nothing is known of his life, though his name suggests that he was from the North African Berber tribe of Zanāta that was known for practicing other forms of fortune telling, particularly scapulomancy (divination by inspection of shoulder blades). One of the great codifiers of geomancy was ʿAbdallāh ibn Maḥfūf who lived, probably in Syria or Egypt, before AD 1265 and whose treatise is preserved today in several Arabic manuscript copies. Brief discussions of geomancy are included in a Persian encyclopedia composed at the end of the twelfth century by the celebrated theologian Fakr al-Dīn al-Rāzī and in short Persian tracts by the mathematician, philosopher, and founder of the observatory at Maragha in northwest Iran, Naṣīr al-Dīn al-Ṭūsī (d. AD 1275).

The majority of existing treatises on the subject are from the fourteenth century and later, with numerous ones still being written in the nineteenth and twentieth centuries. In view of the relatively few written sources on the topic before the fourteenth century, an intricate metal geomantic tablet, now in the collections of the British Museum, is of considerable importance. It was made in AD 1241–1242 (H. 639) by the metalworker Muḥammad ibn Khutlukh al-Mawṣilī, who also made an incense burner in Damascus about AD 1230–1240. This unique device is of a brass alloy inlaid with gold and silver, with a front plate carrying 20 dials and four sliding ares and a back plate engraved with inscriptions, both plates held in a rectangular frame which has a triangular suspensory device on top similar to that commonly found on astrolabes. No writings before or after its construction mention such a mechanical contrivance for establishing a geomantic reading, and there is no other known geomantic device from any culture remotely similar to it. It is evident that the designer of this elaborate device was well-versed in the geomantic literature of his day.

In Iran the term *raml* is applied to two types of divination. One type, frequently described by travelers, employed the throwing of brass dice that were strung together in groups of four. Although these dice are commonly referred to as geomantic dice, they are not marked so as to produce a geomantic figure, and thus the divination using such dice is a form of lot casting or sortilege different from true geomancy. *Raml* is also used in Iran for the traditional form of geomancy, and in modern Persian writings the art often attains an astounding degree of complexity, with successive tableaux generated from previous ones. A large number of lithographed Persian texts were published in India in the nineteenth century.

From the twelfth century until the seventeenth century, geomancy, in a slightly altered form, was very popular in Europe, where only astrology seems to have outranked it in popularity. The Spanish translator Hugh of Santalla working at Tarazona in Aragon appears to have been the first to prepare a Latin paraphrase of an Arabic treatise on the subject, with his slightly younger contemporary working in Toledo, Gerard of Cremona (d. AD 1187), translating another Arabic tract. After the seventeenth century, interest in geomancy faded abruptly in the West, and today it remains relatively unknown there.

There are many non-Western areas where geomancy and derivative methods of divination are still practiced. Geomancy in sub-Saharan Africa and Madagascar, which employs simplified but clearly derivative versions of classical Islamic geomancy, has been the subject of several anthropological studies. The mathematical structure of the practice has also received some scholarly attention. In nearly all Islamic lands geomancy and related methods of divination are still practiced, in forms varying from the simple casting of a favorable or unfavorable geomantic figure to the complex interpretation of tableaux employing a large number of procedures.

Geometry

Frank J. Swetz

Geometry is the branch of mathematics that deals with the partitioning of a physical or abstract space and the relationships induced by that partitioning. Historically, as a human activity, it is said by the Roman historian Herodotus (d. 425 BCE) to have begun in Egypt where the annual inundation of the Nile River obliterated field boundaries. In order to preserve the royal system of land distribution and taxation, official priest-surveyors measured the land and reestablished boundary markers. Their land-measuring techniques were imported to Greece and given the collective name "geometry" (*geo*, "earth"; *metrein*, "to measure"). Thus the practices of land measurement became the science of geometry. However, all peoples and societies possess and use some geometrical knowledge. For example, decorative pottery motifs and textile or basket weaving patterns demonstrate a geometric knowledge and facility on the part of their creators. Certainly the blanket patterns of the Ibans of Borneo and the rafter carvings of New Zealand's Maori people reflect an appreciation of symmetry; a complexity of line relationships is evident in the *sona* tracings of the Tshokwe culture in southern Africa, and a mastery of geometrical figures is illustrated in the sand drawings of North America's Navajos. All these non-Western cultures possess "a geometry" but to survey these traditional geometries would present a monumental task and be beyond the scope of this present survey. Therefore the discussion below will view geometry in a narrower sense, i.e., as an exact science and as a subject of acknowledged societal concern either documented by existing historical records or the evidence of archeological excavations.

Egypt and Babylonia

Egyptian geometry was practical in its conception and tied to measurement and the bureaucratic needs of the state. A small collection of surviving papyrus problems provided a limited glimpse into the workings of Egyptian geometry. The ancient Egyptians possessed correct computation formulas for determining the areas and volumes for a variety of plane and solid figures. Apparently they deduced such formulas by techniques of "dissection and rearrangement." Correct formulas for the areas of rectangles, triangles, and isosceles trapezia were employed. Problem 50 of the Ahmes Papyrus (1650 BCE) gives the area of a circle with known diameter d as $A = (8/9d)^2$ from which it is found that the Egyptians of this time used a value $\pi \approx 3.1605$. Problem 48 of the same sequence provides an illustration that has been interpreted as a polygonal approximation for the area of a circle and from which the formula was derived. In total, the Ahmes Papyrus contains 19 problems of a geometrical nature. The Moscow Papyrus (1850 BCE), in its 14th problem, offers a correct computational procedure for determining the volume of a truncated square pyramid of given height h and with bases whose sides measure a and b in length; $V = h/3(a^2 + ab + b^2)$. Problem 10 of the Moscow Papyrus requires the surface area of a "basket" with known diameter and has resulted in a yet unresolved controversy as to whether the Egyptians were considering the basket as a hemisphere or as a semicylinder. If the former interpretation is accepted this would indicate that the Egyptians possessed rather sophisticated geometrical insights at a very early date. Egyptian geometry remained utilitarian in nature and was never advanced to the status of an abstract science.

In a similar manner, Babylonian geometry was also of a computational nature and devoted to solving practical problems. In our context, the term "Babylonian" designates the civilization that occupied the Tigris–Euphrates region in the period 3500–539 BCE and includes the Sumerian, Akkadian, Chaldean, and Assyrian peoples. Knowledge of Babylonian geometry has been obtained from a limited examination of cuneiform texts and mathematical tables. This examination reveals that their authors possessed computation procedures for obtaining the areas of rectangles, right-angled triangles, isosceles triangles, and trapezia with one side perpendicular to the parallel sides. They knew several numerical properties of a circle and approximated the area of a given circle radius r by $A = 3r^2$. A clay tablet from the Old Babylonian Period (1900–1650 BCE) supplies a more accurate value of π as 3.125. The Babylonians could determine the length of a chord l, given the diameter of a circle d and the length of the sagitta in question a: $l = \sqrt{d^2 - (d - 2a)^2}$. Tablet no. 322 in the Plimpton Collection at Columbia University, whose origin is traced to 1800–1650 BCE, provides a list of Pythagorean triples indicating that the Babylonians of this period were familiar with the "Pythagorean Theorem." A clay tablet excavated at Tell Harmal in Iraq and dated to about 2000 BCE indicates that its users knew some properties of similar triangles and could employ these properties in solving numerical problems involving triangles. Babylonian scribes also could compute the volumes for simple solids and possessed an approximate formula for the volume of a truncated square pyramid of height h and bases of length a and b, i.e., $V = h/2(a^2 + b^2)$. Although several excavated clay tablets bear geometric diagrams, these diagrams serve as illustrations for relevant concrete problem situations and are not theoretical constructions. Apparently for the Babylonians, geometry remained an adjunct to numerical problem solving and did not evolve into a separate discipline.

Ancient India

Geometric activity on the Indian subcontinent can be traced back to the Indus Valley Civilization (ca. 3000 BCE). Excavations at this civilization's urban centers of Harappa, Lothal, and Mohenjo-Daro reveal the existence of a baked-brick technology allowing for the erection of numerous structures: houses, baths, and market places. This construction entailed large-scale city planning and the use of geometry. Archeological evidence indicates that the Indus peoples were familiar with the basic properties of rectangles, triangles, and circles, and could employ right-triangle principles for planning and structural purposes.

With the arrival and dominance of the Aryan culture in the region (1500–800 BCE), there developed a sacred Vedic literature of rituals and customs. Part of this literature concerned the construction of sacrificial fire altars of specific shapes and dimensions. Cord stretching techniques were described to obtain the required results. This collection of construction procedures and techniques became known as the *Śulbasūtras* (800 BCE) or "the rules of the cord." Using cords and pegs, squares, circles, rectangles, and trapezia of specified dimensions and areas could be laid out and constructed by the Vedic priests. Although outwardly religious texts, the *Śulbasūtras* presented a codified system of geometry. Besides obvious geometric constructions, the texts supplied a technical vocabulary for geometrical principles and concepts including a theory of similar triangles. Techniques for transforming shapes while preserving areas considered the quadrature of rectangles and circles, and procedures were also given for doubling the area of a circle and transforming a square into a circle. The principle of constructing a square on the diagonal of a rectangle ("Pythagorean Theorem") was also known to the writers of *Śulbasūtras*. No formal "proofs" were given but some results were justified by arguments.

The subsequent influence of the *Śulbasūtras* on the latter development of Indian geometry is controversial: early researchers such as G. R. Kaye could discern no influence, whereas more modern writers such as T. A. Sarasvati Amma believe that the *Śulbasūtras* established the foundation for all Indian geometry. Whatever the influence of these Veda texts on geometrical thinking, later developments in this field were spotty and isolated. Geometry became closely associated with astronomy and cosmography. It was dominated by numerical problem solving based primarily on the use of right-triangle principles and was mainly concerned with finding the length of circular chords. The post-Vedic period saw the rise of the Jaina school of philosophical and scientific thought. The Jainas, in their cosmological considerations, held two geometric figures – the circle and trapezium – in high regard. Much of their geometry focused on mensuration problems involving these figures. In general, they considered geometry important denoting it as "the lotus of mathematics." The Jainas employed the approximation $\pi = \sqrt{10}$.

The next Indian mathematical text of note to appear was the *Āryabhaṭīya* (ca. 499) of Āryabhaṭa I (476–550). While many of its problems concern the applications of geometry to astronomy, its author also considered the computation of area for triangles, trapezia, and circles, and the volumes of spheres and triangular pyramids. Āryabhaṭa's formula for the area of a circle is correct; his approximation for π is 62832/20000 or 3.1416. However, his results for the volume of a sphere are $V = \pi^{3/2} r^3$. Subsequent mathematical authors would refine and extend Āryabhaṭa's work. Brahmagupta (ca. AD 628) in his *Brahmasphutasiddhānta* (Correct Astronomical System of Brahma) provided sections on *Ksetra* (plane figures), *Khāta* (cubic figures), *Citi* (solids composed of piles of bricks), *Krakaca* (truncated solids), and *Chāyā* (plane figures resulting from shadows). Much of Brahmagupta's results are limited to triangles and quadrilaterals inscribable in a circle. His most notable findings include:

- The correct determination of the area of a cyclic quadrilateral of sides a, b, c, d, with s as its semiperimeter, i.e.,

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)}.$$

- The length of the quadrilateral's diagonals d_1 and d_2:

$$d_1 = \sqrt{\frac{(ac+bd)(ad+bc)}{(ab+cd)}},$$

$$d_2 = \sqrt{\frac{(ac+bd)(ab+cd)}{(ad+bc)}}.$$

- The volume of a cone as 1/3 the product of its base area and its height.

Mahāvīra (ca. 850), a Jaina mathematician, improved upon Brahmagupta's theories in his *Ganitasārasamgraha* (Summary Compendium of Mathematical Astronomy), greatly extending geometric terminology and classification systems. For example, he divided quadrilaterals into five different subcategories: equal sides, opposite sides equal, etc., and triangles into three categories: equilateral, isosceles, and scalene. Bhāskara II (b. 1114), author of one of the most illustrious of Indian mathematical classics, *Līlāvatī* (The Beautiful), obtained accurate formulas for the volume and surface area of a sphere and obtained close approximations for the length of a circular arc in terms of its known chord. Mādhava of Sangamagrāmma (ca. 1340–1425), a Kerala astronomer, is noted for his work on the circle as well as spherical geometry.

Euclid's *Elements* were known and studied in India in the fourteenth century, but the first complete Sanskrit translation of this work appeared in 1718. The translation was performed by Jagannātha Samrāt at the request of his patron king astronomer Jayasimka of Jaipur.

The Islamic World

The founding of Islam in AD 622 was marked by the flight of Muḥammad from Mecca to Medina. Initially experiencing a period of rapid expansion, it was not until the founding of the Abbasid Caliphate, with the establishment of Baghdad as an intellectual and political center (AD 726) that Islamic civilization could begin to express its own intellectual and scientific traditions. The early Abbasid caliphs were patrons of the collection and translation of foreign scientific texts into Arabic, thus establishing a basis for Islamic science. Although Muslim scholars became the heirs of existing western (and eastern) scientific theories and traditions, they did not remain mere translators and passive communicators of this knowledge. In many fields they became true innovators and amplifiers of their mathematical and scientific inheritance. Geometry was one such field that was enriched by Islamic contributions.

The Greek sources that most influence Islamic geometric thinking were Euclid's *Elements*, Archimedes' *On the Sphere and Cylinder*, and Apollonious of Perga's *Conics*, all of which found their way into Arabic during the eighth to the ninth centuries. Muslim geometers pursued the theoretical problems poised in these texts and used their principles in a wide variety of new applications, particularly the study of optics and the design of mathematical instruments. The earliest documented Islamic geometry appears as a separate section of al-Khwārizmī's *Kitāb al-mukhtaṣar fī ḥisāb al-jabr wa 'l-muqābala* (Compendious Book on Calculation by Completion and Balancing), where rules for mensuration and geometric computations involving areas and volumes are stated. The value of π is given as $31/7$. Within 50 years of al-Khwārizmī's work, his successors were involved with far more complex geometric theories.

Thābit ibn Qurra (830–890) discussed the geometric verification of algebraic results in his *Qawl fī taṣḥīḥ masā' il al-jabr bi'l-barāhīn al-handasīya* (On the Verification of Problems of Algebra by Geometrical Proofs). In a private correspondence with a colleague, he expressed dissatisfaction with the existing Socratic proof of the "Pythagorean Theorem" and went on to derive three new proofs, one of which provides a generalization of the theorem to all triangles. Thābit also wrote on the trisection of an angle problem. His grandson, Ibrāhīm ibn Sinan (d. 946), continued researching this problem and provided for "ruler and compass" constructions of the conic sections in his *Rasm al-quṭūʿ al-talātha* (Outline of Three Sections). In approximately AD 950, Abū'l Wafāʾ wrote a book on applied geometry for craftsman, *Kitāb fī mā yaḥtāj ilayh al-ṣāniʿ min al-aʿmāl al-handasiyya* (Book on Necessary Geometric Construction for the Artisan), in which he presented several original constructions for conic sections. Around the year 1000 Abū ʿAbdullāh al-Ḥasan ibn al-Baghdādī published a comprehensive treatment of incommensurables improving on the theory given in the *Elements*.

One of the recurrent themes in Islamic geometry is the concept of parallel lines and the provability of Euclid's fifth postulate. Ibn al-Haytham (ca. 965–1039), known in the West as Alhazen, attempted to reformulate Euclid's theory of parallel lines by assuming the constructibility of the lines. He presented his theory in a work entitled *Maqāla fī sharḥ muṣādarāt kitāb Uqlīdis* (Commentary on the Premises of Euclid's *Elements*). ʿUmar ibn Ibrāhīm al-Khayyāmī, or ʿUmar al-Khayyām (ca. 1048–1126), in investigating the concept of parallelism, developed a series of eight propositions eventually leading to the establishment of Euclid's fifth postulate. ʿUmar al-Khayyām's work was based on the possible relationships of the angles of a quadrilateral. In turn, this work was expanded by Naṣīr al-Dīn al-Ṭūsī (1201–1274). He also explored parallelism with the aid of a quadrilateral, but allowed for the existence of acute and obtuse angles within the quadrilateral seeking to obtain a contradiction to his premises concurring the nature of parallel lines. He published his work on the fifth postulate in 1250; it was entitled *Al-risāla al-shāfiya 'an al-shakk fī al-khuṭūṭ al-mutawāziya* (Discussions which Remove Doubts about Parallel Lines).

Eventually the theories of Islamic scholars such as Ibn al-Haytham and al-Ṭūsī reached Europe; there they profoundly affected the nature of geometric thinking.

China and the Far East

Most geometrical considerations in early China were empirically based. However, during the Mohist school of activity (ca. 300 BCE) a deductive approach to understanding geometry was undertaken. Mohist philosophy and scientific theory were based on the use of logic. The Mohist Canon (*Mozi*) (ca. 330 BCE) develops a formalist approach to plane geometry building upon a concept of points and lines. Mohist theories did not become popular, and the development of a theoretical geometry progressed no further.

The earliest extant references specifically on Chinese mathematics are the *Zhoubi suanjing* (Arithmetical Classic of the Gnomon and the Circular Paths of Heaven) and *Jiuzhang suanshu* (Nine Chapters on the Mathematical Art, ca. 100 BCE). A discussion of right-triangle relationships is given in *Zhoubi*, along with a dissection proof demonstrating that the sum of the squares of the sides adjacent to the right angle in a right triangle is equal to the square of the hypotenuse. Four chapters of the nine chapters of *Jiuzhang* are specifically devoted to geometrical computations involving areas, volumes, and work with right triangles. Correct procedures for finding a variety of areas and volumes are given; the area of a circle of radii r is noted as $A = \pi r^2$ with $\pi = 3$; but the volume of a sphere with diameter d is incorrectly found, $V = 9/16d^3$. An approximation for the area of a circular segment with chord C and sagitta S is given as $A = S/2(S + C)$. Similarity among right triangles is employed in several problem situations.

In the third century, the scholar Liu Hui wrote a commentary on the *Jiuzhang* in which he provided dissection proofs for many of its geometrical formulas. Liu also employed a circle dissection technique involving a 192-sided polygon to estimate π as 3.141024. He extended the right-triangle theory of the *Juizhang* to include more complex problem situations involving pairs of similar right triangles. Using a technique called *chong-cha*, Liu provided proofs for solution procedures and published his findings in an appendix to *Juizhang*. Eventually, this appendix became a separate geometrical classic called *Haidao suanjing* (Sea Island Mathematical Manual). Zu Chongzhi (429–500) refined Liu's approximation for π obtaining a value of 355/113 or 3.1415929. Further, using a geometric slicing technique, Zu found the volume of a sphere, radii r, correctly as $V = 4/3\pi r^3$.

In 656, the geometric theory contained in *Zhoubi suanjing*, *Juizhang suanshu*, and *Haidao suanjing* was sanctioned by the Tang dynasty as a formal curriculum for its scholar officials. This curriculum was also eventually adopted in Japan and Korea, establishing a limited geometrical outlook based on empirical problem solving. This outlook would remain unaltered until the sixteenth century when a translation of Euclid's *Elements* appeared in the Chinese language. This translation of the first six books of Euclid was made by the Jesuit missionary Matteo Ricci and the Chinese scholar Xu Guanggi.

Pre-Columbian America

Although no written records exist to document the geometric knowledge of the early Native American civilizations, archeological sites testify to their use and understanding of geometry. In particular, the city planning and construction techniques employed by the Olmec, Maya, Teotihuacan, Toltec, and Aztec peoples of South and Central America and the Anasazi of the North American Southwest indicate that these peoples utilized the properties of circles, squares, and rectangles and employed right-triangle theory.

Geometry in Africa

Paulus Gerdes

The *sona* tradition is a part of the heritage of the Tchokwe, Lunda, Lwena, Xinge and Minungo peoples that inhabit the northeastern part of Angola, and of the Ngangela and Luchazi peoples of southeastern Angola and Western Zambia. When the Tchokwe met at their central village places or at their hunting camps, they usually sat around a fire or in the shadow of leafy trees spending their time in conversation, illustrated by drawings in the sand. These drawings are called *lusona* (singular) or *sona* (plural).

Most of these drawings belonged to an old tradition. They referred to proverbs, fables, riddles, animals, etc., and played an important role in the transmission of knowledge and wisdom from one generation to the next.

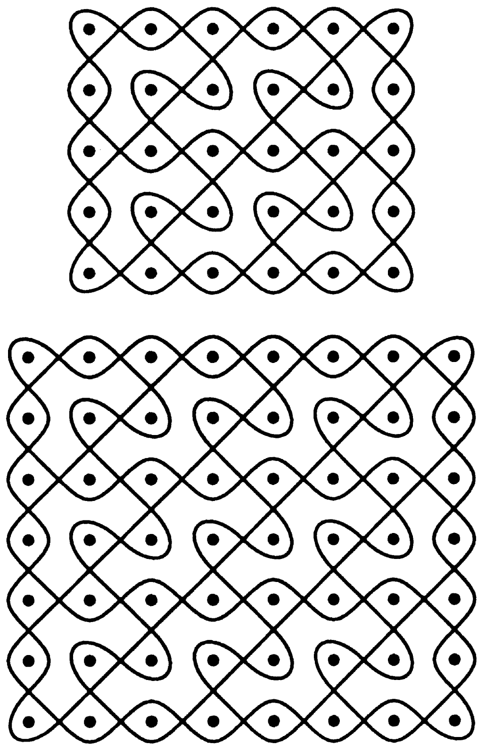
Every boy learned the meaning and execution of the easier *sona* during the intensive schooling phase of the circumcision and initiation rites. The significance and creation of more difficult *sona* were known only by specialists, the *akwa kuta sona* (those who know how to draw), who transmitted their knowledge to their sons.

The designs have to be executed smoothly and continuously. In order to facilitate the memorization of their standardized 'sona', the drawing experts used the following mnemonic device. After cleaning and smoothing the ground, they first set out with their fingertips an orthogonal net of equidistant points. Then one or more lines were drawn that 'embraced' the points of the reference frame. By applying their method, the drawing experts reduced the memorization of a whole drawing to that of mostly two numbers (the dimensions of the reference frame) and a geometric algorithm (the rule of how to draw the embracing line(s)).

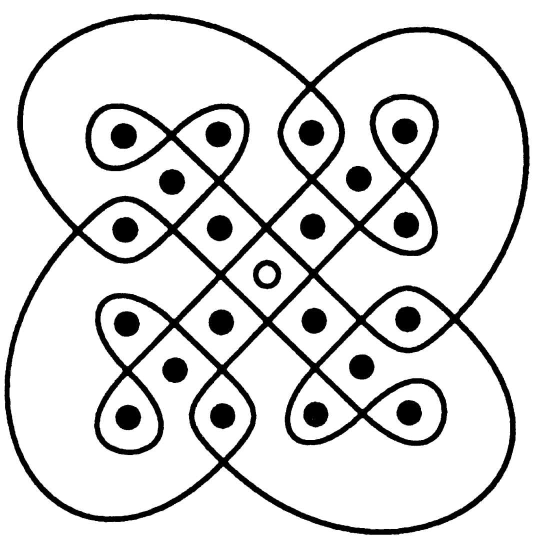
The *sona* tradition vanished almost completely. Tentative designs have been made to try to reconstruct the mathematical knowledge of the drawing experts.

They considered symmetry and monolinearity (i.e. a whole figure made up of only one line) important. Note the example of a *lusona* that is monolinear and that displays a rotational symmetry of order 4 (Fig. 1).

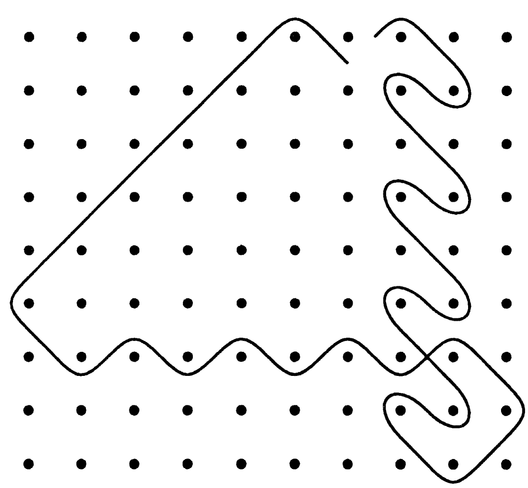
They invented geometrical algorithms for the construction of classes of 'sona'. Fig. 2 displays two monolinear drawings belonging to the same class and constructed in agreement with the same algorithm



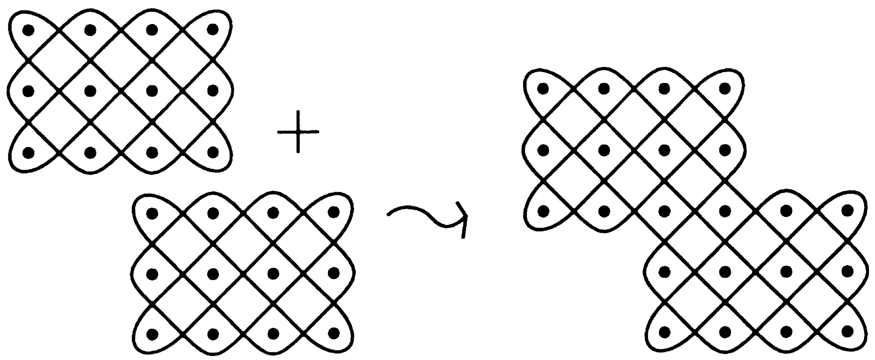
Geometry in Africa. Fig. 2 Two instances of "chased chicken" sona.



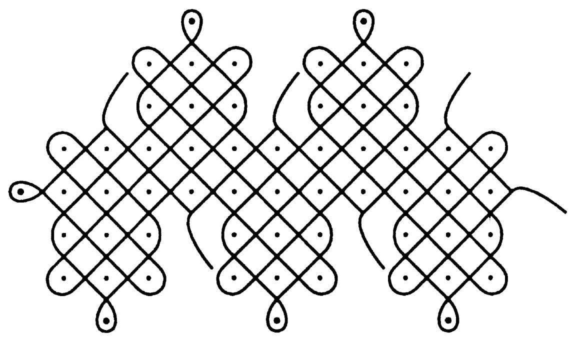
Geometry in Africa. Fig. 1 Monolinear *lusona* with rotational symmetry.



Geometry in Africa. Fig. 3 Geometrical algorithm for "chased chicken" patterns.



Geometry in Africa. Fig. 4 Example of a composition rule.



Geometry in Africa. Fig. 5 Representation of a leopard with five cubs.

(Fig. 3). Both drawings represent the marks left on the ground by a chicken when it is chased.

The drawing experts also invented a series of rules for the systematic construction of monolinear *sona*. They probably knew why the rules were valid: they could prove in one way or another the truth of the theorems that these rules expressed.

Fig. 4 illustrates one such a rule. This rule serves for chaining monolinear patterns and has been applied four times in the Tchokwe representation of a leopard with five cubs (see Fig. 5).

Geometry in Chinese Mathematics

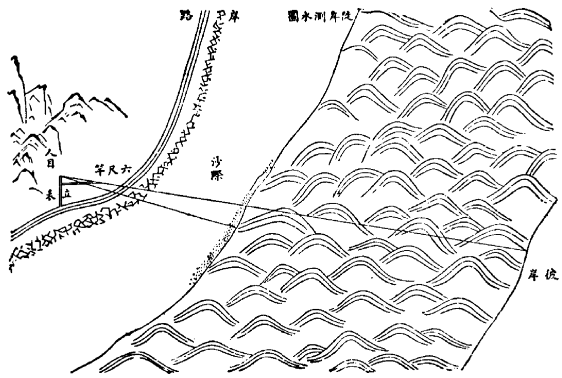
JEAN-CLAUDE MARTZLOFF

The earliest evidence of a systematic organization of regular shapes reproduced on material objects found in China dates from the third millennium BCE or even earlier. Painted motifs displaying geometrical patterns such as symmetrical arrangements of triangles, lozenges, or circles have been found on pottery pieces unearthed at Banpo[1] (near present-day Xi'an) and other archaeological sites. These designs demonstrate an early interest in spatial ordering and are perhaps at the origin of subsequent developments even though we are now unable to establish any continuity between prehistoric and historic Chinese mathematics. Nonetheless, several Chinese myths and legends attest that the plumb line, the compass, the carpenter square, and the gnomon (a post of standard height) were commonly used in Zhou China (1121–256 BCE). This last instrument, in particular, was considered so important

[1] Banpo (Pan-p'o) Neolithic dwelling site, one of the most important of its kind, located in the vicinity of Xi'an, south Shenxi, to the north of the present village of Banpo, on a hillock. It was discovered in 1953 while men were constructing the foundations of a plant. It belongs to the Yangshao culture (ca. 6000 BCE). It comprises the remains of the foundations of 45 huts, 200 silos, painted potteries, animal bones, farming and fishing tools, and a necropolis (more than 200 tombs and 37 funerary urns).

that the Chinese began founding their astronomical and calendrical conceptions on the determination of the length of gnomon shadows.

Chinese mathematical computations based on the gnomon have been preserved in several important sources from Chinese antiquity such as the *Huai Nan Zi* (The Book of the Prince of Huai Nan)[2] and the *Zhoubi suanjing* (The Canon of Gnomon Computations from the Zhou Dynasty) (Cullen 1996). In these sources, gnomons and their shadows are considered as sides of similar right-angled triangles and properties of similarity are applied to the determination of the height of the sun, at noon, above the flat earth. Later on, the same technique was generalized and used for the determination of earthly distances not directly measurable such as the depth of a well, the height of a mountain, or the distance of an island from the shore. Toward the end of the third century AD, these techniques were edited in algorithmic form in a book entitled *Haidao suanjing* (The Sea Island Computational Canon)[3] (Fig. 1).



Geometry in Chinese Mathematics. Fig. 1 A variant of the *Haidao* technique, taken from Problem IV-3 of the *Shushu juzhang* by Qin Jiushao (1248). The drawing explains the process of "measuring the width of stream from a steeply slanting bank" in order to construct a pontoon bridge in view of military operations (Libbrecht 1973).

In a quite different spirit, the Mohists – a sect of preaching friars from the fourth and third centuries BCE – approached geometry from a logical point of view and attempted to define the point, the circle, the square, space, and even parallelism (this last point is controversial). Certain of these definitions bear a striking resemblance to those found in Greek mathematics, particularly in Euclid's *Elements*. Still, there are important differences between both approaches: the Mohist definitions do not concern a single science, geometry, but include optics, mechanics, and economics. Moreover, the Mohists allow their definitions to incorporate familiar objects from the immediate human environment such as the sun, the bolt of a door, and other very concrete notions. More importantly, the grammatical structure of the Chinese language is

---

[2] The prince of Huainan, Liu An, lived under the first half of the Former Han (~206–8), his grand father was Liu Bang (r. ~206 to ~196), the founder of the Han dynasty. The whole text of the *Huai Nan Zi* has been recently translated into French (Le Blanc and Mathieu 2003).

[3] *Haidao suanjing*, one of the Ten Mathematical Manuals (*Suanjing shishu*) of the Tang dynasty (618–907), was composed much earlier by the famous Liu Hui (late third century AD) and commented upon by Li Chunfeng (640–670). From the beginning, it was considered a sequel to the *Jiuzhang suanshu*. Under the Tang dynasty (618–907), it was incorporated in the famous *Suanjing shi shu* mathematical collection composed of ten treatises, just after the *Jiuzhang suanshu*. It was also first officially printed under the Northern Song. None of these antique manuscripts and prints have been handed down to us and the present edition of the text is mainly the result of a late eighteenth-century compilation of incomplete Southern Song dynasty editions, together with excerpts of the text incorporated into the famous encyclopedia, *Yongle dadian* published under the reign of the emperor Yongle (1403–1407).
The *Haidao suanjing* is a very short treatise, composed of only nine problems, all concerned with the determination of inaccessible lengths. Word for word, its title means "Sea *hai* Island *dao* computational *suan* classic *jing*"; it should not be taken literally since only the first problem of the collection has really something to do with a sea island, while some others concern mountain distances, the depth of a well, the width of a river estuary. In a word, its real topic is topometry seen under the angle of various special examples, not maritime surveying. In fact, the title is only here to give an idea of what the book contains by alluding to the specific content of its first problem. It is a kind of mnemotechnic device, a reminder.
As for the problems, their textual structure is uniform, composed as they are in the tripartite form of, first, the statement of a little enigma, second the solving technique and last, the commentary. While the problems are rather realistic, the solving technique is announced in a general way and states the succession of arithmetical operations to be performed in order to obtain the answer from the known data of the text, irrespective of the special numerical values various elements are given in the statement of the problem. In sharp contrast with the commentaries of the *Jiuzhang suanshu*, the present one is not devoted to the rational justification of the sequences of calculations. Rather, they only give some specific details concerning the underlying arithmetic.
The statement and solution of the first problem are as follows: Let a Sea Island be observed. Erect 1,000 *bu* (paces) apart two poles of the same height, three *zhang*, in such a way that both are aligned on an equal level. When moving back 123 *bu* from the front pole and looking from the ground up to the top of the island, the top end of the front pole lies in the alignment. When moving back 127 *bu* from the rear pole and looking from the ground up to the top of the island, the top end of the back pole lies again in the alignment. Question: find the height of the island and its distance from the front pole?
Answer: height of the island 4 *li* 55 *bu*; distance from the front pole 102 *li* 150 *bu*.

such that objects and their properties are not distinguished in any way in the Mohist definitions cf. A. C. Graham, 1978.

Mohist logic did not arouse much interest and was never again studied in China; Chinese geometry developed without concern for geometrical definitions, let alone axiomatic–deductive constructions. But during the Han dynasty (206 BCE–AD 220) Chinese mathematical knowledge was for the first time separated from other domains and recorded in the *Jiuzhang suanshu* (Computational Prescriptions in Nine Chapters, also translated as Nine Chapters on the Mathematical Art[4]). Composed of 243 problems and almost as many prescriptive solutions (*shu* = method, device, prescription, algorithm), this very influential manual was eventually revered as a kind of mathematical Bible, so that as late as the seventeenth century certain respected Chinese mathematicians considered that all imaginable problems and computational methods would necessarily be interpretable in terms of the traditional nine chapters of the *Jiuzhang suanshu*.

In fact, the geometry of the *Jiuzhang suanshu* is not precisely an autonomous body of knowledge and consists essentially in a threefold compilation of problems pertaining to planimetry, stereometry, and right-angled triangles. Planimetry is included in the first chapter of the *Jiuzhang suanshu* and comprises a collection of formulae needed to compute the area of fields in the form of squares, rectangles, triangles, trapezia, circles, rings, and segments of circles. Stereometry is found in the fourth and fifth chapters and concerns the computation of volumes or capacities of cubes, parallelepipeds, pyramids, spheres, as well as that of various prisms, dikes, moat walls, ditches, excavations, and cylindrical or prismatic grain silos. Problems on right-angled triangles are found in the last chapter of the *Jiuzhang suanshu* and bear upon Pythagoras' theorem, where some dimension of a right-angled triangle is sought, given simple algebraic combinations of other dimensions (such as the sum of its base and hypotenuse, its area, and so on). Lastly, the determination of the side and diameter of a square and a circle, respectively, inscribed in the same right-angled triangle are also considered. Nongeometrical subjects are also dealt with in the same chapters (for example, fractions in the first chapter, square and cube roots in the fourth). In addition, various concerns (units of measurement, for example) frequently interfere with the geometrical aspect of problems, so that they seem highly realistic at first sight. In reality, most of them are artificial, since the situations they describe are often the inverse of what would naturally occur in real life: one is often asked to determine the dimensions of a figure given its area or its volume. On the whole, these problems are strikingly similar with those found in the *Suanshu shu (Book of arithmetic)* an arithmetical manual written on bamboo strips from ca. 186 B. C, found in 1983–1984 in a tomb of a Chinese nobleman from the Western Han Dynasty in a site neat Zhangjiashan, Jiangling country, Hubei province.

Given that problems on planimetry, stereometry, and right-angled triangles quite similar to the above ones are also well represented in the known corpus of Babylonian mathematics, it would seem that there is no essential difference between Chinese and Babylonian geometry. That is not the case, however, for on the one hand, the solutions of Chinese problems are practically never stated using particular numbers but rather general formulations, and on the other hand, certain Chinese mathematicians have felt the need to justify geometrical results. Remarkably, these justifications would appear quite correct and even accessible to informal proofs in the eyes of modern mathematicians not at all acquainted with Chinese mathematics.

Chinese proofs of geometrical results have been preserved in various commentaries on the *Jiuzhang Suanshu* composed between the third and the seventh century AD by Liu Hui (fl. ca. end of the third century), the author of most of them, Zu Chongzhi (429–500), a famous astronomer and mathematician known for his approximation $\pi = 355/113$, and Li Shunfeng (602–670), an astronomer and compiler of the *Suanjing shi shu* (Ten Computational Canons), a collection of mathematical manuals representative of Chinese mathematical knowledge from the origins to the seventh century. As may be expected, the commentaries do not focus on mathematics alone, but concentrate also on many other aspects of problems needed to understand their original context and pertaining to history, geography, philology, pedagogy, and philosophy. The commentaries are thus intrinsically nonhomogeneous.

[4] Generally speaking, *shu* means "technique" or "art." For example, in terms like *labanshu*, cerography (lit. the art of cerography), *yaoceshu* (lit. the art of measuring from afar) telemetry, *qieduanshu*, amputation (the art of cutting limbs), *fashu* magic arts, *guoshu* (lit. national arts), i.e., Chinese traditional martial arts and gymnastics, *jianshu*, swordsmanship, *jishu*, technology, *mimashu* (lit. the arts of secret codes) cryptography, *meishishu* (lit. the art of fine eating) gastronomy, *suanshu* (lit. the arts of calculation) arithmetic and sometimes mathematics too, *yinshuashu*, printing, *zhanxingshu*, astrology, *zhiwenshu*, dactylography, and so on. From this, the title *Jiuzhang suanshu* could be said to be "the arts of the nine chapters." However, it is also a fact that the text of the *Jiuzhang suanshu* consists of a list of problems with their *shu*, i.e., their prescriptions - or receipts or "instructions" - which is precisely the special meaning of *shu*, in this context; these *shu*, receipts, are sometimes also called "procedures" in a rather anachronistic way, as if computer listings and algorithms were at stake here. The title *Jiuzhang suanshu* means exactly "the *shu* of the nine chapters," i.e., "the receipts of the nine chapters" or the "computational prescriptions in nine chapters."

In their turn, the proofs themselves are often interspersed with numerous digressions and are no more homogeneous that the rest of the commentaries they are imbedded in. Moreover, they frequently rely on all sorts of results (Pythagoras' theorem, for example) not yet proved when they were first used. Reasoning is thus neither constrained by formal modes of presentation nor by restrictions on what is admissible and what is not. In particular, numerical computations are liberally used, even when strictly speaking they would not necessarily be needed. More surprisingly however, but probably for mnemotechnical reasons, most proofs are formulated in a terse language; deductions are only suggested and based on a limited number of heuristic principles whose formulation is also extremely concise and which are used over and again.

One of these heuristic principles can be described as a generalized form of the so-called "Cavalieri's principle" (named by analogy with a famous proposition found in Bonaventura Cavalieri's *Geometria Indivisibilibus*; Bologna 1635).[5]

In its Chinese version, this principle is limited to solids and states that when the areas of the plane sections of two solids always have the same proportion between them, their volumes also have the same proportion. According to another heuristic principle, when a figure is dissected into several pieces as if it were a puzzle, and when the pieces are adequately reassembled, the area (or the volume) of the initial and final figures is equal. This principle is used with standard colored pieces (*qi*) but these are not necessarily the equivalent of concrete pieces of some puzzle since their number is sometimes infinite and involves the idea of carrying the process to the limit. This is the case, for example, in the derivation of the volume of the pyramid, in a way which reminds us of Euclid's proof of the volume of the pyramid (*Elements*, book 12, prop. 5), as the mathematician and historian of mathematics B. L. van der Waerden has suggested.[6] This dissection technique is so productive that its usage extends beyond the bounds of geometry. Very often, properties that we would call "algebraic" (especially when the equivalent of equations comes into play) are manipulated figuratively by means of dissections, so that algebraic relations are directly visualized without any recourse to discursive reasoning or even to particular computations.

As numerous quotations from classical texts (such as Confucius's *Analects*, the *Yijing* (*I Ching*, Book of Changes) or Zhuangzi's[7] works) found in the commentaries on the *Jiuzhang suanshu* suggest, this approach largely depends on Confucian and Daoist ideas. According to the Confucian conception, when presenting new knowledge, all the details should not immediately be revealed to students in order to oblige them to make efforts which would result in a deeper understanding. Similarly Zhuangzi favored conciseness of expression, but for a very different reason: he believed that, as sophisms show, discursive reasoning is intrinsically limited and therefore any efficient access to knowledge should necessarily include all imaginable modes of apprehension of reality and not only discursive reasoning. On the whole, these conceptions induced defiance toward modes of reasoning based on language alone; hence the recourse to nonlinguistic modes of communication such as those based on computations or figurative techniques. Still it remains possible that the *Jiuzhang suanshu* and its commentaries are also the result of various other influences which did not necessarily originate in the Chinese world. In this respect it should be noted, for example, that Archimedes and other Greek mathematicians already used equivalents of Cavalieri's principle many centuries before the advent of the *Jiuzhang suanshu* and its commentaries. Dissections are also attested in antiquity, particularly in Archimedes' *Stomachion*[8] and even more strikingly, the Chinese proof relating to the volume of the sphere relies, among other things, on the knowledge of the fact that the volume of a solid defined by the intersection of two orthogonal cylinders inscribed in the same cube is equal to two-thirds of the volume of the cube, a result explicitly stated in Archimedes's *Method of Mechanical Theorems for Eratosthenes* and in Heron of Alexandria's *Metrica*.

[5] The original text of Cavalieri's *Geometria Indivisibilibus* is wholly accessible from the Biblioteca Digitale IMSS (Istituto e Museo di Storia della Scienza, Firenze) (▶http://www.brunelleschi.imss.fi.it/bd/).

[6] "Liu [Hui]'s proof is very similar to that of Euclid, and it is based on just the same division of a tetrahedron into two prisms and two smaller tetrahedra" (van der Waerden 1983: 204, 202ff).

[7] Also know as *Zhuangzhou* (ca. 370–300 BCE), this Daoïst philosopher from the Warring States period is the author of the *Zhuangzi* and can be considered as the master of irrationalism.

[8] Cf. E. J. Diksterhuis (1987). The Stomachion: "This is a kind of game, played with ivory pieces in the form of simple planimetrical figures, the object being to fit these various bit together in such a way that various shapes of human beings, animals or different objects were imitated." Note that this conclusion is solidly based on quotations taken from several classical authors. In other words, the Stomachion is a kind of puzzle in use in classical antiquity, more than 2,000 years before the first mention of the tangrams in China, first in the seventeenth century, and above all at the beginning of the nineteenth century.

[9] On this the indispensable reference always remains U. Libbrecht's outstanding masterpiece, *Chinese Mathematics in the Thirteenth Century, the Shu-shu chiu-chang of Ch'in Chiu-shao*. Cambridge, Massachusetts: MIT Press, 1973.

After the seventh century, the Chinese repertory of planimetrical and stereometrical formulae was continuously enriched. Among the most interesting results from this period, one must cite Hero's formula for the computation of the area of a triangle given its sides, which was published in Qin Jiushao's *Shushu juzhang* (Mathematical Works in Nine Chapters, 1247).[9] Despite its title, this work is very different from the *Jiuzhang suanshu* and is better known for its study of the "Chinese remainder problem" (simultaneous congruences) and its algebraic developments. After the seventh century however, and until the seventeenth, geometrical proofs were never again recorded in Chinese mathematical books. This fact perhaps has something to do with the remarkable development of Chinese algebra which took place during the Song and Yuan dynasties, for algebraic computations have the capacity to generate new results by means of mere computations. Nevertheless, we must admit that we absolutely do not know why some eminent Chinese like Liu Hui or Zu Chongzhi became interested in mathematical proofs endowed with a rather strong Greek flavor, from the triple point of view of its methods, contents, and results, during a short interval of time, limited to a few centuries, and in a context where Chinese geometry was previously limited to trivial or semitrivial results (such as $\pi = 3$ in the *Jiuzhang suanshu*).[10]

At the beginning of the seventeenth century, the Chinese became aware of axiomatic–deductive modes of reasoning when, in 1607, the first six books of Christopher Clavius's commentary on Euclid's *Elements* were translated into Chinese by the Jesuit missionary Matteo Ricci (1552–1610) and Xu Guanggi (1562–1633) under the title *Jihe yuanben* (*jihe* = geometry or quantity and *yuanben* = elements, so that *Jihe yuanben* means either "*Elements* of Geometry" or "*Elements* of the Measure of Quantities") – here, the reader will perhaps deem this story unbelievable. Why, from the very beginning, were Jesuits in China more interested in translating Euclid into Chinese rather than the Bible, papal bulls, catechisms, and other religious texts much more in keeping with a missionary activity? In fact, the answer has to do with the Jesuit educational policy in the context of the Catholic counter-reform. In their *Ratio studiorum* the Jesuits stress the importance of deductive mathematics because of its strong connection with theology: mathematics are extremely important because the kind of knowledge they provide depends both on dogmatic assertions – axioms and postulates – and deductive reasoning leading to truth and certainty. In other words, teaching mathematics to the Chinese was felt like the first and necessary step toward the propagation of religious truths.[11] Xu Guangqi was a Christian convert and influential high official responsible for the reform of Chinese astronomy undertaken from 1630 onward on the basis of imported European knowledge. It has often been noted that some Persian or Arabic version of Euclid's *Elements* had already reached the Chinese imperial library three centuries earlier, during the Mongol domination of China, but there exists no evidence of any Chinese translation made during that period, and no trace of influence on subsequent Chinese mathematics has ever been detected.

At first, the new geometry was not much studied save by a few converts and Chinese students of Western astronomy who served the Jesuits at the imperial bureau of astronomy. However, as time went on, many Chinese scholars impressed by the successes of European sciences (especially mathematical predictions of celestial phenomena such as eclipses of the sun and calendrical computations) began to study the *Elements* seriously. The majority of these scholars considered that Euclid stood at the very basis of the new Western knowledge. At the same time they also believed that once properly reinterpreted, the results of the *Elements* were the same as those of their nine mathematical chapters; they also thought it desirable to dissociate the content of the *Elements* from its form. Far from representing the very model of logical clarity and the universal basis of all true knowledge, the formal structure of argumentation was judged inappropriate and even noxious. A textual recasting (of the *Elements*) not only affected demonstrations but also geometrical figures, and mathematicians of the first order such as Mei Wending (1633–1721) did their best to dissociate geometrical figures from the demonstrations to which they were attached. Thus, they sometimes redrew figures so as to make the corresponding theorems directly visible. Taking as it were the appearance of "monstrations," demonstrations changed of nature through the intermediary of tangible figurative representations. At the same time, this major transformation of Euclidean space was accompanied by an extensive "numerization" of geometry. Whereas, in their underlying logic, Euclid's *Elements* dealt with intrinsic properties of numbers in general, without ever quoting any precise number, even when questions of area and volume were at stake, Chinese geometers made

massive use of explicitly mentioned particular numbers, computed if need be with a high degree of precision (Martzloff 1993–1994: 71–72).

Such reactions against the *Elements* were also fairly common in Europe during the seventeenth century, but, in sharp contrast with what happened in China, these European reactions (which often went hand in hand with the rejection of Aristotelianism and scholasticism) were never powerful enough to dominate the mathematical scene, except perhaps in elementary education. In fact, during the seventeenth and eighteenth centuries, China was dominated by a strong reaction against all sorts of speculative reasoning prevalent during the preceding centuries which was designated as the source of Chinese decline. Consequently, numerous scholars advocated the development of concrete sciences (*shixue*), i.e., of applied sciences whose usefulness could be tangibly demonstrated by an increased social welfare. Thus, if mathematics were to be used at all, computational results had to be expressed in the form of easily understandable instructions. In this respect, syllogisms like those of the *Elements* were particularly difficult to use, inasmuch as they also involved numerous repetitions, a characteristic which was also contrary to the canons of Chinese literary composition. In addition, certain critics also wrote that Euclid's *Elements* were written in a cryptic language devised purposefully to obscure simple mathematical results. Many scholars found still another reason to defy geometry; they believed – not without basis – that they had detected an essential similarity between formal discourses typical of the rhetoric of geometrical demonstrations and the scholasticism of the theological speculations widely diffused by the European missionaries. Hence there was a rejection of forms of expression which tended to speculative form.

These ideas remained unchallenged in China until the end of the nineteenth century, but if axiomatic–deductive reasoning was never studied as such during that period, geometrical results were nevertheless taken seriously as early as the second half of the seventeenth century. In particular, a famous mathematician Mei Wending developed at length the computational aspect of the stereometry of regular and semiregular polyhedrons on the basis of a very incomplete description of these that he had found in the *Celiang quanyi* (Complete Treatise on Measurements), a manual based on Clavius's *Geometria practica* and translated into Chinese ca. 1635. Others tried to recast to content of the *Elements* into the mold of the nine chapters of the *Jiuzhang suanshu*. From the end of the seventeenth century, new Chinese and Manchu translations of the *Elements* were realized under the patronage of the Kangxi emperor. These were all given the same title as the former translation of the *Elements* published a century earlier. However, they were very different from

Geometry in Chinese Mathematics. Fig. 2 Alexander Wylie.

Clavius's commentary since they were all essentially based on Father Gaston-Ignace Pardies (1636–1673) (Ziggelaar 1971). *Elements de géometrie*, a French manual very different from Euclid's initial text and intended for the teaching of geometry in Jesuit colleges (Ziggelaar 1971). Pardies' manual (first published in 1671) was so popular that it remained in use in Europe during a whole century and was translated into several European languages. The new translations of the *Elements* all remained in manuscript form, but these eventually gave birth to a final text which was eventually incorporated into a famous mathematical encyclopedia published by imperial order at the end of Kangxi's reign, the *Shuli jingyun* (Collected Essential Principles of Mathematics, 1723). Whereas this encyclopedia remained in use in China for two centuries, the not yet translated part of the first translation of the *Elements* was carried out between 1852 and 1856 by Alexander Wylie (1815–1887) (Fig. 2), a British Protestant missionary, and Li Shanlan (1811–1882), a renowned translator of Western manuals on astronomy, mathematics, botany, and other scientific subjects. This time, the translation was not based on Clavius' commentary but on Heury Billingsley's English translation of Euclid's *Elean eats* released in 1570[12] in seventeen books. After 1760, other elementary Western textbooks on geometry, which have been forgotten since, were again translated into Chinese.

[12] cf. Xu Yibao, "The First Chinese translation of the last nine books of Euclid's *Elements* and its source" *Historia Mathematica*, 2005, vol 32, no.1, pp 4–32.

After the 1911 revolution, Chinese mathematics was never again studied for scientific purposes (except by historians) and China gradually made its way into the international mathematical community. Nowadays, there is of course no distinction between geometry developed in China and in other countries.

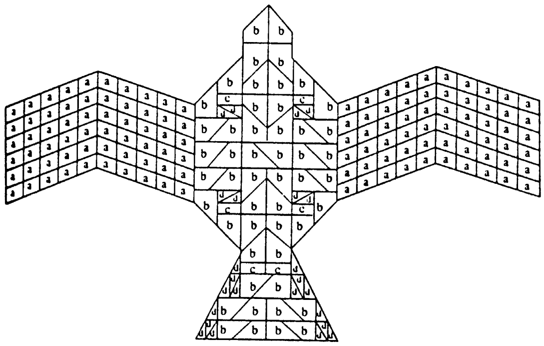
G

Geometry in India

George Gheverghese Joseph

An examination of the earliest known geometry in India, Vedic geometry, involves a study of the *Śulbasūtras*, conservatively dated as recorded between 800 and 500 BCE, though they contain knowledge from earlier times. Before what is conventionally known as the Vedic period (ca. 1500–500 BCE), there was the Harappan civilization dating back to the beginning of the third millennium BCE. Even a superficial study of the Harappan cities show its builders as extremely capable town planners and engineers requiring fairly sophisticated knowledge of practical geometry. An interesting conjecture has been suggested by a drawing on a seal found from Harappa (ca. 2500 BCE): was there an awareness then that the area of a polygon inscribed in a circle approaches the area of the circle as the number of sides of the polygon keeps increasing? This is the basic idea behind techniques that were developed for the mensuration of the circle in a number of mathematical traditions including Indian.

The *Śulbasūtras* are instructions for the construction of sacrificial altars (*vedi*) and the location of sacred fires (*agni*) which had to conform to clearly laid down instructions about their shapes and areas if they were to be effective instruments of sacrifice. There were two main types of ritual, one for worship at home and the other for communal worship. Square and circular



Geometry in India. Fig. 1 The first layer of a Vakrapaksa-syena altar. The wings are made from 60 bricks of type "a," and the body, head and tail from 50 type "b," 6 of type "c" and 24 type "d" bricks. Each subsequent layer was laid out using different patterns of bricks with the total number of bricks equaling 200.

altars were sufficient for household rituals, while more elaborate altars whose shapes were combinations of rectangles, triangles, and trapezia were required for public worship. One of the most elaborate of the public altars was shaped like a giant falcon just about to take flight (*Vakrapraksa-śyena*). It was believed that offering a sacrifice on such an altar would enable the soul of the supplicant to be conveyed by a falcon straight to heaven (Fig. 1).

It is clear that if in the construction of larger altars they had to conform to certain basic shapes and prescribed areas or perimeters, two geometrical problems would soon arise. One is the problem of finding a square equal in area to two or more given squares; the other is the problem of converting other shapes (for example, a circle or a trapezium or a rectangle) into a square of equal area or vice versa. The constructions were achieved through a judicious combination of concrete geometry (in particular what would be known today as the principle of dissection and reassembly), ingenious algorithms, and the application of the so-called Pythagorean theorem. The essence of the dissection and reassembly method involves two commonsense assumptions. The first is that both the area of a plane figure and the volume of a solid remain the same under rigid translation to another place. The second says that if a plane figure or solid is cut into several sections, the sum of the areas or volumes of the sections is equal to the area or volume of the original figure or solid. The reasoning behind this approach was very different from that behind Euclidean geometry, but the method was often just as effective, as shown in the Indian (and Chinese) "proofs" of the Pythagorean theorem.

In the *Kātyāyana Śulbasūtra* (named after one of the authors) the following proposition appears: "The rope (stretched along the length) of the diagonal of a rectangle makes an (area) which the vertical and horizontal sides make together." (2.11). Using this version of the Pythagorean theorem, the *Śulbasūtras* show how to construct both a square equal to the sum of two given squares and a square equal to the difference of two given squares. Further constructions include the transformation of a rectangle (square) to a square (rectangle) of equal area and of square (circle) to a circle (square) of approximately equal area. The constructions "doubling the square" and "squaring the circle" lead naturally to devising algorithms for the square root of 2 and other numbers, for implicit estimates of π, and for constructing similar figures in required proportions of a given figure.

The composers of the *Śulbasūtras* made it clear that their work was not original but could be traced to earlier texts, notably the *Saṃhitās* and the *Brāhmaṇas* of which the most relevant text, *Śatapatha Brāhmaṇa*, is at least 3,000 years old. In spite of its obscurities and archaic character the text is valuable for an early discussion of the technical aspects of altar construction. The instructions given in *Śatapatha Brāhmaṇa* (X.2.3.11–14) for constructing a falcon-shaped altar consisting of 95 layers of bricks are as follows:

$$\text{Area of the body (Atman)} = 56 + \frac{12}{7}\sqrt{56};$$

$$\text{Area of two wings} = 2(14) + \frac{3}{7}\sqrt{14} + \left(\frac{1}{5}\right)\left(\frac{1}{7}\right)(3)(\sqrt{14});$$

$$\text{Area of tail} = 14 + \frac{3}{7}\sqrt{14} + \left(\frac{1}{10}\right)\left(\frac{1}{7}\right)(3)(\sqrt{14}).$$

The total area is about 116 square *purushas*, which is an over-estimate of the required 101.5 square *purushas*, arising in part from a rounding off error involved in taking 14 rather than 13 + 8/15.

A major strand running through the history of Indian geometry and also providing the main motivation for the development of the subject was a recognition of the impossibility of arriving at an exact value for the circumference of a circle given the diameter (i.e., the incommensurability of π). A passage in Āryabhaṭa's *Āryabhaṭīya* (AD 499) – Verse 10 of the section on *Gaṇita* – reads:

> Add 4 to 100, multiply by 8, and add 62,000. The result is *approximately* the circumference of a circle whose diameter is 20,000. (Giving an implicit value of 3.1416 for π. This was the most accurate estimate for π known at that time. About six hundred years earlier (ca. 150 BCE), there was

an implicit estimate of π as the square root of 10 in a Jaina text called *Anuyoga Dwāra Sūtra*.)

It was the word "approximately" that gave food for thought to commentators of Āryabhata's work from Bhāskara I (ca. AD 600) to Nīlakanṭha (b. AD 1445). The first formal proof of the transcendental nature of π was given by the Swiss mathematician Lambert in a paper to the Berlin Academy in 1671. However, about 150 years earlier. Nīlakanṭha's commentary on *Āryabhaṭīya* contained the following statement:

> Why is only the approximate value (of circumference) given here? Let me explain. Because the real value cannot be obtained. If the diameter can be measured without a remainder, the circumference measured by the same unit (of measurement) will leave a remainder. Similarly the unit which measures the circumference without a remainder will leave a remainder when used for measuring the diameter. Hence the two measured by the same unit will never be without a remainder. Though we try very hard we can reduce the remainder to a small quantity but never achieve the state of 'remainderlessness'. This is the problem. (Adapted from Sarasvati Amma 1979)

Once the incommensurability of π was accepted, the approach of the Indian mathematician was to obtain as accurate a value of this quantity as possible, and the strategy to be followed was expressed thus by Śaṅkara Variyār and Nārāyana Kriyākramakarī (ca. 1550)]:

> Thus even by computing the results progressively, it is impossible theoretically to come to a final value. So, one has to stop computation at that stage of accuracy that one wants and take the final result arrived at ignoring the previous results. (Adapted from Sarma 1975)

The major breakthrough came from the revolutionary idea, most probably that of Mādhava (ca. 1340–1425), that it was possible to obtain an infinite series whose sum would be exactly equal to π and that an increasingly close rational approximation of the quantity could be obtained by taking partial sums successively of higher order. While the question of the slow convergence of this series was not explicitly discussed, the need for increasing rapidity of convergence was recognized and some remarkable corrections to be applied to truncated series were deduced. The work on infinite series for circular functions provided an impetus to derivation of other infinite series for trigonometric functions, namely arctangent, sine, and cosine series. Often inductive reasoning (and intuition) built upon geometrical representation helped them to discover these results, but the proof of these results can withstand any rigorous criterion applied to it today. An implicit estimate for π based on infinite-series expansion given by Mādhava around 1,400 is correct to eleven decimal places.

Another area of geometry in which the Indian contribution was significant was in the study of the properties of a cyclic quadrilateral. In the *Brāhma Spuṭa Siddhānta*, Brahmagupta (b. AD 598) gives these results:

1. The area of a cyclic quadrilateral is given by the product of half the sums of the opposite sides, or by the square root of the product of four sets of half the sum of the sides (respectively), diminished by the sides.
2. The sums of the products of the sides about the diagonal should be divided by each other and multiplied by the sum of the opposite sides. The square roots of the quotients give the diagonals of a cyclical quadrilateral.

The derivations of these results are first referred to in a tenth-century commentary on Brahmagupta's work, but find their full expression in the sixteenth century Kerala text *Yuktibhāṣā* by Jyeśṭhadeva. This makes use of Ptolemy's theorem that in a cyclic quadrilateral the product of the diagonals is equal to the sum of the products of two pairs of opposite sides.

Notable extensions in this area are contained in Nārāyana Pandita's *Gaṇita Kaumudī* in the fourteenth century and Parameśvara's *Lilāvati Bhāsya*, a detailed commentary on Bhāskaracharya's *Lilāvati*. In the latter is found a new rule for obtaining the radius of the circle in which a cyclic quadrilateral is inscribed. The great interest in the cyclic quadrilateral in Indian mathematics arose from the fact that it was an important device for deriving a number of important trigonometric results which were in almost all cases used in astronomy.

In India geometry never became idealized in the way it did in Greece. Geometry was largely concrete and empirical in character. It did, however, have an algebraic character which is best seen in the genesis of trigonometry there. Because of their geometric emphasis, the Greeks used chords in their astronomical calculations, whereas the Indians developed the notion of sines and versines (i.e., 1 – cosine of an angle) as early as AD 500. Āryabhata was perhaps the first Indian astronomer to give a special name to these functions and draw up a table of sines for each degree. Approximation formulae were developed for these functions, culminating in the construction of sine tables in Kerala during the fifteenth century where the values in almost all cases are correct to the eight or ninth decimal place, a remarkable degree of accuracy.

Geometry in Islamic Mathematics

Boris Rosenfeld

Many original Muslim geometric works are "books" or chapters of great mathematical, astronomical, and encyclopedic works. Geometrical parts are contained in the algebraic treatise of al-Khwārizmī (ca. 780–850), in the *Miftāḥ al-ḥisāb* (Key of Arithmetic) of Jamshīd al-Kāshī (d. ca. 1430), in the astronomical *al-Qānūn al-Masʿūdī* (Masudic Canon) of Abū'l Rayḥān al-Bīrūnī (973–1048) and in his treatises on astrolabes, as well as in the encyclopedic *Kitāb al-shifā* (Book of Healing) of Abū ʿAlī ibn Sīnā (Avicenna 980–1037). There are also special geometric treatises, commentaries on Euclid, and treatises on geometrical theorems, calculations, constructions, and the foundations of geometry.

Calculations of areas of plane figures and of volumes of solids were considered in the chapter "On mensuration" of the algebraic treatise of al-Khwārizmī. Many rules in this chapter coincide with the rules of Hero's *Metrics* (first century AD) and of Indian mathematicians of the fifth and sixth centuries. For the area S of a circle with radius r, he supplies the rule $S = \pi r^2$, where $\pi = 3\,1/7, \sqrt{10}, 62832/20000$.

The contents of this chapter are similar to the Hebrew *Mishnat ha-middot* (Treatise on Measuring) which was believed to be part of the *Talmud* written in the second century AD. Recently Zarfatti (1968) showed that this book was written after al-Khwārizmī's treatise and under its influence.

Many treatises on geometric calculation were written by Thābit ibn Qurra. In his *Kitāb fī misāḥa al-ashkāl al-musaṭṭaḥa wa 'l-mujassama* (Book on Mensuration of Plane and Solid Figures), he provides many rules for measuring area and volume. For example, there is his general rule for the calculation of the volume V of a right round cylinder, cone, and truncated cone expressed by one formula: $V = 1/3h(S_1 + S_2 + \sqrt{S_1S_2})$.

In his *Kitāb fī misāḥa qaṭ ʿal-makhrūṭ alladhī yusammā al-mukāfī* (Book on Mensuration of a Conic Section Named Parabola) and other works, Thābit tackles many geometric problems. Among these are the problems of calculating the area of a segment of a parabola, the volume of segments of solids obtained by the revolution of segments of a parabola, and of the area of a surface of an oblique round cylinder. Thābit calculated the area of segments of an ellipse by means of an equi-affine transformation of the ellipse onto a circle with equal area. His grandson Ibrāhim ibn Sinān (908–946) in his *Kitāb fī misāḥa al-qaṭ ʿal-mukāfī* (Book on Mensuration of a Parabola) calculated the area of a segment of a parabola by means of a general affine transformation. Wayjan al-Qūhī (tenth to eleventh centuries) and Ibn al-Haytham (965–ca. 1040) calculated the volumes of segments of solids obtained by the revolution of segments of parabolas that Thābit had not considered.

Al-Bīrūnī, in the mathematical part of his *Masudic Canon*, calculated the sides of a regular triangle, square, pentagon, hexagon, octagon, and decagon inscribed in a given circle. Also, he provided the length $C = 2\pi r$ as the circumference of a circle where $\pi = 3.7305910$ in sexagesimal fractions and 1628631471/518400000 in decimal. Al-Kāshī in his *al-Risāla al-muḥīṭiyya* (Treatise on Circumference) calculated the length $C = 2\pi r$ by means of the calculation of the perimeter of regular inscribed and circumscribed polygons with 3.2^{28} sides. The number of sides was chosen on the condition that the difference between these perimeters for the great circle of the sphere of fixed stars must be less than the "width of a horse hair." The result was expressed in sexagesimal and decimal fractions as 3.829440472553725 and 3.14159265358979325. In the last case the calculation is correct up to 17 digits.

The teachers of Thābit ibn Qurra, the brothers Muḥammad (d. 872), Aḥmad, and al-Ḥasan Banū Mūsā ibn Shākir, in their *Kitāb al-shakl al-mudawwar al-mustaṭīl* (Book on an Oblong Round Figure), proposed the construction of an ellipse by means of a string attached to its foci (the so-called "Gardiner's construction"). Thābit himself solved two classical problems of antiquity: the construction of two mean proportional magnitudes between two given ones ($a : x : y : b$), which is the Delic problem of the duplication of a cube (if $b = 2a$), and the trisection of an angle. He also proposed the spatial construction of a semiregular polyhedron with 14 faces, which some now say was discovered by Archimedes.

The great philosopher Abū Naṣr al-Fārābī (ca. 870–950) proposed many geometric constructions of parabolas, regular polygons, squares equal to three given equal squares, constructions with one opening of the compass, and constructions on the sphere. These were also studied by Thābit's pupil's pupil Abū'l-Wafā al-Būzjāni (940–998) in the *Kitāb fī mā yakhtāju ilayhi al-ṣāni ͨmin a ͨmāl al-handasiyya* (Book on What is Necessary from Geometric Construction for the Artisan).

Ibrāhīm ibn Sinān ibn Thābit proposed many ways to construct a parabola (including al-Fārābī's one), ellipse, and hyperbola. One of the constructions of an ellipse is based on the compression of a circle; one of a hyperbola is based on a projective transformation of a circle.

Al-Qūhī described the instrument for the construction of conics, which he invented. It is a compass in which one leg varies in length and the second leg can change the angle of its slope to the plane. Many methods for the construction of conics were described by al-Bīrūnī in *Isti ͨāb al-wujūh mumkina fī ṣan ͨa al-aṣturlāb* (The Exhaustion of Possible Ways of Constructing an Astrolabe). In particular he mentions the "Gardiner's construction" of Banū Mūsā, the perfect compass of al-Qūhī, and constructions of all three kinds of conics based on projective transformations.

Al-Fārābī revised the order of the first definitions of Euclid. The first definition of Book 1 of the *Elements* was that of a point as "that which has no parts." Later Euclid defined a line as "a breadthless length" and a surface as "that which has length and breadth only." In Book 11 he defined a solid as "that which has length, breadth, and depth." Al-Fārābī, following Aristotle, defined a solid as the first abstraction from a physical body, a surface as the abstraction from a thin solid, a line as the abstraction from a narrow surface, and a point as the abstraction from a short line. The same order of geometric definitions was used by al-Bīrūnī in the geometric part of his *Kitāb al-tafhīm li-awā'il ṣināͨa al-tanjīm* (Book of Instruction in the Elements of the Art of Astrology).

In his *Taḥrīr Uqlīdis* (Exposition of Euclid) Naṣīr al-Dīn al-Ṭūsī added to Euclid's axioms that of the existence of points, lines, and surfaces, and the axiom of possibility of choice of a point on an arbitrary line and surface and of a line on an arbitrary surface and through an arbitrary point. There are also analogous axioms ascribed to al-Ṭūsī's version of the exposition of Euclid's *Elements* and in the geometric part of the encyclopedic work of his pupil Quṭb al-Dīn al-Shīrāzī (1236–1311). In both these works there are also attempts to prove Euclid's first three postulates about the ideal ruler and compass.

In al-Shīrāzī's commentaries to al-Ṭūsī, the rules of the theory of syllogisms from Aristotle's *Analytics* are systematically used.

In many Islamic treatises the problem of mathematical atomism was discussed. Aristotle's ideas, on which Euclid's *Elements* is based, ousted the mathematical atomism of Pythagoras and Democritus. According to them, finite solids, surfaces, and lines consist of a finite number of "atoms". Pythagoras said these atoms were points without sizes, and the sizes of finite figures were created by the distances between them. According to Democritus these atoms were particles with very small but finite sizes. In medieval Islam the ideas of mathematical atomism were held by Muslim scholastics, the *muͨtazila* and *mutakallimūn*, who wanted to find a rational explanation for Islam. They believed that time consists of a separate "now" and explained by means of this view that God creates the world anew every instant. Among the *muͨtazila* there were adherents of both types of mathematical atomism. The first school was headed by Abū'l-Qāsim al-Kaͨbī (d. 932) whose nickname al-Kaͨbī means "cubical"; the second was headed by Abū'l-Ḥāshim al-Jubbāͨī (820–933). Democritus' ideas were also held by the philosopher and alchemist Abū Bakr al-Rāzī (865–952). The idea of mathematical atomism was also mentioned by al-Shīrāzī in his commentaries on a treatise by al-Ṭūsī.

Islamic mathematicians often attempted to prove Euclid's fifth postulate on which the theory of parallel lines in his *Elements* is based. This postulate is much more complicated than the first four. It asserts that, if a straight line falling on two straight lines makes the interior angles on the same side together less than two right angles, the two straight lines, if produced indefinitely, meet on that side in which the angles together are less than two right angles. Attempts to prove this axiom as a theorem were made by Archimedes (third century BCE), Posidonius (second to first centuries BCE), Ptolemy (second century AD), Proclus (fifth century), and Simplicius (sixth century). In their proofs there was the logical error of *petitio principii*, i.e., the implicit use of an assertion equivalent to the one being proved.

The first Islamic mathematician who attempted to prove the fifth postulate was al-ʿAbbās al-Jawharī (first half of the ninth century). In his *Iṣlāḥ li-kitāb al-Uṣūl* (Improvement of the Book "Elements") he proposed a proof based on the assertion that a straight line intersecting both sides of an angle can always be drawn through any point inside this angle.

Thābit ibn Qurra made two attempts to prove the fifth postulate. His two treatises on parallel lines were written in Syriac and then translated by him into Arabic. The first proof is based on the assertion of the existence of "a simple motion"; i.e., a parallel translation equivalent to the existence of equidistant straight lines and to the existence of a rectangle. The second proof is based on the assertion that, if two straight lines diverge on one side of a line falling on them, they necessarily converge on the other side. From this follows the existence of a parallelogram. An analogous error was made by al-Faḍl al-Nayrīzī (d. 922) in his *Risāla fī bayān al-muṣādara al-mashhūra min Uqlīdis* (Treatise on the Proof of the Known Postulate of Euclid).

Ibn al-Haytham also made two attempts to prove the fifth postulate. One attempt was based on the same error as in Thābit's first treatise. In this proof Ibn al-Haytham first considered quadrangles with three right angles ("the Lambert quadrangles") and three hypotheses about their fourth angle. The hypotheses of acute and obtuse angles were refuted by means of the existence of a rectangle. The second attempt was written in his last years. Here was the first proof of the fifth postulate which was free from logical error. At first the postulate was replaced by another more evident one and was proved by means of it. This new postulate was: two intersecting straight lines cannot be parallel to a third line. This postulate in the form "if the point A and a straight line a are given, it is impossible to draw more than one not intersecting line through A in their plane." This is now known as "the Playfair postulate" or "the strong Hilbert axiom of parallels," after Europeans who later came up with the same axiom.

Also free from logical error was ʿUmar al-Khayyām's proof of the fifth postulate in his *Sharḥ mā ashkala min muṣādarāt kitāb Uqlīdis* (Commentaries on Difficulties in Introductions of Euclid's Book). In this work Khayyām proved the postulate on the basis of a postulate which he called the "fourth principle of the philosopher (Aristotle)." "Two converging lines intersect and it is impossible for them to converge in the direction of divergence." In this proof he first considered equilateral quadrangles with two right angles at their low bases (which we now call "the Saccheri quadrangles") and three hypotheses about their equal upper angles. The hypotheses of acute and obtuse angles are refuted by means of this fourth principle. These two hypotheses, which are analogous to those of Ibn al-Haytham (his quadrangles are halves of Khayyām's), are fulfilled in hyperbolic and elliptic non-Euclidean geometries, respectively. Ibn al-Haytham and Khayyām actually proved some theorems of these geometries first.

Naṣīr al-Dīn al-Ṭūsī considered the theory of parallel lines. In the treatise, al-Ṭūsī explained the proofs of al-Jawharī, Ibn al-Haytham (only the second) and Khayyām (not completely), and considered the same quadrangles and the same three hypotheses as Khayyām. However, he made the same logical error *petitio principii*. In the book written after the critical letters of Qayṣar al-Hanafī (ca. 1170–1251) he explained the same proof, but before it he formulated the postulate similar to Khayyām's, and thus does not make a logical error.

Al-Shīrāzī also made an attempt to prove the fifth postulate based on a logical error: he supposed that the distance between lines which do not intersect is constant.

We saw that in the proofs of the fifth postulate by Thābit ibn Qurra and Ibn al-Haytham "a simple motion" was used. The application of motion to geometry was used by Pythagoreans who considered lines as traces of moving points and surfaces as traces of moving lines. However, this application was rejected by Aristotle, who considered geometric solids as abstractions from physical bodies, surfaces as abstractions from thin solids, lines as abstractions from narrow surfaces, and points as abstractions from short lines. Following Aristotle, Euclid tried in his *Elements* to avoid the application of motion. Khayyām criticized the application of motion by Ibn al-Haytham.

We also saw that Thābit ibn Qurra and his grandson Ibrāhim ibn Sinān used affine transformations in their geometric treatises, and al-Bīrūnī also used projective transformations.

An astronomical instrument called an astrolabe was very popular in the Middle Ages. It was based on the projection of the celestial sphere onto its plane. Many treatises on the construction of astrolabes contain descriptions of different projections. In the *Kitāb ṣanʿa al-aṣturlāb* (Book of the Construction of the Astrolabe), Aḥmad al-Farghānī (d. 861) described the stereographic projection. That and others were described by al-Bīrūni in his *Exhaustive Ways of Constructing an Astrolabe*. Al-Bīrūnī applied a stereographic projection for determining the azimuth of *qibla* (the direction to Mecca). He also used the stereographic and some other projections of a sphere on to a plane in his *Risāla fī tasṭiḥ al-ṣuwar wa tabṭiḥ al-kuwar* (Treatise on the Projection of Designs on to a Plane and on the Map of Spheres on a Plane), which was devoted to problems of cartography.

In the *Elements*, Euclid used the plane geometrical algebra inherited from the Pythagoreans. In this, he represents the products $a \times b$ as rectangles with sides a and b and provides a geometric representation of algebraic equalities. For instance, there is a representation of the formula $(a+b)^2 = a^2 + 2ab + b^2$ by decomposing the square $(a + b)^2$ on two squares a^2 and b^2 and two rectangles $a \times b$. In Archimedes' *Lemmas* there is an analogous decomposition of a circle with diameter $a + b$ on two circles with diameters a and b and two "arbelons." Analogous representations of the formula $(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$by decompositions of the cube $(a + b)^3$ and of the sphere with diameter $a + b$ were proposed by Abū Saʿīd al-Sijzī (ca. 950–1025).

Apparently the idea of "geometric" names for powers, square–square for x^4, square–cube for x^5, cube–cube for x^6, and so on, was borrowed from Diophantus' *Arithmetics*.

Islamic mathematicians used rectangular and oblique coordinates connected with conics: the axes of these coordinates were one of the diameters of a conic and the tangent line at one of its ends. Each point of a conic was determined by half of its chord conjugate with this diameter from a given point to the diameter and by the segment of this diameter from its end (vertex) to the meeting point of the chord with the diameter. They called these coordinates "ordered lines" and "line cut from the vertex," respectively. (Our terms "ordinate" and "abscissa" came from Latin translations of these expressions.) These coordinates were used by Khayyām in his *Risāla fī'l-barāhīn ʿalā masā'il al-jabr wa'l-muqābala* (Treatise on Demonstrations of Problems of Algebra), which was devoted to the solution of cubic equations by means of the intersection of conics.

Islamic astronomers and geographers following Ptolemy used the geographical coordinates longitude and latitude for the surface of the Earth, and analogous ecliptical coordinates with the same names, the horizontal coordinates azimuth and altitude, and the equatorial coordinates right ascension (or horary angle) and declination for the celestial sphere. Thābit ibn Qurra determined the positions of the ends of the shadows of the gnomon on the plane of a plane sundial by rectangular coordinates which he called, by analogy with the geographical coordinates, longitude and latitude, and by polar coordinates which he called azimuth and length of shadow.

Muḥammad al-Khwārizmī in his geographical treatise *Kitāb ṣūra al-arḍ* (Book of the Picture of the Earth) proposed the classification of curved lines and used the names of different kinds of lines in his descriptions of rivers, seacoasts, and islands between points with given geographical coordinates.

In addition to their original contributions, Muslims made many translations of Greek works. In many cases, the Arabic version of the work is the only one extant today. The most important Greek geometric work, Euclid's *Elements*, was translated into Arabic in the ninth century AD by al-Ḥajjāj ibn Yūsuf ibn Maṭar and Iṣḥāq ibn Ḥunayn al-ʿIbādī. The last translation was edited and supplemented by Thābit ibn Qurra (836–901), who was also the translator of other works of Euclid, of many works of Archimedes, of the *Conics* of Apollonius, and of many Greek mathematical works. These, together with a geometric treatise of his teachers the brethren Banū Mūsā and his *Kitāb al-mafrūḍāt* (Book of Assumptions) constituted the so-called "middle books" which were studied between Euclid's *Elements* and Ptolemy's *Almagest*. Later many Muslim revisions of other Greek mathematical works appeared.

Geometry in Japanese Mathematics

Yoshimasa Michiwaki

Western mathematics is concerned very much with logic based on proof and demonstration. Japanese mathematics in the Edo period (1603–1867), which is called *Wasan*, has its origin in China, and from the beginning put its emphasis on application, mainly on application in daily life. At the beginning of *Wasan*, experts studied practical aspects of mathematics, such as deriving the areas of figures and the volumes of solid bodies. However, in the developing period, they began to devise questions which provided conclusions based on the beauty of figures and complicated calculation. They especially liked questions on geometrical figures, and they had their own ways of studying. When they studied circles, they tried to increase their number, change their positions, and consider them as ellipses. They also tried to expand into three dimensions. Because of the national isolation policy of Japan, *Wasan* experts were kept in guild-like groups. The study of *Wasan* became very complicated; practitioners could not concentrate on the main themes but had to act as if their studies were rather like a hobby.

Wasan was formulated in the latter half of the seventeenth century by a Japanese mathematician, Takakazu Seki (or Kowa Seki) with the text *Jinko-ki* as its basis. The interest of *Wasan* experts in those days was to solve the questions left unsolved in *Jinko-ki* and other mathematical texts: that is, to calculate the areas and volumes of planes and solid figures, and also the length of chords and arcs and the area surrounded by them. Takakazu Seki, before he succeeded in systematizing *Wasan*, tried hard to solve those questions, and in the process studied parabolas, hyperbolas, and also the spirals of Archimedes. And he partially succeeded in measuring ellipses.

In the field of algebra, Seki used a determinant of five dimensions in his work *Kaifukudai-no-ho* published in 1683. In the area of geometry, he derived a relative equation between a side of a regular polygon and radii of an inscribed circle and a circumscribed circle. This arose from a theory on regular polygons. He also made great accomplishments in the field of *Enri*: this word may be translated as "circle principle" or "circle theory", being derived from the fact that the mensuration of the circle is the first subject that it treats. He repeated doubling the numbers of the side of an inscribed, regular polygon, and achieved the correct number for π. He devised a calculation method for circles – integral calculation – studying the relation among the chord, the arrow, and the arc. He also worked in other fields, such as the calendar.

After the publication of such works as *Seiyo Sampō*, *Shinpeki Sampō*, *Sampō Kokon Tsuran*, and *Sampō Tensei-ho Shinan*, interest in *Wasan* was very much aroused. For example, *Sangaku* (Mathematical Tablets) were dedicated to shrines and Buddhist temples. Some of these are beautiful, with figures of red, blue, and yellow. The definitions of the figures are not written on the tablets, but the drawn figures (questions) themselves illustrate the things necessary to solve the questions. These questions posed by *Wasan* experts are combined questions, such as a square and a square, a straight line and a circle, a circle and plural circles (or ellipses). There are questions on the length of a square side, a straight line, and the radius of a circle. There are also questions on the number and areas of circles put into one circle. These questions are expanded from "plane" to "solid" and from "limited" to "unlimited."

Wasan experts tried to derive the theorems to solve questions, and in the process they reached general laws by something like an inductive method. They sought a general equation with some sort of inspiration. One of these *Wasan* experts, Nushizumi Yamaji, stated in his *Sampo Ruiju* (Vol. 3) the same ideas as in Descartes' circle theorem but in a different way. A theorem like Descartes' was introduced in the mathematical texts of the first half of the nineteenth century, such as *Kokon Sankan* by Gokan Uchida.

Wasan in the Bunka and Bunsei period (1804–1818–1829) was at its peak. In *Suri Mujinzo* by Nagatada Shiraishi, one finds a technique or theorem called *Bosha Jutsu*, which has exactly the same idea as Casey's. This theorem is considered an extension of Ptolemy's.

Shingen Takeda wrote *Shingen Sampō*. In the first volume of this work, there is a problem called Clever Ways to Cross the Twenty-Eight Bridges in Naniwa (now Osaka).

Another *Wasan* expert, Zen Hodoji, learned many things through visiting various districts and teaching students in each district. In one of his works, *Kanshinko Sanhen*, there are questions which are close to the present "inversion" formula. We are not sure how he reached the inversion formula, but the result was correct.

As was stated before, *Wasan* experts were inspired to find a solving technique. *Kyokkei Jutsu* and *Henkei Jutsu* should be introduced here. *Kyokkei Jutsu* is explained in *Sampo Kyokkei Shinan* written by Hiroshi Hasegawa and his student, Giichi Akita. Special figures – *Kyokkei* – are used in this method. Beside this, Hasegawa wrote *Sampo Henkei Shinan* with his student, Teishin Heinouchi. In this, you find a sentence which says that "Questions with reasonable conditions, that is, questions with conditions enough to solve them are called "complete questions" while others with too many or too few conditions are called "incomplete questions." Some of these questions can be solved with insufficient conditions, and they are called *Kyoku Dai* (special questions). This book deals mainly with variations of *Kyoku Dai*. Both *Kyokkei Jutsu* and *Henkei Jutsu* deal with figures in special cases instead of general figures, but each technique is different. *Kyokkei Jutsu* has a tendency to make a mistake by trying to get an answer; *Henkei Jutsu* has no such tendency, but you find it difficult to get a *Kyoku Dai*. Each method is unique as a method of geometrical studies.

In the Meiji period (1868–1911), the new education system established in 1872 eliminated *Wasan* studies from public education, and adopted western mathematics.

However, in the Taisho and Showa periods (1912–1928–1988) mathematical leaders such as Tsuruichi Hayashi and Matsusaburo Fujiwara collected materials and wrote theses on various themes of *Wasan*, and its popularity was revived. The History of Science Society of Japan was established in 1941 and Kin-nosuke Ogura, counselor of the society, insisted that Japanese mathematics history be carefully considered. The Mathematics Club, later The History of Mathematics Society of Japan, was established in 1958 mainly to study *Wasan*. Seminar groups appeared in many districts, and magazines and theses were published. In 1979, the *History of Japanese Mathematics before the Meiji Period* (5 Vols.) edited by the Japan Academy was completed. All of the works mentioned in this essay can be found in this set.

Geometry in Mesopotamia and Egypt

Jens Høyrup

This article concentrates on the geometrical knowledge of the scribal traditions, not on what *could* have served for the construction of buildings. It must be observed that high technical precision is often achieved through the combination of quite elementary mathematics and sophisticated non-mathematical techniques. Anyone who has played with rulers and compasses knows that a regular pentagon can easily be made more precise through trial and error than by "exact" construction with all its accumulated errors. It is therefore next to impossible to extrapolate from the high precision of for example prestige buildings to the particular kind of geometry used in their design, unless some kind of blueprint has survived. Even in such cases, when the tracing of a ground plan has subsisted or the building can be seen to be planned around base lines geared to the standard brick, all that may be concluded is often that *some kind* of geometrical knowledge is involved.

On the other hand, in Mesopotamia as well as Egypt, written texts with geometrical contents have survived, most of which are scribe school problems. Even when unambiguous (which is not always the case), they confront us with a problem of bias: scribal mathematics consisted in calculation; the texts always aim at the determination of a number (an area, a volume, the number of man-days needed to dig a ditch, etc.). Geometrical construction was not the concern of the scribes.

Mesopotamia

The sources for our knowledge of Mesopotamian geometry reach back to the later fourth millennium BCE. The earliest sources are not very informative, but they demonstrate that the length and area metrology, together with the basic techniques for area computation, go back to the first phase of writing. Sources from the third millennium become more copious, in particular towards its end. Sophisticated scribe school problems dealing with complex volumes only turn up in the Old Babylonian period (early second millennium) and disappear again from the horizon after 1600 BCE. Finally, some interesting texts have survived from the later half of the first millennium BCE.

Length metrology may have been created in the same process as writing and written administration. Already in the earliest written documents, area metrology is keyed to the length system – but some of its units appear to be old "natural" (irrigation, ploughing, or seed) measures which have been normalized so as to fit, while others have been created anew. These systems survive until the end of the Old Babylonian period. In the late period, new quasi-natural measures (seed measures) allowing easier practical computation take over.

The basic volume measures coincide with the area measures, which are tacitly imagined as provided with the height 1 cubit. The system of hollow measures, on the other hand, is perplexingly complex, involving both traditional measures that have been normalized so as to fit the length system, and corrections introduced in order to facilitate practical computation of rations, cylindrical volumes, etc. A Mesopotamian specialty is the multiplicity of "brick measures", using the terminology of volume measures but referring in fact to the number of bricks, for which several standard dimensions coexisted.

The Old Babylonian texts show us that square and rectangular areas as well as right triangles and trapezia were calculated as we would do it. No unambiguous standard term for the height of a triangle or a trapezium is present, and field plans show us that complex areas, including skew triangles and trapezia, were subdivided into "practically rectangular" quadrangles and "practically right" triangles. No concept of a quantified angle is present, the field plans seem simply to distinguish "right" from "wrong" angles.

In practical mensuration, working in an always slightly uneven terrain and not in an abstract Euclidean plane, what is laid out as a rectangle with traditional methods mostly turns out to have slightly different opposing sides. In this situation, the Mesopotamian scribes calculated the area according to the "surveyors' formula": average length times average width. The result always exceeds the true area, but not significantly if the angles of the quadrangle are approximately right. In school problems, where the formula served as a pretext for calculation, it was occasionally used in situations where the outcome was absurd. In practical field measurement, a single instance is known where the error is at least 100%; whether this reflects general carelessness or the ignorance of a single scribe is not clear (it is even possible that a number written along a side is really meant to be the height, in which case there is no error in the computation but only a somewhat careless diagram). Most often, the circular area was determined as 1/12 of the square on the circumference (which is often the dimension most easily determined in practice by means of a piece of string). Translated into our idiom, this means that 4π was approximated as 12, or that $\pi = 3$. Other computations, such as the determination of the diameter from the circumference, agree with this; the Babylonians were thus aware that the circular area was the semi-product of the radius and the circumference.

Simple volumes (prisms, cylinders) were determined as the product of the base and the height – the formulation being that the base was "raised" to the height. Raising is a general term for multiplication based on considerations of proportionality – derived originally from volume determinations but in general use. The idea which underlies volume determination is indeed one of proportionality, since the base was understood as already provided with a standard height of 1 cubit. Similarly, a length could be understood as provided with a standard width of one length unit, and area computations (when not implicit in the construction of a rectangle) were hence also done by raising.

Complex volumes, such as truncated pyramids and cones, were determined by ad hoc methods, not always correctly or consistently. Several texts determine the volume of a truncated cone as that of a cylinder whose diameter is the average of the diameters of top and bottom. One of them determines the volume of a truncated square pyramid in the same way, but adds a correction term that makes the computation accurate (it is not quite sure whether the underlying reasoning is also correct). Other texts determine the volumes of truncated cones and pyramids by raising the average between top and bottom area to the height.

No later than the Old Babylonian period, the Pythagorean theorem was known and used for diagonal calculations. The purpose of a table text making use of Pythagorean triples is not fully decided, but it seems to be arithmetical rather than geometrical.

Already in the twenty-third century BCE, it was known that the square on the parallel transversal which bisects a trapezium is the half-sum of the squares on the parallel sides. No text tells us how this formula was reached, but it follows without difficulty from consideration of two squares of which one is embedded concentrically in the other. Similar naïve-geometric reflections may have led to the discovery of the Pythagorean theorem; their presence is well attested in the so-called "algebra" texts.

A few texts testify to an interest in geometrical arrangements and in regular polygons; in the actual cases, however, the texts always calculate something (mostly an area). A text with a regular hexagon draws a height in one of the six isosceles triangles from which it is composed and computes its length and uses this in the determination of the area.

The few late Babylonian texts exhibit some changes in the area techniques, such as a more general use of heights in area determination.

Egypt

Third-millennium sources for Egyptian geometry are rare, and even though the precision of the great pyramids demonstrates both architectural and geometrical skill, they tell us little about the geometrical techniques that were in use.

The important mathematical texts – the *Rhind Mathematical Papyrus* and the *Moscow Papyrus* – date from the early second millennium BCE. Together with some minor texts and fragments and with what can be grasped from administrative documents, they present us with a coherent picture. In spite of some unsolved problems of interpretation and the presence of still open questions, nothing suggests that new sources might change our understanding of Egyptian mathematics radically. Nor does Egyptian technology, in spite of its indubitable sophistication, ask for *mathematical* knowledge beyond what we know from the papyri.

The evidence for the length and area metrologies of the third millennium is meager, but sufficient to show that they were intricate; the metrologies of the early second millennium derive from and expand a subset of the third-millennium systems.

In this "classical" period, the most widely used length unit was a "royal cubit" of seven palms. Also in use was a "short cubit" of six palms, together with units equal to the diagonal and semi-diagonal of a square with side equal to the royal cubit.

Area units were derived from the length units. The basic unit for land measurement was $(100 \text{ cubit})^2$; for practical purposes, however, the Egyptians would often think in terms of strips with a standard breadth, as the Babylonians might also do.

Volume and capacity units were also keyed to the length system, but in a way that shows them to have originated independently – how else are we to explain that the basic volume unit was not 1 cubit^3 but 2/3 cubit^3?

The areas of squares, rectangles and right triangles were calculated from length and width. The areas of trapezia and isosceles triangles were found as the product of height and average width, and the Rhind Mathematical Papyrus explains that this calculation of the triangular area means that the triangle is transformed into a rectangle. It should be noted that the height is a given or measured number, not the outcome of a computation.

The area of the circle was found as $(8/9d)^2$, where d is the diameter. Translated into modern terms this means that the interesting constant was not π but $\sqrt{\pi/4}$, which was approximated as 0.888… (where the true value is 0.8862…).

One problem (concerned with a "basket") has been interpreted as the correct determination of the surface of a semi-sphere (equal to twice the cross section of the sphere). Another interpretation is that the text wants to determine the curved surface of a semi-cylinder, which will then also be correct, and would imply that the semi-circumference of the circle was found in agreement with the determination of the area.

Volumes of prisms and cylinders were found as the product of base and height (multiplied with a metrological conversion factor 3/2. The *Moscow Papyrus* gives a correct determination of the truncated pyramid as $(a^2 + ab + b^2)\,(h/3)$ (where a and b are the sides of the upper and lower square and h the height).

Pyramid slopes were measured as horizontal recess, measured in palms, per cubit increased height. Most often, in texts as well as practice, the value is 5 1/4, corresponding to a ratio 3:4 in pure numbers. Countless attempts have been made to demonstrate that the Cheops pyramid hides knowledge of either π or the Golden section (or both!) in its proportions. The proximity of certain ratios to these "mystical" numbers is, however, a mere consequence of the simple determination of the slope. Moreover, as we have seen, the Egyptians were not interested in the ratio π but in the equivalent number $\sqrt{\pi/4}$. There is no reason to believe that the pyramids testify to occult mathematical knowledge beyond the level revealed in the mathematical papyri. As Otto Neugebauer has pointed out, nothing is less secret than the "secret" knowledge of the Egyptians, the Greek magicians, the Gnostics, etc., all of whom have left an immense number of texts on occult topics, exceeding by far anything these cultures ever wrote on mathematics. Had the Egyptians possessed secret mathematical knowledge, we would certainly have been informed, as we are about the secret spells to be used in the Netherworld.

Even the oft-claimed Egyptian knowledge of the Pythagorean theorem (or at least of the fact that a 3-4-5-triangle is right) should be treated with circumspection. No single text suggests so. One of the arguments in favor of the assumption has been that this knowledge *might* have been used to construct right angles. This trivially correct observation made by Moritz Cantor has since then been quoted as information that they did so. The other is that the pyramid recess of 3:4 could have been chosen for this reason. As we have seen, however, the actual number used by the Egyptians was 5 1/4; if the vertical distance was measured in cubits and the horizontal in palms, what was then to be done with the hypotenuse?

All of this concerned the mathematics of the scribes. Egypt, however, offers an exception to the rule that non-scribal geometrical techniques cannot be decoded. This exception regards not least the use of square grids, first of all in the pictorial arts but also in architectural planning. In the pictorial arts the grids were connected to a so-called "canonical system" for the proportions of the human body. That is, whereas scribal geometry aimed at finding numbers from geometrical configurations, the artists determined geometrical configurations from numbers. Quarries and buildings also carry marks in large quantity that inform us about some of the measuring techniques that were used.

General Observations

Histories of mathematics tend to distinguish "exact" from "approximate" formulae. In so far as we are dealing with school traditions built on some kind of didactical argument, this distinction may be defended. Both Babylonian and Egyptian scribal training certainly involved argument, even though it was not deductive. However, when making this distinction we forget that formulae can only be exact with regard to ideal mathematical objects; when it comes to applying the formulae in real-life practice, *all* formulae become approximate.

Histories of mathematics – in particular general histories – also tend to translate into familiar terms. To a certain extent this is necessary, but it hides from view the fact that other cultures may use conceptualizations which are different from ours but just as good and consistent. Speaking of a Babylonian and an Egyptian "value for π" suggests that the Babylonians, as we, looked for the ratio between the circumference and the diameter of a circle. However, to the Babylonians, the fundamental ratio was the ratio between the area of the circle and the area of the square on the circumference, and the terminology they used demonstrates that they really thought of this as a constructed geometrical square. The Egyptians, for their part, were interested in the ratio between the sides of the squared circle and that of the circumscribed square. Both conceptualizations are fully legitimate, also according to the gauge of mathematical theory, but they are certainly different from ours. If we neglect this, we only use the foreign culture as a mirror where we see – ourselves.

Later Developments

In the first millennium BCE, Egypt was conquered first by the Assyrians, then subdued by the Persian armies, and finally – after Alexander – ruled by a Greek dynasty. We cannot follow the phases of this in detail in the rare mathematical texts, but we observe that the Assyrian or Persian administrators and tax collectors brought some of their own methods to Egypt, such as, for instance, the "surveyors' formula". We also see that the practical geometries of the Babylonian and Egyptian cultures served as inspiration for the Greeks when they developed their theoretical geometry. But Greek theoretical development did not influence geometrical practice significantly, in spite of the real or affected efforts of certain Alexandrian mathematicians to educate the practitioners (in particular Hero). The ancient mathematical theoreticians were never sincerely interested in the problems encountered when geometry was to be practised – how to make sure that a ruler is straight, what to do if the compass opening is insufficiently large, how to prevent that the unavoidable imprecision in geometrical construction sums up to something unacceptable (in Euclid's *Elements*, a circle is never drawn; it is presupposed to have been drawn by an anonymous "helping hand", as pointed out by C. M. Taisbak). The synthesis between geometrical theory and geometrical practice was only achieved by the mathematicians of the Islamic Middle Ages, from al-Khwārizmī to al-Kāšī.

Glass in India

Alok Kumar Kanungo

Development of Glass in India

Indian Glass

Foreign travel accounts like Pliny's *Naturalis Historia* (73–77 AD; translated by Bostock and Riley as *The Natural History of Pliny* in 1890), *Periplus Maris Erythraei* (considered to be earlier than *Naturalis Historia*; translated by Schoff as *Periplus of the Erythrean Sea* in 1912) and *Geography of Strabo* (17–23 AD; translated by Jones and cited in Majumdar 1960: 279, 394) considered Indian glass to be of high quality as it was made of pounded quartz rather than silica. It has long been suggested that this may have been the reason behind the high silica content in ancient Indian glass (Stern 1987: 28). In Gudur (Andhra Pradesh), the government glass factory till recently produced glass from crystal. Dr. Brill of the Corning Museum believes that glassmakers throughout Iran, Mesopotamia, and central Asia (cited in Stern 1987: 28) routinely used pebbles instead of sand as the source of silica. In fact, in a Herat (Afghanistan) factory in 1977, the glassmakers still used pebbles collected in the riverbed as their source of silica.

Although glass was commonly made in the west Asian Bronze Age, there is some controversy concerning its manufacture in the Indus valley civilization (Glover and Henderson 1994). Some scholars have tried to trace the origin of Indian glass to the Harappan civilization on the basis of finding glazed pottery and quartz beads. Harappans made glazed pottery, which is ceramic with a thin layer of glass on the surface (Tite et al. 1983). Though no true glass has been found in India from the Protohistoric periods at Mohenjodaro and Harappa, the second millennium BCE saw its people able to mould and fuse excellent articles of faience and glazing their quartz beads with frit, a material similar to glass. All three materials—glass, glaze, and faience—consist of silica and lime, although special modern glass need have neither. Glass and glazes always contain soda or some or the other alkali, whereas faience generally contains only very small quantities of soda. In the evolution of glass, frit, faience, and glaze might have signified certain stages of development (Beck 1934; Forbes 1957: 223; Brill 1963: 120; Biek and Bayley 1979).

Glaze

There is little doubt that glass was an outcome of glaze. Glass and glazes are chemically identical but they are worked and used differently (Forbes 1957; Tite et al. 1983). The glazing technique marks the emergence of the first glass or synthetic material (Barthelemy and Bouquillon 1994). However, a glaze is a glassy layer applied to a core or base of some other material. This is in some cases mixed with the material before firing and in many cases applied to the body after firing. In the fourth millennium BCE glaze was used extensively within the context of the Badarian civilization in Egypt, the Jemdet Nasr period in Mesopotamia and in the third millennium BCE, the Indus valley civilization. The method of grinding quartz and mixing it with a little alkali before firing and producing faience occurred somewhat later in Egypt, in the early pre-Dynastic period (Lucas 1926; Forbes 1957). Marshall (1931: 578, 582, 692) states that the glazing of pottery is an Indian invention and a craft which appears to have been practiced for the first time on the bank of Indus. No example of it has come to light in Mesopotamia before 1000 BCE, nor in Egypt before the Roman period, although in Nubia there is said to be evidence of glazed ware as early as the XII dynasty (1991–1928 BCE). On the strength of the available material at Mohenjodaro and Harappa, Marshall (1931) went on to say that they are so closely allied to glass that it hardly seems possible that glass could have long been delayed. Bhardwaj (1979: 31) thought that the four pieces of glazed pottery found at Mohenjodaro were the handiwork of a potter who was well acquainted with the process of glazing and able to carry it to a high degree of perfection. High temperature stoneware bangles and some glazed pottery have also been recorded from Lothal, Bhagwanpura, Sanghol, Banavali, Bara, Ropar, Chanhudaro, Hulas, and Mithathal (Dayton 1989).

Faience

Faience is nearer to glass in the process of evolution. It is reported from many ancient sites and is likely to have been the predecessor of glass (Brill 1963: 120). In the archaeological sense it is generally agreed that faience consists of a lightly sintered core of crushed quartz grains coated with a translucent blue-to-green glaze, both fluxing due to soda. Such material needs a firing temperature of some 1000°C and a certain amount of sophistication in making it (Biek and Bayley 1979: 3). Crystalline quartz grains with a small amount of glassy material predominate in the case of faience. A few simple variations, whether accidental or deliberate, would have resulted in true glass (Basa 1991). Stone and Thomas (1956: 37) proposed that glass could be produced by heating faience too much or for too long, while adding a little surplus of alkali. They further suggested that it is most probable, then, that the faience makers found this out by simple observation and so became the first makers of real glass. Forbes (1957) and Bhardwaj (1979) have proposed to call most of ancient objects dubbed faience to be glazed siliceous ware, as they have a body consisting of powdered quartz covered with a layer of glaze. This material has been reported from most of the ancient civilizations including Egypt, Mesopotamia, and India (Lucas 1926; Sofianopoulas 1952). Faience was certainly made in India and fashioned into a variety of objects such as amulets, bangles and inlay, segmented beads, spindle-whorls, fluted disc beads, seals, animal figurines, and pots. In the Indus valley itself the people of Mohenjodaro and Harappa are known to have made extensive use of articles from faience, a composition resulting from powdered quartz grains fused at low temperature with the addition of lime. Some of the articles like beads and inlays were found treated with a glaze or frit which does not materially differ from glass. Marshall (1931: 683) and Mackay (1931: 576, 578 and 582) are of the opinion that though no true glass has been recovered from Mohenjodaro and Harappa, the authors of these cultures had perfected a composition which very nearly approached glass. Experiments conducted by McCarthy and Vandiver (1991) have revealed that the Harappan faience has a quite dense body with a continuous glassy phase and a relatively thin skin of glaze. Intentional addition of glass frit and clay are postulated. The Harappan faience bodies are particularly strong, compared with contemporary faience from west Asia and Egypt. A similar technology is not found in Egypt until much later during the New Kingdom, about 1450 BCE.

Brill (1987: 2) gives two reasons in support of the belief that glassmaking grew out of faience manufacture. (1) Both processes involve the pyrotechnology of the same materials (silica and alkali), and (2) faience was made for some fifteen centuries before glass was made. In this regard, the data gathered at Mehrgarh and Nausharo are of great interest since they allow the study of the local evolution of the glazing techniques through time, from the Chalcolithic to the Mature Indus period (Barthelemy and Bouquillon 1997: 63).

Ancient Indian Glass

Bhardwaj (1987) and Singh (1989), on the basis of glazed pottery from Mohenjodaro, have argued that the Harappans were aware of glass making. Bhardwaj

(1987) regards a number of vitreous materials unearthed from Mohenjodaro as weathered unworked glass, but more finds from well-dated contexts are needed before we can be sure that the Harappans had truly mastered the secrets of glassmaking (Singh 1989), and it is possible that glass could have decomposed to the point where it looked like faience.

Singh (1989) cautioned about the possibility that some glass beads might have been classified wrongly as stone beads. Even if the Harappans had this knowledge it seems to have been lost with the collapse of the urban Bronze Age civilization, and the subsequent finds of glass from the subcontinent come only with the Harappan-PGW (Painted Grey Ware) overlap phase at Bhagwanpura in Haryana, datable to about 1450–1200 BCE (Joshi 1976). From this time onwards, glass beads and bangles were regularly made in many parts of the subcontinent (Lal 1987). However, here thorough investigation of faience objects from Chalcolithic sites is required as they are reported to have yielded an enormous quantity of burnt steatite and paste, sometimes also glazed. Here it is important to mention that some of the beads that had been interpreted as shell beads (Wheeler et al. 1946; Casal 1949) have now been identified as corroded glass (Francis n.d.). Too much soda will yield a kind of glass that will be easily corroded by water, though ancient glasses often have a large percentage of soda to achieve a low melting point (Forbes 1957). In some cases faience is also wrongly identified as glass; for example faience excavated in Baoji and Fufeng country of China dated to eleventh to tenth century BCE was for a long time considered to be the earliest glass finding of China (Brill 1995: 270).

From the analysis of 38 specimens found at Alamgirpur (undated), Brahmagiri (Megalithic and Andhra culture), Hastinapur (period V, eleventh to fifteenth century AD) and (period III, sixth to third century BCE), Sar Dheri, Arikamedu (ca. 200 AD), Kausambi (200 BCE–200 AD and 100–200 AD), Bihar (first to second century AD), Orissa (200 AD), Rupar (1000–700 BCE and 200 BCE–600 AD), Vankali (Sri Lanka 1200–1250 AD), Brill (1987) comments that if glass found in India has a high alumina content (Al_2O_3) i.e., 3.5–4.0% or greater, it probably was made in India and that a low lime content (CaO) can also be considered as evidence of local manufacture. Francis (1985, 1990a, 1990b, 1991, 1994, 2002, n.d.) based on his extensive work on Arikamedu glass beads, argues that glass beads from Arikamedu were made from local glass because of the presence of high potassium that was rare in the western glass of that period. In Egypt and the Roman Empire glass consisted of sodium oxide as alkali, whereas in India and Vietnam, as evident from Arikamedu (India) and Oc-Eo (Vietnam), both sodium and potassium oxide were utilized (Francis 1990a). Lead as a coloring agent or opacifier in glass is found more in the West than in India. Glass from Khairadih, dated between 700 BCE to second century AD (Singh and Abdurazakov 1988), Nevasa (Varshney et al. 1988) and Arikamedu (Glover and Henderson 1994) are found to have low lime content. Furthermore, on the basis of scientific analysis of some of the early glass samples, Francis (n.d.) opines that both imported and indigenous glasses were used for bead production at Arikamedu and other contemporary south Indian sites.

In ancient India fragments of glass slag and other debris of glass production have been noticed at Khairadih, period II (*IAR* 1981–1982: 68, Singh and Abdurazakov 1990), Kopia (Roy and Varshney 1953; Dikshit 1969: 39; Sen and Chaudhuri 1985: 64–65; Abdurazakov 1987; Lal 1987: 45), Rajghat (Narain et al. 1976; Singh 1989) and Taxila (Marshall 1951) in the North; Ahmednagar (Chaudhuri 1986: 97), Bhokardan (Deo and Gupte 1974: 197), Brahmapuri (Kolhapur) (Sankalia and Dikshit 1952), Nevasa (Sankalia et al. 1960: 355, 383–85), and Paunar (Deo and Dhavalikar 1968: 82–83) in the Deccan; Sirpur and Tripuri in Central India; Hulas Khera (Tewari et al. 1995–1996); Maheswar (Sankalia et al. 1958) and Nagra (Mehta and Shah 1968: 132–37) in the West; and Arikamedu and Karaikadu in the South. Thus, it is evident that ancient India was not only manufacturing by-products of glass but was also making glass for its use.

Regarding the glass furnace in ancient India, our information is meager. A solitary reference comes from Nevasa, where a glassmaking kiln dated to the period ca. 3rd—and 4th AD was unearthed. It is a circular oven 2′-6″ in diameter with 1′-7″ depth and is made of burnt clay. Around it an abundance of bichrome glass, slag, lime, cow-dung, etc. was found (Sankalia et al. 1960). At one of the points near the periphery was a channeled projection evidently to insert the pipe for the bellows (Deo 2000: 11). Chaudhuri (1986: 99) remarked that most of glass furnaces in ancient India are open-fired type, using solid fuel, and the melting was carried out in a clay pot.

Ancient Literature

Mention of glass (*kāca*) and its by-products, most prominently that of beads, occurs in early *Brāhmaṇical* (Sanskrit) and Buddhist literature. Mukharji (1888), Ghosh (1924), Chaudhuri (1986), Dikshit (1964–1965, 1969) and Deo (1987, 2000) list a few of them; for instance in the *Yajurveda* (c. 1200 BCE) *kāca* is mentioned as one of the articles of which female ornaments were made by means of stringing with gold thread. In *Śatapatha Brāhmaṇa* (c. 800 BCE), the word *kāca* refers to glass beads which were used for decoration of horses in the *Aśvamedha* sacrifice. There are references to women wearing glass beads and to the

T-Kallupatti

wearing of or threading of one hundred and one beads of glass. The *Taittiriya Brāhmaṇa* also refers to the wearing of glass. Coming to the Sutra period (ca. 600 BCE), one comes across references to glass beads in the *Baudhayana Srauta Sūtra* and in *Manava Srauta Sūtra*. The *Māhavagga* section of the Buddhist text *Vinaya Piṭaka* (fifth to fourth century BCE) alludes to the use of shoes ornamented with glass as being forbidden to the Buddhist *bhikshus* (monks). The *Chullavagga* similarly forbids the use of glass bowls. One of the earliest South Indian texts, *Manimekalai* (3, 64), refers to *palingu*, meaning glass or quartz in Tamil, which is possibly a corruption of the Sanskrit word *sphatika*, although the prakrit *phalika* (quartz), occurs in the Bhattiproru inscription of the second century BCE (Srinivasan and Banerjee 1953: 113). *Rāmayaṇa* refers to the makers of glass, the '*kachakara*'. Kautilya's *Arthaśāstra* (third century BCE) alludes to the making of glass at two places. (1) *Adhikarana* 14, *Adhyāya* 1, *Sūtra* 12, says that in order to punish the enemy, obstacles like the smoke of Puti, Karañja leaves.… as in the manufacture of glass, by burning cow dung etc., should deliberately be created. (2) Another passage in the *Adhikarana* 2, *Adhyāya* 14, *Sūtra* 45, though somewhat corrupt, refers to the process of making gold-foiled glass beads. It describes the piercing of glass beads in a molten stage for the purpose of setting ornaments and the setting of glass-fragments (*kśepana*) in gold ornaments for the preparation of the glass gems. Amongst the various punishments inflicted for stealing, it is ordained that a person stealing articles made of copper, bronze, tin, glass and ivory was to be fined 46–96 *paṇas*. Glass is also mentioned in the *Māhābhārata*, and in *Yuktikarata*. The effects on the human system of drinking water out of a glass tumbler are stated to be the same as those of drinking out of a crystal cup. Some of the Puranas such as the Matsya, the Vishnu, and the Bhagawata, assigned to the Gupta period (third to fifth century AD), refer to *kāca*. *BṛhatSaṃhitā* (sixth century AD) also mentions glass. Apart from these, references to glass vessels for preserving medicines can be seen in texts like *Charaka* and *Śusruta Saṃhitā*. In the *Amarakośa* (seventh century AD) mention of glass vessels, cups and dishes are made. In later period, Somnath Kavi (ca. 1446–1539 AD) mentions spectacles in his *Vyasoyogi Charita*.

Spread of Glass in India

On the basis of glass findings at Taxila and Arikamedu, Marshall (1951) and Wheeler et al. (1946) thought them to be of foreign origin. On the contrary, typical Indian designs on some early glass specimens of Taxila, Mohenjodaro's glazed pottery and evidence of glass in the Chalcolithic level at Maski, and at Painted Grey Ware sites (supposed to be devoid of any foreign association) have led Dikshit (1969), Bhardwaj (1987) and Singh (1989) to argue for indigenous origin of glass (Kanungo 2000–2001, 2002a, 2004c). Deo (2000: 26) takes a middle path by mentioning that though much of the glass at Taxila was imported into India through its foreign settlers, there is reason to believe that some of the beads are indigenous. It is difficult to say how far early foreign contacts were responsible for the introduction of glass but the stray specimens reported do not point to anything definite.

The *Periplus* mentions Roman export of both raw glass and glassware. The ancient Indian literary records are silent on importing glass from the western world. However, the archaeological data on Roman glass in India strongly corroborates the references in the *Periplus* to glass imports into India (Gupta 1997). Stern (1986) suggests that it was convenient for Mediterranean shippers to bring raw glass to India as it served as good ballast for transport vessels. On reaching India, Mediterranean glass found a ready market because of the existence of a highly evolved glass working industry in the subcontinent. On their part, the Indians, besides marketing glass products of Roman glass in the domestic arena, exported the products to Southeast Asia and the Mediterranean. Probably, some of this glass really was imported, but there are good reasons for believing that much of this early glass was actually made in India (Brill 1987: 2).

The Indians learned the technique of glass, probably independently, only around 1200 BCE. Since then evidence of glass has been unearthed from more than 200 ancient Indian sites. Kanungo (2002a: 54–120, 2004b, 2004c) lists 204 sites which have yielded evidences of glass. Glass beads occur in about 150 sites and 36 are claimed to have been manufacturing sites (Kanungo 2004a: 123).

The earliest evidence of glass beads (two well-made unweathered black and white tabular eye beads) in

India is reported from Bhagwanpura in the Harappan-Painted Grey Ware overlap phase (period I), *c*. 1400–1000 BCE (Joshi 1993). The occurrence of one glass bead in period II (Protohistoric) at Navdatoli shows that glass was not unknown to the people of this period (Deo 1955: 10). The evidence of glass in the Chalcolithic period is very poor, found only at Maski. During the next cultural phase of Indian history, i.e., Painted Grey Ware, we find that the occurrence of glass is quite common and widespread. It is found at several sites in India, which are widely separated from each other. Glass finds, although limited in number, have been a constant feature in all the levels from the sixth century BCE onwards. However, sites of Ochre Colored Pottery (OCP) culture have yielded only a few beads (Niharika 1993).

The evidence of stratified eye beads from Northern Black Polished Ware (NBPW) phase, which form the next important stage in the study of glass in India, possibly supports the impression that mature glass came to India from the Mediterranean countries.

The technique of glass manufacture was well known since the seventh to sixth century BCE (Margabandhu 1971: 1219, 1985: 327). Once the manufacturing

processes were standardized, during the latter half of the first millennium BCE glass objects were produced on a mass scale. The very material and objects made of the glass found during this period bear an eloquent testimony to the fact that the making of glass in a furnace and later remaking and shaping them to beads had been fully understood and utilized to the maximum extent by the artisans of the times (Margabandhu 1975: 73). The site of Kopia in Santh Kabir Nagar district (earlier part of district Basti), dated to about fifth century BCE, has yielded innumerable glass beads, thousands of glass fragments, fragments of clay crucibles with glass sticking to them, big pieces of glass and lumps of unworked glass (Roy and Varshney 1953; Dikshit 1969: 39; Sen and Chaudhuri 1985: 64–65; Abdurazakov 1987: 38; Lal 1987: 45). One large block of glass weighs about 76 kg and measures 45×30×22.5 cm (Lal 1987: 45). Unfortunately, a few excavation reports of Indian sites yielding glass objects have discussed the manufacturing techniques involved and none the basis of the same (Kanungo 2000–2001, 2001, 2004a).

From 500 BCE onwards and particularly during the Maurya period, glass objects of all kinds came to be manufactured widely (Lad 1983: 67). In Mauryan (fourth to second centuries BCE) and Sunga (second to first centuries BCE) periods, beads of all kinds were plentiful including those made of glass (Alkazi 1996: 7). The best evidence is that of glass seals from Maheshwar, Patna, Ujjain and three glass seals from the Mauryan phase at Taxila. The seals are mostly green and pale blue, carefully moulded and subjected to annealing to remove the internal strain. Spool (externally grooved) shaped earplugs, beads and bangles constitute the bulk of the glass articles known from specimens from Ahichchhatra, Kausambi, Patna and Rajghat.

The beginning of the Christian era witnessed the ushering of foreign cultural elements into Indian life. This is reflected not only in new shapes, but also in the introduction of new materials like the Mediterranean fine-grained corals and glass (Deo 2000: 6). Use of glass became quite common. Findings at Arikamedu, Nevasa, Taxila and other sites present evidence for this. Excavations at Chandravalli, Karad, Kolhapur, Kondapur, Maski, and Nasik have each yielded valuable materials of high quality from the Satavahana period (first century BCE to early third century AD). Wound and drawn beads are often found (Deo 2000: 27). Beads with white stripes are known to have come from Kolhapur, Kondapur, Maski, Nevasa, Prakash and Ter in the Deccan. These beads are common enough at Tripuri and Ujjain. By the dawn of the Christian era, the use of glass for beads became more popular. Many techniques were adopted for the manufacture of beads and ornaments during this period (Margabandhu 1985: 203).

Abdurazakov (1987: 38) speaks of finding fragments of Middle Age glass at nine archaeological sites in India: Ahichchhatra, Arikamedu Assam, Jaipur, Kausambi, Kurukshetra, Nalanda, and Udaigiri. He mentions the evidence of glass and clay pots (used for glass production) at Dargai in Pakistan too.

By the time of Harsa (seventh century AD), glass was no longer a luxury as it must have been in the Satavahana period and was even used by mendicants and aboriginals (Agrawal 1953: 186; Kanungo 2002b). In Deccan, with the establishment of the Sultanates (twelfth to thirteenth century AD), the country witnessed the rise of small-scale cottage industries for the fabrication of glass beads, as evidenced by the discoveries at Kolhapur and Nevasa in Maharashtra, and Maski in Karnataka and Sirpur in Madhya Pradesh (Deo 2000: 6). The lacuna in our knowledge about the other contemporary Indian glass objects is almost certainly due to inadequate excavations of historical sites.

Chemical analysis of the specimens of about eighteen areas shows that Indian workers were well acquainted with the raw materials and coloring agents used for the preparation of glass. In some of the specimens of Taxila glass, the presence of lead oxide and in some of the Tripuri specimens (200 BCE) the presence of barium oxide has been found. Presence of lead in glass gives rise to the formation of crystal glass and that of barium imparts to glass high resistance to heat.

In comparison with commonly occurring archaeological material such as pottery or metals, the glass in ancient sites occurs less frequently. Glass was never produced, on a very large scale, or over so wide an area as other materials. This is due to the fact that it required advanced technological skills to generate and maintain the required temperature for production of glass for long periods. This very often mirrors the general technological level of society. However, considering the spread of proto glass and its by-products in Protohistoric, its contemporary and later periods there is every possibility that glass might have developed independently in India. Glass seems to have appeared 500 to 1,000 years later than in Mesopotamia and Egypt.

In the Indian context, literary data and archaeological evidence point to the same time period for the occurrence of glass. Reference of *kāca* comes from the *Brahmana* group of texts which are assigned to the same time period as that of the Painted Grey Ware. Glass becomes more common in the Northern Black Polished Ware period. This is also reflected in literary data of the fourth to fifth century BCE, which abounds in references to glass.

In the early Christian era glass was not only found throughout the country but its by-products like beads were also produced using indigenous techniques. Subsequently, many places emerged as production centers of a flourishing glass industry, as it had become by now an article of common use and was no longer a precious and rare commodity. Glass is more abundantly seen at the dawn of the Christian era.

No archaeological site except Nevasa has as yet given evidence of a glass furnace. This is probably due to the fact that since production of glass requires a high temperature for a long time period, and in earlier days furnaces were generally made of clay, they collapsed or broke down at a fast rate. Thus in the archaeological context, not only does glass need to be classified and recorded, but the debitage[1] also needs to be carefully collected and catalogued.

The evidence of glass in Indian archaeology is spread in both time and space. Though there have been claims at regular intervals by different authors about the glass being introduced to India from outside, sometime in the Indo-Roman period, the evidence from as many as 29 sites gives ample evidence that glass was known much earlier and could have been produced locally (Map 1). Besides, there is also stray evidence of glass in Bhagwanpura (Painted Grey Ware-Harappan overlapping), Dwarka (late Harappan) and Maski (Chalcolithic), which are of much earlier cultures. Likewise there are 34 sites, which have evidence of glass beads in association with the Northern Black Polished Ware period or in the period in between 600–300 BCE (Map 2). However, with the beginning of the early Historic phase, and more particularly in the early Christian centuries, the evidence of glass from as many as 119 sites suggests large-scale use (Map 3). This period is between 300 BCE and 400 AD and is characterized by red ware, red polished ware, russet coated painted ware, red and black slipped ware, black slipped ware and rouletted ware. All the same, during the Medieval Period there is clear indication that glass was becoming quite common as evidenced by its presence at 70 sites in the early Medieval period (400–1300 AD) (Map 4) and 49 sites in the late Medieval period (1300–1800 AD) (Map 5) (for details see Kanungo 2002a, 2004c). Considering such spread of glass and its by-products in ancient India, it is highly likely that around the early Christian era there should have been more regional major producers of glass other than the established site of Arikamedu in the south. In this regard Kopia in the north with its strategic location, abundance of glass, glass beads, crucibles and other debitage on the surface stands apart, and further work followed by a systematic excavation of this site could result in better understanding of ancient glass technology in India.

[1] Debitage is the collective term used by archaeologists to refer to the sharp-edged waste material left over when someone creates a stone tool (knaps flint). Debitage is probably the oldest artifact-type recognized by archaeologists; the term is a French one but widely used by archaeologists the world over.

Globes

EMILIE SAVAGE-SMITH

The celestial globe is the oldest form of celestial mapping, for its origins can be traced to Greece in the sixth century BCE. The stars were perceived as though attached to the inside of a hollow sphere enclosing and rotating about the earth. The earth, known from early classical antiquity to be spherical, was imagined at the center of the globe, while the stars were placed on its surface. Since this three-dimensional model of the skies presented the stars as seen by an observer outside the sphere of stars, the relative positions of the stars on a celestial globe are the reverse, east to west (or right to left), of their appearance when viewed from the surface of the earth. The sequence of the zodiacal constellations will be counterclockwise when the globe is viewed from above the north pole.

No celestial globes from antiquity have survived, but the basic principles of their design were maintained, with some modifications and elaborations, in the Islamic world, where the earliest preserved celestial globes were made. By the ninth century celestial globes were being made in the Arabic-speaking world. The most important early Islamic center of globe-making was the city of Harran, between the northern reaches of the Euphrates and Tigris rivers. In the ninth and tenth centuries it was an important town at the intersection of major caravan routes and had a prominent Sabian community whose pagan religious interest in the stars and sun was perhaps conducive to the study of astronomy. Many of the early astronomical instrument-makers were members of the Sabian sect at Harran. Several Arabic treatises were composed in the ninth century on the design and use of celestial globes, including one by the famous astronomer of Harran, al-Battānī who was known in the Latin world as Albategni, and others by Ḥabash al-Ḥāsib and Qusṭā ibn Lūqā in Baghdad. In the following centuries, additional treatises on the subject were composed, including one by ʿAbd al-Raḥmān ibn ʿUmar al-Ṣūfī (d. 983) whose treatise on constellations became the model for constellation iconography in the Islamic world.

Over 180 Islamic celestial globes are known to be preserved today. The earliest was made in AD 1080 in Valencia, Spain, and the most recent in Ottoman Turkey in 1882. Regardless of date, the stars represented on Islamic globes are those listed in the medieval star catalogs, and only the 48 constellation outlines recognized in antiquity are indicated. When constellation outlines are drawn around the stars, the clothing and faces of the human figures, such as Orion or Virgo, reflect the artistic conventions common in the artisan's day. Since the positions of the stars change over time with the precession of the equinoxes, the star positions on a globe, correct when the globe was made, remain valid for only three-quarters of a century.

In addition to the celestial equator and the ecliptic (the band of the zodiac through which the sun apparently moves in its yearly course), the Tropic of Cancer and the Tropic of Capricorn were also frequently shown on Islamic globes, as well as the north and south equatorial polar circles. On some later globes the ecliptic equivalents of tropic and polar circles were indicated, apparently in an attempt to complete the symmetry. On every Islamic globe preserved today there is also a set of six great circles at right angles to the ecliptic – six ecliptic latitude-measuring circles, reflecting the common use of ecliptic-based coordinates for measuring star positions. To function as an instrument, the sphere needed to be placed in a ring assembly, allowing for adjustment to a particular location. If supplemented by a gnomon or quadrant providing the altitude of the sun, the globe could then be used by an astronomer or astrologer to determine a range of astronomical data, including the length of the unequal day-time hour for a given day and location, or the time elapsed on a certain day, or data for a horoscope. It is questionable, however, whether many of the globes preserved today were of more than didactic or artistic value.

In terms of design, Islamic celestial globes fall into several distinct categories. The first includes the largest and the most elaborate artifacts, all of which display the 48 constellation outlines and approximately 1,022 stars. Those in the second category do not have constellation outlines. Only a selection of the most prominent stars, usually between 20 and 60, are shown.

The third type of design is one in which the globe has neither constellation outlines nor any stars. In general these globes are the smallest. They have on them only the great and lesser circles (ecliptic, equator, tropic, and polar circles), all of which are labeled. This design is not mentioned in any of the written sources, and evidence so far available suggests it originated in Iran in the late seventeenth or early eighteenth century.

Only a few painted wood or papiermâché Islamic globes have survived, all of them hand drawn or painted. The method that dominated globe making in Europe – namely, laying printed paper gores over a wood or fiber core – seems not to have been practiced in the Islamic world. The vast majority of Islamic globes are hollow metal spheres and were made in two ways: from two hemispheres of cast or raised metal, or cast in one piece by the lost wax process. While globes made of wood or papiermâché or with metal hemispheres are of considerable antiquity, seamless globes, on the basis of evidence so far available, appear to have originated in northwestern India toward the end of the sixteenth century, the earliest confirmed date for one being AD 1589–1590. They became the hallmark of all workshops in the Punjab and Kashmir areas of India through the nineteenth century. The workshop that excelled in this technique was a four-generation family of instrument makers in Lahore (in modern Pakistan). During more than a century, this remarkable workshop produced numerous astronomical instruments, including 21 signed globes (the earliest made in AD 1622). The technique of making seamless globes continued to be practiced in India after this workshop ceased to make them.

Throughout the ten centuries of their production in the Islamic world, celestial globes maintained the medieval tradition of displaying only the classical constellations and stars. On metal globes the stars were usually indicated by inlaid silver points. None of the surviving Islamic celestial globes records the stars and constellations of the southern hemisphere first mapped by Europeans during explorations of the sixteenth century.

While the production of celestial globes was widely and continuously practiced in the Islamic world, there was no comparable tradition of terrestrial globe making. There seems to have been little interest in terrestrial globes until the sixteenth century, when early modern European terrestrial globes became known to Ottoman Turkish astronomers and in the next century to those at the Mughal Indian court.

Gnomon in India

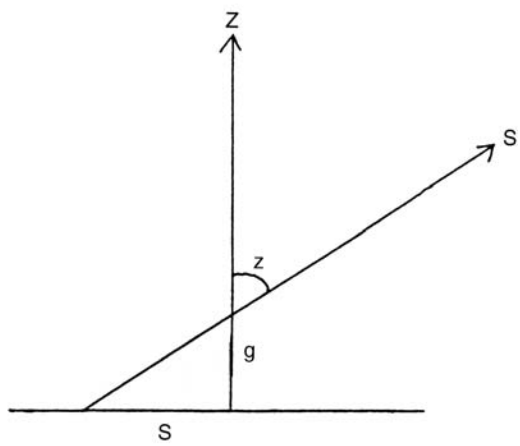
George Abraham

The gnomon is an instrument used widely in early astronomy. The shadow of a vertical rod on a horizontal plane determines the cardinal directions, the latitude of the place of observation, the celestial coordinates of the sun, and the time of the observation.

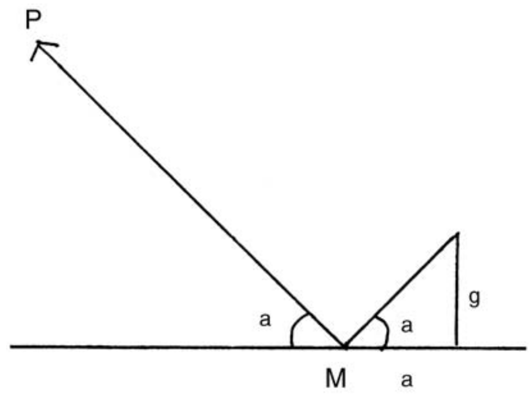
Varāhamihira gave a fairly complete account of its use in India in the *Pañcasiddhāntikā*. This was written in AD 505 and summarized the astronomical information current in India at that time. The *Āryabhaṭīya* of Āryabhaṭa also provides the main results of the theory of the gnomon, and these features appear again in the works of Bhāskara, Brahmagupta, and many later astronomers.

The Cardinal Directions

The procedure is illustrated in Fig. 1. G is the foot of the gnomon. The path of the end of the shadow enters and leaves a circle, center G, at W and E. Then the line EW is in the east–west direction. With E, W as centers, circular arcs are drawn intersecting at N, S. Then NS, the perpendicular bisector of EW, is in the north–south direction and intersects the circle at N and S, the north and south points. The east and west points, E and W,



Gnomon in India. Fig. 2 The noon shadow.



Gnomon in India. Fig. 3 Determining the altitude of the moon or planets.

can be found by the same procedure since they are on the perpendicular bisector of NS.

This method depends on the symmetry of the shadow path about the north–south line. It does not take into account the small change in the declination of the sun during the day. Brahmagupta prescribed a correction for this error in the *Brahmasphuta Siddhānta*. This method of finding the cardinal directions, described in the *Pañcasiddhāntikā*, is found in a much earlier treatise, the *Śulbasūtra*, which contains mathematical topics related to the construction of sacrificial altars. The *Pañcasiddhāntikā* also has an approximate method for finding the meridian direction from any three positions of the shadow. This method assumes that the path of the shadow is a circle, whereas in India, it is a hyperbola.

The Noon Shadow

Trigonometric formulas enable us to find the latitude of the observer and the sun's declination from the shadow of the gnomon at noon, when the sun is on the local meridian. In Fig. 2, g is the height of the gnomon, s the length of the shadow, Z the zenith, S the sun, and z the zenith distance of the sun. On any day, the zenith distance at noon is $z = \o \pm \delta$, where $\o$ is the observer's latitude and δ the declination of the sun. The Indian formula is

$$\sin z = \frac{Rs}{\sqrt{s^2 + g^2}},$$

where the sine of an angle is defined as R times the modern sine function, R being a constant angle, taken to be 120 min in the *Pañcasiddhāntikā*. When the sun is on the equator, $\delta = 0$, and the formula above gives us the latitude in terms of the length of the noon shadow. On other days, the formula yields the change $\pm\delta$, in the zenith distance, as a function of the noon shadow. On the days of the solstices, the declination has the maximum value, ε, the obliquity of the ecliptic (the band of the zodiac through which the sun apparently moves in its yearly course).

When the sun is on the prime vertical (the great circle on the celestial sphere through the east and west points and the zenith), let z_1 be the zenith distance, and $\alpha_1 = 90 - z_1$, the altitude of the sun, and λ, the longitude of the sun. Then the *Pañcasiddhāntikā* formulae are

$$\sin a_1 = \frac{R \sin \delta}{\sin \phi} = \frac{\sin \lambda \sin \varepsilon}{\sin \phi}.$$

With these two formulae, we can find the declination and longitude of the sun from the shadow length, when the sun is on the prime vertical.

With the gnomon, it was also possible to find the time after sunrise, from the length of the shadow, using formulae which are equivalent to those used in modern spherical astronomy.

The second formula above gives the sun's longitude λ and declination δ, when it is on the prime vertical. λ and δ can be determined at any time, from the length of the gnomon's shadow and the distance of its endpoint from the east–west line. The *Pañcasiddhāntikā* also gives an approximate empirical algebraic formula which would have been useful in very early astronomy:

$$\frac{d}{2t} = \frac{s - s_0}{g} + 1.$$

This gives t, the time after sunrise in the morning or the time before sunset in the afternoon, s_0 is the noon shadow, and d the length of daylight. This formula is derived from the following considerations:

1. There is a linear relation between s and $1/t$
2. At noon $2t = d$

3. $s - s_0 = g$ at $4t = d$

The *Yavanajātaka* of Sphujidhvaja also has this formula. Chapter 20 of Kauṭilya's *Arthaśāstra* gives the relation between the time after sunrise and the gnomon shadow. The *Arthaśāstra* also gives the rule for the uniform variation of the noon shadow from zero at the summer solstice to g, the gnomon height, at the winter solstice, a reasonable approximation for an observer on or near the Tropic of Cancer, for example at Ujjain. However, the rule for the uniform variation of the length of daylight from 12 to 18 *muhurtas*, also found in the two books above, implies a latitude of about 35°, which suggests a Babylonian origin.

The theory of the gnomon presented above can be applied to the moon and planets also. The altitude of the moon or planet is determined in the following manner, illustrated in Fig. 3.

The moon or planet (P) is seen reflected in a mirror M in the same horizontal plane as the foot G of the gnomon of height g at a distance d from the gnomon. Then the altitude a is given by the formula

$$\sin a = \frac{R_g}{\sqrt{g^2 + d^2}},$$

d is called the *reversed shadow* and takes the place of the shadow length s in the case of the sun.

The eleventh-century Arabic scholar al-Bīrūnī wrote *Kitāb fī ifrād al-maqāl fī umr al-ẓilā* (The Exhaustive Treatise on Shadows), which contains a comprehensive account of the theory and applications of the gnomon shadow. Al-Bīrūnī refers to many Indian sources, for example:

1. The method described above for finding the cardinal directions. He calls it the method of "the Indian circle."
2. The algebraic formula.
3. The time from the shadow. Al-Bīrūnī follows the procedure of Brahmagupta.
4. Al-Bīrūnī gives the approximate Indian method for determining the meridian from three positions of the shadow. In addition, he describes the procedure, for the same problem, given by Diodorus of Alexandria, a mathematician of the first century BCE. An important result in al-Biruni's book, not mentioned in his Indian sources, is the condition for the shadow path to be a parabola, ellipse, or hyperbola, depending on the latitude of the observer and the declination of the sun.

Gou-Gu Theorem

Joseph W. Dauben

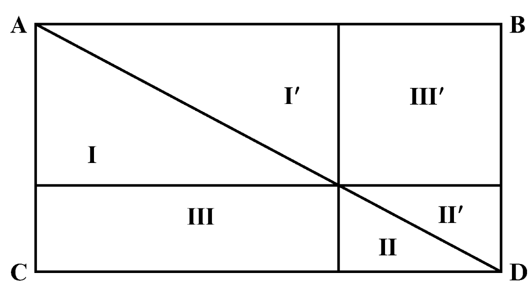
One of the basic theorems of geometry in both the East and West concerns the relationship between the sides of a right triangle and their squares, known in the West as the "Pythagorean" theorem, but understood in an equivalent form as the *Gou-Gu* theorem in China. The ancient Egyptians, Babylonians, and Chinese probably discovered this remarkable property of right triangles by empirically examining the simplest case of 3–4–5 triangles. Whether in its geometric form or more familiar algebraic expression, $3^2 + 4^2 = 5^2$, the theorem concludes that the sum of the squares on either "side" of the right angle is equal to the square on the hypotenuse (*Xian*). In China, this was established for right triangles in general, i.e., not just for the 3–4–5 triangle, or for those with sides of integer lengths. The Greek made this discovery as well, but proved it rather differently in the argument presented at the end of the first book of Euclid's *Elements*, Proposition I-47.

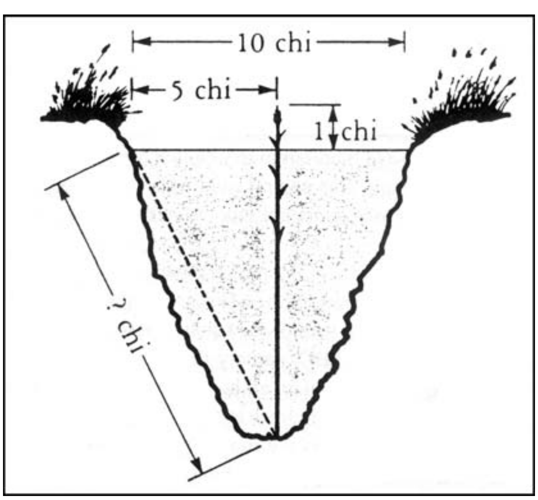
One of the great treasures of Chinese mathematics is the *Jiuzhang Suanshu* (Nine Chapters on the Art of Mathematics). It is the final chapter that is the most famous, in which the *Gou-Gu* theorem is introduced. Even before the *Nine Chapters* was written, results dealing with right triangles had been presented in an earlier astronomical–mathematical work, the *Zhoubi Suanjing* (The Arithmetic Classic of the *Zhou Gnomon*). The *Nine Chapters*, however, goes well beyond the simple applications found in the *Zhou Gnomon* text, which is concerned primarily with applications in astronomy. In fact, Chapter 9 contains 24 problems, each of which deals primarily with right triangles and solutions of quadratic equations. One of these is a variation on one of the oldest of China's mathematical problems (this is Problem 6 in Chapter 9 of the *Nine Chapters*) (see Fig. 1):

> In the middle of a pond that is ten "*chi*" in diameter, a reed grows one "*chi*" above the surface of the water. When pulled toward the edge of the pond, the reed just reaches the perimeter. How long is the reed?

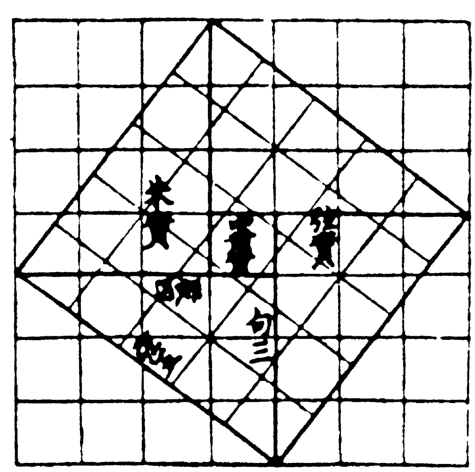
The solution to this problem is a straightforward application of the *Gou-Gu* theorem.

In commenting on a passage from the *Nine Chapters* that reads, "Combining each square of *Gou* and *Gu*, taking the square root will be *Xian* (the hypotenuse)," Liu Hui explains the *Gou-Gu* theorem as follows:





Gou-Gu **Theorem. Fig. 2** A problem that can be solved by applying the *Gou-Gu* theorem (see text: How long is the reed?) (drawing by the author).



Gou-Gu **Theorem. Fig. 3** The *Xian* figure.

> The *Gou*-square is the red square (*Zhu fang*), the *Gu*-square is the blue square (*Qingfang*). Putting pieces inside and outside according to their type will complement each other, then the rest (of the pieces) do not move. Composing the *Xian*-square, taking the square root will be *Xian* (the hypotenuse) (Guo 1990).

The reference to moving pieces inside and outside is related to a diagram, no longer extant, and makes use of the so-called "Out–In" method which was taken as an axiom by ancient Chinese mathematicians. The power of this axiom can be seen, however, from the following illustration, where the two triangles ABC and ACD are equal (Fig. 2):

Since the areas I and I′, II and II′ are equal, then it follows from the "Out–In complementary principle" that III must be equal to III (Wu 1983).

This now helps to explain Liu Hui's commentary on the *Gou-Gu* theorem. First of all, his references to colored squares are similar to colors mentioned in the diagrams illustrating the *Gou-Gu* theorem in the *Zhoubi Suanjing*. There, in the "*Xian* figure," the central square is yellow, while the squares of the *Xian* square are red. Often the *Gou* square is blue (Fig. 3).

Applying the "Out–In" complementary principle to the *Xian* figure, and following Liu Hui's commentary on the *Gou-Gu* theorem, the sum of the squares based on each leg of the right triangle ABC, namely the squares ADEB and BFGC, is equal to the square of the hypotenuse AC, namely the square AHJC (see Fig. 1 above). In accordance with the "Out–In" principle, if we move those parts of the two small squares (ADEB and BFGC) that are on the outside of the large square (AHJC) to its inside, we can see that they fill the inside exactly and that the combined areas of the two small squares equal that of the larger one. Since the areas are analogous to the squared sides of the triangle, the sum of the squared legs equals the squared hypotenuse.

It has been argued that geometry never developed further in China than it did with Liu Hui's commentary because this was sufficient for Chinese needs. After Liu Hui, Chinese geometry does not seem to have made much further progress. Although some authors suggest that this was due primarily to the practical orientation of ancient Chinese mathematics, it may have been its actual success, its comprehensiveness, that caused the stagnation of any further development. As D. B. Wagner has suggested:

> Liu Hui's conceptual framework was adequate, for example, to deal with a much broader range of geometric solids than those which he actually considers in his commentary. Had he felt a need to push his methods to their inherent limits, he would surely have contributed a great deal more to the mathematical tradition. Here we can see the double influence of the enormous prestige of the *Chiu-chang suan-shu*: it provided a challenge and an inspiration; but it was often a strait jacket which confined the interests of mathematicians to certain specific problems.

Like Euclid, Liu Hui summarized his art so successfully that his successors may have felt little need, or room, for improvement.

Gunpowder

Ho Peng Yoke

Gunpowder was probably discovered in China accidentally. Since the Han period (202 BCE–AD 220) Chinese alchemists attempted to make gold or to prepare an elixir of immortality. Sulfur and saltpeter were among the raw materials used for their experiments, and charcoal was among the different types of fuel used in their laboratories. The *Zhenyuan miaodao yaolue* (Classified Essentials of the Mysterious Dao of the True Nature of Things), a book of the late Tang but probably containing material from much earlier dates, carries a note of caution to the alchemists warning them to exercise due care when dealing with sulfur, saltpeter, and charcoal because there were cases where the operators had their hands scorched or their thatched huts set on fire.

In China gunpowder found its early use in amusements, in religious and ceremonial functions, taking the form of fireworks and rockets, and in construction works, such as blasting rocks in the opening of waterways and roads. For example explosives were used by Gao Ping to open a rocky water route linking Guangdong province and Annam in the ninth century. There are no records that show the use of gunpowder in the battlefield before the tenth century. An early fire weapon that the Chinese used was the "incendiary arrow" (*huojian*) to send a variety of ignited substances to the enemy camp. At first naphtha was one of the combustion agents used. By 919 there appeared the force pump that could throw flaming petrol, or "Greek Fire," directed toward the enemy. Both naphtha and "Greek Fire" were imports from the West.

The *Songshi* (Official History of the Song Dynasty) mentions that in 970 Feng Jisheng submitted to the emperor a report on the manufacture of "incendiary arrows" and that in 1000 Tang Fu made "incendiary arrows," "fire balls" (*huoqiu*), and "thorny fire balls" (*huojili*). These were bombs and grenades containing gunpowder for hurling over enemy walls and camps by means of trebuchets. Later on the bombs progressed from those with weak casings to those with stronger ones.

In the middle of the tenth century the "fire-lance" (*huoqiang*) was invented. At first it consisted of a bamboo tube with its septa cleared. Then it was filled with rocket composition and capable of shooting out flames horizontally. According to Needham the "fire-lance" had enormous repercussions in China for some 700 years from the middle of the tenth century, playing prominent roles in many battles. It also marked a transition from the bulky petrol flame-thrower to a much lighter and portable weapon using gunpowder, and heralded the use of the principle of the tube in military technology. Bamboo tubes gradually gave way to barrels made of metal. The "fire-lance" took a big step forward in 1259 when the "fire-emitting lance" (*tuhuoqiang*) was developed. This type of "fire-lance" could fire scrap metal and break porcelain, if not also small darts or arrows, on which poison was sometimes applied. The range of the projectiles was short compared to a single bullet from a gun barrel. The Chinese later developed a similar firearm with a large barrel mounted on a carriage, rather like a field gun but which emitted a large quantity of projectiles instead of a single shell. Again these projectiles could be scrap metal, stone, broken porcelain, arrows, and poisonous or noxious substances.

The earliest document giving the gunpowder formula and describing its applications in various forms of firearms is the Song military compendium, *Wujing zongyao* (Collection of the Most Important Military Techniques), written by Zeng Gongliang in 1044. It describes with illustrations a number of weapons using gunpowder, such as the grenade, the bomb, etc. and gives several gunpowder recipes. The compositions suggest that the earlier Chinese gunpowder was more of the deflagratory type. A much higher ratio of saltpeter for explosives was used later.

Around the year 1000, gunpowder weapons were deployed on the battlefield in China. Large quantities of gunpowder were prepared and stored up during the Northern Song (960–1126). In 1232 the "thunderclap bombs" were brought into action. In the early twelfth century knowledge of gunpowder was acquired by the Jurchen people who eventually occupied northern China and established the Jurchen empire (1115–1234). In 1232 they used the "thunder-crash bomb" and the "flying fire-lance" (*feihuoqiang*) to defend their capital Bianjing against the Mongol invaders. Bianjing fell the next year. Gunpowder and firearm technicians were captured by the Mongols and taken into their service. The Mongols invaded Europe from the year 1236, deploying firearms of the offensive type. For example trebuchets were used on at least two occasions, in July 1237 at the battle of Ryazau, and in July 1241 "incendiary arrows" were used at the battle of Wahlstadt. The Mongols also used their firearms against the Arabs. In 1258 they used "fire-jars" to attack Baghdad, probably a reference to the thunder-crash bombs, which the Mongols also used against the Japanese in a sea battle near Kyushu in 1272. The next important city to fall after Baghdad was Damascus. The Muslims set up the Mamluk caliphate in Cairo and in 1260 defeated the Mongols in a battle in Syria. From then on, the two sides made little headway against each other for some years, during which the Mamluk caliphate turned its attention to military affairs and weaponry. Some Mongolian soldiers surrendered and some firearms and technicians fell into the hands of the Muslims. The Muslims thus acquired the technique of making firearms. They used them successfully against the Sixth Crusade (1248–1254).

By the latter part of the thirteenth century the narrow cylindrical tube of the fire-lance had already developed into one with much wider bore for the cannon (*huopao*). For example cannons were deployed when the Mongolian fleet went to Java in 1292 and 1293. Many examples of Chinese cannon, both of bronze and iron, are known from 1330 onward. Several types of cannons are described in the fourteenth-century military book, the *Huolongjing* (Fire Dragon Manual).

During the second half of the fourteenth century Chinese firearms were unmatched anywhere in East Asia. They were used by Zhu Yuanzhang, the founder of the Ming dynasty, to overthrow the Mongols and to suppress local rebellions. After his victory he kept his firearms in secret arsenals. There was no need to improve these weapons as they met no challenge, so that he only saw the necessity of guarding both the weapons and the knowledge from falling into undesirable hands. This happened during a period when Europe was undergoing great social change and when European firearms began to come to ascendancy. Traditional Chinese weaponry is now something of the past, but firework displays that we see on auspicious occasions around the world today remind us of the original role played by gunpowder in China.

Guo Shoujing

Ho Peng Yoke

Guo Shoujing (1231–1316), an astronomer, mathematician, and hydraulic engineer, was born in Xintai (in modern Hebei province). The names of his parents are not known, although records show that his grandfather, Guo Yong, was knowledgeable in the classics, in mathematics, and in water works. As a boy of 14 Guo Shoujing was able to construct an advanced type of clepsydra, or water clock, for his time: the *lianhualou* (lotus clepsydra), so named because the top of the receiver was in the shape of a lotus flower. In about the year 1251 he restored an old bridge across the Dahuoquan River north of Xinzhou, also in Hebei.

In 1260 Guo accompanied his friend Zhang Wenqian (1217–1283), who was sent by Qubilai Qan to Daming to pacify the local population. There he began to construct astronomical instruments, such as a bronze clepsydra and a bamboo armillary sphere. The same year Zhang Wenqian recommended him to Qubilai for his expertise on irrigation. Guo was soon commissioned to improve irrigation and water communication within the region south of the capital Dadu (modern Beijing) and north of the Yellow River. The mission was successfully accomplished. In the year 1264 Guo again accompanied Zhang to the Circuit of Xixia (in modern Gansu province) to restore the irrigation canals that had been blocked or damaged during the years of war. He reported on what he saw during his travels and made many recommendations to Qubilai on the improvement of irrigation and water communication systems.

There was an urgent need to reform the existing calendar, the *Damingli*. In 1276 Qubilai captured the Southern Song capital, Linan (modern Hangzhou) and thought that the time was ripe to promulgate a new calendar. Guo and Wang Xun (ca. 1235–1281) were commissioned to lead a special bureau established for the project. Guo Shoujing built 17 new astronomical instruments to obtain more accurate astronomical observations on which the accuracy of the new calendar would depend. Thirteen of the instruments were used in the capital Dadu, and four were used for fieldwork. In 1279 Qubilai established an Astronomical Bureau at the capital. Zhang Wenqian was appointed Director, while Guo and Wang Xun were made the two co-Directors. A new observatory was built at the capital along with new bronze astronomical instruments. Guo organized a large-scale measurement of the length of the shadow of the gnomon cast by the sun in different latitudes, from the capital in the north to Nanhai (modern Guangzhou) in the south, to determine the length of the meridian.

Guo used spherical trigonometry and the method of finite difference involving a cubic equation to do his calculations. The new calendar, the *Shoushili*, was completed in 1280. This was the most accurate calendar ever made in traditional China. It was promulgated the next year. Guo Shoujing was promoted to the Directorship of the Astronomical Bureau.

In 1292 Guo held a joint appointment as head of the water works bureau in the capital. The same year he constructed water locks and canals linking various cities to the capital. The Qan was greatly pleased on completion of the project. While he was in the capital Guo made a clepsydra whose bells and drums would chime and sound on the hours for his master. After the death of Qubilai, Timur also sought Guo's advice. Guo died in 1316.

G

Ḥabash Al-Ḥāsib

Lawrence Souder

Ḥabash al-Ḥāsib was one of the earliest Muslim astronomers and a major contributor to the development of trigonometry. He was born in Marw, Turkestan (modern Mary, Turkmenistan) and died between AD 864 and 874. Ḥabash lived during the Abbasid empire, when the caliphs became the stewards of civilization. This empire preserved ancient science and philosophy by translating ancient Greek, Syriac, Sanskrit, and Persian texts into Arabic. Ḥabash himself based his work and methods on Ptolemy's *Almagest*. Ḥabash held Ptolemy in high regard, calling him "the wise Ptolemy" and describing his work as having the "utmost in research and precision" (Langermann 1985). Ḥabash led the way in the Arabic development of astronomy and computational techniques.

As an astronomer Ḥabash worked at calculating more precise celestial distances and at developing more accurate ways of calculating these distances. He calculated such values as the circumference of the earth, the diameter of the moon, and the distance of one minute along the orbit of the sun. Ḥabash's work in trigonometry consisted of calculating tables of trigonometric values and developing new trigonometric functions. He calculated tables (called *zījes*) of sine values at one-degree intervals to three places, and he is considered to be the first to construct a table of tangent values.

In Ḥabash's time much of Muslim science served the needs of the religion. For example, Islam requires the faithful to face Mecca when they pray. To this end Ḥabash developed an analemma, or graphical, method for finding the azimuth to Mecca, called the *qibla*. Muslim calendars were dependent upon the appearance of the new crescent of the moon. Ḥabash is thought to be the first astronomer to calculate when the new crescent appears. Islam also requires the faithful to make a pilgrimage to Mecca. Ḥabash once calculated what he called the distance "by the straight arrow," or the great-circle distance between Baghdad and Mecca to be 677 miles, while the actual overland distance was known to be about 712 miles. In one of his few surviving works, *Kitāb al-ajrām wa-l-ab ͑ad* (The Book of Bodies and Distances), Ḥabash reported that al-Maʾmūn, the caliph at the time and Ḥabash's patron, was pleased with the small difference between the two distances considering the uneven terrain between the two cities.

Hair in Egypt

G. J. Tassie

The ancient Egyptian hairstylist was expected to be able to style hair, as well as cure baldness, make hair (of a rival) fall out, get rid of head lice and cover up the signs of aging by dyeing grey hairs. Ancient Egyptian clients would also require more mundane tasks, such as cleansing and scenting the hair.

Tinting

The Egyptians used natural dyes which are known to coat and partially penetrate the hair's 6–14 layers of cuticles. These natural semi-permanent tints do not leave roots as they wash out of the hair, although a virtually permanent tint may be achieved with frequent application. The main colour the Egyptians would probably have wanted to achieve was black, emulating the dark brown colour of their youthful hair. One recipe was an ointment made of juniper berries and two unidentified plants kneaded into a paste with oil and then heated. The natural blue-purple colouring agent in the plants would rub off on the hair, while the astringent properties of the juniper would stimulate the scalp (Manniche 1989: 46).

Indigotin (*Isatis tinctoria*) is a blue dye that is found in both indigo and woad, and is an obvious choice for Egyptian hair dye as indigo occurs naturally across much of northeastern Africa. There is considerable epigraphic evidence to suggest that deep blue-black was the colour towards which most Egyptians aspired, and this is the colour that is achieved by putting blue dye on the Egyptians' natural dark brown hair. This would have been used on both the person's own natural hair and on hair used to make wigs, as Fletcher (1995) has found traces of indigotin on both. Indigotin also has antiseptic properties and was widely used all over the Middle East on clothing and directly on the skin. As the Egyptians had considerable expertise in so many natural medicines, they are unlikely to have been unaware that trichological (hair science) application of indigotin had a positive side effect as an anti-bacterial agent. On one of the two blonde-haired mummies Petrie found at Gurob was a large black sprang (sprang is closely related to braiding, but it is done on threads which are stretched on a frame, so that the braided fabric builds from both ends towards the middle) headcover that he claimed was worn to cover the person's own blonde hair, possibly to hide the fact that the individual was foreign (1890: 39). However, Fletcher's examination of the hair and head-covering revealed the fact that the blonde hair had been enhanced with yellow henna, and that the sprang headcover was dyed a dark blue-black using indigotin and a small amount of madder (1995: 469).

The later periods of Egyptian Pharaonic history saw the use of tannin to tint hair a dark brown colour, usually in conjunction with iron mordents (Fletcher 1995: 469). A mild form of natural bleach may have been used to enhance or define a style, or to pre-lighten the hair so it could be dyed a brighter colour (Fletcher 1992: 16). Such a substance may have contained natron and lemon juice, a lightening substance that is still used today.

Henna (*Lawsonia inermis* L.; *Lawsonia alba* L.) was also used in the Pharaonic era, but it would be unwise to use this to support the oft-made assertion that Egyptians commonly used henna to die their hair, as we know that that black (see above) rather than red was the favoured hair colour in ancient Egypt. However, while red was seen as being a dangerous colour for most of Egypt's history, henna was certainly used as a hair colorant (although probably not widely) by the higher echelons of society at least. This is reinforced by the iconographic record and actual wigs and hair of mummies, which show very little use of henna up to the end of the New Kingdom (1069 BCE). Brunton suggests that the light red-brown hair of an elderly woman from the Badarian (4500 BCE) cemetery at Mostagedda might have been brought about by an application of henna dye (1937: 45). Smith believes that the brilliant reddish colour of Henttawy's hair and the dark reddish-brown hair of Thutmose IV were tinted with henna (1912: 19 and 44). However, it should be considered that various types of henna produce different colours, from yellow through to nearly black, and that other ingredients can be added in order to produce different effects. The yellowish hue of Ramesses II's hair is not the result of the mummification process, as once believed, but was the result of henna or one of its derivatives being applied to the King's grey hair (Balout 1985: 256) to resemble the King's natural hair colour in his youth.

The hair of Nesikhons was found to have been "thickly strewn with powdered red resin" (Smith 1912: 109). A similar case of a coloured powder being used in this manner was found on the hair of the mummy of the Priestess Tansertemsutenpa, who was found with a thick coat of yellow ochre over the top of her hair, possibly concealing a small bald patch as well as colouring the remaining hair (Smith 1912: 158). While it may be difficult to distinguish intentional dyeing ingredients from naturally occurring materials that inadvertently found their way into the hair, it has been suggested that a small sachet of a fine dark powder, manganese dioxide and quartz – found in the wig-makers workshop at Deir el-Bahari – was sprinkled over the hair for cosmetic reasons (Laskowska-Kusztal 1978: 119–120).

Hair Care

The hair of an ancient Egyptian woman was literally her crowning glory as can be attested to by a number of literary and epigraphic sources where men's apparent fascination with long, sweetly smelling dark hair is made abundantly clear. However, if women had a vested interest in keeping their hair in good order for the benefit of men, it is also evident that men also wished to boost their trichological endowments, paying considerable attention to the many medical recipes for the care and restoration of hair. There is a whole section within the Ebers Papyrus that concerns baldness, hair preservation and general welfare of the hair and scalp, including this one to prevent baldness: "castor oil; the fat from a hippopotamus, cat, crocodile, snake and an Ibex and rub this mixture on your head" (Wreszenski 1913 Spell EB 465). The care of the scalp usually involved various oils such as castor oil or moringa oil (*ben* oil) mixed with other ingredients. Another hair treatment for maintaining the good health of the hair (and scalp) was prepared from “a red mineral; kohl; myrtle berries (?); oil or fat; gazelle dung and hippopotamus fat, mixed to make a paste” (Manniche 1989: 125 Spell EB 471). The most effective ingredient was the oil, which moisturised and nourished the scalp at the same time making the hair feel soft and smooth and look shiny and healthy. The red mineral and kohl may have also added a slight dark reddish hue to the hair.

Head lice (*Pediculus humanus capitis*) were a common parasite in ancient Egypt, and were a major cause of head shaving because washing alone does not kill or remove them from the hair. Head lice are particularly common in children and live just behind the ears and in the nape of their host’s head, preferring clean hair to dirty or oily hair. The Egyptian habit of oiling the hair may have had a preventative effect on louse infestation (Dayagi-Mendels 1989: 76–78), while many other parasites like fleas and flies were trapped by the glutinous substances (including beeswax and resin) which were used to set the hair. Both the Hearst and Ebers medical papyri contain possible recipes to remedy louse infestation or “*hnsyt*-illness of the head”, such as this one: “fruit of the castor-oil plant; ox fat; moringa oil. Combine and mix into a paste, use as an unguent every day” (Wreszenski 1913 Spell EB 437; Hearst 24). The term *hnsyt* has been translated as “that which moves about on the head”. The application of the ointment would probably have improved the condition of the ailment; in the case of head lice it would not only remove the adult lice, but loosen the egg cases as well. While we do not know the composition of all the ancient Egyptian oils used, natural insecticides such as quassi, derris, sassafras and stavesacre (Fletcher 1995: 39) may have been used, probably in collaboration with the de-nitting combs mentioned above.

Highly diluted natron[1] may have been used as a detergent for dissolving greasy deposits when washing the hair (Ghalinoungui 1983: 153), as a fragment of this substance was recovered from the wigmakers’ workshop at Deir el-Bahari, and tests confirmed that it still retained its detergent properties (Laskowska-Kusztal 1978). The use of these harsh detergents may explain why some women had bald patches.

Ancient Egyptians used beeswax and resin to style their hair, although this appears to have been done every few weeks rather than on a daily basis. Beeswax is commonly found in hair and wigs, and as it seems unsuitable for oiling or perfuming the skin, it is probable that it was used to set the hair (possibly at a ratio of 2/3 wax to 1/3 resin (Fletcher 1995; Lucas 1962)). It is unlikely that this mixture of wax and resin comprised the “scent cones” popular in the New Kingdom, as the body/environment would have been unable to reach the melting temperature of wax (60° C = 140°F) in order for it to melt naturally and flow over the hair and body. Lucas therefore concludes that the wax and resin mixture must have been warmed up first and then rubbed into the hair and as it cooled set it in style (Lucas 1962: 31).

From Late Neolithic times (4500–3050 BCE) to the Graeco-Roman Era (332 BCE–AD 306), both men and women would scent and oil their hair. The oiling of the hair to keep it supple and pleasant smelling was done on a daily basis as part of the morning toilette ritual. Lucas’ (1962: 89) examination of residues found in cosmetic containers found palmitic and stearic acids, which probably represented perfumed ointments made of animal fat mixed with scent. The most frequently cited hair oil was a substance known as *Qemi,* which came from the Red Sea region and found widespread use in the anointing of aristocratic coiffures throughout the New Kingdom. The importance of keeping the hair in good order cannot be overstated, judging from the frequent literary references made to divine hairstyles. For example, in “The Song of the Perfumed Hair”, the fragrant locks of the Goddess Shentayt are alluded to thus: “There is perfume, there is perfume in your hair, O holy Shentayt, perfume in your hair” (Nachtergael 1981: 593). In the New Kingdom tomb of Rekhmire the harpist sings: “Put myrrh on the hair (or curls) of Ma’at” (Davies 1943: 60–61). There is also mention of oils being poured over people’s hair during the Old Kingdom (2613–2181 BCE), such as in the Dynasty V tomb of the Vizier Senedjemib where an inscription states that King Djedkare Isesi “Caused that I be anointed with fat” (Breasted 1907: 122).

Although scented oils could be rubbed into the hair by hand, scent cones are commonly depicted in New Kingdom art (Fig. 1). Scenting or festal cones were first introduced into Egypt during the Middle Kingdom (2040–1650 BCE), where they are depicted on a Dynasty XIII (ca. 1795 BCE) stela relief of Amenysonb from Abydos, where his Asiatic brewer Irsi is seen wearing a smallish lump of unguent on his cropped hair (Fletcher 1995: 446). However, scent cones only start to be depicted in any real number from the reign of Hatshepsut (Dynasty XVIII, from 1473 to 1458 BCE) and become even more popular during the reign of Amenhotep III (1390–1352 BCE). Throughout the New Kingdom (1550–1069 BCE) and up to the Ptolemaic Period scent cones were worn (Maraite 1992). They are most frequently represented on tomb scenes, but can also be found on temples and stelae reliefs (Maraite 1992). A sculpted version can be found on figures of nobility such as the statues of Neferhotep and his wife (Davies 1932, frontispiece) and Khay and

[1] Natron was a salt (sodium carbonate and sodium bicarbonate) that was used in the mummification process to dry out the body of the deceased in order to assist in its preservation.

H

Hair in Egypt. Fig. 1 Guests at the banquet with scent-cones on their heads, Tomb of Nakht (TT52) (author's own photograph).

his wife (Muhammed 1966: pl. 8). Cones are sometimes shown being worn by *ushabtis*[2], i.e. those of Tuty (Kozloff and Bryan 1992: 259). The ancient Egyptian name for these cones was *bt*. The cones were worn by men, women and children alike, and they were not just limited to the elite classes, but are shown being worn by musicians, dancers and servants as well. Although Fletcher (1995: 446) has proposed that they were just symbolic of the scenting and oiling of the hair, some Nubian peoples (Bisarin) are known to wear similar scented cones (Keimer 1953: 342 *ff*.). Although in later depictions they become highly stylised and unrealistically tall and thin, it is likely that a small, round tablet of scented animal fat was indeed placed on the hair at banquets and other festive occasions to keep the hair sweet smelling and in good condition. The custom of using scent cones was probably introduced into Egypt from Nubia because of the Egyptian expansion into the region during the Middle Kingdom (2040–1650 BCE).

In ancient Egypt, there was an emphasis on being or looking young, fit, healthy and able. This emphasis is demonstrated by the king having to prove his fitness to rule by running the *heb sed* court on his jubilee. Receding or greying hair is rarely depicted in tomb scenes, particularly on the elite, although the lower orders were sometimes shown in this manner to mark the social distinction between them and the tomb owner (Janssen and Janssen 1996; Robins 1996). The various remedies against baldness and concoctions to colour greying hair show that the youthful ideal was not just an artistic principle but a pivotal part of Egyptian socio-economic culture. The maintenance of the black hair of one's youth was equated with vitality, fertility and potency; receding (completely bald or shaved heads reflected piety and cleanliness) and grey hair were symbolic of disempowerment.

[2] Ushabtis were small figurines made from wood or clay, or occasionally stone or ivory. Often the ushabtis were depicted with tools, or in some act of work. They were buried with Egyptians, so that, if the deceased were called to work in the afterlife, the ushabti would take the deceased's place performing the task.

Hair in Egypt: People and Technology Used in Creating Egyptian Hairstyles and Wigs

G. J. Tassie

The practice of hairstyling in Egypt can be traced back to the Predynastic Period (4000–3050 BCE), and was accompanied by a series of technological changes reflecting this new tradition, especially copper and bronze tools. The oldest tools were bone and wood combs and hairpins, with flint or obsidian blades being used to cut the hair. Although hairstyling was initially mainly utilitarian, Egyptian society's growing complexity led to a proliferation of more extravagant styles. Like most other social status markers, hairstyles helped to maintain and reinforce a person's social position and maintain their privileged access to goods and materials (Trigger 1993). Hairstyles can therefore be grouped with body decoration, clothing, and jewellery in that they all inform the onlooker as to gender, age, status, class, sexuality, ethnicity, and ritual affinities (Fletcher 1995; Robins 1999; Tassie 2002).

There are five main operations that can be performed on hair:

(1) It can be curled or left curly;
(2) It can be straightened or left straight;
(3) It can be plaited, twisted, or teased;
(4) Hair can be added; and
(5) Hair can be taken away.

These five operations may be used separately or in any combination. Accessories may also be added, including hairpins, combs, and fillets.[1] Tinting of the hair may also occur, although this does not come into the above categories of hairstyling. The ancient Egyptians also developed wigs and hairpieces to supplement their own hair, enabling them easily to change their hairstyles to suit the occasion. However, the use of the term "wig" to describe all ancient Egyptian hairstyles is incorrect. Certain statues depict the owner's own hair protruding from beneath a full wig (particularly in the Old and New Kingdom) but other depictions of figures, such as those on the Erotic Papyrus and many of the workers in the fields and other secular tomb scenes are clearly not wearing wigs (Fig. 1). Therefore, unless one is certain that the person is actually wearing a wig, the term "hairstyle" should be used. Wig manufacture and wearing are discussed further below.

The types of hairstyles worn by men and women changed throughout time and space. The social significance of hairstyling became codified after the period of unification, allowing only certain status

Hair in Egypt: People and Technology Used in Creating Egyptian Hairstyles and Wigs. Fig. 1 Close-up of the head of Nofret showing her real hair exposed beneath her full, bobbed wig. Meidum, Dynasty IV, Old Kingdom (photograph by author copyright Egyptian Museum of Antiquities, Cairo).

[1] A fillet is a ribbon or narrow band of fabric worn around the head across the forehead, as an ornament or to hold back the hair.

groups to wear particular hairstyles. Constraints were placed upon the choices of hairstyles that individuals were allowed to wear both by society and the technology open to the ancient Egyptian hairstylist. The hairstyles that a person could wear were temporally dependent upon a person's social position and status. A form of sumptuary laws existed in Egypt regulating social etiquette with regards to what forms of hairstyle were permissible by various classes and statuses of individuals at certain occasions. These laws were not written down but were governed by social and courtly modes of behavior. The hairstylists through their creation of hairstyles and wigs helped to perpetuate the hegemonic situation and reinforced the social relations, even when creating new styles.

During the Old Kingdom shaved heads were sported by both men and women of all status groups, as well as cropped hairstyles. Short, round, curly styles were primarily worn by low to middle class men. The various lengths of bobs were worn by both elite men and women, although with slight variations in the actual dressing. The long tripartite hairstyle was worn by women of any class, but only sacred men (i.e., gods, kings, and the dead). The tripartite hairstyle was symbolic of fertility and rejuvenation. Therefore women as child bearers and sacred men (king – Egypt's fertility, deities – humanities creation, and fertility and the deceased – rebirth) were allowed to wear the style. During Dynasty XVIII (1550–1295 BCE) the gala hairstyle was introduced for elite women, as was the duplex style for elite men. The Nubian hairstyle became popular just before the Amarna Period of the New Kingdom (1352–1323 BCE), during the reign of Amenhotep III, and remained the standard elite hairstyle of both men and women until the reign of Horemheb (1323–1295 BCE) (Aldred 1957). The classic children's hairstyle – the sidelock of youth – remained popular throughout Pharaonic history (Tassie 2005) (Fig. 2).

Hair in Egypt: People and Technology Used in Creating Egyptian Hairstyles and Wigs. Fig. 2 Dyad of Meryneith (Meryre) and his wife Iniura, found in his Saqqara tomb by the Dutch Mission. His title is the "Scribe of the Aten Temple in Akhetaten and Memphis." Her titles are "The favorite and Beloved Wife" and "The Great Lady of the House." Note the more naturalistic rendering of hair at this period in three-dimensional art; Meryneith has a duplex style and Iniura a gala hairstyle. Amarna Period, Dynasty XVIII, New Kingdom, Saqqara, now in the Cairo Museum (author's own photograph? copyright Egyptian Museum of Antiquities, Cairo).

The Ancient Egyptian Hairstylist and Barber

Due to hair's apparent social importance, many hairstylists and barbers plied their trade throughout ancient Egypt. The elites usually had a hairstylist attached to their staff or arranged for one to visit their homes, whereas poorer people would go to a traveling hairstylist. For everyday care and attention, the elite women would have had a maidservant trained to do the dressing. Poorer people would have to rely upon a relative or friend to style their hair. The work of the barber (*h'ḳy*) was not thought to be as highly skilled as that of the hairstylist. Barbers would set up beneath the shade of a tree, placing their stools, and cutting the hair of their clients. Tomb scenes and inscriptions from the Old Kingdom (2613–2181 BCE) the Middle Kingdom (2040–1650 BCE) the New Kingdom (1550–1069 BCE) and Late Period (646–332 BCE) bear witness to the fact that certain hairstylists held a high social rank (Gauthier-Laurent 1935–1938). All except two of these inscriptions refers to men. The word used to describe him is *ir-šn(y)*; the rarely found feminine form is *irt-šn(y)* – literally hairmaker, hairdoer, or wigmaker. There is usually a modifying determinative after the word *ir-sheeny*, denoting that the bearer of the title was either a "royal hairstylist" or an "overseer of hairstylists" (Riefstahl 1952, 1956). Other related words are *nšt*, hairdresser, and *nšy*, which means "to dress hair." These words are used occasionally from the Middle Kingdom onwards, but usually refer to a casual hairdresser. In ancient Egypt hairstylists were frequently important officials who held important offices in addition to their tonsorial duties (Riefstahl 1956) (Fig. 3).

Wigmaking

Although many publications refer to any Egyptian hairstyles as "wigs," true wigs were in fact fairly rare, and then almost exclusively the preserve of the elite. That the rulers of the proto-kingdoms were probably using extravagant hairstyles, wigs, and headdresses to signify status is evidenced by the elaborate hairstyle of the elite Naqada II (ca. 3600 BCE) woman in Burial 16 at HK43. This is the earliest palaeoethnotrichological evidence for the wearing of false hair so far recovered in Egypt. The hair was shoulder length, tinted with henna, and augmented with a considerable number of false hair swatches. The finished hairstyle was very

voluminous with matted tresses (reminiscent of modern dreadlocks) and with a lot of height. Another Naqada II female mummy from Hierakonpolis (Burial 333) had what we now call a Mohican-type hairstyle.[2] Also found at Hierakonpolis HK43, in the double burial 154, is the oldest toupee so far found in Egypt – early Naqada II. This hairpiece was made of either "goat or sheep's wool" and had been secured in place over the bald patch of an elderly man's scalp by weaving strands of the man's own hair into the hairpiece (Friedman 2001: 12). The intricacy of the styling techniques involved in creating these styles indicates that it took many hours of work and was probably performed by a professional hairstylist (Fletcher 1998). There is also epigraphic evidence of wig wearing. On the famous pair of Dynasty IV (ca. 2613 BCE) statues of Rahotep and Nofret from Meidum, Nofret's own hair can be seen combed flat beneath a full bob wig. Archaeologists found a wig dating from the First Intermediate Period (2181–2040 BCE), in the Dynasty VIII tomb of Hefefi at El-Hagarsa. This wig was shoulder length and black, consisting of long, straight braids made of twisted flax fiber and set with beeswax and resin (Kanawati 1993: 21, 65). The archaeological record shows an increase in the number of wigs surviving from the Middle Kingdom; notable examples include the numerous wigs found in their original wig boxes in the Dynasty XII (1985–1795 BCE) tombs at Lisht. These wigs were made of human hair and were styled into long braids (Lansang 1933). The records show a dramatic increase in the amount of false hair that survives from the New Kingdom, as do subsequent periods. However, there is evidence that the wearing of wigs fell out of favor during the Late Period (Fletcher 2000a, b).

Human hair was the main material used for constructing wigs and hairpieces, sometimes in association with date palm fiber, reeds, and linen (especially during the Graeco-Roman Period – 332 BCE–AD 306; Tassie 2002). No animal hair was ever used (apart from the HK43 toupee) (Lucas 1930, 1962; Eisa 1953), and in every case except that of Maiherpri, cynotrichous (Caucasian) rather than heliotrichous (Negroid) hair was used in wig construction (Fletcher 2000a, b). There are epigraphic indications that wigs were valuable assets: they were listed alongside gold and incense in the account lists from Kahun (Fletcher 2000a, b), while a single wig (probably of fiber) constituted two-thirds of a woman's dowry in a marriage contract from 219 BCE (Tassie 2002). Although false braids could be made from the wig owner's own hair, the vast amount of hair used in wig manufacture was probably shaved from the heads of foreign captives or was sold to the wigmakers by its impoverished prior owners. Hair was traded extensively throughout the Roman Empire, and was sufficiently valuable to cause a specific custom duty to be paid on it (Fletcher 2000a, b).

Once the hair had been processed, cleansed and detangled, it was ready to be made into wigs and postiches (hairpieces). The processed lengths of hair would then have been styled into plaits, curls, and wefts before being fastened directly onto the head or onto a wig foundation. The wig foundations were usually made of plaited hair (or, more rarely, incorporating leather straps and linen strings) as an open-mesh base or a series of knotted wefts of hair. These mesh bases and wefts were then often sewn on to a linen cap with a drawstring, so that it could be secured to the head

[2] The author has only seen a photograph of this hairstyle and has not examined the mummified remains. Mohican-like was how the director of Hierakonpolis - Dr Renée Friedman - described the hairstyle in a lecture. The modern-day Mohican hairstyle is shaved at the sides with a line of hair sticking up from the center of the skull, like a cockerel's comb, whereas a Mohawk is shorter and normally squared off with the central section of hair starting just above the occipital bone. The photograph of the hairstyle in Grave 333, HK43 did not appear to have shaved sides but was combed into the medial line of the head giving a Mohican-like appearance to this hairstyle.

(Tassie 2002). There was considerable variability across time and space in terms of wig manufacture. For example, Merit's wig consists of wefts of hair knotted together to form a kind of marteaux or diamond mesh around a medial plait with a central parting (Chiotasso et al. 1992), while the British Museum wig is composed of some 300 locks of hair (each containing about 400 hairs) on a foundation of finely and tightly plaited human hair forming a hair net with rhomboidal apertures (Fig. 4).

Hair in Egypt: People and Technology Used in Creating Egyptian Hairstyles and Wigs. Fig. 4 Wigs in the Cairo Museum: (a) *left to right*: lady Istemkhebs short curly wig – JE26252h, duplex wig – JE26252g, Ahmose-Hentempet short curly wig JE46913; (b) wig of thick triple braids (JE23412) found in side-chamber of Amenhotep II's Tomb (KV35), New Kingdom and Third Intermediate Period (photographs courtesy Joris van Wetering ? copyright Egyptian Museum of Antiquities, Cairo).

The root end of each lock was secured by looping it around part of the mesh, pressing it back against the hair stem and fastening it with substrands of the root section; this was then locked in place with beeswax and resin (Cox 1977). The greatest collection of ancient Egyptian wigs is in the Egyptian Museum of Antiquities, Cairo where there are 23 full wigs and numerous hairpieces (Tassie 2002). The Egyptians protected their wigs by keeping them in wig boxes, such as Merit's large rectangular cupboard-like wig box found in her husband Kha's tomb in Thebes with poles to hang the wig from (Chiotasso et al. 1992) or Tutankhamun's square wig box found in his tomb KV62 with a mushroom-like stand in the center for hanging the wig on (Reeves 1990: 193) (Fig. 5).

While our knowledge of wig morphology and structure is considerable, the details of the wig construction process were unclear until the discovery of a wigmaker's workshop dating to between 1800 and 1700 BCE in a crevasse overlooking the Temple of Mentuhotep II at Deir el-Bahari. The workshop contained four alabaster vases in a linen sack with various wigs in different stages of production, tufts of hair, hair wefts (on threads), swatches (tied up with fibers), and a thread net-foundation. A papyrus case found in the workshop held a bronze awl, five bone hairpins, and fragments of two flint knives. In another container

Hair in Egypt: People and Technology Used in Creating Egyptian Hairstyles and Wigs. Fig. 5 Large wig box recovered from the tomb of Yuya and Thuya in the Valley of the Kings, Thebes. It is made of papyrus stalks supported by reeds, and measures 107 cm long by 51 cm deep. The box stands on four reed legs, and had an outer lid, and an interior double leaved lid opening from the middle to form a tray. This lid was tied down with linen thread and sealed with black clay seals. The front of the wig box is ventilated by three windows, one at each and the other in the middle of the front panel. The wig box may originally have held Yuya's duplex wig CG51185, which was found in a niche in his tomb KV46, Dynasty XVIII, New Kingdom, Cairo Museum (photograph courtesy Joris van Wetering ? copyright Egyptian Museum of Antiquities, Cairo).

were pieces of linen (probably for the skullcap), solid soda "soap," leather straps, bone beads, and other oddments. A unique model head made of wood was also found and is believed to have been used for laying out the wigs while in production. Black lines had been traced to show the outline of the wig's attachment and its long and short axis (Laskowska-Kusztal 1978).

Hairstyling was not done for fashionable reasons but was used to convey the class and status of the wearer. However, the hairstyles of the ancient Egyptians were far from static, and evolved to express changes in Egyptian society. This flux gave rise to a large assemblage of tools, unguents and hair products that can be seen in many of the world's museums, along with the mummies whose hair was treated in the ways discussed above. Some museums may hold only a hand-mirror or a razor, whereas others, such as the Metropolitan Museum of Art, New York include whole wigs in their displays of ancient Egyptian hairdressing and beauty paraphernalia.

The art of hairdressing was already well developed by 3000 BCE in Egypt. The social importance of hair was such that ancient Egyptian hairstylists were highly regarded, especially those allowed to work on the hair of the pharaoh. There was even a goddess of hair and hairstyle (Khonsut) and a god of the royal beard and barbers (Duwar).

Acknowledgments

I would like to express my gratitude to Dr Lawrence Stuart Owens for his editorial skills and also to Ms Janet Johnstone for her encouragement and comments on this entry and my other entries in this volume.

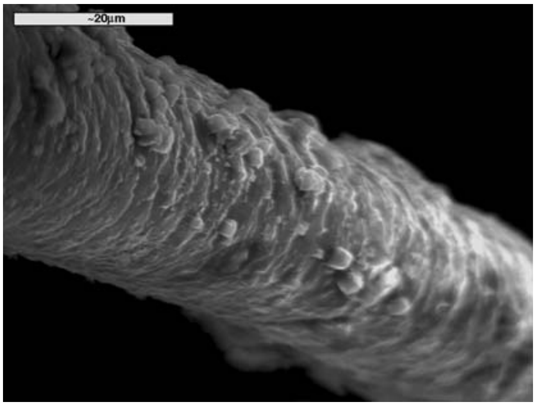
Hairstyling Technology and Techniques Used in Ancient Egypt

G. J. Tassie

Three types of cutting equipment were available to ancient Egyptian hairstylists: the razor, the "composite tool" (a combination of scissors and hair-curler) and the comb. Of these, the razor was the main implement used for cutting the hair. The hairstylist would probably take the bulk of the unwanted hair away using the razor, using a bodkin (hairpin) to separate the hair not being worked on. They would then work on the free section, sculpting with the razor and snipping off any stray hairs with the scissor part of the composite tool before releasing the next section to be cut. The process worked around the hairline first, then up to the crown. The client would view the results in a bronze hand-mirror (Fig. 1).

Microscopic examination of the cut ends of hair on wigs and mummies has revealed the majority to be of the tapered variety and very clean-cut (Fig. 2). This indicates that it was cut with a sharp razor while wet (Fletcher 1994a), as the razor requires the lubrication of water to make it glide over the hair and give a clean cut. There are modern parallels: many Indian hairstylists and barbers use a razor against a piece of wood, combing the hair flat across the wood, then pulling the razor across it to give a straight line and a smooth-looking finish to the style. However, no depictions of ancient Egyptian hairstylists cutting long hair have been found, so the method employed must remain just supposition at the moment.

After cutting, the next step was plaiting or curling the hair. The former would probably be done wet, whilst the hair would be dried before carrying out the latter. The curling would be done using curling-tongs (composite tool), then dressed and set using beeswax and resin and an assortment of hair accessories such as combs, hairpins or more ornamental head dresses (Fig. 3).



Hairstyling Technology and Techniques Used in Ancient Egypt. Fig. 1 Scanning electron microscope (SEM) photographs at 1,100X magnification of Romano-Christian hair, ca. third century AD, Egypt. The ends of the hair in this period have been cut using scissors leaving a blunt end. The cortex (central part of hair) and medulla (middle segment of hair shaft) have virtually disappeared due to calcification, which can clearly be seen on the surface of the cuticles (outside layers) (Photo by author).

Tools Available to the Ancient Egyptian Hairstylist

The Razor – Form and Development

The copper razor (*s3*) had its beginnings in the Protodynastic Period (3350–3050 BCE). It was probably derived from the copper flaying knife (Petrie 1917) rather than the lithic "razor" which was no more than a side scraper. Originally there were two types of razor: an asymmetrical variant with a single lateral cutting edge and a symmetrical spatula-like tool (Fig. 4a) with parallel sides and a rounded cutting edge (Davies 1977: 110). The asymmetrical type soon fell out of use, and by the end of the Old Kingdom (2613–2181 BCE) had been almost completely replaced by the symmetrical type. This form went through a series of variations; in general terms, the sides proceeded to splay out (Stead 1986: 50) throughout the Old Kingdom.

During the Middle Kingdom (2040–1650 BCE) the cutting edge of the symmetrical razor began to protrude laterally (Fig. 4b). Coming in at this time (Dynasty XII, 1985–1795 BCE) is the scalpel-like razor or *dg3* type razor (Davies 1977). This type was made of a thin strip of metal (Fig. 4e), sharpened at one end, which later incorporated a loop (often in the form of an animal, bird or deities' head), in which to rest the little finger in order to help rotate the razor (Petrie 1917: 50). By Dynasty XVIII (1550–1295 BCE), the *mh'k* razor - one of the most characteristic pieces of toilette equipment of the New Kingdom (1550–1069 BCE) – had evolved into a hatchet-like form, with a wooden handle almost at a right angle to the cutting edge and a spur projecting from the rear of the razor. This is thought to have served as a counter-weight, to ensure proper balance and handling (Stead 1986: 50) and also as a little finger rest. Petrie called this type of razor the (horizontal) rotating razor (Fig. 4c). The rotating strip metal razor resembled the later splayed symmetrical razor and proceeded to evolve throughout the New Kingdom, with small varieties becoming more popular. Eventually the symmetrical razor evolved into a vertical rotating form, with its cutting edge splaying out even more to form a half-moon arc (Fig. 4d). By the end of the New Kingdom (ca. 1069 BCE), the rotating razor had superseded the scraping form. From the Middle Kingdom the handles of the scraping form were made in increasingly ornate forms, and by the New Kingdom the handles displayed zoomorphic designs and representations of deities of love and birth such as Bes and Taweret.

The Razor–Usage

The early razors were all of the scraping variety and were used with the hand grasping the handle or the end of the cutting edge (which was either on the inferior or lateral aspect of the tool). The development of the strip and rotating razor saw a technical change: the razor was grasped in the middle of the blade (by the handle or the blade itself) and rotated around the grip in a sawing motion, pushing the cutting edge through the hair. Epigraphic evidence and razor morphology suggest that the stylist would shave off the bulk (or all) of the hair using the large rotating razor and would possibly even style the hair/wig with it as well. The small razor was probably for personal use, and for the precision cutting of the intricate areas of the head and body that the larger razor could not safely reach. The inclusion of both types of razor in the toilette sets of the New Kingdom – such as those of Tutankhamun (Davies 1977) and Kha and Merit (Schiaparelli 1927) – seem to support the differing functions of the *mh'k* and *dg3* razors (Davies 1977).

Razors were sharpened on a whetstone made of tapered grained crystalline stone, (i.e. quartzite, diorite, basalt or even hard sandstone) using water and/or oil as

Hairstyling Technology and Techniques Used in Ancient Egypt. Fig. 4 Examples of the various types of razors: (a) Spatula razor, symmetrical, parallel sides and ivory handle (UC 40660) - scraping type, Old Kingdom; (b) Protruding or axe-shape razor (UC 40539) - scraping type, Middle Kingdom; (c) Horizontal rotating razor (UC 38368), New Kingdom; (d) Vertical rotating razor (UC 30134) with the God Bes for the handle, New Kingdom; (e) Looped strip metal rotating razor with goose head as handle (UC 40657), New Kingdom (Photos by author copyright Petrie Museum of Archaeology, University College London).

a lubricant. To stop the razor becoming blunt too quickly, it could be kept in a wooden razor case inside a leather pouch or case.

The Composite Tool (Curling-Tongs) and Tweezers

Other types of tools were available for the removal of unwanted hair, including tweezers and the composite tool. Tweezers are known from Dynasty I (ca. 3050 BCE) onwards; they had either pointed or squared ends, and varied in length from 2 cm to 10 cm, depending on the part of the body they were to be used on. The tweezers are made of a single piece of copper, bronze, iron or – more rarely – gold. The shape of the tweezers varied from triangular with sharp ends to more ornate varieties with paddle-like ends (Petrie 1917). These tweezers were easily bent out of shape, so were often set around a tapered bone, ivory, stone or wooden block that was shaped to fit the interior of the tweezers and thus prevent them from being misshapen (Fig. 5a). Tweezers would be used to remove any hairs not completely shaved off by the razor and to shape the eyebrows.

The most peculiar tool used by the Egyptian hairstylist was the composite tool or curling tongs, consisting of two metal (bronze) elements pegged together with a pin. One element is a trough-shaped piece of metal pointed at both ends, while the other element has a flat knife-like blade at one end and a cylindrical point at the other (the latter was sometimes omitted and replaced by a zoomorphic figure – Petrie 1917). The knife-like blade fit neatly into the other section, and could thus be used like scissors, while the other ends acted like tongs (Fig. 6a). As well as curling tongs, these instruments could also be used as a razor or as scissors, for cutting off any stray ends. These composite tools are found from Dynasty IV onwards and vary in size from about 5 cm to 20 cm in length, with various circumferences for giving different-sized curls. They were not as effective as scissors – which are not found until the Roman Period – because the cutting edges were not sharp enough and do not meet precisely enough for this purpose. As Petrie (Petrie 1917: 49) notes, the knife-like blade was the least important part of the tool, as it is diminished or is entirely absent in some later forms, being replaced by figures of a running jackal, galloping horse, running leopard, a pelican, or crane (with the hinged opening representing the jaws) or the Goddess Taweret (Fig. 6b). Some rather large knife-like blade types are found in Dynasty XVIII, and were used as curling tongs. The technique involved heating the tool over an open fire or brazier in order to set the curl, but this must have been tempered by a hot plate or boiling water – to avoid burning the hair – as the tongs show no sign of having been exposed to open flames. Some of these tools may have been set in wooden handles, as suggested by a gift list

in the Amarna Letters, which states, '29 spatulas of silver with handles of boxwood and ebony with which one curls the hair' (Kozloff and Bryan 1992: 428). Another indication that these tools were indeed used to curl hair is an example in the Manchester Museum which still has a curl of hair attached to it.

Combs and Hairpins

Pins and combs were used to keep the hair in place whilst it was being dressed, cut or styled, and for decorating it afterwards. These implements have their origins in the Predynastic but seem to have become very popular throughout the Pharaonic Period, where numerous combs and hairpins have been found in association with other beauty (cosmetic) equipment in houses and tombs throughout the country. The majority of well-provenanced combs are dated to the Ramesside Period (1295–1069 BCE) (Kozloff and Bryan 1992: 360).

The ancient Egyptian word for comb was originally *nši*, but this changed in the New Kingdom, where the *"n"* was replaced by a *"p"* to give *pši* or "divider" (Janssen 1975: 178–9). Combs were usually made of wood, ivory or bone. The choice of material and design suggest that they were designed to bend slightly in order to avoid splitting, some incorporating a long handle and a tapering effect from the top of the handle down to the tip of the teeth. Predynastic combs tended to be fairly ornate in design, and were sometimes made in two pieces and with large grip handles (Figs. 7a and b). The handles were often elaborately decorated and could constitute up to ¾ of the comb's total length, while the teeth lengths and widths were also highly variable. One comb with extremely long teeth of Naqada I date (3900–3700 BCE) is now in the Bolton Museum, No. 76.09.5 (Adams 1988). However, predynastic combs with very narrow handles and short teeth have also been discovered (Petrie 1896). Pin-tail combs first appear in the Naqada I Period, and consist of a square comb (usually of wood or ivory) with a long, thin "tail" protruding from the middle of the comb's body (Fig. 7d). This type of comb could be used as decoration in the hair with the teeth keeping it in place or to style the hair, the tail being used to tuck in the hair tips and arrange the hair, to select sections of hair to be styled or even for scratching the scalp.

Bird designs were by far the most popular motif in the Early Predynastic Period: a particularly fine example of an ivory comb with a double bird emblem is now in the British Museum, EA 18666. Spade and wild animal motifs were also present in the Naqada I Period; two ivory examples can be seen in the British Museum (EA 63075 - spade, and EA 63406, ibex). Anthropomorphic, zoomorphic and animal-headed designs including cow (probably the Goddess Bat or Hathor) headed designs increased in popularity during the Late Predynastic, although all designs were present throughout the period (Adams 1988; Garetto 1955). Early Dynastic combs tend to be shorter with the teeth cut more closely together, some as close as 2 mm (Garetto 1955), although some large ornate examples can still be found. One of the finest examples of such a comb (assigned to King Djet) has a very large handle, a centrally positioned niche palace facade *serekh*, with two *was*-sceptres and an *ankh* on the sides (Fig. 7c). The teeth of the comb are fairly fine and not very long in comparison with the handle (Emery 1961; Garetto 1955).

Hairstyling Technology and Techniques Used in Ancient Egypt. Table 1 Egyptian Chronology

Date	Period	Culture/Dynasties
7,000 BCE	Epi-Palaeolithic (7,200–6,000 BCE)	Qarunian
6,000 BCE		
5,000 BCE	Neolithic (5,200–4,000 BCE)	Merimdian, Faiyumian, Badarian, Omarian

All photos by the author except C, which is courtesy Joris van Wetering, objects D and E copyright Petrie Museum of Archaeology, University College London.

Old and Middle Kingdom combs were simplified, with the handle becoming thinner and the teeth relatively longer, more similar to modern combs except for the highly ornate decoration with semi-precious stones or faience beads (Fletcher 1995: 441; Garetto 1955). From the New Kingdom onwards, comb designs became increasingly variable, generally becoming more ornate and with more stylistic categories. The comb's teeth start to vary in length, width and spacing, reflecting the fact that they were designed to serve different purposes rather than the all-purpose combs of earlier eras. The combs with short, closely spaced teeth would have been used for denitting and grooming. The combs with long, widely spaced teeth were primarily designed to be worn in the hair (as reflected in their usually high level of decoration) once it was dressed, or for detangling the hair. The intermediate form (medium length, intermediately-spaced teeth) would have been used to comb the hair into style. A fine wooden example with incised lotus petals on the handle, originally with blue paste filling the spaces, was found at Abusir el-Malek. Measuring 17cm long by 5cm high, this comb is dated to Dynasty XVIII, JE 36233 - CG 44316 (Freed 1987: 182). Other examples of these simple combs were found in the tomb of Kha. The two small combs belonging to his wife Merit were 7.5 cm × 4 cm and were undecorated, except for a slight trace of gilding (Garetto 1955). Rectangular double-sided combs without any handle also appeared in the New Kingdom and were usually designed to be multifunctional with closely spaced teeth on one side and widely-spaced teeth on the other (Fig. 7e). Pintail combs also reoccur in the New Kingdom.

Hairpins or bodkins were usually made from ivory or wood and measured between 10 cm and 16 cm. They derived their Egyptian name (*3b*) from the term for ivory *3bw*, although they were also made of copper, bronze, bone, or sometimes tipped with gold or other precious metals. Predynastic and Early Dynastic hairpins were often ornately decorated with zoomorphic or anthropomorphic figures and geometric designs (Fig. 8). The Old Kingdom and Middle Kingdom hairpins tend to be less ornate, with a simple engraved top, minimal (or absent) incised decoration and a bulbous or pommel head. While plain pins were used throughout Egyptian history, the range of new designs and decorations in New Kingdom pins is marked. Made from a range of materials including gold (both leaf and solid), elite versions were often decorated with zoomorphic or anthropomorphic designs. Precious metal examples include several gold hairpins that were found in Kha's tomb (Schiaparelli 1927), while a fine example of a well-executed zoomorphic design in ivory is that of a hairpin head upon which an ibex turns her head with affection to observe her suckling calf. The recurring image of the ibex (i.e., the comb mentioned above) reflects the importance of Hathor to rituals of beauty and the artefacts related to those rituals. This fine hairpin is 9.5 cm long and is exhibited in the Boston Museum of Fine Arts (Freed 1981).

Hairstyling Technology and Techniques Used in Ancient Egypt. Fig. 8 A variety of different hairpins in the Cairo Museum, Predynastic Period (Photo by author copyright Egyptian Museum of Antiquities, Cairo).

The hairpins were used both to dress (keeping locks in place) and to decorate (after dressing) the hair. Depictions of hairpins in use are again rather limited, although more numerous than those depicting combs. One of the finest examples is the Middle Kingdom hairdressing scene where Queen Neferu's maidservant Henut has pinned the top section of her mistress's hair out the way with an ivory bodkin whilst weaving a braid into the hair (Riefstahl 1956: pl. IX).

By the middle of the Old Kingdom, the increasing availability of copper tools meant that ancient Egyptian hairstylists were able to cut, curl, tint, set, and plait the hair in numerous ways. As technology and alchemy progressed and the Egyptian empire expanded in the New Kingdom, hairstylists developed new styles as well as various ways to perfume and dress the hair fostered by emulation and increasing social complexity.

Haridatta

K. V. Sarma

Haridatta was the promulgator of the Parahita system of astronomical computation widely used in Kerala in South India, from where it spread to the neighboring state of Tamil Nadu. There are two basic texts of the system: the *Grahacāranibandhana* and the *Mahāmārganibandhana*, the latter of which is no longer extant. Haridatta inaugurated the system, as the legend goes, on the occasion of the 12-yearly religious festival held at the temple town of Tirunāvāy on the banks of the Bhāratappuzha River in AD 683. The system was called *Parahita* (suitable to the common man), because it simplified astronomical computation and made it accessible for practice even by ordinary people.

Haridatta based his system on the *Āryabhaṭīya* of Āryabhaṭa (b. 476), but made it simpler in several ways. First, he dispensed with the rather cumbersome and terse numerical symbolism used by Āryabhaṭa and substituted the facile, easily manipulated *ka-ṭa-pa-yā-di* system of notation. In this system, specific letters were used for representing digits, which could be arranged to form meaningful words and even sentences, which could be remembered with much less possibility of error.

Computations in Indian astronomy involved long numbers for planetary revolutions and other parameters for the aeon. To avoid these long numbers in multiplication and division, Haridatta ingeniously introduced a subaeon of 576 years or 210,389 days, and accurately determined the zero-correction for this subaeon for the mean motion of the several planets. In actual practice, Haridatta directed the aeonary days for any current day being divided by the subaeonary days. The quotient would then give the number of completed subaeons, and the remainder the days in the current subaeon. The above quotient multiplied by the subaeonary zero-corrections of the several planets would give the mean planets at the commencement of the current subaeon. In order to make calculation easier, when a large number of years passed, Haridatta gave these zero-corrections for chunks of six subaeons. To find the mean motion of the several planets for the completed days in the current subaeon, Haridatta gave certain sets of simple multipliers and divisors. The mean motion arrived at using these, when added to the mean position at the commencement of the current subaeon, would give the mean planet for the current date. In order to obviate the large numbers that would accumulate to mean planets when the Āryabhaṭan parameters were used, Haridatta prescribed a corrective called *Vāgbhāva* (Corrections to be Applied to the Different Planets from AD 523).

H

The Parahita system promulgated by Haridatta has been extremely popular in Kerala, and a very large number of texts and tracts based on the system have been produced in that part of India, both in Sanskrit and in the local language Malayalam. The system has also been regularly used for the computation of the daily almanac.

Ḥasdai Crescas

TONY LÉVY

Ḥasdai ben Abraham Crescas (1340–1412) was one of the most influential personalities of Spanish Jewry in the end of the fourteenth century. As chief rabbi of the Aragonian Jewish communities during the persecutions of 1391, he was responsible for their reconstruction. Although his literary work was not very large, it constitutes an important contribution to the history of philosophical and scientific ideas, mainly as a critique of medieval Aristotelianism.

Under the influence of Maimonides' *Guide for the Perplexed* (translated from Arabic into Hebrew in the beginning of the thirteenth century), Aristotelianism had spread in Jewish circles, raising many controversies. Besides those who opposed the study of philosophy only on the ground that it undermined religious beliefs, others invoked scientific and philosophic arguments to give support to their own critique of philosophy. Crescas is certainly the most important of the latter critics.

Apart from a short composition, *Biṭṭul ʿIqqarey ha-Noṣrim* (Refutation of the Principles of Christianity), Crescas' main work is his *Or Adonay* (Light of the Lord) completed in the last years of his life. In the first part of this book the fundamental concepts of Aristotle's physics and metaphysics, as adapted by Jewish philosophers, were analyzed and criticized.

Crescas' main purpose was to establish that the existence of God, His unity and His incorporeality could not be fully proved by demonstrative reasoning, as Maimonides had argued: "it is impossible to arrive at a perfect understanding of these principles except by way of prophecy, …, and yet it will be shown that reason agrees with the teachings thus arrived at." In this sense, one could say that Crescas did not criticize philosophy as such, but rather the intellectualization of religion by Aristotelian scholastics. Actually, in many respects, Crescas opposed to Aristotelian philosophical notions other philosophical notions, more relevant – according to him – to the purposes of philosophy itself.

The main importance of Crescas' contribution lies in his critique of Aristotle's concept of the infinite, and its applications to the notions of space, number and time.

There are three main conclusions of Crescas' analysis which are relevant to history of science. The first is in opposition to Aristotle who had argued that the place of a body (i.e., space) was the inner limit of the enclosing body, Crescas asserted that space was prior to bodies and that the place of a body was equivalent to its extension. Thus the existence of a void was not self-contradictory. Secondly, again in opposition to Aristotle who had argued that the universe was finite, because nothing could be infinite, neither a body nor a substance, Crescas claimed that there was no absolute limit to space. Space was an infinite receptacle, which could contain many other worlds. By analogy, space could be thought of as God's omnipresence. Finally, Aristotle and Aristotelians argued that an infinite quantity was impossible, because it would lead to the absurd conclusion of one infinite quantity being greater than another. Crescas' reply was of importance since it could be viewed as anticipating some modern concepts: the relations "equal to," "greater than," and "smaller than" do not apply to the infinite, in the same manner that they apply to finite quantities. Thus, the notion of an actual infinity is not self-contradictory.

Hay'a

F. Jamil Ragep

The Arabic term *hay'a* had several distinct significations when used in the medieval astronomical context. Its basic meaning is "structure" or "configuration"; it was used as such to connote the physical structure of the universe as a whole (*hay'at al-ʿālam*) or a distinct part of that structure, as in the *hay'a* of the Earth or of Venus. It also referred to those works of theoretical astronomy in which that structure is dealt with in detail. As part of the phrase *ʿilm al-hay'a* (the science of *hay'a*), it came to refer, especially after the eleventh century, to astronomy in a general sense. This is an indication of the importance given to physical cosmography in Islamic astronomy. Here the main focus will be on *hay'a* in the sense of the Islamic astronomical genre devoted to cosmography.

Before proceeding, it is important to note two points. Although the term *hay'a* was occasionally used to indicate a religious cosmology, works on *hay'a* are mainly cosmological in the scientific and not the religious sense. Second, this tradition, though departing from it in numerous ways, owes its origins and inspiration to the Hellenistic scientific tradition.

The main ancient sources for the Islamic *hay'a* tradition were the cosmological writings of Aristotle, in particular his *De Caelo* and his attempt in the *Metaphysics* to give a coherent structure to the models of Eudoxus, and the astronomical writings of Ptolemy, especially his *Planetary Hypotheses*. These works provided the fundamental assumption of Islamic theoretical astronomy, namely that the subject matter of astronomy was the simple *physical* bodies, both celestial and sublunar. An astronomer writing in the *hay'a* tradition was charged with transforming mathematical models of celestial motion, usually those of Ptolemy's *Almagest*, into physical bodies that could be nested, along with the sublunar levels of the four elements, into a coherent cosmography (*hay'a*). Despite the obvious connection and dependence on Greek natural philosophy, this "astronomical" (or external) cosmology was often contrasted with both the tradition of Aristotle's *De Caelo* and the astrological corpus, both of which were held to deal with the essential (or internal) aspects of the bodies. Note that because *hay'a* was intended to give a general picture of the universe, it also dealt with the "configuration" of the four sublunar elements. Thus most general treatments of astronomy after the eleventh century came to have a section on the "configuration of the Earth" that included general discussions of geography.

The prevalent *hay'a* was that the universe was a plenum composed of nine contiguous, solid, spherical bodies called orbs, all concentric with an immobile, spherical Earth. The lowest of these, that of the moon, enclosed the four sublunar levels of the four elements: fire, air, water, and earth. Each of the "concentrics" had embedded within it additional, nonconcentric, spherical orbs called eccentrics and epicycles, the former hollowed-out spheres surrounding the Earth, the latter full spheres within the eccentrics. There was one concentric each for the seven "planets" in the following order – moon, Mercury, Venus, sun, Mars, Jupiter, Saturn – another for the fixed stars, and a starless ninth that was the source of the daily motion. Except for the sun, which was embedded within an eccentric, the planets were situated on the inside surface of their epicycles. Opinions varied as to how motion occurred but generally this was held to result from a combination of the proper motion effected by the orb's own soul and the accidental motion that was a consequence of being contained inside other orbs. All the celestial orbs were composed of a special fifth element called "aether," unlike the four sublunar elements, it could only rotate with uniform motion. Among the most famous and influential works on *hay'a* were the *Hay'at al-ʿālam* (Configuration of the World) by Ibn al-Haytham (d. ca. 1040), the *Tadhkira fī ʿilm al-hay'a* (Memoir on Astronomy) by Naṣīr al-Dīn al-Ṭūsī (d. 1274), and *Al-mulakhkhas fī al-hay'a al-basīṭa* (Epitome of Plain *hay'a*) by al-Jaghmīnī (thirteenth or fourteenth century).

Although the above cosmography derived for the most part from Ptolemy's *Planetary Hypotheses*, Islamic theoreticians found much to complain about and proposed numerous alternatives that were meant to reform or supersede his models. In his *Doubts About Ptolemy*, Ibn al-Haytham pointed to certain devices that Ptolemy had introduced in the *Almagest*, such as the equant, that violated the principle of uniform circular motion; as such, it was not possible to physicalize such models in any straightforward way. In the thirteenth century, a number of writers, beginning with Naṣīr al-Dīn al-Ṭūsī, who was the first director of the Mongol-sponsored Marāgha observatory, proposed alternative models that were meant to reform the Ptolemaic system. These efforts continued for at least three more centuries and included the work of his colleague Mu'ayyad al-Dīn al-ʿUrḍī, his student Quṭb al-Dīn al-Shīrazī, Ibn al-Shāṭir, the timekeeper of the Umayyad Mosque in Damascus during the fourteenth century who proposed an astronomy without eccentrics, and a number of people associated with the Samarqand observatory in the fifteenth century.

A much more radical attempt to transform the Ptolemaic system occurred in twelfth-century Islamic Spain. A number of Aristotelians, including the famous philosopher Averroes (Ibn Rushd), sought a radical reform of Ptolemaic astronomy that would rid it of epicycles and eccentrics altogether. The motivation was to return to a purer astronomy in which there was only a single center of celestial motion. The end product of this movement was the work of al-Biṭrūjī. His system, reminiscent of that of Eudoxus, was not very successful from a mathematical point of view, but it was quite influential in the Latin West.

This was not the only case in which Islamic *hay'a* influenced science in other cultures. Byzantine astronomers were certainly aware of this tradition; we also know of several *hay'a* works that were translated into Sanskrit in the eighteenth century. Given that the *Planetary Hypotheses* was unknown during the Latin Middle Ages, it is clear that the main source for the European *theorica* tradition was Islamic *hay'a*; Ibn al-Haytham's *Configuration of the World* was certainly quite influential. In recent years, very strong similarities between the models and motivations of several Renaissance astronomers (including Copernicus) and the late *hay'a* tradition have been discovered, and it now seems quite likely that the former were influenced by Ṭūsī, Ibn al-Shāṭir, and other post twelfth-century writers on *hay'a*. However, because their works seem not to have been translated into Latin, the most likely means of transmission is through Byzantine sources that made their way to Italy (and perhaps Vienna) in the fifteenth century.

Hazama Shigetomi

Jochi Shigeru

Hazama was a Japanese mathematician and astronomer in the Edo era. He was born at Osaka, the sixth son of Toichiya Gorobei, on March 8, 1756. His family were merchants and managed the Shichiya (bank) at Osaka.

In 1795, the Shogun government planned to make a new calendar using Western astronomy. The former calendar, the Horeki calendar (1754), was a quite traditional Eastern Asian calendar, although Shogun Tokugawa Yoshimune (1684–1751, eighthShogun, r. 1716–1745) wanted to use Western science. But there were no astronomers who had mastered Western astronomy in the Bakufu Tenmongata (Shogun's Astronomical Observatory). They asked Asada Goryu (1737–1799) to make a new calendar. However, Asada was already over 60 years old, so he recommended two students, Takahashi Yoshitoki (1764–1804) and Hazama Shigetomi.

Takahashi was a *Doshin* (police officer) and a Samurai warrior. As Hazama was a merchant, Takahashi did the main work, and Hazama supported him financially. They worked in the Bakufu Tenmongata at Asakusa, Edo. Then Takahashi went to Kyoto to observe in 1796, and Hazama remained at Edo. They

Hazama Shigetomi. Fig. 1 Hazama Shigetomi's picture at the Osaka Museum of History.

Hazama Shigetomi. Fig. 2 Hazama Shigetomi's Tomb at the Tokoku-ji temple, Chausuyama, Tennoji, Osaka.

wrote the *Rekiho Shinsho* based on Kegler's (Part 2 of) *Li Suan Quan Shu* (1742, China, the same name as Mei's book) in 1797. They began using the Kansei calendar the next year.

There were two original points in this calendar. 1) They observed the position of the sun from its under edge when they observed the solar eclipse. 2) They defined the twilight, saying that it was two and half *Koku* (one day was 100 *Koku* at that time) before the sunrise and sunset on the Spring and Autumn Equinox Day in Kyoto.

Hazama also promoted the engineering of astronomical tools.

He died on March 24, 1816[1] in Osaka.

[1] Nihon Gakushiinn (1960): 211 describes that he died in 1838, but we obey Nihon Gakushiinn (1954) vol.4: 141, that is to say, in 1816.

Health Sciences in India: Traditional Health Sciences and their Contemporary Application

Darshan Shankar, Padma Venkat

The healthcare scenario in urban India and globally is undergoing dramatic transformation, evolving into systems that emphasizes preventive health, customized care, body-mind medicine and the use of natural products. It is in this context that there has been in recent decades a resurgence of interest in the traditional Indian systems of medicine (ISM). The ISMs are based on the use of natural products. They view the human being and other life forms holistically in terms of both body and mind. They assess the uniqueness (*prakṛti*) of each individual and their universal principles can be tailored to the needs of every individual.

The transformation that is taking place in the healthcare scenario is reflected in the marketplace. The global market for herbal products is booming. The *Task Force Report of the Indian Planning Commission on Conservation and Sustainable Use of Medicinal Plants* (2000) estimated it to be about 62 billion per annum and rising at the rate of 15% per annum. A large percentage of the population in Asia, Africa and South and Central America also depend on traditional knowledge and medicinal plants for their primary health care needs (WHO 1993). This dependence is likely to continue, as rising costs of conventional healthcare make the traditional plant-based solutions the most viable, safe and affordable option.

Observers of the health sector believe that any societal model of healthcare based on a single system of medicine will soon become obsolete unless it broadens out to combine with complementary systems of medicine. The world's oldest codified and living systems of healthcare are Āyurveda, of Indian origin, and Traditional Chinese Medicine.

It is in the context of this growing consumption of traditional products that questions regarding quality standards have become a matter of concern to policy makers, consumers and to the regulatory authorities. Due to the difference in epistemologies, centuries of clinical evidence and practical methods for quality assurance that are available in the traditional ISM cannot automatically be transferred onto the parameters of western biomedicine, and such translations need to be supported by serious inter-cultural research and epistemologically sensitive methodology. An inter-cultural approach is inevitable because most herbal products originate from non-Western health sciences.

The English word "science" refers to a special kind of knowledge, which is clarified through reason and analysis. We find that our unclarified perceptions of the world are often too narrow, and that our assumptions and beliefs are all too often prejudiced. Accordingly, we use our scientific reason in two ways. On the one hand, we can put our narrow perceptions together, thus building them into broader pictures of the world. The world is thus described objectively, by relating objects in conceptual pictures. Through systematic reasoning, these pictures grow into coherent fields of knowledge. Each field of knowledge has its own consistency, as a conceptual system, and each one has its place among the other fields.

On the other hand, in order to correct mistakes, our scientific reasoning can function in reverse. Instead of building pictures up, it can reflect back down, in order to investigate assumptions and beliefs. This reflective reason is essentially subjective. Its purpose is to educate, by asking questions that correct the questioner's own understanding. In Sanskrit, this corrective education is described by the word *śāstra*. Literally, "śāstra" means "correction" or "governance", but it is often used as a traditional word for science. It thus conceives of science as a correcting governance that is administered reflectively, through inward-turning reason.

These two ways of using reason have a long history of working together, since the beginnings of ancient science. But in the last few centuries, the objective way has prevailed. Unfortunately, the development has been one-sided. Our modern sciences have a tendency to emphasize the objective and calculating use of reason. So there has been a corresponding neglect of subjective education. It could well be argued that our current environmental crisis comes from this neglect of a more deeply reflective education, which is now needed to make better use of our specialized objective capabilities. The neglect has gone so far that the word "subjective" is routinely assumed to mean just "personal", and a subjective use of reason is thus put outside the essential and proper functioning of science.

Since science is essentially concerned with knowledge, it cannot be just personal. The problem is that our personal faculties are partial. They are partial faculties of body, sense and mind, which show us partial and differing appearances. No such appearance is entirely correct. Each bodily or sensual or mental appearance needs correction, to allow for different points of view. Therefore an impersonal standardization is essential to all sciences. But it can be approached in two ways, which are again objective and subjective. The objective approach is directed externally, by prescribing standard techniques and instruments in the external world. The subjective approach is turned back in, through a reflective investigation of common principles that different people share, beneath the differing phenomena that nature manifests to them.

In the modern physical sciences that have developed in the last few centuries, the standardization is restrictedly objective. It requires that all theories are tested and applied through standardized instruments and machines, which we fabricate and use in the external world. Subjective reflection is specifically confined to the intuitive creation of ideas and theories. Once the theories are created, they must be tested and applied through their calculation of predicted results, which are measured and observed by a mechanical technology.

In older sciences, which have been developing for some thousands of years, more use is made of subjective reason. Here, reason works through education. Ideas are tested and applied in a living process of learning from experience, through common principles that underlie the variations of personality. The older sciences are based upon that inward investigation, towards a depth of knowing which is both subjective and impersonal. That depth of subjectivity is described by the Sanskrit words *ātma* and *ātmīya*.

The word "*ātma*" means "self". It describes the self as a knowing subject at the inmost depth of personality, beneath the outward appearances of body, sense and mind. The word "*ātmīya*" means "subjective". It refers to an inmost subjectivity, which is attained by reflecting back within. Here the word "subjective" is not being used to mean just "personal". The self-called *ātma* is an inner principle of consciousness or spirit, and the word "*ātmīya*" thus means "spiritual". It refers to a pure spirit that is found by inward detachment from outgoing personality[1].

[1] The above discussion on science, vijñana and on objective and subjective standards has borrowed from the unpublished article on Knowledge Before Printing and After of Ananda Wood, an eminent scholar and philosopher of science.

To place the above discussion in the specific context of healthcare, Table 1 gives a picture of the different epistemological foundations of western biomedicine and Āyurveda. It is important to appreciate these epistemological differences per se and not in terms of which is right or wrong or more superior or less. They represent different ways of knowing and viewing nature.

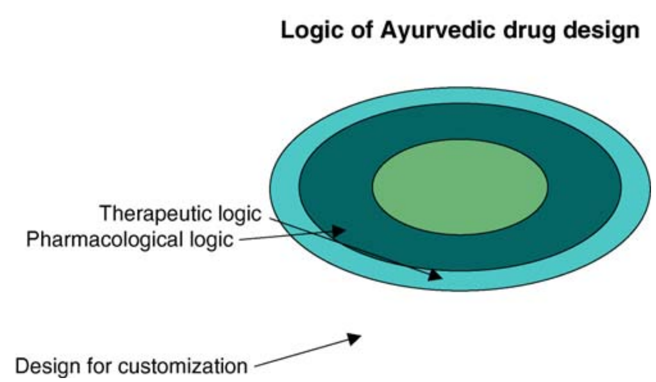
The traditional Indian systems of healthcare also have their own internal quality standards and logic for drug design and therapeutics. Table 2 illustrates the different logic of drug design and therapeutics used in Āyurveda.

Āyurveda is primarily based on the notion of "homeostasis". This outlook is different from the

Health Sciences in India: Traditional Health Sciences and their Contemporary Application. Table 1 Two different knowledge systems

	Āyurveda, Indian health system	**Biomedical science**
Differing foundation	Based on nine existential entities: Earth (*pṛthivī*), Water (ap), Fire (agni), Air (*vāyu*), Space (*ākāśa*), Mind (manas), Time (*kāla*), Direction (dik), and the Soul (*ātman*)	Based on three existential entities: Matter, time and space
Differing worldview	Recognizes physical, biological and spiritual worlds	Recognizes physical and biological worlds
	Sāṃkhya	Logical positivism and later schools
Differing logical system	Nyāya *Vaiśeṣika*	Aristotelian logic and its evolution
Differing categories	*Guṇa*	Phyto-chemistry and pharmacology
Differing pathogenesis	Loss of homeostasis	Infection via bacteria, parasite, virus

Health Sciences in India: Traditional Health Sciences and their Contemporary Application. Table 2 Logic of Ayurvedic drug design



Therapeutic logic
- To break the chain of pathogenesis of a particular disease
- To alleviate specific symptoms of particular disease
- To block progression of the disease
- To reduce complication or associated diseases

Pharmacological logic
- To select principal drugs and adjuvants having balanced therapeutic action
- To enhance bioavailability, spread and penetration, through appropriate dosage forms, time of administration, method and route of intake
- To design a combination of ingredients that does not cause unintended side effects

Design for customization
- Drugs should suit Prakriti (genotype), age, customs, mental poise of the patient
- Drugs should suit local habitat and climate in which the patient resides
- Drugs should suit the digestive capacity (agni) and food habits of the patient

Source: based on the *Carakasaṃhitā*.

theoretical approach of western medicine, which is largely based on disease causation due to infection, structural damages and systemic disorders whose etiology is poorly understood.

It is Āyurveda's hypothesis that any disease, whether acute, chronic, degenerative, infectious or functional, occurs only when there is an internal imbalance or loss of equilibrium in the physiological or psychological functions of the body. The Āyurvedic treatments are designed to restore the specific kinds of imbalances caused by a particular disease. They are designed not only to resolve the immediate problem of the patient but also contribute to his/her sustained quality of health (*Āyushyam*). A drug is only one part of treatment. A holistic treatment also includes diet, non-drug therapies (like yoga and pancakarma) and life style changes.

In an emerging era of medical pluralism the project of developing modern inter-cultural standards for quality, safety and efficacy of traditional ISM is not only important for Indians but also for global consumers. This article outlines the strategy for building upon traditional knowledge to create internationally acceptable modern quality standards.

Do Traditional Quality Standards Really Exist?

Any living, evolving system of traditional medicine which has served society for several millennia – such as we see in Asia, Africa and Latin America – could not have survived without possessing quality standards of its own. In most societies in these regions, health traditions remain undocumented because they are transmitted orally from generation to generation. This oral transmission, despite its remarkable efficiency, outreach and cost-effectiveness, is poorly understood. There are also codified medical traditions with theory and clinical practice documented in the form of thousands of medical manuscripts in India and China.

In all traditional health cultures, quality standards do exist. They are expressed in the form of descriptions, advice and recommendations for identifying, collecting, processing and therapeutic use of natural products. The criteria for collecting plants, for instance, may include the best season and stage of growth for the plant to be most therapeutically active, and the best regions for gathering them in order to heighten their medicinal potency. There are also standards for storage, post-harvest, processing, and for finished products. Standards also exist for safety and efficacy.

In traditional societies, the health functionaries – the plant collectors, those who store the plants, and the physicians who prepare and administer the medicines – usually belonged to the same community as their customers. In earlier times the knowledge and integrity of the collectors and physicians served as an assurance of high standards. Today, the traditional quality standards can no longer be applied as those involved in preparing the medicines never meet their millions of customers face to face. Moreover, many more people are involved in the production and distribution chain. There is also a problem of soil, water and air pollution that can contaminate the raw materials.

The Inter-Cultural Approach to Building Quality Standards

An inter-cultural approach involves the use of the modern scientific tools of physics, chemistry and biology to establish universally verifiable quality standards. The identification of the quality parameters that are to be standardized, however, does necessarily need to be based on the traditional knowledge systems from which the products are originally derived.

The evolution of inter-cultural standards is not an easy task as it assumes cross-cultural understanding and needs to engage experts in traditional knowledge and modern science in a mutually respectful dialogue. This is not a short-term task; institutions for inter-cultural research need to be created. The starting point for creating quality standards is to establish the identity of the raw materials that go into the making of natural product. To identify the raw material (a plant, for instance), a reliable traditional source – texts as well as traditional knowledge holders – must be consulted. Tradition identifies materials by vernacular names and descriptions. It is necessary to link the vernacular names and descriptions of plants to the appropriate botanical entity. For example *Tulasi* is the vernacular name of a plant which when pointed out to a botanist would be correlated to *Ocimum sanctum.* In the case of certain vernacular names, however one vernacular name may correspond to more than one botanical entity. For example in the case of the plant referred to as *brahmi,* the Āyurvedic texts correlate this name to two distinct botanical entities *Baccoba monneri* (Neer brahmi) and *Centella asiatica* (Mandūkaparni) (Sastri 1993). Other vernacular names like *pashan bhed* and *śankhapushpī* also have several botanical sources and acceptable regional substitutes, which are different species that possess similar pharmacological activity. There is another kind of complexity connected with vernacular names. This is the problem of synonymy wherein a single traditionally used plant entity may have as many as 70 vernacular synonyms, and one needs the help of traditional scholars to group all the vernacular synonymy that refers to a particular plant. This can be best illustrated by citing the case of a very important Āyurvedic text called the *Carakasaṃhitā*. In this text there are 12,000 plant names, but after resolving the problem of synonymy, these 12,000 vernacular names refer to only around 620 unique plant entities (Gopal 2004). These are the kinds of problems that are involved in establishing the botanical identity of a vernacular plant name. It should be clear from the above that in order to establish the correct identity of a plant it is essential for botanists and traditional physicians to work very closely with each other because the inter-cultural correlation between vernacular names and botanical entities needs the intelligent involvement of both.

Since biological materials possess genotypic and phenotypic variability, while establishing standards in the case of a species with either a wide distribution range or even in the case of endemic populations, the sampling size should be adjusted to represent this diversity. For example *Phyllanthus emblica* is distributed right from the coastal plains to sub-tropical habitats and therefore standardizing such a material would require a statistically valid sampling strategy for this purpose.

The next stage in quality assurance of a raw material is to standardize collection procedures based on traditional recommendations regarding season, region and maturity of collection. and how it is processed and stored. Traditional medical texts under the topic *deśa vicara* specify the collection of raw materials at specific times of the plant's life cycle or advise collection from specific habitats. For example, the traditionally recommended mature tubers of the plant *Ipomea mauritiana* are richer in terms of both their bioactivity as well as in phytoconstituents than their immature counterparts (Venkatasubramanian 2004). Another similar case involves the difference between the bioactivity of fresh and dry brahmi. Another example of collection standards is the case of Turmeric (*Curcuma longa* L.) whose rhizomes for therapeutic purposes are collected at nighttime. Preliminary studies indicate that bioactivity of turmeric collected at night was significantly different from that collected during the day. *Neem* (Azardicta indica) manifests its best therapeutic properties when collected from hot, dry and arid habitats (e.g. Rajasthan) than when it is collected from a high rainfall area (e.g. Kerala).

The more complex aspect of quality assurance arises in respect to the standardization of the finished product. Traditional products of different cultures use a wide range of processing techniques and also dosage forms, from simple powders made from a single plant, to extracts made from many plants. The finished products may be aqueous extracts, herbal wines, herbal oils, baked products, plant starches or alkalis. Standardizing all these myriad process and products poses a real challenge to modern scientists. An interesting example of the relevance of traditional advice regarding processing can be seen in the case of an important pepper (*Piper longum*). This species is very widely used in Āyurveda. The extract of this plant in milk rather than water is better for therapeutic application. Bioassays indicate that the extract of the plant in milk is 27 times more active than the aqueous extract.

The Inter-Cultural Gap in Pharmacoepias

Today's Western-knowledge based pharmacopoeias – official handbooks on medical treatments – of traditional medicine like the US Pharmacopoeia, WHO monographs and even the Āyurvedic Pharmacopoeia of India, largely fail to adopt a comprehensive inter-cultural approach in setting quality standards. The quality standards they lay out for the drugs are limited to the presence of particular ingredients that are assumed to be active rather than the whole range of compounds that may be responsible for the drugs therapeutic actions. Most pharmacopoeias list aspects such as morphology, microscopy, physicochemical characteristics, nature of phytoconstituents and chromatography profiles, but are not as yet much informed by, or sensitive to collection protocols that are critical for the quality standards established by traditional health cultures. They are usually silent on the standards for several traditional dosage forms and online processes involved in their manufacture. This is partly because the information on traditional quality standards is not available in one place as a "ready reckoner" but mainly because an inter-cultural perspective is absent in their design.

International Regulations on Traditional Medicine

The biggest challenge lies in setting modern standards for evaluating a traditional drug's efficacy. This probably calls for a paradigm shift by designing a more holistic approach undertaking clinical trials. Most systems of traditional medicine adopt a multi-pronged approach to treatment. This involves drugs, diet and non-drug therapies. They aim at improving both mental and physical well-being. Furthermore, the causes of disease and their classification in traditional systems of medicine do not have a one-to-one correlation with Western counterparts. Finally traditional treatments are designed to achieve homoeostasis, rather than to eliminate a single invasive agent.

These differences in the approaches to treatment give rise to two issues. The first is that unconventional evaluation protocols are needed to assess an entire treatment "package", rather than one specific drug. The second is the need to use appropriate clinical, physiological, psychological or biochemical indices for evaluating outcomes which correlate well with the traditional understanding of cure.

In cases where differential diagnosis and treatment is indicated by TM for patients who from the western biomedicine perspective are suffering from the same disease, the conventional double-blind, placebo-controlled clinical trials might not always be necessary or appropriate. Case studies and observational studies –in which a clinical investigator monitors the effectiveness of treatment – can be valuable (Chaudhury and Chaudhury 2002). Clinical trials need to be generally designed to evaluate a management

H

regime, rather than a particular drug, although in the case of OTC drugs, the conventional design of drug trials is perhaps relevant.

In recent times regulatory authorities in importing countries such as Germany have restricted the role of traditional medicines to supplements that can be used only for "indications such as invigorating and strengthening" and which cannot be "intended to cure or treat disease" (Blumenthal 1998). This is because investing in efficacy studies based on inter-culturally sensitive research models has not been recognized as an important enough area. In clinical research, most of the pharmacopoeial standards that are now available have been restricted to single plant extracts or at most extracts of five herbs as fixed combinations. This restrictive approach to the use of traditional medicine is depriving consumers round the world of many of the benefits of several sophisticated poly-herbal traditional remedies.

With respect to safety, traditional remedies will need to be assessed within the same parameters now used for modern pharmaceutical, nutraceutical and cosmeceutical products. The WHO has accepted that traditional medicines may need less rigorous preclinical toxicological evaluations since their safety of use has been documented historically (Venkatasubramanian 2004). However in the case of traditional products that are based on the use of metals and minerals, whereas they are known to be therapeutically potent, it is extremely important to ensure that the traditionally prescribed processes are rigorously adhered to else the products can result in toxic side effects. In fact the traditional pharmacy texts themselves underline the need for such rigor. For example in the case of *bhasmas* the particle size of the finished products is expected to be smaller than the intracellular space and the products should no longer carry any trace of the metal in its original form. Modern tools like the electron microscope and atomic absorption spectrometer can aid in the evaluation of such products.

The latest EU regulations on traditional medicine state that traditional products must be safe and meet prescribed standards of quality if they have been used for at least 30 years. A catch in this legislation is that 15 years had to be within the European Community itself (Chaudhury and Chaudhury 2002). This is in principle a progressive rule because it recognizes the value of traditional knowledge. Its practice however needs to be worked out in a way that is fair and makes best use of traditional medical cultures that are located outside the European Union.

Policymakers and medical researchers should understand that the evaluation of traditional systems of medicine and their inherent standards involves intercultural research. This is a vital pursuit, as it can enrich the field of medical pluralism – which in its turn seems to be the best route towards the advancement of world medicine.

Holography[1]

JEHANE RAGAI

"Appearance and Reality"

This article attempts to show that an ancient period of human creativity as expressed in Egyptian art has an analog in the twentieth century discovery of holography. Parallels are perceived between both the "frontal-profile stance" and the "canonical tradition" of Egyptian art and the model of the hologram. These analogies appear on both the "empirical" and "conceptual levels".

Recent breakthroughs in modern physics (Capra 1980; Zukhav 1980; Jones 1983) have drawn attention to the innumerable parallels between the new ways of interpreting modern physics and Eastern mysticism. Capra (1980) in his Tao of Physics reflects this trend when he observes:

> …The basic elements of the Eastern world view are also those of the world view emerging from modern physics… Eastern thought provides a

[1] It is to be noted that an earlier version of this article appeared in 1986 both in English and in French, in Aujourd'hui l'Egypte. Permission to reproduce an updated version was granted to the author by the editor of Aujourd'hui l'Egypte: Mr. Jean Chamas.

consistent and relevant philosophical background to the theories of contemporary science…

Similar to modern physics, holograms also lead to a world view which is essentially mystical (Bohm 1980). The roots of such a view can be found in an earlier period of human creativity, that of Ancient Egypt, where the belief in the mystical reality of art gave impetus to the unparalleled artistic productivity of its people. Through the examination of the frontal-profile stance and the canon, we will demonstrate how the hologram and Ancient Egyptian works of art, which at first glance may seem totally unrelated, share many common features. The paper concludes by suggesting that these two complementary manifestations of the human mind are united in their mystical view of the world.

It is hoped that the ideas expressed in this paper will prove relevant in showing that there is an essential harmony and complementarity between the humanities and science leading to a better understanding of the world around us.

Frontal-Profile Stance in Ancient Egyptian Art

To the Ancient Egyptians an intimate relationship existed between art and the fundamental belief of how to live and die. Where an obsessive horror of death and extinction was reconciled with an absolute faith in immortality, art played an active role.

The Egyptian artist was concerned not with representing a fleeting impression captured transiently, but with what he regarded as an individual's personal eternity. Principal figures were shown at an undefined age, conforming to preconceived standards of bodily health and vigour. Individual features showed little variation and personal traits were generally avoided. Figures in general were not intended as portraits of the deceased but "…symbolic representations of a perfect man and his family…" (David 1975) a representation of what was expected to exist for perpetuity.

Each individual object had therefore to be represented in its entirety, as a "whole", with no parts hidden or distorted by shifts of perspective, "because parts omitted were considered missing and bound to mar the eternal image of the objects they represented" (Iversen 1975).

This led to one of the fundamental features of Ancient Egyptian art: the principle of "frontal images" or the "aspective" (Shafer 1974) as opposed to the "perspective" approach.

Egyptian artists selected in their two-dimensional renderings, only those possibilities which were free from the illusion of perspective, in which characteristic individual parts of an object were set unforeshortened almost as a series of juxtaposed phases.

Applied to human figures, this "frontal-profile" aspect was expressed in an extraordinary treatment of the human body. Apart from rare instances the head and the neck were invariably represented in profile yet the eye was presented full face (Fig. 2). The torso was turned square to the spectator with the nipple seen in profile and the navel "en face". Legs and feet were represented in profile with the left leg foremost (Fig. 2).

Such an impossible physical contortion avoided the perspectival solution to the problem. Through the integration of the front and side views, Ancient Egyptians thus managed to achieve a three-dimensional representation of objects on a plane surface.

It is in this "aspective" expression of Egyptian art, where each element of the representation was scrupulously reproduced that a first analogy may be perceived with modern holography. To clarify this point and demonstrate the parallels, a few words of explanation about holograms are in order.

Holography is a method of lenseless photography in which the wave field of light scattered by an object is recorded as an interference pattern. When the photographic record called a "hologram" is placed in a light beam, the original pattern is regenerated and the observer sees a three-dimensional picture that is an amazingly realistic image of the original object.

If one moves one's head, one can see a top, bottom and side view, just as if the object actually existed in space before one's eyes.

To make a hologram, one starts with a single monochromatic and coherent beam of light from a very small source:

> …This single beam is then split into two components, one of which is directed towards the object, the other is directed to a suitable recording medium, usually a photographic emulsion. The component beam that is directed to the object is scattered, or diffracted by that object. The wave that proceeds directly to the recording beam is termed the "reference beam". Since the object and reference waves are mutually coherent, they will form a stable interference pattern when they meet at the recording medium… the detailed permanent record of this interference pattern on the photographic emulsion, which we call the "hologram" consists of a complex distribution of clear and opaque areas corresponding to the recorded interference fringes. When this in turn is illuminated with a beam of light which is similar to the original reference wave, light will only be transmitted through the clear areas, resulting in a complex transmitted wave. The latter conveniently divides into three separate components, one of which exactly duplicates the original object wave. Thus "holography" is a two-step process by which images can be formed.
>
> In the first step a complex interference pattern is recorded and becomes the hologram. In the second

> step, the hologram is illuminated in such a way that part of the transmitted light is an exact replica of the original object wave (Smith 1975) (Fig. 5).

The concept of three-dimensional realism with only two in use is therefore encountered in both Ancient Egyptian art and modern holography.

Such a parallel becomes even more evident by considering De Rachewiltz's (1960) description of Ancient Egyptian two-dimensional representations:

> …on a flat surface (space) an image is drawn which at the same moment (time) evokes a plurality of individual visions. It is almost as if the figure were visualised from several sides, seen simultaneously in profile and from the front in its essential "reality" which is derived from one vision of the various sides synthesized on the flat surface.

Canons as Holograms

Another striking feature of Egyptian Art, both in the sculpture and in the painting, is the serenity and immutability of the people and the scenes.

A sense of inner life and power imbued with calmness emanates from the various art works. The representation of the human figures suggests that the Egyptian artist's aim was to establish for all times the laws of harmony and perfection. Such harmony was expressed in idealized human figures free from physical defects and enjoying the blessings of life (Fig. 1).

Holography. Fig. 1 Triad of king Menkaure (picture taken by Dr. John Swanson and reproduced through his permission and that of the director of the Cairo museum Dr. Wafaa al Sadek).

Technically, such standards of beauty were reached by making use of the well-known "artistic canon". The latter was encountered in Ancient Egyptian art since the beginning of the dynastic times and represents a system of proportions which was used to indicate the mutual relations of the different parts of the body in its artistic representation. According to Iversen (1975) and Harris (1971), the problem faced by the Egyptians of how to scale the various parts of the body was solved by resorting to an accurate standardization of the natural proportions of the body.

His arguments were based on the premise that within distinct types and ethnic groups, the relations of the various parts of the human body are constant and immutable in all individuals, irrespective of any differences in size and dimensions.

Recent investigations (Robins and Miszellen 1976) have, however, indicated that Egyptians gave their figures idealized proportions which reflected certain standards of beauty and were not necessarily totally in correspondence with the natural proportions of the body.

Here we are reminded of Plato (1963), according to whom "…Egyptian artists abandoned the truth and gave their figures not the actual proportions but that which they considered beautiful…". Whether or not such was the case, there definitely existed a standardized relation between the various parts of the represented figures and these were based on anthropometric measurements.

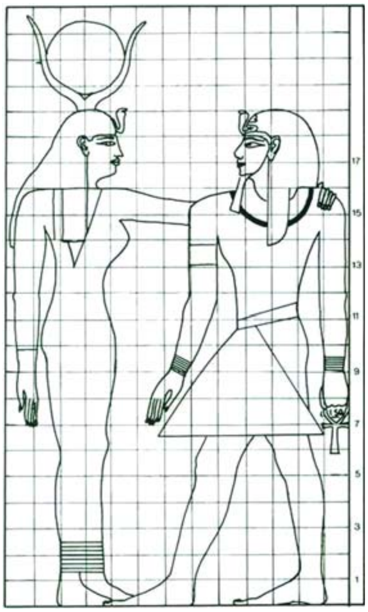
For the practical application of such a system the Egyptians invented the so-called "grids", a system of squares in which the width of the grid square was taken as a rough guide for the width of the fist:

> On the rectangular blocks intended for sculpture in the round, the squares were drawn or incised on at least two sides, and on the plane surfaces prepared for two-dimensional representations, they were either ruled with a straight edge or marked by means of strings dipped in red ochre (Robins and Miszellen 1984).

A canon of proportions thus evolved as early as the Old Kingdom (3200–2280 BCE), and from the Middle Kingdom (1991–1786 BCE) onwards it became normal practice to relate the parts of the body to a grid consisting of 18 squares from the soles to the hairline (Robins and Miszellen 1983; Fig. 2).

Such a "classical" grid was from the 26th Dynasty (664 BCE), replaced by the "late" grid, known as the "Saite Canon", dividing the height of the male figure into 21 squares from the sole to a new measuring point at the root of the nose.

Without changing the mutual relations of the parts, the dimensions of all proportions of any figure could be altered indefinitely by the simple process of changing the length of the modular square (1/18 or 1/21 of the height depending on what canon was used).



Holography. Fig. 2 The Ancient Egyptian canon of proportions.

Egyptian artists were therefore able, for more than two millennia, “to find a complete harmonious expression within a single tradition, without once changing its principles and ideas – with the sole exception of the Amarna age” (Harris 1971).

Robins and Miszellen (1983) recently showed that during the latter period a canon of proportions based on 20 squares from the sole to the hairline was introduced.

It is in this canonical tradition of Ancient Egyptian art that a further analogy may be perceived with modern holography. To appreciate such a similarity let me point out another crucial property of holograms.

In holography the light scattered from each point of the object spreads out as to cover the entire photographic plate. This means that there is no longer a one-to-one correspondence between a portion of the hologram and a region of the object. The information of any single point is recorded over the “whole” plate.

Because of this only a small portion of the hologram is required to form an image of the whole object (Smith 1975; Develis and Reynolds 1967; Butters 1971). If the hologram were to be shattered into thousands of splinters of glass, it would still be possible to form, on any small particle of glass, the entire representation.

This key new feature which is apparent in holography, that of an unbroken wholeness, where each part contains information about the entire object, is also apparent in the Ancient Egyptian canon of proportions. Any small part of the artistic figure gives, through its dimensions, information of the whole.

The following argument will also show that just as in a hologram, the representation is “everywhere” in the glass plate, shot through it, the communication or message conveyed by the canon is contained everywhere in the work of art (Ross 1982).

The observation of Egyptian representations as well as a detailed reading of published work (David 1975; Iversen 1975; Shafer 1974; Smith 1975; De Rachewiltz 1960; Harris 1971; Robins and Miszellen 1976, 1983, 1984; Plato 1963; Ross 1982; Aldred 1980; Davies 1982; Steindorff 1949; Kielland 1955; Romano and Bothmer 1958) on Ancient Egyptian art convinces us that through the symbols and metaphors embodied by the canon, a “mystical” message is conveyed that is highly consonant with modern physics (Capra 1980; Zukhav 1980). Such a message incorporates the ideas of the interrelatedness of all things, the transcendence of the notion of an individual self-coupled with the firm belief that all observations are but manifestations of the same ultimate reality and finally the idea that space and time are constructs of the mind.

That all things and events perceived by the senses are interrelated and connected is, by virtue of the canon, metaphorically suggested throughout the Ancient Egyptian work of art. The standardized relation between the various parts of the figures such as the relation of thumbs to fingers, fingers to palm, palm to forearm, forearm to height and breadth symbolically confirms this interdependence. All things are seen as inseparable parts of this cosmic whole.

The canonical tradition, by allowing the tomb owner and his family to be represented as idealized humans with slender bodies and youthful beauty free from physical defects and devoid of individual and personal traits, expresses a transition from differentiation to sameness. What appears to be different finally is seen to be the same. The canon, throughout the art work, allows the individuality to be dissolved into an undifferentiated oneness where the notion of an individual self is transcended leading to an identification with the same ultimate reality (Figs. 1 and 4).

Iversen (1975), referring to the lack of specification of Ancient Egyptian works of art in the spatio-temporal plane, writes:

> In order to prevent any temporal aspect to influence the existence of the individual representations the indications of any particular moment in their corruptible state was studiously avoided…

Ancient Egyptian works of art, created out of their spatio-temporal appearances, suggest that space and time are constructs of the mind. Such a message can be shown to be “hologrammed” by the canon.

Indeed a close observation of Ancient Egyptian figures suggests that each single part in the Ancient Egyptian work of art is given a form that is appropriate to its meaning, conveying to the figure as a whole a message valid for eternity.

Starting with the representation of the "feet" (Fig. 2), it is observed that the arch which is generally closed on the outside is shown to appear from the exterior, also "legs" are in most cases depicted as being a pace apart, even when surrounded by seated or kneeling people. Observation of Fig. 2 also suggests that the "hand" hanging open behind the back is mostly so placed that the thumb is turned away from the body. Shafer (1974), commenting on the position of the hands, makes the following conclusions:

> …This strange positioning of the hands poses great problems as long as the human figure is taken to be the rendering of a single real view. But it does the artist an injustice to consider his work in this way…

The intermingling in these representations of the concepts of "back" and "front", "inner" and "outer" as well as those of "rest" and "movement" indeed does suggest an arrest in time and space.

In their depiction of "parts" as well as of the "whole" in figures, Egyptian artists were thus inclined not to follow their visual impressions. Instead they sought to convey the significance of a subject by portraying it in an abstract manner, outside space and time (Fig. 3).

Holography. Fig. 3 Queen Nefertari.

It is also noteworthy that in these artistic renderings facial representations were generally devoid of all signs of emotion and of details specifying human feelings and passions (Fig. 4).

Holography. Fig. 4 Tutmsosis III (picture taken by the late Dr. Bernard Bothmer) reproduced by permission of Mrs. Bothmer and Mrs. Sanaa Ahmed Ali (director of the Luxor museum).

The images had a tone of extreme dignity, almost of a higher existence which has been achieved and of which the subject was completely aware. Here, once more, we become aware of artistic expressions taken out of their ephemeral temporal representations.

It becomes clear that the adaptation of the artistic production to a "canon", considered as an expression of the divine law of harmony, has allowed the full expression of an unbroken wholeness through which is "hologrammed" a highly mystical message. The artist fashioned an image that expresses in generalized terms the nature of "man" as such.

His prime concern being to create not a likeness but first and foremost "a symbol".

Conclusion

This article has attempted to link an ancient period of human creativity, as expressed in Egyptian art, with a modern twentieth century discovery: holography. Ancient Egyptian works of art and holograms are seen to have striking parallels both on an "empirical" as well as on a "conceptual" level.

Both techniques, in spite of their different approaches, have succeeded in achieving a mapping of three dimensions on to two. Ancient Egyptian artists did not base their representations on perspective but were rather concerned to communicate all of the details of the figure by giving every vital part its full definition. If the head were shown frontally the definition of the nose would be lost for eternity. Similarly the eye and torso had to be exhibited in their most characteristic light and were therefore shown frontally legs and feet which would have been foreshortened if shown frontally were indicated in profile. Such an approach thus gave the "complete" information about the represented figure.

Similarly, holography by reproducing an exact replica of the original object provided an illusion of three-dimensional concreteness from which could be extracted the "whole" information relating to the object.

An additional property, common to both holograms and Ancient Egyptian works of art and also evident on an empirical level, is that: just as in a hologram any fragment, which is very small, gives information on the whole object, in Ancient Egyptian works of art by virtue of the canon, any part of the figure allows the computation of the dimensions of the other parts and of the whole.

From a conceptual point of view, both holograms and Ancient Egyptian works of art similar to modern physics lead to an essentially mystical world view.

Thus as observed by Bohm (1980):

> Holograms provide an immediate perceptual insight into what is meant by undivided wholeness in which the classical idea of the analyzability of the world into separately and independently existing parts is denied.

In an analogous manner Ancient Egyptian art works are "…created as a UNITY in which every detail and measurement is determined in relation to the whole…" (Kielland 1955). The interdependence and interconnectedness of all things are again made evident here.

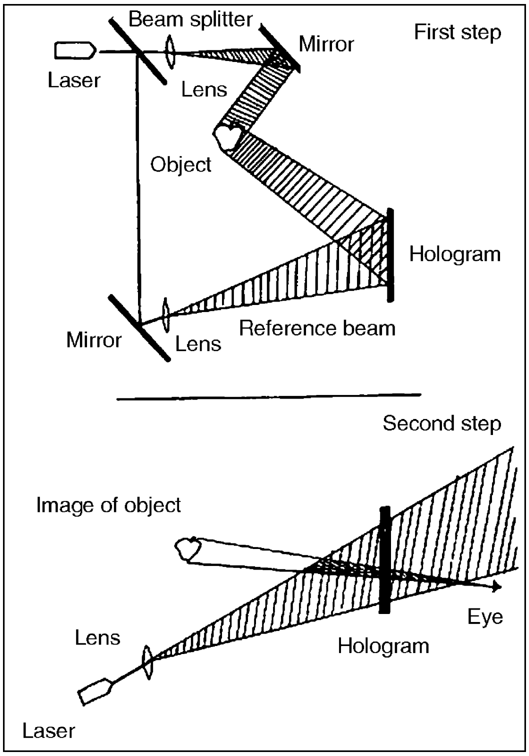
This highly mystical approach is not only conveyed by considering the Ancient Egyptian art work in its entirety, but is also seen to be "hologrammed" throughout the individual parts.

As Plato suggests:

> The Egyptians managed to penetrate a reality beyond the "merely" seeming presenting this comprehensive intuition in artistic form, as a vision of underlying order in the universe (Plato 1963; Davies 1982).

In the same line of thought, we may reflect on Bohm's suggestions that the "universe itself may be a hologram", a realm of frequencies and potentialities underlying an illusion of concreteness, or what he calls the "enfolded" order.

What we actually "see" is the "unfolded" order giving recognisable images of "whole" objects (Bohm 1980; Milbourn unpublished). Bohm suggests that our reality is of objects rather than waves "because our senses are lens systems" (Fig. 5):



Holography. Fig. 5 Creating a hologram.

> If the universal reality is based on the holographic principle, then what is needed to tune into this reality is a means of bypassing the lens system of the senses and experience the waves of the enfolded order directly (Milbourn unpublished).

We are reminded here of Steindorff's (1949) description of Egyptian non-perspectival art as an art "that concerns itself with the object not as it appears to the eye, but as it exists in the imagination of the artist", representing a mental image that transcends the world of senses.

Thus both Ancient Egyptian works of art and holograms may be conceived as resulting from an awareness raised to a level above the brain's sensory input, in which the different aspects of nature, whether recorded as an interference pattern of scattered light or whether resulting from what may be termed the "holographic activity" of the Ancient Egyptian brain, have led to a blurring of the demarcation line between "appearance" and "reality".

Acknowledgements

I would like to thank the late Dr. Bernard Bothmer, Professor of Egyptian Art (Institute of Fine Arts, New York University) for his encouragement, his useful comments and his assistance in providing resources unattainable in Egypt, when this article was first written. I also thank the late Dr. Cynthia Nelson, Professor of Anthropology (The American University in Cairo), for her insightful comments which have improved the quality of this text. I would also like to thank the late Dr. S. J. Gregg, formerly of the department of Chemistry (the University of Exeter) for his unfailing encouragement. Last but not least, grateful thanks go to Dr. Wafaa al Sadek, Mrs. Sanaa Ahmed Ali, Mrs. Bernard Bothmer and Dr. John Swanson for their permission to use some of the present pictures.

Honey and Medicine

Rachel Hajar

There is evidence that man has long known that honey is a valuable food source. Early rock paintings on cave walls in Africa and eastern Spain show people gathering honey from trees or rock crevices while bees fly around them (Crane 1999). A rock painting called the "Man of Bicorp" shown in Fig. 1 was discovered in 1921 in the *Cueva de la Arana* (Spider Cave) in Valencia, Spain. The painting depicts a human figure near a cavity where there is a beehive. Hanging on three lianas, he is picking up honeycombs, while nearby are some stylized bees. The painting is believed to be over 15,000 years old and dates back to the end of the Paleolithic Period. Rock art from other caves has been found, which shows figures surrounded by bees without being stung.

Prehistoric honey gatherers probably learned by accident that bees are driven away from the honeycomb by smoke as an offshoot of using fire for "warding-off" or driving other animals. Most likely early humans observed the habits of bees and learned that wild bees made their home in the hollow limbs of trees or in hollow places in the trunks of trees. Even now, bee trees often can be found by walking through the woods on

Honey and Medicine. Fig. 1 "Man of Bicorp" ca. 15000 BCE. Paleolithic rock painting showing honey collection from a wild nest, Cueva de la Arana, Bicorp, Valencia, Spain (Drawing E. Hernandez-Pacheco). ►http://www.rupestre.net/tracce/bicorp.html.

bright sunny days and looking into the tops of the trees and watching for the bees coming and going.

The "Man of Bicorp" cave painting is clear proof that early humans actively sought honey as part of their diet. We do not know, however, whether prehistoric man used honey for medicinal purposes.

Honey hunting is an ancient tradition that is still practiced in isolated cultures in Africa, the Indian subcontinent, Southeast Asia, Australia, and South America. Reports of such activities in the popular press describe the practice as heavily permeated with ritual. This is not surprising since the tradition was passed down for generations and has its origins from our distant past.

Honey hunting is a dangerous pursuit since a bee sting could be fatal. Throughout history, there have been alternatives to honey as a sweetener, such as dates and figs. Yet, humans seem to prefer honey and one wonders why humans like honey so much.

Honey in Mythology and Religion

The widespread perception that honey is "good" has its genesis from folklore. Myth has played an important role in folklore. Oral and written records abound with the life-giving qualities of honey.

Quantitative studies of hunter–gatherer diets are scarce. The *Veddas*, or Wild Men, of Sri Lanka esteem honey so highly that they regularly risk their lives to obtain it. The results of a study among some Australian aboriginal tribes reveal that wild honey is regularly consumed although it is difficult and challenging to obtain. Unfortunately, research into the nutritional role of honey is scanty. However, studies of primitive tribal diets indicate that honey is highly nutritious. For example, among the Guayaki Indians of Paraguay honey is the very basis of their diet and culture (Fallon and Enig 1999).

Mythology offers rich insights into the perceived life-sustaining qualities of honey. In Greek mythology, Zeus, mightiest of the Greek gods, was hidden from his father who wanted to devour him and was raised on honey and milk by the bee-nymph, Melisseas. Honey made him so strong and tough that when he grew up he seized his father's throne.

Another myth is that *ambrosia* was the food of the gods and goddesses. Since their gods' food consisted only of ambrosia, the ancient Greeks attributed the immortality of their gods to ambrosia, which they believed consisted of honey, milk, and nectar. Ambrosia was thought to be a nine-fold extract of honey – a sweet treat enjoyed by mortals throughout the ages. Honey was a divine symbol for the Greeks and honey mixed with blood was the sweetest oblation.

Besides its nutritious benefits, the ancients may have believed that honey had properties to preserve or enhance beauty. It is claimed that many of Cleopatra's cosmetics were honey-based. Many women in Arabia still believe honey softens their skin and regularly apply it as facial mask.

In Egyptian mythology, "when the God Re wept, his tears fell to the ground and were turned into bees. The bees began to build and were active on all flowers of every kind belonging to the plant kingdom. Thus wax came into being, thus was created honey from the tears of the God Re" (Ancient Egyptian beekeeping).

The ancient Egyptians offered their gods honeycombs overflowing with honey as a valuable gift to show devotion and worship. In the twelfth century BCE, Ramses III offered 15 tons of honey to Hapi, the god of the Nile. Jars of honey were buried with the dead as sustenance for the afterlife. Archaeologists have found clay pots filled with honey in a Pharaoh's tomb in the city of Thebes. The inscription on the clay pot read: *Good Quality Honey*. Large quantities of honey in jars were also found in the tomb of Tutankhamen (Salim 1988). Burying the dead (especially nobility) in or with honey was common practice in Egypt, Mesopotamia [Iraq], and other regions. It is rumored that Alexander the Great was buried in honey.

The Pharaohs also used honey in their wedding celebrations. This custom was passed on to Greco-Roman culture and handed down to Medieval Europe. Newlyweds drank honey wine (mead) for a month after the wedding ceremony for good luck and happiness. The ritual gave rise to the word *honeymoon*. Egyptian hieroglyphics dating back at least 3,000 years indicate that honey was used as the principal sweetener in the Egyptian diet and as a base for medicinal unguents. The Egyptians also collected beeswax for use in molding wax images for metal casting and in the "varnishing" of pigments (Shaw and Nicholson 1995).

The first written record of beekeeping can be traced back to Egypt from about 2400 BCE. Fig. 2 depicts a

Honey and Medicine. Fig. 2 Beekeeping in Ancient Egypt (Tomb of Pabasa). Relief shows cylindrical hives made of clay. © Kenneth J. Stein Illustration from ►http://nefertiti.iwebland.com/timelines/topics/beekeeping.htm.

H

relief of hives in ancient Egypt, which are very much similar to the woven wicker baskets covered with clay that are still used in Sudan today.

Temples kept bees in order to satisfy the demand for honey as offerings to the gods as well as for other domestic uses such as mummifying, boat, and ship building, and as a binding agent for paints and in metal casting. However, the Egyptians valued wild honey more than the homegrown variety. A passage from the Papyrus Harris reads, "I appointed for thee archers and collectors of honey, bearing incense to deliver their yearly impost into thy august treasury" (Breasted 1906).

Honey is frequently mentioned in the Bible. Moses led his people to the "land of milk and honey." Solomon in Proverbs 24:13 advised, "My son, eat honey; it is good. And just as honey from the comb is sweet on your tongue, you maybe sure that wisdom is good for the soul. Get wisdom and have a bright future." The Jews believed honey made a person "mentally keen."

In early Christianity, honey had a deep mysterious meaning and it was given in christening ceremonies as a symbol of renovation and spiritual perfection. When St. John, the Baptist, was in the desert, he lived on honey and locusts. Bees were revered because of their ability to produce wax and therefore provide light, in many cases for religious practices. Before the advent of electricity, candles were important for lighting. In many religions, candles are still used for religious ceremonies. The Roman Catholic Church regarded the bee as an example of godliness and believed beeswax to be "pure" since virgins – i.e. nonmating worker bees – produce it. Monks kept bees to provide beeswax to make candles for the church.

Honey as Medicine in History

It is possible that prehistoric human's experiences with honey as a valuable food source became encoded in our mythology. In time, the mythic belief that honey was the "food of the gods" passed into ancient writings. Since it was the food of the gods, it must contain the ingredient of immortality, fostering the perception that honey contains the secret to a long and healthy life. It was prescribed as panacea for various ailments and diseases.

"Healing for Mankind"

"Thy Lord taught the Bee to build its cells in hills, on trees and in man's habitations; Then to eat of all the produce of the earth… From within their bodies comes a drink of varying colors, wherein is healing for mankind." (*Qurʾān*, Surah XVI: 68–69). The prophet Muḥāmmad advised his followers to "Use the two curatives: honey and Qurʾān."

Likewise, the Bible contains many references to honey. "But Jonathan [son of Saul]… reached out the end of the staff that was in his hand and dipped it into the honeycomb. He raised his hand to his mouth, and his eyes brightened." (1 Samuel 14:24).

The Hindu Vedas, composed about 1500 BCE and written down about 600 BCE, speak of "this herb, born of honey, dripping honey, sweet honey, honied, is the remedy for injuries; moreover it crushes insects." In the section on *Hymn To All Magic And Medicinal Plants*, honey is used as a universal remedy: "The plants… which remove disease, are full of blossoms, and rich in honey" (Blomfield 1973).

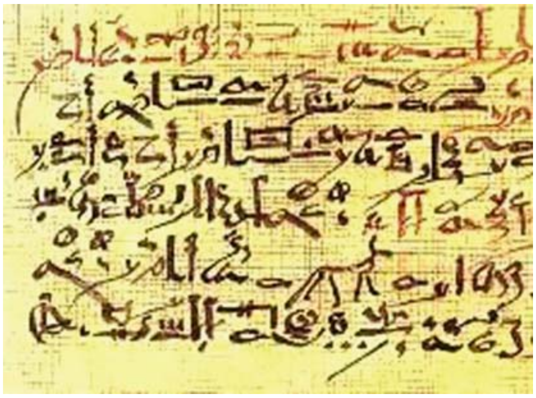
All the sacred books, including those of China, praise honey as food, beverage, and medicine (Jones 2001).

Ancient Writings

There are abundant references to honey as medicine in ancient scrolls, tablets, and books. It was prescribed for a variety of illnesses. Excavated medical tablets from Mesopotamia indicate that honey was a common ingredient in many prescriptions. In ancient Egyptian medicine, honey was the most frequent ingredient in all the drug recipes for both internal and external uses listed in the Ebers and Edwin Smith Papyri (Estes 1993). Honey was used for treatment of stomach pain, urinary retention, and as an ointment for dry skin. It was used for wounds and burns, skin irritation, and eye diseases.

The author of the Smith Papyrus shown in Fig. 3 directed that honey be applied topically, with few if any other possibly active ingredients, to wounds. An example appears below:

> Instructions Concerning A Wound In His Head, Penetrating To The Bone:
>
> If thou examinest a man having a gaping wound in his head, penetrating to the bone, thou should'st



Honey and Medicine. Fig. 3 Excerpt from the Edwin Smith Papyrus (Illustration taken from Ancient Egypt. The Edwin Smith Surgical Papyrus. ►http://nefertiti.iwebland.com/timelines/topics/smithpapyrus.htm)

> lay thy hand upon it (and) thou should'st palpate his wound. If thou findest his skull uninjured, not having a perforation in it…
>
> Thou shouldst bind fresh meat upon it the first day, thou shouldst apply two strips of linen; and treat afterward with grease, honey, (and) lint every day until he recovers.

In ancient Egypt, honey was the only active ingredient in an ointment described in the Ebers Papyrus for application to the surgical wound of circumcision. Ebers also specifies that an ointment for the ear be made of one-third honey and two-thirds oil. The concentration of honey in seven oral remedies in the Chester Beatty VI Papyrus ranges from 10 to 50%, while its proportion in other remedies ranges from 20 to 84%. Honey could very well have provided some kind of protection from the kinds of bacteria most likely to infect wounds, at least enough protection to permit wounds to begin healing on their own.

The ancient Egyptians were not the only people who used honey as medicine. The Chinese, Indians, ancient Greeks, Romans, and Arabs used honey in combination with other herbs and on its own, to treat wounds and various other diseases.

Aristotle (384–322 BCE) believed that eating honey prolonged life (Jones 2001). Dioscorides (AD 40–90), a Greek physician who traveled as a surgeon with the armies of the Roman emperor Nero, compiled *De Materia Medica* (shown in Fig. 4) around AD 77. *De Materia Medica* was the foremost classical source of modern botanical terminology and the leading European pharmacological text until the fifteenth century.

In addition to excellent descriptions of nearly 600 plants and 1,000 simple drugs, Dioscorides described the medicinal and dietetic value of animal derivatives such as milk and honey. Dioscorides stated that honey could be used as treatment for stomach disease, a wound that has pus, hemorrhoids, and to stop coughing (Salim 1988).

> Honey opens the blood vessels and attracts moisture. If cooked and applied to fresh wounds it seals them. It is good for deep dirty wounds. Honey mixed with salt could be dropped inside a painful ear. It will reduce the pain and swelling of the ear. It will kill lice if infested children's skin is painted with it. It may also improve vision. Gargle with honey to reduce tonsil swelling. For coughing, drink warm honey and mix with rose oil (Dioscorides 65 AD).

A tenth century Arab philosopher mentioned uncooked honey for swollen intestines whereas cooked honey was good to induce vomiting when a poisonous drug had been ingested. Al Rāzī (Rhazes, AD 864–932), a renowned Muslim physician famous for writing a treatise distinguishing measles from smallpox, claimed that honey ointment made of flour and honey vinegar was good for skin disease and sports nerve injuries, and recommended the use of honey water for bladder wounds (Salim 1988). His book, *Al Hāwī* (Encyclopedia of Medicine), a comprehensive medical textbook of medicine, which was translated from Arabic to Latin in the thirteenth century and became a standard textbook of medicine up to the 1700s stated:

> Honey is the best treatment for the gums. To keep the teeth healthy mix honey with vinegar and use as mouth wash daily. If you rub the teeth with such a preparation it will whiten the teeth. Honey does not spoil and could also be used to preserve cadavers.

Ibn Sīnā (Avicenna), another famous Muslim physician whose great medical treatise, the *Canon*, was the standard textbook on medicine in the Arab world and Europe until the seventeenth century, wrote:

> Honey is good for prolonging life, preserving activity in old age. If you want to keep your youth, take honey. If you are above the age of 45, eat honey regularly, especially mixed with chestnut powder. Honey and flour could be used as dressing for wounds. For lung disease, early stage of tuberculosis, use a combination of honey and shredded rose petals. Honey can be used for insomnia on occasions.

Throughout the ages, honey was prescribed for a variety of uses, frequently mixed with herbs, grains, and other botanicals. Remedies were passed down through the millennia because they seemed to be effective. Many ancient remedies survive today, lumped

(Arabic Translation of Discorides' *De Materia Medica*. Iraq, Abbasid Period, 13th Century ca. 1224) together by modern medicine under the term "folk medicine" since their effectiveness has not been scientifically proven through clinical trials.

The belief in honey as a remedy for ailments is still pervasive. Honey for coughs and sore throats remains a popular remedy around the world. Honey is frequently mixed with tea and cinnamon as remedy for cold and sore throat. Some antiseptic lozenges contain honey.

In underdeveloped countries, where synthetic medicines are expensive, honey is one of the cornerstones in their pharmacopoeia. For example, lotus honey is used for eye diseases in India. It is used as topical eye ointment in measles to prevent corneal scarring (Molan 2001). Honey is used to treat infected leg ulcers in Ghana and earaches in Nigeria. Other uses include treatment of gastric ulcers and constipation (Getz 1991).

Honey in the Twentieth Century Before Antibiotics

In the early part of the twentieth century, the medical literature contained reports on the antimicrobial and healing properties of honey. Russian soldiers during World War I used honey to prevent infections in wounds and to accelerate healing (Bergman 1983). The effectiveness of honey to heal wounds spurred research into its antimicrobial activity, which was attributed to "inhibine." In 1963, inhibine was identified as hydrogen peroxide (White et al. 1963), a powerful oxidizer that kills bacteria, viruses, and fungi. During the first half of the twentieth century, there were many research papers documenting the wound-healing properties of honey. The medical profession did acknowledge the value of honey in the treatment of wounds, leg ulcers, and burns. The introduction of antibiotics shifted the focus to synthetic and mass-produced treatment. The medical uses of honey as effective treatment in wounds were forgotten.

Revival of Honey in Medicine

In 1976, an editorial in the *Archives of Internal Medicine* on medical folklore arrogantly dismissed honey as a "worthless but harmless substance" (Soffer 1976). Over the last two decades, reports from different parts of the world affirmed the effectiveness of honey in treating various wounds, burns, and serious infections. These reports and the emergence of drug resistant infections stimulated a number of scientists to conduct studies on honey, bringing about a resurgence of interest in the medical uses of honey. Recent research on honey has shed light on the mechanisms underlying its antimicrobial effects (Molan 1992). In summary, the antibacterial effects are due to

- *Osmotic effect*: Honey is a supersaturated sugar solution of fructose and glucose, which comprise 84%. The interaction of the sugar molecules with water molecules leaves very little water available to support the growth of microorganisms.
- *Acidity*: Honey is acidic, with a pH ranging from 3.2–4.5 which is low enough to inhibit the growth of many pathogens.
- *Hydrogen peroxide* is the major antibacterial compound in honey. Bees secrete the enzyme glucose oxidase from nectar. It converts glucose in the presence of water and oxygen to glucoronic acid and hydrogen peroxide. Both the acid and hydrogen peroxide preserve and sterilize the honey during the ripening process.
- *Nonperoxide antibacterial factors*: There have been reports of isolation of various antibacterial chemical substances from honey that are not hydrogen peroxide but their concentration is reportedly too low to contribute much antibacterial activity.

Honey has been reported to have an inhibitory effect to around 60 species of bacteria including aerobes and anaerobes, gram-positives and gram-negatives (Subramanyan 1991).

There are differences in the antibacterial activity of different honeys. Honey is produced from many different floral sources and its antibacterial activity varies with origin and processing. Long ago, both Aristotle and Dioscorides recommended that honey collected in specific regions and seasons, and presumably from different floral sources, be used for the treatment of particular ailments. Research has since shown that honey has certain organisms sensitive to it while others are resistant, and the sensitivity varies depending on the source of the honey. *Staphylococcus aureus* is one of the species most sensitive to the antibacterial activity of honey (Cooper et al. 2002).

Other beneficial effects of honey include (Molan 1992):

- Stimulation of the healing process, especially leg ulcers and diabetic ulcers.
- Speedy clearance of infection when used as dressing on infected wounds. Honey is reportedly extremely effective in the treatment of wounds infected with antibiotic resistant bacteria.
- Cleansing action on wounds: Honey has a debriding effect (removing dead, contaminated tissue) on wounds so that surgical debridement is unnecessary or only a minimum is required.
- Stimulation of tissue regeneration: Honey promotes the formation of clean healthy granulation tissue and growth of epithelia over the wound, thus helping skin regenerate. It has also been reported that dressing wounds with honey gives little or no scarring.
- Comfort honey dressings: Honey is nonirritating and the pain or discomfort associated with changing dressings is minimized.

The current main medical use of honey is in the treatment of infected wounds, chronic leg and skin ulcers, bedsores, especially in settings of drug-resistant infections (Cooper et al. 2002). The effectiveness of honey in wounds and ulcers has been known empirically for thousands of years and has recently been documented in clinical studies.

Honey is reportedly used by ophthalmologists for treating corneal ulcers in India and Russia where it has been used for chemical and thermal burns to the eye, conjunctivitis, and infections of the cornea.

Other traditional folklore medical indications of honey include peptic ulcers and gastroenteritis. At least two studies demonstrated that natural honey, but not commercial honey, was bactericidal against the bacterial isolates obtained and that different types of honey exhibited varying bactericidal concentrations (Haffejee and Moosa 1985).

Much of the wisdom of folk medicine has its roots in ancient beliefs held by people who understood neither chemistry nor anatomy. Honey is just the latest of the ancient remedies to be "rediscovered." There are abundant references in ancient writings indicating the beneficial effects of honey and other bee products.

The humble bee makes honey from countless varieties of plant blossoms, and it is logical to assume that by-products from the beehive such as honey contain many substances of medicinal value that modern medicine has yet to discover.

Huangdi Jiuding Shendan Jing

Fabrizio Pregadio

The *Huangdi jiuding shendan jing* (Book of the Divine Elixirs of the Nine Tripods of the Yellow Emperor) also known as *Jiudan jing* (Book of the Nine Elixirs) is one of the earliest extant Chinese alchemical texts. Quotations and other references in Ge Hong's *Baopu zi neipian* suggest that the text circulated in a form at least substantially similar to the current one by the end of the third century. The extant version, dating from the latter half of the seventh century, is found in the *Daozang* (Daoist Canon). It is followed by an extended commentary that represents in its own right a compendium of early medieval Chinese alchemy.

Besides its early date, the *Book of the Nine Elixirs* is significant as it provides one of the most complete descriptions of the alchemical practice in China, from the preliminary rituals to the compounding and ingestion of the elixirs. The ritual features include purifications, interdictions, secrecy, retirement, choice of time, delimitation of space, and ceremonies for transmitting the text, for starting the fire, and for ingesting the elixirs.

The compounding begins after the preliminary ritual practices. The first step consists in the preparation of an amalgam of refined lead and mercury, said to contain the essences of Heaven and Earth, or *Yin* and *Yang*. This compound is used as a layer in the crucible together with the ingredients of the elixirs. Then one prepares a mud used for sealing the crucible and prevent the loss of *qi* (energy), thus recreating inside the vessel conditions similar to those of primeval chaos.

The methods of the Nine Elixirs proper are based on processes of sublimation (*fei*). The substances most commonly used are mercury, orpiment, realgar, malachite, arsenolite, magnetite, cinnabar, alum, and hematite. The ingredients are first placed in a tightly sealed crucible, and heated on a fire progressively made more intense. After the required number of days, the crucible is left to cool and is opened. The essence is carefully collected from the higher part of the crucible, and mixed with a moistening substance. The elixirs should be ingested at dawn, facing the sun. Their ingestion is said to bestow eternal life, command over gods and spirits, protection from calamities, and sometimes magical powers. Some of the Nine Elixirs can be transmuted into alchemical gold. The text emphasizes that the purpose of this final transmutation is to make sure that the compounds have been correctly prepared.

Huangdi Neijing

RICHARD BERTSCHINGER

The *Huangdi Neijing* (Yellow Emperor's Inner Canon) is the most famous and oldest medical classic of China, being complied by various unknown authors from the period of the Warring States (475–221 BCE) onward. The book consists of two main sections, each of 81 chapters: the *Suwen* (Plain Questions) and *Ling Shu* (Miraculous Pivot), the latter being earlier entitled the *Zhen Jing* (Needling Classic).

These texts are the very earliest to be written on Chinese medical theory. However, Keegan has shown conclusively that none of the *Neijings* now extant are the original. Lu and Needham also summarized the evidence and considered that the corpus was probably already well formed by the first century BCE.

The Canon achieved something close to its known form with the recension (ca. AD 762) which came about with the editorship of Wang Ping during the Tang dynasty. Another edition, the *Huangdi Neijing Taisu* (Great Simplicity), recently discovered in Japan, may be considered closer to the original text. The insertion of chapters into the text, including those on *wuyun liuqi* (The Theory of the Five Elemental Cycles and Six Climates), undoubtedly took place some time close to the mid-tenth century (Lu and Needham 1980). Since this date, however, the contents have been fixed.

The book takes on a question and answer form, in which the legendary Yellow Emperor questions his ministers about the need for a medical reformation, in accord with the prevailing tone of Han thought. In the opening paragraphs the Emperor questions his minister-physician Qi Bo:

> The Yellow Emperor asked: "I have heard that the men of ancient times lived through a hundred springs and autumns, and remained active and did not reach senility. Now our men only reach half that age and they are senile. Are we so very different? Or have we missed something?"
> Qi Bo replied: "The men of ancient times, they understood the Way, they modelled themselves on Yin and Yang and were at peace with the arts of guiding their destiny. They ate and drank in moderation, they rose and retired at regular hours, neither made wild schemes, nor wearied their bodies at work… The men of the present day are not the same. They drink liquor to excess, they take wild thinking as the norm. When drunk they perform the act of love, seeking to exhaust their energies and waste their lives. They do not know how to be content. They have no time to control the passage of their thoughts, looking only for what cheers – not for the joys of health" (Ch. 1).

This sets the tone for the preventative and rehabilitative character which dominates Chinese medicine. Later in the chapter, the same need for ataraxia (peace of mind) is stressed:

> Detach and be at peace, humble and empty – and the true energies will follow. The vital spirit, guard it within! How then can disease arrive?

Among the Canon's other ideas are the well-developed tract system of 12 main channels and numerous collaterals (the *jingluo*); and the science of the five elements (*wuxing*): fire, earth, metal, water, and wood. It also introduces the classificatory dialectical tool of *Yin/Yang* (earth/heaven, dark/light, night/day, solid/hollow, etc.). Many chapters also describe the relationship between human beings and their environment, and refer in great detail to circadian, or internal, rhythms within the body. These biological clocks foreshadowed the modern science of chronobiology.

Surgery is also mentioned, and the *bian* stone needle as the forerunner of acupuncture. The Canon accurately identifies gangrene in the feet and says it is more common in the toes, where it advises amputation to save lives. This is just one of the many ideas prevalent in the book which accords with modern medical theory.

Huangfu Mi

Hong Wuli

Huangfu Mi was born in 215 in Anding Chao'na (now Pingliang County, Gansu Province) and died in 282. He was born to a poor family and did not receive any education until he was twenty years of age, after which he devoted all his time to reading, extensively and intensively, all kinds of ancient literature. He eventually became a great master in the art of classics.

During the period 256–260, he suffered *Feng Bi* or apoplexy and became hemiplegic. From then on, he began to study medicine. In view of the overlapping of many texts in several medical classics, he decided to compile a new book on the art of acupuncture and moxibustion under the principle of "sorting out the similarities, excluding the meaningless and useless words and sentences, deleting unnecessary repetition and extracting the essence". He did this by incorporating the relevant portions from the three classics, namely *Huangdi Neijing su wen* (*Plain Question of Huangdi's Inner Canon*), *Zhenjing* (*Classic of Acupuncture*), and *Ming tang kong xue zhen jiu zhi yao* (*Essentials of Treatment for Acupuncture and Moxibustion with Anatomical Charts and Acupoints*). A twelve-volume *Zhen jiu jia yi jing* (*A–B classic of Acupuncture and Moxibustion*) was written and divided into two parts. One of them deals with the physiology of the human body, indications for each acupoint, diagnostic measures, way of puncturing, and pathophysiology. The other part is devoted to clinical knowledge, including internal medicine, surgery, pediatrics, and gynecology, with special reference to internal medical science. Emphasis is laid on the unification of channels and acupoints and on exploration of indications and contraindications for acu-moxibustion therapy. This work, from which most of the works on acupuncture and moxibustion of later ages were derived, exerted great influence on the development of the art of acupuncture and moxibustion in successive generations. Erudite and learned, Huangfu Mi was very productive in his writings, including works on history and classical literature.

During his time, it was a custom to swallow processed stone remedies for seeking longevity and as an aphrodisiac. Huangfu Mi also practiced this behavior and was brought to the brink of death after a critical illness. After he fortunately recovered, he wrote a book, *Han shi san lun* (*On Stone Powder To Be Swallowed Cold*) to advise people to avoid such harmful and potentially fatal behavior.

Ḥunayn Ibn Isḥāq

Albert Z. Iskandar

Abū Zayd Ḥunayn Ibn Isḥāq al-ʿIbādī (Johannitius AD 808–873), a physician, philosopher, and translator, was born in al-Ḥīrah (Hira), now southeast of al-Najaf (Iraq). He and his ancestors were Syrians who belonged to the Nestorian church. The family nickname, al-ʿIbādī, is derived from "al-ʿIbād," a Christian Arab tribe.

Ḥunayn studied medicine in his youth in Baghdad. The thirteenth-century medical historian, Ibn Abī

Uṣaybiʿa, author of the book *ʿUyūn al-Anbāʾ fī Ṭabaqāt al-Aṭibbā* (Sources of Information about the Classes of Physicians), gives a lively account of the difficulties that confronted Hunayn as a student of medicine. Yūḥannā Ibn Māsawayh (Mesue d. AD 857) was a famous physician and a highly respected teacher of medicine. He conducted classes in a vast room in his large house. Questions from young Hunayn, who was very keen on amassing knowledge, interrupted the serenity of Mesue's lessons. Mesue reprimanded Hunayn several times without effect, then finally ordered him out of the classroom and told him to give up medicine. Mesue advised him to trade in coins instead, which he believed would be financially more rewarding than the practice of medicine. Mesue had in mind the fact that most of the residents of Hira were merchants and money changers. So far as one can tell, Hunayn abandoned Mesue's tutorship and decided on self-education.

Bakhtīshūʿ Ibn Jibrāʾīl, a contemporary of Ḥunayn, held regular meetings at which physicians and philosophers debated questions and problems raised by Caliph al-Mutawakkil (d. AD 861). Ḥunayn was invited to attend these meetings at which he showed medical acumen. Al-Mutawakkil is reported to have endowed a school of translation, and appointed Hunayn as its head. Among the members of this school were Ḥunayn's son, Isḥāq Ibn Ḥunayn (d. AD 910), who translated from Greek into Syriac and Arabic. He also took charge of revising, against the original Greek, translations by his colleagues. It is worth noting that Isḥāq's translations were carefully revised and corrected, whenever necessary, by Ḥunayn himself. Towards the end of his life, Ḥunayn embarked on an Arabic translation of Galen's *De partibus artis medicativae* (*On the Parts of Medicine; Fī Ajzāʾal-Ṭibb*), of which he had earlier rendered the Greek text into Syriac. Death prevented him from completing his translation. Isḥāq attended to Ḥunayn's unfinished work.

Another eminent translator in Ḥunayn's school was his nephew, Ḥubaysh Ibn al-Ḥasan al-Aʿsam, who was involved in translating Galen's (d. ca. AD 200) *De anatomicis administrationibus* (*On Anatomical Procedures; Fī ʿAmal al-Tashrīḥ*) into Arabic. This work consists of 15 books. It was translated into Syriac by Ayyūb al-Ruhāwī (Job of Edessa) for Jibrāʾīl Ibn Bakhtīshūʿ (d. AD 828–829). A revised Syriac translation was made by Ḥunayn himself for Yūḥannā Ibn Māsawayh. It is generally accepted that Ḥubaysh produced an Arabic version about the end of Ḥunayn's life, and with his active collaboration.

Ḥunayn's school of translation helped to establish a firm foundation upon which medieval Arabic medicine and allied sciences were securely built. Renowned Arabic-speaking physician–philosophers, like al-Rāzī (Rhazes d. AD 925) and Ibn Sīnā (Avicenna d. AD 1037), and many others, owe Ḥunayn and members of his school a great debt for rendering fundamental Greek texts of antiquity into Arabic, the language of learned men at the time.

Al-Mutawakkil elevated Ḥunayn to the post of Chief Court Physician and dismissed Bakhtīshūʿ Ibn Jibrāʾīl. The latter conspired against Ḥunayn, and, unfortunately, Ḥunayn fell from grace. Al-Mutawakkil ordered the sequestration of Ḥunayn's entire library.

Ḥunayn was 48 when he compiled the first draft of his *Risālat Hunayn Ibn Isḥāq ilā ʿAlī Ibn Yaḥyā fī Dhikr mā Turjima min Kutub Jālīnūs bi-ʿIlmih wa-baʿd mā lam Yu-tarjam* (Missive to ʿAlī Ibn Yaḥyā on Galen's Books Which, so far as Ḥunayn Knows, Have Been Translated, and Some of Those Books Which Have Not Been Translated). The fact that Ḥunayn's *Missive*, which presents impressive information about some of his predecessors and contemporaries, was compiled, he says, after the loss of his library, indicates his complete dedication to his work. ʿAlī Ibn Yaḥyā, to whom Ḥunayn's *Missive* was dedicated, was a powerful friend and a private confidant of Caliph al-Mutawakkil. Through his intercession, Ḥunayn later recovered his own library.

The following are a few examples to shed light on the depth of Ḥunayn's involvement in translating Galen:

- The *Pinax* (*Index; Fīnaks*) was translated into Syriac for a doctor named Dāʾūd and into Arabic for Muḥammad Ibn Mūsā
- *De ordine librorum suorum* (*On the Order of His Books*; *Fī Marātib Qirāʾat Kutubih*), into Arabic for Aḥmad Ibn Mūsā
- *De sectis ad eos, qui introducuntur* (*On Sects; Fī'al-Firaq*, into Syriac when Ḥunayn was 20 years of age, and another translation for Ḥubaysh when Ḥunayn was 40
- *De febrium differentiis* (*On the Types of Fevers; Fī Aṣnāf al-Ḥummayāt*), the first book to be translated by Ḥunayn, into Syriac, and another translation for his son when he discovered textual gaps which he filled in by collating against other manuscripts, and again into Arabic for Abu'l-Ḥasan Aḥmad Ibn Mūsā
- *De crisíbus* (*On Crisis; Fī'al-Buḥrān*). First Ḥunayn corrected a Syrīac translation by Sergius of Resaina (d. AD 536), then produced an Arabic version for Muḥammad Ibn Mūsā. All these and many more are discussed in detail in Ḥunayn's *Missive*

In spite of his fame as a translator, he was scoffed at by doctors when he wished to practice the art of physic. They admitted that he was an excellent translator, yet he was not a doctor, in the same way that a blacksmith could forge a beautiful sword without himself being a swordsman.

Ḥunayn was also a medical author in his own right. His books are mainly based on Greek sources, such as: *Fī Awjāʿ al-Maʿidah* (*On Stomach Ailments*) and *al-Masā'il fi'l-Ṭibb li'l-Muta'allímīn* (*Questions on Medicine for Students*). His book entitled *al-'Ashar Maqālāt fi'l-'Ayn* (*The Ten Treatises on the Eye*), covering both the theory and practice of medicine, ranks highly among medieval books of ophthalmology.

Historians of medicine and science are greatly indebted to Ḥunayn and his school of translation. Without their efforts, many of the works of antiquity would have probably been lost forever. Two examples will suffice. Galen's *On Anatomical Procedures* (*Fī'Amal al-Tashrīḥ*) of which Books IX (in part) and X–XV (inclusive) are lost in the original Greek, is preserved in its entirety in Arabic manuscripts. Again, Galen's book *De optimo medico cognoscendo* (*On Examinations by Which the Best Physicians are Recognized*) is entirely lost in the original Greek. Ḥunayn's Arabic version has survived in two manuscripts.

Huntian

Christopher Cullen

Huntian is the Chinese name for a scheme of cosmography, often mentioned as in opposition to the *gaitian*. According to explanations of this scheme, heaven is a sphere surrounding a flat earth whose upper surface lies across its diametral plane. Heaven is therefore continuous (*hun hun ran*), unlike the situation described by the *gaitian*, under which heaven has a boundary. The heavenly sphere rotates once daily about an axis inclined at 35° to the horizontal, carrying with it the heavenly bodies, whose risings and settings occur as they move above and below the plane of the earth's surface. The Chinese observer is imagined to be at the center of the earth, and hence at the center of the heavenly sphere. Since the latitude of most ancient Chinese capitals was about 35° north, the *huntian* universe acts as a sort of cosmic planetarium for the official astronomers at those capitals. Observers near the edge of the earth would see a very odd and asymmetrical series of celestial phenomena, but the diameter of the sphere is so large (one version gives a figure equivalent to over 140,000 mile) that the entire inhabited world is effectively at the center of the universe.

The first full account of the *huntian* cosmography is that of Zhang Heng, written ca. AD 117. Thereafter it is the usual scheme referred to by those concerned with mathematical astronomy, and a number of texts point out its advantages compared with the *gaitian*. The innovation of the *huntian* was apparently connected with the introduction of the armillary sphere in China at some time after 100 BCE. The nested rings of such an instrument are highly suggestive of the skeleton of the celestial sphere. It would be a mistake, however, to see debates on cosmography as a crucial concern for astronomers in China, since the algebraic/arithmetic character of Chinese mathematical astronomy meant that the detailed geometry of the cosmos was much less of an issue than it was in ancient Greece and Rennaissance Europe.

H

I

Ibn ʿAbbād

Zeina Matar

Abū al-Qāsim Ismāʿīl Ibn ʿAbbād Ibn al-ʿAbbās Ibn ʿAbbād Ibn Ahmad Ibn Idrīs, also known as Kāfī al-Kufāt, and al-Ṣāḥib, was a famous vizier and man of letters of the Buwayhid period. There is disagreement about his place and date of birth, but he was probably born at Iṣṭakhr on 16 Dhū'l-qaʿda 326/14 September 938. His family included high dignitaries, and his own father had been a *kātib* (clerk) and then vizier, or minister of state, under the Buwayhid Prince Rukn al-Dawla (r. 35/946–366/976).

Ibn ʿAbbād himself became the disciple and secretary of Abū'l-Faḍl Ibn al-ʿAmīd (d. 360/970), the father of the Buwayhid vizier Abū'l-Fatḥ Ibn al-ʿAmīd (b. 337/948–9). His close relationship to the Buwayhid *amīrs* (princes) is said to have begun in 347/958, when he accompanied Mu'ayyid al-Dawla (reigned 366/976–373/983) to Baghdad as a clerk. He was later confirmed in this office when Mu'ayyid al-Dawla became governor of Isfahan. Ibn ʿAbbād's career took a more significant turn when he was appointed vizier, replacing Abū'l-Fatḥ Ibn al-ʿAmīd.

Ibn ʿAbbād served two rulers: Mu'ayyid al-Dawla and Fakhr al-Dawla (reigned 373/983–387/997). The main source for the study of his vizierate remains the volume of the *Rasāʾil* (ʿAzzam 1946), which is a collection of administrative pieces, appointment, and other official letters by Ibn ʿAbbād. According to the sources, the personality of Fakhr al-Dawla was not really compatible with that of Ibn ʿAbbād, although he recognized the latter's administrative skills and talents. When Ibn ʿAbbād died on 24 Safar 385/30 March 995, Fakhr al-Dawla confiscated his property, and from that time onward, no other member of his family was to be appointed to a high official position.

Ibn ʿAbbād was not only a statesman and a politician, but he was also a talented writer whose works cover a very wide spectrum. In their article in the *Encyclopedia of Islam*, Claude Cahen and Charles Pellat give a classification of his works: dogmatic theology, history, grammar and lexicography, literary criticism, poetry, and belles-lettres.

In Abū Ḥayyān al-Tawḥīdī's *Mathālib al-Wazīrayn*, a comprehensive list of Ibn ʿAbbād's works is given. Some of the most important are:

- *Kitāb al-Muḥīṭ bi-ʿl-lugha* (The Comprehensive Treatise About Language) in 10 vols
- *Kitāb Dīwān rasā'ilihi* (Collection of Letters) in 10 vols
- *Kitāb al-Kāfī. Rasāʾil* (The Book of al-Kafī [that which is sufficient]. Letters [or Correspondence])
- *Kitāb al-Aʿyād wa-faḍā'il al-Nowrūz* (The Book of Feasts and the Excellent Qualities of New Year's Day)
- *Kitāb al-Wuzarāʾ* (The Book of Viziers)
- *Kitāb Dīwān Shiʿr(ihi)* (Collection of Poetry)

In the *Yatīmat al-dahr* (III, 204), al-Thaʿālibī commented on a *Risāla* on medicine said to have been written by Ibn ʿAbbād:

> I found that it combined beauty of style, elegance of expression, and mastery of the subtleties and particularities of medicine, and it showed that he was thoroughly familiar with this science, and had a penetrating knowledge of its intricacies.

Ibn ʿAbbād often inspired very contradictory opinions and feelings as is shown by Abū Ḥayyān al-Tawḥīdī's hostility on the one hand, and by al-Thaʿālibī's praise and admiration on the other. However, regardless of personal like or dislike, he certainly was a highly exceptional personality in Muslim history. Maybe one can refer to him as a "patron-vizier", a talented individual who had the ability to mix politics and literature, and a poet whose court once counted as many as 23 poets.

Ibn Al-ᶜArabī

William C. Chittick

Muḥyī al-Dīn ibn al-ᶜArabī is one of the most influential Muslim thinkers of the past seven hundred years. Born in Murcia in present-day Spain in 1165, he set out for the western lands of Islam in 1200, traveled in the Arab countries and Turkey, and, in 1223, settled in Damascus, where he lived until his death in 1240. He wrote voluminously and attracted the attention of scholars and kings during his own lifetime. His magnum opus, *al-Futūḥāt al-makkiyya* (The Meccan Openings) – inspired sciences that were "opened" up to his soul during his pilgrimage to Mecca – will fill some 15,000 pages in its new edition. His most widely studied work, *Fuṣūṣ al-ḥikam* (The Bezels of Wisdom), is a short explication of the various modalities of wisdom embodied by 28 of God's prophets, from Adam to Muhammad.

Ibn al-ᶜArabī's writings investigate every dimension of Islamic learning, from the *Qurʾān* and the *ḥadīth* (the sayings of Muḥammad) to grammar, law, philosophy, psychology, and metaphysics. His basic intellectual project was to illustrate the unity of all human endeavors and the underlying, interrelated functions of all human thinking. He cannot be classified as a philosopher, theologian, scientist, or jurist, though his works address most of the basic epistemological issues of these disciplines. He saw himself as an inheritor of the wisdom of the prophets, but one who was given the duty of explaining this wisdom in the subtlest intellectual discourse of the day – at a period that is looked back upon as the high point of Islamic learning. He provides no system, but rather a unified vision that is capable of spinning off innumerable systems, each of them appropriate to a given field of learning or level of understanding. He offers many ways of approaching the basic questions of human existence, such as the nature of reality itself, the role of God, the structure of the cosmos and the human psyche, the goal of human life, and the relationship of minerals, plants, and animals to other creatures. In short, he provides basic patterns for establishing complex systems of metaphysics, theology, cosmology, psychology, and ethics.

Ibn al-ᶜArabī was followed by a number of major thinkers who systematized his "openings" in various ways, depending upon their own orientations and intellectual contexts. The diverse interpretations given to his works are especially obvious in a series of over 100 commentaries that have been written on his *Bezels of Wisdom* from the thirteenth century down to modern times. His stepson Ṣadr al-Dīn Qūnawī (d. 1274) had probably the keenest philosophical mind among Ibn al-ᶜArabī's followers. Qūnawī in turn trained many disciples, several of whom wrote widely influential works. Saᶜīd al-Dīn Farghānī (d. 1296) provided systematic expositions of the teachings of both Qūnawī and Ibn al-ᶜArabī in Arabic and Persian. Fakhr al-Dīn ᶜIrāqī (d. 1289) was a poet who wrote a delightful summary of Qūnawī's teachings in mixed Persian prose and poetry that helped popularize Ibn al-ᶜArabī's teachings. Muʾayyid al-Dīn Jandī (d. ca. 1300) wrote in Arabic the first detailed commentary on Ibn al-ᶜArabī's *Bezels of Wisdom*. The intellectual tradition established by Ibn al-ᶜArabī and Qūnawī gradually merged with various branches of Islamic philosophy, yielding a wide range of intellectual perspectives that dominated the Islamic wisdom tradition down to the coming of Western colonialism.

In order to grasp Ibn al-ᶜArabī's importance for the history of scientific thought in Islam, one needs to understand his basic accomplishment, which was to establish an honored place in the Islamic intellectual tradition for supra-rational knowledge. From their inception in the eighth and ninth centuries, the mainline schools of theology and philosophy in Islam had endeavored to understand the Quranic revelation on the basis of rational modes of investigation taken over from the Greek heritage. Parallel to this, there developed a more practical, existential approach that found the goal of human life in direct experience of the presence of God. This second approach, which came to be called by the umbrella term "Sufism," laid stress upon supra-rational modes of knowledge that are collectively known as *kashf* (unveiling), i.e., the lifting of the veils that separate the human soul from God. Unlike some Sufis, Ibn al-ᶜArabī was not opposed to acknowledging the authority of reason. However, he maintained that unveiling was a higher form of knowledge, because it grows out of the unmediated perception of God's actuality. In Ibn al-ᶜArabī's way of looking at things, reason tends innately to divide and discern. It eliminates connections between God and the cosmos and understands God as distant and transcendent. In contrast, unveiling works by seeing sameness and presence; hence God is perceived as near and immanent. Perfect knowledge of God and of reality as a whole depends upon a happy balance of reason and unveiling. Only through this balance can God be perceived in appropriate modes as both absent and present, near and far, transcendent and immanent, wrathful and merciful. Ibn al-ʿArabī's works are devoted largely to explaining the vast range of these appropriate modes.

The long term effect of the marriage between reason and unveiling effectuated by Ibn al-ʿArabī is symbolized by his meeting when still a boy – of perhaps 15 years – with the philosopher Ibn Rushd (Averroes d. 1198). Ibn al-ʿArabī had already experienced the opening of the unseen worlds, and Ibn Rushd, who was a friend of his father, had asked to meet him. In the brief exchange that took place, Ibn Rushd asked if unveiling and reason achieved the same goals. Ibn al-ʿArabī replied, "Yes and no." Then, in cryptic language, he affirmed that reason was a valid route to achieve knowledge of the nature of things, but he denied that it exhausted the possibilities of human knowing. In the West, the teachings of Ibn Rushd were employed to help establish nature as an autonomous realm of intellectual endeavor. Under the discerning eye of reason, God was abstracted from perceived reality, eventually becoming a hypothesis that could be dispensed with. The world of nature was now the proper site for rational analysis and dissection, and the result has been the ever-increasing fragmentation of human knowledge, with a total divorce between science and ethics. In contrast, Ibn Rushd was forgotten in the Islamic world, but Ibn al-ʿArabī and his followers succeeded in establishing a harmony between reason and unveiling. Hence Muslim intellectuals were never able to conceive of nature as a realm cut off from God. If God is present in all things, then the ethical and moral strictures that he establishes through revelation need to be observed at every level. It becomes impossible to investigate the natural world without at the same time investigating its relationship with God and recognizing the moral and ethical demands that this relationship entails.

Ibn al-ʿArabī's career and teachings exemplify the dimensions of Islamic learning. The worldview to which he gave detailed expression provided a perspective from within which Muslim intellectuals were able to answer the deepest questions of the human mind. Ibn al-ʿArabī's achievements contributed to an intellectual equilibrium that refused to subordinate the spiritual demands of human beings to corporeal demands and that gradually established a vast framework within the context of which the intellectual disciplines came to be ever more united and interrelated. This holistic perspective on knowledge in turn prevented the fragmentation of the Islamic worldview and allowed no room for "declarations of independence" by specific schools of science or philosophy. Given that ethics, morality, and spiritual development lay at the heart of this perspective, it was impossible to divorce any branch of science or learning from these concerns.

Ibn Al-Aʿlam

Raymond Mercier

Ibn al-Aʿlam, Abū'l-Qasim ʿAlī ibn ʿIsa al-Husain, al-ʿAlawī, al-Sharīf was a tenth century astronomer, apparently established in Baghdad. The year of his death is recorded by Ibn al-Qifṭī as 375/985. The *Zīj* (astronomical handbook with tables) which he wrote is lost, but substantial information about it may be gleaned from notices in the work of other astronomers. His work was patronized by the Būyid ruler ʿAḍūd al-Dawla but suffered from lack of support in the disturbed period which followed his death in 372/982.

A near contemporary, the great astronomer Ibn Yūnus of Cairo, reports that Ibn al-Aʿlam had fixed the length of the year as 365; 45, 40, 20 days, determined the position of Regulus (α Leonis) in the year 365/975–6 as 15; 6 Leo, and also fixed the rate of precession, one degree in 70 Persian years. He remarks that Ibn al-Aʿlam was known everywhere for the exactitude of his observations and the extent of his geometrical knowledge.

Al-Bīrūnī in his work *Tamhīd al-mustaqarr li-taḥqīq maʿnā al-mamarr* (On Transits) gives the name of his *Zīj* as *al-ʿAdūdī*, and incidentally provides values for the radius of the epicycles for each of the planets.

In spite of the loss of the *Zīj* full information about its parameters may be obtained from two sources compiled in the fourteenth century, the Persian *Zīj-i Ashrafī*, and an anonymous Arabic collection known as the *Dastūr al-Munajjimīn*. Information is also available from Greek sources, in which Ibn al-Aʿlam is referred to as Alim (‘*Αλημ*). The Greek manuscripts are of the fourteenth and fifteenth centuries, but they preserve texts older than the Persian and Arabic compilations. These include *scholia* to the *Almagest* datable to AD 1032 which refer to tables composed for the Greek calendar from the work of Ibn al-Aʿlam, as well as two horoscopes for the years AD 1153 and AD 1162 which have been calculated from such tables, apparently for the Emperor Manuel Comnenus. The tabulation of the equations indicates that the technique of “displacements” was used in order to provide values of the equations which were always positive.

Ibn al-Bannāʾ

Emilia Calvo

Ibn al-Bannāʾ al-Marrākushī, Abū-i-ʿabbās Aḥmad ibn Muḥammad ibn ʿUthmān al-Azdī was born in Marrakesh, Morocco on 29 December 1256 and died, probably in Marrakesh, in 1321. He studied the Arabic language, grammar, the *Quʾrān*, *Ḥadīth* (commentaries of the prophet), and also mathematics, astronomy, and medicine; but his fame is due to his knowledge of mathematics. His teachers in this field were Muḥammad ibn Yaḥyā al-Sharīf, Abū Bakr al-Qallūsī, and Abū ʿAbd Allah ibn Makhlūf al-Sijilmāsī. He also studied medicine with al-Mirrīkh.

Among his disciples were al-Lajāʾī, teacher of Ibn Qunfūdh, Muḥammad ibn Ibraḥim al-Abūlī, Abū-l-Barakāt al-Balāfiqī, and Ibn al-Najjār al-Tilimsānī.

He is credited with having written more than 80 works. Among them are an introduction to Euclid, a treatise on areas, an algebra text, a *Kitāb al-anwāʾ* (about asterisms and stars used in meteorology and navigation), an almanac, two abridgements of treatises by Ibn al-Zarqāllu on the use of the *ṣafīḥas* (astrolabes) *zarqāliyya* and *shakkāziyya* entitled, respectively, *Risālat al-ṣafīḥa al-mushtaraka ʿalā al-shakkāziyya* (Epistle on the Shakkāziyya Plate), in 23 chapters, and *Taqbīl ʿalā risālat al-ṣafīḥa al-zarqāliyya* (Epistle on al-Zarqālī’s Plate). However, his two most important works are the *Minhāj* and the *Ṭalkhīṣ*.

The *Kitāb minhāj al-ṭālib li taʿdīl al-kawākib* (The Way of Him Who Seeks the Equation of the Planets) is a very practical book for calculating astronomical ephemerides. This *zīj* (astronomical handbook with tables) is based on the one by Ibn Isḥāq. The two of them are highly dependent on Ibn al-Zarqāllu’s astronomical theories.

The *Talkhīṣ aʿmāl al-ḥisāb* (Summary of Arithmetical Operations) was widely diffused in the Arabic world because of its conciseness, which makes it easy to memorize. Al-Qalaṣādī, among others, wrote an important commentary on it. A different version of this work, more extensive and complete, has been edited recently by Saidan (1984) under the title *Al-maqālāt fī ʿilm al-ḥisāb li-Ibn al-Bannāʾ* (The Treatises on the Science of Computation by Ibn al-Bannāʾ). The procedures found in the *Talkhīṣ* are studied here in a more detailed way.

Ibn al-Bayṭār

Emilia Calvo

Ibn al-Bayṭār al-Mālaqī, Ḍiyāʾ al-Dīn Abū Muḥammad ʿAbdallāh ibn Aḥmad, was a pharmacologist born in Málaga, Spain at the end of the twelfth century (ca. AD 1190–1248). He studied in Seville with Abū-l-ʿAbbās al-Nabātī, ʿAbdallāh ibn Ṣāliḥ, and Abū-l-Hajjāj. He was interested in the works of al-Ghāfiqī, al-Zahrāwī, al-Idrīsī, Dioscorides, and Galen.

Around AD 1220 he migrated to the East and, in 1224, arrived in Cairo where he was named chief herbalist by the Ayyūbid Sultan al-Kāmil. He traveled through Arabia, Palestine, Syria, and Iraq. Ibn Abī Uṣaybiʿa was one of his followers and left a mention of his teacher full of praise in his *ʿUyūn*.

Among Ibn al-Bayṭār's works we can mention *Al-Mughnī fīʾl-adwiya al-mufrada* (The Complete Book on Simple Drugs), dedicated to al-Kamil's son, Sultan al-Ṣāliḥ and dealing with the simple medicines, and *Al-Jāmiʾ li-mufradāt al-adwiya wa-l-aghdhiya* (Compendium of Simple Drugs and Food), which enumerates alphabetically some 1,400 animal, vegetable, and mineral medicines, as well as some 150 authorities including al-Rāzī and Ibn Sīnā.

Ibn al-Bayṭār's main contribution is the systematization of the discoveries made by the Arabs during the Middle Ages in this field. He was also concerned with synonymy, finding the technical equivalents between the Arabic and Persian, Berber, Greek, Latin, and Romance languages. The *Jāmiʾ* had great influence in the Near East, but less in the West. Andrea Alpago used it in his works on Ibn Sīnā.

Other works of Ibn al-Bayṭār, less known than the aforementioned two, are *Mizān al-ṭabīb* (The Measure of the Physician), *Risāla fīʾl-aghdhiya waʾl-adwiya* (Treatise on Food and Medicines), *Maqāla fīʾl-laymūn* (Treatise on the Lemon), and *Tafsīr kitāb Diyusqūrīdis* (Explanation of Dioscorides' Book) in which he inventories 550 medicines found in the first four books of Dioscorides.

Ibn al-Hāʾim

Julio Samsó

ʿAbd al-Ḥaqq al-Ghāfiqī al-Ishbīlī is known as Ibn al-Hāʾim. He was an Andalusian astronomer, probably from Seville. He dedicated (ca. 1204) his very important *al-Zīj al-Kāmil fīʾl-Taʿālīm* (The Perfect Handbook on Mathematical Astronomy) to the Almohad Caliph Abū ʿAbd Allāh Muḥammad al-Nāṣir (1199–1213). This work, which is extant in a unique and incomplete manuscript in the Bodleian Library at Oxford University, was influential in the Maghreb and contributed to the development there of a new kind of astronomy in the Andalusian tradition. As a *zīj* (astronomical handbook with tables), it is exceptional in Western Islam, because it contains a highly technical and complete exposition of Ptolemaic astronomy with geometrical demonstrations, and not a simple set of instructions for the use of the tables. It also conveys new information on the astronomical works of the Toledan school of the eleventh century, the main representative of which was Ibn al-Zarqāllu/Azarquiel (d. 1100), as well as new planetary parameters. Ibn al-Hāʾim appears as a defender of Zarqāllian orthodoxy and harshly criticizes Ibn al-Kammād (fl. beginning of the twelfth century) for his modifications of Ibn al-Zarqāllu's doctrines. Ibn al-Hāʾim's *zīj* contained numerical tables (three have been preserved in the *zīj* of Ibn Isḥāq, who flourished in Tunis at the beginning of the thirteenth century) but an incomplete copy must have circulated early for Ibn al-Raqqām (d. 1315) states that Ibn al-Hāʾim did not include any tables in his work.

Ibn Al-Haytham (Alhazen)

Roshdi Rashed

Among the mathematicians of classical Islam, few are as famous as al-Ḥasan ibn al-Ḥasan ibn al-Haytham (Alhazen in the Latin West). A physicist and astronomer as well as mathematician, he quickly gained a wide reputation, first in Arabic, in the Islamic East as well as the Islamic West, and then from the translations of his works in optics and astronomy into Latin, Hebrew, and Italian.

But his renown, completely justified by the importance of his contributions and especially of the scientific reforms accomplished in them, contrasts singularly with the paucity of information we have on the man, his teachers, or his scientific milieu. Also, the significance of his works surrounded the man with the aura of a legend. Sources available to us consist of narratives recounted by ancient bibliographers where legend becomes mixed up with the rare historical evidence. These same narratives are precisely what modern bibliographers continue to reproduce partially or totally until today. After a critical reading of these sources, very little information remains: born in Iraq, most likely in Bassorah, sometime in the second half of the tenth century, Ibn al-Haytham arrived in Cairo, under the reign of Faṭimid al-Ḥākim. He proposed a hydraulic project to control the waters of the Nile, but it was rejected by the Caliph. He continued to live in Cairo until his death, after 432/1040.

From the thirteenth century until today, biographers have confused al-Ḥasan ibn al-Haytham with Muḥammad ibn al-Haytham, a philosopher and theorist of medicine who lived in Baghdād at the same time. This confusion, due undoubtedly to similarity of the two names of these contemporary authors, is serious as it brings into question the authenticity of certain writings attributed to al-Ḥasan ibn al-Haytham.

Biobibliographers, notably al-Qifṭī, cite 96 titles of Ibn al-Haytham, not all of which have survived. Half of his writings are in the field of mathematics, 14 on optics, including the authoritative and voluminous *Kitāb al-Manāẓir* (Book of Optics), 23 on astronomy, two in philosophy (one on the *Place* and the other on the *Indivisible Part*), three on statics and hydrostatics, two on astrology, and four on various other topics. This accounting shows clearly that Ibn al-Haytham grappled with all the mathematical sciences of that time, or at least the most advanced part of this discipline. We will see that he was always at the leading edge of research or at the culmination of one tradition and the beginning of a new period. It is precisely this quality which distinguishes his contributions. Ibn al-Haytham lived at a privileged time, his work following a century of intense research in these fields by eminent scholars such as the Banū Mūsā, Thābit ibn Qurra and his grandson Ibrāhīm ibn Sinān, al-Qūhī, and Ibn Sahl, to name a few. We will now briefly examine the principal aspects of his research.

Mathematics

Ibn al-Haytham's mathematical research was particularly in the field of geometry and not of algebra. Ancient biobibliographers attributed a boọk on algebra to him, but it has not survived. From the outset, geometers wanted to combine closely the study of the positions of figures and their metric properties: in other words, to combine the geometry of Apollonius with that of Archimedes. This combination is not a static synthesis, but a new organization of geometry which possessed a real heuristic value. Already initiated by al-Ḥasan ibn Mūsā and followed by Thābit, this work led to the study of geometric transformations and of projective methods. It was this work which Ibn al-Haytham developed further in his own geometrical studies.

The contributions of Ibn al-Haytham in geometry can be divided into several groups, the most important of which are in infinitesimal mathematics and the theory of conic sections and their applications. He composed 12 treatises on infinitesimal mathematics and then on conic theory. To those can be added a third area in which Ibn al-Haytham takes up several problems relating to the foundations of mathematics and their methods in his treatise *Maqāla fī'l-taḥlīl wa 'l-tarkīb* (On Analysis and Synthesis), his *Kitāb fī al-ma 'lūmāt* (On the Known Things), his *Sharḥ Uṣūl Uqlīdis fī 'l-handasa wa 'l-ʿadad wa talkhīṣuhu* (Commentary on the *Elements* of Euclid), and his *Kitāb fī Ḥall shukūk Kitāb Uqlīdis fi 'l-uṣūl wa-sharḥ maʿānīh* (Solutions to Doubts) again concerning Euclid. In these books, he deals as much with the constitution of a new discipline, a kind of proto-topology, as with the theory of the demonstration within the difficulties raised by the fifth postulate of Euclid, or with the theory of parallels. Ibn al-Haytham also edited an important paper on number theory, four treatises on arithmetic, and the same number on practical geometry.

Of the 12 papers on infinitesimal mathematics, only seven have survived. The first three are devoted to the study of lunes and the quadrature of a circle. Note that the calculation of the area of lunes involves the calculation of sums or differences of areas of sectors or of triangles, the comparison of which has recourse to that of the ratio of angles or of the ratio of segments. In the most important of the three papers, Ibn al-Haytham begins by setting up four lemmas, the results of which demonstrate the role of the function f, defined as

$$f(x) = \frac{\sin^2 x}{x}$$

in the study of lunes.

In his study *Tarbīᶜ al-dāʾira* (On the Quadrature of a Circle), he examines the relationship between proving the existence of a magnitude or a property and the question of effectiveness of its construction.

Other treatises on infinitesimal mathematics deal with the volume of a solid curve: *Misāḥat al-mujassam al-mukāfiʾ* (The Measurement of a Paraboloidal Solid) and *Misāḥat al-kura* (The Measurement of a Sphere). In calculating the volume of a paraboloid, Ibn al-Haytham deals rapidly with the volume of a revolving paraboloid, which had already been studied by Thābit ibn Qurra and al-Qūhī. He then moves on to his own invention: how to calculate the volume of a paraboloid obtained from the rotation of a parabola around its ordinate. He shows that this volume is 8/15 of the volume of the circumscribed cylinder. His calculation is equivalent to that of the integral

$$\pi \int_a^b k^2 (b^2 - 2b^2 y^2 + y^4) \mathrm{d}y = \frac{8}{15} \pi k^2 b^5 = \frac{8}{15} V,$$

with V being the volume of the circumscribed cylinder.

Ibn al-Haytham proceeded in this study with the help of the method of integral sums, which he also applied in calculating the volume of a sphere. In order to do this calculation, Ibn al-Haytham generalized the proposition X-1 of Euclid's *Elements*. He devoted the seventh paper in this group to that. This group includes an important treatise devoted to isoperimetric and isepiphane problems. It was the most advanced mathematical work of its time and for several centuries following. In it, to study these *extrema*, he had to undertake the first substantial research on the theory of a solid angle. Moreover he combined both a projective method and an infinitesimal method.

Ibn al-Haytham's second group of mathematical writings dealt with the theory of conic sections. He was well acquainted with the *Conics* of Apollonius and had copied them in his own hand, so he knew that, in Greek, the eighth and last book was lost. He tried to reconstruct the book according to the indications of Apollonius. In addition to his writings on conics, he applied the theory of the intersection of conics to the resolution of problems which cannot be constructed with a compass or ruler, problems either passed down (for example, the regular heptagon) or posed by him (for example, the solution of a solid arithmetic problem). Ibn al-Haytham was one of the first mathematicians who insisted on demonstrating the existence of the point of intersection of two conics in these last examples.

It is impossible in this space to explicate the mathematical results of Ibn al-Haytham's work. But let us simply note his expression of what is called Wilson's theorem, and the converse of Euclid's theorem for perfect numbers.

Indeed, in the course of solving the problem called the Chinese Remainder, he stated Wilson's theorem, which can be written as:

n is prime

$$(n-1)! - 1 (\mathrm{mod}\, n).$$

As for the converse of Euclid's theorem of perfect numbers, he tried to show that any even perfect number is in Euclidean form, in other words in the form $2^p(2^{p+1} - 1)$ with $(2^{p+1} - 1)$ prime.

Optics

A brief look at the work of Ibn al-Haytham on optics reveals not only its revolutionary nature but also its comprehensiveness, touching all the known branches of optics: optics in its proper sense in his *Book on Optics* and his *Discourse on Light*; catoptrics, notably burning mirrors (parabolic and spherical burning mirrors); dioptrics, in *al-Kura al-muḥriqa* (The Burning Sphere); and meteorological optics in *Dawʾal-qamar* (The Light of the Moon), *Aḍwāʾ al-kawākib* (The Light of the Stars), *Fī ṣūrat al-kusūf* (On the Shape of the Eclipse) and *al-Hāla wa-qaws quzaḥ* (The Halo and the Rainbow). With this extension, Ibn al-Haytham modified the meaning of optics. Optics is not any more reduced to a theory of direct vision, a geometry of the gaze with which a theory of vision is associated, but also bears significantly on the theory of light, its propagation, and its effects as a material agent. This leads us to the revolution accomplished by Ibn al-Haytham in optics and more generally in physics.

Ibn al-Haytham sought to bring about a program of reform, which led him to take up a whole range of different problems. The basic aspect of this reform was to clarify the difference between the conditions of the propagation of light and the conditions of the vision of objects. This led, on the one hand, to giving physical support to the rules of propagation – making a firm mathematical analogy between a mechanical model of the movement of a solid ball thrown against an obstacle and that of light – and on the other hand to proceeding geometrically at all times, both by observation and by experimentation. Optics consisted henceforth of two parts: one, a theory of vision and the associated physiology of the eye and psychology of perception, and the other, the theory of light to which are linked geometric optics and physical optics. The organization of the *Optics* reflects this new situation: there are chapters devoted entirely to propagation, such as the third chapter of the first book and books IV to VII; others deal with vision and related problems. This reform also resulted in the emergence of new problems, such as Alhazen's problem in catoptrics, the examination of the spherical lens and the spherical diopter, not only as burning instruments but also as optical instruments in dioptrics, and to experimental control, viewed as much as a general practice of investigation as the norm of a proof in optics, and more generally in physics. Let us now take a quick look at how this reform in optics was carried out.

Ibn al-Haytham rejected any doctrine of a ray stemming out from the eye, called a visual ray, in order to defend the intromissionist theory of visible forms. But unlike the intromissionists of antiquity, he did not believe that objects sent off "forms" or totalities which emanated from the visible under the effect of light. He saw them rather as forms reducible to their elements: a ray emanating toward the eye from every point of a visible object. Looked at thus, the eye becomes a simple optical instrument. Ibn al-Haytham then explained how the eye perceives the visible with the help of its rays emitted from all points. In the *Optics* he devotes the first three chapters to the foundations of this theory. In the three following chapters, he deals with catoptrics. The seventh and last chapter is devoted to dioptrics. His theories rest on two qualitative laws of refraction and on several quantitative rules, all controlled experimentally with the help of an instrument which he designed and built himself. The two qualitative laws, known to his predecessors Ptolemy and Ibn Sahl, can be stated as follows:

1. The incident ray, the normal at the point of refraction, and the refracted ray are in the same plane; the refracted ray gets closer (respectively, far away) from the normal, if light passes from a milieu less (respectively, more) refringent to a milieu more (respectively, less) refringent
2. The principle of inverse return

Instead of pursuing the path opened up by his predecessor Ibn Sahl, Ibn al-Haytham returned to a study of angles in order to establish the quantitative rules. He devoted a substantial part of the seventh book to a study of the refracted images of an object, notably if the surface of separation of two milieux is either planar or spheric. It was in the course of this study that he fixed his attention on the spherical diopter and the spherical lens. He returned to the spherical lens in his treatise *On the Burning Sphere*, one of the high points of research in classical optics, in order to improve upon certain results that he had already obtained in his *Optics*. This treatise was the first deliberate study on the spherical aberration for parallel rays falling on a glass sphere and giving off two refractions.

Astronomy

By their number, their thematic variety, the power of the analysis they show, and by their results, the works of Ibn al-Haytham in astronomy yield nothing to his works in mathematics or optics. It should be noted only that an elementary treatise of Muḥammad ibn al-Haytham, the *Commentary on the Almagest* is often erroneously attributed to Ibn al-Haytham. The attribution of the book *On the Configuration of the Universe* to him is also doubtful. The authentic works of Ibn al-Haytham have not yet been seriously studied, *a fortiori*, apart from a few rare and particular contributions, such as the *Samt al- ibla bi-al-ḥisāb* (Determination of the Direction of Mecca by Calculation). It remained for subsequent astronomers, notably al-ʿUrḍī, one of the founders of the school of Marāgha, to recognize their debt to Ibn al-Haytham's book *al-Shukūk ʿalā Baṭlamyūs* (Doubts on Ptolemy). Before assessing his contribution in astronomy, we must wait until his books have received the editing and study that they deserve.

The impact of the work of Ibn al-Haytham varies according to the field. In mathematics, his influence can be seen in the works of Ibn Hūd, al-Khayyām, Sharaf al-Dīn al-Ṭūsī, and al-Samaw'al, among others. But we do not know anything of successors who might have tried to follow up on his research on lunes, the solid angle, or the measurement of figures and solid curves. In optics, the Latin translation of his *Optics* (under the title *Perspectiva* or *De Aspectibus*, reedited in 1572 under the title *Opticae Thesaurus*) and his treatise *On Parabolic Burning Mirrors* provided a basis of research for centuries of scholars such as Witelo, Roger Bacon, J. Peccham, Frederick of Fribourg, Kepler, and Snell, among many others. In Arabic, there is the commentary of Kamāl al-Dīn al-Fārsī. Finally in astronomy, there is the work of al-ʿUrḍī which shows the influence of his work. It is too soon to measure the impact of the writings of Ibn al-Haytham on his successors in this field also, but they appear to be immense.

Ibn al-Kammād

Julio Samsó

Abū Jaᶜfar Ahmad ibn Yūsuf ibn al-Kammād was an Andalusian astronomer who flourished in Cordoba toward the end of the eleventh century and the first half of the twelfth. He was probably a direct disciple of Ibn al-Zarqāllu/Azarquiel (d. 1100) as well as the student who helped him in observations made in Cordoba during his last years. He compiled three sets of astronomical tables (*zījes*) of which only one (*al-Muqtabis*) is extant in a Latin translation made by Johannes of Dumpno in Palermo (1262). In it he appears as a follower of the Zarqallian tradition, although he often corrects his master's parameters. Toward 1204, Ibn al-Hāᵓim makes a strong criticism of one of his other two *zījes* (*al-Amad ᶜalāᵓl-abad*, Valid for all Eternity) because of his departures from Zarqallian orthodoxy. Also extant, in Arabic, is a small astrological work in which Ibn al-Kammād studies the problem of the length of human pregnancy and the determination of the exact moment of the conception.

His work was influential in late Maghribean and Egyptian astronomy, for quotations and tabular materials from his *zījes* appear in the thirteenth century *zīj* of Ibn Isḥāq al-Tūnisī in Abūᵓl-Ḥasan ᶜAlī al-Marrākushī's treatise on *mīqāt* (Astronomy Applied to Muslim Worship) and in a fourteenth century anonymous Egyptian treatise on the same topic.

Ibn al-Majūsī

Sami Khalaf Hamarneh

Abū'l-Ḥasan ᶜAlī ibn al-ᶜAbbās ibn al-Majūsī was considered one of the leading Muslim physicians of his time. He was of Zoroastrian ancestry, and therefore called the Magian, and he is known in Latin as Haly ᶜAbbās. He was born in the old Persian city of Arrajān, in the southwest of Iran, at the end of the first quarter of the tenth century. He studied medicine under a leading medical tutor (*shaykh*) named Abū Māhir Mūsā ibn Yūsuf ibn Sayyār, who died ca. AD 983.

When he had developed a reputation for excellence and skill, Ibn al-Majūsī was invited to become a physician-in-ordinary at the palace of King ᶜAḍud al-Dawlah Fannā Khusraw, who reigned from AD 949 to 983 in Shīrāz. He was the Buwayhid Shāh who founded al-ᶜAḍudī Bīmāristān, the famous hospital in Baghdad that lasted for almost three centuries. In that period, the Buwayid Dynasty's power and glory reached their apex.

In recognition of the King's generosity and patronage to the sciences and the arts, Ibn al-Majūsī dedicated his medical encyclopedia, *Kāmil al-Ṣināᶜah al-Ṭibbīyah*, known also as *Kitāb al-Malikī* (Latin *Liber regius*, presented to the King's royal library) in Shīrāz.

The book comprises two parts, the theoretical and the practical, each of which has ten treatises. It brought together original contributions on public health, preventive medicine, dietetics, materia medica, therapy, surgery, clinical observations, and practical medicoethical procedures. *Kitāb al-Malikī* was first rendered into Latin by Constantine Africanus (AD 1020–1087) under the title *Pantegni*, without giving credit to its original author. Al-Majūsī was fully recognized when the book was translated from Arabic into Latin by Stephen of Antioch in 1127. Since then, many editions in Latin and Arabic have appeared, and a facsimile edition was published in 1985 in two volumes.

Among the Arabic compendia on the theme of the healing arts in Islam, Majūsī's *Kitāb al-Malikī* stands as one of the leading texts in its style, systematization, and precision. It was well read among students and practitioners alike. The judge and historian Ibn al-Qifṭī praised Majūsī by saying that he "excelled in the study of medicine, [and] worked hard to comprehend its doctrines and laws from the original sources."

Ibn al-Majūsī died in Shīrāz in AH 384/AD 994, leaving behind an essential document in the Arabic legacy to the history of the medical sciences in this golden age.

Ibn al-Nafīs

Albert Z. Iskandar

Ibn al-Nafīs, ʿAlāʾ al-Dīn Abu'l-Ḥasan ʿAlī Ibn Abī al-Ḥazm al-Qurashī, was born in a village near Damascus (Syria). He studied medicine at the Great Nūrī Hospital (*al-Bīmāristān al-Nūrī*) in Damascus, founded by the Turkish ruler Nūr al-Dīn Maḥmūd Ibn Zankī (d. AD 1174). He chose to live, practice, and teach medicine in Egypt, where he eventually became a Chief of Physicians, and was also a personal doctor to the then-ruler al-Ẓāhir Baybars (r. ca. AD 1260–1277).

In addition to practicing medicine, he was a Shāfiʿī jurist, thoroughly educated in Islamic theology and jurisprudence at the Masrūriyya School (*Madrasa*) in Cairo. Hence, he is classed as a "jurist physician," thus deviating from the traditional image of the physician–philosopher Galen (d. ca. AD 200), which was so faithfully emulated by many medieval Arabic-speaking doctors, as for example al-Rāzī (Rhazes, d. AD 925) and Ibn Sīnā (Avicenna, d. AD 1037).

Ibn al-Nafis was a prolific author. Among his medical works is *Kitāb al-Shāmil fi 'l-ṣināʿa al-Ṭibbiyya* (Comprehensive Book on the Art of Medicine). He jotted down preparatory notes for this voluminous book in 300 volumes, of which he managed to publish only 80. Its manuscripts, so far unpublished, are to be found in Cambridge University Library (Cambridge, England), the Bodleian Library (Oxford, England), and al-Muthaf al-ʿIrāqī (Iraq). In 1960, three autographed manuscripts of this book were discovered in the Lane Medical Library (Stanford University). The first, referred to by Ibn al-Nafis himself as the 33rd *mujallad* (bound volume), is dated AH 641/AD 1243–1244. According to the author, the two other manuscripts are its 42nd and 43rd volumes.

It is of historical significance that Ibn al-Nafīs, in *Kitāb al-Shāmil*, divides the procedure to be followed by doctors in surgical operations into three stages: first, the "stage of presentation for clinical diagnosis"; second, the "operative stage"; and third, the "postoperative period," during which the patient remains under the doctor's supervision until full recovery is achieved.

Another important work is *Sharḥ Tashrīḥ Kitāb al-Qānūm fi 'l-Ṭibb li-Ibn Sīnā* (Commentary on Anatomy in Avicenna's Canon of Medicine). In it he gives the earliest known account of pulmonary circulation: "…This is the right cavity of the two cavities of the heart. When the blood in this cavity has become thin, it must be transferred into the left cavity, where the pneuma is generated. But there is no passage between these two cavities, the substance of the heart there being impermeable. It neither contains a visible passage, as some people have thought, nor does it contain an invisible passage which would permit the entry of blood, as Galen thought. The pores of the heart there are compact and the substance of the heart is thick. It must, therefore, be that when the blood has become thin, it is passed into the arterial vein (pulmonary artery) to the lung, in order to be dispersed inside the substance of the lung, and to mix with the air. The finest parts of the blood are then strained, passing into the venous artery (pulmonary vein) reaching the left of the two cavities of the heart, after mixing with the air and becoming fit for the generation of pneuma…"

Ibn al-Nafīs' discovery of pulmonary circulation antedates the accounts mentioned by Michael Servetus (AD 1553), Realdo Colombo (AD 1559), and Andrea Cesalpino (d. AD 1603). Andreas Vesalius (d. AD 1564), who does not mention blood circulation, refutes Galen in his statement: "…I do not see how even the smallest amount of blood could pass from the right ventricle to the left ventricle, through the interventricular septum…" We now say it was William Harvey (d. AD 1657) who, through experimentation which lasted almost 20 years, discovered the entire path of blood circulation.

Ibn al-Nafīs wrote a large textbook, *Al-Muhadhdhab fi 'l-Kuḥl al-Mujarrab* (The Polished Book on Experimental Ophthalmology), divided into two sections: "On the Theory of Ophthalmology," followed by detailed accounts of "Simple and Compounded Ophthalmic Drugs."

A very popular and concise book was Ibn al-Nafīs' *Mūjiz al-Qānūn fi 'l-Ṭibb* (Abstract of Ibn Sīnā's Canon of Medicine). It has been claimed – probably unfairly – that the tedious prolixity of Ibn Sīnā's *Canon of Medicine*, together with the incomprehensibility of some of its statements, and Ibn al-Nafīs' *Abstract of Avicenna's Canon of Medicine*, with its undue brevity and popularity among Arabic-speaking students of medicine, led to the decline of late medieval medical education.

On the philosophy of religion, Ibn al-Nafīs wrote *Al-Risāla al-Kāmiliyya fi'l-Sīra al-Nabawiyya* (Missive on the Complete Prophetic Conduct), also known by the title *Fāḍil Ibn Nāṭiq*. It was written along the lines of Ibn Ṭufayl's (d. AD 1185) *Ḥayy Ibn Yaqẓān*. In it, Ibn al-Nafīs imagines the generation – inside a cave on a deserted island – of a human being. The author guides the reader to the way in which this lone human being would arrive at the discovery of science and philosophy, then the knowledge of prophecies, and particularly the *Sīra* (conduct) of the Prophet Muḥammad, and the legal doctrines of Islam.

In his old age, Ibn al-Nafīs bequeathed his own house, including an extensive private library, to the Qalāwūn Hospital, founded in AD 1284 by Sultan Qalāwūn (r. AD 1279–1290). Ibn al-Nafīs died in his 80s, a bachelor who devoted all his time to the practice of medicine on which he wrote several books. He died on 17th December 1288 (11th Dhu'l-Qaᶜdah 687).

Ibn al-Quff (al-Karakī)

Sami K. Hamarneh

Abū'l-Faraj ibn Yaᶜqūb ibn Isḥāq Ibn al-Quff al-Karakī was born on the 22nd of August 1233, in the city of Karak (hence the name al-Karakī) in the district of Transjordan in larger Syria (*Bilād al-Shām*). The first and most intimate biography, by a friend of al-Karakī's family, was by Abū'l-Faraj's first teacher in the healing art – the prominent physician and historian of medicine Ibn Abī Uṣaybiᶜah (d. 1270). The meeting between al-Karakī's family and Uṣaybiᶜah took place in Ṣarkhad, Syria. As Uṣaybiᶜah was the physician-counselor to the governor (*wālī*) of Ṣarkhad and the entire province, al-Karakī's family moved from Karak north to Ṣarkhad. The father was summoned by the governor to serve as a secretary to the Department of Welfare (*dīwān al-birr*). A very close friendship developed between the physician as a leading and resourceful practitioner, and Yaᶜqūb al-Karakī as an able secretary, adviser, historian, linguist, and man of letters.

At that time, the son Abū'l Faraj was 11 or 12 years of age, a bright fellow who had acquired the basics in education in Karak. The father asked the physician if he would teach his son the healing art, and Uṣaybiᶜah willingly accepted the challenge. He soon taught him the basics of the field: the theory and practical aspects of medicine, methods of treatment, and the identification of causes and symptoms of diseases.

The major texts which were studied included some of the writings of Hippocrates (known as the Hippocratic *corpus*, such as the *Aphorisms and Prognoses*) and some of the medically important catechisms, such as *Al-Masāʾil* by Ḥunayn ibn Isḥāq (809–873), and the major writings of al-Rāzī (Latin Rhazes, 865–925), particularly the clinical and therapeutic texts.

After the fall of the Ṣarkhad province into the hands of the Ayyūbid King, al-Ṣāliḥ Najm al-Dīn (1245–1249), al-Karakī's family moved to Damascus (the Syrian capital of the Ayyūbids) where the father was promoted to a higher position. The son continued his study under some of the most illustrious physicians at the time. Damascus had great hospitals, including the hospital located in the Citadel for the Royal family, civil servants, and army personnel. There Ibn al-Quff had his training to become a physician.

This medieval period had witnessed great cultural, political, and technoscientific changes. There was the fall of the prestigious Fātimiḍ (Shīᶜite) dynasty in Cairo, and the rise of the Ayyūbid (Sunnite) dynasty in Cairo and Damascus under the leadership of Sultān Ṣalāḥ al-Dīn (Saladin, r. 1171–1193) and his successors. There was also the rise of the *Bahri Mamluks* (slave sultans 1250–1381). However, the true founder of the "Slave" dynasty was Sultān al-Ẓahir Baybars (d. 1277), who was first purchased to serve in the Ayyūbid army and then became their ruler. During this time, the healing arts reached new heights.

Having had excellent training and having become a worthy practitioner-surgeon, Ibn al-Quff was summoned in about 1262 (at the age of 29) to be the physician-surgeon in ᶜAjlūn, his home country in Transjordan. There he served the profession for a decade, at the end of which he published his first medical encyclopedia *Al-Shāfī-al-Ṭibb* (The Comprehensive of the Healing Arts), completed in early 1272. It is composed of 12 treatises encompassing the entire medical field. It was a significant contribution to the field at the time and contained many timely observations and innovations.

From ᶜAjlūn, al-Karakī was summoned to the Syrian capital, Damascus. There he served at its Citadel and hospital from 1272 until his untimely death in early July 1286 at the age of 52. We know that many medical students came to hear his lectures and listen to his eloquence. He also continued to fulfill his duty in caring for the sick and the wounded and continued his research and publications. Among these are two commentaries: one on the Hippocratic *Aphorisms*, entitled *al-Uṣūl*, edited in Cairo, and the other a commentary on the generalities of the *Qānūn* of Ibn Sīnā (d. 1037). The last *Sharh* was complete about 1274.

His other work is *Jamiᶜ al-Gharaḍ*, on preventive medicine and the preservation of health in 60 chapters, completed about 1275. It is extant in several manuscripts. This is possibly the finest work of its kind in medieval times, and it needs translation into English for wider audiences.

Al-Karakī's best and most renowned manual is *al-ᶜUmdah* on surgery. It was published in Hyderabad, India, in 1356 AH/1937 and ranks second after *al-Taṣrīf* (The Thirtieth Treatise) by al-Zahrāwī (Abulcasis, ca. 939–1013).

Only recently have al-Karakī's literary contributions begun to draw wider recognition. His writings should place him among the greatest physician-surgeons and public health experts during the Arab-Islamic Golden Age.

Ibn al-Raqqām

Julio Samsó

Muḥammad ibn al-Raqqām al-Andalusī (d. 1315) was an Andalusian astronomer, mathematician, and physician. He was probably born in Murcia and left the city when it was conquered by Alfonso X in 1266. He lived in Bejaia (Algeria), Tunis and, after 1280, accepted the invitation of Muḥammad II (1273–1302) and established himself in Naṣrid Granada where he taught mathematics and astronomy (as well as medicine and law). Among his students in astronomy we find king Naṣr (1309–1314). His son, Ibrāhīm ibn Muḥammad ibn al-Raqqām, was an astrolabe maker: one of his instruments (made in Guadix in 1320) is still preserved in Madrid.

Among his extant works we should mention his *Risāla fī ʿIlm al-Ẓilāl* (Treatise on the Science of Shadows) as well as two sets of astronomical tables (*zījes*), the first of which was probably compiled in Bejaia in 1280–1281, while the second was made in Tunis and later adapted to the coordinates of Granada. His book on *Shadows* is a brilliant treatise on Gnomonics where Ibn al-Raqqām explains how to build all kinds of sundials (among which we find a portable sundial which includes a compass) using projections on a plane which, ultimately, derive from Ptolemy's *Analemma*. The first of his *zījes*, entitled *al-Zīj al-Shāmil fī Tahdhīb al-Kāmil* (A General Set of Astronomical Tables in which [Ibn al-Hā'im's] Kāmil Zīj is Corrected), follows narrowly the theoretical contents of Ibn al-Hāʾim's *al-Zīj al-Kāmil fī'l-Taʿālīm* to which Ibn al-Raqqām adds the numerical tables which had been lost in the manuscript of Ibn al-Hā'im's work. His second *zīj al-Zīj al-Qawīm fī Funūn al-Taʿdīl wa-l-Taqwīm* (The Solid Handbook to Calculate Equations and Planetary Positions) is a summary and adaptation of the first one to the coordinates of Tunis and Granada. Both works bear witness to the diffusion of Ibn al-Zarqāllu's astronomical ideas in the Maghreb and Andalusia.

Ibn Al-Shāṭir

David A. King

Ibn al-Shāṭir, ʿAlāʾ al-Dīn ʿAlī ibn Ibrāhīm was born in Damascus ca. 1305. He was the most distinguished Muslim astronomer of the fourteenth century. Although he was head *muwaqqit* at the Umayyad mosque in Damascus, responsible for the regulation of the astronomically defined times of prayer, his works on astronomical timekeeping are considerably less significant than those of his colleague al-Khalīlī. On the other hand, Ibn al-Shāṭir made substantial advances in the design of astronomical instruments. Nevertheless, his most significant contribution to astronomy was his planetary theory.

In his planetary models Ibn al-Shāṭir incorporated various ingenious modifications of those of Ptolemy. Also, with the reservation that they are geocentric, his models are the same as those of Copernicus. Ibn al-Shāṭir's planetary theory was investigated for the first time in the 1950s, and the discovery that his models were mathematically identical to those of Copernicus raised the very interesting question of a possible transmission of his planetary theory to Europe. This question has since been the subject of a number of investigations, but research on the astronomy of Ibn al-Shāṭir and his sources, let alone on the later influence of his planetary theory in the Islamic world or Europe, is still at a preliminary stage.

Ibn al-Shāṭir appears to have begun his work on planetary astronomy by preparing a *zīj*, an astronomical handbook with tables. This work, which was based on strictly Ptolemaic planetary theory, has not survived. In a later treatise entitled *Taʿliq al-arṣād* (Comments on Observations), he described the observations and procedures with which he had constructed his new planetary models and derived new parameters. No copy of this treatise is known to exist in the manuscript sources. Later, in *Nihāyat al suʾl fī taṣḥiḥ al-uṣūl* (A Final Inquiry Concerning the Rectification of Planetary Theory), Ibn al Shāṭir presented the reasoning behind his new planetary models. This work has survived. Finally, Ibn al-Shāṭir's *al-Zīj al-jadīd* (The New Astronomical Handbook), extant in several manuscript copies, contains a new set of planetary tables based on his new theory and parameters.

Several works by the scholars of the mid-thirteenth century observatory at Maragha are mentioned in Ibn al-Shāṭir's introduction to this treatise, and it is clear that these were the main sources of inspiration for his own non-Ptolemaic planetary models.

The essence of Ibn al-Shāṭir's planetary theory is the apparent removal of the eccentric deferent and equant of the Ptolemaic models, with secondary epicycles used instead. The motivation for this was at first sight aesthetic rather than scientific, but his major work on observations is not available to us, so this is not really verifiable. In any case, the ultimate object was to produce a planetary theory composed of uniform motions in circular orbits rather than to improve the bases of practical astronomy. In the case of the sun, no apparent advantage was gained by the additional epicycle. In the case of the moon, the new configuration to some extent corrected the major defect of the Ptolemaic lunar theory, since it considerably reduced the variation of the lunar distance. In the case of the planets, the relative sizes of the primary and secondary epicycles were chosen so that the models were mathematically equivalent to those of Ptolemy.

Ibn al-Shāṭir also compiled a set of tables displaying the values of certain spherical astronomical functions relating to the times of prayer. The latitude used for these tables was 34°, corresponding to an unspecified locality just north of Damascus. These tables display such functions as the duration of morning and evening twilight and the time of the afternoon prayer, as well as standard spherical astronomical functions.

Ibn al-Shāṭir designed and constructed a magnificent horizontal sundial that was erected on the northern minaret of the Umayyad Mosque in Damascus. The instrument now on the minaret is an exact copy made in the late nineteenth century. Fragments of the original instrument are preserved in the garden of the National Museum, Damascus. Ibn al-Shāṭir's sundial, made of marble and a monumental 2 × 1 m in size, bore a complex system of curves engraved on the marble which enabled the *muwaqqit* to read the time of day in equinoctial hours since sunrise or before sunset or with respect to either midday or the time of the afternoon prayer, as well as with respect to daybreak and nightfall. The gnomon is aligned towards the celestial pole, a development in gnomonics usually ascribed to European astronomers.

A much smaller sundial forms part of a compendium made by Ibn al-Shāṭir, now preserved in Aleppo. It is contained in a box called *ṣandūq al-yawāqīt* (jewel box), measuring 12 × 12 × 3 cm. It could be used to find the times (*al-mawāqīt*) of the midday and afternoon prayers, as well as to establish the local meridian and the direction of Mecca.

Ibn al-Shāṭir wrote on the ordinary planispheric astrolabe and designed an astrolabe that he called *al-āla al-jāmiʾa* (the universal instrument). He also wrote on the two most commonly used quadrants, the astrolabic and the trigonometric varieties. Two special quadrants which he designed were modifications of the simpler and ultimately more useful sine quadrant. One astrolabe and one universal instrument actually made by Ibn al-Shāṭir survive.

A contemporary historian reported that he visited Ibn al-Shāṭir in 1343 and inspected an "astrolabe" that the latter had constructed. His account is difficult to understand, but it appears that the instrument was shaped like an arch, measured three-quarters of a cubit in length, and was fixed perpendicular to a wall. Part of the instrument rotated once in 24 h and somehow displayed both the equinoctial and the seasonal hours. The driving mechanism was not visible and probably was built into the wall. Apart from this obscure reference, we have no contemporary record of any continuation of the sophisticated tradition of mechanical devices that flourished in Syria some 200 years before his time.

Ibn al-Shāṭir died in Damascus ca. 1375. Later astronomers in Damascus and Cairo, none of whom appears to have been particularly interested in his non-Ptolemaic models, prepared commentaries on, and new versions of, his *zīj*. In its original form and in various recensions this work was used in both cities for several centuries. His principal treatises on instruments remained popular for several centuries in Syria, Egypt, and Turkey, the three centers of astronomical timekeeping in the Islamic world. Thus his influence in later Islamic astronomy was widespread but, as far as we can tell, unfruitful. On the other hand, the reappearance of his planetary models in the writings of Copernicus strongly suggests the possibility of the transmission of some details of these models beyond the frontiers of Islam.

Ibn al-Yāsamīn

AHMED DJEBBAR

The name of this mathematician is Abū Muḥammad ʻAbdallāh ibn Muḥammad ibn Hajjāj al-Adrīnī, more commonly known as Ibn al-Yāsamīn. As his name indicates, he was originally from a Berber tribe from the Maghreb (North Africa), and, according to Ibn Saʿīd, he was black like his mother. We know nothing about the exact date of his birth, but can reasonably place it in the second half of the twelfth century. We also know nothing specific about his place of birth, which could have been in the Andalus (Spain) or the Maghreb. But since some historians have given him the surname al-Ishbīlī, he may have been born or grown up in Seville. In any case, Ibn Saʿīd states that his formative education occurred in Seville.

This education was not restricted to mathematics, since we know he also became famous in the fields of law and literature, particularly in the Andalusian poetry of the Muwashshaḥāt. That being said, however, we know nothing of the context in which he received this rich education nor of his teachers. The only information we have is from Ibn al-Yāsamīn himself about one of his professors, Abū ʿAbdallāh Muḥammad ibn Qāsim al-Shalūbīn, who taught him algebra and the science of calculation.

We also do not know exactly when Ibn al-Yāsamīn began to publish his mathematical writings. Ibn al-Abbār tells us only that Ibn al-Yāsamīn's famous algebraic poem was drafted in Seville and that, in 1190 also in Seville, he was using it in his teaching.

Concomitant with his mathematical activities was Ibn al-Yāsamīn's dedication to poetry, and according to Ibn Saʿīd, some of his poems had even been set to music and sung at this time. It may have been his literary success which led to his frequenting the court of the third Almohad caliph Abū Yūsuf Yaʿqūb (1184–1199) and of his successor Muḥammad al-Nāṣir (1199–1213). These frequent court visits and the fame of his literary and mathematical publications probably gained Ibn al-Yāsamīn some enemies. Also some of his contemporaries accused him of leading a dissolute life. But none of these can be seen as the cause of his assassination in 1204 in Marrakesh.

The Mathematical Writings of Ibn al-Yāsamīn

The best-known work of Ibn al-Yāsamīn is a poem of 53 verses in rajaz meter entitled *al-Urjūza al-yāsmīnīyya fi al-jabr wa ʻl-muqābala* (Poem on Algebra and Restoration). In it the author defines the algebra known in his time – number, root, and sequence, then the six canonical equations of al-Khwārizmī with the processes of solving them, and finally, the operations of algebra – the restoration, comparison, multiplication, and division of monomials.

This poem has been widely read throughout the centuries both within the Maghreb and beyond. Thus, there are many commentaries on it by other famous mathematicians such as Ibn Qunfudh (d. 1407) and al-Qalaṣādī (d. 1486) in the Maghreb, Ibn al-Hāʾim (d. 1423) and Sibṭ al-Māradīnī (d. 1501) in Egypt and elsewhere.

For a long time, the contribution of Ibn al-Yāsamīn to mathematics was known only through his *Urjūza* in algebra. It is quite possible, moreover, that it was the success of this poem which led him to write a second one on irrational quadratic numbers and maybe a third on the method of false position. But the distribution of these last two poems was relatively modest, compared to that of the first one, and aside from the rare copies that exist, we have not yet found any explicit reference to the contents of the two other poems in any works on calculation written after the twelfth century.

The same situation exists for Ibn al-Yāsamīn's fourth written work on mathematics, entitled *Talqīḥ al-afkār bi rushūm ḥurūf al-ghubār* (Fertilization of Thoughts with the Help of Dust Letters [Hindu Numerals]). This work is much more important than his poems, as much in quantity as in quality. Indeed, it is a book of 200 folios which contains classic chapters on the science of calculation and on geometry. Among the works of the Muslim West which have come down to us, it is the only one which consolidates these two disciplines. Its importance is also due the nature of its materials and its mathematical tools which make it an original book and also one which is totally representative of this period of transition in which three mathematical traditions were juxtaposed – of the East, the Andalus, and the Maghreb – before they became blended in the same mold.

For example, the following elements contribute both to the originality of his work and to its being anchored in the great Arab mathematical tradition of the ninth to eleventh centuries:

In arithmetic, contrary to the Maghrebian tradition which prevailed from the fourteenth century on, Ibn al-Yāsamīn treats multiplication and division first, before addition and subtraction. This approach, which can be found again later in the work of Ibn al-Zakariyā' al-Gharnāṭī, seems to be based on Andalusian mathematical practice.

For fractions, the remarks and suggestions of Ibn al-Yāsamīn concerning the reading of certain expressions demonstrate that the symbolism of fractions had not been established definitively in his time. This was not the case, it appears, for the symbolism of equations which had been established relatively early, since there is no difference between the symbols used in the *Talqīḥ al-afkār* of Ibn al-Yāsamīn and those used in the *Bughyat aṭ-ṭullāb* (The Hope of Students) of Ibn Ghāzī al-Miknāsī (d. 1513).

As for the presence of geometry in a work on the science of calculation, this is not exceptional in regard to the Arab mathematical tradition, viewed in its entirely, in so far as similar chapters (i.e., chapters which deal with problems in metric geometry) had already been inserted in works edited in the East, such as the *Takmila fi l-ḥisāb* (Complement to Calculus) of ʿAbd al-Qāhir al-Baghdādī or the *Kitāb al-Kāfī* (The Sufficient Book) by al-Karajī.

In spite of what we have noted about the contents of *Talqīḥ al-afkār*, there has not been any explicit reference to the book in Maghrebian mathematical writing. There could be at least two possible explanations for this. First, a break in the tradition whose cause is to be found outside the scientific milieu of that time. This hypothesis is not implausible if one takes into account the personality of Ibn al-Yāsamīn and his controversial behavior and also his close ties to Almohad power.

The second reason, which is also plausible and which can be added to the first, can be found in mathematical practice after Ibn al-Yāsamīn, a practice which bore the strong imprint of mathematicians from Marrakesh, like Ibn Munʾim (d. 1228), al-Qāḍi al-Sharīf (d. 1282–1283), and Ibn al-Bannāʾ (d. 1321). We have observed this same phenomenon of the absorption of a mathematical tradition first in the East with the first written Arab arithmetical works from the ninth century and, in particular, with the work of al-Khwārizmī, and then in the Andalus with writings of the tenth century, like those of al-Majrīṭī and his pupils.

Ibn Al-Zarqāllu

Emilia Calvo

Ibn al-Zarqāllu, Abū Isḥāq Ibrāhīm ibn Yaḥyā al-Naqqāsh, sometimes known as Azarquiel, was born in the first quarter of the eleventh century to a family of artisans. He entered the service of the *qāḍī* (judge) Ṣāᶜid of Toledo first as an artisan, and after as the director of a group which carried out astronomical observations. Ibn al-Zarqāllu lived in Toledo until ca. AD 1078, when he moved to Cordoba where he composed his last works under the patronage of the king of Sevilla al-Muᶜtamid ibn ᶜAbbād and where he died in AD 1100. His work exerted considerable influence on later authors such as Ibn al-Kammād, Abū'l-Ḥasan ᶜAlī Ibn al-Bannā', Abraham ibn ᶜEzra, Ibn al-Hāʾim, Ibn Isḥāq, and Ibn Bāṣo.

Ibn al-Zarqāllu's works are basically astronomical, although an astrological treatise by him is also extant. Other works of Ibn al-Zarqāllu are described below:

The *Almanac* is a reelaboration by Ibn al-Zarqāllu of the work of an unknown author called Awmātiyūs. It allows the determination of planetary longitudes, without computation, by combining Ptolemaic parameters with the Babylonian doctrine of the goal-years. The goal-years consisted of cycles peculiar to each planet. These cycles included an entire number of solar years which, in turn, comprised an exact number of synodic and zodiacal revolutions. These cycles were known by the Babylonian astronomers, and they are also found in Ptolemy's *Almagest*. The advantage of these cycles for astronomers is that the positions of the planets can be calculated for a complete cycle which will be repeated, so these positions will always be the same for a given date within the cycle.

Treatise on the Motion of the Fixed Stars is preserved in a Hebrew translation. It is probably the most complete medieval text on the trepidation theory. Trepidation consists of a back-and-forth vibration within fixed limits, which is supposed to account for the variation in velocity of the slow eastward motion observed in the fixed stars. The treatise proposed three different geometrical models to demonstrate this theory.

Fīsanat al-śams (On the Solar Year) was probably written between AD 1075 and 1080 and based on 25 years of solar observations. Here Ibn al-Zarqāllu established the proper motion of the solar apogee to be of 1° in 279 Julian years. The text is lost but it can be reconstructed from the works of later astronomers like Ibn al-Kammād, Ibn al-Hāʾim, Ibn Isḥāq, Ibn al-Raqqām and Ibn al-Bannāʾ.

Risālat al-ṣafīḥa al-zarqāliyya (Treatise on the Zarqaliyya Plate) and *Risālat al-ṣafiḥa al-shakkāziyya* (Treatise on the Shakkāziyya Plate) are two treatises on the use of a universal astrolabe called *ṣafīḥa* (plate). There is an Alphonsine translation in the *Libros del Saber de Astronomia* of the treatise on the use of the *ṣafīḥa zarqāliyya*. This instrument offers the possibility of making calculations for any given latitude by means of only one plate.

Kitāb al-ᶜamal bi'l-ṣafīḥa al-zījiyya (Treatise on the Plate for the Seven Planets) describes the equatorium, an instrument consisting of the representation, drawn to scale, of a planetary model, which is used to determine the position of a planet at a given moment. Both his treatise on its construction and his treatise on its use are extant.

He also took an active part in the elaboration of the *Toledan Tables* which seem to have been the result of the work of a group of astronomers directed by the *qāḍī* Ṣāᶜid.

Finally, he was probably the author of a treatise on the construction of the armillary sphere, translated or adapted by Isḥāq ibn Sīd, which was incorporated into the Alphonsine *Libro de las Armellas*.

Ibn Baṭṭūṭa

Bilal Ahmad

Ibn Baṭṭūṭa (1304–1369) was the greatest Muslim traveler of his time. He was born in Tangier to a well-educated Moroccan family that produced many judges. After receiving basic education in his home town, at age 21 he headed toward Mecca both to make a pilgrimage and to study under some notable Muslim scholars in Egypt, Syria, and Hejaz. After reaching Egypt via Tunis and Tripoli, he decided to become a traveler to gain firsthand knowledge about as many parts of the world as possible. Ibn Baṭṭūṭa's fascination for travel took him to Syria, Iraq, southern Iran, and Azerbaijan. He then decided to spend the next 3 years (1327–1330) in the holy towns of Mecca and Medina in Hejaz. Ibn Baṭṭūṭa's next expedition (1330–1332) started from the seaport of Jidda. He sailed across the Red Sea to Yemen, traveled across Yemen by land, and from Aden he sailed along the coast to various trading ports of East Africa. On his way back, he turned his boat to the Persian Gulf area and concluded this trip by another pilgrimage to Mecca.

Ibn Baṭṭūṭa's travels were supported by the contributions of the rulers, governors, and other prominent residents of the places that he visited. After hearing of the benevolence of Muḥammad bin Tughlaq – the ruler of Delhi, India – Ibn Baṭṭūṭa decided to go to India. This time he adopted a very unusual route: by moving northward, he first passed through Egypt and Syria; he then traveled extensively in Anatolia (Asia Minor) and the territories of the Golden Horde where he was well received by the local sultans and other prominent people. Ibn Baṭṭūṭa's *Riḥlah* (Book of Travels) provides a clear and lucid picture of Constantinople, Saray (the capital of the Khan of the Golden Horde), and other Sultanates. After crossing the Steppes with a caravan, Ibn Baṭṭūṭa passed through the towns of Bukhara, Samarkand, Balkh, and Herat. He then crossed the Hindu Kush Mountains and visited many important towns and cities in the Indus Valley – particularly Sukkur, Multan, and Lahore – before he finally reached Delhi. Sultan Muḥammad bin Tughlaq received him with respect and presents. The Sultan also appointed him the chief justice of Delhi. Ibn Baṭṭūṭa enjoyed the patronage of the Sultan for several years.

In 1342, he appointed Ibn Baṭṭūṭa the ambassador to China. After his ship wrecked near Calicut on the Malabar Coast of India, he decided to go to the Maldives where he married into the royal family. In the following years, Ibn Baṭṭūṭa visited Sri Lanka (Ceylon), supported the Sultan of the Maldives in a war, went again to the Maldives, and visited Bengal, Assam, and Sumatra. The Sultan of Sumatra provided him with a new ship to go to China. He arrived at the Chinese port of Zaytun and reached Beijing via the inland waterways. On his return journey, he eventually reached Mecca via Sumatra, Calicut, the Persian Gulf, Baghdad, Syria, and Egypt. Ibn Baṭṭūṭa's narrative for this entire journey is sketchy and some scholars doubt that he ever reached Beijing.

In April to May of 1349, Ibn Baṭṭūṭa embarked for his home from Alexandria via Tunis, Sardinia, and Algeria. He eventually reached Fez (Morocco), from where he went to the Kingdom of Granada, in Spain. His next destination was western Sudan. After traveling across the Sahara, he visited the Empire of Mali and returned to retire in Fez.

Ibn Baṭṭūṭa was an outstanding adventurer. His education and experience earned him numerous honors and awards, including the position of judge in many parts of the Muslim world. After his retirement, he again held the office of *qāḍī* (judge) in a Moroccan town and dictated his recollections to Ibn Juzayy – a royal poet. Ibn Baṭṭūṭa's *Riḥlah* is a valuable document for understanding the ways of life in the fourteenth-century Muslim world.

Ibn Buṭlān

Roger Arnaldez

Abū'l-Ḥasan al-Mukhtār ibn ʿAbdūn ibn Saʿdūn Ibn Buṭlān was a physician, philosopher, and Christian theologian from Baghdad (eleventh century). He had for a teacher a Nestorian priest, Abū'l-Faraj ibn al-Ṭayyib, a commentator on Aristotle, Hippocrates, and Galen, who was interested in botany and wrote on the humors, wine, and natural qualities. Teaching at the hospital founded in Baghdad by ʿAḍud al-Dawla, he directed his pupil in reading and the use of several medical works. He taught him so well that later, Ibn Buṭlān, in a controversy with the physician Ibn Riḍwān, maintained that one could understand the basic precepts of medicine by simply reading books.

On the subject of the *al-Masāʾil fi'l-Ṭibb fi'l-Mutaʿallimīn* (Questions on Medicine for Students) by Ḥunayn ibn Isḥāq, he believed that Ibn Riḍwān, who had refuted it, had not understood it at all, "because he didn't study it under the direction of masters in this art." That is why, in spite of his great knowledge of the works of the Ancients, he refused to conform blindly and to the letter. Also he asked why clear-sighted doctors had lost the habit of caring for certain maladies, as the Ancients had done, with warm medicines, and preferred to use cold ones. It seems also that Ibn Buṭlān was instructed in the practice of medicine by Abū'l-Ḥasan Thābit ibn Ibrāhīm al-Ḥarrānī, about whom many praises were said.

Ibn Buṭlān left Baghdad, crossed Syria, and arrived in Egypt, where he undertook several polemics with Ibn Riḍwān. These covered diverse subjects, touching in particular the philosophical questions and ideas of Aristotle concerning place, movement, and the soul on which Ibn Riḍwān had commented before. He returned to Constantinople, where he arrived in 446/1054, at the time of the schism which would eventually separate the Greek from the Latin church. The patriarch Michel Cérulaire asked him to edit a treatise on the Eucharist and the use of bread without leavening. That was also the year when a terrible epidemic of the plague broke out in the capital of the Byzantine Empire. Ibn Buṭlān kept a diary and cited the names of several savants who had succumbed to it. After this he went to Antioch where he directed the establishment of a hospital. Eventually he retired from traveling, and died in 460/1068.

His work is very diverse, covering theology, philosophy, logic, and medicine. His interpretation of the work of the Ancients is original and animated by a critical spirit. He relied on logic and the grammar of languages, and attempted to explain apparent opposition by showing that they had very different points of view. Thus Aristotle studied organic forces relative to their nature, while Galen did so relative to their perceptible action in the organs which were their instruments. Aristotle divided the organs according to their physical constitution, Galen in relation to the illnesses which affected them. In the same way, with regard to the "egg yolk" color of bile, Ibn Buṭlān tended to agree with Galen who explained it by the predominant action of heat, which rends the bile hotter and lighter. On the other hand, Ḥunayn ibn Isḥāq explained it as the result of a mixture of bile and phlegm. These differences can be explained by the ambiguity of the term *muḥḥ*, which signifies at the same time both the egg yolk alone and the entire interior of the egg, both the yellow and the white.

Ibn al-Qifṭī retained for us a list of the problems that Ibn Buṭlān posed. For example, he wondered about the chemical nature of the force of physical attraction between lovers. In the field of physiology, he questioned why it is that when men dream they are urinating, they wake themselves up without urinating in their beds, while when they dream of a sexual encounter, there is an emission of sperm. He wondered why this was so, when you consider how much easier it is to urinate than to ejaculate when one is awake.

Ibn Buṭlān's most important medical work is the *Taqwīn al-ṣiḥḥa* (Strengthening of Health), a treatise on hygiene dedicated to general questions on the four elements, the humors, and the temperaments. The author studied the nature and value of nutrition, as well as the influence of the environment, water, climate, and housing on health. The originality of the work lies in its form: it is presented in small tableaux. It was translated into Latin and German. Another noteworthy work is *Daʿat al-Aṭibbā* (The Physician's Banquet), on the subject of medical ethics, which included a satire on charlatans and ignorant physicians. There is also a treatise on the maladies caused by food, with recommended remedies used by monks. Finally, there is a treatise devoted to a discussion of whether a chicken is hotter than a smaller bird.

Ibn Ḥawqal

Emilia Calvo

Ibn Ḥawqal al-Nasibī Abū'l-Qāsim Muḥammad ibn ʿAlī was born in Nisibis (now Nusaybin, Turkey) in the second half of the tenth century. He worked as a merchant and traveled, beginning in AD 943, through the Muslim world, visiting the Maghreb and Andalusia between 947 and 951; Egypt, Armenia, and Azerbaijan around AD 955; Iraq, Persia, Transoxiana, and Khwarazm between 961 and 969. In AD 973, he was in Sicily.

Ibn Ḥawqal is the author of a book on geography entitled *Kitāb al-masālik wa'l-mamālik* (Book on the Routes and Kingdoms), also known as *Kitāb ṣūrat al-ʿarḍ*, which belongs to the category of the so-called *Atlas of Islam*. It consists of a description of the Islamic countries, although some non-Islamic regions of Sudan, Turkey, Nubia, and Sicily are also described.

Ibn Ḥawqal based his work on al-Iṣṭakhrī's book and incorporated new material from his travels which led to three successive revisions of his *Kitāb al-masālik*: the first one in AD 967, dedicated to Sayf al-Dawla; the second ca. AD 977, and the third ca. 988. The final result was a book whose descriptive part surpassed the works of earlier authors.

From the contents of his work, his sympathy with the Fāṭimid movement can be deduced. He showed a certain interest toward Fāṭimid politics, although he cannot be considered a Fāṭimid *dāʿī* (propagandist). He also gives economic information. His interests are focused not on rare or precious goods but on basic agricultural and artisanal products.

Ibn Ḥawqal's *Kitāb al-masālik* influenced the work of later geographers such as Abū'l-Fidā. He is also the author of a book on Sicily which is not preserved.

Ibn Hubal

E. Ruth Harvey

Muhadhdhib al-Dīn Abū'l-Ḥasan ʿAlī ibn Aḥmad ibn ʿĀli ibn Hubal al-Baghdādī was a famous physician, medical authority, and accomplished poet. Born in Baghdad in 1121 (AH 515), he migrated to Khilat (modern Ahlat, on the shore of Lake Van, Turkey), and became very prosperous in the service of the local ruler. He later moved to Mardin to serve another lord, and died at Mosul (in modern Iraq) in 1213 (AH 610). His chief work, *Kitāb al-Mukhtār fī al-Ṭibb* (The Choice Book of Medicine), was written in about 1165. It resembles the medical encyclopedias of Ibn Sīnā and al-Rāzī in that it is a compendium of Galenic medical knowledge, supplemented by personal clinical practice. *The Choice Book* is divided into three main parts, comprising anatomy and general principles, a pharmacopoeia, and a list of maladies arranged according to the affected organs, running from head to foot. Although this large book does not seem to have been translated into Latin during the Middle Ages, the number, diffusion, and varying ages of the manuscript copies attest to its popularity. No copy appears to survive of Ibn Hubal's *Kitāb al-Ṭibb al-Jamāli* (Book of Medicine for Jamal al-Din al-Wazir). A short work on logic, *al-Ārāʾ wa'l-mushāwarāt*, in manuscript in Paris (B.N. MS 2348) is ascribed to him.

The manuscripts of *The Choice Book* in Leiden, Paris, Cairo, and India are listed in Brockelmann; there are also several copies in Turkey, and fragmentary ones in Princeton and the British Library in London (the London text starts with the diseases of the brain). The whole Arabic text was edited in Hyderabad 1943–1944, but Albert Dietrich maintains that a proper critical edition is still badly needed. Two chapters of Ibn Hubal's medical encyclopedia were published from the Leyden manuscript with an accompanying French translation; they describe the causes, symptoms, and treatment of stones in the kidneys and bladder. Ibn Hubal employs the usual medieval medical terminology derived from earlier Greek physicians: four fluids, or humors, within the body (blood, phlegm, choler (yellow bile), and melancholy (black bile)) are held to constitute in their balance and proportions the essential foundations of good health; pain and disease reveal an evil condition or imbalance among the fluids. Most remedies and treatments consist of trying to correct the malfunctioning fluid through diet, bleeding, or alteration of the patient's physical surroundings. In spite of what we might today consider the erroneous basis of his theoretical approach, Ibn Hubal shows an impressive concern for personal observations and clearly relies on extensive clinical practice. In discussing stones, for instance, he attributes the condition to excessive bodily heat which causes phlegm, a "thick fluid," to form deposits in the kidneys and bladder. He prescribes medicines such as horseradish, ginger, and chicken soup to break up the stones or cause them to be passed. He also cites his own personal experience of a more desperate remedy which he witnessed: a surgical operation to remove a bladder stone from a boy. He cites al-Rāzī and Rufus of Ephesus, but conveys the impression of a knowledgeable practical physician, mindful of the agonizing pain caused by the condition he is discussing.

Ibn Isḥāq Al-Tūnisī

Julio Samsó

Abū-l-ʿAbbās Aḥmad ibn ʿAlī ibn Isḥāq al-Tamīmī al-Tūnisī was a Tunisian astronomer of the early thirteenth century. He compiled an impressive astronomical handbook with tables (*zīj*) a manuscript of which (copied ca. 1400) was discovered by David A. King. It contains an important set of tables (completed ca. 1218) which mark the starting point of a Maghribian (North Africa) astronomical school. Parts of these tables seem original and are based, according to the famous historian Ibn Khaldūn, on observations made by a Sicilian Jew. The rest is a miscellaneous collection of materials which derive from Andalusian sources, many of which seem lost, by Ibn al-Zarqāllu (d. 1100), Ibn Muʿādh al-Jayyānī (d. 1093), Ibn al-Kammād (fl. ca. 1125), Ibn al-Hāʾim (fl. ca. 1204) as well as others. The canons (instructions for the use of the numerical tables) were not written by Ibn Isḥāq but by some later author who also used materials derived from the aforementioned Andalusian *zīj*es. Ibn Isḥāq's *zīj* is, therefore, a first rate new source for the study of both Andalusian and Maghribian astronomy.

Ibn Juljul

Emilia Calvo

Ibn Juljul al-Andalusī, Sulaymān ibn Ḥasan, was born in Córdoba in AD 943 and died ca. 994. He studied medicine with a group of Hellenists presided over by Ḥasdāy ibn Shaprūṭ, a Jewish physician and vizier of the Caliph ʿAbd al-Raḥmān III, and later became the personal physician of Caliph Hishām II (976–1009).

Ibn Juljul is the author of *Ṭabaqāt al-aṭibbāʾ wa 'l-ḥukamāʾ* (Generations of Physicians and Wise Men), the oldest extant summary in Arabic on the history of medicine (it was finished in AD 987), after Isḥāq ibn Ḥunayn's *Taʾrīj al-aṭibbāʾ* (History of the Physicians). It contains 57 biographies grouped into nine generations. Thirty-one of them concern Asian authors, and the rest refer to African and Andalusian scholars.

Ibn Juljul used Eastern sources (Hippocrates, Galen, Dioscorides) and Western ones (Orosius, Isidore) and established the chronological limits of the Latin influence on medicine in Andalusia. The work has chronological errors but provides interesting information about the oldest translations into Arabic, in the time of the Caliph ʿUmar II (AD 717–719).

Other works of Ibn Juljul are *Tafsīr asmāʾ al-adwiya al-mufrada min kitāb Diyusqūridūs* (Explanation of the Names of the Simple Drugs from Dioscorides' Book), written in 982, from which only a fragment is preserved, containing the transcription of the Greek names of 317 simple medicines, their translation into Arabic and their identification; *Maqāla fī dhikr al-adwiya al-mufrada lam yadhkurha Diyusqūridūs* (Treatise on the Simples not Mentioned by Dioscorides), which includes 62 simple medicines not mentioned in Dioscorides' *Materia Medica*; *Maqāla fī adwiyat al-tiryāq* describing the components of the theriaca; and *Risālat al-tabyīn fī-mā ghalaṭa fīhi baʿḍ al-mutaṭabbibīn* (Treatise on the Explanation of the Errors of Some Physicians).

Ibn Jumayʾ

HARTMUT FAHNDRICH

A contemporary of the great Jewish doctor and philosopher Moses Maimonides, Ibn Jumayʾ, was one of the physicians in the service of Ṣalāh ad-Dīn. He was born of a Jewish family in Fustat (Egypt) and studied with another physician of some renown, ʿĀdnān ibn al-ʿAynzarbī (d. 548/1153). The relevant biographical dictionaries mention Ibn Jumayʾ's talents in medicine as well as his highly developed linguistic consciousness, inducing him always to carry al-Jawharī's *Kitāb aṣ-ṣaḥāḥ* (The Truthful Guide) to class so he could check words of which he was uncertain. Ibn Jumayʾ died in 594/1198.

In Ibn Abī Uṣaybiʾa's dictionary of medical doctors, *ʿUyūn al-anbāʾ fī ṭabaqāt al-aṭibbāʾ* (Sources of Information About the Classes of Physicians), Ibn Jumayʾ is presented as the author of eight works on medical or medicine-related subjects, the most important of them being *Kitāb al-irshād li-maṣāliḥ an-nufūs wa 'l-ajsād* (Guide to the Welfare of Souls and Bodies), a compendium of the different fields of the art of medicine. Others also deal with practical questions of the doctor's craft such as first aid or nutritive advice.

The only one of Ibn Jumayʾ's works published to date, *al-Maqāla aṣ-ṣalāḥīya fī iḥyā aṣ-ṣināa aṭ-ṭibbīya* (Treatise to Ṣalāḥ ad-Dīn/Saladin on the Revival of the Art of Medicine), is not mentioned by Ibn Abī Uṣaybiʾa. It is a deontological work, i.e., it deals with the doctor's profession on a more theoretical level.

This treatise, as Ibn Jumayʾ mentions in the introduction, owes its composition to a conversation he had with his sovereign on the deplorable state of medicine in his time, the reasons for this, and ways to ameliorate the situation. Thus, formally the work stands in the literary tradition of the epistle, a genre frequently employed by Ibn Jumayʾ in other works and by Arabic medical authors in general. Its contents – the complaints about the declining state of the art and considerations about its improvement – were not unknown in his time either. The theme goes back to Galen or even Hippocrates.

The treatise falls into three chapters: Chapter 1 concerns the presentation of medicine, including the qualities of medicine and the need for it, as well as the difficulties of medicine and their consequences; Chapter 2 deals with the reasons for the decline of medicine, including a brief presentation of its history; and Chapter 3 suggests ways to revive the art of medicine.

Whereas compendia of a more technical presentation of medicine in medieval Arabic literature are comparatively numerous, the same cannot be said about this kind of work, with its introductory and deontological character. In that lies the importance of this doctor of the twelfth century AD, Ibn Jumayʾ.

Ibn Khaldūn

CHARLES E. BUTTERWORTH

ʿAbd al-Raḥmān ibn Khaldūn (1332/732–1406/808) spent the first two-thirds of his life in North Africa and Muslim Spain, fleeing in 1382/784 to Egypt, where he remained until his death. Though he is best known for the lengthy Introduction (*Muqaddima*) to his massive philosophical history of civilization (*Kitāb al-ʿIbar*), Ibn Khaldūn spent much of his life in political activities. Born and raised in Tunis, he read the *Qur'ān* and studied the religious sciences as well as Arabic and poetry, then was educated in logic, mathematics, natural science, and metaphysics. He also received specialized training in court correspondence and administrative matters, subjects that allowed him to become a court secretary to the Marinid ruler Abū ʿInān in Fez at about the age of 22.

After some vicissitudes, including almost 2 years of prison, Ibn Khaldūn went to Grenada in 1362 to become an advisor and tutor to Muḥammad V. That position lasted only about 2 years, no longer than his subsequent position as prime minister or *ḥājib* to Prince Abū ʿAbd Allāh of Bougie. Following these forays into practical politics, Ibn Khaldūn endured several years of upheaval (1366/766–1375/776), settled for about 4 years in Qalʿat Ibn Salāma near Oran and began work on his history, then moved to Tunis under the patronage of Abū al-ʿAbbās in order to have access to documents and libraries. After a few years there, court intrigues led him to seek tranquility in Egypt.

During the next quarter of a century he served the Mamlūk Sulṭān Barqūq as judge (*qāḍī*) and chief judge (*qāḍī al-quḍā*), professor at various universities (including the prestigious al-Azhar), and one time university president. A few years before his death he met with the famous Mongol chieftain Tamerlane. But the period in Egypt was, above all, a time for revising his *Kitāb al-ʿIbar* and working on the Introduction (*Muqaddima*) to it.

The *Kitāb al-ʿIbar* is a multivolume effort that, in his words, sets forth "the record of the beginning and the suite of the days of the Arabs, Persians, Berbers, and the most powerful of their contemporaries." Its Introduction consists of six very long chapters that explore the character of human civilization in general and Bedouin civilization in particular, as well as the basic kinds of political associations, and then the characteristics of settled civilization, the arts and crafts by which humans gain their livelihoods, and, finally, the different human sciences. Ibn Khaldūn starts by explaining the merit of history and how to go about writing it. Properly speaking, the reason to write history or the "inner meaning of history" is, by means of reflection, to get "at the truth, subtle explanation of the causes and origins of existing things, and deep knowledge of the how and why of events." Though his enterprise is therefore "rooted in philosophy" and to be considered a branch of it, Ibn Khaldūn acknowledges a problem with the way history has come down. Many unqualified people have trammeled with the books of history written by competent Muslim historians; they have introduced tales of gossip imagined by themselves as well as false reports. Moreover, other historians have compiled partial reports of particular dynasties and events without looking to the way things have changed over time, without looking at natural conditions and human customs. Consequently, Ibn Khaldūn considers his task to be that of showing the merit of writing history, investigating the various ways it has been done, and showing the errors of previous historians. What needs to be known, and thus what he sets out to make known, are "the principles of politics, the nature of existent things, and the differences among nations, places and periods with regard to ways of life, character, qualities, customs, sects, schools, and everything else … plus a comprehensive knowledge of present conditions in all these respects … complete knowledge of the reasons for every happening and … [acquaintance] with the origin of every event." Yet in the end Ibn Khaldūn hints that he has almost digressed in the whole undertaking. What he wanted to do was to explain the nature of civilization and its accompanying accidents, but he fears he has strayed from his basic point.

I

Ibn Khurdādhbih

Sayyid Maqbul Ahmad

Abuʾl-Qāsim ʿUbayd Allāh ibn Khurdādhbih (also spelled Ibn Khurradādhbih), the first scholar to write on world geography in Arabic, was born in ca. AH 205/AD 820 (or AH 211/AD 825), and died in ca. AH 300/AD 912. Probably born in Khurāsān, he was brought up in Baghdad. His grandfather, Khurdādhbih, was a Zoroastrian, latter converted to Islam, and his father was the governor of Ṭabaristān. When he grew up, he became the director of posts and information in Jibāl (Media) and subsequently became director-general of the same department in Baghdad and later in Sāmarrā (Iraq). He became a companion of the ʿAbbāsid Caliph al-Muʿtamid (AH 256–279/AD 870–892).

Ibn Khurdādhbih was a versatile writer; besides writing on geography, he wrote on history, genealogy, music, wines, and even on the culinary art. Al-Nadīm, in his *al-Fihrist*, lists at least eight works to his credit. The Arab historian Abuʾl-Ḥasan ʿAlī ibn al-Ḥusayn al-Masʿūdī (d. AD 956) considered him an *imām* (leader) in authorship and mentions his voluminous historical work dealing with the ancient kings and peoples of Iran (*Murūj* 1965). Ibn Khurdādhbih also claimed to have translated into Arabic the geographical treatise of Claudius Ptolemy (ca. AD 90–168) from a "foreign language" (probably Syriac or Greek), but the translation is not extant.

However, Ibn Khurdādhbih's major work on geography, entitled *Al-Masālik al-Mamālik* (Roads and Kingdoms), was published by M. J. De Goeje in 1889. In fact, this work is an abridgement (prepared not later than AD 885–886) of his larger work (not extant) written in ca. AD 846–847. Considering the vast amount of information contained in the work and the early date of its compilation, it may be said that Ibn Khurdādhbih was the father of Arab-Islamic geography; no work of such magnitude existed before him. *Al-Masālik al-Mamālik* deals briefly with mathematical and physical geography, but the major portion of the work is devoted to descriptions of land and sea routes in the four directions emerging from al-Sawād. Then, it deals with marvels of the world, seas and mountains, sources of the rivers, and reports on countries like India and Central Asia.

It is not unlikely that Ibn Khurdādhbih relied heavily for his information on the ancient Sassanian government records which must have become available to him as the person in charge of the department of posts and information in Baghdad and elsewhere. Again, in his methodology and arrangement of the material and in the use of geographical terms and Persian couplets, a distinct Persian influence is discernible. The ancient Persians used to divide the known world into seven circular regions called *kishvars* (kingdoms) with Irānshahr at the center and the remaining six circles drawn around it. Such an arrangement is observable in his descriptions of the various routes emerging from al-Sawād, which, he says, was called *dil-i Irānshahr* (the heart of Iraq).

Ibn Khurdādhbih was not only the first to write on geography in Arabic, but he also set the style for writing on descriptive geography. Several later Arab-Islamic geographers utilized his work as a major source of information.

Ibn Mājid

Sayyid Maqbul Ahmad

Shihāb al-Dīn Aḥmad ibn Mājid ibn Muḥammad ibn Amr ibn Faḍl ibn Duwayk ibn Yūsuf ibn Ḥasan ibn Ḥusayn ibn Abī Maʿlaq al-Saʿdī ibn Abu'l-Rakāʾib al-Najdī was the greatest Arab navigator of the fifteenth century AD and one of the greatest of the Middle Ages. We do not know the date of his birth or death, but he must have died at an advanced age sometime in the first decade of the sixteenth century. Born in Julfār (Oman), he belonged to an illustrious family of navigators. Both his father and grandfather were *muʿallims* (masters of navigation) of repute.

Ibn Mājid wrote a number of works, both in prose and poetry, on nautical theory and on describing the seas (mainly the Indian Ocean) which served as guides for the Arab navigators of later periods. Among his important works in prose is the *Kitāb al-fawāʾid fī ʿuṣūl ʿilm al-baḥr wa'l-qawāʿid* (The Book of Benefits on the Principles of the Science of Navigation), dated AH 895/AD 1489–1490. This book and many others have been reproduced in the editions mentioned in the bibliography.

Ibn Mājid considered himself the fourth of the great Arab navigators of the Middle Ages; the other three were Muḥammad ibn Shādān, Sahl ibn Abān, and Layṭ ibn Kahlān, who belonged to the Abbāsid period. He thought his own works were more accurate than theirs, since they were more current and since many of the ports mentioned in the older works no longer existed. Apart from his practical experiences as a navigator, he had studied and improved upon the work of his father (*al-Ḥijāzīya*) and had studied a number of earlier Arabic works on astronomy and geography.

On the practical side of navigation, it is not unlikely that Ibn Mājid was in contact with the Indian navigators of his time, the *Ṣūliyān* (Cholas of Tamil Nadu, India) and with the Gujarati and the Konkani (Maharashtra, India) navigators, whose *qiyāsāt* (readings of the ports and harbors) he seems to have known. He was particularly knowledgeable about Siam and Bengal, and these navigators frequented these regions more than the Arab navigators did.

In his works Ibn Mājid covered a number of subjects relating to navigation, nautical astronomy, oceanography, and geography. In his *Kitāb al-fawāʾid*, he pays special attention to subjects of a more general nature, like guidelines to navigators such as the prerequisites for sailing on the sea, and he describes the lunar mansions, the stars corresponding to the 32 divisions (*aqnān*) of the compass card, the winds and seasons of the seas, nautical instruments, and the essentials required by captains of boats. These include knowledge of the rising and corresponding settings of the stars (*al-anwāʾ*), latitudes and longitudes, landfalls, and tides. He emphasizes that before sailing, captains should see that their instruments are in perfect order, the sailors obedient, and the seasons suitable. They should be patient and soft-spoken, should not deprive merchants of their rights, and they should be courageous, literate, and well behaved. He also presents a systematic description of the sea coasts of the Oikumene (the known world at that time), which no geographer had done before. From his writings, it appears that he did not conceive that a *terra incognita* existed in the southern quarter of the earth, as other geographers of his time believed. He thought that the Indian Ocean was connected with the Atlantic through a sea channel, which he calls *al-madqal* (place of entry).

Ibn Mājid claimed to have made several contributions to navigation and to determining the direction of the *qibla* (Mecca) from different positions of the earth with the help of the compass card. He also claimed to have fixed a magnetized needle on the mariners' compass (probably on a day box). Ibn Mājid had met Vasco da Gama, and had guided him to Calicut, India. Although the Portuguese sources do not mention him by name in this regard, we know from an Arabic work, *al-Barq al-Yamānī fīʾl-fatḥ al-ʿUṭmānī* (The Yemenite Lightning on the Ottoman Conquest) by al-Nahrawālī that it was he who directed Vasco da Gama from Malindi (East Africa) to India.

Ibn Māsawayh

Danielle Jacquart

Abū Zakariyyāʾ Yūḥannā ibn Māsawayh was born in Baghdad during the caliphate of Hārūn ar-Rashid (786–809), and not in 777 as was stated by Leo the African. His father, Māsawayh, was a pharmacist in the service of the physician Jibrāʾīl ibn Baḫtishūʿ, with whom he came from Jundīshāpūr (in Persia) to Baghdad. His mother was a slave, named Risala, whom Māsawayh bought from the physician Dawūd ibn Sarābiyūn. Thus, Yūḥannā ibn Māsawayh belonged to the milieu of Christian Nestorian physicians, who played an important part during the eighth and ninth centuries. He married the daughter of his colleague Abdallāh at-Tayfūrī and had a son of poor intelligence. He was very famous as a teacher and practitioner; he became the personal physician of four successive caliphs from al-Maʾmūn to al-Mutawakkil. He died in Samarra in 857.

As for many other authors of this period, it is difficult to distinguish legend and history in his biography. It was said that he did translations from Greek into Arabic, but none is extant under his name; most probably, he only commissioned some of them. For instance, it is well attested that Ḥunayn ibn Isḥāq undertook the translation of Galen's *Methodus medendi* (Arabic *Kitāb hīlat al-burʾ*; Methods of Healing) at Ibn Māsawayh's request. The relationship between both physicians was nevertheless strained, at least at the beginning: Ibn Māsawayh is supposed to have driven Ḥunayn out of his teaching position, who then went traveling in order to learn Greek and purchase manuscripts. It was also reported by Arabic medieval historians that Ibn Māsawayh had the opportunity of dissecting an ape, which had been given to the caliph by the prince of Nubia in 836 as a present. Following in Galen's footsteps Ibn Māsawayh afterward wrote an anatomical monograph, which can perhaps be identified with his *Kitāb at-tashrīḥ* (Book of Anatomy). Apart from his knowledge of Greek medicine, Ibn Māsawayh had access to some Indian works: he quotes, for instance, Āryabhaṭa in his ophthalmological treatise *Kitāb dafal al-ʿain* (Book on the Defectiveness of the Eye).

Ibn Abī Uṣaybiʿa listed 42 works; some others were quoted by al-Rāzī and al-Bīrūnī. But only 31 are extant, as far as we know, and very few have been edited or studied. Those that have been edited – and sometimes translated into English or French – are the *Aphorisms*, the works on barley water, simple drugs, and perfumes, as well as the medical calendar; the ophthalmological treatises have also been analyzed. It seems that among the works which were translated into Latin during the Middle Ages under the names of "Mesuë" or "Johannes

Damascenus," only the *Aphorismi Johannis Damasceni* and some ophthalmological fragments can be attributed to Ibn Māsawayh; the other ones, mainly pharmacological, are probably apocryphal for the most part. The *Aphorismi* – a faithful translation of *Nawādir aṭ-ṭibb* – were largely diffused from the twelfth century; a second translation appeared as the sixth book of Rāzī's *Secrets of Medicine*: it was done during the thirteenth century by the Dominican Giles of Santarem.

Some original features of Ibn Māsawayh's medicine can be drawn from his *Nawādir aṭ-ṭibb*. Dedicated to Ḥunayn ibn Isḥāq and modeled on the Hippocratic *Aphorisms*, this short work was intended to give practical advice. The eight first aphorisms can be considered as a kind of commentary on the first Hippocratic aphorism: "Life is short, art long, opportunity fleeting, experiment dangerous, judgment difficult." They stressed the necessity for physicians to be both learned and skilled. Throughout the remaining 124 aphorisms the following topics are covered: the link between body and soul, the observance of astrological and climatological rules, the attention that physicians have to pay to the healthy nature of their patients, the numerical ratios which rule human temperaments, as well as natural substances used for treatment. It has to be noted that this last idea was deeply developed by Ibn Māsawayh's contemporary, al-Kindī. Ibn Māsawayh seems also to have been very much attached to the idea that physicians must mainly reinforce nature by using drugs similar to it; medical treatment with substances contrary to disease had to be prescribed cautiously and their sole goal was to purge. Physicians had to be cautious not to alter nature too much. For example, Ibn Māsawayh stated: "It is important that, against diseases, the strongest contrary is not introduced into the body, since this would be very harmful; it can be compared with a very cold wind which, during the same day, blows after a very hot one" (aph. 60). In the same manner, treatment by diet was preferred to pharmacopoeia: "If the physician can treat with food, to the exclusion of drugs, he will be very successful" (aph. 108). In addition to several pharmacological treatises, Ibn Māsawayh composed an important work on dietetics.

Ibn Māsawayh's works remain very little known, despite their importance in the history of Arabic medicine. Detailed studies would shed light on the decisive stage constituted by the beginning of the ninth century, before the spread of Ḥunayn's translations.

Ibn Muʿādh

A. Mark Smith

Ibn Muʿādh al-Jayyānī, Abū ʿAbd Allāh Muḥammad (d. ca. 1093) has traditionally been assigned a birth date of 989. However, recent scholarship suggests that Ibn Muʿādh was born somewhat later, in the early eleventh century. The only secure date we have for him is 1079, the year of a solar eclipse he describes from first-hand observation. The ending "al-Jayyānī" to his name indicates that he was from Jaén in Andalusia, where he evidently served as a *qāḍī* (judge) for much of his life. Among his few surviving astronomical and mathematical works are included the *Tabulae Jahen*, a set of astronomical tables based on those of al-Khwārizmī and probably translated into Latin by Gerard of Cremona; *Maqāla fi sharḥ al nisba* (On Ratio), a commentary on Book 5 of Euclid's *Elements*; and *Kitāb majhūlāt qisiyy al-kura* (Determinations of the Magnitudes of the Arcs on the Surface of a Sphere), a work on trigonometry. Certainly the most original, and perhaps the most historically significant of his extant works, is the brief treatise *On Twilight and the Rising of Clouds*.

While no Arabic exemplar has yet come to light (the original title was probably *Ma'l-fajr wa'l-shafaq*), this work has nonetheless reached us in three other linguistic forms: a fourteenth-century Hebrew translation from the Arabic (represented by one manuscript), a late twelfth-century Latin translation from the Arabic, probably by Gerard of Cremona (represented by 25 manuscripts), and a fourteenth-century Italian translation from the Latin (represented by one manuscript). The sheer number of Latin manuscripts – plus the Italian translation – indicates the seriousness with which this treatise was received and disseminated in the medieval West. That it was commonly misattributed to Ibn al-Haytham, author of the magisterial *Kitāb al-manāẓir* (*De aspectibus*), may have had something to do with this. There is also clear, albeit indirect, evidence that *On Twilight* exerted its share of influence in the medieval East as well.

Ibn Muʿādh's purpose in *On Twilight* is to determine the height of the atmosphere under the assumption that the first light of dawn is produced when rays from the rising sun tinge vapors at the very upper edge of the atmosphere. Although he offers no practical justification for this inquiry, he does, in a couple of querulous asides, berate those (religious conservatives?) who would squelch rational inquiry out of mere ignorance. The determination itself depends upon four basic parameters: the depression of the sun below the horizon at first light (18°); the mean distance between earth and sun (1,110 terrestrial radii); the relative size of sun and earth (5.5:1 in terrestrial radii); and the circumference of the earth (24,000 mile). On the basis of these parameters and using simple trigonometric functions, Ibn Muʿādh calculates the atmosphere to be around 52 mile high. This figure remained canonical in the Latin West until the end of the sixteenth century, when Tycho Brahe raised the issue of atmospheric refraction to prominence. Within this context, it soon became clear that Ibn Muʿādh's calculation was useless because it failed utterly to take atmospheric refraction into account. Consequently, his figure of 52 mile was drastically reduced by Johan Kepler and succeeding astronomers.

Ibn Munʿim

Ahmed Djebbar

The oldest mathematical work from the Maghreb which deals with combinatory problems is the *Fiqh al-ḥisāb* of Ibn Munʿim, a scholar originally from Andalusia, living in Marrakesh in the Almohad era. To our knowledge, his book was the first in the entire history of mathematics to have devoted a whole chapter to these types of problems and to have stated them and solved them according to a common procedure.

Aside from Ibn ʿAbd al-Malik, the biographers of the Maghreb do not mention Ibn Munʿim, even though they write at length about mathematicians of lesser significance, and they use the contents of his book. The little information we do have on Ibn Munʿim comes from his own introduction to his mathematical text, cited above, and from the book of Ibn ʿAbd al-Malik.

According to the latter source, Ibn Munʿim's full name was Aḥmad ibn Ibrāhīm ibn ʿAli Ibn Munʿim al-ʿAbdarī. He was originally from the town of Denia on the east coast of Spain, near Valencia, and he lived in Marrakesh where he taught and where he died in 626H/1228. He was known as one of the best scholars of his era in geometry and number theory. At the age of 30, he began to study medicine which he practiced successfully at the same time as his mathematical activities.

Only three of Ibn Munʿim's numerous mathematical texts and letters are known today: one on magic squares, another on geometry, and the third on the science of calculation. And of these, only the last, *Fiqh al-ḥisāb*, is extant. Ibn Munʿim wrote it under the reign of the fourth Almohad caliph, al-Nāṣir (1199–1213). During his reign celebrated scholars like the grammarian Abū Mūsā al-Jāzūlī, the algebraist Ibn al-Yāsamīn, and the doctors of the Ibn Zuhr family all lived in the Almohad capital, or even within the court itself. This leads one to believe that there was a variety of scientific activity, thanks to a generous and often enlightened patronage.

Combinatory analysis is taken up the 11th section of the first chapter of *Fiqh al-ḥisāb*, entitled "an accounting of words which are such that human beings can express them only by one of them." This section is not, however, in the eyes of this author, a complete overview of practical calculations. He takes care to explain, in the course of his exposition, that he proposes first to treat the problem in a general manner, even though he is obliged, in order to make his ideas clear, to formulate it in specific terms using the Arabic alphabet. In fact, this study goes beyond the linguistic framework in which it is formulated, as much by the way of posing the problems and linking them to each other, by the methods of reasoning used, as by the established results.

Ibn Munᶜim begins by setting out the problem as a mathematician; he defines precisely the framework in which he is stating the chosen hypotheses and the degree of generality researched. Then he establishes, using a set of colors of silk as an abstract model, a rule which enables one to determine all the possible combinations of n colors p times p. In order to do that, he constructs, in accordance with an inductive method, a triangular numeric table, identifies its elements, with the desired combinations, and deduces the relationships:

$$C_n^p = C_{n-1}^{p-1} + C_{n-2}^{p-1} + \ \ldots \ + C_{p-1}^{p-1}.$$

Thus, he presents, to our knowledge for the first time, the famous arithmetical triangle which algebraists from the Muslim East like al-Karajī (d. 1029) had already constructed but for other purposes and using another procedure.

Ibn Munᶜim's study continues by establishing, using induction, relative formulas with permutation, with or without repetitions, of a group of letters such that they give, by recurrence, the number of possible readings of a word of n letters, taking into account all the signs (vowels and sukūns for Arabic) used by a given language. This is the content of problems 2, 3, and 4. In problem 5, the author concludes the first part by establishing a formula of arrangements, without repetition, of n objects p times p, which take into account the vowels and the sukūn accompanying the letters.

The second part, much longer, seeks to enumerate the combinations with repetitions, adopting a method analogous to the preceding one and which necessitates recourse to the table of numbers. It was moreover this same method that the French scholar Mersenne rediscovered and applied to his work in the seventeenth century.

To set up problem 6, Ibn Munᶜim goes back to his model of bunches and proposes to solve a difficult dilemma, apparently removed from the initial problem and stated thus: being given threads of silk in n colors, we want to determine the number of bunches it is possible to make with p threads of k colors, so that $p_1, p_2, \ldots, p_k$ threads are, respectively, of the same color.

All these propositions, and even more the techniques, allow the resolution of the problem which Ibn Munᶜim formulates as follows: to determine the number of words of 1–10 letters which it is possible to make with the letters of the Arabic alphabet, including all possible repetitions of letters in a words, and including vowels and the sukūn which can appear on letters.

The third part of his study includes, along with several applications, a series of tables which enables the determination, more and more closely, of all the elements (P_n, A_n, C_n,…) which occur in the counting of words that it is possible to pronounce in a given language.

In addition to the results included in this chapter of *Fiqh al-ḥisāb*, the way in which Ibn Munᶜim established his results is also notable. In fact, he uses two types of reasoning which can be called inductive and combinatorial. While inductive reasoning is a traditional tool of Islamic mathematics with its privileged domains and unique stature, one cannot say the same for combinatorial reasoning which appeared, to our knowledge for the first time, in the *Fiqh al-ḥisāb*. His systematic use of combinatorial reasoning for establishing general propositions appeared as a clear acknowledgment of its mathematical character.

One can even suppose that if combinatorial reasoning had enjoyed a quantitative development in the field of application, it would have resulted in its explicit recognition as a process of reasoning beside analysis, synthesis, induction, and reasoning *ad absurdum*.

The elaborate nature of his procedures and results which appear in the *Fiqh al-ḥisāb*, as well as the spirit of the method which emerged from them leads to the theory that the beginning of the mathematization of combinatorial problems within the framework of Arabic science occurred prior to the work of Ibn Munᶜim.

While we await the confirmation, or correction, of this conjecture, the *Fiqh al-ḥisāb* remains the oldest known Arabic work from the Muslim West in which an autonomous chapter on combinatorial analysis appeared. But its importance does not end there: with regard to the linguistic tradition of the Maghreb, the book was a culmination in that it laid out a general solution to a given problem. Also, for mathematics, the work represents an important link, marking the end of one stage in the progress of combinatorics, that of calculation using tables, and the beginning of another stage, that of the extension of formulas and their use in solving problems.

Ibn Qunfudh

Y. Guergour

Abū'1^ɔAbbās Aḥmed Ibn al-Ḥasan Ibn 'Ali Ibn al-Khaṭīb was known under the two names of Ibn Qunfudh and Ibn al-Khaṭīb. He was born in 710 AH (AD 1339) in Constantine, Algeria and came from an old family which was cultured and well to do. We know that Ibn Qunfudh began his studies with his father and his maternal grandfather, in order to follow them eventually under the direction of other professors from his same town.

After his elementary education, he returned to Fez, in Morocco, where he remained for 18 years. There he studied with several professors, covering different scientific themes, and teaching and publishing some of his own work. We know that it is in this city that he edited in 771 (1370) his most important mathematical work, the *Ḥaṭṭ an-niqāb* ^ɔ*an wujūh* ^ɔ*amāl al-ḥisāb*, which is a commentary on the *Talkhīṣ a*^ɔ*māl al-ḥisāb* of Ibn al-Bannā^ɔ, written in 721 (1321). We think that he acquired his advanced education either completely or partially during his stay in Fez.

During the period of famine which raged in all of Maghreb in 776 (1374), Ibn Qunfudh went back to Constantine in order to take up duties as a *khaṭib* (preacher), *mufti* (jurist), and *qāḍī* (judge). At the same time, he devoted himself to the teaching and editing of scholarly work. No information has come down to us on the subject of the contents of this teaching, and we do not even know if he taught the contents of his own mathematical writings at Constantine or in the cities where he was posted, or even if he was content only to edit them, following in that the tradtion of several older authors, who wrote on subjects which were very different from each other without having taught them.

What follows is an attempt to give a glimpse of Ibn Qunfudh's contributions to mathematics, of which we know only four titles:

1. *Mabād' as-sālkin fī sharh rajz Ibn al-Yāsamīn* (Principles for Those who are Concerned with the Commentary on the Poem of Ibn al-Yāsamīn). Ibn Qunfudh began this poem according to the traditional procedure of commentators of the Middle Ages. What is not traditional is his use of mathematical symbolism to resolve equations and to represent polynomials. This was to become normal practice during this period, since this commentary was adopted by his students. The symbolism was universally used in mathematical works from Maghreb. This hypothesis is reinforced by the presence of this same symbolism in the book *Ḥaṭṭ an-niqāb* and in the book written by Ya^ɔqūb al-Muwāḥidī *Tahṣīl al-munā fī sharh Talkhīṣ Ibn al-Bannā*.
2. *Bughyat al-fāriḍ min al-ḥisāb wa l-farā'id* (The Desire of the Genealogical Specialist to Know Arithmetic and Successional Division). To this day, no copy of this book has been found.
3. *at-Talkhīṣ fī shzarh at-Talkhīṣ* (Abridged Commentary on *Talkhīṣ*). This is a resume of *Ḥaṭṭ an-niqāb*, of which two copies are extant today.
4. *Ḥaṭṭ an-niqāb* ^ɔ*an wujūh* ^ɔ*amāl al-ḥisāb* (Lifting the Veil on the Operations of Calculation). Five copies of this work are extant.

Since this is Ibn Qunfudh's most important work, it is useful to describe certain aspects of its contents. Reading it permits us to make several important observations on mathematical writing in this era. The author begins his book with some advice and directions designed to facilitate the reading of any book; then he provides a detailed list of the writings of Ibn al-Bannā^ɔ. In the beginning of each chapter, he gives an abstract of its contents, something which one finds nowhere else in the literature of other mathematicians of this time. It is also important to note again the existence of Ibn Qunfudh's mathematical symbolism, particularly in the chapters on roots and on algebraic equations. However, recent research reveals that this symbolism had been used previously at the end of the twelfth or beginning of the thirteenth century, especially in Ibn Yāsamīn's book *Talqīḥ al-afkār*. Elsewhere, Ibn Qunfudh supplies arithmetic rules which one does not find in Ibn al-Bannā^ɔ's work, notably in the chapter on the product. Ibn Qunfudh's terminology also differs significantly from Ibn al-Bannā^ɔ's.

Finally, one finds in the work of Ibn Qunfudh an equation of which the second number is zero, an equation which had formerly been studied by Ibn Badr. His originality lies in the symbolic way in which he expressed it:

ـشـ
0 ـل 7 لا 8.

or, in modern symbols, 8.*r*–7 = 0.

Ibn Qunfudh died in 810 AH (AD 1407).

Ibn Qutayba

Paul Kunitzsch

Ibn Qutayba, Abū Muḥammad ʿAbdallāh ibn Muslim, was born in 828 in Kufa or Baghdad, and died in 884 or 889 in Baghdad.

Ibn Qutayba was a scholar of typical Arabic–Islamic education. His studies included all branches of the traditional Arabic and Islamic knowledge of his time: religion, history, biography, philology, lexicography, literature, and some science. He left twenty works of varying lengths covering all the fields mentioned. In his career, for some years he was *qāḍī* (a judge according to Islamic rules) in Dinawar (northern Iran); later he lived and taught in Baghdad, where he also died. Of particular scientific interest is his *Kitāb al-anwāʾ* (Book on the anwāʾ). *Anwāʾ* are asterisms and stars used by the Arabs in pre-Islamic and early Islamic times to determine seasons, predict weather—especially rain, and guide them in their nightly desert travels. Many Arabic philologists and lexicographers wrote books of this type, but most of these did not survive. Therefore Ibn Qutayba's *Book on the anwāʾ*, which was printed in Arabic, in Hyderabad/Deccan (India) in 1956, is of great interest. In it, the author has assembled information on the popular astronomical and meteorological knowledge of the old Arabs, from the time before their acquaintance with Greek, Persian, and Indian astronomy. Facts, traditions, terminology, and nomenclature are amply described. Much of this material continued to be used later in the most active period of Arabic – Islamic astronomy. And some of it even lived on into our time, as, for example, the star name Aldebaran (for α Tauri).

Ibn Riḍwān

Albert Z. Iskandar

Abu'l-Ḥasan ʿAlī Ibn Riḍwān ʿAlī Ibn Jaʿfar, a self-educated physician philosopher, was born in AD 998 at Gīzah, a suburb south of Cairo (al-Fusṭāṭ). He was the son of a poor baker (*farrān*) and had to earn money in his youth by practicing medicine, teaching, and telling people's fortunes from astrological signs. When he was 59, he wrote a book entitled *Fī Sīratihī* (On His Own Conduct). The work is now lost, but its text is partly preserved in Ibn Abī Uṣaybiʿa's *ʿUyūn al-Anbāʾ fī Ṭabaqāt al-Aṭibbāʾ* (Sources of Information About the Classes of Physicians).

In his youth, he believed in astrology (*ʿilm al-nujūm*) and was convinced that the stars at the time of his birth indicated a prosperous medical career. To realize his ambition, he first sought out a popular teacher in Cairo, who instructed Ibn Riḍwān to memorize Ḥunayn Ibn Isḥāq's (d. AD 873) *Kitāb al-Masāʾil fi'l-Ṭibb li'l-Mutaʿallimīn* (Questions on Medicine for Students). Ibn Riḍwān watched him teaching: pupils read the text; the teacher listened but did not utter one word of explanation and did not even bother to correct their errors. Ibn Riḍwān sought to find other teachers and put questions to each of them, based on the writings of Hippocrates and Galen, which they displayed on shelves in their private libraries. He concluded that they merely knew the titles of books but were ignorant of their contents. He pondered over traveling to Iraq for further education, but financial difficulties prevented his going there. He decided on self-education at the tender age of 15. From perusing Galen's *On the Doctrines of Hippocrates and Plato*, he concluded that he should first study geometry and logic. He studied the well-known books on these two subjects, then proceeded to read textbooks on medicine proper. In this way he reached an understanding of the principles of the art of healing.

Ibn Riḍwān worked very hard as a practicing doctor until he reached the age of 32, when he became well known and earned enough money to build his own residential Palace of Candles (*Qaṣr al-Shamʿ*). At the age of 59 he divided his time between practicing medicine, daily physical exercise (*al-riyāḍah*), and reading books on literature, Islamic law, and medicine. His fame reached the Fātimid Caliph al-Mustanṣir (r. AD 1036–1094), who appointed him Chief of Physicians (*Raʾīs al-Aṭibbāʾ*) in Egypt. He was kind-hearted, treated the poor for free, and was always willing to extend a helping hand to the needy.

In old age, Ibn Riḍwān's mind became disturbed (*taghayyar ʿaqluhu*) as a result of being robbed of all his cherished possessions. He had adopted an orphan young girl whom he brought up in his own house. She absconded with all the precious items he had accumulated and 20,000 gold dīnārs which he had kept in the house. An extensive search for the girl was abortive. Ibn Riḍwān died in AD 1067.

Among Ibn Riḍwān's extensive bibliography are his treatise *Fī Dafʿ Maḍārr al-Abdān fī Arḍ Miṣr* (On the Prevention of Bodily Ills in Egypt) and the *Al-Nāfīʿ fī Kayfiyyat Taʿlīm ṣināʿat al-Ṭibb* (Useful Book on the Quality of Medical Education).

In *On the Prevention of Bodily Ills*, he describes the Nile and the Muqaṭṭam Hills on both sides of the river. The hills in the east hold back the "hot and humid" winds, which are most favorable for the temperament (*mizāj*) of animals and which do not reach *al-Fusṭāṭ*. Ibn Riḍwān gives an account of "the six non-natural causes" (*al-asbāb al-sitta al-ḍarūriyya*) which determine health and sickness: the air surrounding the body, food and drink, movement and rest, sleep and wakefulness, retention and evacuation, and psychic events.

Ibn Riḍwān was discourteous in criticizing members of the medical profession. For example, chapter 5 of this treatise is entitled "On the Incorrectness of Most of Ibn al-Jazzār's [d. AD 1009] Reasons for the Unhealthy Air in Egypt." Furthermore, disagreements arose with Ibn Buṭlān of Baghdad. These are well documented by Meyerhof and Schacht (1937).

In his *Useful Book*, Ibn Riḍwān preserved for posterity a unique document, the late Alexandrian medical curriculum (sixth to seventh century AD). In it he attributes the decline of medicine in his time to the popularity of poor-quality compendia (*kanānīsh*) and summaries and commentaries of the books of Hippocrates and Galen, compiled by incompetent physicians. The Alexandrian curriculum specifies the titles of textbooks of logic, medicine proper, and mathematics (including astronomy). It consists of preparatory (introductory) courses and main courses. The preparatory courses contain optional subjects, including language and grammar, and compulsory subjects: physics, arithmetic, numerals, measurement, geometry, the compounding of drugs, astrology, and ethics.

The main courses include logic and medicine proper. Sixteen of Galen's books were to be studied in seven grades: Grade 1 included Galen's *On Sects*, *On the Art of Physics*, *On the Pulse*, *To Teuthras*, and *To Glaucon on Therapy*. In the final and seventh grade, students studied Galen's *On the Method of the Preservation of Health*.

Ibn Rushd (Averroës)

Albert Z. Iskandar

Abu'l-Walīd Muḥammad ibn Aḥmad ibn Muḥammad ibn Rushd (Averroës, AD 1126–1198), a native of Cordoba, Spain, was the namesake of his famous grandfather. Later, to avoid any confusion, he was nicknamed *al-ḥafīd* (grandson). Like his father and grandfather, he was a well-known jurist. By profession, following in the footsteps of his father, he became a *qāḍī* (judge), who specialized in religious matters, and at one time was the Imam of the great mosque of Cordoba. He adhered to the Mālikī sect, one of the four great sects of Islam, and wrote *Kitāb al-Muqaddimāt al-Mumahhidāt* (A Book of Introductions that Pave the Way), for the followers of the sect.

At his father's insistence, Ibn Rushd studied Islamic law (*Sharīʿa*) under the teacher, al-Ḥāfiẓ Abū Muḥammad Ibn Rizq. Ibn Rushd also studied the science of Tradition (*Ḥadīth*), but he is known to have been more interested in Islamic law. He memorized the *Muwaṭṭaʾ* of Imam Mālik and was also greatly impressed by the Ashʿarite science of *Kalām* (Theology). Later, he turned against the Ashʿarī school of thought and attacked its proponent, the Imam al-Ghazālī (d. AD 1111). Ibn Rushd was also acquainted with the doctrines of the Muʿtazila theology.

His teachers of medicine were Abū Marwān Ibn Jurrayūl, a first-class practitioner, and Abū Jaʿfar Hārūn al-Tarjālī, a well-known physician philosopher in Seville, who was knowledgeable about Aristotelian philosophy, as well as the medical writings of the Ancients. Al-Tarjālī was employed by the Almohad (*al-Muwaḥḥid*) ruler Abū Yaʿqūb Yūsuf (r. AD 1163–1184). Abū Yūsuf Yaʿqūb al-Manṣūr (r. AD 1184–1199), before succeeding his father, attended meetings in Seville, to which notable philosophers, physicians, and poets were invited. Abū Bakr Ibn Ṭufayl (Abubacer), Ibn Zuhr (Avenzoar), and Ibn Rushd were regular attendants at these meetings. Ibn Rushd's education under al-Tarjālī qualified him as a physician-philosopher; his studies in religious law, under al-Ḥāfiẓ, entitled him to be considered a jurist (*faqīh*).

In 1153, when he was in Marrakech (Morocco), Ibn Rushd supported the Almohad ruler ʿAbd al-Muʾmin (d. AD 1163) in furthering education by founding colleges. From his commentary on Aristotle's *De Caelo*, one learns that Ibn Rushd conducted astronomical observations when in Marrakech, and in his commentary on the *Metaphysics*, he mentions his yearning for his early studies in astronomy. Ibn Rushd studied the writings of Arabic-speaking astronomers and expressed his own opinion regarding the three kinds of planetary motions: those that can be detected by the naked eye, those that can be seen by instruments of observation (remarking that some occurred over long periods of time that exceeded the lifetime of observers), and those planetary movements whose existence can only be surmised by reasoning. Between AD 1169 and 1179, Ibn Rushd visited many places in the Almohad realm. He was actively researching matters pertaining to astronomy when he met Ibn Ṭufayl, a philosopher and astronomer in his own right. Ibn Ṭufayl enhanced Ibn Rushd's career by introducing him to Abū Yaʿqūb Yūsuf, who appointed Ibn Rushd as *qāḍī* of Seville in AD 1169. Ibn Rushd returned to Cordoba in AD 1171, at which time he was still holding the office of *qāḍī*. In AD 1182, he succeeded Ibn Ṭufayl as a personal doctor to Abū Yaʿqūb Yūsuf, and was elevated to the office of grand *qāḍī* of Cordoba.

For 10 years Ibn Rushd enjoyed the patronage of Abū Yaʿqūb Yūsuf. Out of jealousy, jurists (*al-fuqahāʾ*) of the Mālikī sect, whose influence had grown as a result of their religious zeal during the period of the Crusades, successfully conspired against him for his free-minded views. He was summoned to appear in court, and his philosophical writings were deemed contrary to the teachings of Islam. Ibn Rushd fell from grace in AD 1195 and was banished to Lucena, a province of Cordoba.

Very little is known about Ibn Rushd as a teacher of medicine. Nevertheless, the names of two of his students are known: ʿAbd Allāh al-Nadrūlī and ʿĪsā ibn Aḥmad ibn Muḥammad ibn Qādir. The latter transcribed the whole text of Ibn Rushd's book *Al-Kulliyyāt* (Generalities) from the author's own autograph, during his lifetime, and with his approval.

Kitāb al-Kulliyyāt (Latin, *Colliget*) consists of seven books: *Tashrīḥ al-Aʿḍāʾ* (The Anatomy of Organs), *al-Ṣiḥḥa* (Health), *al-Maraḍ* (Disease), *al-ʿAlāmāt* (Symptoms), *al-Adwiya wa'l-Aghdhiya* (Drugs and Foods), *Hif ẓ-al-ṣiḥḥa* (Hygiene), and *Shifāʾ al-Amrāḍ* (Recovery from Disease). The purpose of the book, according to the author, is to provide medical men with an introduction to concise accounts of the different parts of medicine (*ajzāʾ al-ṭibb*).

Scientific collaboration existed between the eminent practitioner Ibn Zuhr (Avenzoar, d. AD 1162) and Ibn Rushd. Ibn Rushd asked Ibn Zuhr to write a book on therapy, which he did. It was called *al-Taysīr fi'l-mudāwāt wa'l-tadbīr* (An Aid to Therapy and Regimen). *Al-Taysīr* and the *Kulliyyāt* together were meant to cover the whole science of medicine, possibly instead of Ibn Sīnā's (Avicenna, d. AD 1037) *Kitāb al-Qānūn fi'l-Ṭibb* (Canon of Medicine), which Ibn Zuhr severely criticized.

A merchant from Baghdad presented Ibn Zuhr with a beautifully transcribed and ornamented copy of Ibn Sīnā's *Kitāb al-Qānūn*. After reading it for the first time, Ibn Zuhr condemned the book and kept tearing off the margins of its leaves, which he used for jotting down prescriptions for his patients. It took almost a century before a copy of *Kitāb al-Qānūn*, completed by its author in Hamadan (Persia), actually reached Cordoba, Ibn Rushd's home town.

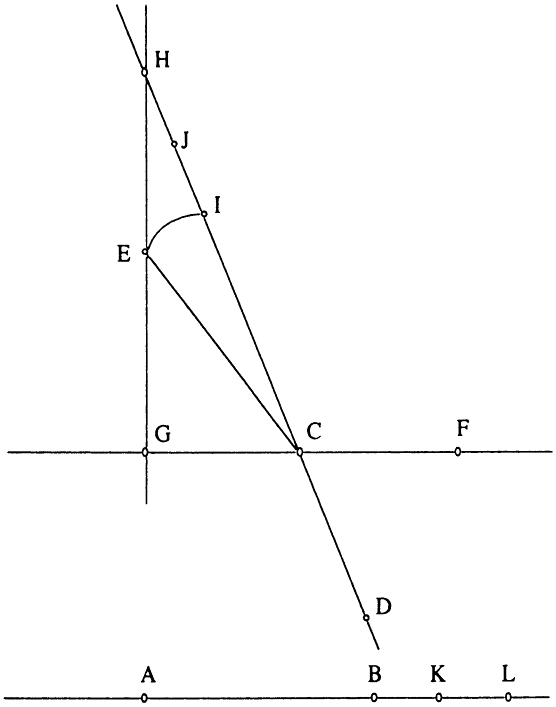
Ibn Sahl

Roshdi Rashed

Ibn Sahl, Abū Saʿd al-ʿAlāʾ, was a first-class mathematician. From his correspondence as well as from diverse information transmitted by mathematicians of the second half of the tenth century, we can deduce that he flourished under the Buwayhid Dynasty, and probably in Baghdād, between 970 and 990. Many of Ibn Sahl's important writings have been lost, namely two treatises, *On the Measurement of the Parabola* and *On the Centers of Gravity*, and a kind of anthology of problems about which we have no direct information. His book *Fī al-Ḥarrāqāt* (On Burning Instruments) was also on the point of being lost. This book, written in Baghdād around 984, is the first known contribution on the geometric theory of lenses.

Let us begin with the contribution of Ibn Sahl to optics. He wrote a memoir on the transparency of the celestial sphere, which was commented on by Ibn al-Haytham. The memoir and the commentary have come down to us. In this, composed in the course of his reading of Book V of Ptolemy's *Optics*, Ibn Sahl takes up not only the rules of refraction set out by his predecessor, but also demonstrates that every medium, including the celestial sphere, is invested with a certain opacity which defines it. Ibn al-Haytham had already captured this idea perfectly when, on reading this same memoir of Ibn Sahl, he wrote that his predecessor wanted to demonstrate that "there is no limit to transparency, and, for each transparent body, another always exists which is more so." That is to say that the mathematician better understands the notion of a medium and its definition by a certain characteristic opacity.

But Ibn Sahl's real discovery takes place when he poses the still unthought-of question of burning by refraction. He no longer defines the medium by a certain opacity, but characterizes it by a constant ratio. It is this concept of constant ratio distinguishing the medium which is the masterpiece of his study of refraction in lenses. This ratio, postulated by Ibn Sahl but never calculated, is nothing but the inverse of the refraction index *n* of the medium in relation to air. It therefore deals with Snellius' law of refraction, its formulation being very close to Snellius' own formulation some six centuries later. Let us look again at *On Burning Instruments* (Fig. 1).



Ibn Sahl. Fig. 1 Refraction in lenses.

At the beginning of the study of refraction in lenses, Ibn Sahl considers a plane surface GF limiting a piece of crystal. He considers the straight line DC following which light propagates in the crystal, the straight line CE according to which it refracts in the air, and the perpendicular at G to the surface GF which cuts the straight line CD at H and the refracted ray at E.

Here Ibn Sahl clearly applies the law by which the ray CD in the crystal, the ray CE in the air, and the perpendicular GE to the surface plane of the crystal, are all on the same plane. As usual, with no conceptual comment, he writes:

> The straight line CE is therefore smaller than CH. We separate from the straight line CH the straight line CI equal to the straight line CE; we divide HI in half at point J; we set the ratio of the straight line AK to the straight line AB equal to the ratio of the straight line CI to the straight line CJ; we extend the straight line BL along AB and set it equal to the straight line BK.

In these sentences, Ibn Sahl concludes that CE/CH is less than 1, which he will use throughout his research on lenses constructed in the same crystal. He will not fail to give this same ratio again, nor to reproduce this same figure, each time he discusses refraction in the crystal.

This ratio is nothing but the inverse of the index of refraction in the crystal in relation to air. In fact, let us consider i_1 and i_2, the angles formed, respectively, by CD and CE with the perpendicular GH. One has

$$\frac{1}{n} = \frac{\sin i_1}{\sin i_2} = \frac{CG}{CH}\frac{CE}{CG} = \frac{CE}{CH}.$$

Ibn Sahl takes on segment CH point I such that CI = CE, and point J at the middle of IH. One has

$$\frac{CI}{CH} = \frac{1}{n}.$$

The division CIJH henceforth characterizes the crystal for all refraction.

Ibn Sahl made innovations not only in optics, but also in mathematics. Among his mathematical inventions, I shall mention only one paper, set down as a follow-up to his contemporary, the mathematician al-Qūhī: his study of the method of projection of the sphere. Al-Qūhī is, in fact, the author of a treatise on *The Art of the Astrolabe by Demonstration*. This treatise is composed of two books, of which the first opens with an introductory chapter on the theory of projections. The propositions which al-Qūhī set forth seemed "difficult to understand" to one of his contemporaries, who turned to Ibn Sahl for clarification of the notions found therein and for the proof by synthesis of what al-Qūhī showed by analysis. We have here a situation of privileged history: we are witness to the elaboration of a new chapter of geometry by two contemporary mathematicians.

In conclusion, I remark upon the emergence of Ibn Sahl, a figure until recently almost unknown, and two chapters: anaclastics and the study of projection of the sphere. Ibn Sahl also made a substantial contribution in infinitesimal mathematics as well as in construction problems – the regular heptagon, for instance.

Ibn Sarabi (Serapion)

E. Ruth Harvey

There are two different Arab authors known to the medieval Latin west as "Serapion," and the confusion between them in all of the authorities seems inextricable. The elder of the two authors was a Syrian, Yuḥannā ibn Sarabiyun, who lived in the ninth century. He wrote two books in Syriac, which were translated into Arabic: they are called the *Large Kunnāsh* (it was in twelve parts) and the *Small Kunnāsh* (in seven parts). Manuscript copies of the Arabic versions exist in European libraries; what sounds like a whole copy of the *Large Kunnāsh* is in Istanbul. Both works deal with medicine and diet, but not surgery; al-Rāzī (Razes), who may have been a younger contemporary, cites Serapion, naming the *Kunnāsh*, and ʿAlī ibn ʿAbbās al-Majūsī (d. 994) criticizes Serapion for ignoring surgery. The *Small Kunnāsh* was translated into Latin by Gerard of Cremona (d. 1187) and entitled *Practica Joannis Serapionis dicta Breviarium*. There are many manuscript copies of this version and some early printed texts. Moses ben Mazliach translated Gerard's version into Hebrew, and a manuscript of this translation still survives.

The younger Serapion is an even more obscure figure. He was the author of a treatise on drugs called *Kitāb al-adwiya al-mufrada*, which was translated into Latin as *Liber de medicamentis simplicibus* by Simon de Cordo of Genoa and Abraham of Tortosa in about 1290. The younger Serapion cannot have lived earlier than the eleventh century, because he cites among his authorities not only al-Rāzī, but also Ibn al-Wāfid (997–1075). There are many manuscript copies of the Latin translation, and several early prints. Usually the works of both Serapions appear together. In the Latin text, the author explains that he intends to collect and reconcile the views of Dioscorides and Galen on a wide variety of medicinal substances, and then to add in the opinions of others. In his chapter on pearls, for instance, he describes the generally accepted power of pearls to strengthen the heart; he then goes on to cite four Arab authorities on the effects of pearls on the eyesight, the blood, the nerves, melancholia, and as a dentifrice.

Ibn Sīnā (Avicenna)

Mehdi Aminrazavi

Abū ʿAlī al-Ḥusain ibn ʿAbdallāh ibn Sīnā (980–1037), also known as Avicenna, was born in the city of Būkhārā in the Eastern part of Persia into an Ismaʾili family. He demonstrated an incredible genius for learning, and having mastered the *Quʾrān* and the sciences of his time, became a physician at age 16. Ibn Sīnā gained favor with the Sāmānid dynasty for having cured Prince Nūḥ ibn Manṣūr and was thus allowed to use the royal library. He mastered other sciences such as psychology, astronomy, chemistry, and pharmacology by age 18, and toward the end of his life said he had learned everything he knew by then.

Ibn Sīnā lived in a tumultuous time when different princes were engaged in a power struggle, resulting in his traveling from city to city. He first went to Gorgān, an area close to the Caspian Sea, crossing the desert on foot, and after a while traveled to Khorāsān, Rayy, and Qazwīn, until he finally settled in Hamadān at the request of prince Shams al-Dawlah. In 1022, following the death of the prince, Ibn Sīnā went to Iṣfahān where he found the peace and serenity that the intellectual life demands. In 1037 while traveling with ʿAlāʾ al-Dawlah he became ill and died as the result of colic. He is buried in Hamedan.

Ibn Sīnā gained the title of *Shaykh al-Raʾīs* (Master of the Wise) because he composed numerous treatises, 276 of which have been alluded to by his commentators. It is noteworthy that he wrote a great number of these works on horseback while fleeing from one city to another.

Ibn Sīnā's most extensive and elaborate work is *Kitāb al-shifāʾ* (The Book of Healing) which itself consists of four segments: *al-Manṭiq* (Logic), *Tabīʿiyyāt* (Natural Philosophy), *Riyāḍāyāt* (Mathematics), and *Ilāhāyyāt* (Metaphysics). To this monumental work should be added *Kitāb al-nijāt* (The Book of Deliverance), a synopsis of the *Shifāʾ*, and his last major work *al-Ishārāt wa'l-tanbīhāt* (The Book of Directives and Treatments). Among his other philosophical works are *ʿUyūn al-ḥikmah* (Fountain of Wisdom), *Kitāb al-hidāyah* (The Book of Guidance), *al-Mabdaʾ wa'l-maʿād* (The Book of Origin and End), and the first major work written in Persian for ʿAlāʾ al-Dawlah, *Dānishnāmah-yi ʿAlāʾī* (The Book of Knowledge). Finally, there are a few works which are mystical and visionary, such as *Ḥayy ibn Yaqẓān* (Son of the Living Awake), and *Risālat al-ṭaīr* (Treatise of the Bird).

Ibn Sīnā was a great synthesizer in that he not only incorporated the ideas of some of his predecessors such as al-Kindī and al-Fārābī, but also made extensive use of Greek philosophy, in particular Neoplatonism, Plato and Aristotle. From Plotinus he adopted the emanation scheme, from Plato his theory of archetypes, and from Aristotle his logic, physics, and psychology. The genius of Ibn Sīnā was in interpreting these different thoughts within the unitary matrix of Islam.

Ibn Sīnā has been called "philosopher of being" for he brought the question of being and the study of ontology to the forefront of philosophical debates and thereby corrected a deficiency that he saw in Greek philosophy, in particular in Aristotle. Ibn Sīnā divided all beings into three categories: necessary, contingent, and impossible. Furthermore, he argued that existent beings were made up of an essence and existence. This distinction became the central theme of medieval ontological discussions as well as of the subsequent debates within the Islamic philosophical tradition.

Ibn Sīnā, who had studied the Ptolemaic and Aristotelian systems, adopted the Islamic astronomical view based on the nine spheres and interpreted them within the scheme of the emanation of intellects. Each order of intellect accordingly corresponds to one of the heavens. For example, the second intellect corresponds to the highest heaven which is located above the fixed stars, and the tenth intellect corresponds to the moon below which the corporeal domain of our world is located.

Medicine

Ibn Sīnā was in the tradition of such grand Muslim physicians as al-Rāzī and al-Majūsī. By the age of 20, he had already become an accomplished physician and gained the respect of the court for having cured several members of the royal family. Eventually he came to be known as the "prince of physicians". He is the author of the *Qānūn al-Ṭibb* (The Canon of Medicine), which became a standard text both in the Christian West and the Islamic world. In addition to his *magnum opus*, Ibn Sīnā wrote a number of treatises on medicine both in Arabic and Persian some of which deal with particular diseases. He also wrote a book in which principles of medicine are written as poetry in order to facilitate their memorization by medical students.

In medicine, Ibn Sīnā was in many ways a follower of Greek ideas on medicine. However, he made the following revisions:

1. Unified the central principles of Greek medicine and interpreted them within an Islamic framework.
2. Made the theoretical and practical aspects of medicine represent a unified whole.

3. Documented the effects of medications on the body and commented on the necessity of a methodology in the study of pharmacological issues.
4. Introduced a number of medications and treatments for illnesses unknown to Greeks.

Ibn Sīnā believed that the science of medicine was divided into two categories, theoretical and practical. Illnesses were brought about either by internal or external causes. Internal illnesses were caused by an imbalance of temperament in the human body. These causes could also be the result of psychological elements.

Ibn Sīnā is known to have prescribed a variety of treatments for ailments, ranging from psychotherapy and diet to exercising. In the first volume of the *Canon of Medicine*, he states that medicine is the science of knowing the structure of the human body, and he goes on to discuss the fundamental principles necessary to maintain human health. He discusses surgery as an independent branch of medicine and elaborates on the science of anatomy. In the second volume, Ibn Sīnā explains various healing properties of simple and compound drugs and their various applications. In the third and fourth volumes, he presents his diagnosis of a variety of illnesses known to him, ranging from meningitis and cancer to tuberculosis and gastrointestinal illnesses. In the fifth volume of this work, Ibn Sīnā offers an extensive discussion of pharmacology, providing a detailed description of the effects of medications on body.

Some of his observations are extraordinarily advanced for his time. For example, he attributed the cause of plague to mice, commented on a number of contagious diseases, used single hair lines of horses for stitching after surgery, experimented with various drugs as anesthetics when operating on patients, described surgical processes for many operations such as gall bladder, used spices to stop bleeding after surgery, and understood the relationship between temperature and the spread of diseases. He even experimented on animals using different drugs.

Ibn Sīnā's treatment of the subject of psychology as a science which is both independent and part of the field of medicine is extensive. He first argues for the existence of a soul which is rather similar to the Aristotelian *psyche* and then shows how this incorporeal part of man interacts with his corporeal dimension. Ibn Sīnā then goes on to say that the health of the body to a large extent depends on the health of the soul and he offers much elaboration on that point throughout his works.

Perhaps one of the most important contributions of Ibn Sīnā to the field of medicine is the technical medical terminology which he introduced and which is still used by physicians in the Islamic countries.

Psychology

In *The Book of Healing*, Ibn Sīnā treats the subject of the "three kingdoms" (minerals, plants, and animals). He extends the hierarchy of the incorporeal world to the material world, concluding that whereas each domain has its soul it is only in humans that these souls reach their completeness. Ibn Sīnā's treatment of the human soul, its relationship with the body and the active intellect, is extensive. He introduces five internal senses and their equivalent five external senses.

The scope of Ibn Sīnā's writings on sciences includes such topics as motion, the process of sedimentation, and classification of minerals in the *Shifāʾ*, which came to be known in the West as *De mineralibus*. In a famous debate with al-Bīrūnī, Ibn Sīnā responded to ten questions on Aristotle's *De Caelo* and eight other questions such as how vision is possible, the relationship between water and light, the nature of a vacuum, heat, cooling, and how it is that ice floats on water.

Ibn Sīnā's philosophy remained the dominant philosophical school in the medieval west where he became known through translations of his works in Islamic Spain by Avendeuth, who was a Jewish philosopher and Gerard of Cremona. The Sicillian school also benefited much from Ibn Sīnā who was translated by Michael Scot. Ibn Sīnā's works continued to be translated through the sixteenth century influencing such western philosophers as the Augustinian Gundisalvo, Alberttus Magnus, William of Auvergne, Alexander of Hales, Roger Bacon, and Duns Scotus.

Ibn Sīnā left an indelible mark on the history of science, medicine, and philosophy.

Ibn Ṭāwūs

Zeina Matar

Raḍī al-Dīn Abū-l-Qāsim ᶜAlī ibn Mūsā ibn Jaᶜfar ibn Muḥammad ibn Aḥmad ibn Muḥammad ibn Ṭāwūs was a religious scholar, historian, and astrologer. He was born in al-Ḥilla (Iraq) on 15 Muḥarram 589/21 January 1193. He belonged to a distinguished family of scholars, the Banū Ṭāwūs, whose ancestry can be traced back to ᶜAlī ibn Abī Ṭālib.

Ibn Ṭāwūs grew up in the town of al-Ḥilla, which had been established by the famous scholar Abū Jaᶜfar al-Ṭūsī (385–458/995–1066) as a center of learning boasting five *madrasas* (institutions for the study of the Islamic sciences). Ibn Ṭāwūs spent his formative years in his native town, and in Baghdad where he lived for 15 years. He made pilgrimages to the holy Shīᶜī shrines of Najaf, Kerbela, and al-Kazimayan. He had a reputation for saintly powers, and concerned himself extensively with popular religious practices.

Ibn Ṭāwūs concentrated mainly on devotional literature, but he also wrote in the fields of history and astrology (see the listing of primary sources in the bibliography). In AH 650/AD 1252, he owned over 1,500 volumes in his private library. Professor E. Kohlberg of the Hebrew University of Jerusalem has contributed a superb reconstruction of this library and a detailed critical analysis of the works it contained.

Ibn Ṭāwūs was one of the most prolific medieval Shīᶜī scholars, who aimed at providing the believer with a set of guiding moral and ethical principles. The sources stress his "erudition, knowledge, asceticism, devoutness, trustworthiness, understanding of *fiqh* (science, or knowledge), loftiness and godfearingness [along with his talents as] poet, man of letters, writer, and eloquent speaker" (Āghā Buzurg Tihrānī 1983). A man of deep faith, concerned with religious matters, Ibn Ṭāwūs could also display wisdom in sensitive political situations, as in this apocryphal story:

> When Sultan Hulagu conquered Baghdad in 656/1258, he ordered that the scholars give an opinion on which was preferable: the unbelieving but just sultan, or the Muslim despotic one. The scholars were then gathered in al-Mustanṣiriyya for this purpose. They refrained from answering. Raḍī al-Dīn ᶜAlī Ibn Ṭāwūs was present at this Council. When he saw their hesitation, he took the *futya* (*fatwa*, legal opinion), and wrote that the unbelieving but just ruler was preferable to a Muslim despot.

Although Ibn Ṭāwūs declined the office of Naqābat al-Ashrāf under the Caliph al-Mustanṣir (d. 640/1242), he apparently changed his mind during the Mongol Period, and received the title from Naṣīr al-Dīn al-Ṭūsī (d. 672/1273). This important office, which had originated under the Buwayhids (also Buyids, a dynasty in Persia and Iraq, 320–454/932–1062), enabled the Sayyid families to represent their community in political, religious, and scholarly matters.

The date on which Ibn Ṭāwūs died in Baghdad is generally accepted as 5 Dhū-l-qa ᶜda 664/9 August 1266, and he was probably buried in Najaf.

Ibn Tibbon

Emilia Calvo

Ibn Tibbon, Jacob Ben Machir, is known as Profeit in Romance languages and as Prophatius Judaeus in Latin. These names come from the translation of *mehir* (prophet) into the languages of Southern France.

Ibn Tibbon was probably born in Marseille ca. 1236. His family was originally from Granada and, for four generations, had been devoted to the translation of Arabic religious, philosophical, and scientific texts. Through these translations, Arabic learning and therefore Greek scientific traditions were made available to the scholars of medieval Europe. Ibn Tibbon studied medicine at Montpellier and probably lived in Gerona, Spain between AD 1266 and 1267. He spent most of his life in Lunel, where his great-grandfather had established and practiced medicine at the beginning of the twelfth century, and Montpellier where he died in AD 1305.

Ibn Tibbon translated works by Autolycus of Pitane, Euclid, Menelaus of Alexandria, Qusṭā ibn Luqa, Ibn al-Haytham, Ibn al-Ṣaffīr, Ibn al-Zarqāllu, al-Ghazālī, Jābir ibn Aflaḥ, and Ibn Rushd from Arabic into Hebrew.

He is also the author of some works dealing with astronomy:

> *Robaᶜ Yisrael* (Quadrant of Israel), written between AD 1288 and 1293, in which an astronomical instrument, called the *quadrans novus*, is described. It consists of a simplification of the face of the astrolabe. Some examples of this instrument have been preserved.
>
> The *Almanac*, calculated for Montpellier and dated 1 March 1300. It is based on Ibn al-Zarqāllu's reelaboration of Awmātiyūs' almanac, although the author says that he has used the Toledan Tables, which is incorrect.

Ibn Tibbon is also the author of the Prologue to Abraham bar Hiyya's *Sefer Hesbon Mahlekot ha-Kokabim* (Calculation of the Courses of the Stars).

Ibn Ṭufayl

E. Ruth Harvey

Abū Bakr Muḥammad ibn ᶜAbd al-Malik ibn Muḥammad ibn Muḥammad ibn Ṭufayl al-Qaisi was an Arab physician famous for his encyclopedic learning. He was born at Guadix in Granada (modern Spain) in the first decade of the twelfth century. He served local rulers as physician and diplomat, and eventually became the court physician to Abū Yaᶜqūb Yūsuf, the Almohad prince who became the most powerful Muslim ruler of his day. Ibn Ṭufayl enjoyed a close friendship with Abū Yaᶜqūb until the latter's death in 1184; he was esteemed and cherished by Abū Yaᶜqūb's successor, Abū Yūsuf Yaᶜqūb, until his own death in 1185–1186.

Ibn Ṭufayl's importance for history is twofold: the influence of his unique work, *Ḥayy ibn Yaqẓān*, and his patronage of one of the most important Muslim philosophers of the Middle Ages, Ibn Rushd (known to the west as Averroes). The medieval Arab historian, ʿAbd al-Wāḥid al-Marrākushi, recorded that Ibn Ṭufayl would bring all sorts of learned men to his sovereign's notice. It was in this way that Ibn Rushd was given audience with Abū Yaʿqūb Yūsuf, and there was led on by the praise and encouragement of Ibn Ṭufayl to demonstrate his familiarity with Aristotelian philosophical traditions. The Sultan himself joined in the discussion, and Ibn Rushd was commissioned to compose his great commentaries. It was through the mediation of Ibn Rushd's works that Aristotle was reintroduced to the Latin West. The astronomer al-Bīṭrūjī (known in the West as Alpetragius) was a disciple and friend of Ibn Ṭufayl; he mentions Ibn Ṭufayl's criticisms of the traditional astronomical theories on epicycles and eccentrics.

Ibn Ṭufayl was said to have written poetry as well as works on medicine and astronomy, but nothing seems to survive except *Ḥayy ibn Yaqẓān* and (possibly) a poem on medicine recently rediscovered (see Russell 1986). The highly unusual *Ḥayy ibn Yaqẓān* (Life, Son of Awareness) is a philosophical tale in the form of a table: it tells how Ḥayy, cast up as a baby or spontaneously generated on an island, is fostered by a doe and grows to adulthood without any human contact whatsoever. Ibn Ṭufayl's interest lies in positing the natural unfolding of the human reason from the blank of infancy to the highest possible intellectual development; Ḥayy reaches the summit of human possibility in a mystical experience of the godhead. Eventually Ḥayy meets another human being who is so filled with awe at Ḥayy's intellectual and spiritual attainments that he persuades him to make an attempt to convert human society to wisdom. Humanity proves to be unworthy of Ḥayy's teaching, and Ḥayy and his new-found friend retreat back to the island again to spend the rest of their lives in contemplation.

Ḥayy ibn Yaqẓān draws on the philosophy of Ibn Sīnā. It was edited as early as 1671 by Edward Pocock, who provided a Latin translation, thus inserting Ibn Ṭufayl's ideas into the mainstream of European culture. The *Philosophus Autodidactus*, as Pocock named it, was sent to Huygens, Locke, and Leibniz; it was possibly an influence on Defoe's *Robinson Crusoe*, and almost certainly one on Rousseau's *Emile*. English translations have been appearing since 1686; there are Dutch, German, French, Catalan, Hebrew, Persian, and Russian versions. It is still stirring up scholarly debate and controversy.

Ibn Wāfid

EMILIA CALVO

Ibn Wāfid Abū'l-Muṭarrif ʿAbd al-Raḥmān ibn Muḥammad was a pharmacologist and physicist who lived and worked in Toledo during the first half of the eleventh century (ca. 1008–1075). He studied the works of Aristotle, Dioscorides, and Galen in Cordoba but then he moved to Toledo where he planted a botanical garden for the king of this city, al-Maʾmūn.

Ibn Wāfid is the author of a book entitled *Kitāb fī-l-adwiya al-mufrada* (Book on the Simple Medicines) which is a synthesis of Dioscorides and Galen. It is an extensive work to which the author devoted 20 years. It was abridged and translated into Latin by Gerard of Cremona. Translations into Catalan and Hebrew are also extant.

Ibn Wāfid is also the author of a pharmacopeia and manual of therapeutics entitled *Kitāb al-wisād fī ʻl-ṭibb* (Book of the Pillow on Medicine) which, according to Juan Vernet, could be a misreading of the Arabic title *Kitāb al-rashshād fī'l-ṭibb* (Guide to Medicine). This work can be considered complementary to the preceding one because Ibn Wāfid describes compound medicines in it, and it is a practical book: the information given is based on experience. Ibn Abī Uṣaybiʿa attributes to Ibn Wāfid a work entitled *Mujarrabāt fī-l-ṭibb* (Medical Experiences) which could probably be identified with this Book of the Pillow.

Ibn Wāfid is also the author of two works entitled *Tadqīq al-naẓar fī ʿilal ḥāssat al-baṣar* (Observations on the Treatment of Illness of the Eyes) and *Kitāb al-Mughīth* (Book on Assistance) which are not preserved, and of a treatise on balneology which is preserved in a Latin version entitled *De balneis sermo* (Venice 1553).

Ibn al-Abbār attributes to Ibn Wāfid a book entitled *Majmuʿ al-Filāḥa* (Compendium of Agriculture) although his authorship is now being questioned.

Ibn Yūnus

David A. King

Ibn Yūnus, Abu'l-Ḥasan ʿAlī ibn ʿAbd al-Raḥmān ibn Aḥmad ibn Yūnus al-Ṣadafī was one of the greatest astronomers of medieval Islam. Unfortunately nothing of consequence is known about his early life or education. As a young man he witnessed the Fatimid conquest of Egypt and the founding of Cairo in 969. In the period up to the reign of Caliph al-ʿAzīz (975–996), he made astronomical observations that were renewed by order of the Caliph al-Ḥākim, who succeeded al-ʿAzīz in 996 at the age of eleven and was much interested in astrology. Ibn Yūnus' recorded observations continued until 1003.

Ibn Yūnus' major work was a monumental *zīj* or astronomical handbook with tables. The *Ḥākimī Zīj*, dedicated to the Caliph, is distinguished from all other extant *zījes* by beginning with a list of observations made by Ibn Yūnus and others made by some of his predecessors. Despite his critical attitude toward these earlier scholars and his careful recording of their observations and some of his own, he completely neglects to describe the observations that he used in establishing his own planetary parameters – nor does he indicate whether he used any instruments for these observations. Indeed, the *Ḥākimī Zīj* is a poor source of information about the instruments he used. In view of the paucity of this information, it is remarkable that the statement that Ibn Yūnus worked in a "well-equipped observatory" is often found in popular accounts of Islamic astronomy. Sayili has shown how this notion gained acceptance in Western literature.

Ibn Yūnus' *Zīj* was intended to replace the *Mumtaḥan Zīj* of Yaḥyā ibn Abī Mansūr, prepared for the Abbasid Caliph al-Maʾmūn in Baghdad almost 200 year earlier. When reporting his own observations, Ibn Yūnus often compared what he observed with what he had computed using the *Mumtaḥan* tables.

The observations he described are of conjunctions of planets with each other and with Regulus, solar and lunar eclipses, and equinoxes; he also records measurements of the obliquity of the ecliptic (Chap. 11) and of the maximum lunar latitude (Chap. 38).

In spherical astronomy (Chaps. 12–54) Ibn Yūnus reached a very high level of sophistication. Although none of the several hundred formulae that he presents is explained, it seems probable that most of them were derived by means of orthogonal projections and analemma constructions, rather than by the application of the rules of spherical trigonometry that were being developed by Muslim scholars in Iraq and Iran.

The chapters of the *Zīj* dealing with astrological calculations (77–81), although partially extant in the anonymous abridgment of the work, have never been studied. Ibn Yūnus was famous as an astrologer and, according to his biographers, devoted much time to making astrological predictions.

Ibn Yūnus' second major work was part of the corpus of spherical astronomical tables for timekeeping used in Cairo until the nineteenth century. It is difficult to ascertain precisely how many tables in this corpus were actually computed by Ibn Yūnus. Some appear to have been added in the thirteenth and fourteenth centuries. The corpus exists in numerous manuscript sources, each containing different arrangements of the tables or only selected sets of tables. In its entirety the corpus consists of about 200 pages of tables, most of which contain 180 entries each. The tables are generally rather accurately computed and are all based on Ibn Yūnus' values of 30°0′ for the latitude of Cairo and 23°35′ for the obliquity of the ecliptic. The main tables in the corpus display the time since sunrise, the time remaining to midday, and the solar azimuth as functions of the solar altitude and solar longitude. Entries are tabulated for each degree of both arguments, and each of the three sets contains over 10,000 entries. The remaining tables in the corpus are of spherical astronomical functions, some of which relate to the determination of the five daily prayers of Islam. The impressive developments in astronomical timekeeping in fourteenth-century Syria, particularly the tables of al-Khalīlī for Damascus, also owe their inspiration to the main Cairo corpus.

It is clear from a contemporary biography of Ibn Yūnus that he was an eccentric, careless, and absent-minded man who dressed shabbily and had a comic appearance. One day in the year 1009, when he was in good health, he predicted his own death in 7 days. He attended to his personal business, locked himself in his house, and washed the ink off his manuscripts. He then recited the *Qurʾān* until he died – on the day he had predicted. According to his biographer, Ibn Yūnus' son was so stupid that he sold his father's papers by the pound in the soap market.

Ibn Ẓuhr

Munawar Ahmad Anees

Abū Marwān ʿAbd al-Mālik ibn Ẓuhr (Latin: Avenzoar; 484–557/1092–1162) belonged to the Arabian tribe of Iyād, Banū Ẓuhr. His father, Abū al-ʿAlā ibn Ẓuhr (d. 525/1131), was a respected physician in the courts of the Murābiṭ dynasty (482–541/1090–1147). He trained his son in the art and craft of medicine.

Like his father, Ibn Ẓuhr started his career in the service of the Murābiṭ dynasty and earned a good reputation. During the reign of ʿAli ibn Tashfīn (499–537/1106–1143), he served at the palace in Marrakesh, Morocco, where his life was full of trials and tribulations. In ca. 535/1141, he was stripped of his official position and imprisoned. Although he was pardoned and released, he endured a hard life in prison and the experience left a resentment in his heart against the ruling dynasty.

The beginning of the reign of al-Muwāḥḥidūn proved to be a blessing for Ibn Ẓuhr. He was not only appointed as an official physician but also became a *wazīr* in the court of Abū Muḥammad ʿAbd al-Mūmin (d. 558/1163). During this period, Ibn Ẓuhr transmitted his knowledge and skills to his children with meticulous attention. His son and daughter both became famous physicians. One of Ibn Ẓuhr's treatises, *al-Tadhkirah* (The Remembrance), was dedicated to his son in appreciation of his achievements.

At least nine of Ibn Ẓuhr's works are known, but only a few are extant. He is said to have written two works and dedicated them to ʿAbd alʾ-Mūmin. *Al-Aghdhīyyah* (On Dietetics) is a text on the therapeutic properties of selected foods. *Al-Tiryāq al-Sabʿīnī* is a book of antidotes against poisoning by enemies. This work, perhaps, was Ibn Ẓuhr's way of expressing gratitude to his benevolent patron.

Al-Taysīr fī al-Mudāwāt wa al-Tadbīr (On Preventive Regimen and Treatment), in 30 treatises, is considered to be his monumental work. His friend Ibn Rushd considered it a great source of medical knowledge and therapeutic advice. In its Latin version, *Alteisir scilicet regiminis et medelae*, the treatise remained in wide circulation across Europe for centuries. Both Arabic and Latin copies of this work are extant. True to the medical norms of his days, Ibn Ẓuhr presented in this work a mix of astrology and folklore blended with therapeutics and pharmacology. *Al-Kulliyāt* (The Collection), a general compilation on medical practice, appears as an appendix.

The great historiographer Ibn Abi ʿUṣaybiʿah, in his encyclopedic work *ʿUyūn al-Anbā fī Ṭabaqāt al-Aṭibbā*, listed only seven of Ibn Ẓuhr's works:

I

1. *Fī al-Zīnah* (On Beautification)
2. *Al-Tiryāq al-Sabᶜīnī* (On Antidotes)
3. *Fī ᶜIlāl al-Kilā* (On Diseases of the Kidney)
4. *Fī ᶜIllat al-Baraṣ wa al-ᵓBahaq* (On Leprosy and Vitiligo)
5. *Al-Aghdiyyah* (On Dietetics)
6. *Al-Tadhkirah* (The Remembrance)
7. *Al-Taysīr fī al-Mudāwāt wa al-Tadbīr* (On Preventive Regimen and Treatment)

He does not mention two of his treatises. One of the missing ones is *Al-Iqtiṣād fī Iṣlāḥ al-Anfūs wa al-Ajsād* (Treatment and Healing of the Soul and Body). Addressed to the general reader, it focuses on problems of hygiene and therapeutics. The second is *Jāmiᶜ al-Asrār al-Ṭibb* (Compendium of Medical Wisdom). In addition to a discussion on dietetics, this work describes the physiology of several organs including the spleen, liver, and bladder.

Ibn Ẓuhr was a prolific writer and a highly successful medical practitioner. Some of his work showed the influence of the Hippocratic and Galenic traditions, but his original insights came from a rich family heritage in medical practice. Thus, going against the Greco-Roman medical dictates, Ibn Ẓuhr engaged in experimental work and recorded his observations. His detailed study of the pericardial abscess, pharyngeal paralysis, intestinal and mediastinal tumors, and inflammation of the middle ear were great improvements over the work of his predecessors.

Ibn Ẓuhr was one of the great Muslim clinicians and therapists. Through numerous translations of his works, he remained highly influential in the medical academies of the West. In his later age, he suffered from a malignant tumor that ultimately caused his death. He was buried in Seville, Spain.

Ibrāhīm Ibn Sinān

Roshdi Rashed

Ibrāhīm Ibn Sinān Ibn Thābit Ibn Qurra was born in Baghdad in 296/909 where he died 37 years later in 335/946. Grandson of the famous mathematician Thābit Ibn Qurra, cousin of the famous literary figure Hilāl al-Ṣābiᵓ, son of a great physician and mathematician Sinān Ibn Thābit, he thus belonged to an intellectual aristocracy whose members frequented the corridors of power and the upper levels of the worlds of science and medicine. Ibrāhīm was born into and raised in this world, before being the object of a short-lived persecution to which he makes allusion but explains neither the cause nor the duration. Ibrāhīm Ibn Sinān was not only the "heir" to great tradition, but also a mathematician of genius in his own right who made his own mark on the mathematics of his era.

Ibrāhīm Ibn Sinān was also heir to a historical tradition. He belonged to a privileged generation, the fourth since the Banū Mūsā. The translation of the major mathematical texts had been essentially completed and the great traditions of research had already been well established: that of the algebraists, beginning with al-Khwārizmī and extended by Abū Kāmil; that of the geometers, al-Jawharī, al-Nayrīzī, etc., who followed the work of Euclid; and the tradition of the Banū Mūsā which, thanks to mathematicians like Thābit Ibn Qurra, had already gathered considerable results, developed new methods, and elaborated theories. Ibrāhīm Ibn Sinān was clearly a part of this tradition in which Archimedean geometry, a geometry of measurement, and the geometry of Apollonius, which was concerned with the properties of positions, were all combined. Profiting from scholarly works, especially those of his grandfather Thābit Ibn Qurra, Ibrāhīm Ibn Sinān developed the study of geometric transformations and their applications to conic sections, as well as to the measurement of the area of a portion of a parabola. He extended their work on sundials in developing a theory of a whole class of instruments. Finally the questions posed by his predecessors about analysis and synthesis prompted him to write the first treatise worthy of the name on the subject.

Ibrāhīm Ibn Sinān explained the composition of his work in his own autobiography which happily still exists. He published the autobiography after his 25th year, in 934. According to his own account, he began his research at age 15; at 16 or 17 he had written a first version of his book *Fī Alāt al-aẓlāl* (On Instruments of Shadows), which he revised at the age of 25. A year later he was discussing and criticizing Ptolemy's views on The Determination of the Anomalies of Saturn, Mars, and Jupiter (*Fī istikhrāj ikhtilāfāt Zuḥal wa al-Mirrīkh wa al-Mushtarī*) in a treatise that he completed 6 years later, at the age of 24. In geometry, Ibn Sinān wrote *Fī al-dawā*ˀ*ir al-mutamāssa* (The Tangent Circles), *al-Taḥlīl wa*ˀ*l-Tarkīb* (Analysis and Synthesis), *Fī al-masaā*ˀ*il al-mukhtāra* (Selected Problems), *Fī misāḥat qiṭ*ˀ *al-maḥrūṭ al-mukāfī*ˀ (The Measurement of the Parabola), and the *Fī rasm al-quṭū*ˁ *althalātha* (Drawing of the Three Conic Sections). All these works had been published and revised before Ibn Sinān was 25.

To illustrate the approach of Ibn Sinān let us look briefly at his *Measurement of the Parabola*, beginning with what he wrote about his own studies:

> My grandfather had determined the measurement of this section. But several contemporary geometers led me to understand that a work of al-Māhānī on the same subject, which they presented to me, was easier than my grandfather's. I was not pleased that al-Māhānī's work was more advanced than my grandfather's without there being one among us who surpassed his work. My grandfather had determined his result in twenty propositions. He proceeded from several arithmetic lemmas included in the twenty propositions. The question of the measurement of the section appeared to him clearly through the method of *reductio ad absurdum*. Al-Māhānī also proceeded from arithmetic lemmas. He then demonstrated his demand by the method of *reductio ad absurdum* in five or six propositions, which involved lengthy discussions. I myself then determined the measurement in three geometric propositions without recourse to any arithmetic lemma. I demonstrated the surface area of this same section using the method of direct proof, and I did not need the method of *reductio ad absurdum*.

In addition to expressing pride in his heritage and the certainty of an exceptional scholar, these remarks also reflect the qualities of Ibn Sinān as a mathematician: brevity, ease, and elegance.

Ibn Sinān's approach is the following: in a first proposition, he demonstrates that the affine transformation conserves the ratios of the areas in the case of triangles and polygons; he then demonstrates in a second proposition that it is the same for the ratio of the area of a portion of a parabola to that of an associated triangle.

Ibn Sinān again had recourse to geometric transformations in his *Drawing of the Three Conic Sections*. In this treatise, he constructed an ellipse by transforming the circle by an orthogonal affinity – a process already found in the works of the Banū Mūsā. It was also by means of an affinity that he deduced all the hyperbolas of a particular hyperbola for which the latus rectum is equal to the transverse axis.

The intensity of mathematical activity, the large amount of work done, the new demands of brevity, elegance, and rigor in demonstration, as well as the general interest in geometric transformations, all led Ibn Sinān to take up the theory of analysis and synthesis again. Thus he published the first treatise devoted to this subject. He wrote "I found that the geometers of this time had neglected Apollonius's method of analysis and synthesis, as was the case for the majority of things I brought up, and that they had limited themselves just to analysis, limiting themselves to such a degree that they led analysis to the point of letting people think that this analysis was not the synthesis that they were doing."

In this treatise, Ibn Sinān undertook two tasks at once: one didactic, the other logical. On the one hand, he proposed a method (*ṭarīq*) for geometry students which allowed them to solve geometry problems; on the other hand, he reflected on geometric analysis itself, proposing a classification of geometry problems according to their numbers and the hypothesis that they are to verify, and explaining for each class of problems the respective parts of analysis and synthesis.

There is not enough space here to take up, even very briefly, the works of Ibn Sinān. But the examples discussed above do show how this eminent geometer left his mark on all the fields in which he worked, including mathematics and philosophy. The import of his work can be discovered in the work of Ibn al-Haytham who followed up on the research of Ibn Sinān in his own treatise on analysis and synthesis and in his writings on sundials.

Ikhwān al-Ṣafāʾ

Gregg de Young

The 48 treatises composed by the Ikhwān al-Ṣafāʾ (Brethren of Purity) constitute an encyclopedia of the sciences which has had a long and influential career in Islamic civilization. The collection was prepared by a group of scholars who preferred anonymity. This anonymity has generated considerable debate among historians over their identity. Current scholarship places the date of composition in the last half of the fourth AH/AD tenth century, and the place of composition in Basra. This collection of treatises continues to play an important role in the intellectual milieu of modern Islam, especially among groups influenced by Shiʿite and Ismāʿīlī ideas.

The treatises contain a strong gnostic element, an emphasis on esoteric knowledge that exists within the exoteric or phenomenal features of everyday life but is accessible only to the initiated. This interest in esoteric or inner knowledge does not imply that they were uninterested in the physical world. It is necessary to have a thorough understanding of nature in order to penetrate to the inner truth that it expresses. An appreciation of nature, therefore, is one of the first steps toward union with the Divine Knowledge.

Their gnostic orientation can be seen in the classification of knowledge proposed by the Ikhwān. The student begins with introductory or preparatory (*riyāḍiyy*) topics, advances to religious (*sharʿiyy*) sciences, and finally reaches the highest, or philosophic (*falsafiyy*) sciences. This system is at odds with traditional Islamic discussions of the arrangement of the sciences in that it makes religious sciences subordinate to philosophic or intellectual sciences. In the organization of their treatise, the Ikhwān begin with mathematical sciences, advance to physical sciences, human sciences, and finally to metaphysical and revealed sciences.

The gnostic tendencies of the authors appear in the Neo-Platonic and Neo-Pythagorean descriptions of cosmogony and cosmology embedded within these treatises. God created the universe through a series of emanations from himself. First to appear was Intellect, followed by its Archetypes and the World Soul. (Intellect, the Ikhwān tell us, instructs the World Soul through the Archetypes.) The World Soul, through further emanations, produces individual souls or faculties that individuate, or give form to, prime matter. The first of these individuating emanations were the nine celestial spheres (the invisible *primum mobile*, the sphere of the fixed stars, and the spheres of the seven naked-eye planets: Saturn, Jupiter, Mars, Sun, Venus, Mercury, and the Moon), followed by the four terrestrial elements (fire, air, water, and earth). This represents the farthest separation of soul from God. Drawn by an irresistible desire for union with the unity of God, it commences a return ascent heavenward through a process of purification from the contamination of matter achieved through personal morality and deepening esoteric knowledge of the one.

The treatises contain little scientific information that is new. The treatise on geometry (the second treatise of the collection) reports a few simple results from Euclid: the sum of the interior angles of the triangle is two right angles, an exterior angle is equal to the two opposite interior angles, etc. However, there is no discussion of the demonstrations that validate these facts. Rather, the Ikhwān are interested in facts only when related to other facts so as to provide insight into the deeper, esoteric, meanings of the knowledge. They discuss the relation between sensory and intellectual geometry. This is followed by a discussion of magic squares (numbers placed in geometric arrays) and their almost magical usefulness as talismans. Interspersed with these discussions are meditations on the usefulness of intellectual geometry (because, abstracted from the sensations, it exercises the soul for moving beyond phenomena toward the invisible one) and on the necessity for human cooperation and brotherhood in the effort.

Although the treatises provide little insight into the state of intellectual activity in the sciences, they give an intriguing summary of what the educated non-scientist knew about the results of scientific research as they existed in that time. They also offer a window into what might be called a sub-scientific culture, a culture aware of some of the results of science and mathematics, but adapting these results for non-scientific (in this case, largely social and religious) purposes.

Ino Tadataka

Nakayama Shigeru

Ino Tadataka, 1745–1818, was a Japanese cartographer and an energetic field observer. A major astronomical and geodetic problem of the time in Japan was finding the length of a meridian by Japanese measure. Since Sino-Jesuit works had set zero longitude at Beijing, that of Japan had to be accurately measured so that, in predicting a solar eclipse, the Sino-Jesuit method could be employed for the Japanese longitude. After making over 2,000 measurements of latitude, Ino calculated the length of a meridian which agreed (within several tenths of a second of a degree) with the figure given in the Dutch translation of Lalande's *Astronomie* which had been imported into Japan.

He did not excel in devising new methods or new theories in either astronomy or geodesy. While he was active, knowledge of Western astronomy was available through Dutch translations and Sino-Jesuit works and after, through the works of Lalande. But Ino had no knowledge of Dutch or dynamics and little understanding of astronomical theories. When calculating the length of the meridian, he considered the earth as a perfect sphere rather than a spheroid. Moreover, when observing the position of fixed stars, he did not take into account the effects of refraction, parallax, or nutation.

In his surveying, Ino did not use modern triangulation but relied upon the old traverse method. His mapmaking approach resembled the Sanson–Flamsteed method (it is presumed that his method was developed independently), which is appropriate only for small areas. Ino none the less used the method for an area as large as all of Japan. Despite Ino's scientific failings, his map of Japan, based upon surveys covering the length and breadth of the land, has an important place in geographical history.

Inoculation

Subhash Kak

The first reliable account of inoculation is found in the eighteenth-century reports by British doctors concerning the Indian treatment of smallpox. In the method, believed to have been discovered sometime before AD 1000 in India (Henderson and Moss 1999), one deliberately inoculated, either into the skin or by nasal insufflation, scabs, or pustular material from lesions of patients. This resulted in an infection that was usually less severe than an infection acquired naturally. From India, the practice spread to China, western Asia, and Africa and finally, in the early eighteenth century, to Europe and North America.

It appears that the idea of inoculation derived from both *agada-tantra*, one of the eight branches of traditional Āyurveda (Indian medicine) that deals with poisons and toxins in small dosages, and from the application of specific concoctions to punctures in the skin for treatment of certain skin diseases (*Suśruta Samhitā* in *Cikitsāsthāna* 9.10). The *Caraka Samhitā* speaks of how deadly poisons can be converted into excellent medicine and how two toxins can be antagonistic to each other. The Samhitas speak of organisms that circulate in the blood, mucus, and phlegm. In particular, the organisms in the blood that cause disease are said to be invisible.

The *Suśruta Samhitā*, Chap. 54 of *Uttaratantra* or *Kāyacikitsātantra* (General Medicine), suggests a treatment regimen that includes avoidance of fatty foods and sweets. In the *Nidānasthāna* (Diagnosis), Chap. 5, it is indicated that physical contact and sharing the same air can cause such diseases to spread. Later, in Chap. 13, there is mention of the eruptive boils of the disease *masūrikā*. It appears that originally it meant chicken pox, but by the twelfth century the term was also being used for smallpox, as in the case of the commentator Dalhana.

The best source concerning the Indian method of treatment of smallpox is a report by Dr. John Z. Holwell in 1767 for the College of Physicians in London. This report is an excellent source for understanding the mind of the Ayurvedic doctor of the eighteenth century.

Holwell says that inoculators

> are delegated for this service from the different Colleges of Bindoobund [Vrindavan], Eleabas [Allahabad], Banaras, &c. over all the distant provinces; dividing themselves into small parties, of three or four each, they plan their traveling circuits in such wise as to arrive at the places of their respective destination some weeks before the usual return of the disease (Holwell 1971: 150–151).

One would presume that they were Ayurvedic vaidyas or their assistants.

> They inoculate indifferently on any part, but if left to their choice, they prefer the outside of the arm, midway between the wrist and the elbow, for the males; and the same between the elbow and the shoulder for the females. Previous to the operation the Operator takes a piece of cloth in his hand, (which becomes his perquisite if the family is opulent) and with it gives a dry friction upon the part intended for inoculation, for the space of eight or ten minutes, then with a small instrument he wounds, by many slight touches, about the compass of a silver groat, just making the smallest appearance of blood, then opening a linen double rag (which he always keeps in a cloth round his waist) takes from thence a small pledget of cotton charged with the variolous [smallpox] matter, which he moistens with two or three drops of the Ganges water, and applies it on the wound, fixing it on with a slight bandage, and ordering it to remain on for six hours without being moved, then the bandage to be taken off, and the pledget to remain until it falls off itself… *The cotton which he preserves in a double callico rag, is saturated with matter from the inoculated pustules of the preceding year, for they never inoculate with fresh matter, nor with matter from the disease caught in the natural way, however distinct and mild the species*.

The patient was to abstain from fish, milk, and ghee before and after inoculation for a period of 1 month. Holwell claimed that when the inoculation regime was strictly followed, it is next to a miracle to hear that it "failed in one in a million." He added that since

> this practice of the East has been followed without variation, and with uniform success from the remotest known times, it is but justice to conclude, it must have been originally founded on the basis of rational principles and experiment.

This is how Holwell described the explanations offered to him by Ayurvedic vaidyas:

> The *immediate* (or instant) cause of the smallpox exists in the mortal part of every human or *animal* form; that the *mediate* (or second) *acting* cause, which stirs up the first, and throws it into a state of fermentation, is multitudes of *imperceptible animalculae* [microorganisms] floating in the atmosphere; that these are the cause of all epidemical diseases, but more particularly of the smallpox; that they return at particular seasons in greater or lesser numbers… That these animalculae touch and adhere to every thing, in greater or lesser proportions, according to the nature of the surfaces they encounter; that they pass and repass in and out of the bodies of all animals in the act of respiration, without injury to themselves… smallpox is more or less epidemical, more mild or malignant, in proportion as the air is charged with the animalculae, and the quantity of them received with the food (Holwell 1767: 155–156).

Holwell understood the idea behind inoculation in this manner:

> That when once this *peculiar* ferment, which produces the smallpox, is raised in the blood, the *immediate (instant) cause* of the disease is totally expelled in the eruptions, or by other channels; and hence it is, that the blood is not susceptible of a second fermentation of the same kind.

In other words, he believed that when the disease in its natural form or when introduced in its weak form by the inoculation had run its course, the patient was safe. The difference between these two forms was that in its natural course it is often fatal, whereas when introduced through inoculation, it was only an inconvenience.

It is significant that the spread of disease was taken to be caused by the imperceptible animalculae (microorganisms). This old insight of the *Āyurvedic Samhitās* was a forerunner to the germ theory of disease that arose in the nineteenth century.

Iron Pillar at Delhi

R. Balasubramaniam

The Delhi iron pillar (Fig. 1) is testimony to the high level of skill achieved by the ancient Indian ironsmiths in the extraction and processing of iron. Hadfield (1912) undertook the first systematic scientific study of the Delhi iron pillar. Results of scientific studies conducted in 1961 were summarized in a special issue of the *NML Technical Journal* (vol. 5, 1963). A review of its corrosion resistance appeared in 1970 (Wranglen 1970). While Anantharaman (1997) has reviewed the known scientific facts about the Delhi iron pillar, Balasubramaniam (2002, 2005) has compiled several new insights into the historical, scientific, and technical aspects of the Delhi iron pillar.

The history of the pillar is revealed in the die-struck three-stanza six-line Sanskrit inscription at a level of about 7 feet from the stone platform (Balasubramaniam 2000a). King *Chandra*, mentioned in the inscription as the royal donor of this *standarc* for Vishnu, is probably identical with Chandragupta II Vikramaditya (AD 375–414), as was also suggested by the use of the name "*Chandra*" on that king's Archer-Type gold coins (Balasubramaniam 2000a). The original erection site of this pillar was Vishnupadagiri (literally "hill of the footprint of Vishnu") as mentioned in the inscription. Vishnupadagiri is most probably identified with Udayagiri in central India, in the close vicinity of Besnagar, Vidisha, and Sanchi (Balasubramaniam 2000a; Dass 2001). The astronomical significance of its erection site has been understood (Balasubramaniam and Dass 2004). The pillar was positioned so that the early morning shadow of the pillar fell in the direction of one of the important bas-reliefs at Udayagiri, i.e., the *Anantaśāyin* Vishnu panel in Cave 13, in the period around the summer solstice. The *chakra* image that originally crowned the iron pillar capital additionally served to highlight its astronomical significance (Balasubramaniam et al. 2004). The Delhi iron pillar was relocated to its current location in New Delhi in the courtyard of the Quwwat-ul-Islam mosque (near the Qutub Minar) around 1233 AD by Iltutmish (Dass 2001; Balasubramaniam 2002) (Fig. 2).

Iron Pillar at Delhi. Fig. 1 Delhi iron pillar located in the Quwwat-ul-Islam mosque in the Qutub Complex at New Delhi.

Engineering Design

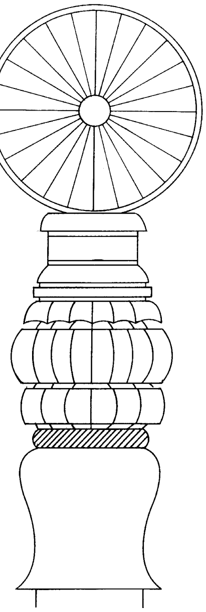
The current burial level of the pillar was not the original burial level of the pillar when it was erected at Udayagiri. Hammer-marked cavities are still visible on the surface of the pillar in the rough region just below the smooth surface-finish region (Fig. 3). The rough portion of the pillar was originally buried in the ground and later left exposed outside when the iron pillar was relocated at Delhi around 1333 AD. Beglar, an assistant of Alexander Cunningham, constructed the stone platform around the base of the iron pillar in 1871.

A critical analysis of the dimensions of the main body of the pillar allows an appreciation of the pillar's symmetrical design (Balasubramaniam 1997a). The rough surface occupies one-fourth (60U) and the smooth surface three-fourths (180U) of the pillar main body length, excluding the decorative top (Fig. 4). The decorative bell capital (Balasubramaniam 1998a) is again a symmetrical object. A *chakra* (circular discus) image was originally located atop the capital (Balasubramaniam et al. 2004) and this would have been approximately 20U in length thereby making the total length of the

Iron Pillar at Delhi. Fig. 2 Well-preserved Sanskrit inscription on the iron pillar. This is the oldest inscription on the pillar.

I

Iron Pillar at Delhi. Fig. 3 Hammer marked cavities are still visible on the surface of the pillar in the rough region. The rough region was originally buried under the ground when the pillar was located at Udayagiri.



Iron Pillar at Delhi. Fig. 5 The Delhi iron pillar decorative capital showing the discus image (*chakra*) that was originally located at the top of the capital.

decorative top 60U (Fig. 5). Therefore, the depth of burial below ground level was equal to the height of the decorative capital, indicative of the engineering design of the pillar. The unit U is equal to 1 modern inch.

Iron of Delhi Pillar

Several analyses of the Delhi pillar iron's composition are available (Table 1). The variation in the published compositions and the high phosphorus content of the Delhi pillar iron must be noted. Compositional analysis near the surface regions of a sample from the iron pillar revealed that the composition of copper (0.05%), nickel (0.05%), manganese (0.07%), and chromium (Nil) was uniform through several millimetres into the sample from the surface (Bardgett and Stanners 1963).

The presence of phosphorus is crucial to the atmospheric corrosion resistance of the Delhi iron pillar. The Delhi pillar iron contains a relatively large amount of phosphorus compared to modern-day iron (produced in the blast furnaces). The relatively higher phosphorus content in ancient Indian irons is related to the kind of slag that was created in the extraction process (solid-state reduction). Lime was not added in the ancient Indian furnaces. The absence of calcium oxide in the slags leads to a lower efficiency for removal of phosphorus from the metal, which invariably resulted in higher phosphorus contents in ancient Indian irons. Thermodynamic analysis of phosphorus removal from iron in the absence of calcium oxide in the slag also provides the same answer (Vikas Kumar and Balasubramaniam 2002).

Some aspects of the microstructure of the Delhi pillar iron are also known. All the available published microstructures have been described in Balasubramaniam (2003). It possesses a nonuniform grain structure and slag inclusions are irregularly distributed. Medium

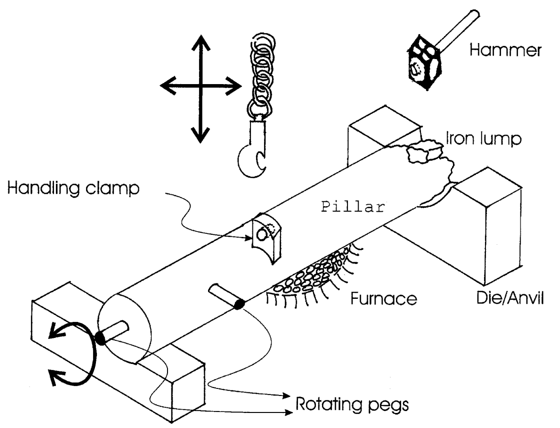
Specific gravity	7.81	7.672–7.747		7.5	

to coarse polyhedral grains of ferrite with slip bands were revealed in some grains near the surface. The surface regions were free from pearlite that seemed to increase toward the interior. The absence of a uniform distribution of pearlite is indicative of the segregation of phosphorus because, in such areas of phosphorus segregation, carbon diffuses out and the material becomes poorer in carbon content. The interior portions were comparatively rich in carbon. Therefore, the Delhi pillar iron exhibits a wide variation in structure and this is also a characteristic feature of ancient Indian iron.

The pillar is a solid body with moderate mechanical strength (yield strength of 23.5 tons per sq. in., ultimate tensile strength of 23.9 tons per sq. in. and 5% elongation (Ghosh 1963)). The similarity of yield strength and ultimate tensile strength are indicative of the composite structure of the pillar iron. In fact, a cannonball fired at the Delhi iron pillar in the eighteenth century (either by Nadir Shah in 1739 or Ghulam Quadir in 1787) failed to break the pillar.

Manufacturing Methodology

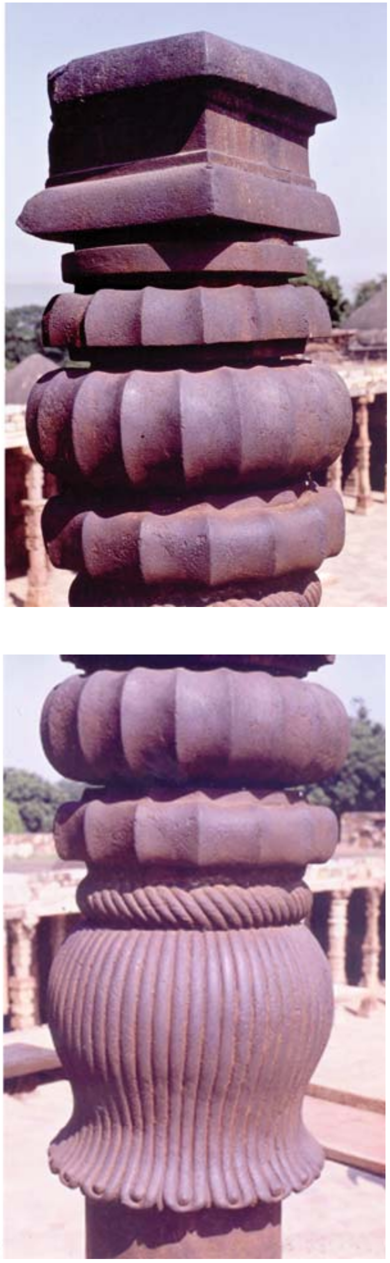
The pillar was manufactured using iron lumps and the method used to fuse the lumps together was forge welding. The individual iron lumps were extracted in bloomery furnaces. The likely manufacturing method has been deduced based on a critical analysis of various aspects concerning the manufacturing methodology like the hammering method, heating method, forging method, use of inserts, use of dies and ease of handling (Balasubramaniam 1999a). The heated iron lumps were placed on the side surface of the pillar and hammered on to the same by the use of hand-held hammers (Fig. 6). The addition of metal would have been sideways with the pillar in the horizontal direction. The pillar's vertical and horizontal movements would have been aided by handling clamps provided on the surface of the pillar, the protruding portion of which must have been chiseled away during the surface finishing operations.



Iron Pillar at Delhi. Fig. 6 Horizontal forge welding technique for manufacture of the main body of the pillar.

Visual proof for the presence of these clamps has been discussed in detail elsewhere (Balasubramaniam 1999a).

The decorative bell capital of the Delhi iron pillar has been described in great detail elsewhere (Balasubramaniam 1998a). The decorative bell capital consists of seven distinct parts, excluding the circular discus that was originally atop the capital (Fig. 7). There are several evidences at the joints between members to indicate that lead solders were utilized for joining the pieces together (Balasubramaniam 1998b, 1999b). The bottom-most part is the reeded bell structure, which has been manufactured by utilizing iron rods of uniform diameter. Atop this comes the slanted rod structure. The next three members are rounded structures, with the top one being only half rounded because when the pillar is viewed from the bottom, this part would appear curved when viewed in perspective from the bottom. A round disc comes above this and finally the box pedestal is placed on the top of the capital. The box capital contains holes that are empty at the four corners. The top of the pillar presently contains a hollow slot (Fig. 8), in which a



a

b

Iron Pillar at Delhi. Fig. 7 The (a) top and (b) bottom portions of the decorative bell capital.

chakra image was originally fit (Balasubramaniam et al. 2004). As regards the fitting methodology, the seven components of the capital were shrunk fit around a hollow cylinder, and this was joined to the main body of the pillar by means of a metallic insert (Balasubramaniam 1998a).

Corrosion Resistance

Several theories that have been proposed to explain the superior corrosion resistance of the pillar can be broadly classified into two categories: the environmental and material theories. These theories have been critically reviewed elsewhere (Wranglen 1970; Balasubramaniam 1997b, 2000b). The proponents of the environment theory state that the mild climate of Delhi is responsible for the corrosion resistance of the Delhi iron pillar, as the relative humidity at Delhi does not exceed 70% for significant periods of time in the year. It is known that atmospheric rusting of iron is not significant for humidity levels less than 70%. On the other hand, several investigators have stressed the importance of the material of construction as the primary cause for its corrosion resistance. The ideas proposed in this regard are the relatively pure composition of the iron used, the presence of phosphorus and absence of sulfur/manganese in the iron, its slag enveloped metal grain structure, passivity enhancement in the presence of slag particles and formation of phosphate film. Other theories to explain the corrosion resistance are also to be found in the literature. They include the mass metal effect, initial exposure to an alkaline and ammonical environment, residual stresses resulting from the surface finishing (hammering) operation, freedom from sulfur contamination both in the metal and in the air, presence of layers of cinder in the metal which do not allow corrosion to proceed beyond the layer (cinder theory) and surface coatings provided to the pillar after manufacture (treating the surface with steam and slag coating) and during use (coating with clarified butter).

Iron Pillar at Delhi. Fig. 8 The top surface of the pillar capital presently contains a hollow slot.

That the material of construction may be the important factor in determining the corrosion resistance of ancient Indian iron is attested by the presence of ancient massive iron objects located in areas where the relative humidity is high for significant periods in the year (for example, the iron beams in the Surya temple at Konarak in coastal Orissa (Graves 1912) and the iron pillar at Kodachadri Hills on the western coast (Anantharaman 1999)). Moreover, a freshly exposed cut surface of the pillar acquires the color of the rest of the pillar in a relatively short period of time (Balasubramaniam 2001), thereby implying that surface coatings were not intentionally applied.

Sanyal and Preston (1952) proposed that the large mass of the pillar implies a large heat capacity for the iron. In that case, the pillar would heat or cool faster than the surroundings. The role of the Delhi environment on the wetting and drying of the pillar has been mathematically modeled (Halder et al. 2004) and the benign role of the large mass of the pillar was noted.

Rust samples obtained from the region just below the decorative bell capital were characterized by X-ray diffraction (XRD), Fourier transform infrared (FTIR) spectroscopy, and Mössbauer spectroscopy (Balasubramaniam and Ramesh Kumar 2000). The XRD analysis proved the existence of crystalline iron hydrogen phosphate hydrate, FTIR and Mössbauer spectroscopy proved the presence of magnetite and several oxyhydroxides in the amorphous form.

The process of protective film formation during alternate wetting and drying cycles of the Delhi iron pillar has been outlined (Balasubramaniam 2000b) based on rust characterization results. Initially, the corrosion of the matrix is relatively fast due to the presence of second phase particles in the microstructure. The usual corrosion products that are observed in the case of mild steels exposed to atmosphere are generated: α-FeOOH (goethite), γ-FeOOH (lepidocrocite), $Fe_{3-x}O_4$ (magnetite) and X-ray amorphous matter. The initial enhanced corrosion of the matrix leads to the enrichment of phosphorus concentration at the metal-scale interface, which results in the formation of a compact layer of amorphous δ-FeOOH layer next to the metal-scale interface. The formation of this layer confers the initial corrosion resistance to the pillar iron. Conversion of amorphous δ-FeOOH to nanocrystalline goethite is possible on longer exposure times (Yamashita et al. 1994). The enrichment of phosphorus in rust continues with prolonged exposure as observed in P-containing weathering steels (Misawa et al. 1974). Enrichment of phosphorus follows the mesoscopic variation of phosphorus in the matrix (Dillmann et al. 2002). This enrichment should be responsible for the precipitation of the insoluble phosphate, identified by XRD. The formation of this phase at the metal-scale interface provides further corrosion resistance.

A kinetic model for the growth of rust on the Delhi iron pillar has been proposed (Balasubramaniam 2002), based on the known nature and structure of the rust on the Delhi iron pillar and other corrosion resistant ancient Indian irons. According to this model, the initial fast rate of corrosion is followed by a period where the corrosion rate is reduced drastically. Growth rates have been roughly estimated for these two regions based on available Delhi iron pillar rust thickness measurements (Balasubramaniam 2002).

The Delhi iron pillar is a marvel of ancient Indian metallurgical skills. I have explained the engineering design of the pillar followed by a description of the manufacturing methodology for the main body of the pillar. The characteristics of iron of the pillar and the possible reason for its high phosphorus content have been discussed. The theories of corrosion resistance of the pillar have been reviewed and the importance of the protective passive film mechanism has been highlighted. The nature of this protective passive film has been addressed based on a detailed characterization of its rust. The corrosion resistance of the Delhi iron pillar is due to both Delhi (with the environment providing alternate wetting and drying conditions) and iron (with its high phosphorus content conferring protection by the formation of a protective passive film).

Irrigation in India and Sri Lanka

Claude Alvares

Assessments by historians of Asia's irrigation systems and irrigation-related civil engineering techniques have been based on the scantiest of historical or empirical data. Naturally, they have ranged from one extreme to the other. Of these, the one most easily recognized and debated was provided by Karl Wittfogel whose theories led to the idea of "hydraulic civilizations".

A diametrically opposite assessment has been provided by some Indian historians who have concluded that there was no significant irrigation technology in use at all. Symbolic of this view is R. Majumdar and H. C. Raychaudhuri's *An Advanced History of India*, in which the authors make a categorical statement on the "comparative absence of artificial irrigation" in eighteenth century India.

However both views – fairly representative of the historiographical terrain – have had to be revised considerably because of the emergence of new historical materials and investigations. These are reflected in new literature specifically devoted to the subject. Illustrative of these materials is the report of Alexander Walker, an English specialist who toured India in the eighteenth century. Walker produced an elaborate treatise on Indian agriculture in which he drew the conclusion that:

> the practice of watering and irrigation is not peculiar to the husbandry of India, but it has probably been carried there to a greater extent, and more laborious ingenuity displayed in it than in any other country.

This display of ingenuity, however, is not restricted to eighteenth century India and has indeed found expression in a plethora of irrigation systems in Asia each designed to appropriate its own specific ecosystem potential. There is evidence of large-scale irrigation works in several Asian countries including China and Sri Lanka. The systems studied on the subcontinent include gigantic artificial lakes, large-scale and small-scale embankments, and diversion channels. They include schemes for taking water up a hill against gravity, elaborate canal distribution networks, innovations like the *khazans* on the west coast of India, where unmanned wooden sluice gates control the sway of salt and sweet water in low-lying paddy fields adjoining the coastal or tidal rivers, and storage tanks with a bewildering variety of names.

"The irrigation history of Indian has been studied only in fragments" (Sengupta 1993). But even this admittedly fragmentary picture that is emerging is far more fascinating than the simplistic or impressionistic scenarios of Wittfogel or later historians like Raychaudhuri and Majumdar. The most fundamental aspect of irrigation technology and civil engineering works to be noted is that almost all of them are related to monsoon precipitation in one way or another. Over 90% of the annual runoff in the peninsular rivers and 80% in the Himalayan rivers occur during the 4 months of the monsoon. Thus, unlike the case of temperate ecosystems, irrigation becomes extremely crucial: in the wet season which stretches approximately 4 months, in several places less, there can be too much precipitation over intense bursts. This is followed by a dry season during which there is no precipitation at all. The result is predictable: periods of excess water followed by drought.

In this context, the basic design of irrigation technology is intimately related to precipitation: how to save it, store it, and divert it, so that spatially it reaches areas where there is no water (diversion techniques) or temporally makes it available during the dry months (storage techniques). Thus, rain-fed rivers are diverted into channels, or river basins are interconnected. Or the rainfall is directly collected in huge storage facilities on the land.

If this is the scenario (and it is as valid today as it was in 3000 BCE), one would normally expect a much richer history of irrigation techniques in Asian conditions – where rice is a basic crop adapted to growing largely in water – than in any other part of the planet, particularly the temperate zones. It would also follow that the irrigation designs evolved for coping with such situations would not readily be available in other ecosystems. For this reason, it has taken some time for engineers and historians trained in other culture areas to appreciate their worth and function.

The irrigation experience of China is documented in Joseph Needham's *magnum opus*, *Science and Civilisation in China*, and will not concern us here. We shall restrict ourselves in this essay to a consideration of the irrigation and civil engineering techniques that arose in the Indian subcontinent including Sri Lanka and which were the result of a close interaction and adaptation between overall environmental situations and human ingenuity.

Irrigation Technologies

In the circumstances related above, it stands to reason that the primary design objective of irrigation engineers would be predominantly in the direction of a water storage system. The following listing is given by Shankari and Shah.

There were storage systems designed purely for drinking water: *nadi*, tanks, *bowari*, *jhalara*, and *pokhar*. Some were reserved only for human beings; others were for human beings and animals. These we shall ignore here.

The second category of storage technologies relates to irrigation, and there is considerable evidence of the spread of such technologies through the length and breadth of the subcontinent. Though the structures here were all designed for irrigation, they also provided other useful functions of soil conservation and ground water percolation and recharge.

Irrigation water stored in such storages was conveyed through two methods: first, under the force of gravity, or gravity irrigation, and second, through extractive or lift techniques or devices of some kind, including for instance the Persian wheel.

There were three main classes of such irrigation-related storage systems. The first comprised tank and pond irrigation systems. These in turn were of two types: *above surface* storage works, where a reservoir was created above the ground through a fairly long embankment. The corresponding structures were called *Keri*, *Eri*, *Cheruvu*, *Kalvai*, and *Kunta* in South India and *Ahar* in Bihar (northern areas). The second category involved *below surface* storage works, which included dug ponds from which water was lifted by some means manual or mechanical: *pokhar*, *talab*, *jhil*, *beel*, and *sagar*.

The second class of irrigation systems comprised land inundation systems: the land was flooded and saturated before cultivation and then drained off prior to planting (another term used is flood irrigation). These were primarily above surface types or referred to (in India) as submergence tanks. Important variations of these are the *khadin* and the *johad* in Rajasthan and the *bundhies* of Madhya Pradesh.

The *bundhies* were built generally in a series and therefore captured every possible drop of rainwater that fell. If there were a surplus, a waste weir was provided. There was generally a sluice at the deepest part of the storage reservoir. A *stambh* or pillar would indicate the location of the sluice. Sluices could be of different types: pipe sluices or sluices made of masonry for the larger tanks. (Some sluices open, as in the *khazans*, with the pressure of the incoming tides and discharge water automatically when the tide has fallen; these are made from wood.) The crop which was grown in the *bundhies* after the water was drained did not require any irrigation until harvest.

The third class comprised in situ techniques through which storage facilities were created to retain precipitation and ground water infiltration. The difference between classes 2 and 3 was that in the former, cultivation followed drainage; in the latter it occurred simultaneously.

The sizes of these storage tanks varied and the tanks themselves were generally known from the command areas they irrigated: the smallest ones irrigated around 50 acres, the medium ones about 100, and the major ones 500 and above. The large tanks were clearly impressive in scale. The Veeranam Tank in Tamil Nadu has a bund (embankment) 16 km in length. The Gangaikonda Cholapuram tank, also in Tamil Nadu, was constructed by a Chola king from AD 1012 to 1044 and survives even today with a 25 km embankment.

The construction of tanks was a widely dispersed skill. To create a tank reservoir, an earthen embankment, usually curved, was erected in a concave form across the flow of water. The water was retained in the belly of the curve from where it was drawn and directed through channels to irrigate plots at lower levels through gravity irrigation. After the tank was emptied, the tank bed itself could be used temporarily for raising a crop utilizing residual moisture. Many of the tanks in an area were interlinked and functioned as parts of an integrated system. The tank at the higher level released its surplus water as runoff to tanks at a lower level and the next in turn. These were called *chain tanks*. There were also tanks which were fed by canals from a river. Chain tanks were generally created in the upper reaches of the river basin and river-fed tanks in the lower reaches. Their construction would have required detailed cooperation among several communities in the region.

In Mysore in 1866 Major R. H. Sankey, Chief Engineer, wrote:

> Of the 27,269 square miles covered by Mysore, nearly 60% has, by the patient industry of its inhabitants been brought under the tank system. Unless under exceptional circumstances, none of the drainage of these 16,287 square miles is allowed to escape. To such an extent the principle of storage has been followed, that it would now require some ingenuity to discover a site within this great area suitable for a new tank.

The profusion of such tanks was not a feature of Karnataka alone. Experience was similar in Tamil Nadu, Goa, or Bihar. The area north of the Vindhya mountain range in middle India for instance had more than 8,000 submergence tanks. In one district of Rajasthan alone, there were more than 500 *khadins*.

In Sri Lanka, dry areas were populated with what are known as "tank villages". "The one-mile to an inch topographical maps of the island," writes D. L. O. Mendis:

> show nearly 15,000 of these, of which over 8000 are in working condition today. Tradition has it that some 30,000 of these small tanks had been constructed down the ages and there is a reference in the chronicles to 20,000 in the ancient province alone in the 12th century.

Water Conveyance

Apart from the storage works, the subcontinent witnessed the emergence of competent and impressive water conveyance systems designed to divert waters of rivers and flowing streams. Some diversions were accomplished without a check or embankment across the river; in such instances, the flood waters of the river were drained through a natural diversion. The *Kuhls* or *Guls* in the Himalayan areas, the *dongs* of the Northeastern states, and the *pynes* of Bihar all reflect this feature.

The second category involved check dams as a basic feature: the river bed was first raised and the resulting raised water diverted into a channel as was the case with the *band-haras*. Some of these schemes were fairly small, like those in the hilly areas. Others could be extremely large-scale and it is the reports of the latter that probably gave Wittfogel material for his speculations. According to Major T. Greenway, these were works of "truly gigantic magnitude, vast embankments and drainage channels equal to ordinary English rivers in capacity."

Historical Development of Irrigation Techniques

The interesting question that is now being asked is whether one can talk in terms of an evolution of irrigation technologies and civil engineering techniques from the earliest times to the present? The question is important in view of the fact that many of these storage systems, diversion channels, and embankments are largely intact and still in use. There are still parts of the country where Persian wheels are operated. Tanks and storage vessels are once again being made functional and weirs continue to be constructed.

The answer seems obvious: while more complex technological mechanisms did emerge as time passed, the earlier and the later techniques have continued to coexist. The only major new innovation seems to be the idea of dams; these are new in terms of function, since the generation of hydropower was not intended in earlier times. The idea of large dams, once considered the temples of modern India, has taken a severe beating in recent years. They are now considered unsuited to tropical ecosystems, since the reservoirs invariably lead to displacement of large numbers of people, submergence of forests, and destruction of wildlife, and in places like Sri Lanka, submergence of smaller functioning reservoirs.

This being said, it is possible still to identify certain periods as distinct historical events in a possible history of irrigation and civil engineering on the subcontinent. There is archeological evidence of artificial irrigation from pre-Harappan and Harappan times (ca. 5500–3500 BCE): this took the form of a large number of wells. One well found had a brick lining going down 12 m. Post-Harappa, the major irrigation find is Inamgaon on the west coast of India where under the influence of the Jorwa culture (ca. 3400–3000 BCE), one finds evidence of a major diversion scheme reflected in a massive embankment 240 m by 2.2 m wide to divert the river into a channel. The channel itself was 200 m long and 4 m wide.

The first storage tanks in their rudimentary form appear around 2500 BCE – also in Sri Lanka – with the invention of iron tools. Hereafter, there are increasing references in literary works of both Sanskrit and Tamil up to the Gupta (AD 350) period. There are tank-related inscriptions which give details of tank construction, maintenance, sources of funds for maintenance, and so on. The word *eri* also comes into circulation by the seventh century as a term for tanks.

The *anicut* (weir) technique is probably older than the *eri* or tank. The most famous of the *anicuts*, the Kaveri Anicut on the river Kaveri, is linked to a Chola king of the second century AD. It involved a dam on the river Kaveri 300 m long and 12–18 m wide and 5 m deep. There is a dispute about the age of the *anicut*, since the *anicut* technique itself bears a strong resemblance to the Sri Lankan technique of massive stone dams and sluices, a technique which developed, according to Sri Lankan historian R. A. L. H. Gunawardene, only in the seventh century AD.

Sir Arthur Cotton paid eloquent testimony to the engineering talent involved in the large-scale irrigation works. He wrote:

> There are a multitude of old native works in various parts of India… These are noble works, and show both boldness and engineering talent. They have stood for hundreds of years… it was from them that we learnt how to secure a foundation in loose sand of unmeasured depth. In fact, what we learnt from them made the difference between financial success and failure, for the Madras river irrigations executed by our engineers have been from the first the greatest financial successes of any engineering works in the world, solely because we learnt from them… With this lesson about foundations, we built bridges, weirs, aqueducts, and every kind of hydraulic work… we are thus deeply indebted to the native engineers…

Social Arrangements/Religious Sanction

A significant feature of these irrigation works related to their construction and maintenance. Since water availability could be problematic with monsoon failure, those associated with the emergence of these works could gain religious merit for their deed. Though large systems were often sponsored by the state – to include kings, queens, local chieftains, *zamindars* (landowners) – village communities, temples, and even individuals are associated with their construction. Thus a public park in Pondicherry bears an inscription recording a tank built by a *dasi* – a temple dancer/courtesan – while another inscription in Karnataka (AD 1100) records a tank and shrine constructed by a village watchman.

All the major dynasties including the Mauryas (Sudarshan Lake near Kathiawar), the Cholas, the Hoysalas, and the Vijayanagar Kings and Muslim Sultans were associated with irrigation works. Of these, the most impressive schemes are associated with the Cholas. However, these kings depended upon a cadre of skilled hydraulic engineers. Dikshit records the performance of one such engineer in the fourteenth century:

> The Kalludi (Gauribidanur taluk) inscription of 1388 AD is well known. According to it, when Vira Harihara Raya's son Sri Pratapa Bukkaraya was in Penugonda city in order that all the subjects might be in happiness – water being the life of the living beings – Bukkaraya in open court gave an order to the master of ten sciences, the hydraulic engineer (Jalasutra) Singayya Bhatta that he must bring the Henne (Pennar) river to Penugonda. Accordingly Singayya Bhatta conducted a channel to the Siruvara tank and gave the channel the name Pratapa Bukka Raya Mandalanda Kaluve.

The day-to-day operation and maintenance of both large and small works were mostly in the hands of local communities and of special professionals like the *nirkattis* of Tamil Nadu. In many areas, production from certain lands was set aside specifically to meet the maintenance costs of tanks. During the installation of the colonial regime, these revenues were appropriated by the colonial power and consequently the maintenance of such irrigation works fell into bad times leading to declines in efficiency.

Irrigation in the Islamic World

Lucie Bolens

From Andalusia to the Far East, from the Sudan to Afghanistan, irrigation in Islamic countries is the basis of all agriculture and the source of all life. After the Roman empire, the classical Islamic empires relied on the great cities like Damascus, Baghdad, Cairo, Cordoba, and Fez. In the countryside, all the small villages, made up of groups of rush huts or houses of stone, wood, or concrete were organized around a water source: a mountain fed by a living spring, a cistern of rain water, or wells bringing water up to the surface from deep beds. The Arabic word for water, *Mā*ʾ, is also the word for center. The water for religious ablutions at the center of the courtyard facing every mosque is the symbolic echo of a physical fact.

Islamic irrigation recovered pre-Islamic purviews while at the same time developing and expanding them. The historical record describes a vast network of canals from hot climatic zones to cold, rainy ones. The first were developed in the river valleys of semiarid and arid regions. The Nile, the Tigris and Euphrates, and the Guadalquivir have offered rural and urban communities from earliest times both water and silt, a means of providing refreshment and nourishment.

Where no great rivers existed, human societies dug wells and prospected deep lying aquifer beds, in the south of the Arabian peninsula, in Yemen, and in Hadramawt, as well as in the Sudan. There, where the effects of Indian monsoons are often felt, a tropical agriculture (coffee trees, date palms, banana, and tamarind trees) served as a point of departure for those tropical plant species to Mediterranean regions.

Lastly, on the borders of agricultural zones stretched vast steppes with winter rainfalls varying from 50 to 150 mm per year, seminomadic lands which had been used for thousands of years. Animal husbandry and intensive agriculture at oasis sites have for centuries contributed to the economic base of Yemenites and Maghreb tribes. This association between seminomadic grazing and intensive irrigated agriculture is a distinctive characteristic of Islamic irrigation, a system of a complementary nature between field, pasture, and natural resources in the environment.

For classical Islam, written documentation is inseparable from the latest results of rural archeology; all of the *Kitāb-al-Filāḥat* (Books of Agriculture) – Maghrebian, Andalusian, Egyptian, Iraqi, Persian, or Yemenite – insist meticulously on the deployment of equipment and on the control of water. What are examined are the means of water distribution, following the season and the species being cultivated. A Tribunal of Waters looks at legal cases, and that of the Islamic writer Valence has lasted from the time of the Christian *Reconquista* in 1248 until today. Irrigation was linked to a social time, following necessities of nature but also following the social rank of the users.

In the current state of research, one of the oldest calendars of irrigation was found in the *Filāḥat al-Nabaṭiyyah* (Nabataean Agriculture, by Ibn Waḥ shiyyah), which in the 1000s gave information on pre-Islamic Mesopotamia and Abbasidian Iraq. For western Islam, jurisprudence provided historians with precise details of daily life and ecological behavior, and explained the elements relating to the history of that environment, such as torrential rains in the autumn and the spring, the shifting of waterholes, and complaints from the owners of cultivated estates which had been deprived of water from one day to another. The *fiqh* Islamic juris, had to regulate any unexpected events from case to case. The joint purchase of land and water, inherent to the *fiqh*, confronted the fact of the capriciousness of nature: the agrarian weather of microclimates really was the final law. In Islamic law ownership of land is always linked to ownership of waters.

Lastly, financial writings integrate the agrarian dependence on water into the framework of the whole political and social evolution of Islamic history. Irrigation is the crucial element of agriculture in Islamic lands.

The rains follow two dominant climatological patterns: one Mediterranean, the other tropical and subtropical. The Mediterranean basin, along with southern Africa and California, has the only climate which has rain in the winter and maximum heat in the summer. The vegetation there needs a hot, humid season in its tillage phase. In other respects, the torrential spring and autumn rains create a major risk for the thin, mountainous soil which is predominant in the Mediterranean basin. A negative quality can thus indeed have positive effects.

This link between the climate and the soil in Andalusia entailed three inseparable factors: an extremely fragile ecology at risk of erosion, a highly organized and detailed system of irrigation which was adapted to regional conditions, and a stable political and administrative system (except in time of war).

In certain historical cases, like that of Andalusia, in spite of the fluctuating tides of conquest and reconquest, there existed a true ecological pattern which lasted for several centuries and which served as a real ecological laboratory for eastern and western Islamic statutes, based on a high level of natural science, climatology, and botany. The extensive spread of theoretical and technical knowledge made of the Andalusian model a precedent which could be applied to all societies, ethnic, and religious differences aside, which were trying to understand the environment in its historical dimension.

It was water which governed the classification of land types. The rich agronomical and administrative literature of Arabic Islam divided cultivatable land into rainy land and irrigated land. The former were those lands which received enough winter rain to permit the cultivation of olive trees, grape vines, and citrus trees, the Mediterranean trilogy. Irrigated plantings used water stored in deep beds; the surface of the land was hot and irrigated and was worked in squares irrigated by ditches or *acequias*. The device which allowed the flowing of water into the ditches across fields, squares, or gardens was a wheel of variable dimension called a *noria*. More simply, on river banks and along the shore a system of scales and counterweights called *shaduf* was used.

The plan of irrigated water brought about a kind of intensive horticulture comparable to that achieved in the great Asiatic deltas. In the development of the countryside irrigation allowed plant species which became the basis of the popular diet – e.g., rice and legumes rich in protein – to become acclimated to the Muslim west. In Andalusia, sugar cane, rice, and cotton were cultivated.

In plateau regions (Meseta, Morocco, Iran) where aquifer beds were deep, the most profitable procedure was the traditional system of *qanats*. The *qanats* were deep drainage tunnels which directed water to springs or artesian wells. Some were over 16 km long, and their deep tunnel was dug from the outlet up to the mother-well. The gradient incline of the aquifer bed can range from almost zero to very steep. Well sites were marked and were used for ventilation and disposition of debris from land clearing. The science of the *qanats*, traditionally, was based on empirical knowledge and was passed down by gesture or through oral tradition. The earliest descriptions are Iranian. Later they were developed on the Castilian Meseta (Madrid) and in Morocco (in Marrakesh). Today, one can see them in Central America; they are the oil-qanats.

In between the canals of flowing water and the system of *qanats* the Islamic world watered its gardens and fields, its city courtyards and domestic patios, and its mosques, with water from wells whose volume was increased through a process described by Ibn al-ʿAwwām in the *Kitāb al-Filāṭḥat* and in *Nabatean Agriculture.* Chapters relevant to finding the underground water level and sinking wells are followed by considerations on ways to increase the volume of water stored, ways to raise water from wells that are too deep, and ways to modify the taste of brackish or salty water.

The detailed observation of the earth or of its vegetation, in order to identify the presence of water, as well as the empirical nature of the investigation to sample the earth, in order to define various qualities of water, such as neutral, salty, or brackish and bitter, systematically mobilized the senses. Empiricism was able to bring about the creation of an irrigated, productive agriculture area. This success was built on the very controlled work of the *fellahs*, a political encouragement of individual appropriation, and on a high level of applied knowledge.

This multisecular, integrated system was the reason behind the development of numerous plant species crucial to the existence of civilization.

Irrigation in South America

Gray Graffam

Large-scale irrigation systems (canal irrigation) went hand-in-hand with the rise of cities and truly complex societies on the coast of Peru during pre-Hispanic times. Such systems delivered water to hundreds of hectares of potentially fertile land along a dry desert coast. Relatively late in prehistory, from 300 BCE onward, a number of well-known urban cultures (e.g., Moche, Lima) undertook the construction and expansion of irrigation works, which supported dense populations. This process culminated around AD 1000 in the construction of exceptionally large and sophisticated works by the Chimu, including an intervalley canal of impressive proportions from the Rio Chicama. These works made it possible for a population of some 25,000 to reside at the capital city of Chan Chan. Irrigation agriculture played a primary role in sustaining urban communities near the coast, where large irrigable plains of potentially fertile land were brought into production.

Similar irrigation systems in the Andean highlands are also of note. Some researchers, such as Michael Moseley, believe that irrigation agriculture developed here, as an extension of hunter–gatherer practices. Because of the steep slope, short canals would have been sufficient to water desired areas, and over the course of a millennium or more, a sophisticated irrigation technology developed. By AD 600, canal irrigation brought hundreds of hectares of otherwise unusable land into production in the Ayacucho valley of south-central Peru. These networks helped support a population of some 20,000 or more at the urban site of Huari, which is situated at an elevation of some 3,000 m, above any substantial acreage of arable land.

Other agricultural systems are also known for the Andes, and for elsewhere in South America. These include (a) sunken gardens on the desert coast, where plots of land were dug down to the water table and then planted, (b) terraces along the highland slopes, which served to retain moisture and enhance production, and (c) raised or drained fields along lake margins and in the Amazon basin, which served to reclaim inundated wetland. Aspects of irrigation technology theoretically come into play with each. Upland irrigation tends to create a higher water table downslope, which can make sunken fields possible in otherwise very dry areas. Slope irrigation can deliver a supply of water to terraced fields, and such systems are documented for the Inca. During the dry season, spring water can be run into the swales of raised field systems, which can allow for double cropping in some settings, e.g., Lake Titicaca. Irrigation plays a role in other agricultural systems of the Andes. All of these agricultural systems were geared toward intensive production, as a means for dense human adaptation to the Andean environment.

In general, the construction and maintenance of irrigation systems are portrayed in the archaeological literature as a powerful force leading to the rise of civilization and urban life. This theory is based upon the view expressed by Karl Wittfogel, and subsequently anthropologists such as Julian Steward, that water management plays a key role in crystallizing political authority; it is also referred to as the "Hydraulic Hypothesis." According to this theory, highland peoples came to control a scarce resource of high value – water – which led to a hierarchical system for its management and distribution. Such a scenario is thought to have led inevitably to the formation of stratified society and subsequently state bureaucracy. Political power is seen as a direct outgrowth of the struggle for water, from which centralized authority and state-level government emerge. Not everyone agrees, and some scholars, such as Robert Adams, have argued forcefully that irrigation is the consequence of political power, rather than its cause.

The Peruvian data do not support the "Hydraulic Hypothesis" of civilization's emergence. A strong maritime economy typified subsistence strategy along the coast during preceramic times, and large agglutinated settlements that housed hundreds of people were built along the coast between 2500 and 1800 BCE, e.g., Huaca Prieta, El Paraiso, Rio Seco, Playa Culebras, and others. There is an active debate on the role that crops, including maize, had in this developmental process, but it seems quite clear that irrigation agriculture played little part and certainly not to the scale of later times. According to Michael Moseley, the sociopolitical organization that accompanied these settlements was highly evolved, incorporating the management of labor mobilization (a form of taxation) on a regional basis. Irrigation agriculture took hold around 1800–900 BCE in the prehistoric sequence for Peruvian cultures. By this time, authority figures and labor taxation systems had already emerged. Irrigation technology did not bring them about, but vice versa.

Still, the matter of irrigation's impact on society is a topic of central concern. For the north coast of Peru, it has been argued that irrigation technology went hand-in-hand with hierarchical social organization during late pre-Hispanic times. According to Patricia Netherly, water was a valuable commodity, and groups benefited from a hierarchically organized social structure, capable of resolving conflict when it occurred. Michael Moseley adds the perspective that large-scale irrigation projects were designed and engineered by rulers in these settings. Together both views provide a clear understanding of how irrigation was carried out, on the one hand through kinship organization, and on the other through government intervention in labor-intensive projects. Irrigation may not have given rise to civilization and urban life in the Andes, but it clearly evolved within the power structure of subsequent developments.

Today, systems of native irrigation management are under study, as are the impacts of modern attempts to improve them (Mitchell 1991; Bolin 1990). It is noted that highland communities often attempt to maintain their rights to water use and management, although in Peru such rights no longer exist in the legal sense. All water belongs to the Peruvian state, and there are national laws and regulations that govern its use. Highlanders, especially those who regard themselves as

"Owners of the Water," fall into conflict with people in the lowland valleys. According to Bolin, there is a great need for agricultural and government agencies to investigate the indigenous patterns of water use, and the competition between and within villages for access to irrigation water. As revealed by Mitchell and Netherly, such patterns of water rights are likely to be deeply embedded within kinship organization and indigenous social structure.

Isa Tarjaman

Sun Xiaoli

During the Yuan dynasty (1271–1368) the Arabs played a role in Chinese science and technology similar to that of the Indians in the Tang, bringing in stimulating outside influences which were then incorporated and synthesized into Chinese mathematics, astronomy, and medicine. Isa Tarjaman (1227–1308) or Aixue in Chinese, was a remarkable example. Isa Tarjaman, sometimes called Isa the Interpreter or Isa the Mongol, was a Nestorian Arab from Syria. He was skilled as a mathematician and astronomer as well as in medicine and pharmacy. He came to China in about 1247, then worked for the Mongol Khans till his death in 1308. In 1263 Kublai Khan appointed Isa the director of the Muslim Astronomical Bureau and Medical and Pharmaceutical Bureau. During this time he suggested that Kublai prepare a new calendar in the Arabian style which he finished in 1267 in cooperation with a Persian astronomer Zhama Ludin or Jamāl al-Dīn, who was working in China too. This was called the *Wan-nian* (ten thousand years) calendar. Meanwhile, they made seven kinds of Arabian astronomical instruments for the Huihui (Muslim) Observatory. All of these exerted some influence on the Chinese astronomer Guo Shoujing (1231–1316) and his work.

From 1283 to 1286, Isa was sent to Il-khan as a member of a delegation. There he visited the famous Maraghā Observatory and worked together with some Arabian and even Chinese astronomers who were working there for a time. Then he brought some of these astronomical and mathematical works back to China. These were studied by staff members at the Muslim Astronomical Bureau in Beijing.

As the director of the Medical and Pharmaceutical Bureau, Isa Tarjaman established a Capital Hospital to introduce Arabian medicine to China; his wife Sara also worked there. An important Arabian medical work entitled *Huihui Yaofang* (Collection of Muslim Prescriptions) was compiled under his leadership. It is interesting that some of the contents of this work were taken from Ibn Sīnā's *Canon*. Therefore, Isa made a great contribution to the history of the Sino-Arabian scientific exchange, and he thus was praised by the Mongol Khans. After returning from Il-Khan he rose to be a Hanlin Academician, then the minister of State in 1297. After his death the Mongol court made him the Fuolin Prince. He was the only Arab to attain such a high official position in China.

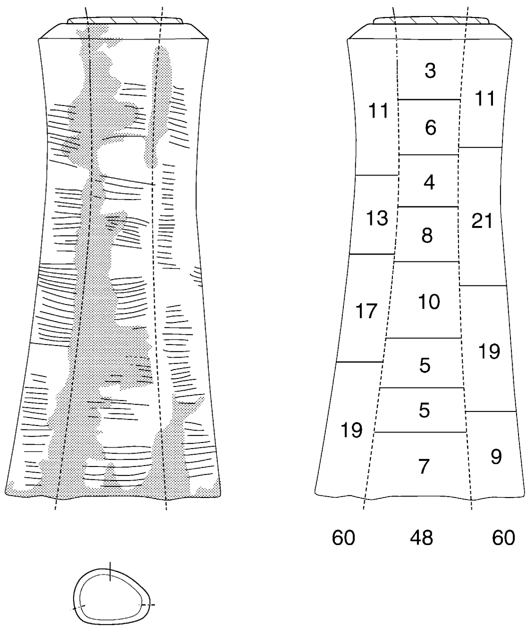
Ishango Bone

Anne Hauzeur

The engraved bone drew international attention as soon as it was described by J. de Heinzelin in 1957. Its uniqueness, as well as its geographical and chronological position, were astonishing.

Ishango is located on the top of a fossil terrace of the Semliki River, at the mouth of Lake Edward/Rutanzige,

Ishango Bone. Fig. 1 The engraved bone from Ishango, with a quartz at the tip (photo and ©RBINS).



Ishango Bone. Fig. 2 Uurolled sketch of the Ishango bone, and number in each group of notches (after de Heinzelin, 1957).

in the Democratic Republic of Congo. There were several prehistoric occupations from 20,000 till 5000 BC, when the volcano Katwe erupted. The different levels of human occupation are characterised either by a great amount of small-sized tools in a translucent white quartz, but most of all by numerous bone harpoons. Those latter evolved from a one-barbed sided to a two-barbed sided type. The settlement of Ishango would illustrate an old step of this harpoon production, whose pattern would have been widespread from the Great Lakes region towards Western Africa and the North in Sudan and Egypt. Rainfall was increasing during this time, so that the way of life was more devoted to fishing. This fishing tradition went on after sedentarisation and the introduction of animal breeding.

The engraved bone has several points of interest. It is the only piece among the whole artefacts assemblage to have a series of notches engraved in a very ordered rhythm (Fig. 1). As with the other tools, it was made on the settlement. A diaphysis [the mid-section of a long bone] from an unidentified animal was prepared and worked. At one end a little piece of white quartz was shafted to be used as a tool. Without any archaeological evidence the function is unknown; perhaps it was used to incise or engrave. The "shaft wears" groups of notches, displayed in three rows on its periphery. When adding all the groups of each row, the sum is 48 or 60, a multiple of 12 (Fig. 2). Each group of notches sums either prime numbers between 10 and 20, or numbers multiplied by 2, or 10 ± 1. It could illustrate a numerical converter system of base 10/base 12. In such a case, the Ishango bone could be considered as the oldest computing machine, used during the times of the hunter-gatherer nomads. It would be the oldest transcribed testimony of the mathematical intelligence of our ancestors, right in Central Africa, some 20,000 years ago. Originally, the antiquity of the piece was questioned, but new dating has proved its age.

Archaeological facts demonstrate the wide spread of the harpoon tradition, i.e., from Central Africa to the Nile basin. Traditional scholars teached that the first mathematics came from the Ptolemaic period and the Golden Age of Alexandria.

Isḥāq Ibn Ḥunayn

Gregg De Young

Isḥāq ibn Ḥunayn (215–298 AH/AD 830–910) is best known for his role in the translation of Greek texts, both philosophical and mathematical, into Arabic. In addition to his work in the translation institute founded for his father, Ḥunayn ibn Isḥāq (193–263 AH/AD 809–877), he served as a physician to the court under caliphs al-Muʿatamid and al-Muʿatadid. Although Ḥunayn was a Nestorian Christian, some sources imply that Isḥāq converted to Islam.

As a translator, Isḥāq followed the scientific approach developed and applied by his father with such success to the Galenic corpus. Rather than translate mechanically word-by-word, he attempted to capture the meaning of each Greek thought unit in an appropriate form in the target language. (Both Isḥāq and his father are said to have preferred to translate first from Greek into their native Syriac, only later producing an Arabic version based on the Syriac. Assuming such reports to be true, the paucity of Syriac translations among extant manuscripts remains puzzling to historians.)

Isḥāq's greatest contributions lay in his translations of Greek philosophical texts, especially the works of Aristotle. He produced Syriac versions of a part of the *Prior Analytics* and all of the *Posterior Analytics* and the *Topics*. He also rendered the *Categories*, *On Interpretation*, *Physics*, *On Generation and Corruption*, *On the Soul*, parts of the *Metaphysics*, and the *Nichomachean Ethics* into Arabic. He may also have translated the *Rhetoric* and the *Poetics*. In addition to Aristotle's works, he translated Galen's *Number of the Syllogism* and part of his *On Demonstration*, as well as some logical and philosophical works by Alexander of Aphrodias, Porphyry, Themistius, and Proclus.

Isḥāq was also instrumental in translating several important Greek mathematical treatises into Arabic. These include Euclid's *Elements*, *Optics*, and *Data*, as well as the *Almagest* of Claudius Ptolemy, *On the Sphere and Cylinder* by Archimedes, the *Spherics* of Menelaus, and minor works by Autolycus and Hypsicles. It is reported that Isḥāq's translations of Euclid and Ptolemy were revised by the mathematician, Thābit ibn Qurra. Apparently, Thābit compared the Arabic version with additional Greek manuscripts which he had at his disposal and noted differences between the Arabic and Greek versions. Whether any other editing was involved, we do not yet know. All extant Arabic manuscript copies of Euclid seem to reflect some aspects of this editing process, although no manuscript contains the complete set of known comments attributed to Thābit. The relationship of Isḥāq's version of Euclid to the earlier transmission attributed to al-Ḥajjāj ibn Yūsuf ibn Maṭar is difficult to establish because the earlier version has disappeared. In the case of the *Almagest*, however, both Arabic versions appear to be extant, allowing some conjectures to be made concerning the translation principles applied by both men.

Isḥāq also produced a number of original works on medicine. Unfortunately, these seem not to have survived. His *Tārīkh al-Aṭṭibāʾ* (History of Physicians), an extended version of a Greek book of the same title by John Philoponus, does survive. Isḥāq has added the names of philosophers active during the lifetime of each physician mentioned. This work has been helpful to historians of both medicine and philosophy.

I

Jābir Ibn Aflaḥ

Richard P. Lorch

Almost nothing is known of Jābir's life, but remarks by Maimonides (d. 1204), e.g., that he knew Jābir's son, place Jābir probably in the first half of the twelfth century, and the name "al-Ishbīlī" establishes a connection with Seville. Indeed, legend associates his name (wrongly) with the building of the Torre del Oro and of the tower now belonging to the cathedral in Seville. Jābirs' principal work was a commentary (or correction, *iṣlāḥ*) on Ptolemy's *Almagest*, the standard textbook on mathematical astronomy, which he had seen in two translations from the Greek. In this treatise he not only simplified the mathematics and separated theory from calculation (there are no tables in the book), but also indulged in violent criticisms of Ptolemy. The introduction to the commentary contains a list of Ptolemy's "errors", which are considered in detail in the body of the book. His best known astronomical claim of this kind was his assertion, against Ptolemy, that Venus and Mercury must lie above the Sun because of their lack of parallax.

Jābir's lasting contribution was his statement of the requisite theorems in trigonometry. The essence of his plane trigonometry is to be found in the *Almagest* itself, but his clear enunciations of his results for triangles obviated the need for construction lines that cluttered so many diagrams. Again, his theorems on spherical triangles, which replaced Ptolemy's theorems involving six quantities by proportions involving four, were clearly taken over from a group of scholars, such as Abū 'l-Wafāʾ and Abū Naṣr ibn ʿIrāq, who worked in Baghdad and elsewhere in the eastern provinces of Islam about AD 1000. Curiously, Jābir quotes no Arabic author in his work, not even Ibn Muʿādh, who had lived and worked in eleventh-century Seville.

The text of the *Iṣlāḥal-majisṭī*, at least in the trigonometrical part, was revised, perhaps by the author. Ibn Rushd (*ḍ*. 1198) and al-Biṭrūjī in Spain were both influenced by the work. It was also known in the East, for al-Shīrāzī (d. 1311), one of the Marāghā astronomers, made a compendium of it. There were two translations into Hebrew, by Moses ben Tibbon (1274) and by Jakob ben Makhir (revised by Samuel ben Yehuda of Marseilles, 1335), and Jābir appears to have had considerable influence in Hebrew astronomy. But the most lasting influence of the work was through the translation into Latin by Gerard of Cremona (d. 1187). For the Latins not only was "Geber" a vigorous critic of Ptolemaic astronomy, but his treatise established trigonometry in the West. This can be seen in an anonymous commentary, in an anonymous compilation of the plane trigonometry, *De tribus notis* (On Three Known [quantities]), and in the works of Simon Bredon, Richard of Wallingford (both fourteenth century), and others. Finally, "Geber" was the source of much of Regiomontanus' *De triangulis* (On Triangles), perhaps the source for the trigonometrical section of Copernicus' *De revolutionibus* (On the Revolutions [of the Heavenly Spheres]).

Jābir Ibn Ḥayyān

S. Nomanul Haq

Abū Mūsā/Abū ʿAbd Allāh Jābir ibn Ḥayyān, for a long time the reigning alchemical authority both in Islam and the Latin West, is at the same time among the most important and most enigmatic figures of the history of Islamic science. Doubts already existed in the medieval Arabic tradition as to whether the large corpus of alchemical, philosophical, and religious texts attributed to Jābir were authentic. Scholars of modern times have shared these doubts, and some have gone as far as to conclude that Jābir may never have existed at all, and that contrary to the received view, the Jābirian corpus is not the work of a disciple of the sixth Shīʿī Imām Jaʿfar al-Ṣādiq (d. 765); rather, it was produced piecemeal by several generations of Ismāʿīlī authors, the oldest of whom lived no earlier than the second half of the ninth century.

This essentially is the widely accepted position of Paul Kraus who still remains the greatest Jābirian scholar of modern times. Some historians have disagreed with this position, and others have tended to revise it. At this juncture, then, very little about Jābir can be claimed with certainty. It might be safe to say on the basis of the most recent evidence that Jābir was a historical Muslim figure of the eighth century, that there was a small authentic core of Jābirian writings, and that out of this core developed the largely apocryphal and grand Jābirian corpus as we know it today.

Jābir is generally referred to as an alchemist. But if turning base metals into gold is the essential preoccupation of alchemy, then Jābir is hardly an alchemist, for transmutation of metals was only a minor part of his concerns. He was concerned, rather, with developing an all-embracing metaphysical and natural scientific system based upon immutable universal principles. It is this search for universal principles that led him to the study of language, music, and numbers. The Pythagoreans said that things are numbers; Jābir says that things are the names that designate them. An analysis of the name of a thing is for Jābir an analysis of the thing itself; this daring ontological claim of an equivalence between language and reality sounds more metaphysical than alchemical.

Jābir did write extensively about chemical processes and techniques, and in this field he made some highly original and historic contributions. For example we find in his treatises the theory that all metals are composed of sulfur and mercury existing in various proportions. It was this idea that led to the phlogiston theory of modern chemistry. Another Jābirian contribution is the introduction of sal ammoniac in the repertoire of chemistry. Two varieties of sal ammoniac were distinguished: natural (ammonium chloride) called *al-ḥajar*, and derived (ammonium carbonate) called *al-mustanbaṭ*. The latter was obtained by the dry distillation of hair and other animal substances. Again, the use of organic materials, both plant and animal, in addition to the inorganic, is a monumental Jābirian innovation.

Jābir's chemical processes are never carried out in a theoretical vacuum; we find in his writings both a developed theory of matter and a sophisticated cosmology. He believed that matter was ultimately composed of four "natures" – hot, cold, moist, and dry. But unlike the familiar Aristotelian qualities, Jābir's natures were not abstractions; rather, they were real, material, and independently existing entities; hot, cold, moist, and dry were the "first elements" out of which were born the "second elements": air, water, earth, and fire. The former were simple, the latter were compound; the former were primary, the latter were derived; the second elements could be resolved into natures, but natures were immutable. Jābirian natures were, then, the ultimate building blocks of the world.

A striking aspect of Jābir's cosmology is his parallel idea of the "first creation" and the "second creation." The former was an act of God, the latter an act of man. The difference between these two is that God acts in a timeless fashion, whereas man effects his creation in a temporal domain. Thus man can imitate God's work, but he requires time to accomplish it. From this emerges the Jābirian idea of artificial generation. Birds, for example, are found in nature, but these creatures can also be produced over a period of time in a laboratory; so can human babies. Through a manipulation of natures man can generate even such living beings as are not found to exist naturally – monsters, dwarfs, giants, freaks, and so on. Indeed, Jābir's idea of artificial generation sometimes strikes one as thoroughly modern.

If Jābir is the first alchemist of Islam, then he is the pioneer of all that is important and characteristic of Islamic alchemy: the sulfur–mercury theory, the introduction of sal ammoniac, the use of organic substances, the idea of artificial generation of life, the production (though not recognition) of mineral acids, and the conceptual distinction between heat and temperature. He was widely known in Medieval Europe, and at least three of his treatises were translated into Latin.

Jagannātha Samrāṭ

K. V. Sarma

Paṇḍita Jagannātha (1652–1744), who bore the title "Samrāṭ", writer on astronomy and mathematics, and designer of astronomical instruments, was the religious preceptor and collaborator in astronomical pursuits of Jai Singh Sawai (1688–1744), the astronomer-prince of Jaipur in Rajasthan. Born into a Vedic family, the son of Gaṇeśa, Jagannātha was attached to the court of Jai Singh from an early age and assisted his patron in all his social, religious, and scientific activities.

At Jai Singh's behest, Jagannātha mastered Arabic and Persian, the two foreign languages prevalent in the Mughal court, which he utilized in the study of Islamic astronomy and put to beneficial use translating into Sanskrit texts in those languages for his patron. In this way, Jagannātha produced his *Rekhāgaṇita* and *Siddhāntasārakaustubha*, which are translations of Euclid's *Elements of Geometry* and Ptolemy's *Almagest*, respectively, from their Arabic versions by Naṣīr al-Dīn al-Ṭūsī. It is interesting that in the case of *Rekhāgaṇita*, Jagannātha himself coined more than a hundred Sanskrit equivalents of technical terms.

In his original work *Siddhānta-samrāṭ*, composed at the behest of Jai Singh, Jagannātha described the construction and application of a number of astronomical instruments. He also mentioned the reasons that his patron, who was obsessed with metallic instruments like the astrolabe for making celestial observations and reading out the results, later opted for huge outdoor observatories with stone and mortar. The reason was that Jai Singh found that the metallic instruments did not give minute readings, and were also susceptible to wear and tear, and to climatic conditions, which brick observatories were not. His *Yantraprakāra* is a more elaborate work on the subject of astronomical instruments, which includes descriptions of some more instruments, computations, a number of tables, and allied data.

Jagannāha's *Siddhānta-samrāṭ* and *Yantraprakāra* carry a number of recordings of celestial observations of different types, for periods short or long, which demonstrate how the instruments designed, and observatories constructed, as above, had been put to use for correcting parameters, preparing almanacs and the like. The part played by Jagannātha in these endeavors was considerable and significant.

Jai Singh

Virendra Nath Sharma

Jai Singh, or Jai Singh Sawai (Jaya Siṃha Savā'ī), the eighteenth century statesman–astronomer of India, was born on November 3, 1688 to the royal house of Amber, in the present state of Rajasthan, India. His ancestors were semiautonomous rulers of their princely state under the Mughals and occupied important posts at the Mughal court. Jai Singh lived his life during one of the most troubled, uncertain, and critical periods of Indian history, and he was involved directly or indirectly in just about every political or military conflict of his time. With his diplomacy and political maneuverings, he acquired a great deal of authority and influence throughout the Mughal empire. Making full use of his prestige and power, Jai Singh embarked upon a program of reviving astronomy in his country.

Jai Singh displayed an early inclination toward astronomy and mathematics and soon acquired mastery over these two subjects. He realized that the astronomical predictions based on the Hindu, Islamic, or European books (which were available to him) did not agree with actual observations. He reasoned that the disagreements between predictions and observations were primarily due to the outdated parameters found in the astronomical books, and would not be alleviated until new parameters based on careful observations were made available. Consequently, he decided to obtain new parameters.

With the blessings of the reigning emperor, Muḥammad Shāh, Jai Singh initiated a multifaceted program in astronomy. He designed instruments, built observatories, compiled an excellent library, assembled competent astronomers of different scientific backgrounds, and sent a fact-finding scientific mission to Europe. His scientific career lasted for more than 20 years. He died in 1743, at the age of 54.

Jai Singh started out first with traditional instruments of brass built according to the designs given in the texts of the Islamic school of astronomy. However, the metal instruments did not measure up to his expectations; he discovered with disappointment that the instruments gave inaccurate results once their axes wore down, displacing their centers. The instruments were also unsteady during observing because of their portable nature. He discarded these instruments, therefore, in favor of the instruments of masonry and stone of his own design and tried to achieve the desired precision from their large sizes and steadiness from relatively inflexible structures. His instruments range anywhere from 1 to 25 m in height.

Jai Singh built five observatories in cities of north India, at Delhi, Jaipur, Varanasi, Ujjain, and Mathura, and equipped them with instruments of his own design. His observatory in Delhi was completed in 1724 and the others within a decade. His observatories, all except that of Mathura, are still extant in good to fair states of preservation. His observatory at Jaipur has the largest number of instruments and is in the best preserved state. The observatories of Delhi and Jaipur are big tourist attractions these days and visited by hundreds of thousands of people each year.

An inventory of Jai Singh's major instruments of stone and masonry is presented in Table 1.

The Samrāṭ, Ṣaṣthāṃs'a, and Dakṣinottara Bhitti are Jai Singh's high precision instruments. With these instruments, he extended precision to the very limit of naked eye observing, i.e., 1′of arc.

Although the telescope had become common with European astronomers and had acquired refinements such as the micrometer and crosshair, there is no evidence that Jai Singh benefited from it. His instruments do not use a telescopic sight, and with all their ingenuity of concept and design are no more than what may be called "naked eye tools" somewhat in the tradition of the medieval astronomers such as Ulugh Beg of Samarkand. It is reasonable to believe that the invention of the telescopic sight, which had come into vogue with European astronomers only a few decades earlier, did not come to his attention early enough. It should be pointed out, however, that Jai Singh was familiar with the telescope and had observed with it. His personal library inventory lists a telescope bought for him at a cost of 100 rupees.

Jai Singh's early training as an astronomer had been under Hindu *pundits*, and they remained the mainstay of his program until the very end. At one time there were at least 22 astronomers working at the observatory of Jaipur alone. Jagannātha Samrāṭ, Kevalarāma, and Nayanasukhopādhyāya were his principal astronomers. These astronomers constructed instruments, collected data, translated books, and compiled original works in astronomy. The translated works included Ptolemy's *Almagest*, Euclid's *Elements*, and De La Hire's *Tabulae Astronomicae*.

Jai Singh was equally interested in the Islamic and the European traditions of astronomy. He collected astronomical works in Persian and Arabic, and patronized Muslim astronomers of the Persian–Arabic school. The Muslim astronomers included Muḥammad Ābid, Sheikh Asad Ullah, Sheikh Muḥammad Shafī, and Dayānat Khān. These astronomers procured astronomical books for the royal library, constructed instruments, helped with the translations, collected data at the observatories of Delhi and Jaipur, and traveled to distant lands at the command of their patron (Fig. 1).

By 1725, the involvement of the Muslim *nujūmīs* or astronomers in Jai Singh's astronomical program began to taper off and, in its place, the involvement of Europeans, primarily Jesuit priests, increased. The European astronomers included De Bois, Figuerado, Boudier, Gabelsberger, and Strobl. The Europeans played the role of conveyors of European knowledge to

the Raja. Accordingly, they led a delegation to Europe, procured texts and instruments, translated De La Hire's tables, and carried out mathematical computations. However, the knowledge these Europeans brought to Jai Singh and his astronomers had already become outdated in Europe, for it did not include the theories of Galileo, Kepler, or Newton; nor did it include observational techniques such as those employed by Flamsteed in England.

In 1727, Jai Singh dispatched a scientific delegation to Europe after learning that "the business of the observatory was being carried out there." The delegation, first of its kind from the East, was led by Figuerado, and it reached Portugal in January 1729. The delegation stayed on in Portugal for over a year. It did not travel to Paris or London, however, where the most advanced work in astronomy was being done. In 1730, the delegation returned to Jaipur, the capital of Jai Singh's state at the time, with some instruments, books on mathematics, and the tables of De La Hire. The delegation did not bring any books elaborating the heliocentric world view, such as proposed by Newton, Kepler, or Copernicus, since these publications were prohibited by the Catholic Church.

After collecting data for nearly a decade, Jai Singh succeeded in obtaining new astronomical parameters. With these parameters, he prepared a set of astronomical tables called a *Zīj*. The *Zīj*, completed sometime between 1731 and 1732, was dedicated to the reigning monarch, Muḥammad Shāh and is, therefore, called *Zīj-i Muḥammad Shāhī*. *Zīj-i Muḥammad Shāhī* is a 400-page long traditional work of astronomy similar to the *Zij-i Sulṭānī* of Ulugh Beg. *Zīj-i Muḥammad Shāhī* may be considered Jai Singh's most important contribution to the astronomy of India. The *Zīj* remained a valuable resource for traditional astronomers of the country for nearly 150 years.

For the sake of rejuvenating astronomy in his country, Jai Singh expended a great deal of energy as well as his personal fortune, but he failed to initiate the new age of astronomy in India. He himself remained unaware of the Copernican revolution that had swept the intellectual circles of Europe. Lack of good communication systems, and a complex interaction of intellectual stagnation, religious taboos, theological beliefs, national rivalries, and the simple human failings of his associates share the blame for it. Jai Singh's scientific accomplishments were medieval in retrospect, but his scientific outlook was quite modern.

Jamu

Christine Tuschinsky

Jamu is the Indonesian and Malay term for indigenous pharmaceuticals made from fresh or dried medicinal herbs. These medicines are popular among the ethnic Malays in the whole Malayan Archipelago (Malaysia, Singapore, Brunei Darussalam, and Indonesia). It is assumed that *jamu* originates from the Javanese principal courts. On the other hand there are different local recipes and ways of preparation with an old tradition, which contribute to the idea of a common popular knowledge.

Jamu can be an infusion of herbs, a mixture of fresh, dried or dried and powdered medicinal plants, and even an extract of herbs. It can be made of a single plant, but mostly it is a composition of up to 40 different ones. Today *jamu* is sold in the form of powder, tablets, pills, tonics, and capsules for internal use; and in the form of ointments, oils, tonics, or compresses for external use. The powdered *jamu* are packed in individual portions, which are then sold in nearly every small shop across Indonesia. Today these *jamu* as well as pills and capsules are available in Malaysian and Singaporean supermarkets, too.

In the traditional way, *jamu* is produced at home. An experienced family member provides friends and relatives with the homemade version of the product. To supplement family income, female family members sell the surplus to neighbors or villagers. These "*jamu* women" are still a familiar sight in Indonesia, even in the big cities. As a kind of peddlar, the *jamu* woman wanders through villages or capital streets, offering the contents of her *jamu gendong* (*jamu* being carried on the back) to a regular clientele.

Indonesia was, and is, the trendsetter in the production, development, and marketing of *jamu*. At the beginning of the twentieth century her *jamu* production reached a turning point. Some innovative entrepreneurs began to produce homemade *jamu* for their sale, thereby founding a flourishing cottage industry. The profits which accrued in this fashion kicked off a process which led to the modern *jamu* industry, in which more than 350 factories are registered in Indonesia. Their product is exported to several countries, the largest consumers being Malaysia and Singapore. The industrialization of *jamu* manufacture had severe consequences. It altered the outer appearance of *jamu*, and demanded more and more modernizing and profitable sale strategies. It was necessary to change the image from an old fashioned herbal remedy to a proudly promoted "ancestral heritage," which fit better into the Western back-to-nature trend.

Jamu concentrates on aspects and interrelationships which Western medicine does not take as seriously. The *jamu* idea of medication is based on a broad conception of body, health, and sickness; the notion of care and therapy, for example, tend to be kept less separate. *Jamu* is more than a pharmaceutical in the Western sense; it is food supplement, prophylaxis, and specific remedy all at once. Keeping healthy also necessitates staying beautiful and attractive as long as possible. Cosmetics, general tonics, and, above all, aphrodisiacs are very popular, and have considerable stature in *jamu* medicine.

Culturally different world views and concepts of knowledge find their expression in all aspects of culture, including the "hardware" of medicine, the pharmaceuticals. If we characterize the Western world view roughly as individualistic, bound to linear thinking, the ideas of cause and effect and the explanation of isolated phenomena on a microlevel, the Malay world view can be seen as sociocentric, bound to the mutual dependency of microcosmos and macrocosmos, and to the maintenance of balance and harmony on all levels of existence.

Medicines reflect these different aspects. Western pharmaceuticals consist of molecular defined substances or mixtures of substances, which are considered to be active. Any function of inactive substances is denied. The number of ingredients tends to be kept low in order to avoid synergistic effects. In contrast *jamu* are preparations of dozens of entire plants, with all active, inactive, and unknown substances plus the fibrous material. *Jamu* is a whole cosmos of ingredients, in which each part is supposed to play its proper role. *Jamu* has to be taken regularly for some weeks or months, and helps, in a long run, to balance the state of health between the poles of hot and cold.

Jamu cannot be completely analyzed. Pharmacologists are able to screen only some of the active ingredients, not to mention those which are called *inactive*. Synergistic effects are a matter of course and are considered to be of special importance in the efficacy and safety of *jamu*. The discussion of synergism and risk reduction started in 1976, when the Indonesian scientist Sutrisno formulated his SEES (side effect eliminating/secondary effectiveness enhancing substance) theory which postulates fewer side effects and a well-balanced total efficacy of entire plant extracts. Western science considered the SEES theory not sufficiently proven. Much research has been carried out to prove that some of the active *jamu* ingredients have curative value. This is an attempt to translate a non-Western medical concept into a Western one, which soon reaches methodological limits.

These facts are not perceived as contradictions by the Malay – or, in a melting pot like Singapore also Indian and Chinese – clients. As a vivid element of Malay culture *jamu* is consumed in any form, in tiny villages and big capital cities, and plays a constant role in everyday health care.

Jayadeva

K. V. Sarma

Ācārya Jayadeva is an early Indian mathematician, known only through a long aphoristic (*Sūtra*) quotation in 20 verses from an unknown work of his. In this passage, Jayadeva sets out, step by step, an ingenious method for solving the indeterminate equation of the form $Nx^2 \pm C = y^2$. This quotation was extracted by Udayadivākara, an astronomer of Kerala, in his commentary called *Sundarī* on the *Laghu-bhāskārīya* of Bhāskara I (b. 629). Udayadivākara flourished about AD 1073. This means that Jayadeva lived before that date.

The above extract was made in the context of an astronomical problem involving two simultaneous equations (1) $7y^2 + 1 = z^2$ and (2) $8x + 1 = y^2$. Here, Udayadivākara states that the value of y in the first equation can be found by an ingenious method called *varga-prakṛti* (lit. "square-nature") enunciated by Ācārya Jayadeva, and the value of x in the second equation by the method of inversion.

The extract from Jayadeva forms an account of *varga-prakṛti* as he conceives it and solves problems through it. First he defines the term: "When (in an equation of the type $Ax^2 \pm C = y^2$) the square of an optional number is multiplied by a given number and then the product is increased or decreased by another number, and the result is in the nature of a square, such an equation is called *varga-prakṛti*." He then goes on to explain the technical terms which would be used in the course of his exposition, such as *Kaniṣṭha-mūlam* (lesser root), *jyeṣṭha-mūlam* (greater root), *kṣepa* (interpolator), *bhāvanā* (visualization), and its two forms, *samāsa-bhāvanā*, and *viśesa-bhāvanā* or *tulya-bhāvanā* and *atultya-bhāvanā*, all of which form the step by step processes for the solution of the indeterminate equation envisaged. Working through these processes is called the *cakravāla* (cyclic method) through which any number of solutions can be found. The actual method of solving the equation is given in the last five verses, toward the close of which Jayadeva quips, "Thus have we identified a very ingenious method for solving the problem which is as difficult as it is for a flea to fly against the wind." Jayadeva is perhaps justified in making such a comparison, for his cyclic method was set out later by other authors like Bhāskara II (b. 1114) and Nārāyaṇa (1356). The historian of mathematics Hermann Hankel has remarked: "It is above all praise; it is certainly the finest thing which was achieved in the theory of numbers before Lagrange."

Jia Xian

Ang Tian Se

Little is known of Jia Xian's life except that he served as a minor functionary during the reign of Emperor Renzong of Northern Song dynasty in the first half of the eleventh century. He learnt mathematics from Chu Yan, a famous astronomer and mathematician (fl. AD 1022–1054). Jia Xian was said to have written two books, *Huangdi Jiuzhang Suanjing Xicao* (Detailed Workings of the Nine Chapters on Mathematical Art), and *Suanfa Xuegu Ji* (A Collection of Ancient Mathematical Rules). While the latter was irretrievably lost, the former was largely found in Yang Hui's *Xiangjie Jiuzhang Suanfa* (A Detailed Analysis of the Mathematical Rules in the Nine Chapters) of AD 1261 preserved in Ms. form in chapter 16,344 of the *Yonglo Dadian* encyclopedia compiled by Xie Jin in 1407 during the Ming dynasty. In his preface, Yang Hui explicitly stated that his text was an attempt to expound and preserve the works of his predecessors, notably those of Jia Xian.

Jia Xian's main contribution to mathematics lies in his innovative method for the solution of numerical equations of higher degrees. The processes for square and cube root extractions began with *Jiuzhang Suanshu* (Nine Chapters on the Mathematical Art) at the beginning of the Christian era, and continued to appear in all later mathematical books without many improvements. It was Jia Xian who came out with a method called *Zengchang Kaifang* (Method of Multiplying and Adding for Root Extractions) which could be extended to the solution of numerical higher equations for approximate values of roots. This method is similar to that developed by Ruffini (1765–1822) and Horner (1786–1837) in 1802 and 1819, respectively.

Accompanying the method was an array of binomial coefficients up to the sixth power tabulated in the form of a triangle similar to that by Blaise Pascal (1623–1662) in 1665, now commonly known as the Pascal Triangle. This triangle of binomial coefficients was subsequently copied and expanded by Zhu Shijie in the thirteenth century. Thus, Jia Xian's mathematical knowledge to some extent laid the foundation for the rapid development of mathematics during the twelfth and thirteenth centuries.

Jiuzhang Suanshu

Karine Chemla

The Nine Chapters on Mathematical Procedures (*Jiuzhang suanshu* 九章算術, hereafter abbreviated to *The Nine Chapters*) is the oldest Chinese book devoted to mathematics that has been handed down through a written tradition. Mainly composed of problems, answers to them, and algorithms solving them, the book was probably compiled in the first century after the Common Era. The earliest piece of evidence bearing witness to its existence is the mention of its title in the inscriptions borne by a standard measuring vessel enacted by the Chamberlain for the National Treasury (*Dasinong* 大司農) in 179.

The main reason why *The Nine Chapters* survived may well be that, soon after its completion, it became a "Canon" (*jing* 經). This is the term which the first commentator whose comments on it came down to us, Liu Hui 劉徽, uses for it. Consequently, several commentaries were composed on it, two of which were selected by the tradition to be handed down with the Canon: Liu Hui's commentary, completed in 263, and the commentary composed by a group under the supervision of Li Chunfeng 李淳風, and presented to the throne in 656. In fact, there is no surviving edition of *The Nine Chapters* that does not contain these commentaries. Liu Hui's and Li Chunfeng's commentaries mention the works of other scholars: Zhang Heng 張衡 (78–142), Zu Chongzhi 祖沖之 (429–500), and his son Zu Geng (or Zu Gengzhi), attesting to a tradition of research on the topics dealt with in *The Nine Chapters* that historical evidence confirms. The Song dynasty testified to a keen interest in *The Nine Chapters*. The Department of the Imperial Library printed it in 1084, the reprint of this edition by Bao Huanzhi 鮑澣之 in 1213 being today the earliest extant edition. Moreover, new commentaries were composed, such as: Jia Xian 賈憲's *Detailed Procedures of Huangdi's Canon of The Nine Chapters on Mathematics* (*Huangdi jiuzhang suanjing xicao* 黃帝九章算法細草), in the first half of the eleventh century, and Yang Hui 楊輝's *Detailed Explanations of The Nine Chapters on Mathematical Methods* (*Xiangjie jiuzhang suanfa* 詳解九章算法) in 1261.

During the Song dynasty, the status of *The Nine Chapters* as a "Canon" was regularly and forcefully emphasized. Hence, in one of his prefaces, Yang Hui, quoting the preface composed by Rong Qi when he had Jia Xian's commentary printed in 1148, states:

> When the government instituted the examinations in mathematics to select officials, they chose *The Nine Chapters* to be the most important of the mathematical Canons, since, indeed, it is like the six Canons of the Confucians, the (*Canon of*) *Difficulties* and the (*Grand*) *Simplicity* of the medical schools, the *Book of Master Sun* of military art!

The matching of the book with the Confucian Canons expresses the immense value bestowed on it, echoing with the fact that it was then believed to have been written by some mythical Emperor or some Sage of Antiquity. In any case, all the practitioners of mathematics of the Song–Yuan period whose writings came down to us, Qin Jiushao, Li Ye (or Li Zhi), Yang Hui, and Zhu Shijie, drew inspiration from it, taking this Canon as a key reference work. This testifies to the significance of the book for the mathematical traditions that developed in China from the beginning of the Common Era up until the golden age of the Song–Yuan period and beyond.

The nine chapters of the Canon embody a traditional organization of mathematical knowledge in ancient China in “nine parts of mathematics (*jiushu* 九數).” According to the *Rites of Zhou* (*Zhouli* 周禮), the education of the children of the high dignitaries included the teaching of six arts, the last of which consisted in “the nine parts of mathematics” or “the nine procedures.” Quoting on this point the Chamberlain for the National Treasury (*Dasinong* 大司農) Zheng Zhong 鄭眾 (?–83), the scholar and commentator Zheng Xuan 鄭玄 (127–200) interpreted these as branches of mathematics that, for the main part, gave their names, and hence corresponded, to the various sections of *The Nine Chapters*. Probably the process of “recovery” of the damaged Canon included the identification of what the *Rites of Zhou* meant by the “nine parts of mathematics” or the “nine procedures.” Let us review briefly how *The Nine Chapters* provides an interpretation of this organization of mathematics.

Chapter 1: “Rectangular field” (*fangtian* 方田)

This chapter describes algorithms to carry out the basic computations on fractions, on the basis of numerators and denominators. It also contains algorithms to compute the areas of the fundamental figures or “fields”: the rectangle, the triangle, the circle, the annulus, the spherical sector, etc.

Chapter 2: “Millet and husked grains” (*sumi* 粟米)

This chapter is devoted to the rule of three and some of its applications. There, the rule is mainly used for computing equivalence between grains, according to official rates enacted by the National Treasury and relating to the payment of taxes in kind.

Chapter 3: “Parts weighted according to degree” (*cuifen* 衰分)

The algorithm for dividing a given whole into unequal parts defined by given coefficients constitutes the main topic of this section. The main field of reference for the algorithm consists in sharing gratification between officials having different status in the bureaucracy.

Chapter 4: “Small length” (*shaoguang* 少廣)

The chapter gathers together various sorts of “division”: divisions with fractionary numbers and root extractions, which were conceived of as divisions: square root and cube root extraction, as well as “circular” and “spherical” root extraction. In it, irrational numbers of the type “square root of 2” are introduced.

Chapter 5: “Discussing works” (*shanggong* 商功)

Mainly devoted to the organization of civil works, this chapter describes algorithms to compute the volume of fundamental solids: the parallelepiped and the cylinder, the trapezoidal prism, the pyramid and the truncated pyramid with squared basis, the tetrahedron, the cone and the truncated cone, etc.

Chapter 6: “Paying taxes in a fair way according to transportation” (*junshu* 均輸)

The title of the chapter refers to the topic of the first problems, devoted to a fair distribution of taxes or corvée (labor exacted by a local authority for little or no pay or instead of taxes) among various administrative units. The various problems gathered usually require combining rules of three or unequal sharing.

Chapter 7: “Excess and deficit” (*ying buzu* 盈不足)

The chapter is devoted to the rules that in the Latin West were to be called of false double position.

Chapter 8: “Measures in square” (*fangcheng* 方程)

An algorithm for solving the systems of n linear equations with n unknowns is described and progressively extended throughout the chapter. It is equivalent to what is today called the “Gauss elimination method.” In order to carry out this algorithm in all cases or to use it with full generality, positive, negative, and zero coefficients are introduced.

Chapter 9: “Base and height” (*gougu* 句股)

These are the two technical terms for designating the sides of a right-angled triangle, the treatment of which is the topic of this section. An algorithm corresponding to the so-called “Pythagorean theorem” opens the chapter. The following problems lead to solving some of the fundamental problems linked to the right-angled theorem. In this chapter, one of the problems is solved by using a quadratic equation.

The Nine Chapters displays mathematical knowledge in the form of algorithms. The book attests to specific ways of carrying out research on algorithms and manifests some of the theoretical trends guiding this research. In particular, the algorithms contained in *The Nine Chapters* are general. This feature relates to the fact that generality was one of the main theoretical values prized by the practitioners of mathematics in ancient China. This key fact accounts for properties that algorithms contained in *The Nine Chapters* regularly exhibit. They make use of assignment of variables, conditionals, and iterations. Furthermore, with the help of these techniques, the algorithms of the Canon can cover distinct cases that a given problem may present. They can also integrate distinct procedures and hence allow solving various types of problems. All these features contribute to shaping algorithms that are as general as possible. Such is the Canon that, in mathematics like in any other field of inquiry, commentators set out to expound.

Two kinds of evidence shed light on the historical process that led to its composition. As a canon, *The Nine Chapters* is not ascribed to any "author." Liu Hui's preface to his commentary mentions two scholars who contributed to its "edition." According to him, the Canon took shape in high antiquity and was damaged by the process of transmission. Later on, Zhang Cang 張蒼 (ca. 250–152 BCE) and Geng Shouchang 耿壽昌 (fl. 50 BCE) successively strove to restore the book, as it had been composed in antiquity. This indicates that, early enough, the process that produced *The Nine Chapters* was understood to have extended over centuries, and probably Liu Hui thought he was carrying it out further. In addition, a mathematical book was recently unearthed from a tomb sealed around 186 BCE: the *Book of Mathematical Procedures* (*Suanshushu* 算數書). This piece of evidence is extremely important for two reasons. On the one hand, it provides us with the first known mathematical writing preceding the compilation of *The Nine Chapters*. On the other hand, it is a book that was not handed down by the written tradition, but arrives to us in exactly the shape it had at the beginning of the second century before the Common Era. It shares many algorithms with *The Nine Chapters*, which indicates that the Canon had much in common with documents of that type. Furthermore, by comparison, it appears that the Canon contains algorithms obtained from other algorithms attested to in the *Book of Mathematical Procedures* by abstraction. What is even more interesting is that, when Liu Hui comments on the abstract algorithms of the Canon, he interprets them concretely along the lines of algorithms found in the *Book of Mathematical Procedures*. This piece of evidence thus also casts light on the process of composition of the commentaries.

The earliest exegete whose commentary was handed down, Liu Hui, appears today as being the most important of them all. However, almost nothing is known concerning his biography, except that he composed a commentary on *The Nine Chapters* as well as a small treatise, originally conceived as restoring a missing part of the Canon and devoted to geometrical methods of surveying: the *Mathematical Canon of the Sea Island* (*Haidao suanjing* 海島算經).

The significance of Liu Hui's commentary for the history of mathematics cannot be underestimated.

First, in contrast to *The Nine Chapters*, which consists mainly of problems and algorithms solving them, the exegetes systematically established that the algorithms provided by the Canon were correct. This implies that, in contrast to Euclid's *Elements*, the proofs of which establish that theorems are true, the commentaries' goal is to prove the correctness of algorithms. Moreover, to do so, they seem to follow stable patterns of reasoning, which indicates that proofs were conducted according to procedures that were normalized. Liu Hui's commentary hence bears witness to the earliest known practice of mathematical proof in China. How should this branch of the history of mathematical proof be integrated in a world history of proof? As far as I know, this question has not yet been addressed.

Furthermore, Liu Hui's commentary provides evidence showing how he read *The Nine Chapters*. On the one hand, his testimony sheds light on actual mathematical practices in ancient China. On the other hand, it discloses his expectations with respect to, and his approach of, a book of the kind of a Canon. In both respects, the evidence he provides is essential for recovering the details of mathematical activity and intellectual pursuit in ancient China.

Last, but not least, Liu Hui quotes several philosophical texts, thereby pointing to a relationship between mathematics and philosophy in ancient China. In addition, he stresses, and comments on, theoretical aspects of the mathematics he is dealing with. He thereby gives essential clues regarding the theoretical dimensions of mathematical activity as it developed in China.

Kamalākara

K. V. Sarma

Kamalākara was one of the most erudite and forward-looking Indian astronomers who flourished in Varanasi during the seventeenth century. Belonging to Maharashtrian stock, and born in about 1610, Kamalākara came from a long unbroken line of astronomers, originally settled at the village of Godā on the northern banks of the river Godāvarī. Towards AD 1500, the family migrated to Varanasi and came to be regarded as reputed astronomers and astrologers. Kamalākara studied traditional Hindu astronomy under his elder brother Divākara, but extended the range of his studies to Islamic astronomy, particularly to the school of Ulugh Beg of Samarkand. He also studied Greek astronomy in Arabic and Persian translations, particularly with reference to the elements of physics from Aristotle, geometry from Euclid, and astronomy from Ptolemy. He wrote both original treatises and commentaries on his own works and those of others.

Kamalākara's most important work is the *Siddhānta-Tattvaviveka*, written in AD 1658. The work which is divided into 15 chapters and contains over 3,000 verses, faithfully follows the *Sūryasiddhānta* in the matter of parameters, general theories, and astronomical computation. However, in certain matters Kamalākara made original contributions and offered new ideas. Though he accepted the planetary parameters of *Sūryasiddhānta*, he agreed with Ptolemaic notions in the matter of the planetary system. He presented geometrical optics, and was perhaps the only traditional author to do so. He described the quadrant and its application. He proposed a new Prime Meridian, which is the longitude passing through an imaginary city called Khalādātta, and provided a table of latitudes and longitudes for 20 important cities, in and outside India, on this basis. Kamalākara was an ardent advocate of the precession of the equinoxes and argued that the pole star also does not remain fixed, on account of precession. Kamalākara wrote two other works related to the *Siddhānta-Tattvaviveka,* one a regular commentary on the work, called *Tattvavivekodāharaṇa*, and the other a supplement to that work, called *Śeṣāvasanā*, in which he supplied elucidations and new material for a proper understanding of his main work. He held the *Sūryasiddhānta* in great esteem and also wrote a commentary on that work.

Kamalākara was a critic of Bhāskara and his *Siddhāntaśiromaṇi*, and an arch-rival of Munīśvara, a close follower of Bhāskara. This rivalry erupted into bitter critiques on the astronomical front. Thus Ranganātha, younger brother of Kamalākara, wrote, at the insistence of the latter, a critique on Munīśvara's *Bhaṅgī* method (winding method) of true planets, entitled *Bhaṅgī-vibhaṅgī* (Defacement of the *Bhaṅgi*), to which Munīśvara replied with a *Khaṅḍana* (Counter). Munīśvara attacked the theory of precession advocated by Kamalākara, and Ranganātha refuted the criticisms of his brother in his *Loha-gola-khaṇḍana* (Counter to the Iron Sphere). That in turn was refuted by Munīśvara's cousin Gadādhara in his *Loha-gola-samarthana* (Justification of the Iron Sphere). These kinds of astronomical and intellectual battles were typical of the philosophical and religious disputes which were common in ancient India.

Kerala School of Astronomy and Mathematics

M. S. Sriram

After Bhāskara II (b. AD 1114), the most significant contributions to mathematics and astronomy in India came from Kerala, in the southwestern part of India. Kerala has had a continuous tradition of astronomy and mathematics from much earlier times. Sarma has listed nearly 750 independent works on astronomy, astrology and mathematics including minor works by 110 authors in the Kerala tradition.

Vararuci (date unconfirmed), who is credited with the authorship of 248 *Candravākyas* (sentences for computation of the moon's longitude) by the manuscript tradition, is considered to be the father figure in the astronomical tradition of Kerala. *Āryabhaṭīya* (ca. AD 499) of Āryabhaṭa which set the tone for all further work on mathematical astronomy in India, appears to have become popular in Kerala soon after its composition. In fact, out of the 20 or so available commentaries on *Āryabhaṭīya*, as many as 12 are from Kerala. The astronomical parameters in *Āryabhaṭīya* were revised by a group of astronomers who had gathered in the religio-educational centre of Tirunavay in northern Kerala in AD 683–684. Haridatta in his *Grahacāranibandhana* enunciated the revised system called *Parahita-gaṇita*. Many later works refer to the *Parahita* system.

Laghubhāskarīya and *Mahābhāskarīya* of Bhāskara I, which expounded the Āryabhaṭan school in detail, were also popular in Kerala. Govindasvāmin (AD 800–850) wrote an elaborate commentary on *Mahābhāskarīya* and his student Śaṅkaranārāyaṇa (AD 825–900) wrote one on *Laghubhāskarīya.* Udayadivākara (eleventh century), who wrote a detailed commentary titled *Sundarī* on *Laghubhāskarīya,* also probably hailed from Kerala. This work contains a method for solving quadratic indeterminate equations or *Varga – prakṛti* and ascribes it to Jayadeva. It is in fact the same as the famous *Cakravāla* algorithm, expounded in detail later by Bhāskara II in his *Bījagaṇita.* Suryadeva Yajvan (AD 1191–1250) wrote detailed commentaries on both *Āryabhaṭīya* and *Laghumānasa* of Manjulācarya.

The Kerala tradition entered a new phase with Mādhava of Saṅgamagrāma (AD 1340–1425). His *Venvāroha* and *Sphuṭacandrāpti* both contain an efficient computational procedure to calculate the true longitude of the Moon every 36 min. Those books and *Agaṇitagrahacāra* are conceptually not major works. However all the later astronomer–mathematicians from Kerala attribute the path-breaking results in the infinite series for the inverse-tangent, sine and cosine functions and many innovations in astronomical calculations to him. He is also hailed as *Golavid* (master of Spherics). Parameśvara of Vatasseri (AD 1360–1455), a student of Mādhava, was a prolific writer, authoring about 30 works. Emphasising the need for revising the planetary parameters through observations, he thoroughly revised the *Parahita* system and introduced the *Dṛggaṇita* system. Apart from *Dṛggaṇita,* the other important works of Parameśvara are *Goladīpikā* in three parts, *Bhaṭadīpika*, a commentary on *Āryabhaṭīya*, *Mahābhāskarīyabhasya* and *Siddhānta-dīpikā*, a super-commentary on Govindaswamin's *Mahābhāskarīyabhāṣya*, and *Grahaṇamaṇdana* on eclipses. He was one of the astronomers to discuss in detail the geometrical model of planetary motion implied in the conventional calculational procedures in Indian astronomy in his *Siddhāntadīpikā* and *Goladīpikā.*

No full-fledged work of Dāmodara, son and disciple of Parameśvara is known, but he is quoted at several places by his famous pupil, Nīlakaṇṭha Somayāji or Somasutvan (AD 1445–1545) of Tṛkkaṇṭiyur. Nīlakaṇṭha's *Tantrasaṅgraha* ranks along with *Āryabhaṭīya* of Āryabhaṭa and *Siddhāntaśiromaṇi* of Bhākaracārya as one of the major works which significantly influenced all further work on astronomy in India. In *Tantrasaṅgraha,* Nīlakaṇṭha introduced a major revision of the traditional Indian planetary model. There are also important innovations in mathematical techniques especially related to the series expansion of the trigonometric functions and systematic and exact treatment of spherical astronomy problems.

In addition to *Tantrasaṅgraha*, Nīlakaṇṭha composed many other works. *Āryabhaṭīyabhāṣya,* composed late in his life, is perhaps the most elaborate commentary on *Āryabhaṭīya.* He himself calls it a *Mahābhāṣya* (from *mahā*, great and *bhāṣya*, commentary), which is amply justified considering the wealth of information in it. Apart from the detailed explanation of mathematical results and procedures, it discuses the geometrical model of planetary motion, eclipses, and even some "physical" concepts like the planets' being illuminated by the Sun. Some of his other major works are *Golasāra* on spherical astronomy, *Siddhānta-darpaṇa,* in which he presents the planetary parameters as verified through his own observations, *Candracchāyā-gaṇita* on 'shadow' problems, and *Grahaṇanirṇaya* on lunar and solar eclipses. *Jyotīrmīmāmsā* of Nīlakaṇṭha has a unique place in the history of Indian astronomy, as it is the only work which focuses on epistemological issues concerning the science of astronomy and mathematics. It falsifies the claim of many scholars that Indian astronomy, in contrast to the Greek tradition, did not have a scientific methodology worth the name. It strongly emphasises the role of observations and experimentation in revising astronomical parameters. Sundararāja, a contemporary of Nīlakaṇṭha hailing from Tamilnadu, sought clarifications on many topics in astronomy from Nīlakaṇṭha, the answers to which formed the work *Sundararāja-praśnottara,* as stated by Sundarāja himself in his *Vākyakaraṇa*. Clearly, it is a work different in nature from texts and commentaries. The manuscripts pertaining to this work have yet to be traced.

Jyeśṭhadeva (ca. AD 1500–1610) of the *Parakroda* or *Paroṇṇoṭṭu* family, was also initially a pupil of Dāmodara and received instructions from Nīlakaṇṭha Somayāji later. In his *Gaṇita-Yuktibhāṣā* (Rationale of Mathematics and Astronomy), popularly known as *Yuktibhāṣā* composed around AD 1530, we see an elaborate and systematic exposition of the rationale of mathematics in Part I and of astronomy in Part II. Though it claims to explain the contents of *Tantrasaṅgraha* and provide the rationale for the calculational procedures in it, it is really an independent work (especially part I). It is a unique work in Indian astronomy/mathematics for two reasons (1) it is exclusively devoted to proofs and demonstrations, including the infinite series for π and trigonometric functions, and explanations for all astronomical calculational procedures current at that time and (2) it is written in Malayalam, the local language of Kerala. Perhaps this is one of the reasons for the title of the book, *Yuktibhāṣā* (the language which is spoken is called *Bhāṣā*). A Sanskrit version of the text is also available, but it is clearly a rough translation into Sanskrit of the Malayalam original. Śaṅkara Vārier of Trikkutaveli (AD 1500–1560) was a disciple of Nīlakaṇṭha Somayāji, and as he himself stated, was also deeply influenced by Jyeśṭhadeva. He is the author of two commentaries on *Tantrasaṅgraha*, namely *Laghuvivritti* (in prose), and a far more elaborate *Yuktidīpikā* (in verse). He is also the author of a major portion of the commentary on *Līlāvatī* called *Kriyākramakarī* which was completed by Mahisamangalam Nārāyaṇa. *Yuktidīpikā* and *Kriyākramakarī* are also devoted to proofs and demonstrations, and there are similarities between the treatment of various topics in them and in *Yuktibhāṣā*.

Citrabhānu (AD 1475–1550), the author of *Karaṇāmrta* was also a disciple of Nīlakaṇṭha, whereas Acyuta Piśaraṭi (AD 1550–1621) of Trkkaṇṭiyūr was a student of Jyeśṭhadeva. It was Acyuta who discussed the "Reduction to ecliptic" in detail in his *Sphutanirṇayatantra* and *Rāśigolasphutāniti.* Putumana Somayāji's (AD 1660–1740) *Karaṇapaddhati* provides rationale for astronomical algorithms. *Sadratnamālā* of Prince Śaṅkara Varman (AD 1800–1838) is a compendium of the Kerala school of mathematics and astronomy. The tradition continued up to modern times with works incorporating some of the results of modern positional astronomy.

Apart from these major works, there are several short texts which interpret and discuss specific formulae and procedures associated with specific topics. These texts have the words *Yukti* or *nyāya* (rationale) attached to their titles. Examples are *Grahaṇa-nyāya-dīpikā* on the computation of eclipses by Parameśvara and *Gaṇita-yuktayaḥ* by an anonymous author. There are also a large number of works devoted to astrology. Many of them are in the Kerala tradition but by non-Keralite authors.

There is great emphasis on observation in the Kerala school. In his *Siddhāntadīpikā,* Parameśvara refers to the numerous eclipses observed by him over a long period. In his *Āryabhaṭīyabhāṣya,* Nîlakaṇṭha observes that Parameśvara revised the planetary parameters in his *Dṛggaṇita* after observing eclipses and planetary occultations for 55 years. In his *Jyotirmīmāmsā* he argues:

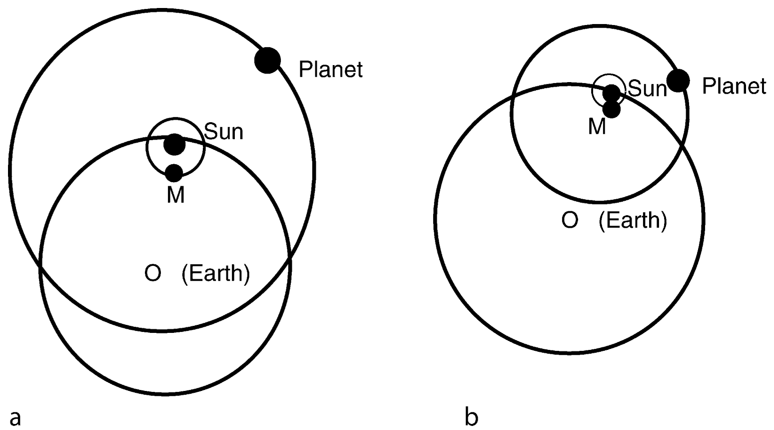
> One has to realise that the five *siddhāntas* had been correct at a particular time. Therefore, one should search for a *siddhānta* that does not show discord with actual observations (at the present time). Such accordance with observation has to be ascertained by (astronomical) observers during times of eclipses etc. When *siddhāntas* show discord, that is, when an earlier *siddhānta* is in discord, observations should be made of revolutions etc. (which would give results in accord with actual observations) and a new *siddhānta* enunciated.

K

Major Contributions

Astronomy

In his *Tantrasaṅgraha*, Nīlakaṇṭha introduced a major revision of the traditional Indian planetary model. He arrived at a unified theory of planetary latitudes and a better formulation of the equation of centre for interior planets (Mercury and Venus) than was available, either in the earlier Indian works, or in the Islamic or European traditions of astronomy until the work of Kepler. In his other works *Golasāra, Siddhāntadarpaṇa* and *Āryabhaṭīya bhāṣya*, Nīlakaṇṭha outlined the geometrical picture of planetary motion that follows from his model. According to this picture, the five planets Mercury, Venus, Mars, Jupiter and Saturn move in eccentric orbits inclined to the ecliptic around the mean Sun, which in turn goes around the earth. This is similar to the model of Tycho Brahe (AD 1583). Nīlakaṇṭha's



Kerala School of Astronomy and Mathematics. Fig. 1 Nīlakaṇṭha's geometrical model of planetary motion for (a) an exterior planet, and (b) an interior planet. In each case, *M*, which is in the direction of the aphelion (the point in the orbit of a planet, comet or other celestial body that is farthest from the Sun), is the centre of the eccentric orbit.

"heliocentric" planetary model is depicted in the accompanying figure (Fig. 1).

The discussion on physical distances of planets in the last chapter of *Tantrasaṅgraha* indicates that Nīlakaṇṭha meant it to be a physical model. Parameśvara anticipated many of the ideas of Nīlakaṇṭha regarding the geometrical picture of planetary motion in some of his works. The model is discussed in detail in *Yuktibhāṣā* also.

In *Tantrasaṅgraha,* we have a discussion of the instantaneous velocities of planets, including the correct expression for the derivative of the inverse – sine function. There is a systematic treatment of spherical astronomy problems with exact spherical trigonometry formulae and with applications to the determination of time from the shadow, *Lagna* (orient ecliptic point), eclipses, exact angular separation between the centres of the solar and lunar disks, and elevation of lunar cusps. There is emphasis on methods rather than mere computational algorithms, in contrast with the other *Tantra* texts in Indian astronomy. All the spherical astronomy results are proved in detail in *Yuktibhāṣā*.

The Moon moves in an orbit inclined to the ecliptic, and as noted earlier, Acyuta Piśaraṭi provided the expression for the correction to the orbital longitude of the Moon to reduce it to the ecliptic. Interestingly, Tycho Brahe (AD 1546–1601) who discussed the "reduction to the ecliptic" for the first time in the European tradition, was a contemporary of Acyuta.

Mathematics

The crowning achievements of the Kerala school in mathematics are the infinite series expansion of the inverse-tangent function (*Yuktibhāṣā, Yuktidīpikā* and *Kniyākramakarī*), and the sine and cosine functions (*Yuktibhāṣā, Yuktidīpikā*). In modern terminology:

$$\mathrm{Tan}^{-1}\, x = x - \frac{x^3}{3} + \frac{x^5}{5} - + \cdots,$$

$$\mathrm{Sin}\,\theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - + \cdots,$$

$$\mathrm{Cos}\,\theta = 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - + \cdots.$$

As noted earlier, these are all ascribed to Mādhava. Geometrical proofs for the above are to be found in *Yuktibhāṣā*. When $x = 1$, the inverse tangent series reduces to

$$\frac{C}{4D} = \frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \cdots,$$

where C and D are the circumference and diameter of a circle.

Earlier, Nīlakaṇṭha had noted the irrational character of π in his *Āryabhaṭīya bhāṣya.*

The above series for π is slowly convergent. A systematic procedure to calculate π with a finite number of terms and a suitable "remainder" or "correction" term is discussed in *Yuktibhāṣā* with the final result:

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \cdots + (-1)^{n-1}\frac{1}{2n-1} + (-1)^n \frac{n^2+1}{(4n^3+5n)}.$$

When $n = 50$, this leads to a value of π correct to 11 decimal places. In *Sadratnamālā* (AD 1823) of Śaṅkara Varma, the value of π is given as 3.14159265358979324, which is correct to 17 decimal places. This value was probably obtained using the same procedure, with the correction term evaluated to a higher degree of accuracy.

It is possible to obtain a fast convergent series for π by incorporating the correction terms from the beginning itself. Two of the fast convergent series for π mentioned in *Yuktibhāṣā* in this context are

$$\frac{\pi}{16} = \frac{1}{1^5 + 4.1} - \frac{1}{3^5 + 4.3} + \frac{1}{5^5 + 4.5} - \frac{1}{7^5 + 4.7} + \cdots,$$

$$\frac{\pi}{4} = \frac{3}{4} + \frac{1}{3^3 - 3} - \frac{1}{5^3 - 5} + \frac{1}{7^3 - 7} - \cdots.$$

Use of the sine-series to compute the sine of an arbitrary angle to a high degree of accuracy with the aid of simple mnemonics is found in *Yuktdīpikā.*

The differential of the sine (cosine) function is proportional to the cosine (sine) function. These differentials are used with confidence in various applications to problems in astronomy in *Tantrasaṅgraha* and *Yuktibhāṣā.* The correct expression for the differential of the ratio of two functions involving sine/cosine functions is given in Acyuta's *Sphutanirṇayatantra.* Integration procedures to calculate the area and volume of a sphere are also given in *Yuktibhāṣā*. The area and circumradius of a cyclic quadrilateral in terms of the sides are some of the other topics discussed in *Yuktibhāṣā*.

Another characteristic feature of Kerala mathematics is the geometrical demonstration of many algebraic and arithmetical results. Multiplication, division, squaring, etc. are all illustrated geometrically in *Yuktibhāṣā.* An advanced example is the geometrical proof of

$$1^3 + 2^3 + \cdots + n^3 = \frac{n^2(n+1)^2}{4}$$

in Nilakaṇṭha's *Āryabhaṭīyabhāṣya*.

Kitora Burial Mound

Simon Potter

Inside the Kitora Burial Mound at Asuka, Nara prefecture, in Japan is a tomb that dates to ca. AD 700 and has a celestial map and murals of cosmological significance. Both the map and the murals bear evidence of scientific and artistic diffusion from China to Japan via the Korean peninsula, but the map has the added significance of being the oldest extant celestial map that is currently known to be scientific in spirit and, more or less, complete. Since research on the map and murals is still in progress and might yield changes in details, readers are directed to the asterisked websites in the references for photographs, taken from small cameras which were inserted into the tomb, and related illustrations.

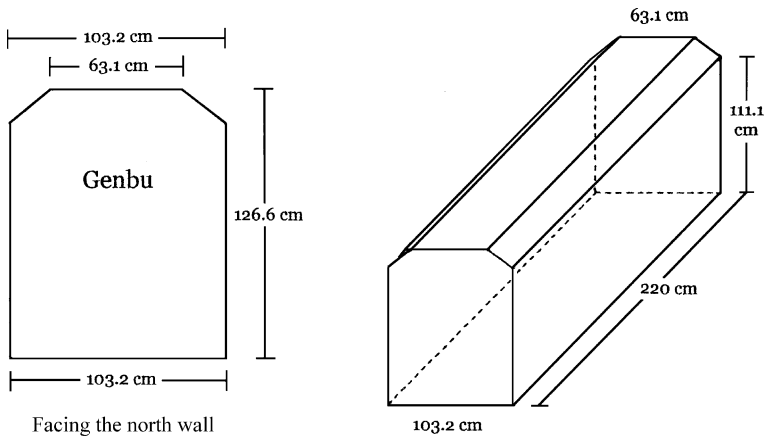
The Mound and the Tomb

Kitora's date of ca. 700 makes it a rather late burial mound since most of those in Japan were constructed during the fourth, fifth, and sixth centuries AD. Although it had been replaced by nearby Fujiwara in 694 (until 710), Asuka had served as the capital city throughout the seventh century, and Kitora seems to have been built in the aftermath of a period of significant Korean influence on higher learning and its applications in Japan. It is not yet clear who was buried in the Kitora tomb, but it might reasonably be assumed that he or she was from a family of importance during or toward the end of Asuka's primacy.

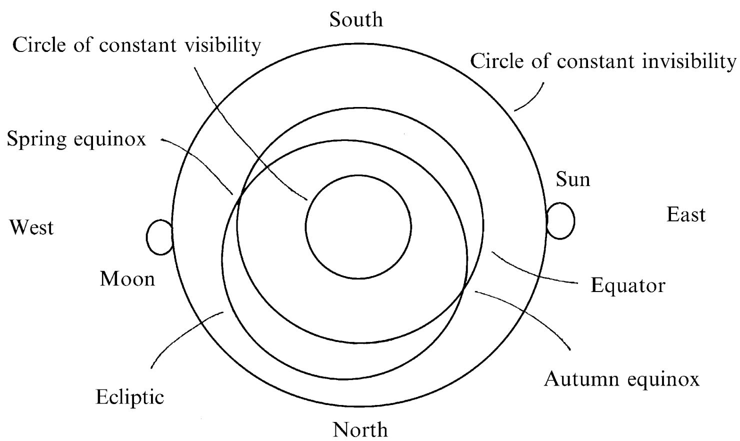
The burial mound stands 3-m high, is conical in shape, and archeologically is classified as a circular mound with its diameter at the base being 14 m. Inside it is an essentially rectangular stone tomb that measures approximately 220 × 103.2 × 126.6 cm, with the ceiling disrupting the geometry by having a centered flat part of 63.1-cm width that is flanked on either side by small slopes that make the walls along the length of the tomb stand at 111.1-cm high (Fig. 1). Other than the celestial map and murals which are discussed subsequently, the chamber is devoid of any artifacts and apparently was raided centuries ago.

The Celestial Map

Volume 2, Book 2 (1994) of *The History of Cartography* series demonstrates that East Asia has a rich heritage in celestial cartography, and the foundations for this regional or "Chinese" tradition were laid centuries before Kitora was constructed. Chinese astronomy involved the likes of observing celestial phenomena, compiling catalogs of stars, and making diagrams of the night sky, all of which contributed to improvements in scientific knowledge that was applied in such fields as calendar-making, government, and prognostication. Important cartographic features included the celestial equator, the plane of the ecliptic, the line of constant visibility (within which were the circumpolar stars, i.e., those which could always be seen), the line of constant invisibility (beyond which no stars could ever be seen), the 28 lunar lodges that tracked the path of the moon through its monthly cycle, and other constellations which were not directly associated with the moon. Although the earliest celestial maps cannot be tracked down, it is known that astronomy and other sciences such as medicine spread to the Korean peninsula and, from there during a period of peninsular instability from the mid-sixth century, to the western part of



Kitora Burial Mound. Fig. 1 The dimensions of the chamber containing the star map and murals inside the Kitora Burial Mound (drawing by the author).



Kitora Burial Mound. Fig. 2 The main circles of the Kitora star map (drawing by the author).

the Japanese archipelago. The route of diffusion was southward from the northern kingdom of Koguryŏ to Paekche, the weakest of the three independent Korean kingdoms, which transmitted knowledge to Japan through specialists and books in a time of political trouble. This background is useful for establishing an intellectual premise to argue that the celestial map inside Kitora was not a product of independent innovation in Japan, something which may also be said of its murals as well.

The Kitora map includes the four circles mentioned above as well as constellations which may be traced to China. Both the circles and the stars were formed by chiseling into the stone, with the grooves of the circles having been filled with cinnabar and the holes for the stars evidently with gold leaf, and the disposition of the circles and stars suggests that an azimuthal or zenithal equidistant projection was employed. The diameters of the three concentric circles have been estimated from photographs to be 18 cm (constant visibility), 42.5 cm (equator), and 64 cm (constant invisibility), while the offset ecliptic is also about 42.5 cm. Outside the western and eastern edges of the circle of constant invisibility, but just touching it, are, respectively, an orb for the moon and another for the sun (Fig. 2).

Two of the circles have significant errors, both of which might be explained by the circumstances faced by the craftsmen. One is that the circle of constant invisibility is smaller than it ought to be (about 67 cm) based on the radii of the circle of constant visibility and the equator, and this probably was due to an attempt to fit all of the map within the 63.1 cm, flat part of the ceiling since only a part of the outer circle and the entire lunar and solar orbs are on the slanting parts. The ecliptic has two errors, one being that it is circular rather than an oblate circle slightly larger than the equator as it should be on the zenithal equidistant projection (and therefore does not correctly display the equinoxes), and the other being that it is offset toward the northwest rather than toward the northeast. Whereas the first is most likely attributable to a drawing compass having been used, the latter could be adduced to the workmen having confused the cardinal directions while transferring the model diagram to the ceiling.

If the circle of constant invisibility had been drawn in correct proportion to the other concentric circles, it would be possible to derive a reasonably accurate estimate for the terrestrial latitude of observation of the sky shown in the Kitora map. Despite this and other problems regarding the placement of the stars, a less reliable estimate based on the radii of the circle of constant visibility and the equator was calculated to be about 38°24′ north, which might be simplified to between 38° and 39°. For the Japanese archipelago, these latitudes lie in central Tōhoku and suggest that the Kitora map shows the sky as it might have been viewed from present-day Yamagata and Miyagi prefectures, a frontier region of Japanese rural settlement around 1,300 years ago. For comparison, Asuka itself lies at 34°30′ north, yielding a difference of about 4° or 450 km in latitude.

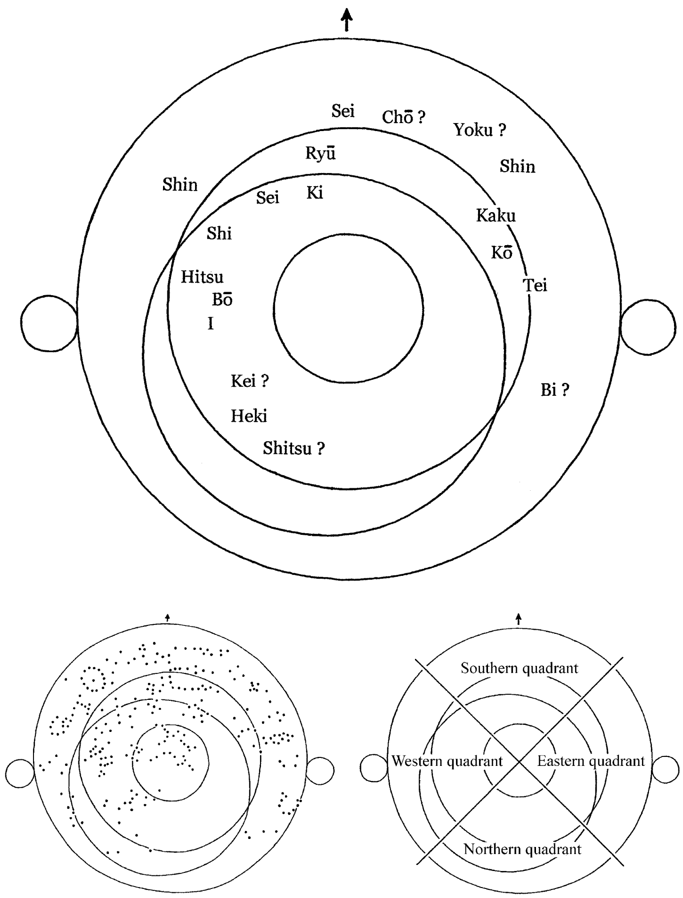
Because 38°–39° is considerably to the north of the Japanese cultural hearth in the Nara Basin and corresponds to an area within the archipelago that hardly interested the Japanese at the time, it would seem that the Kitora map was based on observations made elsewhere and, therefore, on an imported star map that served as its model. The ancient major Chinese centers of Cháng'ān (now at Xī'ān) and Luòyáng lie between 34° and 35° north, the same as the Nara Basin, and Dūnhuáng and Āsītǎnā which have Táng dynasty (AD 618–907) celestial diagrams or maps inside archeological sites are, respectively, at about 40° and 43° north, while a capital city prior to 510, Píngchéng at present-day Dàtòng, was also at approximately 40° north. On the Korean peninsula, the only cultural center north of 36° at the time was P'yŏngyang, which at 39° north had served as the capital of Koguryŏ from AD 427 until its absorption by Silla in 668. It is therefore suspected that the original map from which that inside the Kitora tomb was derived aimed or pretended to show the sky at or near P'yŏngyang.[1]

Although the Kitora enterprise has been dated to ca. 700, dating the celestial map which served as its model has been difficult to do. One of two estimates places the date of observation in the latter half of the fifth century, when P'yŏngyang was a capital city, yet there is little confidence in this mainly because the celestial north pole does not coincide with the center of the concentric circles. The other estimate, derived by considering the positions of the stars according to their right ascensions, suggests ca. 65 BCE as a possibility, but is not reliable because of insufficient data, differing values according to which stars are used, and errors that can be attributed to the workmanship and/or the photographs used for study. Despite their roughness, these estimates could be pointing at a synthetic map in which a graticule for the P'yŏngyang area was superimposed on a distribution of stars according to a Chinese catalog or survey from the first century BCE, the inconsistencies having been of little or no concern to the compiler(s).

Such a synthetic, incorrectly layered map could conceivably have been put together in the heyday of P'yŏngyang, and the best evidence which might be cited to support this idea is a verbal reference on a late fourteenth-century circular star map to its own alleged model, a stone engraving which was sunk in the Taedong River in AD 670 when Koguryŏ fell to Silla. At least one rubbing of the map had been made before the stele was sunk because the inscription on the *Ch'ŏnsang Yŏlch'a Punya ji Do* (Map of the Sphere with Images in the Heavens and the Line of Lodges), another stele made in 1395–1396 and reengraved approximately 300 years later, relates this history. Other documentary evidence supports this as well as the idea that celestial diagrams in general had existed in Koguryŏ, and calculations from the engravings of the *Ch'ŏnsang Yŏlch'a Punya ji Do* indicate that it could have been based on an original with stars surveyed roughly 2,000 years ago, that is possibly around the same time as the suspected model for the Kitora map. The biggest problem in linking the Kitora map with the *Ch'ŏnsang Yolch'a Punya ji Do*, however, is that a detailed comparison reveals that they differ considerably from each other, perhaps to the point that they used different models.

Detailed star maps such as the *Ch'ŏnsang Yŏlch'a Punya ji Do* and a Chinese circular map at Sūzhōu that was engraved in stone in AD 1247 have been useful for identifying the lunar lodges and other constellations, many of which are given away by the red lines that connect stars. Although a complete picture cannot be derived because of damage to the ceiling over time, the reasonably good assessment of the southern half of the map that has been made argues that the map was engraved with an appreciation of scientific detail and an intention to get the important stellar information reasonably correct. Notable is the distribution of the

[1] The calculations in previous research have assumed that the ratio of the radii of the circle of constant visibility and the equator is correct. Another line of reasoning might be that the circle of constant invisibility is in correct proportion to one of the other circles, and the calculations for latitude would yield approximately 39°30′ if it were correct vis-à-vis the circle of constant visibility (meaning that the equator would be slightly too large) or approximately 44°30′ if it were correct vis-à-vis the equator. Although the latter calculation would put the latitude for the circles in the Gobi or in northernmost Koguryŏ, the former helps support the hypothesis of the P'yŏngyang area having been meant by the circles.



Kitora Burial Mound. Fig. 3 The distribution of the identified and possibly identified lunar lodges in the Kitora star map. Of the two smaller diagrams, that on the left shows the distribution of the stars according to the photographs taken and that on the right divides the sky into quadrants, within each of which are supposed to be seven lunar lodges (drawing by the author).

identified and possibly identified lunar lodges, which demonstrates that they were positioned within their proper directional quadrants, seven to each, with all seven of the south having been identified despite the possibility of two of them having been switched (Fig. 3). Other constellations such as Gunshi (Army Town), Bunshō (Written Prosperity), Taibien (Big Faint Fence), and Hokutoshichisei (Seven Stars of the Northern Ladle) have also been identified by the patterns created by the lines that connect their stars, and their placement is correct in a relative context. Analysis of the lunar lodges and other constellations has also revealed that they and, vis-à-vis the geometry of the constellations, their stars are larger than usual, while the errors made in positioning them were greater than those on the *Ch'ŏnsang Yolch'a Punya ji Do* and other celestial maps that were used for comparison.

The Murals

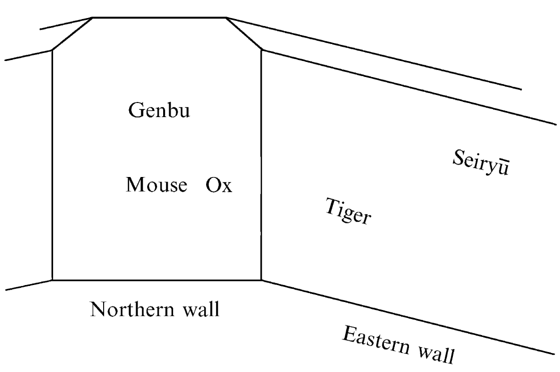
Two sets of illustrations have been discerned on the walls inside the Kitora tomb, and both are easily traced to Chinese cosmology. One set in particular, that of the four spirit-beasts which originated in China, is useful evidence of the diffusion of continental art into a Japanese cultural hearth and, in terms of esthetics, can be used to argue for a high probability of Korean immigrants and/or their descendants having worked on the Kitora project.

The four spirit-beasts – a term derived from the Chinese characters that comprise the Japanese word *shinjū* – are also known as the four spirits (*shijin*) which are often described as tutelary or protective deities of the north, east, south, and west. Their Japanese names are, respectively, Genbu (Black Warrior; actually a turtle and snake entwined), Seiryū or Seiryō (Blue Dragon), Suzaku or Shujaku (Red Bird), and Byakko (White Tiger), and all four still exist on the appropriate walls inside the Kitora tomb. Three had previously been found inside the Takamatsuzuka Burial Mound, about 1 km north of and contemporaneous with Kitora, but because its southern wall had been damaged by a break-in, it could only be surmised that Suzaku must have been painted on that wall to complete the set. The discovery of

Suzaku inside Kitora supports this idea; it generated a fair amount of excitement within the community of art historians and others interested in ancient culture because it was the first time that the complete set of spirit-beasts had been found inside a Japanese tomb.

Perhaps the more interesting set of murals appears to have been 12 smaller creatures drawn in threes on the four walls below the spirit-beasts. Because of deterioration of the walls, this set is no longer complete and educated guesses have been made from examining photographs of remnants of the murals based on their location. The first to have been examined is on the eastern wall, not far from the northern, and appears to be a person with the head of an animal that has been inferred to be a tiger. Other markings have been observed, notably two along the northern wall that occupy positions which suggest that the heads would have been those of a mouse and an ox (Fig. 4). An interesting point about what remains of these illustrations is that this is the first time that the 12-animal set has been found to have been painted on tomb walls anywhere.

These animals belong to the 12-animal Chinese zodiac which popularly gets linked to a cycle of 12 years, but they also have directional and temporal equivalents which are of greater importance here. Along the northern wall of the tomb the boar or pig (north–north–west), mouse (north), and ox or cow (north–north–east) would be expected to be shown; along the eastern would be the tiger (east–north–east), rabbit (east), and dragon (east–south–east); along the southern would be the snake (south–south–east), horse (south), and sheep (south–south–west); and along the western would be the monkey (west–south–west), cockerel or bird (west), and dog (west–north–west). Each of these animals, in the same sequence, corresponds with a 2-h block of time which makes sense in a geographical context so that, for example, the animals along the northern wall



Kitora Burial Mound. Fig. 4 The location of three markings which were probably murals of figures with heads of animals that symbolize geographical direction and 2-h blocks of time (drawing by the author).

correspond with night (the sun never entered the northernmost sky in the Chinese world), the hours for the rabbit are 5–7 a.m. when the sun comes up in the eastern sky, the horse overlaps midday from 11 a.m. to 1 p.m. when the sun is due south and at its highest, and the cockerel or bird symbolizes sunset in the west between 5 and 7 p.m.

Korean Provenance

Both the science and the art with scientific implications inside Kitora may be traced ultimately to ancient China, yet the evidence argues not only for one or more countries on the Korean peninsula as the agent for cultural transmission, but also for the strong probability that migrants from the peninsula and/or their descendants were directly involved in the Kitora project. The estimated latitude for stellar observation, mentioned previously, contributed to this line of thinking and surmising that the star map might be related to that noted in the inscription for the *Ch'ŏnsang Yŏlch'a Punya ji Do* as having been lost during the seventh-century turmoil between the Korean kingdoms. Examination of the murals, however, has provided more depth to argue for Korean provenance, as the following briefly notes.

An important lead in the early investigations was the fact that both a celestial diagram and murals of the four spirit-beasts were found inside the tomb, something that was far more common in Koguryŏ than in the Chinese or even the other Korean states. Although there is no known celestial map with the scientific spirit of that inside Kitora that either predates or is contemporaneous with it, that on the ceiling of the Takamatsuzuka tomb having been a square diagram without any of the scientific circles, archeological evidence from contemporary and later tombs suggests that there was no specific model for such celestial diagrams. In the case of the murals of the four spirit-beasts, though, there were similar drawings inside earlier tombs in Koguryŏ as well as inside Takamatsuzuka at Asuka to use for artistic comparison. When those and other murals inside Takamatsuzuka were discovered in 1972 – 11 years before Genbu, 26 before Byakko and Seiryū, and 29 before Suzaku were discovered inside Kitora – experts from northern and southern Korea were quickly invited to examine them, and the reasonable probability of Korean influence on them cannot be discounted, which may also be said to be true for the spirit-beasts inside Kitora because of the similarities between the three that are found in both tombs at Asuka. Further suggestive evidence of a Korean provenance for the murals inside Kitora is that influential artists of seventh-century Japan were settlers from the Korean peninsula, who most likely brought models which could have been used for the murals, and their descendants. Speculation has notably focused on an artist known as Kibumi and his school.

K

Knowledge Systems in China

Yang Di-Sheng

The science and technology developed in China often led the world before the fifteenth century. Statistics of significant discoveries in the world from the sixth century BCE to the nineteenth century AD show that before the year 1500, discoveries made in China comprised more than half of the total (Guo Jianrong and Guo Guangyin 1987). Then, the percentage dropped rapidly, and in the nineteenth century it became less than 1%.

The mode of development of science in China is, roughly speaking, a slowly progressed "mode of accumulation." It is not full of ups and downs like the Western saddle-shaped "mode of revolution".

In contrast to the West, Chinese scientific and technological achievements mainly belonged to the technical and empirical type. The Chinese were less inclined to use theoretical and experimental methods. The four best known inventions – compass, gunpowder, paper, and printing – when they came to Europe, exerted a great influence on the West.

The most developed sciences in ancient China were astronomy, mathematics, medicine, agronomy, and other related branches. This was determined by the needs of the agricultural Chinese society.

The characteristics of the development of science and technology in China were formed by factors that existed before the Christian era. At that time Chinese culture was already very different from Greek culture. There were both a different value orientation and a different way of thinking, which had long-term influences over the directions of the development of Chinese society and Chinese science and technology.

In regard to value orientation, the highest goal for Chinese ancient thinkers was in searching for the harmony and balance in one's mind, and in the relationship between Man and Man, Man and Society, and Man and Nature. The core of the Confucian thought is *ren* (loving people). Therefore, the only important criterion for learning is usefulness for humanity's purpose; other factors do not matter at all. In this regard, it is very different from ancient Greece, where study was for knowledge's sake only and without any practical intention.

Huishi was the only exception among Chinese ancient thinkers. But thinkers from all the other schools such as Confucians, Daoists, Mohists, and Legalists uniformly criticized him, and they suppressed him. This contributed to the fact that the ancient Chinese were strong in technological achievements and relatively weak in theoretical ones. Even though the Mohists discussed almost all the problems contained in classical logic, they never made a single step toward formalization or axiomization. Therefore, they never came up with their own axiomatic system. The main reason for this was that logic, at that time, did not seem to have any practical use.

The Chinese also developed mathematics to a very high level. For example, in the *Shushu Jiuzhang* (Mathematical Treatise in Nine Sections) compiled by Qin Jiushao in 1247, there was a method of solving high degree equations. However, the Chinese never developed axiomatic systems similar to Euclidean geometry. Therefore, despite the fact that China had the most complete, most systematic astronomical records in the world at that time, and that she was rich in cosmological constructions, such as the *gaitian* (hemispherical dome), the *huntian* (celestial sphere), and the *xuan ye* (infinite empty space) hypotheses, she never produced any geometric cosmological models similar to Ptolemy's or Copernicus'. Chinese mathematics characteristically took practical use as its aim and centered around calculation. Its earliest representative work is *Jiuzhang Suanshu* (Nine Chapters on the Mathematical Arts) written in the Western Han dynasty. Ancient Western mathematics was mainly geometry; ancient Chinese mathematics was mainly algebra. Today, when computing technique once again is the primary concern of so many mathematicians, the practical value of ancient Chinese mathematical inclination becomes more and more obvious.

The development of modern science and technology makes people realize that it is a double-edged sword; it can bring benefits as well as destruction. Therefore, its development must be controlled ethically and politically, under strict management and control. In this respect, Chinese value orientation is a very significant model.

In regard to ways of thinking, Chinese traditional philosophy has always inclined to an organismic view of nature. Chinese philosophers regarded heaven, earth, and man as a united whole. This was fundamentally different from other ways of thinking, as there was no distinction between Object and Self. French thinker L. Levi-Bruhl (1857–1939) misunderstood when he considered the chinese way of thinking primitive. The Chinese idea of the unification of heaven and man mainly emphasizes that humans are only a part of heaven (nature); the Way of Heaven and the Way of Man are one and the same. Humans should be in a harmonious existence with nature, and these two should not be opposed to each other.

Chinese philosophy also claims that heaven, earth, and everything else are constituted by a pair of contradictions. Chinese philosophers use two symbols, *yin* and *yang*, to represent this pair of contradictions. *Yinyang* is a unity of contradictions. There is an antagonistic as well as a complementary and containing relationship between them. There is *yang* in *yin* and there is *yin* in *yang*. They can convert to each other under certain conditions. Therefore, in order to achieve harmony in nature, the stability of a society, and a long rule with eternal peace, as well as the health of individuals, "the doctrine of the mean" has to be applied to keep a dynamic balance between *yin* and *yang*. The philosophy advocates that nothing should be overdone, and all actions should be done appropriately. This way of thinking is different from the dichotomy in two-valued logic (A or $\tilde{A}$), in which every proposition is either true or false. Its symbolic representation is the *yinyang* fish *taiji* pattern (Fig. 1).

A mechanistic mode of thought has never been dominant throughout Chinese history. This organismic way of thinking affected the development of Chinese science to a very large degree. It can be found in ancient

Knowledge Systems in China. Fig. 1 Two-valued logic and the *yinyang* fish *taiji* pattern.

Chinese cosmology, astronomy, medicine, agronomy, and social theories. It contributed tremendously to keeping peace and stability during the Middle Ages. However, at the same time it restrained the growth of capitalism, and served as one of the most important reasons that prevented China from having a scientific revolution.

According to the Chinese traditional view, the origin of the universe is the result of the changes of *yin* and *yang*. Imbalances of *yinyang* caused natural disasters like earthquakes, as well as social disturbance. The *yinyang* theory is also the theoretical foundation of Chinese medicine. It considers the human body as a whole. If a body loses its balance of *yin* and *yang*, the person becomes sick. The task of a medical doctor is to use every method to help the patient to resume this organismic dynamic balance. However, Chinese medicine is not a two-value system; it is a multiple-value system, totally different from the Western medical system. But these two can go hand in hand and complement each other, thereby enriching the treasury of our medical knowledge.

The Chinese traditional way of thinking is an organismic one which emphasizes integrity and perceivability, and allows fuzziness. It is, relatively speaking, weak at analytical thinking and it does not value axiomatic systems. Generally it is not good for macrocosmic descriptions in the area of physics, especially mechanics. However, it is closer to the microcosmic world of modern science, such as the area of quantum mechanics, or to descriptions of cosmological, artificial intelligence, and social systems. The return from accuracy back to fuzziness is one of the main indications of contemporary science. Nowadays many scientists realize that this Chinese way of thinking could indeed bring helpful inspirations to the progress of modern science.

Knowledge Systems of Aboriginal Australians: Questions and Answers Arising in a Databasing Project

Helen Verran

Why Use a Databasing Project to Tell About an 'Other' Knowledge Tradition like that of Aboriginal Australians?

There are many reasons for being interested in 'other' peoples and their knowledge. A general or removed interest about 'others' often arises out of curiosity. Satisfying that curiosity can put into perspective our selves, our times and places, our cultures and accepted ways of going on. There are many different ways of knowing. Recognising some differences and similarities between knowledge traditions helps to see the strengths and limitations of our own ways.

Sometimes there are more specific reasons for learning and puzzling about other knowledge traditions. In this article I consider knowledge traditions of Aboriginal Australians comparatively, by referring to a particular contemporary way of 'doing knowledge'. The aim of the project I write out of is to devise some specific forms of databasing that might be useful for Aboriginal people. You can find out more about this project at ►http://www.cdu.edu.au/centres/ik/. This contribution takes the form of questions and answers that are frequently asked about Aboriginal Australian knowledge traditions in the context of such projects.

The databasing project involves the intersection of two quite different knowledge traditions. The intersection 'reveals' both technoscientific knowledge traditions and Aboriginal Australian knowledge traditions.

Engagements of various sorts must occur in an Aboriginal digital databasing project, and studying that process is helpful from the point of view of comparatively learning about Aboriginal Australian knowledge traditions.

How Can Asking About Knowledge in the Context of a Databasing Project Help in Understanding Aboriginal Australian Knowledge Traditions in General?

Many Aboriginal communities in northern Australia are interested in using digitising technologies – computers, video and still cameras, audio recorders, and written texts – to generate digital items that can contribute to the various forms of collective memory in Aboriginal communities. Just as in the sciences, collective memory in its various guises is important in using and making knowledge in Aboriginal knowledge traditions.

When it comes to actually doing the work of assembling a collection of digital objects that might be useful to an Aboriginal community however, several aspects of how to do it immediately become problematic. For example, what sorts of things digital objects *are* in an Aboriginal context of knowing turns out to be surprisingly puzzling and difficult to predict. How a database might be organised so that it could be useful to Aboriginal people as they do their knowledge in their own ways, using their own forms and structures, is likewise not at all clear in the beginning. Needing to think through those questions helps to understand knowledge traditions generally, and Aboriginal Australian and technoscientific knowledge traditions in particular.

Why Use the Term 'Knowledge Traditions' Rather than 'Knowledge Systems' When Discussing Databasing of Aboriginal Knowledge?

Both 'systems' and 'traditions' are metaphors, working images of how we understand knowledge using and knowledge making. 'Tradition' comes from the Latin word *tradere*, 'to give'. Traditions emphasises human communities 'doing' their knowledge, giving across generations and to other knowledge communities. 'Systems' come from the ancient Greek term *systēma* meaning 'set'. Systems imply a concern with boundaries and focus on framings and separations. It emphasises the structures of knowledge.

In using traditions I am not denying the importance of structure in knowledge. The practical difficulties that can arise in working disparate knowledge traditions together are often caused by differences in the ways things are framed and structured. In using 'knowledge traditions' I mean to draw attention to the fact that all human communities have complex and varied ways of dealing with such issues in their practices of knowledge using and making. The ways that framings and re-framings are managed when knowledge traditions work together is part of what is at stake in a project like Aboriginal databasing. When we want to compare and contrast knowledge traditions we need to think about and discuss the various sorts of re-framings we need to do so that we can usefully juxtapose knowledge traditions.

What Are the Terms We Can Use in Discussing the Various Sorts of Re-Framing We Need to Do so that We Might Compare and Contrast Knowledge Traditions?

In using and making knowledge there are some framings that people are very aware of. There are others that are deeply hidden. For example all knowledge traditions have experts in various fields and disciplines. Access to expert knowledge must be managed. There is 'outer', 'inner' and 'secret' knowledge, and institutional ways of managing access to those levels. The institutional arrangements involved in using and making knowledge express theories about what knowledge is in that knowledge tradition. The social arrangements involved in working a knowledge tradition embody the ways that knowledge is justified as true. 'Epistemic' is the general term we use to name this aspect of knowledge. Discussing and considering the management of these institutionalised structurings and re-framings is epistemology. These terms come from the Greek word for knowledge, *epistēme*. The *-ology* bit of the term means 'to study'.

There are also divisions and definitions that knowledge users and makers are far less aware of. Becoming sensitive to this level of difference can be crucial in successful working together of disparate knowledge traditions. These structural differences are embedded in language use and in the ordinary generalising we do when we use numbers. Here people are working at the level of assumption; things are usually just taken for granted as people go on together. In working disparate knowledge traditions together people must bring these assumptions and what they take for granted out into the open. Often, especially in the beginning, that is not comfortable. Philosophers name this profound level of framing the ontic (referring to the existing reality) level. Ontology is the study of what there is. 'Ontic' and 'ontology' come from the ancient Greek term *onto-* a form of the verb form *eimi* or 'am' in English, part of the verb 'to be'.

How Do Epistemic Differences Arise When People Try to Work Technosciences and Aboriginal Knowledge Traditions Together?

One of the many reasons for researching Aboriginal databasing is the need to manage epistemic differences that emerge when environmental scientists and Aboriginal land owners try to work together to conserve biodiversity. In northern Australia perhaps the most valuable tool for ecological management is firing the bush. By maintaining a sophisticated regime of firings, a complex mosaic of dynamic ecological successions is achieved. Aborigines have been doing this in Australia for millennia. Science, which has been working with Australian nature for only a little over 200 years, seems to be much less successful at achieving complex dynamic mosaics. And besides, much of the land in northern Australia is owned by Aboriginal Australians who have a right to work their lands according to the standards of their own knowledge traditions.

A firing is judged as a valid and efficacious instance of the knowledge tradition of Aboriginal Australians in several ways. These are epistemic concerns. Theories of knowledge determine the forms of witnessing and evaluating any instance of applying and engaging knowledge. In Aboriginal knowledge traditions it is most important that particular knowledge authorities participate in specific roles in the planning and execution of the firing. Expressions of knowledge are not valid unless this condition is met.

Firing of any particular place must always begin in a specific spot and proceed in certain ways, through a series of contiguous particular named spots in the landscape. The names of a series of contiguous spots in the landscape must be publicly and collectively recited before a firing begins. The knowledge authorities are those who know which spots are where, and the directions in which the various sequences of names move across the land. In addition it is important that particular items of food are gathered in the process of firing and distributed to appropriate persons in the correct relative amounts. This distribution of various foods collected from the multiple micro-ecological zones that constitute the area fired expands the number of people who can attest a firing episode as legitimate. A particular firing will imply that people are moving through places where it is recognised that particular foods are found. Being able to present the appropriate food items to others is a form of proof that the firing was valid. These institutionalised forms of proof and witness go along with epistemology which sees that true knowledge can only be performed and enacted in place.

These forms of Aboriginal witnessing and evaluating an episode of firing are very different from the ways epistemic concerns are institutionalised in environmental science. There, scientists plan their firings with maps that allow areas to be delineated. They collect observations on the fire and its effects on vegetation and assemble the results in scientific papers that are published, reports that other environmental scientists might read. These reports attest and witness the efficacy of the firing. These forms express an epistemology which understands knowledge as representing an 'out-there' reality.

Nowadays when it comes to managing Australia's northern savannas to promote a robust biodiversity through firing, there are two incommensurable standards. There are no possibilities for an Aboriginal way of judging a firing to be a valid expression of knowledge to have salience in science. In the same way it is literally inconceivable that scientific validation could legitimate in Aboriginal traditions. The epistemic differences are unresolvable as such.

Yet perhaps digitising technologies can help us get around this problem. It is possible to imagine assembling digital objects during planning, execution and evaluation of firing. Audio files can capture what is said, and still images, movies, and spoken commentaries might also be gathered, along with the foodstuffs, and/or the measurements, as Aborigines and scientists go about their tasks of planning, execution, and witnessing firing episodes.

Imagine storing these digital items in a structure free digital matrix. In databasing terms this implies that there is no distinction between data and metadata. If we want to go further we could imagine two quite differently configured interfaces by which the set of digitised objects might be interrogated. One interface can express the epistemic concerns of science, the other can be configured in a way that embeds the epistemic concerns of Aboriginal Australian knowledge traditions. To do this of course the two sets of epistemic standards must be translated into digital interfaces. In each case, in becoming database interfaces, the epistemic standards take up new forms of institutionalisation. In actuality of course, those sorts of translations require a lot of work and resources.

How Do Ontic Differences Arise When People Try to Work Technosciences and Aboriginal Knowledge Traditions Together?

Different knowledge traditions make very different assumptions about what there is. One set of clues we can get about this level of difference lies in the grammars of different languages. Grammars are deeply embedded in and express the ontic. Another set of clues can be winnowed out by considering the everyday forms of generalising we find working in a knowledge tradition. We can look at what is involved in using numbers for example. In the case of Aboriginal Australian communities we need to consider the generalising that makes up their very different form of mathematics. You can read about this in my other entry in this encyclopaedia 'The Mathematics of Aboriginal Australia'. Yet another set of clues can be found in the stories that peoples tell about the origins of the worlds they know and the things that comprise it. This is generally called the metaphysics of a knowledge tradition. That is the subject of my next question.

Imagine a scientist watching an old Aboriginal man demonstrating the process of making fire by rubbing two sticks together. The old man has chosen sticks from bushes that look very different. He uses one as a base and cuts a notch in the middle. He uses the other stick like a drill bit. Seating it in the notch he twirls it very fast between his palms. Gradually a pile of hot sawdust accumulates and when it is smoking he tips this smouldering pellet into a nest of shredded bark which when blown on breaks into flame.

Enthusiastic and interested, the scientist asks the names of the two bushes from which the fire making sticks were plucked. It is quite clear to him that the plants are very different – they belong to different biological families. He is genuinely shocked when the old man insists that they are *really* the same. While the old man accepts that the plants might look different, he insists that what is important is that *logically* they are 'the same one'. The old man and the scientist have been confronted with an ontic difference.

Is this ontic difference resolvable? Yes, but only by opportunistically assuming the existence of a third translating domain. This move involves an ontology that is both and neither Aboriginal and scientific. But this is not a meta-ontology. It is not an ontic domain which supervenes and contains the other two. On the contrary, it is an infra-ontology, an inside connection. It takes enough of what matters ontologically to Aborigines when they are dealing with firings, and enough of what matters to scientists when they are engaged in doing their prescribed burns. Learning how to do this in on-the-ground situations is not easy because it involves working with contradictions in disciplined ways. Particularly for scientists it is difficult, because contradiction is usually outlawed in science.

'Same and different' are constituted through different framings in science and Aboriginal knowledge traditions. It often shocks people when they experience this form of difference. Another similar sort of experience is often associated with differences around 'whole and part'. Recognition of this sort of difference can also emerge when Aborigines and scientists try to learn each others' firing regimes.

Scientists assume that a thing like a habitat is an entity found in nature. While there may be many attributes and characteristics which could be the subject of quite different scientific disciplines – pedology, botany, hydrology – the habitat itself is just a single given object. Many different representations of this given, whole thing might be made, and they tell of the various parts of a single whole thing. The differences between the experiences of the separate groups of scientists are downplayed and backgrounded. This being so, when scientists report their burning of an area, they tell their activities in accordance with the assumption that they are about a single entity. They go to great pains in the introduction and conclusion of their reports to show that all the separate experiences of the scientists really relate to one thing – the habitat under observation.

But when Aborigines report their episodes of burning, they completely fail to attend to the place as a whole. They emphasise and recognise only the diverse involvements of the groups who have variable interests at stake in a collective episode like a firing. The singularity achieved in different kin groups working together in a single purposeful episode is taken for granted background in any reporting. Aborigines do not assume that places exist in the here-and-now as single whole things. Places might achieve a form of ephemeral singularity when a firing or some other such collective activity occurs – if all the correct people are present and things are done in a correct manner. Those ephemeral unities of actual existence are achieved re-enactments of an originary act of creation by spiritual ancestors.

As scientists see things, reports of firings given by Aborigines fail to attend to the place as a whole. In contrast Aborigines feel that scientists fail to credit properly the multiplicities that inhere in place. This is another instance of ontic difference. It too, with care and caution, can be worked around well enough for Aborigines and scientists to feel confident in going on together.

How Are Aboriginal Accounts of the Origins of Knowledge Different to Technoscientific Understandings of Origins of Knowledge?

As well as issues of epistemology, such as theories of knowledge and truth, and issues of ontology, commitments to particular sorts of things being in the world and issues of metaphysics, such as originary stories, are involved in working disparate knowledge traditions together. The metaphysics of Aboriginal Australian knowledge traditions is very different to that of the technosciences. They have very different accounts of the origins of knowledge.

In Aboriginal Australian traditions knowledge is taken as already always in the land. However, knowledge needs the correct circumstances for true expression. In Aboriginal Australian knowing, there is no given or a priori separation of places and persons who belong to that place. Knowledge is in the land and in people by virtue of their belonging to the land.

The origin of knowledge/place/persons is often named in English as 'The Dreaming'. This is a transcendental time parallel to the secular time of the ordinary here-and-now. From The Dreaming the creative impulse for the world arose and continues to arise. This creative impulse of The Dreaming emerges from the complex collective lives of a multiplicity of beings, both human-like and non-human in form. Entities that can be known in Aboriginal Australian knowledge are framed primarily as here-now expressions of The Dreaming. Knowledge and the spiritual life of religion are not separate in Aboriginal traditions, so all things have an intrinsic spiritual dimension.

As well as an ultimate division between the eternal Dreaming and the secular here-and-now world of everyday individual experience, there is a subsidiary division between the world's two sides. There is exhaustive division of both the secular domain and The Dreaming, into formal opposites. Amongst the Yolngu Aboriginal clans in northeast Arnhem Land for example, these two sides or moieties are named *Yirritja* and *Dhuwa*. Everything is either Dhuwa or Yirritja.

Knowledge in the ordinary world of the secular is the outcome of *Dhuwa* Dreaming knowledge and *Yirritja* Dreaming knowledge working together to generate true expressions of The Dreaming. Knowledge in the here-and-now is justified as a true expression of The Dreaming if relevant knowledge authorities of the opposed moieties with interests in the particular set of issues at hand, witness and attest a particular expression of The Dreaming as valid.

In the technosciences, while many practitioners might profess religious belief, Islamic, Buddhist, or Christian for example, these spiritual commitments are not embedded in the forms of technoscientific knowledge. The entities of technoscience do not possess an intrinsic transcendental element. Knowledge of the world is taken as distinct from the world itself. Knowledge is a representation. Knowledge is about the world and the origin of knowledge is the human mind which knows the world. There is some disagreement over whether the ultimate structure of knowledge reflects the structure of the human mind, or the structure of the world. Most philosophers agree that it is some form of combination of both.

In the sciences there is a fundamental division of people as knowers and things (including places) as known about. Things known are matter that extends in space and time and is situated in an empty space–time frame. In a secondary or derived way abstract things like numbers are understood by analogy to primary material things. True knowledge about those material and abstract things is taken as accumulating through the application of proper scientific method. Knowledge is justified as true if it can be shown to have been produced in valid ways.

Aboriginal Knowledge is Taken as in the Land Itself. How Can Knowledge be Stored in the Land and in Databases Too?

How can we understand Aboriginal people when they say 'knowledge is in the land?' How can science learn how to take that claim seriously? The land is a set of sites with meaning embedded, with information there in place. But those meanings, necessarily organised in some way, are accessible only to those who have been sensitised and trained in the right traditions.

One way to think about databasing in an Aboriginal context is to understand a computer as a simplistic and 'outside' version of one of those meaning full sites in land. 'Doing databasing' can contribute to the remembering/forgetting that is inherent in community life, as can 'doing ceremony' which mobilises information embedded in the land.

Databasing can be understood as a way of doing outside collective memory with digitised materials. Images made with digital cameras – video and still, audio files, and written texts typed up on a computer can record something that might be re-presented later in another forum in such a way as to help those involved in some endeavour to remember in a helpful way. Seeing things this way reminds us of the importance of developing some protocols around generation of digital objects.

What Are the Knowledge-Making Sites in Aboriginal Australian Knowledge Traditions? How Are They Similar to or Different from Knowledge-Making Sites in the Technosciences?

Aboriginal knowledge-making centres around ceremonies, some of which might involve firing episodes. In much the same way technoscientific knowledge-making pivots around the workings of laboratories and field sites. Just as there are many and varied types of laboratories, so too there are many different sorts of ceremonies in Aboriginal life. These are religious ceremonies, but they are not repeated rituals. No two ceremonies are identical in Aboriginal life. Each is concerned with spiritual practice and knowledge making with respect to particular times and places and groups of people.

We can describe scientific knowledge making in laboratories and field sites through elaborating the specific sorts of social institutions involved, the material routines that are crucial in knowledge making, and the literary texts and literacies involved. But to give a complete picture we need also to include the paradigms, theories, or imaginaries in which these processes make sense. These same headings can be used to describe the workings of Aboriginal ceremony and the knowledge making that occurs in them. Just as the entities that emerge from laboratories and field sites remake their worlds, so do the entities that emerge from the ceremonies of Aboriginal Australian life.

Ritual and Ceremony Are Parts of Aboriginal Knowledge. How Can You Recognise the Role of Ritual and Ceremony When Knowledge is Stored in Databases?

In ritual and ceremony Aboriginal knowledge authorities use many diverse sources of information. In ceremony, dance, painting, song and story need to be performed correctly and under the right auspices to become knowledge making.

Often people see databases as 'archives'. But in this project we are *not* seeing them as tiny digitised museums. We are asking if databasing can become a useful additional experience. Can digitised information feed into, complement and extend the already well-developed ways that information is handled and managed in Aboriginal communities to support Aboriginal people in doing their knowledge? Under what conditions might databasing become a useful form of managing information? These are empirical questions and Aboriginal people are the ones who must drive the process to come up with answers.

Aborigines Have Local Knowledge But Databases Are Universal. How Is Local Knowledge Consistent with Having Databases?

The notion of databases as somehow universal knowledge assumes two things. First it takes for granted the existence of 'facts' – little pieces of knowledge referring to a single reality. And second it assumes that if you could only get enough of them together in one place, facts would eventually link up into one complete system of knowledge. In many traditions of Indigenous knowledge (and in many sciences) both assumptions are seen as wrong.

Anyone who thinks about the notion of universality for very long will see that facts are always generated and 'made solid' in specific places and times by particular groups of people. Knowledge is always done in specific ways. It is a commonplace that it is actually very difficult to get things to link up. It is sometimes very difficult actually to link working databases – for example those that have been assembled in doing biodiversity. Data are just as diverse as biological organisms are.

We found this when we started searching for databases in northern Australia that included 'indigenous knowledge'. A database *is* a form of local knowledge. It is a collection in digitised form of data items that have been generated using very specific local methods.

Of course Aborigines have local knowledge. All knowledge is local. It remains true that sometimes with prodigious collective effort some, or even many, local knowledges can be linked. Sciences often are good at linking up their local knowledges, although sometimes it is very difficult to get different sciences to work together. Sometimes and in some places scientific knowledge and Aboriginal knowledge can be usefully linked.

How Could Elements of Traditional Culture be Strengthened by Encouraging Aboriginal People to Use Digitising Technologies?

A problem arises if we think of traditional Aboriginal knowledge as 'anti-modern', the opposite of modern culture. Then we will begin to think of traditional cultures as stuck in the past and want to put them in a museum and close the exhibit case. Understanding 'traditional' in that way, we think of it as somehow inconsistent, perhaps even incompatible, with computers.

Traditional cultures are contemporary forms of life just as modern cultures are. They are rich in modes of innovation as well as having ways for preservation of cultural forms. We can understand traditional cultures as involving non-modern forms of identity. They have ontologies that make modern assumptions about knowledge and knowing look strange. Digitised information arranged in ways that make sense and are useable by those working within non-modern cultures can surely be devised. As long as we do not make assumptions based on modern ways of using digital objects, if we proceed in open ways, empirically researching how indigenous people actually use digitising technologies, there is the possibility of strengthening traditional forms of cultural innovation with computers.

Traditional forms of passing knowledge from an older generation to a younger one often involves young and old being in the same place at the same time doing things together, talking about it. It involves a process of re-imagining it together, finding new forms in which to express the understandings in sharing them.

We often find that indigenous communities want to assemble collections of digitised items for specific reasons. They want to be able to intervene in a specific context in a particular way. Assembling digitised items in these projects becomes a site, a time and place where young and old, with their varying competencies work together. Databasing can become an impetus for young and old to work together in ways that can empower and educate the young while recognising older people as knowledge authorities.

What About Protecting Intellectual Property? Can Databases Not Easily Lead to Indigenous Peoples Losing Control over the Natural and Cultural Resources Their Groups Own?

Protecting collective intellectual property is important in all 'closed' knowledge economies. Aboriginal societies are no different from American corporations in this. The issue is one of controlling who knows and how much they know. Strategic revealing and hiding is involved.

Modern companies protect their intellectual property with patent laws, by various technical means, and by selectively authorising and commissioning various knowers. Aboriginal clans have equally effective means of managing the strategic revealing and hiding of intellectual resources.

There are two rather separate elements that need to be considered in thinking about intellectual property and indigenous knowledge with respect to collections of digitised items that point to natural and cultural resources.

The first relates to forms of management for these collections that express indigenous ways of doing intellectual property. Workable ways of respecting different clan ownership of various elements, and recognising differential individual access need to be found. Our stance at this point is to restrict our research to secular contexts. We avoid engaging with knowledge that is sacred and religious. Second, maintaining collections of digitised material in ways that protect the collections appropriately to avoid piracy from outside interests is important.

Can We Articulate Some General Principles for Thinking About Engaging Disparate Knowledge Traditions?

Genuine recognition of difference can be painful. It involves beginning to doubt our own knowledge traditions as sources of absolute certainty and see them as having limits. Accepting that every knowledge tradition is inherently and systematically partial is challenging. It is sometimes difficult to accept the profound significance of difference and at the same time persevere in learning about 'the other' and in considering how our familiar ways of knowing might engage with other ways of knowing. Very often we approach other knowledge traditions thinking that they are just an odd or unusual version of the ways we know. That is a form of inauthenticity.

The odd aspect of seriously engaging with the other is that in order to recognise difference in knowledge traditions we need to 'make strange' our own. In part that is what I have tried to do in these questions and answers, telling of some of the issues that arise when Aborigines and scientists work together. Beginning to explore how digitising technologies might contribute, I engaged in a process of 'strangification'. I 'made strange' the epistemological assumptions of science, revealing them by setting them alongside another way of 'witnessing' valid expressions of knowledge associated with an alternative account of truth. To make strange our own knowledge traditions we must begin to open up questions of metaphysics.

Eventually we must find ways to do a form of 'experimental metaphysics'. This way we make both sides strange with respect to each other. An experimental metaphysics is a framing of issues of difference that takes elements of both metaphysical systems to develop what we might call an ad hoc hybrid translation borderland. This can help us begin to accept the limits of our own ways of being certain about what we know – our own types of epistemic standards. It can also provide a way to imagine how we might connect in partial, strategic, and opportunistic ways. Some entities that might be usefully linked in partial ways – like Aboriginal firings and the prescribed burns of science can be identified. The on-the-ground activities that enable strategic linking can be identified. Each firing can begin to make some sense in the other knowledge tradition through the use of a metaphysically explicit translating zone.

K

Knowledge Systems of the Incas

R. Tom Zuidema

On the fourteenth of November, 1533, Francisco Pizarro and a small Spanish army entered the town of Cajamarca. On the next day they took Atahuallpa, the last Inca king, prisoner after he had come to their encounter with a large army. It was the first and the last time that the Spaniards received a glimpse of the independent Inca state which had conquered an empire into southern Colombia and northern Argentina and Chile. Perhaps the empire had already been weakened by the civil war that Atahuallpa had won over his brother Huascar, the crowned king. While in prison, Atahuallpa had Huascar killed, and after some months in Cajamarca the Spaniards executed Atahuallpa. But more than these events, it was the possession of superior arms, including horses, and the help of native troops choosing their side, that allowed the Spanish army to cross the country almost without resistance and to enter the capital of Cuzco a year later. Here they set up Manco Inca as a puppet king. Less than two years later Manco Inca fled Cuzco and withdrew to the eastern slopes of the Andean mountains where heavy forest made it difficult to defeat him and his successors. In 1572, thirty-six years later, the last Inca king, Tupac Amaru, was captured and executed in Cuzco. It was the end of Inca resistance, and the viceroy Francisco de Toledo could consolidate a colonial government that ruled until the early nineteenth century when the Andean countries of Colombia, Ecuador, Peru, Bolivia, Argentina, and Chile declared their independence.

Some of the first Spaniards that described their participation in the conquest of the Inca empire included in their accounts valuable information about its people. But only after some 20 years did the first chronicles appear, by Juan de Betanzos [1551],[1]one of the first Spaniards to learn the Inca language of Quechua well, and Pedro Cieza de Leon [1551]. These give an integrated view of Inca culture, referring to aspects of history, social and political organization, agriculture and husbandry, and religion. Although much of this information derived from the memory of Inca nobles in Cuzco, it was not based on direct observation of a thriving culture with all its rituals and feasts. Moreover, Andean civilization never developed a system of writing, recognized by the chroniclers as such, through which we would be able to hear the independent voices of its peoples on what they thought about their cosmos, their gods and goddesses, and their myths and rituals, without being directed by the questions of representatives (administrators, lawyers, priests) of Spanish domination. Almost all the documentation needed for Inca administration was recorded on knotted cords with numerical information organized in bundles, called *quipus*. Hundreds of these *quipus* have been found in graves on the desert coast of Peru. Most are from Inca times but some are from the earlier Wari culture, demonstrating a different system of knots and chords. We can study the sophistication of Inca mathematics, analyze some of the information, mostly on bureaucratic and economic but also on ritual matters, as released by *quipu* specialists through Spanish prodding, and be aware of additional information on the Inca past and culture memorized by the specialists. But most of this research is still in its infancy (Ascher 1981).

Other promising sources of information on Inca culture are the many textiles that survived in coastal graves, were conserved in heirlooms from colonial times, and were represented in colonial art. The Incas inherited sophisticated techniques of weaving from earlier cultures, but the style of their art was very much their own. Certain types of male tunics show highly standardized geometric patterns. Others include a wide variety of square designs, *tucapus* that in their distribution as possible signs with meaning are reminiscent of a writing system, although only for a few *tucapus* are there clues to their interpretation. None the less, a careful comparison with written sources on the use and iconography of Inca textiles can help us to establish this art as an independent, pre-Hispanic source of documents on aspects of Inca culture.

The colonial chroniclers provide us with the only written knowledge of Andean culture at the time of the Spanish conquest. Beginning with Betanzos and Cieza, they organize their material in a historical framework. Thus they tell how Manco Capac, the first Inca king, came out of a cave some 50 km south of Cuzco with three brothers and four sisters and founded the future capital. At the time of his writing, the conquered people in the valley of Cuzco still remembered their pre-Inca past. From here the Incas first conquered surrounding valleys and gave their kingdom an administrative structure recognizing the old local lords as lower-ranked members of their own nobility. This nobility consisted of different ranks defined according to criteria of kinship to the reigning king and queen; thus the local lords were defined by the chroniclers as "Incas by privilege". Like the Inca nobility, they themselves were exempt from contributing labor to Cuzco but their subjects were not. Moreover, they and their subjects participated in the ritual organization of the town. From this base the empire was conquered.

When the Spaniards were still in Cajamarca, they had some inkling about the enormous extent of the Inca empire but no idea how it was obtained and who had been the successive conquerors. On their arrival in Cuzco, they reconstructed the last two royal successions before the Spanish conquest. Twenty years later a certain consensus was arrived at of the earlier dynasty. But as this list of kings was not based on historical records, its reconstruction conformed more to a pattern of western than of indigenous ideas about royalty, succession, conquest, and history. One of the most arduous tasks of research deals therefore with the questions of evaluating how the Spaniards reconstructed the conquest of the Inca empire, how their Inca informants presented this conquest to them, and how the conquered peoples, especially those outside the original kingdom, understood how this Inca domination had occurred.

Betanzos, Cieza, and others after them, especially Pedro Sarmiento de Gamboa [1572], placed as the central person in the epic of Inca conquests the ninth king, called Pachacuti Inca. Cuzco had been attacked by the kingdom of the Chancas during the reign of his father, Viracocha Inca. As the latter fled from town, Pachacuti Inca defeated the enemies and was crowned king even though he had not been designated as crown

[1] Square brackets after the name of an old author indicate the date of writing or of first publication.

prince. He rebuilt the city, reorganized the people who lived in its valley, elevating in rank those who had helped him in the defense and lowering others, and he established different institutions of government. Thus he divided the valley into districts based on the system of agricultural irrigation; he organized a system of worship of those ancestral mummies that he decided to recognize as such; he assigned administrative posts to relatives and other nobles; and he established the calendar of state celebrations.

The story of Pachacuti Inca has all the characteristics of a foundation myth and with its help we can get an understanding of how the histories of the Incas before and after this king were constructed in colonial times. Memories of earlier times were organized according to the ancestral system, wherein a ranking order of mummies was used to establish a dynastic order. But the dynastic sequence after Pachacuti Inca cannot be taken without critical examination either. The many conquests of the Inca empire toward Colombia and Chile and Argentina were said to be accomplished mostly by Pachacuti Inca's son, Tupa Yupanqui, and grandson, Huayna Capac. (The latter died some seven years before the Spaniards arrived). But the Inca informants to Spanish questioning recognized that some rulers after Pachacuti Inca had been suppressed from the official list of kings. Thus it is very possible that the history of Inca conquest was not as short as suggested. Here the memories of the conquered peoples can help us to arrive at a more realistic picture of Andean history.

Intensive documentary research beginning some 50 years ago on various local kingdoms integrated into the Inca empire allows us to get some idea of their cultural and institutional differences and their ties to earlier peoples whose art and archaeology we study. Perhaps the most important kingdoms that the Incas conquered were those of the Chimu on the north coast of Peru and around Lake Titicaca. All had had a prestigious history of their own. The Chimu had built a kingdom along the coast from about the valley of Lima to near the present-day border of Peru with Ecuador. Their capital of Chanchan had been the largest city in South America. They were the descendants of the Mochica people (ca. AD 0–700) whose pottery with realistic painted scenes established one of the high points of Andean arts. The Chimu are the only kingdom on which we have some dynastic information from before the Spanish and even Incaic conquests. Recently, much work has been accomplished reconstructing their culture and political organization (Moseley and Cordy-Collins 1990).

Around Lake Titicaca the cultures of Pucara (ca. 200 BCE–AD 400), north of the lake, and Tiahuanaco (ca. AD 200–900) south of it once flourished. The impressive stone ruins of their ceremonial centers played an important role in Inca mythology. Chroniclers constructed the myth of a creator god coming from Lake Titicaca or Tiahuanaco, called Tunupa, around the lake and Viracocha in Cuzco. In the sixteenth century three different languages were spoken: Aymara that extended to the west of Cuzco and near Lima, Puquina, and Uru. Puquina was probably the most important language at the time of Tiahuanaco, and Uru may have been there and in the high plains of Bolivia even earlier. But since colonial times Uru was retained mostly by people with a fishing and hunting economy, and Puquina died out. Today, Aymara is mostly spoken by people living south and east of Lake Titicaca.

Most of our historical information on Aymara culture derives from colonial administrative documents. Among these are, however, two of the most important ones for research on local government and economic organization in the Andes at the time of Spanish conquest. The first, from 1567, describes the former kingdom of the Lupaca south of Lake Titicaca. Its economy was based not only on highland crops grown there but also on crops from distant valleys down on the Pacific coast. Instead of obtaining these lowland crops through trade it had sent its own people to grow them. The second document, from 1568–1570, concerns a former kingdom north of the lake; here cultivation of coca in the lower valleys east of the Andes had been important.

In conquering Chimu and Lake Titicaca, the Incas had concentrated their rule near former centers of power. In other cases they established new provincial capitals away from such centers. The most important and best researched example of this kind is the city of Huanucopampa in central Peru near the eastern slopes of the Andes. It formed part of a chain of provincial capitals going north from Cuzco, including Vilcas Huaman, Bombon, Huanucopampa, Cajamarca, Tumibamba (present day Cuenca in Ecuador) and Quito. Huanucopampa was perhaps the largest of all. It is also best preserved, as its location on a high plateau did not attract later Spanish settlement. Huanucopampa expresses in an admirable way the basic ideas of Inca town planning. Around a huge rectangular plaza the four quarters of town were organized, each with its own pattern of social activities. In the center of the plaza stood the Ushnu. Chroniclers describe the Ushnu in the plaza of Inca towns as a platform or pyramid near a small round structure of stone where offerings of corn beer were pledged to the Sun god, the ancestors, and the forces of the underworld. Cuzco had such a ritual complex but the platform was probably a temporary structure used only during special feasts. But in Huanucopampa the large platform was built of stone and could have served also during military parades. On the east side of the plaza and aligned with the Ushnu stood the palace of the Inca governor. The king probably resided here when passing through town. It contained three courtyards, as one chronicler also describes for a royal palace in Cuzco. Thus we can assume that Inca and non-Inca subjects could enter the first and largest courtyard, that only nobility entered the second courtyard, and that the family of the governor or the king had exclusive access to the third and smallest courtyard to which were attached their living quarters. There was a straight road leading from the plaza to the inner court and the various gates through which visitors had to pass still stand, each crowned by two stone lions facing one another like on the lion gate of Mycenae. Above the town, on its outskirts, can still be seen the hundreds of storehouses for the tribute brought by the people of the province of Huanucopampa. Two extensive documents from 1562 describe in detail the demographic composition of this province and the contributions that its villages had to make to the state. Huanucopampa and its province have provided us with the best opportunity for research on the organization of an Inca province and its economy.

Many documents now being studied allow us to reconstruct the local sociopolitical situations in Inca times. Regular forms of organization, like those consisting of moieties and of three or four local groups, reveal patterns of regional variation which have survived in many places. Although the social functions of these organizations may have changed after almost half a millennium, they retain their ritual importance. A form of state organization that could be combined with the ones already mentioned consisted of bringing together families in numbers of 10, 50, 100, 500, 1,000, 5,000, 10,000, and finally 40,000, the latter number expressing an ideal way of organizing an Inca province. In a similar way, the population of Cuzco itself consisted of ten *panacas* and ten *ayllus,* the first referring to the relatives of the king who administered these groups. *Panacas* and *ayllus* played a crucial role in the calendrical rituals of the capital.

With the Inca conquests of the empire, the administrative model of Cuzco was replicated in the organization of the whole empire. For instance, the four quarters of town, the *suyus,* were extended into the four provinces of the empire. Inca nobles and lords of the Incas-by-privilege became imperial administrators (*tucricuc*) supervising local lords (*curacas*) who themselves governed their territories like the king in Cuzco. But *curacas,* or their representatives or sons, also had to visit Cuzco. Periods of four months' or a year's residence in town are mentioned, but we do not known how regularly they were repeated. A specially important time for such visits was after harvest, when lords came with their tribute and presents for the Inca king. He consulted with them about their governments and discovered who did not want to comply with his obligations. Presents that the king received from one province were awarded by him to the lords of another.

Of particular interest is the imperial (re-)organization of the *acllas,* the "chosen ones." Girls were selected in local organizations according to set criteria of beauty and assigned tasks, like weaving and making corn beer, in houses built for that purpose. From there they could be reselected and sent to provincial capitals and even to Cuzco. Their organization touched on almost all aspects of Inca culture. Ranking was expressed in an idiom of age-classes, and these applied also to men from their time of initiation and marriage to the time that they turned over their social obligations to their sons. Some *acllas* were married off by their *curaca,* an Inca governor or the king, either as a principal or as a secondary wife, or were dedicated to a role in Inca religion. When, with the Spanish conquest this organization fell apart, one way *acllas* were dealt with was by converting them to nuns. But their roles were not really comparable to those of nuns, because this female organization with the queen at its head in most respects paralleled the male hierarchy. The concept of *aclla* also played a central role in the imperial organization of sacrifice, the *capac hucha,* as this practice had grown out of the calendrical organization of local rituals in Cuzco. Children were selected as *acllas* and dedicated to various but always specifically recorded purposes. Thus they were sacrificed, including couples of a boy and a girl. In their own locality, sacrifice might be for the purpose for obtaining good pottery clay. In far-away places sacrifices commemorated important events, such as winning a battle. In Cuzco it was part of a great state ritual, either for the time of planting, of the December solstice or of the harvest. *Aclla* sacrifice was the culminating act in an organization of rituals that crystallized the cosmological values of Inca government.

Inca religion forms an integral part of Andean religion in general as observed in various parts of the empire. Because of the importance of Cuzco as imperial capital and the intellectual interest of the Spanish in its history, we are also well-informed about Inca religion. However, for reasons of colonial history we also have extensive accounts of myths, rituals, and religion in the mountain provinces of Huarochiri and Cajatambo, central Peru, where in the early seventeenth century the Spaniards believed they observed a resurgence of indigenous beliefs that they tried to eradicate. While the original belief systems in Cuzco and the two other provinces may not have been that wide apart, the circumstances of their recording were very different. Chroniclers in Cuzco, among whom there were well-educated people, came to the Inca past through their own curiosity and were informed by Inca nobles. Initially, both parties may have looked for a common intellectual basis. However, the religious expressions in Huarochiri and Cajatambo were seen as a rebellious return to pagan beliefs in villages after more than 80 years of teaching that Christianity was the only true religion. I will deal here with the problem of studying Inca religion, although many myths and rituals may have been recorded in Huarochiri and Cajatambo in a form closer to pre-Hispanic reality.

Unlike the situation of extensive pantheons in Aztec and Maya religions and of illustrations of gods, goddesses, and priests dressed as such in pre-Hispanic and early colonial codices and chronicles, the Spaniards described only a few gods and goddesses for the Incas, and even those were not visualized in any way in Inca art. Nevertheless, documents and chronicles are replete with names of sacred places in the form of mountains and rocks, lakes and springs, and all other kinds of natural and man-made objects with ritual significance. Foremost were three male gods, the Sun, the Thunder, and Viracocha and one female god, Pachamama, the "mother earth." The ruling king was considered to be the son of the Sun, but from Cuzco we have no mythical description of the latter's actions. The Thunder god was seen in various parts of the country as an active mountain god, but in Cuzco only indirect references to his deeds occur. The god Viracocha seems to have corresponded to a type of mythical figure, known elsewhere in the Andes under various names. The myth of the god Coniraya in Huarochiri, there compared to Viracocha, has perhaps best preserved this pre-Hispanic image. He pursues a woman along a river down to the Pacific Ocean. Here she escapes as he cannot follow her any further. Along the way and through various acts that present him as a trickster, he defines the interests of people in their land for cultivation, water for irrigation, and wild animals for use in rituals. An original way of representing Viracocha in Cuzco, although found in a late chronicle, is as a force of nature, a giant, who during a month of heavy rain comes down the Villcanota river near Cuzco, flowing from the southeast to the northwest, threatening to destroy it. But Betanzos and Cieza describe Viracocha as a god who brought forth from the island of Titicaca (the rock of the cat), in the lake of the same name southeast of Cuzco, the sun, the moon and the ancestors of different peoples. Viracocha sends these underground to their local places of origin, from where they reemerge to establish local government. Viracocha himself also travels northwest, following the Villcanota river near Cuzco, but continues until he arrives at the sea in Ecuador. There he disappears, not into the sea but over it toward the horizon. This version of the myth was well adapted to the imperial interests of the Incas and may have also received a colonial reinterpretation because of the Spanish interests of including Peru in a universal empire. Soon the exploits of Viracocha were also phrased in terms of those of two early apostles, Saint Bartholomew or Saint Thomas, who had been said to have traveled through the country bringing Christianity long before the Spaniards did. According to this colonial reinterpretation, Viracocha was the creator god of the Incas. But his mythology became embedded also, in fragmentary form like that of other gods, in the legendary history of kings. Stories were told of the eighth king, Viracocha Inca, that were more fitting for his namesake the god Viracocha, and in a similar vein his son Pachacuti Inca was associated with the Thunder god. In fact, one chronicler recognizes these relationships as such when he says that each king took as his name of nobility that of his god. Pachamama was the great goddess of the earth, but again no stories of her exploits are told. The myths of some Inca queens are more interesting, considered in their roles as ancestral deities. Probably, the attention to Pachamama was mostly developed in early colonial times.

Of more immediate interest for the study of Andean religion are the numerous sacred places, the huacas, mentioned in various local documents. Sometimes myths are told about them as actors like humans. Two indigenous chroniclers from the early seventeenth century give us extensive hierarchies of huacas of more than local importance, although our sources tell us little about their possible organization. In about 1560, however, the Spaniards had become aware that in Cuzco the cult of the huacas was organized according to a highly sophisticated scheme of directions as seen from the temple of the Sun in the town. Families each took care of the cult of a particular huaca and larger social groups were associated with the huacas along one direction, the ceque, or with groups of ceques. The organization of the ceques served various social purposes. For instance, the topographical description of the valley was of interest for land distribution in agriculture, irrigation, husbandry, and mining, especially in terms of quarries of stone used for building purposes. Through the ceque system a formal description can be given of Cuzco's political organization including its calendrical organization of state rituals as defined in terms of its system of astronomical observation. Polo de Ondegardo, the chronicler who discovered the ceque system in Cuzco, mentions that other villages, towns, and provinces of southern Peru and Bolivia also had their ceque systems. Some interregional ceques are described, of use in the imperial system of capac hucha sacrifice that suggests a hierarchy and network of ceque systems. Ceque systems were recorded on quipus. They supported an Andean way of reflecting in an abstract way on cultural values.

Andean civilization did not direct its interests toward the use of writing like Mesoamerican civilization did. Thus the intellectual aspects of Inca culture are difficult to grasp. But so much can still be studied of early Andean practices through those of their descendants, as in techniques of agriculture and weaving that it will become possible to define the originality of Andean civilization.

Knowledge Systems in India

A. V. Balasubramanian

Traditionally all knowledge in India has been traced to the Vedas. The Vedas are considered to be divine revelation. They were organized into four major branches: *Ṛgveda*, *Yajurveda*, *Sāmaveda*, and the *Atharvaveda*. Various other branches of knowledge grew up as auxiliaries that were to be developed in order to interpret and put to practical use the material of the Vedas.

There were a total of 14 *Śāstras* or branches of knowledge: the four Vedas, the four Upavedas (auxiliary Vedas), and the six Vedāṅgas (parts of the Vedas). The four Upavedas were (1) *Āyurveda*, literally "The Science of Life," which constituted the medical system; (2) *Arthaśāstra*, which constituted state craft and political theory; (3) *Dhanurveda*, literally, archery, but practically constituting the art of warfare in its varied aspects, and (4) *Gāndharvaveda*, constituting music, drama, and the fine arts.

Similarly, the knowledge systems required for understanding, interpreting, and applying the Vedas were organized into six branches called *Vedāṅgas*, literally "the limbs of the Vedas," with the Vedas personified in a human form. The six *Vedāṅgas* are *Vyākarana* (Grammar), *Chandas* (Metrics), *Śikṣā* (Phonetics), *Nirukṭa* (Etymology), *Kalpa* (Ritual), and *Jyotiṣa* (Astronomy and Mathematics).

These *Vedāṅgas* were essential, since the Vedas had to be understood correctly (needing etymology and grammar), pronounced and chanted accurately (needing metrics and phonetics), and used properly in various contexts (needing ritual), and the times for these performances had to be computed correctly, requiring the knowledge of computation of the flow of time and of planetary movements (needing astronomy and mathematics). Even though the *Śāstras* originally evolved in the context of the Vedas, they also developed an independent identity and their own corpus of literature and applications that extended well outside the originally formulated requirements of the Vedic context.

In later periods the list of *Śāstras* became much larger and the area covered was much wider. For example, in his famous text *Kámasūtra*, the author Vātsyāyana provides a list of 64 arts with which any scholar should be familiar.

Since the various branches of Indian knowledge systems are extremely diverse, we will focus upon a few that can best illustrate some characteristic different features. These are (1) the fact that linguistics occupied a seminal place even for exact sciences (unlike Western knowledge systems); (2) the nature of theorization and theory building in Indian tradition; (3) the algorithmic nature of Indian computation, and (4) the sociology of organization of knowledge –the "classical" and the "folk" streams and their interrelation.

In any scientific discourse it is essential to achieve precision and rigor. In the Western tradition, the geometry of Euclid is considered the paradigm of an ideal theory, and various other branches of knowledge tried to emulate Euclid by setting out their knowledge on the basis of a formal axiomatic system. In contrast, in Indian tradition, an attempt was made to use natural language and to refine and sharpen its potential by technical operations so that precise discourse was possible even in natural language. This is so, particularly in Sanskrit, where we find that even the most abstract and metaphysical discussions regarding grammar, mathematics, or logic are still written in natural language. In Indian knowledge systems, it is the science of linguistics that occupied the central place which, in the West, was occupied by mathematics.

Linguistics

Linguistics is the earliest of Indian sciences to have been rigorously systematized. This set an example for all the other Indian sciences. Linguistics is systematized in *Aṣṭādhyāyī* – the text of Sanskrit grammar by Pāṇini. The date of this text is yet to be settled with any certainty. However, it is not later than 500 BCE. (The dates mentioned here are those based on Western scholarship. An indigenous Indian dating and chronology in this matter have yet to be established.) In the *Aṣṭādhyāyī*, Pāṇini achieves a complete characterization of the Sanskrit language as spoken at his time, and also manages to specify the way it deviated from the Sanskrit of the Vedas. Given a list of the root words of the Sanskrit language (*dhātupatha*) and using the aphorisms of Pāṇini, it is possible to generate all the possible correct utterances in Sanskrit. This is the main thrust of the generative grammars of today that seek to achieve a purely grammatical description of language through a formalized set of derivational strings. It is understandable that until such attempts were made in the West in the recent past, to the Western scholars the Paninian aphorisms (*sūtras*) looked like nothing but some artificial and abstruse formulations with little content.

Science in India seems to start with the assumption that truth resides in the real world with all of its diversity and complexity. Thus for the linguist what is ultimately true is the language as spoken by the people. As Patañjali, a famous grammarian who wrote a commentary on Pāṇini's *Grammar* emphasizes, valid utterances are not manufactured by the linguist, but are already established by practice in the world. Nobody goes to a linguist asking for valid utterances, the way one goes to a potter asking for pots. Linguists do make generalizations about language as spoken in the world, but these are not the truth behind or above the reality. They are not the idealization according to which reality is tailored. On the other hand, what is ideal is real, and some part of the real always escapes our idealization of it. It is the business of the scientist to formulate these generalizations, but also at the same time to be attuned to the reality, to be conscious of the exceptional nature of each specific instance. This attitude seems to permeate all Indian science and makes it an exercise quite different from the scientific enterprise of the West.

Astronomy and Mathematics

Indian mathematics finds its beginning in the *Śulbasūtras* of the Vedic times. Purportedly written to facilitate the accurate construction of various types of sacrificial altars of the Vedic ritual, these *sūtras* lay down the basic geometrical properties of plane figures like the triangle, the rectangle, the rhombus, and the circle. Basic categories of the Indian astronomical tradition were also established in the various *Vedāṇga Jyotiṣa* texts.

Rigorous systemization of Indian astronomy begins with Āryabhaṭa (b. AD 476). His work *Āryabhaṭīya* is a concise text of 121 aphoristic verses containing separate sections on basic astronomical definitions and parameters; basic mathematical procedures in arithmetic, geometry, algebra, and trigonometry; methods of determining the mean and true positions of the planets at any given time; and descriptions of the motions of the sun, moon, and planets along with computation of the solar and lunar eclipses. After Āryabhaṭa there followed a long series of illustrious astronomers with their equally illustrious texts, many of which gave rise to a host of commentaries and refinements by later astronomers and became the cornerstones for flourishing schools of astronomy and mathematics. Some of the well-known names belonging to the Indian tradition are Varāhamihira (d. AD 578), Brahmagupta (b. AD 598), Bhāskara I (b. AD 629), Lalla (eighth century AD), Muñjāla (AD 932), Śrīpati (AD 1039), Bhāskara II (b. AD 1115), Mādhava (fourteenth century AD), Parameśvara (ca. AD 1380), Nīlakaṇṭa (ca. AD 1444), Jyeṣṭhadeva (sixteenth century AD), Gaṇeśa, and Daivajña (sixteenth century AD). The tradition continued right up to the late eighteenth century, and in regions like Kerala, original work continued to appear until much later.

The most striking feature of this tradition is the efficacy with which the Indians handled and solved rather complicated problems. Thus the *Śulbasūtras* contain all the basic theorems of plane geometry. Around this time Indians also developed a sophisticated theory of numbers including the concepts of zero and negative numbers. They also arrived at simple algorithms for basic arithmetical operations by using the place-value notation. The reason for the success of the Indian mathematician lies perhaps in the explicitly algorithmic and computational nature of Indian mathematics. The objective of the Indian mathematician was not to find "ultimate axiomatic truths" in mathematics, but to find methods of solving specific problems that might arise in astronomical or other contexts. The Indian mathematicians were prepared to set up algorithms that might give only approximate solutions to the problems at hand, and to evolve theories of error and recursive procedures so that the approximations might be kept in check. This algorithmic methodology persisted in the Indian mathematical consciousness until recently, so that Ramanujan in the twentieth century might have made his impressive mathematical discoveries through its use.

Āyurveda: The Science of Life

The third major science of the classical tradition is *Āyurveda*, the science of life. Like linguistics and astronomy this finds its early expression in the Vedas, especially the *Atharvaveda*, in which a large amount of early medicinal lore is collected. Systemization of *Āyurveda* takes place during the period from the fifth century BCE to the fifth century AD in the *Caraka Saṃhitā*, *Suśruta Saṃhitā* and the *Aṣṭāṇga Saṇgraha*, the so-called *Bṛhat-trayee* texts which are still popular today. This is followed by a long period of intense activity during which attempts are made to refine the theory and practice of medicine. This process of accretion of information and refinement of practice continued right up to the beginning of the nineteenth century.

Folk and Classical Traditions

There exists a vast amount of knowledge which represents the wisdom of thousands of years of observation and experience. While in any given area (such as medicine) there may be a body of experts or learned professionals, knowledge also prevails in more diffuse or scattered forms. In Indian tradition, it seems to be a general principle running through all types of learning that knowledge can and does prevail in various forms and also gets communicated in many ways.

The general picture that emerges seems to be that the "classical texts" in any area of learning may set out broad general principles as well as their application in a given context, say a particular region of the country. But in various different contexts or regions, knowledge gets expressed based on the given situation, and the generalities get adopted, modified, or even overridden sometimes based on the specificity. This can perhaps best be illustrated in the case of medicine, where classical medical texts themselves deal with this issue. A classical text of *Āyurveda* such as *Caraka Samḥitā* expounds general principles of drug action on the six factors: *Dravya*, *guṇa*, *Rasa*, *Vīrya*, *Vipāka*, and *Prabhava*. It also discusses remedies for several diseases and lists specific drugs. These may get modified to suit local conditions. In any recipe for a drug, one can substitute a nonprincipal component with an equivalent, which may be listed in the text or selected on the basis of the principle of *Rasa, Vīrya*, etc. From time to time traditional physicians produce texts and manuals which set out prescriptions for drugs in any given area based on what is available and suitable to the requirements of that area. For example, the text *Rājamṛgaṇka* lists 129 recipes, and in his foreword the editor states that it is a compilation that must have been made by a *vaidya* (physician) from Tamil Nadu, since it contains recipes based on herbs readily available in Tamil Nadu. Such recipes are not only easier to formulate, but they are also more suited to the area, in accordance with Caraka's dictum, "For a person who belongs to a particular country or a region, herbs from the same region are most wholesome."

The fact that it is the particularity of the context that is the overriding consideration and that Sastric (i.e., scientific) principles are to be considered as precepts and guidelines and not applied in a mechanical or legalistic manner is clearly stated in many classical texts. "A Vaidya who comprehends the principles of *Rasa*, etc. would discard treatment if not wholesome to the patient in a given situation, even if it is prescribed in the texts; on the contrary he would adopt treatments that are helpful to the patient, even if they do not find a mention in the texts."

It is also interesting to note what the texts of *Āyurveda* say about folk knowledge. The *Caraka Saṃhitā* states that "the goatherds, shepherds, cowherds and other forest dwellers know the drugs by name and form." Similarly, the *Suśruta Saṃhitā* states "one can know about the drugs from the cowherds, tapasvis, hunters, those who live in the forest and those who live by eating roots and tubers."

This is an overview of Indian knowledge systems and does not go into the details of achievement in a variety of areas, particularly those pertaining to material sciences. Our attempt is to highlight basic characteristics of these knowledge systems, particularly in those respects where they differ from their modern counterparts.

Knowledge Systems of Indigenous America

LAURELYN WHITT

First Words

> "Knowledge is inherent in all things" (Luther Standing Bear 1933).

Luther Standing Bear's observation that knowledge inheres in all things openly expresses what many indigenous knowledge systems presuppose, and what, by being presupposed, shapes several of their distinctive features. The inherency of knowledge, and the inclusiveness of its scope, are reflected in what is taken to be primary or fundamental – in what knowledge is held to be knowledge *of*. They are also reflected in a web of prescriptions and proscriptions that guide the process of knowing. In both respects, indigenous knowledge systems stand in contrast to their counterparts originating within the West (a location more ideological than geographic).

We can only begin with our own assumptions, with what is taken for granted in what follows. And that is that knowledge systems are diverse and their value is contextual. Oppressive relations of power, however, have shaped their histories and continue to inflict the present, in ways that obscure or override this diversity. As a result, the existence and value of indigenous knowledge systems, in the Americas and elsewhere, has been systematically denied. In the origin stories of the dominant culture, indigenous peoples have superstitions, myths, or belief systems based on ignorance. They do not have knowledge systems.

These stories no longer have the force they once did. There are two reasons for this. The first is that the dominant knowledge system has begun to falter in ways that are obvious even within the West. While some have seen this as a matter of inadequacy or incompleteness, others believe the problem lies deeper. The second is that indigenous peoples across the planet are presently engaged in various and vigorous projects of recovery: of language and land, of law and sovereignty, and of knowledge and value systems. We will touch only lightly on the first two of these, but linger on the third. Indigenous peoples, in the Americas and elsewhere, are intent on restoring and protecting their knowledge systems. And they are using many different approaches and every means available to do this. This story of resistance and recovery is essential to understanding not only the politics of indigenous knowledge systems, but also their substance, and their vital role in the world.

It is a story we attempt to relate here by drawing on as many different voices as possible, mindful that "writing things up gives authority to a particular view and a particular writer… writers are insulated from the discipline imposed on purveyors of knowledge in an oral culture – from the collective analysis and judgment of a community, each of whose members share equal authority to interpret reality" (Castellano 2000).

Relatedness and the Inherency of Knowledge

> "In each place they lived, they learned the subtle, but all important, language of relationship" (Cajete 2000).

If knowledge inheres in all things, it can only properly be educed or drawn forth. So coming to know another entity or process is best approached as an eductive process that turns on establishing certain relations with it. Coming to know it well involves strengthening and sustaining those relations. So knowledge within indigenous knowledge systems is always knowledge of relations; it is not individual entities or processes which are primary or basic, but the relations that hold between and among them. Indigenous knowledge, Battiste and Henderson (2000) note, is "the expression of the vibrant relationships between the people, their ecosystems, and the other living beings and spirits that share their lands." Relatedness, or affiliation, is best understood in its primary – genealogical – context. One of its clearest and simplest expressions is in the Lakota invocation *mitakuye oyasin* ("I am related to all that is"). It is reflected as well in the Andean concept of an *ayllu* – a group of related persons, human, and nonhuman, who live in a particular place: "*Ayllu* refers not only to relationships between human beings but to the relationship between all members of the *Pacha*… they are all relatives and are at once children, parents, and siblings" (Rivera 1995).

K

Those seeking knowledge must first elicit, or solicit, then sustain relations with whatever it is they hope to know. As Deloria (1992) states, the "principle of relatedness always remained the critical interpretive method of understanding phenomena." Because knowledge is a matter of establishing connections with other entities, or of recognizing bonds that already exist, the process of knowing is dynamic, interactive. Both parties are actively engaged in knowing as well as in being known. Since most things are held to be animate, rather than inanimate, they are fully capable of engaging in relationships, of entering into relations with human beings. Knowledge of them is not, as the dominant knowledge system would tend to have it, a unilateral process, the result of an active knowing subject working upon a passive object that is known. Within indigenous knowledge systems, coming to know other entities is always a bilateral, and most often a multilateral, process. This involves and encourages an awareness of interdependency: "Only through interdependence could the human beings survive. Families belonged to clans, and it was by clan that the human being joined with the animal and plant world. Life on the high, arid plateau became viable when the human beings were able to imagine themselves as sisters and brothers to the badger, antelope, clay, yucca, and sun. Not until they could find a viable relationship to the terrain – the physical landscape they found themselves in – could they *emerge*" (Silko 1996).

Another implication of Standing Bear's comment that knowledge inheres in all things is that knowledge is not an exclusively human project. Other than human entities are capable of knowing, of making and maintaining relations; if they were not, we would not be able to know them. Moreover, if alternative ways of knowing the world were not possible for us, the scope of human knowledge would be severely constrained. Indigenous knowledge systems place considerable value and significance on gaining access to the perspective of the other than human. By expanding "our understanding of the sense of being relatives," Deloria (1992) observes, "We discover that plants, birds, and animals often gave specific information to people."

Indigenous accounts of knowledge as a process of relating and of acknowledging relatedness, of making connections and sustaining bonds with other entities, allow great latitude in what can be known and how one comes to know. They embrace "the relational potentiality of all peoples and all creation" (Williams 1997). Their commitments to epistemological pluralism and nonanthropocentrism, to coming to know the world through perspectives that are diverse and not restricted to that of the human, run counter to those of the dominant knowledge system. They are at odds too with the idea that knowledge requires separating the knower from the known in order to capture the one way the world really is, independently of the human beings who know it. As Momaday (1976) comments, nature is not something apart from the human, but the element in which the human exists.

If human beings are in fact inextricably bound up in relations – to one another and to the entities and processes in the natural world – what is vital is understanding those relations, knowing how our behavior threatens them and how we can best sustain them. Indigenous knowledge systems do not purport to offer knowledge in the sense of universal truth, or of accurate accounts of the one way the world really is independently of us. Their virtue is that they enable survival, by helping us realize relatedness, the role and contribution which all entities make, and how those roles may best be preserved and continued.

Sovereignty, Responsibility, and Respect

> Yet within the Aboriginal community a paradox seemingly exists. In no other place did the individual have more integrity or receive more honour than in the Aboriginal community. The individual's ability as a unique entity in the group to become what she or he is ultimately meant to be, was explicitly recognized. There was explicit recognition of the individual's right in the collective to experience his or her own life. No one could dictate the path that must be followed (Ermine 1995).

Indigenous construing of knowledge as relatedness, as a matter of appreciating how we are bound to other entities and processes, makes integration with them possible, desirable and necessary for survival. Our fates and futures are understood to be conjoined with theirs. Knowing them commits us to cohering and cohabiting with them. Indigenous knowledge systems enable such coherence, such holding and living together. To acknowledge affiliational ties with other entities in the natural and social worlds is to acknowledge that and how our lives are linked together with theirs. Connection or affiliation with them makes survival possible, and because we are so connected our survival can only be mutual. We are allied and responsible for one another.

This leads to an understanding of sovereignty that diverges markedly from those that have prevailed within the West. Sovereignty is held to be relational, rather than absolute; it is conditioned by responsibility and respect. It is also applicable to all entities, human or not. Relations of domination and assimilation have no place within such a concept of sovereignty; self-determination is held to be compatible with, and constrained by, mutual interdependence. The *Gus-Wen-Tah*, the Two Row Wampum Treaty Belt hat the Iroquois presented to the United Nations, visually expresses this view of relational sovereignty. According to it, differing peoples may be allied and interdependent, yet retain their full distinctiveness and ability to live according to their own laws, customs and ways: "We shall each travel the river together, side by side, but in our own boat. Neither of us will steer the other's vessel" (Penner 1983). The same vision of a relational sovereignty in which power and agency are constrained by responsibility and respect, was expressed by a delegate to the United Nations Working Group on Indigenous Populations: "We need to begin to think of self-determination in terms of peoples existing in relationship with each other…[T]he right of a people to self-determination is not a right for peoples to determine their status without consideration of the rights of other peoples with whom they are presently connected and with whom they will continue to be connected in the future. For we must realize that peoples, no less than individuals, exist and thrive only in dialogue with each other. Self-determination necessarily involves engagement with and responsibility to others…" (Scott 1996). Sovereignty, so construed, is accountable. It enables and endorses collective survival but is inconsistent with domination and assimilation.

Human power and agency are thus limited in fundamental ways by the relationships that bind us to other entities, as Coffey and Tsosie (2001) suggest. Knowledge of other beings involves acknowledgement of them, that is, respect for their role in and responsibilities to the alliances that bind us together. In other words, to know is to value. The processes of knowing and valuing are integrated in indigenous knowledge systems; they mutually inform, and are informed by, one another. This is evident in the fact that one of the primary virtues within indigenous value systems, respect, is as much a cognitive virtue as an ethical one. Knowledge that is not conditioned by respect cannot be had, nor can there be respect in the absence of understanding. Among the Iroquois, respect, or the "wish-to-be-appreciated," is the "fundamental shared perception – the first principle – of existence. As long as everything is appreciated for what it does and what it shares to sustain the cycles of Creation, the world will be in balance and life will continue" (Barriero 1992). The Anishinabe concept of *minobimaatisiiwin* (the good life) expresses a similar notion. "Implicit in minobimaatisiiwin," LaDuke (1992) notes, "is a continuous habitation of place, an intimate understanding of the relationship between humans and the ecosystem and of the need to maintain this balance." It describes, "how you live your life according to natural law, how you behave as an individual in relationship with other individuals and in relationship with the land and all the things which are animate on the land" (LaDuke 1997). In this manner, indigenous knowledge systems offer accounts of knowledge "intended to incite humans to act in such ways as to ensure the protection and reproduction of all creatures in the universe" (Holmes 2000).

Story: Experience and Imagination in Indigenous Knowledge Systems

> "There is a story connected with every place, every object in the landscape" (Silko 1996).

Since knowing other entities involves sustaining relations with them that acknowledge mutual responsibilities and respect, knowledge is so intimately tied to experience and imagination as to be inconceivable without them. Stories are acts of the imagination that enable us to enact and re-enact experience. They do so, typically, by focusing on characters who establish relations with one another, and respond to one another in various ways. One source of their richness as pedagogical vehicles is their facility in demonstrating how knowing and valuing implicate, and are implicated in, one another. Another is that they permit us some access to the perspectives of other beings, often those very different from ourselves. We come to know them by relating ourselves to them, by imaging what it is like to be them, and to experience the world – including ourselves – through them.

Stories have long figured as indispensable aspects of indigenous legal and political knowledge practice. As Williams (1997) observes, "Indian diplomats recognized that making connections with others was a most difficult process. Successful treaty-making required the use of great acts of the imagination so that the two sides could come to see themselves as related in their needs and sufferings as fellow human beings… this is why a treaty was told as a special kind of story, a way of imagining a world of human solidarity where we regard others as relatives." The integrative power of stories, the way they help us initiate and maintain relations with others who may appear different from us, is especially needed to guide human interaction with the other than human world. Stories are related to convey the behavioral constraints that should guide us if we are to act responsibly, if we are to understand and respect the role of other entities and their unique contribution to the natural world we share. Many different peoples have many different stories about what happens when someone, human or otherwise, violates these constraints.

The significance of stories within indigenous knowledge systems lies as much in the telling as in what is told. The intergenerational transmission of knowledge from elders is both a responsibility and a gift. Stories are only told in the context of particular relationships and are a means of maintaining and nurturing those relationships. Part of the responsibility of telling stories lies in determining when and to whom they should be told.

> Elders often decline to have their words printed or to be videotaped because they insist that what they have to say must be communicated in person. Aboriginal people know that knowledge is power and that power can be used for good or evil. In passing on knowledge the teacher has an obligation to consider whether the learner is ready to use knowledge responsibly.…Teachers who allow these things relinquish the possibility of adjusting their teaching to the maturity of the learner and thereby influencing the ethical use of knowledge (Castellano 2000).

As vehicles of experience, stories relate empirical knowledge about the relations that connect us to the world and to one another, and about how those relations can be well or adversely affected. Such knowledge is the product of careful observations, spanning generations, of how entities in particular places are interrelated and of the complex dynamics of their relationships. While it is temporally "deep" or historically replete, it is also spatially located or endemic knowledge – intimately bound to the land, to specific places and the entities located there. It is, thus, presentational rather than representational knowledge: its continuation, its transmission, its possibility turn vitally upon the presence of the natural world and on the kind of experiences that world offers.

> The need to walk on the land in order to know it is a different approach to knowledge than the one-dimensional, literate approach to knowing. Persons schooled in a literate culture are accustomed to having all the context they need to understand a communication embedded in the text before them… Persons taught to use all their senses – to absorb every clue to interpreting a complex dynamic reality – may well smile at the illusion that words alone, stripped of complementary sound and colour and texture, can convey meaning adequately (Castellano 2000).

It is in this sense that knowledge inheres in the world; it is caught up in experience and cannot be extracted from its context. The value of knowledge, so construed, the ultimate test of its validity, "is whether it enhances the capacity of the people to live well" (Castellano 2000).

The Politics of Knowledge: Resistance and Recovery

> "If we do not resist, we will not survive. Our resistance will guarantee our children a future" (LaDuke 1997).

Knowledge has not become politicized; it always has been so. Indigenous knowledge systems explicitly recognize this by their responsiveness to the normative aspects of knowledge, to how human power and agency must be constrained if relations of affiliation with other entities are to be acknowledged and maintained – relations that enable our mutual, and multigenerational, survival. Yet the ideology of Western science, wedded as it is to the thesis of value-neutrality, insists that issues of power do not enter into knowledge making, or shape the dynamics of knowledge systems. The relations of domination and assimilation that characterize imperialism – whether in its historical or contemporary variants – are thus neither acknowledged nor acknowledgeable.

And so the endangered status of indigenous knowledge systems is recognized, but responsibility for it, complicity in it, is denied.

> Critical analysis of *why* Indigenous Knowledge is threatened rarely moves beyond simplistic assertions that 'Elders are dying' or the assumption that IK systems are more vulnerable… because they are oral… The answers to how and why our knowledge has become threatened lie embedded in the crux of the colonial infrastructure (Simpson 2004).

With the aid of such depoliticization, and often under the guise of humanitarian concern, powerful Western institutions – corporate, academic, and legal – have joined together to "save" indigenous knowledges by documenting them before they disappear. The disappearance of indigenous peoples, their cultures, and languages, by contrast, is assumed to be inevitable. Thus are the rich contexts that constitute living indigenous knowledges reduced to texts. "Documenting and digitizing Indigenous Knowledge is a seemingly benign way of appearing to recover Traditional Indigenous Knowledge while at the same increasing access to the knowledge and vastly increasing the potential for its exploitation" (Simpson 2004).

It is a process that is both extractive and assimilative. What is held to be of value is removed and processed, made over in the image of knowledge as formulated within the dominant knowledge system, by methods which "seek to remove knowledge from the person, its proper place (location), and the process from which it is embedded… its context" (McGregor 2004). Indigenous agricultural and medicinal knowledge, along with traditional medicines, plant genetic resources and the cell-lines of the peoples themselves, are "discovered," processed in laboratories, legally transformed into private intellectual property, rendered as commodities and placed for sale. A pattern that began with indigenous land and tangible resources, continues now with indigenous knowledge. The response to these developments from indigenous communities, elders, activists, and scholars has been twofold: (1) a fierce resistance to and critique of such ongoing imperialism coupled with (2) a wide-ranging effort to recover and preserve indigenous knowledge systems and all that they inhere in – language, land, and culture.

The resistance begins with an insistence that this contemporary phase of colonization be recognized for what it is. Since the way in which knowledge is conceived has ethical and political implications, knowledge systems must be assessed in those terms. The tendency to abstract, isolate, and immunize the various "extractive" projects of the dominant knowledge system has been subjected to vigorous critique. Indigenists have insisted on contextualizing recent research initiatives like the Human Genome Diversity Project and the Genographic Project, both historically in terms of the impact of earlier comparable research as well as currently in terms of how such research is situated within powerful social alignments that perpetuate inequities. They have mounted strong advocacy internationally, within both political and legal fora, for the inclusion of broader human rights standards in scientific research. Individual tribes and tribal members have initiated lawsuits to protect genetic materials and resources. Throughout these struggles, extraordinarily effective use has been made of modern communication technologies to exchange information, to generate solidarity and to ensure publicity and exposure. Organizations like the Indigenous Peoples Council on Biocolonialism (IPCB) is representative of these efforts by indigenous peoples across the globe. The IPCB provides educational and technical support "to assist indigenous peoples in the protection of their genetic resources, indigenous knowledge, cultural and human rights from the negative effects of biotechnology" (►www.ipcb.org).

Resistance has spawned numerous projects of recovery. In article after article, indigenous scholars and activists speak of "an Indigenous renaissance," of how native peoples are "taking control of their destiny," of the "revitalization of aboriginal societies." Evidence for this is plentiful and promising. It includes a range of initiatives to take control of education through curricular development and the creation of tribally controlled programs and schools. These consist of various measures to restore indigenous languages, such as language immersion programs and internet classes. The connection between language preservation and knowledge preservation is often underscored.

> Our native language embodies a value system about how we ought to live and relate to each other… It gives a name to relations among kin, to roles and responsibilities among family members, to ties with the broader clan group… There are no English words for these relationships… if you destroy our languages you not only break down these relationships, but you also destroy other aspects of our Indian way of life and culture, especially those that describe man's connection with nature, the Great Spirit and the order of things" (Taylor 1992).

Efforts are also underway to revive spiritual ceremonies and protect the land and ecosystems that sustain indigenous peoples themselves. "The ecologies in which we live are more to us than settings or places; they…do not surround Indigenous peoples; we are an integral part of them and we inherently belong to them" (Battiste and Henderson 2000).

What is at stake in all of this is more than continued physical existence. "Survival for Indigenous peoples… is an issue of preserving Indigenous knowledge systems in the face of cognitive imperialism. It is a global issue of maintaining Indigenous worldviews, languages and environments…a matter of sustaining spiritual links with the land" (Battiste and Henderson 2000). Determined to replace the politics of disappearance with the politics of debate and dialogue, indigenous people, and communities worldwide are pursuing these and other strategies of resistance and recovery (Shiva 1993). "Disappeared" knowledge systems are political acts, ones of omission as much as commission, and assumptions that the disappearance of indigenous knowledge systems, languages and peoples are somehow inevitable often lie behind both. The indigenous response has been that nothing in this is foreordained. It is in our power to prevent further loss. "It was not inevitable that Western knowledge would conquer Indigenous knowledge, or that our ways of life had to end. At any point in history we could have worked jointly toward conditions that would facilitate the return of Indigenous ways of being while appreciating the knowledge that supported those ways. Even now this is not an impossible task" (Wilson 2004).

Extra 1: Indigenous American Knowledge Transmission

Native American societies have utilized various forms and technologies of representation and achievement in order to execute, preserve, and transmit knowledge of many kinds across time and space. Knowledge-bearing objects, from the near and distant past, are still found embedded in the landscapes of the Americas. Knowledge as embodied in objects, texts, images, and practices may also be found in great abundance in museum collections of material culture and, most importantly, in the modern lives of Native American peoples, sometimes openly shared with the world and sometimes confined to the kiva or other sacred tribal spaces.

Some workers in Indigenous Studies have followed the lead of other disciplines (such as Cultural Studies), broadening the theoretical notion of the "text" to include any "object of study" which has a semiotic or tacit component. This is a recognition that indigenous knowledge may be found in any cultural artifact capable of communicating meaning or of transmitting knowledge and culture, whether through language, image, implicit relationship, structure, procedure or performance. Thus, in its most broadly inclusive sense, the term "knowledge bearing text" may refer to story, dance, calendar, map, architecture, textiles, hunting and farming practice, rock art, trails, spaces, stone placement or any other form in which knowledge may be fixed, discerned or performed.

One important dimension of this approach is the assumption that indigenous knowledge traditions cannot be subsumed in particular language texts, whether written or spoken, or in single objects, such as a maps and quipus, or in environments, altered and constructed, or in performance, such as agricultural practice or dance. Rather, knowledge is only fully apprehended by exploring connection, relationship, kinship, and reciprocity. In Indigenous America, all knowledge is ecological – a multiplicity of narratives, local practices, artifacts, and ontologies taken together with their intersections and interactions, physical and cultural.

Extra 2: International Resolutions and Declarations

Over the last quarter century, there has been no shortage of documents, issued by a range of international organizations and conferences, which recognize the intellectual stature and continuing social validity of indigenous modes of thought. These reports, resolutions and declarations usually emphasize the integrity and value of traditional knowledge while also attempting to bring indigenous knowledge and modern science into a more productive, and at the same time more socially equitable, working relationship.

Efforts to achieve such a reconciliation are manifest across a broad spectrum of social practices, such as agriculture, health care, and environmental and resource management, raising important and difficult issues in relation to sustainable development, equity in resource governance, knowledge access and control, intellectual property rights, the maintenance of biological and cultural diversity, and more.

Such matters have remained a major concern of UNESCO, which has commissioned, over a period of time, a number of reports on knowledge, culture and development, all of which have taken strong positions opposing past policies of cultural assimilation, policies which have been viewed, almost universally by indigenous peoples, as culturally destructive and even genocidal. The rhetoric and content of these reports can be seen in the brief extracts given below from two major UNESCO documents appearing in 1981 and 1995.

More recent UNESCO declarations have explored forging new links between indigenous knowledge systems and Western techno-scientific knowledge. In a 1999 Declaration adopted by the World Conference on Science in Budapest (jointly sponsored by UNESCO and the International Council for Science (ICSU), this position was developed in some detail. (See extract below)

Such initiatives as that taken at the Budapest conference, while widely welcomed, have generated serious tensions on both sides of the knowledge divide. For example, when the ICSU General Assembly was asked to ratify the above Declaration, major doubts were voiced, suggesting that unqualified approbation of indigenous knowledge was likely to encourage the advocates of pseudosciences, like astrology and intelligent design. The GA resolutions then "reaffirmed its support for the values and methods of verifiable science" while recognizing that the "relation between traditional knowledge and modern science is both important and a highly complex political and sociological question that cannot be addressed in a few lines of a wide ranging document."

These developments led the ICSU to set up a Study Group to prepare a report giving the question more thorough examination. The Study Group report was issued in 2002 in two different formats both of which strongly reassert the original thrust of the Budapest Declaration, while providing guidelines for distinguishing between indigenous knowledge and the pseudosciences. The Study Group report also gives limited recognition to the importance of reversing the trend for the "gradual weakening and disappearance of traditional knowledge." (See below for links to both of these documents.)

Finally, it is must be noted that these Resolutions and Declarations have brought few significant benefits to indigenous cultures around the world. Indeed, some scholars have taken the position that such documents, however well intentioned, have simply expedited the exploitation of these peoples.

UNESCO: Report on Endogenous Development and the Transfer of Knowledge Extracts from: *Domination or Sharing?* (1981)

What sort of transfer of knowledge would it be that had as its purpose or consequence the stifling of the culture of such groups or peoples, that sought to impose uniformity upon them by forcing them to adopt a model or systems devised and developed by an elite or a dominant nation?

This was the failing of colonialism. The danger is the same today… we introduce them to ways of life, techniques and economic imperatives which have the effect of destroying their traditions, imprisoning them in a new state of dependence, preventing them from making their own distinctive contribution.

Thought should be given to the desirability for each country to determine the models, the systems of representations and values and the technical knowledge that have been supplanted by those imposed from abroad. Some ancient practices… are proving essential to further progress. Evidence of this is to be found in such different fields as agriculture, physical education, medicine, art and philosophy…. Everywhere the curtain is being lifted on civilizations which, only yesterday, were still despised by the West…. The objective is not merely to preserve the national heritage but… the rehabilitation of traditional forms of knowledge and, above all, of the potentialities which have been stifled by the pressure of the dominant countries or groups.

What is the possible starting point for this innovative effort?… On the one hand, traditional education transmits knowledge and systems of representations and values that are peculiar to a society or group but does not prepare the ground satisfactorily for the receipt of knowledge from abroad. On the other hand, models of education imported from dominant countries detract, deliberately or otherwise, from everything that has its origin in the basic culture, while encouraging those dominated to seek the particular type of education which, in their eyes, is the only avenue to advancement in the new society. If the transfer of knowledge is to offer any opportunity for endogenous creative activity, it must be fed with resources from within.

UNESCO: World Commission on Culture and Development Extracts from: *Our Creative Diversity* (1995)

Cultural ethnocide is the process whereby a culturally distinct people loses its identity… as the use of its language and social and political institutions, as well as its traditions, art forms, religious practices and cultural values, is restricted… The challenge today for nations committed to cultural pluralism and political democracy, is to develop a setting that ensures that development is integrative… and inclusive. This means respect for value systems, for the traditional knowledge that indigenous people have of their society and environment, and for their institutions in which culture is grounded.

If the communities of the world are to improve their human development options they must first be empowered to define their futures in terms of who they have been, what they are today and what they ultimately want to be. Every community has its roots, its physical and spiritual affiliations reaching back symbolically to the dawn of time, and it must be in a position to honor them. It is crucial that a people's understanding of its values, beliefs, and other cultural patterns be developed – in the first place by the people directly concerned.

Through centuries of living close to nature, indigenous peoples throughout the world have acquired detailed knowledge of their environment and its natural resources…. Equally, ecological concerns are embedded in their very struggles for survival, identity, autonomy, and in many cases democratic rights and governance. Who decides the fate of tribal culture and nature?

UNESCO: World Conference on Science – Budapest Extracts from: *The Declaration on Science and the Use of Scientific Knowledge*

Version adopted by the Conference (1 July 1999)

26. That traditional and local knowledge systems as dynamic expressions of perceiving and understanding the world, can make and historically have made, a valuable contribution to science and technology, and that there is a need to preserve, protect, research, and promote this cultural heritage and empirical knowledge,

38. There is also a need to further develop appropriate national legal frameworks to accommodate the specific requirements of developing countries and traditional knowledge, sources, and products, to ensure their recognition and adequate protection on the basis of the informed consent of the customary or traditional owners of this knowledge.

Extracts from *Science Agenda-Framework for Action*

Version adopted by the Conference (1 July 1999)

2.2 Science, environment and sustainable development.

32. Modern scientific knowledge and traditional knowledge should be brought closer together in interdisciplinary projects dealing with the links between culture, environment and development in such areas as the conservation of biological diversity, management of natural resources, understanding of natural hazards and mitigation of their impact. Local communities and other relevant players should be involved in these projects.

33. Governments, in co-operation with universities and higher education institutions, and with the help of relevant United Nations organizations, should extend and improve education, training and facilities for human resources development in environment-related sciences, utilizing also traditional and local knowledge. Special efforts in this respect are required in developing countries with the co-operation of the international community.

3.4 Modern science and other systems of knowledge

83. Governments are called upon to formulate national policies that allow a wider use of the applications of traditional forms of learning and knowledge, while at the same time ensuring that its commercialization is properly rewarded.

84. Enhanced support for activities at the national and international levels on traditional and local knowledge systems should be considered.

85. Countries should promote better understanding and use of traditional knowledge systems, instead of focusing only on extracting elements for their perceived utility to the S&T system. Knowledge should flow simultaneously to and from rural communities.

86. Governmental and nongovernmental organizations should sustain traditional knowledge systems through active support to the societies that are keepers and developers of this knowledge, their ways of life, their languages, their social organization and the environments in which they live, and fully recognize the contribution of women as repositories of a large part of traditional knowledge.

87. Governments should support cooperation between holders of traditional knowledge and scientists to explore the relationships between different knowledge systems and to foster interlinkages of mutual benefit.

Knowledge Systems: Indigenous Knowledge of Trees and Forests

Klaus Seeland, Mihir K. Jena

Trees and forests act as indicators of cultural phenomena when interpreted in the context of a society. Their sociocultural interpretation indicates specific social needs and cultural values, while stimulating culturally distinct economic and technological processes. Methodologically, it is difficult to understand what *trees and forests* mean in a particular culture, as they are descriptive terms, not analytic ones. They invoke aesthetic and religious perceptions, botanical and silvicultural classifications, and economic valuations. The indigenous perspective is always an amalgamation of these perceptions and valuations, which characterizes the development of the local culture (Harrison 1993; Bahuchet 1993) and even culture in general.

Forests represent a legacy and are a testimony to the evolution or migration of biological species, flora and fauna, in various societies. Forests, trees, and their products are managed by indigenous people, who are knowledgeable about local consumption, in largely self-sustained rural communities often located in remote areas. To make use of these resources and manage them, indigenous knowledge of trees and forests encompasses locally available renewable natural resources and social and spiritual energies. At the same time, scientifically based commercial forestry has a specialized professional knowledge of how to manage forest resources, predominantly the production of timber for a market economy. The dilemma in dealing with forests and their products is that the commercial and indigenous approaches each serve different interests of people living in different social worlds. What "forest" and "knowledge of forests" mean to members of any culture are reflections of their worldview and traditions, which vary according to their different stages of economic and technological development. This knowledge goes beyond technical (i.e. botanical) knowledge, hunting skills, wood harvesting know-how, or non-timber forest product usage.

More than two decades ago, indigenous technical knowledge became an important topic in the debate over the economically and culturally sound development of communities, based on self-sustained agriculture in Third World countries (Brokensha et al. 1980). Ever since then, it has predominantly been discussed with regard to the development of appropriate new agricultural techniques, rather than the application of existing traditional ones that were once part and parcel of a self-sustaining mode of production (Warren et al. 1995). "Indigenousness" refers to something that originates locally in natural surroundings and is performed by a native community. It emerges in the form of an ethnic community's perceptions and experiences within their environment and continues as a process of observation and interpretation in relation to the locally acknowledged everyday rationalities and transcendental powers. Indigenousness constitutes a context of local social performance that makes sense between people who share a common rural habitat, language, and knowledge, be it exoteric (open to all) or esoteric (secret knowledge). Indigenous knowledge of trees and forests is a very important part of human life experience in a distinct and unique local setting. The local context is perceived as the universal framework in which knowledge matters, and is an authentic representation of being. This context is comprised physical facts and social interactions among people in the surroundings they perceive as their material world, and it combines with spiritual beliefs. Indigenous knowledge of trees and forests is not taught formally, but is an inherited or individually acquired configuration of knowledge, skills, know-how, and practical experience that grows inside this encapsulated world. It is bound to the environmental context and is acquired from and makes use of the local surroundings. The acquisition of indigenous knowledge is generally guided by utilitarian considerations. It is neither shared equally among all of the inhabitants of a locality nor is it a standardized and comprehensive account of *what is known*; it varies, sometimes tremendously. Often gender-specific knowledge separates what is known among people of the same area into different worlds. Indigenous knowledge is applied at the level of human senses – such as seeing, touching, and feeling – as well as by remembering natural phenomena. To our knowledge, there is no published record of indigenous people being interested in the traditional or local knowledge of another forest dwelling community. Knowledge for the sake of knowledge mostly does not exist in an indigenous community; curiosity – about flora, fauna, or other natural phenomena that do not have any practical value – is rare.

There is always a fundamental basis of inherited knowledge in every community, representative of the society in its typical geographical and climatic surroundings, that is individually interpreted, modified, and passed on for generations. The experience and knowledge of a people's ancestors are generally passed down orally to the younger generations, but increasingly often this transmission is limited by cultural change. Indigenous knowledge of trees and forests consists of a rather solid fund of knowledge, although the pace at which environmental conditions change may vary, becoming slower or quicker in the wake of social and cultural evolution. Devaluation of indigenous knowledge can have many causes: intruding alternative lifestyles, new modes of production, and degradation of important natural resources, as well as forest dwellers' being displaced into territories unknown to them or their world's being affected by laws and modernisation from outside.

The world of a forest dwelling community is an encompassing natural and social entity, a configuration of related natural and spiritual phenomena that gives cultural meaning to a particular location (Ballée 1994; Descola 1994; Jena et al. 2002). These entities are linked, for example, by language, using identical terms as metaphors for the same objects or symbols. Employing certain plants or animals or natural phenomena to represent supernatural, religious phenomena make up a common context or a sacred landscape.

A tree or forest is – in any society, and particularly in traditional non-Western societies – a matter of definition based on cultural values and perceptions. For instance, trees are venerated and deified as sacred phenomena in animistic cults. Or they are worshipped as representations of deities in more complex religions based on Holy Scriptures and an extensive iconography, as, for example, in Hinduism, where tulsi (*Ocimum basilicum* L.) is considered a sacred "tree" in which the Hindu god, Vishnu, resides. In other cultures, they are perceived as beautifying elements in a landscape or garden or simply as biomass or an economic commodity. In still other cultures, trees are predominantly viewed in terms of their functions, such as providing shade or shelter. In many forest dwellers' cultures there is kinship among humans, plants, and animals, either in the form of clan totems that regulate the social structure of a community or of symbolic marriages between humans and plants or animals. Rituals in which forest plants and animals play a significant role are based on the nature-based cosmogony of a forest dwelling community. Forests can be hunting grounds, wild gardens or swidden patches amidst the primeval forest, foraging grounds, sacred groves or some combinations of uses for indigenous communities.

The following example involves the Kuttia Kondh (Jena et al. 2006), a forest dwelling tribe in Orissa (India). The Kuttia Kondh perception of the life cycle of a tree is quite close to that of natural science.

The Kuttia Kondh are aware of the life cycle of a tree, because of the different changes that occur during its growth, described as a sequential process. At the time of birth, unlike human beings and animals, plants do not have a distinct shape and they are virtually indistinguishable from one another. During the later stages of growth, however, new structures (organs) evolve. Animals and human beings, in contrast, have structural (organ) limitations, and over time their organs age but do not change. In short, at birth the plants are all alike, but at later stages of growth they develop different characteristics and thus become distinct plants. The phenomenon of the birth of plants is known as *sate* (emerging from the earth) and the birth of animals and human beings is *pdite* (coming out of genital organs).

The changes observed in the lifespan of plants are described in the Kui language. Planting or dibbling a seed in the earth is known as *penka mete*, when the germinating seed breaks through the upper soil layers it is known as *tana genjite*, and when it emerges from the soil it is known as *kana aate*. The stage when foliage appears is termed *aaku gate*. The growth of shoots is *peda late*, and the emergence of inflorescence, a tree's floral axis, *tula parite*. The flowering stage is called *punga pute*, while the shedding of petals is known as *punge dumbite*. *Padasi kadgai ate* refers to the early fruiting stage. *Padasi juri ate* refers to the fruit maturation stage. Finally, the fruit drying stage is known as *padasi bachite*, and the bursting of fruit to scatter seeds is known as *penka ate*.

K

The Kuttia Kondh claim that the different stages from *penka mete* to *penka ate* describe the life cycle of a plant/tree, from the pre-germination to the post-germination phase. Trees are bound to a certain locality and, therefore, appear to be constant. The Kuttia people believe that trees are formed more than once within their life cycle, however, and that consequently what distinguishes plants from animals/humans is that, relative to a specific locality, the former are believed to go through a sequence of lives, while the latter live only one life from birth to death.

The life cycle of a plant is dependent upon water. According to the Kuttia Kondh, water is the most fundamental element necessary for a plant's survival. The skin (*palla*) and the plant's internal water transportation system (*lenja*) keep the water in the plant. If *lenja* is not working, *palla* can still absorb water; but if *palla* is absent, the water absorbed by *lenja* evaporates. The Kuttia Kondh believe that any abnormality occurring in the plant is due to a failure of the water transport system; for example, the drying up of a tree or parts of a tree comes from inadequate water absorption. *Paskadi* is a disease caused by the irregular swelling of parts of a plant as a result of a blockage in the water supply to the affected areas. *Bachine* refers to the drying up of a plant due to the lack of a water supply from the roots. *Kita bachine* is the drying of one part of the plant, and *pakodake bachine pakodake silali* refers to the drying of one lateral half of it while the other part remains alive.

Their understanding of the relationship between water and *palla* is demonstrated by a technique known as "girdling", which is used by the tribe to kill a tree. The Kuttia do not fell large trees. Instead, they use a labour-saving technique that involves the removal of a ring of bark at the tree base. The tree dies after a few days. The death of trees and plants following the removal of the *palla* is known as *mara grudu sate*, literally meaning "tree full dead". *Eju* (water), *daki* (the root base), and *palla* give plants and trees *jella* (life force). *Eju* is a metaphor for *jella*, which is believed to move up and down in the infant stage of plants. *Eju* is thought to become stationary at *daki* when the plants attain maturity. It is thus considered that *palla* and *jella* are mutually supportive and cannot survive without each other. The tree survives or perishes according to the relationship between *jella* and *palla*.

Now let us look at how the same community classifies its forest world. The type of natural vegetation growing on the hilltops has a particular significance for the Kuttia Kondh. They regard their hill god (*Soru penu*) as being solely responsible for the distribution of such vegetation. They believe that the god of the forest, usually named after a hill, bases his decision about the type of tree species that will grow there on the locality. It is claimed that he favours a tall tree on a hilltop for his abode, where he can enjoy the first touch of virgin rain. This provides an excellent vantage point for observing the lives of the villagers living at the foot of the hill. He uses the network of tree creepers to move from one place to another inside the forest, meeting the other *penus* and discussing the welfare of the Kuttia Kondh. He allows the growth of the grass at the base of the trees to make the forest floor softer so that divine beings can roam around freely.

Bati

The term *bati* has several meanings. *Bati* is the most common name for the forest, yet the term also refers to bushy vegetation, including undergrowth, shrubs, creepers, and herbs that lie between the foothills and hill slope areas. The Kuttia Kondh consider this to be forest in its primeval state. They also believe that the spreading branches of the trees (*kena*) inside the *bati* provide space for small plants to flourish (*ningine*). Their perception of the *bati* is that its vegetation grows quickly in soft soil (*dea vira*) that has an abundant water supply (a supply which is greater than that of the *kambani*, as its rainfall is supplemented by water runoff from the hilltop). The fertility of the *bati* is also enhanced by the many fast growing species which, after atrophying, add to the fertility of the soil.

The enormously varied fauna inside of the *bati* includes snake (*rachu*), such as the python (*masi*), monitor lizard (*boda*), porcupine (*saju*), pangolin (*jerandi*), many different varieties of bird, jungle fowl, peacock, rabbit, deer (*kateri*), and the occasional bear. The Kuttia Kondh believe that the larger snakes favour the coolness of the *bati*. The snakes feed on mice and fowl. The pangolin and porcupine are known to create underground burrows.

Umda (Grove)

This term is used to describe a patch of forest surrounded by rocky or barren land. *Umda* is commonly found on hilltops noted for their rocky, stony ground. The vegetation in such surroundings generally is comprised *Ficus benghalensis*, *Ficus religiosa*, and *Ficus scandens* (which are naturally dominant) along with *Terminalia tomentosa*, *Buchanania lanzan*, *Shorea robusta*, *Pterocarpus marsupium*, and *Acacia pinnata*. The term *umda*, however, is not restricted to this particular territory. Other small patches of forest found in non-rocky areas containing a wide variety of small trees and plant species (*ladenga*) at the centre of an open space are also called *umda*.

Tuleni (Burial Ground)

The term *tuleni* refers to an area of forest used by the Kuttia Kondh as a burial ground. A remote patch of land is chosen as a suitable site, as it is not clear whether the spirits of the dead roaming the *tuleni* will be malevolent or benevolent, and all forms of human interference should be limited. As a result, visitors to the *tuleni* are rare. Among the different plant species growing here, the sal tree (*Shorea robusta*) is given special status, as it is believed to be the abode of the *Dukeli penu* (god of ancestral spirits), the god most closely associated with the *tuleni*. Because firewood collection, tree felling, and the harvest of resins and edible products are activities that have traditionally been, and still are, prohibited within these areas, the sal trees have remained virtually undisturbed. The dead are considered to be forest dwellers (*kambanate*) and taking anything from the *tuleni* is considered to be synonymous with depriving the ancestral spirits of the food on which they subsist. The Kuttia Kondh are aware that so much as picking a leaf or snapping a twig inside the *tuleni* is taboo. There are three exceptions to this general rule. First of all, certain medicinal plants that are considered highly effective remedies for particular diseases are rarely collected in the *tuleni* by anyone other than the medicine man (*Kutaka*), who has the Dukeli penu's permission to use certain herbs and roots. Secondly, the funeral rites conducted by the village priest (*Jani*) involve breaking a brush stick to offer to the dead person; then with permission from the dead person's spirit, others can break brush sticks. Thirdly, the wood used for cremation is collected inside the *tuleni*, because wood from other areas is forbidden inside the *tuleni*. These taboos are believed to have existed since the times of the earliest settlements, and gradually certain myths have evolved concerning these lone virgin patches of wilderness. The fear felt by the Kuttia Kondh has ensured that such restrictions are upheld, which in turn guarantees the preservation of vegetation inside the *tuleni*.

A large variety of animals roam in this forest, such as deer, mouse deer, porcupine, sambar (*Cervus unicolor*), and boar. Yet hunting inside the *tuleni*, although not prohibited, is rare. On these occasions, the Kuttia Kondh hunt during daylight hours and as a group, rather than individually, for fear that ghosts and spirits may infect them with a fatal illness. During burial or cremation ceremonies, the village attendants pray to *Dukeli penu* so that he will provide them with sufficient game, even on a hunting expedition that takes place during the mourning period (*Dasah*) between the third and seventh day after a death. If *Dukeli penu* is satisfied with their prayer, the hunt is a success.

The villagers rarely move the location of the *tuleni*, for they believe that by doing so they disturb the spirits of their ancestors. The few circumstances that force them to abandon a site include an outbreak of a plant disease, the spread of certain parasite creepers (*Gachchi*), and forest fire (to which the sal species is especially susceptible). The leasing of forest patches by government departments to outsiders is also another reason for their abandonment of the *tuleni*. The Kuttia Kondh are required to ask permission from the *Dukeli penu* before deserting the site. The *tuleni* is not associated with any particular location, although it must be situated on a hill or in a forest and kept at a reasonable distance from any settlement.

Katani (Hill Forest)

In Kui, the language of the Kuttia Kondh, the term “wild” (*boti ne ajine*) has a number of definitions in reference to a description of the forest. In general, however, the wilder a forest, the greater the growth of vegetation and the presence of animals. According to the Kuttia Kondh’s definition, a forest is particularly wild when the concentration of trees is dense enough to prevent the penetration of sunlight (*ujada*). They also believe that trees compete among themselves as to who can grow closest to the sky (*wani*). The term *Katani* also means “wild”, and here it refers to wild vegetation, rather than to the presence of certain species of plants or animals. The *Katani* is a “four storied forest”. The ground cover consists of wild grass (*randa*) and herbs, the second storey is comprises bushes, and the third and fourth floors are or have *bati* and *kambani*, respectively.

What seems to be the most relevant appeal of indigenous knowledge of trees and forests emerging out of the principles of a local subsistence economy is a certain amount of political independence. The use of local indigenous knowledge of trees and forests spares forest dwellers from being turned into clients of the state administration, at least not the elder ones; right or wrong, they stick to their own traditions and customs (Seeland and Schmithüsen 2000). In periods of deregulation and decreased administrative capacity, an independent, self-sufficient social performance is very important.

The recent history of the expropriation of tribal societies by post-colonial nations is, in most cases, a depressing account of environmental colonialism, where ethnic sections of young developing nations are pauperized and expelled from their territories. They often vanish with the forests they used to live in. The knowledge of forest dwellers and poor peasants thus becomes the legacy of a cultural heritage and tradition that shaped the face of the forests. It is from here that some of today’s cultures originate.

The attempt at integrating indigenous knowledge of trees and forests into the development process of a society in transition would be naïve the society not to recognize the massive political obstacles confronting it. Contemporary environmental problems attempt to find solutions which are an up-to-date match to them (Seeland and Schmithüsen 2003). Although it may sound odd to some people, the traditional indigenous knowledge of past generations can be a valid match for today’s problems. Not only does it contain environmental knowledge in a technical sense, it also holds the accumulated wisdom of cultural traditions that have messages for those who are ready to listen to them. Although they lack the political bargaining power essential today, indigenous resource users and their knowledge may survive and be helpful in times of administrative deregulation and facilitate responsible management of resources in the regions where they live.

Knowledge Systems: Local Knowledge

DAVID TURNBULL

The concept of local knowledge has recently come to the fore in the field of the sociology of scientific knowledge, where it is a common empirical finding that knowledge production is an essentially local process. Knowledge claims are not adjudicated by absolute standards; rather their authority is established through the workings of *local* negotiations and judgments in particular contexts. This focus on the localness of knowledge production provides the condition for the possibility for a fully fledged comparison between the ways in which understandings of the natural world have been produced by different cultures and at different times. Such crosscultural comparisons of knowledge production systems have hitherto been largely absent from the sociology of science. A necessary condition for fully equitable comparisons is that Western contemporary technosciences, rather than being taken as definitional of knowledge, rationality, or objectivity, should be treated as varieties of such knowledge systems. Though knowledge systems may differ in their epistemologies, methodologies, logics, cognitive structures, or in their socioeconomic contexts, a characteristic that they all share is their localness. Hence, in so far as they are collective bodies of knowledge, many of their small but significant differences lie in the work involved in creating assemblages from the "motley" of differing practices, instrumentation, theories, and people (Hacking 1992). Much of that work can be seen as strategies and techniques for creating the equivalences and connections whereby otherwise heterogeneous and isolated knowledges are enabled to move in space and time from the local site and moment of their production and application to other places and times.

In this view, all knowledge systems from whatever culture or time, including the contemporary technosciences, are based on local knowledge. However within the master narrative of modernism, local knowledge is an oxymoron. Exploring this contradiction and the manifold meanings of local requires a brief excursion into postmodernism as well as some of the arguments underpinning the sociology of scientific knowledge.

Though postmodernism eludes definition and is more likely a stage of modernism than a marked epistemological break, there has been a recent coalescence of strands of thought in a wide variety of areas that have questioned the assumptions underlying modernism. Postmodernism is most frequently equated with the collapse of the concepts of rationality and progress held to accompany the emergence of the postindustrial society and is consequently concerned with the rejection of universal explanations and totalizing theories. But perhaps the strand that is most truly pervasive in the constellation of reformulated approaches to understanding the human condition is the emphasis on the local.

In physics, ecology, history, feminist theory, literary theory, anthropology, geography, economics, politics, and sociology of science, the focus of attention has become the specific, the contingent, the particular. This is the case whether it is a text, a reading, a culture, a population, a site, a region, an electron, or a laboratory. Within this diversity of uses of local there seem to be two broad and rather different senses being used. On the one hand there is the notion of a voice or a reading. The voice may be purely individual and subjective or may be a collection of voices belonging to a group, class, gender, or culture, but in all cases the notion captures one of the basic characteristic elements of postmodernism, courtesy of deconstruction, that all texts or cultures are multivocal and polysemous. That is they have a multiplicity of meanings, readings and voices and are hence subject to "interpretive flexibility" (Collins 1985). On the other hand, local is used both in the more explicitly geopolitical sense of place and in the experiential sense of contextual, embodied, partial, or individual. A range of disciplines from meteorology to medicine now recognize the necessity of focusing on the particular conditions at specific sites and times rather than losing that specificity in unlocalized generalizations.

The sociology of scientific knowledge is one of the most classically post of all modernisms and is therefore an area in which the local is also a thematic presence which is only now coming into focus. Some philosophers of science have come to re-evaluate the role of theory and argue that scientists practicing in the real world do not deduce their explanations from universal laws but rather make do with rules of thumb derived from the way the phenomena present themselves in the operation of instruments and devices. Similarly philosophers and sociologists of science alike have recognized for some time the lack of absolute standards and the role of tacit knowledge in technoscientific practice, and have sought to display the context in which the practice of science is manifested as craft skills and collective work. However the recognition of the social and material embodiment of skills and work in the cultural practice of individuals and groups has only recently coalesced into the general claim that all knowledge is local. Knowledge, from this constructivist perspective can be local in a range of different senses. “It is knowledge produced and reproduced in *mutual interaction* that relies on the *presence* of other human beings on a direct, face-to-face basis” (Thrift 1985). It is knowledge that is produced in contingent, site, discipline, or culture specific circumstances (Rouse 1987). It is the product of open systems with heterogeneous and asynchronous inputs “that stand in no necessary relationship to one another” (Pickering 1992). In sum scientific knowledge is “situated knowledge” (Haraway 1991).

Perhaps the most important consequence of the recognition of the localness of scientific knowledge is that it permits a parity in the comparison of the production of contemporary technoscientific knowledge with knowledge production in other cultures. Previously the possibility of a truly equitable comparison was negated by the assumption that indigenous knowledge systems were merely local and were to be evaluated for the extent to which they had scientific characteristics. Localness essentially subsumes many of the supposed limitations of other knowledge systems compared with western science. So-called traditional knowledge systems have frequently been portrayed as closed, pragmatic, utilitarian, value laden, indexical, context dependent, and so on. All of which was held to imply that they cannot have the same authority and credibility as science because their localness restricts them to the social and cultural circumstances of their production. Science by contrast was held to be universal, nonindexical, value free, and as a consequence floating, in some mysterious way, above culture. Treating science as local simultaneously puts all knowledge systems on a par and renders vacuous discussion of their degree of fit with transcendental criteria of scientificity, rationality, and logicality. Now the multidisciplinary approaches to understanding the technosciences which together constitute the sociology of scientific knowledge can be made more fully anthropological by the addition of a new subdiscipline called comparative technoscientific traditions.

Emphasizing the local in this way necessitates a reevaluation of the role of theory which is typically held by philosophers and physicists to provide the main dynamic and rationale of science as well as being the source of its universality. Karl Popper claims that all science is cosmology and Gerald Holton sees physics as “a quest for the Holy Grail,” which is no less than the “mastery of the whole world of experience, by subsuming it under one unified theoretical structure” (Allport 1991). It is this claim to be able to produce universal theory that Western culture has used simultaneously to promote and reinforce its own stability and to justify the dispossession of other peoples. It constitutes part of the ideological justification of scientific objectivity, the “god-trick” as Donna Haraway calls it; the illusion that there can be a positionless vision of everything. The allegiance to mimesis has been severely undermined by analysts like Richard Rorty, but theory has also been found wanting at the level of practice, where analytical and empirical studies have shown it cannot provide the sole guide to experimental research and on occasion has little or no role at all. The conception of grand unified theories guiding research is also incompatible with a key finding in the sociology of science: “consensus is not necessary for cooperation nor for the successful conduct of work.” This sociological perspective is succinctly captured in Leigh Star’s description:

> Scientific theory building is deeply heterogeneous: different viewpoints are constantly being adduced and reconciled… Each actor, site, or node of a scientific community has a viewpoint, a partial truth consisting of local beliefs, local practices, local constants, and resources, none of which are fully verifiable across all sites. The aggregation of all viewpoints is the source of the robustness of science (Star 1989, 46).

Theories from this perspective have the characteristics of what Star calls “boundary objects”; that is they are “objects which are both plastic enough to adapt to local needs and constraints of the several parties employing them, yet robust enough to maintain a common identity across sites.” Thus theorizing is itself an assemblage of heterogeneous local practices.

If knowledge is local we are faced with a problem: how are the universality and connectedness that typify technoscientific knowledges achieved? Given all these discrete knowledge/practices, imbued with their concrete specificities, how can they be assembled into fields or knowledge systems; or in Star’s terms “how is the robustness of findings and decision making achieved?” Ophir and Shapin ask, “How is it, if knowledge is indeed local, that certain forms of it appear global in domain of application?” The answers, considered here, lie

K

in a variety of social strategies and technical devices that provide for treating instances of knowledge/practice as similar or equivalent and for making connections, that is in enabling local knowledge/practices to move and to be assembled.

Research fields or bodies of technoscientific knowledge/practice are assemblages whose otherwise disparate elements are rendered equivalent, general, and cohesive through processes that have been called "heterogeneous engineering" (Law 1987). Among the many social strategies that enable the possibility of equivalence are processes of standardization and collective work to produce agreements about what counts as an appropriate form of ordering, what counts as evidence, etc. Technical devices that provide for connections and mobility are also essential. Such devices may be material or conceptual and may include maps, calendars, theories, books, lists, and systems of recursion, but their common function is to enable otherwise incommensurable and isolated knowledges to move in space and time from the local site and moment of their production to other places and times.

Some of these devices have been revealed relatively unproblematically through direct observation. Others are less susceptible to investigation and analysis, being embodied in our forms of life. One way to catch a glimpse of these hidden presuppositions and taken for granted ways of thinking, seeing, and acting, is to misperceive, to be jolted out of our habitual modes of understanding through allowing a process of interrogation between our knowledge system and others. Such an interrogative process of mutual intertranslation can enable us to catch sight of the cultural glasses we wear instead of looking through them as if they were transparent.

This challenging of the totalizing discourses of science by other knowledge systems is what Foucault had in mind when he claimed that we are "witnessing an insurrection of subjugated knowledges" and corresponds to an emphasis on the local that has emerged in anthropology at least since Clifford Geertz's *Interpretation of Cultures*. In his critique of global theories and in his emphasis on "thick description" Geertz pointed out that cultural meanings cannot be understood at the general level because they result from complex organizations of signs in a particular local context and that the way to reveal the structures of power attached to the global discourse is to set the local knowledge in contrast with it.

Equally there is the pervasive recognition characterized as postcolonialism that the West has structured the intellectual agenda and has hidden its own presuppositions from view through the construction of the other. Nowhere is this more acute than in the assumption of science as a foil against which all other knowledge should be contrasted. In the view of Marcus and Fischer we are at an experimental moment where totalizing styles of knowledge have been suspended "in favour of a close consideration of such issues as contextuality, the meaning of social life to those who enact it and the explanation of exceptions and indeterminants." In this emphasis on the local we are postparadigm.

However we should not be too easily seduced by the apparently liberating effects of celebrating the local since it is all too easy to allow the local to become a "new kind of globalizing imperative" (Hayles 1990). In order for all knowledge systems to have a voice and in order to allow for the possibility of intercultural comparison and critique, we have to be able to maintain the local and the global in dialectical opposition to one another. This dilemma is the most profound difficulty facing liberal democracies now that they have lost the convenient foil of communism and the world has Balkanized into special interest groups by genders, race, nationality, or whatever. By moving into a comparatist mode there is a grave danger of the subsumption of the other into the hegemony of western rationality, but conversely unbridled cultural relativism can only lead to the proliferation of ghettos and dogmatic nationalisms. We cannot abandon the strength of generalizations and theories, particularly their capacity for making connections and for providing the possibility of criticism. At the same time we need to recognize reflexively that theory and practice are not distinct. Theorizing is also a local practice. If we do not recognize this joint dialectic of theory and practice, the local and the global, we will not be able to understand and establish the conditions for the possibility of directing the circulation and structure of power in knowledge systems. It is in the light of this recognition that I want to consider the ways in which the movement of local knowledge is accomplished in different knowledge systems and their consequent effects on the ways in which people and objects are constituted and linked together; that is their effects on power. The essential strength of the sociology of scientific knowledge is its claim to show that what we accept as science and technology could be other than it is. The great weakness of the sociology of scientific knowledge is the general failure to grasp the political nature of the enterprise and to work toward change. With some exceptions it has had a quietist tendency to adopt the neutral analyst's stance that it devotes so much time to criticizing in scientists. One way of capitalizing on the sociology of science's strength and avoiding the reflexive dilemma is to devise ways in which alternative knowledge systems can be made to interrogate each other.

Considerable advances in understanding the movement of local knowledge have been made possible through Bruno Latour's insightful analysis. For Latour the most successful devices in the agonistic struggle are those which are mobile and also "immutable, presentable, readable, and combinable with one another." These immutable mobiles are the kinds of texts and images that the printing press and distant point perspective have made possible. These small and unexpected differences in the technology of representation are on his account the causes of the large and powerful effects of science. That which was previously completely indexical, having meaning only in the context of the site of production, and having no means of moving beyond that site, is standardized and made commensurable and representable within the common framework provided by distant point perspective. Hence that which has been observed, created, or recorded at one site can be moved without distortion to another site. At centers of calculation such mobile representations can be accumulated, analyzed, and iterated in a cascade of subsequent calculations and analyses.

Latour's account has been augmented by the work of Steven Shapin and Simon Schaffer in the *Leviathan and The Air Pump* (1985). They have shown that experimental practice in science is sustained by a range of social, literary, and technical devices and spaces that we take for granted but which had to be created deliberately to overcome the fundamentally local and hence defeasible character of experimentally derived knowledge claims. In the seventeenth century, the problem for Robert Boyle, one of the earliest experimentalists, was to counter the arguments of his opponent Thomas Hobbes about the grounding of true and certain knowledge which they both agreed was essential in a country riven by dissent and conflicting opinion. Reliable knowledge of the world, for Hobbes, was to be derived from self-evident first principles, and anything that was produced experimentally was inevitably doomed to reflect its artifactual nature and the contingencies of its production; its localness would deny it the status of fact or law. Boyle recognized the cogency of these arguments and set out to create the forms of life within which the knowledge created at one site could be relayed to and replicated at other sites. In order for an empirical fact to be accepted as such it had to be witnessable by all, but the very nature of an experimental laboratory restricted the audience of witnesses to a very few. Boyle, therefore, had to create the technology of what Shapin calls virtual witnessing. For this to be possible three general sorts of devices or technologies had to be developed. Socially groups of reliable witnesses had to be formed. Naturally in the seventeenth century they were gentlemen. These gentlemen witnesses had to be able to communicate their observations to other groups of gentlemen so that they too might witness the phenomena. This required the establishment of journals using clear and unadorned prose that could carry the immutable mobiles, experimental accounts, and diagrams. The apparatus had to be made technically reliable and reproducible, but perhaps most importantly the physical space for such empirical knowledge had to be created.

Hobbes, of course, was right: experimental knowledge is artifactual. It is the product of human labor, of craft and skill, and necessarily reflects the contingencies of the circumstances. It is because craft or tacit knowledge is such a fundamental component of knowledge production that accounts of its generation, transmission, acceptance, and application cannot be given solely in terms of texts and inscriptions. A vital component of local knowledge is moved by people in their heads and hands. Harry Collins, a sociologist of science, has argued that this ineradicable craft component in science is ultimately what makes science a social practice. Because knowledge claims about the world are based on the skilled performance of experiments their acceptance is a judgment of competence not of truth. An example of the centrality of craft skill is the TEA laser, invented in Canada by Bob Harrison in the late sixties, which British scientists attempted to replicate in the early seventies. "No scientist succeeded in building a laser using only information found in published or other written sources" and furthermore the people who did succeed in building one were only able to do so after extended personal contact with somebody who had himself built one. Now TEA lasers are blackboxed and their production is routine and algorithmic. But in order to become routinized, Harrison's local knowledge had to be moved literally by hand.

Joseph Rouse (1987, 72) in considering the contemporary production process of scientific knowledge has summarized the implications of this understanding of science:

> Science is first and foremost knowing one's way about in the laboratory (or clinic, field site etc.). Such knowledge is of course transferable outside the laboratory site into a variety of other situations. But the transfer is not to be understood in terms of the instantiation of universally applied knowledge claims in different particular settings by applying bridge principles and plugging in particular local values for theoretical variables. It must be understood in terms of the adaptation of one local knowledge to create another. We go from one local knowledge to another rather than from universal theories to their particular instantiations.

According to the historian of science Thomas Kuhn the way a scientist learns to solve problems is not by applying theory deductively but by learning to apply theory through recognizing situations as similar. Hence theories are models or tools whose application results from situations being conceived as or actually being made equivalent. This point is implicit in the recognition that knowledge produced in a laboratory does not simply reflect nature because nature as such is seldom available in a form that can be considered directly in the lab. Specially simplified and purified artifacts are the typical subject of instrumental analysis in scientific laboratories. For the results of such an artificial process to have any efficacy in the world beyond the lab, the world itself has to be modified to conform with the rigors of science. A wide variety of institutional structures have to be put in place to achieve the equivalences needed between the microworld created inside the lab and the macroworld outside in order for the knowledge to be transmittable. The largest and most expensive example of this is the Bureau of Standards, a massive bureaucracy costing six times the R&D budget. Without such social institutions the results of scientific research are mere artifacts. They gain their truth, efficacy, and accuracy not through a passive mirroring of reality but through an active social process that brings our understandings and reality into conformity with each other.

The result of the work of Latour, Collins, Shapin, Star, Hacking, Rouse, and others has been to show that the kind of knowledge system we call Western science depends on a variety of social, technical, and literary devices and strategies for moving and applying local knowledge. It is having the capacity for movement that enables local knowledge to constitute part of a knowledge system. This mobility requires devices and strategies that enable connectivity and equivalence, that is the linking of disparate or new knowledge and the rendering of knowledge and context sufficiently similar as to make the knowledge applicable. Connectivity and equivalence are prerequisites of a knowledge system but they are not characteristics of knowledge itself. They are produced by collective work and are facilitated by technical devices and social strategies. Differing devices and strategies produce differing assemblages and are the source of the differences in power between knowledge systems.

In conclusion, it has been argued that Western science, like all knowledge in all societies, is inherently local, and furthermore other non-Western societies have developed a variety of social and technical devices for coping with that localness and enabling it to move. Some of them are technical devices of representation like the mason's templates, and the Incan *ceques* and *quipus*. Some of them are abstract cognitive constructs, like the Anasazi and Incan calendars, and the Micronesian navigation system. All of them also require social organization, rituals, and ceremonies. All of them have proved capable of producing complex bodies of knowledge and in many cases have been accompanied by substantial transformations of the environment. The major difference between Western science and other knowledge systems lies in the question of power. Western science has succeeded in transforming the world and our lives in ways that no other system has. The source of the power of science on this account lies not in the nature of scientific knowledge but in its greater ability to move and apply the knowledge it produces beyond the site of its production. However at the end of the twentieth century we can now perceive that there is a high cost to pay for science's hegemony. Much of that cost in terms of environmental degradation and ethnocide is due not so much to the totalizing nature of scientific theories but to the social strategies and technical devices science has developed in eliminating the local.

The task of resisting and criticizing science may now be addressed by reconsidering the causes of its dominating effects. Without the kinds of connections and patterns that theories make possible we will never be able to perceive the interconnectedness of all things. Without the awareness of local differences we will lose the diversity and particularity of the things themselves. Thus, rather than rejecting universalizing explanations what is needed is a new understanding of the dialectical tension between the local and the global. We need to focus on the ways in which science creates and solves problems through its treatment of the local. Science gains its truthlike character through suppressing or denying the circumstances of its production and through the social mechanisms for the transmission and authorization of the knowledge by the scientific community. Both of these devices have the effect of rendering scientific knowledge autonomous, above culture, and hence beyond criticism. Equally problematic is the establishment of the standardization and equivalences required in order that the knowledge produced in the lab works in the world. The joint processes of making the world fit the knowledge instead of the other way round and immunizing scientific knowledge from criticism are best resisted by developing forms of understanding in which the local, the particular, the specific, and the individual are not homogenized but are enabled to talk back.

Knowledge Systems of the Olmec

Carolyn E. Tate

People in Formative Period Mesoamerica (2000–250 BCE) developed an array of empirical knowledge and technological adaptations that became the foundation for the later great civilizations. These included domesticated plants, skilled ceramic production, lithic technologies, and long-distance travel and trade.

This essay will focus on the little-studied topic of Olmec knowledge of the human body. It uses as evidence the hundreds of Olmec three-dimensional sculptures of the human figure in stone and clay (Fig. 1). Apparently the Olmec recorded their empirical observations about the process of human gestation and about the innate energies of the adult human body in many kinds of sculptures (Fig. 2). The practice of encoding knowledge and lore in sculpture characterizes all Mesoamerican cultures. It is documented for the sixteenth-century Yucatec Maya, whose word "its" refers to art not as a category of objects made to be admired, but the related knowledges of science, art, philosophy, and wisdom.

Between 1000 and 400 BCE, Mesoamericans made small stone figurines that could be transported across linguistic zones to convey the new knowledge. By

K

900 BCE, the subjects of these sculptures and of the incised symbol system were quite consistent in cultures across southern Mesoamerica. Most of the sculptures portrayed human beings, and some of these showed humans in specific stages and states of being. Many sculptures illustrated Olmec knowledge of human gestation, bodily organs, and mental disciplines of the body. Because the sculptures and the knowledge they encoded were linked to ritual practice, we might consider the sculptures as illustrations of spiritual technologies. However, Olmec knowledge of gestation and the disciplines of the human body also informed agriculture, and calendrics, and was part of a long-distance trade technology.

The name "Olmec" was given in the early twentieth century to the inhabitants of ancient Mexican Gulf Coast civic centers such as La Venta and Tres Zapotes. At that time, little evidence of the Formative Period existed, and many scholars assumed that most early culture traits originated in the Gulf Coast region. Since then archaeologists have shown that nascent civilizations in Central Mexico, Highland Oaxaca, the Pacific Coast, Guerrero, and the Gulf Coast all contributed to an ideological system that coalesced by the Middle Formative. This article follows the (debatable) convention of referring to all the groups who participated to some extent in this ideological system as "Olmec."

By no means did ALL Olmec sculptures portray these scientific subjects. Many sculptures showed humans as a part of creation stories or engaged in political events (Fig. 3). However, a significant number of monumental and small sculptures displayed Olmec knowledge of life processes, beginning with gestation.

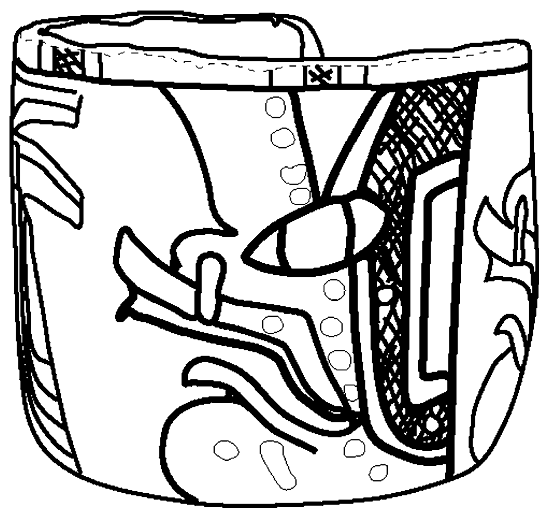
The Human Embryo

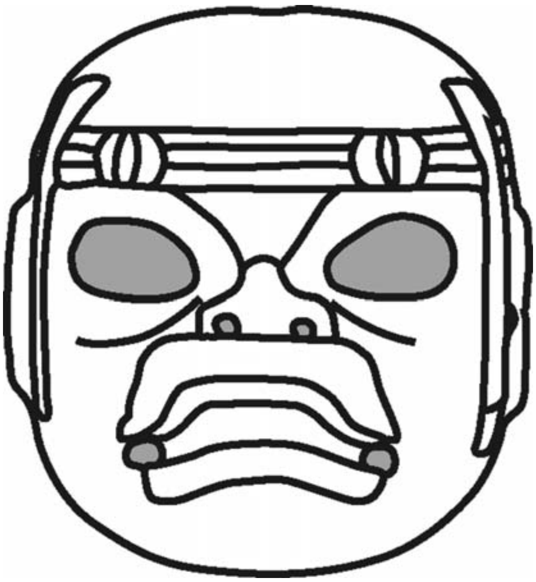
Recent research strongly suggests that a human embryo image formed part of the earliest symbol system of Mesoamerica. A figurine from Oaxaca (made in the Tierras Largas Phase, about 1400 BCE, at the cusp of the appearance of "Olmec" traits in Mesoamerica) portrayed a human female with a fetus enclosed in a cavity in the abdomen (Marcus 1998). In the Basin of Mexico around 1200 BCE, villagers created a stylized image of the human embryo at about 48–56 days of gestation (Fig. 4). Within the next 300 years, many groups throughout Mesoamerica forged, shared, and adapted an ideological system, or a set of interconnected concepts and metaphors. To show alliance to these concepts and the supernatural and meta-environmental powers they indexed, men wore images of the human embryo in greenstone (Fig. 5). This kind of exotic, elite regalia evoked powers of creation, vital energy, and the dawn of life. The "embryo" symbol was one of the most widespread characteristics of the "Olmec" civilization. Earlier in the twentieth century, scholars referred to the symbol as "were-jaguar," "were-snake," or "were-crocodile." The interpretation of it as "embryo" remains controversial (see Extra).



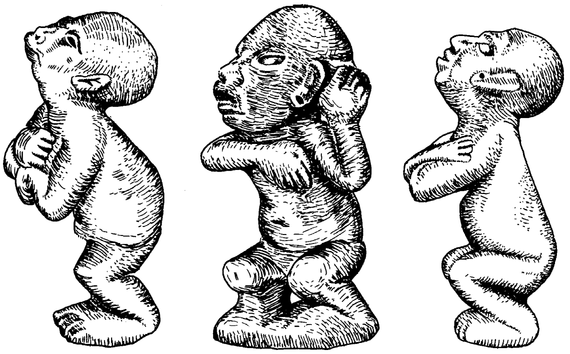
Knowledge Systems of the Olmec. Fig. 4 An early form of the stylized embryo image on a ceramic vessel from Tlapacoya, a village in the Basin of Mexico. About 1200 BCE. Drawing by Corey Escoto.

The Human Fetus

The argument that the Olmec focused on the human embryo as a major symbol of vital spirit is strengthened by the fact that they also made sculptures of the human fetus (Fig. 6). About 50 such sculptures are known, many from the Gulf Coast. One small fetus figurine was excavated, along with an embryo figurine and two of children, from La Venta, which demonstrates that the fetus was a legitimate subject of sculpture (not the invention of modern forgers). Also, three colossal fetus sculptures were found at La Venta in the 1940s and recently installed at the site museum. Fetus sculptures have the disproportionately large head and flexed limbs of a human fetus. They must have been modeled on fetuses that aborted, yet all are portrayed alive. Their meaning is less clear, but I suspect that they were considered to be intermediaries between the world of humans and that of the supernatural life forces.



Knowledge Systems of the Olmec. Fig. 5 A greenstone headdress ornament of the embryo face adorned with a headband. Private collection, drawing by Corey Escoto.



Knowledge Systems of the Olmec. Fig. 6 Olmec sculptures of the human fetus. Author drawing.

The human infant

Olmec exploration of the human gestation process continued with representations of infants (Fig. 7). These most often appear in the form of large, sometimes life-sized, hollow ceramic figurines. The proportions and faces of some of these figures seem older than infants, so the significance of the hollow figures seems to vary. Nevertheless, they seem to have celebrated the rapid growth and vitality of infants as well as an acknowledgment of the precariousness of human life in its early years. Just as many communities today carry statues of specific saints into the agricultural fields to bless and promote the fertility of the crops, these hollow babies may have brought their vital energy to ancient crops (Fig. 8).

Human Gestation and the 260-Day Calendar

The ancient focus on human gestation explains the priority of the 260-day calendar in Mesoamerican ideology, and ties ancient knowledge of lunar cycles ($9 \times 29 = 261$) to menstruation and gestation. The 260-day calendar seems to have been established in Oaxaca (where the earliest known figurine of a woman with a fetus in an abdominal cavity occurred), well before the existence of the Long Count. It continued to serve as a divinatory calendar, primarily consulted by female

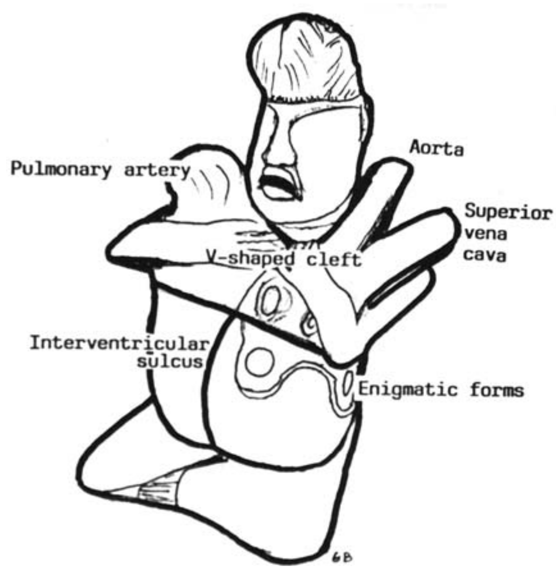
Knowledge Systems of the Olmec. Fig. 8 This embryo sculpture and canoe of "matching" jadeite were found together at Cerro de las Mesas. The excavator, Drucker (1955), noticed that the figurine "fit" into the canoe. On each end of the canoe is an incised embryo symbol. Drawing by Corey Escoto.



Knowledge Systems of the Olmec. Fig. 9 A drawing of a small ceramic vessel representing a seated human with an outsized, but fairly accurate, human heart, Drawing by Gordon Bendersky.

clients, into the sixteenth century and even later. Many Mesoamerican groups considered the life cycle of maize to be 260 days, like the gestation of humans, despite the fact that from the Western point of view, it is shorter. Rituals conducted before the planting of maize and after its harvest extended the life of maize to parallel the period of human gestation. The Maya believed that humans were made of maize. "Humans are maize" was a major operative metaphor of many Mesoamerican cultures.

Olmec Art as Medical Illustration

Not only did the Olmec illustrate the processes of embryogenesis and human infancy, they also explored and illustrated certain organs and congenital anomalies.

One small hollow ceramic vessel illustrates a seated human figure with an exposed heart of exaggerated size (Fig. 9). Gordon Bendersky, MD, a cardiologist, has discussed the relative accuracy of the portrayal, concluding that the image must have been made from direct observation of a heart but that certain features were changed "to display the organ more symmetrically and to facilitate the placement of the head directly on the sulcus" (Bendersky 1997). As with Olmec representations of the human embryo, the representation of the subject in sculpture was modified (or in artistic terms, "stylized") – the actual thing was transformed into a symbol.

Dr. Bendersky (2000) has also made a case that a number of figurines with a normal number of facial features served to illustrate an incidence of congenital defects in the small farming community of Tlatilco, on the shore of Lake Texcoco in highland Mexico. A number of figurines from the site exhibit two heads, or sometimes, double-facedness, with two noses and mouths and three or four eyes (Fig. 10). While these figurines have traditionally been interpreted as mythological beings, Bendersky found a 1:1 correspondence between documented cases of a congenital anomaly called diprosopus and the range of features shown in the Tlatilco figurines.

The case is compelling that Formative Period Mesoamericans were fascinated with the processes of human gestation and physical development. Another class of objects, stone figurines of humans, suggests that they were also interested in the potential of the disciplined body, in what we might call mind-body communication.

Exploring the Spiritual Potential of the Adult Body

Small-scale stone images of the human figure occur across Mesoamerica (except in the Maya area) in the later Formative Period (900–400 BCE). From Guerrero to the Gulf Coast to the Pacific Slope, "Olmec" people made stone figurines in only a few variations: standing figures, seated figures, kneeling or half-kneeling, and lying on the belly with the legs bent backward so the feet touch the head.

Over 100 "standing figures" with an exceptionally consistent posture have been published. The best known of these are the sixteen that constitute a group known as La Venta Offering 4. Each figure is made of a different stone, probably by a different sculptor, yet the poses are nearly identical. The figures neither wear costumes nor hold regalia, so the focus of the piece is

Knowledge Systems of the Olmec. Fig. 10 *Left*: Tlatilco figurines, from about 1100 BCE, exhibit multiple features or heads. Drawing by Gordon Bendersky, used with kind permission. *Right*: Photo of an individual exhibiting a form of diprosopus, courtesy Gordon Bendersky.

on the pose itself (Fig. 11). The figures stand with their weight distributed symmetrically. The knees are flexed and the pelvis is tilted to straighten the spine (Fig. 12). The limbs are loose and muscles are not articulated, providing a sense of focused relaxation. In sum, the figures exhibit a perfectly straight spine with relaxed limbs and a focused gaze. This pose looks comfortable, but it is deceptively difficult to maintain. Flexing the knees demands effort from the quadriceps, the largest muscle in the body. After a minute of standing this way, the heart begins to pound. This posture is common to several physical-spiritual disciplines. In Hatha Yoga, this position is called Tadasana, the Mountain Pose. It is said to teach endurance, steadiness, contentment, and enable a person to experience the flow of energy spiraling up from the feet to the top of the head. In T'ai Chi, the pose is called Hun-Yuan Kung or Beginning Posture. In this position, it is said that the earth is invoked by the rootedness of the feet, the sky by the verticality of the spine, and humanity by the sinking of energy to the Dan T'ien, an energy center below the navel. In both traditions, the pose is used to focus the mind or meditate. However, although both Asian traditions are at least as old as 1000 BCE, no known portrayals of this pose survive from Asia from this era.

Not all Olmec standing figures portray nude figures in this pose. A few wear clothing and hold weapons or ritual items. Their meaning is distinct from that of the standing meditators.

Seated stone figurines are more rare in the Olmec corpus, but the few that exist (about eight, half of which are from archaeological contexts) also seem to exhibit a disciplined posture (Fig. 13). Each sits cross-legged with a straight spine. In a few, the hands are resting on bent knees. At least two sit in a half-lotus position, with one foot resting on the other knee.

Knowledge Systems of the Olmec. Fig. 11 Standing figures from La Venta Offering 4. Photo by John Verano.

Quite a few Olmec sculptures portray a human in a pose clearly based on a very difficult disciplined posture. The figure reclines on the stomach and bends backward to form a wheel (Fig. 14). The elbows support the elevated chest and head. The back and legs arch so that the feet touch the top of the head. Hatha Yoga includes several such postures. Within the many

systems of yoga, these postures are ascetic disciplines whose practice and attainment involves controlling the body and mind, sometimes with the goal of realizing oneness with the divine consciousness. In the past, these backward arching figures have been called “acrobats” and considered to be “court jesters.”

Another subject of Olmec stone figurines shows a person kneeling or half-kneeling with hands on the knees. In many of these, an animal skin partially covers the human figure. The skin has split and is peeling away, like that of a snake or lizard that sheds its skin. Kent Reilly (1989) has interpreted such figures as humans transforming into an animal alter ego. In light of the focus on the human embryo in Olmec sculpture, symbolic of the rapid transformation of the human “seed” into various animal-like forms and finally into a human form, the fetus, this adult transformation makes sense as a part of larger ideological structures.

In summation, While Formative Period people were domesticating food plants, building early public architecture, engaging in long-distance travel and trade, getting to know their environment, and establishing the ideology that would permeate later Mesoamerican cultures, they were also exploring the human body itself. One major focus was on the mysteries of human development from the stage of the embryo, which appears as much like a tailed animal, bird, or fish as a human, to the fetus, which is clearly human, to infancy. No later Mesoamerican civilization focused to this extent on the early stages of life, the "seed" stages, as did the people in these seminal societies. It is also clear that a guiding metaphor of Mesoamerican civilization, "humans are maize," so clearly expressed in the Maya *Popol Vuh,* originated in the Formative Period. Another major focus of their research, which they expressed in sculpture, was that of the physical-spiritual disciplines of the body. Although later cultures, notably the large central Mexican city of Teotihuacan, made similar standing and seated stone figures, the postures are less specifically "disciplined" and the meaning of these figures seems to have changed in the Classic Period.

Extra: Human Embryo or Were-Jaguar in Olmec Sculpture?

One of the characteristic features in Olmec art is a symbol that is widely known as a were-jaguar. The symbol appeared as a disembodied head on headdress ornaments, as a whole body in the form of figurines (Fig. 15) and large ritual axes, and on monumental stelae (Figs. 16 and 17). First advanced in 1946, the interpretation of this symbol as a were-jaguar has survived many attempts to replace it with alternatives. All of these have pointed out that the symbol lacks the pointed ears, fangs, claws, whiskers, tail, spots, and body of a jaguar. The only vaguely jaguar-like features are a puffy upper lip, a flat nose, and an open mouth, usually toothless. Newer interpretations contend that the symbol was based on another animal: a crocodile, snake, or a fantastic creature or represents a deity. It was considered a hallmark of Olmec art that the Olmec portrayed "biologically impossible creatures." Very recent research strongly suggests that the symbol IS biologically based and that it represents the human embryo of about 56 days (Fig. 18).

To explore the proposal that this image represents the human embryo, this discussion compares the features of a human embryo

Knowledge Systems of the Olmec. Fig. 15 Figurine representing and Embryo with a pronounced crest on its head. Private collection, drawing by Corey Escoto.

of 56 days to those of two Olmec pieces, a figurine and an "axe" (Fig. 19):

- *Overall proportions*: in each case, the head is very large in proportion to the body. The human embryo's torso from the base of the head to the rump head is about 1.25 times the size of the head. The same is true of the Olmec figurine. On the axe, the head is even larger than the rest of the stylized body.
- *Head*: the embryo's forebrain, midbrain, and hindbrain form bulges that create the shape of the head. Soft bony portions are separated by large sutures called fontanels. The anterior fontanel is diamond-shaped. The Olmec figurine's head shows these typical swelling masses. The stylized forms on the axe give the head a slightly curved, tapering rectangular shape. Both the figurine and the axe show the anterior fontanel. In the figurine it is subtle but present; in the axe it takes the stylized "cleft-head" form. In other examples it is diamond-shaped.
- *Eyes*: lidless oval eyes sit on the sides of the head in the human embryo (Fig. 20). The eyes are still open but eyelids begin to form between days 52 and 57. On the figurine and axe, the eyes are widely spaced and lidless although on the figurine, which seems to show an embryo of about 57–58 days, lids are beginning to close over the eyeball (Fig. 21).
- *Nose and mouth*: at four weeks, the embryo exhibits a single, arching slit where the nose and mouth will soon develop. In the 5th–6th week, buds at the corners of the slit, called maxillary prominences, grow rapidly toward each other to form an upper lip that separates the nostrils from the mouth. The maxillary prominences are just that – prominent or puffy. At this stage, the nose barely projects above a swollen upper lip. This facial development occurs rapidly and at the stage during which the embryo is frequently lost from the womb (this will be explained below). Anyone who had seen several embryos would have noticed the swollen upper lip and shallow nasal pits. The principal feature of the Olmec symbol is its "puffy upper lip" and arching mouth, usually toothless. Above the upper lip are the flat nostrils of a human embryo. Sometimes Formative Period people added the dentition of various animals to the basic image to confer certain mythical associations or animal-like qualities on the symbol (see Fig. 22).
- *Ears*: on an embryo the ears first appear as small arches on the sides of the neck. They do not move up onto the head until Week 10. Similarly, on the figurine, ears are not shown. On this axe, the maker included the cultural symbols of the headband and long earflaps but no ears.
- *Limbs*: in the developing embryo, the arms appear in Week 4, slightly before the legs. Hand plates appear in Week 6 but toe rays only in Week 7. Most of the Olmec images show short arms with poorly differentiated fingers. Both the figurine and axe show arms that are better developed than legs. Apparently the Olmec took care to show the developing stages of the limbs in both naturalistic and conventionalized images.

The degree of correspondence between the Olmec symbol and the human embryo is so high that there is little question that the symbol indeed is a stylized representation of an embryo. The use of the embryo as a symbol points to knowledge of the human gestation process. Could this be possible? Access to embryos in the Formative Period was at least as high as it is today. Since about 20% of recognized pregnancies in the modern industrialized societies terminate between 42 and 56 days, (Weeks 6–8) it is also likely that miscarriage was at least that common in the past. The embryo measures from 20 to 30 mm at that stage, and so is quite visible. Human embryos were described in texts from other cultures, such as in the *Garbha Upanishad* (1400 BCE, India), so clearly ancient people did observe them.

Although there are no written texts from the Formative Period to corroborate the notion that the symbol represents an embryo, there are many references by modern indigenous people to embryos, placentas, conception, and gestation. Two modern stories illustrate the survival of this cultural focus. These stories illuminate what the embryo might have meant to the Olmec.

The first story comes from Nahuatl (Aztec) speakers. In a village in Veracruz, people place a cedar box in the shrine of the earth mother, Tonantsij. Her domain includes ruling over her children, known as the seed spirits, who are "…the life force or potential for fertility of each crop" (Sandstrom 1991: 244). These "seed spirits" seem to be a modern version of the ancient embryo symbol. From woman-made paper, villagers form elaborately dressed figures of the seed spirits and place them in the box. These are cleaned, renewed, and redressed annually. Throughout the year they are given offerings of food, so they will not want to return to their mountain-cave home. The most important seed spirits, those of maize, are called 7-Flower and 5-Flower, and are considered to be divine human twin children. Also, the Amatan people make bundles out of bandanas. They call these "elote child" and say they represent spirit and flower of maize. Three ears of corn are tied together, one for its backbone and two for its face. Marigolds, (representing the fiery energy of conception) emerge from the opening at the top and a candle, representative of the phallus, is inserted into this womb-like bundle to bring male energy in the form of fire.

Similarly, the twentieth-century Maya of Santiago Atitlán keep a box representing the womb of one of the three Marias in a shrine. In the box is a bundle called "Heart of the Placenta." It is wrapped in a woven, beribboned cloth decorated with three faces called the corn girls, which a shaman places on the belly of a pregnant woman to give her fetus its face. Hanging from the ribbons, which represent umbilical cords, are two small bags filled with dry corn paste. The Atitecos call these bags "divine twins" – one male, one female – and consider them to be the original placentas that wrap the original seeds of the human race: the "root of children" (Tarn and Prechtel 1986: 175–176).

The ultimate spiritual technology in Olmec ideology seems to have been the evocation of the embryo (seed) spirit as the vital force that animates crops and human life.

Kūshyār ibn Labbān

Michio Yano

In his book *al-Madkhal fī ṣinā'at aṣkām al-nujūm* (Introduction to the Art of Astrology) the author calls himself Kūshyār ibn Labbān ibn Bāshahrī al-Jīlī. This name indicates that Kūshyār was a son of Labbān who was a son of Bāshahrī and that he hailed from Jīlān, a region of modern Iran south of the Caspian Sea. The date of the book is some time around AD 992, the year for which positions of the fixed stars are given. In the same book he refers to his two earlier books on astronomical tables (*zīj*es), *al-Zīj al-jāmi'* (Comprehensive) and *al-Zīj al-bāligh* (Far-reaching). In some manuscripts "Abū al-ṣasan" (the father of al-ṣasan) is added at the top of his name. No further information is available about his family and life.

One of the most famous of his books is the *Kitāb fī uṣūl ṣisāb al-hind* (Book on the Principles of Hindu Reckoning) which is known as the oldest surviving Arabic book on arithmetic using Hindu numerals. The Arabic text is divided into two parts. In the first section of the first part Indian numerals and the decimal system of notation are introduced. In the following sections are (2) addition, (3) subtraction, (4) multiplication, (5) results of multiplication, (6) division, (7) results of division, (8) square root, and (9) arithmetic checks. The second part comprising sixteen sections is devoted to sexagesimal computations using sexagesimal tables.

According to Kennedy's (1956) classification of the subject matter of Islamic *zīj*es, Kūshyār's *Comprehensive Astronomical Table* covers the following subjects: chronology, trigonometric functions, spherical astronomical functions, equations of time, mean motions, planetary equations, planetary latitudes, stations and retrogradations, parallax, eclipse theory, visibility conditions, geographical locations, star tables, and astrological tables.

Kūshyār's book on astrology seems to have been one of the most popular handbooks on this subject, especially in the eastern half of the Muslim world, as is witnessed by the abundance of surviving Arabic manuscripts and translations into Persian, Turkish, and Chinese. The book consists of four books, following the model of Ptolemy's *Tetrabiblos*. Almost all the chapters in the first book have corresponding ones in the *Tetrabiblos*. The second book deals with so-called judicial astrology where Kūshyār shows his knowledge of topics of Persian and Indian origin. Most of the subjects in the third and fourth books are found in Books III and IV of the *Tetrabiblos*. The last two chapters of the third book are devoted to a subject which was not unknown to Ptolemy but which found a significant development in Persian astrology, namely, the rules for computing the so-called *tasyīr* arc for determining the length of an individual's life.

In the introduction of this book he clearly distinguishes between two branches of the science of stars: astronomy and astrology in modern terms. The former, dealing with spheres of planets, their motion, and the computation of their positions, is more fundamental and is grasped by instruments and observation, and is to be proved by geometry. The latter branch concerns the knowledge of human deeds which is derived from the planets, their power, and their influence upon whatever is below the sphere of the moon. This is grasped by experience and analogy (*qiyās*).

K

Lalla

K. V. Sarma

Lalla, an eighth century Indian astronomer, was an exponent of the school of astronomy founded by Āryabhaṭa (b. AD 476). He was the son of Tāladhvaja and grandson of Sāmba alias Trivikrama, and hailed from Daśapura in Mālava in Western India.

Lalla was a popular astronomer who wrote both on astronomy and astrology. His most important work is the *Śiṣyadhīvṛddhida* (Treatise Which Expands the Intellect of Students), which, as he says, was composed to expatiate astronomy as set out by Āryabhatṭa. He uses the parameters enunciated in the *Āryabhaṭīya*, but propounds corrections to them every 250 years commencing from AD 498, the time of Āryabhaṭa. The first such correction falls in AD 748, which gives an indication of Lalla's date. The *Śiṣyadhīvṛddhida* is in two sections, entitled *Grahādhyāya*, dealing with planetary computations, and *Golādhyāya*, dealing with spherics, and theoretical and cosmological material. The first section, which is comprised of chapters I–XIII, treats of the mean and true planets, the three problems relating to diurnal motion, eclipses, rising and setting of the planets, the moon's cusps, planetary and astral conjunctions, and complementary situations of the sun and the moon. The second section (chapters XIV–XXII), deals with the graphical representation of the motion of the planets, the rationale of the rules enunciated earlier, rejection of popular false notions on astronomy, and astronomical instruments. Another work of Lalla, known from quotations by later authors on astronomy, is *Siddhāntatilaka*.

Lalla wrote a work on natural astrology, entitled *Ratnakośa* which is still in manuscript form. Lalla's verses on mathematical topics are frequently quoted by later writers, but the complete text from which these verses are taken has yet to be found. This provides the justification for Lalla's being referred to in later works as *Tri-skandhavidyākuśalaikamalla*, "the one stalwart versed in all three branches", that is, mathematics, astronomy and astrology.

Though Lalla follows Āryabhaṭa in certain aspects, he follows Brahmagupta (b. AD 598), and Bhāskara I (fl. AD 629), in certain others. It is also interesting that some of his innovations are followed by later astronomers like Śrīpati (tenth century), Vaṭeśvara (ca. AD 900), and Bhāskara II (b. AD 1114). This makes Lalla an important link in Indian astronomical tradition.

Leather Work in Ancient Egypt

André J. Veldmeijer, Janet Laidler

Our knowledge of skin and leather products in ancient Egypt is surprisingly scanty and only a few substantive publications have appeared. Three are of special importance for the present work. Forbes (1966) might be slightly outdated (see below) but still provides a good overview. Van Driel-Murray (2000) contains a wealth of information and is the only publication to date that predominantly relies on fieldwork and the study of the leather artefacts themselves. Not only does Van Driel-Murray provide a good overview, she clearly pin points the problems and priorities with leather in ancient Egypt. Schwarz's (2000) book deals not only with the artefacts but also with other aspects of leather and compares it with traditional European and African leather crafts. Furthermore, she incorporates texts and depictions in her study and her book contains many illustrations of leatherwork and related objects, making it an important reference for the present work.

Technology

Skin Processing

The processing of skin into leather[1] is rather universal and described in various handbooks, giving a good picture of the process. The following general summary is largely based on Forbes (1966: 1–21) and Van Driel-Murray (299–306). After flaying the skin, the preservation process was started with removal of the underlying fat. Next, hair was usually (but not always) removed (depilation), using urine, ash or a mixture of flour and salt, rubbed into the haired surface. Curing then took place, arresting the degenerative process (not irreversible in contrast to tanning). Curing in oil seems to have been the preferred method, although mineral curing was probably also practiced, particularly in the predynastic period. After soaking in oil, the skin was pulled back and forth over a beam to make it supple (staking). The remaining oil was worked into the skin using stones, wooden, or leather pounders or tools called "slickers". Finally, the skin was dried on a wooden stretching frame.

Vegetable tanning is the only means of producing chemically stable leather which is imputrescible (not subject to decay), flexible and waterproof. Current scholarly opinion is that this process was unknown in Egypt before the Ptolemaic period and only became common in the Roman period. There may be a number of explanations for this and one might be that the arid conditions rendered this more complex process unnecessary for the ancient Egyptians. These arid conditions are in themselves excellent for preservation and account for the amount of recovered leather items rather than the advanced methods of skin processing. The Romans, however, had experienced wetter environments forcing them to adopt the use of tanned leather.

The Objects

The range of objects made from leather is fairly large and ranges from parts of musical instruments and furniture to clothing, footwear and cordage. Research in progress suggests that the objects were sewn with simple seams and stitches made of flax but mostly leather thongs (and to lesser extent sinew).

Decoration Techniques

Before the New Kingdom (1550–1069 BCE), mineral dyes predominated. A full range of colours is hard to establish as their survival is dependent upon the conditions for preservation and the likelihood is that certain shades are more susceptible to discolouration. Here too, little research has been done, using modern analysis, accounting for our limited knowledge.

According to Van Driel-Murray (2000: 306) "red was achieved with iron and, perhaps, lead compounds and green was created with copper compounds". Favoured curing methods produced a very light leather so white was probably obtained by manipulation of the already pale surface with pastes of chalk mixed with fats such as egg yolk and brains. Blue does not seem to be represented with leather despite the availability of minerals such as cobalt. There is no explanation for this other than blue may be one of the colours which do not survive. After the 18th dynasty vegetable dyes such as madder (red), indigo (blue) and pomegranate (yellow and black) appear and alum is featured as a mordant. Other mordants used would have included urine and vinegar. In dyeing leather, the colour seems to have been generally confined to the grain surface and was applied after curing the complete skins. Staining and gilding came into use as late as the Coptic period.

There are examples of stamped and incised decoration; appliqué (multicoloured) is known, for instance from the funeral tent of Queen Istemkheb dating from the 21st or 22nd dynasty (1069–715 BCE) and examples of openwork by the cutting out of figures are represented in the archaeological record.

Tools[2]

Apart from the large pots for dipping, the trestled beams used for staking and the low stools and platforms upon which much of the cutting and working was carried out, a leather working toolkit seems to have comprised the following items. Needles of bone and probably copper were used for stitching leather from the earliest times. Awls of bone and later of metal were also used for piercing, as were marlin spikes. Horns were used to enlarge the holes.

Most of the leather cutting was carried out using curved, broad or narrow bladed knives which seem to have appeared in the New Kingdom (Stocks 2001: 443). Longer knives, still with curved blades, were used in earlier periods.

Leather was often pricked to facilitate easy penetration with a needle. This was done with awls or a comb-like tool. Stone and leather or wooden pounders for smoothing, depilation, working in oils and fats etc. would also have been widely used. Slickers, blades with triangular anti-clogging holes, could have been used for any of the above mentioned purposes and would have been preceded by the flint scraper (Van Driel-Murray 2000: 303; Davies 1943: 50; Stocks 2001: 443). There

[1] Although we use the term "leather" technically speaking this term only refers to tanned or tawed (converting (skin) into white leather by mineral tanning, as with alum and salt) skins rather than cured skins. In Egypt, tanned or tawed skin did not occur in Pharaonic times.

[2] Schwarz (2000: 78–123) is a particularly important source. Not only are all possible tools discussed and illustrated, she also compares Egyptian with traditional European and African leather working.

would also have been tools for incised decoration and, although it is not clear exactly what form these tools took, there are plenty of examples of pointed tools which could have served this purpose. Stamps would probably have been cast from metal or carved from stone or possibly wood, although no examples were found for inclusion in the present work.

The Importance of Skin Products

Little is known about the status of leather workers, the most well-known source to date being the *Satire of the Trades* which is heavily biased and, therefore, unhelpful (for example Lichtheim 1973). A monetary economy did not exist in dynastic Egypt, but there was an efficient system of exchange in most commodities which were "priced" in terms of their equivalent value in *deben*, a standard weight of copper. The only community from which price lists survive is the New Kingdom workmen's village at Deir el Medina, which is probably not representative of the rest of the country (Janssen 1975: 562). Furthermore, leather is not mentioned in these lists in sufficient detail to be useful (Janssen 1975: 526).

Perhaps the first thing to consider when trying to establish the monetary value of leather is the value of the animals from which skin products were obtained. It is tempting to assume a direct correlation between the value of the animal and its hide/skin. If this is the case, then bovid hide will have been the most expensive as bovidae were the most highly prized animals commonly used for leather.

Because taxes were collected in leather goods in the New Kingdom, and payment for work by the state and the temples was made in things like leather sandals, it can be assumed that leather goods had generally recognised values (Stocks 2001: 283). Furthermore, leather sandals could cost as much as a whole sheep or goat which may imply that the expertise required for the processing of finished leather goods was quite highly prized (Janssen 1975: 525–526).

The importance of leather to ancient Egyptian civilization seems to have differed over time. According to Van Driel-Murray (2000: 307) skin was widely used in the Badarian (5500–4000 BCE) and Amratian (=Naqada I) (4000–3500 BCE) periods and was handled with considerable skill and confidence but was largely superseded in the Gerzean (=Naqada II) period (3500–3100 BCE) by cloth (Petrie 1940: 128). This may have been due to the development of a more settled sedentary lifestyle over time conducive to the large-scale undertaking of craft activities such as weaving (Bard 2000: 61–62). Cow, sheep, goat and gazelle have been identified from predynastic contexts (Van Driel-Murray 2000: 308) and remained the most commonly used skins for leather throughout Pharaonic Egypt. Besides those listed, other animal skins known to have been utilised are lion, panther, cheetah, antelope, leopard, camel, hippopotamus (Reed 1972: 86) and crocodile (own observation).

In the Old and Middle Kingdoms, the use of leather declined in favour of fibre and textiles. Skin seems to have been of secondary importance to the meat at this time (Van Driel-Murray 2000: 300).

The Second Intermediate Period (1650–1550 BCE) represents a continuation of early predynastic traditions in that cattle hides, decorated leather garments, containers and pouches of high quality occur again but these are mainly associated with the "pan-grave" culture which belonged to a semi-nomadic tribe of Nubian cattle herders who entered Egypt during the Middle Kingdom and the Second Intermediate Period (Shaw and Nicholson 1995: 255). During the New Kingdom leather was much more widely used. New weapons technology such as the chariot was partially responsible for this (Van Driel-Murray 2000: 309). Also, the New Kingdom saw a change in slaughterhouse practices with more attention being paid to hides and skins as products in themselves.

It is difficult to say whether the use of leather continued to the same extent into the Third Intermediate Period (1069–747 BCE) because tombs were becoming smaller with a paucity of grave goods. The range of uses was no longer represented among the goods, most of the surviving items from this and the Late period being mummy braces.

The lack of material from the Late and Ptolemaic periods has been partially explained above. However, the leather from the Roman period is much better represented (Bowen 2002; Phillips 1999, 2001; Veldmeijer 2007, Winterbottom 1991, 2001), due to the relatively large number of finds. Then, the use of tanned leather became widespread and a clear increase in the level of technological skill can be seen. According to Forbes (1966: 35) skin products were both imported and exported at this time and the sale of leather goods seems to have been free like that of linens.

Technologically, ancient Egyptian leather working up to the Ptolemaic period remained essentially Neolithic. The idea that it was advanced from the earliest times (Hasanien 1997) is based upon misconception because full vegetable tanning which produces the leather with which we are familiar today was unknown in Egypt until the Ptolemaic period and was not common until the Roman period. In fact, pre-Ptolemaic skin products, many of which are referred to here as "leather", are no more than lightly cured pseudo-tannages which only survive because of Egypt's naturally favourable conditions for preservation.

Dyeing techniques were relatively basic and the properties of alum as a mordant were not appreciated in Egypt until long after her influential neighbour, Mesopotamia, had rendered its use commonplace.

When elaborate and colourful decoration was fashionable, it was achieved by appliqué techniques which were often coarsely executed. Compared to the skill and patience needed to produce the exquisitely fine New Kingdom network loin cloths (which seems to be from Nubian origin) or the skills seen in the Roman material, the Pharaonic leatherwork might be judged as "poor", or perhaps better "pragmatic". As also remarked by Van Driel-Murray, the Nubian material is unequalled in Egypt and leather might have played a much more important role in Nubia than in Egypt (Van Driel-Murray, personal communication).

The extent to which leather was used varied greatly over time with the periods of greatest use being the early predynastic and New Kingdom. It is important to note that this is at least partially due to a bias in archaeological record. For example, the amount of material which survives from the New Kingdom is largely due to the fact that elite burials of this period were generally rich and elaborate with a whole range of material deposited with the body for use in the after life (Spencer 1982: 50–51). Because much of the Pharaonic Egyptian archaeological record is constructed from tomb goods, burial practices are a major contributing factor in terms of what survives. Another example is the fact that little archaeology has been done in true Ptolemaic layers. Finally, many Roman settlements have been excavated, largely accounting for the numerous leather finds. (The fact that much Roman material has been tanned also accounts for this.) It has been claimed that leather was of "marginal importance" in ancient Egypt in all periods (Van Driel-Murray 2000: 299) but considering the amount of surviving material and the range of uses represented, this conclusion should be challenged. Leather goods were used as currency but their actual value is impossible to quantify accurately.

Egyptian leatherwork is still poorly understood and much in need of reassessment which should include, for example, detailed analysis of technology (seams, stitches), shape (especially footwear) and, mentioned by Van Driel-Murray (2000: 300), extensive analyses on well-dated samples for both curing and colouring agents as a framework for future investigation. Fortunately, in recent years interest in leatherwork has increased and variousstudies are currently being executed.

Leo the African

Thomas F. Glick

Leo the African was born in Islamic Granada as Al-Ḥasan ibn Muḥammad al-Wazzān al-Zayyātī around 1485 and was educated in Fez, where his family settled several years before the conquest of Granada. He is known primarily for his geographical writings based on four trips. The first, from Fez to Constantinople, probably took place in 1507 and 1508. The second, sometime between 1509 and 1511, was his first to Timbuctu following the caravan route south, probably as far as the Niger river. The third trip (1512–1514) took him across the Sahara via Lake Chad to Egypt, providing important information on the Sudan. The fourth trip (1515–1518) took him to Constantinople as ambassador of the Moroccan sultan, Egypt, and Arabia; on his return he was captured by the Italian pirate Pietro Bovadiglia. In Italy he was given as a slave to Pope Leo X whose name he took upon his conversion to Christianity.

Although he wrote an Arabic–Hebrew–Latin vocabulary in 1524, he is best known for his geographical treatise written and published in Italian as *Della descrittione dell'Africa* (Venice, 1550), although it was no doubt based on an Arabic draft. The treatise is divided into nine books, whose principal significance was to provide European cartographers with detailed information about areas of sub-Saharan Africa practically unknown in the West. Leo also made a substantial contribution to natural history. In his description of African plants, animals, and minerals he points out errors made by ancient writers such as Pliny. Leo's *Description* also contains invaluable information on Islamic institutions such as, for example, his description of the *muhtasib*, or market inspector, of Fez. Leo returned to North Africa in 1529, reconverted to Islam, and died in Tunis sometime after 1554.

Levi Ben Gerson

J. L. Mancha

Levi Ben Gerson (1288–1344), also known as Gersonides or Leo de Balneolis, his Provençal name, was one of the most original Jewish thinkers of the Middle Ages, and he wrote on logic, philosophy, biblical exegesis, mathematics, and astronomy. He lived in Orange, where the de Balneolis family was prominent, and occasionally in Avignon (France). During the last years of his life he maintained relations with the papal court of Clement VI (1342–1352), to whom he dedicated a Latin version of his work on trigonometry and on the Jacob Staff (*Tractatus instrumenti astronomie*, 1342).

On mathematics, his *Maʿaseh Hoshev* (Work of the Computer, 1321) deals with arithmetic, summations of series, algebra, and combinatorial analysis. At the request of the French musical scholar Philippe de Vitry, he composed his *De numeris harmonicis* (On Harmonic Numbers, 1343, extant only in Latin) to demonstrate that numbers belonging to geometrical progressions of ratio

2 or 3 and first term 1, or generated by product of terms in these progressions, differ by a number greater than 1, excepting pairs 1–2, 2–3, 3–4, and 8–9. On geometry, he wrote a commentary on Books I–V of Euclid's *Elements*, a treatise on Euclid's parallel postulate, preserved incomplete, and commentaries apparently lost on Menelaus' *Sphaerica* and Thābit ibn Qurra's *Risāla fī Shakl al-qaṭṭā*ʿ (On the Secant Figure).

Levi's most important scientific achievements are contained in the *Sefer Tekhunah* (Book of Astronomy), in fact, part 1 of the fifth book of his main philosophical work, *Milḥamot Adonai* (Wars of the Lord). Preserved in Hebrew and Latin versions, it is a lengthy work, divided into 136 chapters, which contains planetary observations and research from 1321 to 1340, and is based on a profound understanding of the astronomical tradition as well as on a sound criticism of some of his predecessors, mainly Ptolemy and al-Biṭrūjī. Levi's purpose was to construct a true astronomy, able to satisfy at the same time the requirements of experience, natural philosophy, and metaphysics. The crucial role attributed to observation led him to construct the Jacob Staff (an instrument for determining the angular distance between two stars or planets widely used in navigation until the eighteenth century, whose precision he increased by inventing a transversal scale for linear measurement, later also applied to the astrolabe), and to investigate successfully the theory of the *camera obscura*, which he used for observing eclipses. Levi employed his own observations both for deriving parameters for his new solar and lunar models and for testing them. Of special interest is his lunar model, which avoided the inadequacy of Ptolemy's model at half-moon phase (when it ought to appear twice as large as at opposition) and eliminated the use of the Ptolemaic epicycle (which would allow us to see both sides of the moon, again contrary to appearances). Using his own solar and lunar models, Levi composed ca. 1335 a set of tables and canons for computing eclipses, later partially modified when it was incorporated into the *Sefer Tekhunah*, which includes tables for the sine function, spherical astronomy, and solar and lunar mean motions and corrections. The chapters of the work dealing with planetary models are apparently unfinished, but a measure of Levi's originality is his theory of planetary distances and sizes: although Levi considered as not fully decided the problem of the position of Mercury and Venus with respect to the sun, assuming that these planets were placed above it, he computed the distance of the sphere of the fixed stars to be $159 \times 10^{12} + 6.515 \times 10^{8} + 1.338 \times 10^{4} + 944$ earth radii (instead of Ptolemy's 20,000 earth radii, generally accepted in the Middle Ages).

L

Li Bing

SUN XIAOLI

Li Bing (fl. 322–247 BCE) is famous in Chinese history as an expert in irrigation works. He had a good knowledge of astronomy and geography as well as of engineering and technology. In 316 BCE Shu (Sichuan province) was conquered by the State of Qin. In order to establish the province as an important base and to harness the Minjiang River floods, King Huizhao (r. 306–2551 BCE) appointed Li Bing governor of Shu.

During 277–250 BCE Li decided to build the large waterworks at Guanxian county, from where the river flows into the plain of Sichuan. The whole project is known as Dujiang Yan. Li decided to divide the river into two great feeder canals, the Neijiang (Inner Canal) on the east and Waijiang (Outer Canal) on the west. This was done by means of piled stones, known as *Yuzui* (Fish Snout). The inner canal was used for irrigation, while the outer one, the mainstream, acted as a flood channel, and also carried some boat traffic. In order to construct the inner canal Li made a great rock cut through the end of a ridge of hills. This is known as the Bapoing Kou (Cornucopia Channel). Between the primary division-head and the rock cutting the channels were separated by the Feisha Yan (Flying Sands Spillway) which was adjusted to regulate the volume of flow into the inner canal.

In order to measure the water level so as to control it, three stone figures were put at three different places at the canal intake. With the help of observing the water level at the inner canal intake the feeding capacity into that canal was controlled by division dams of the Yuzui, Feisha Yan, and Baoping Kou. The whole engineering operation made it possible to supply water for an area of 4.4 million acres to support a population of five million people, most of them engaged in farming, while at the same time remaining free from drought and floods. It can be compared with the ancient works of the Nile, and it is still in use today. Apart from this great contribution, Li also developed the deep-drilling technology for producing well salt and built six bridges near Guangdu (Chengdu). The exploitation of water resources and the manufacture of well salt greatly promoted the development of agriculture, industry, and commerce in the Sichuan area and made it become a famous "Land of Abundance" in China since Li's time.

Li Chunfeng

JENNIFER W. JAY

Li Chunfeng (602–670) was a Chinese mathematician, astronomer, and early historian of science. A native of Shaanxi province in northwest China and influenced by his Daoist father, Li Chunfeng served as a high-ranking court astronomer and historian for several decades in the early Tang dynasty (618–906). Both Li Chunfeng's son and grandson successively occupied the position of court astronomer.

As a mathematician Li Chunfeng is not considered to be original, but he played a role in indeterminate analysis, or the Chinese remainder theorem. He is credited, along with Zu Chongzhi in the fifth century, with developing the *zhaocha* method of finite or divided differences in mathematical astronomy. Using algebra to deal with the *ping* (floating differences) and *ding* (fixed differences) Li Chunfeng calculated the "angular speed of the sun's apparent motion" (Needham 1959).

Li Chunfeng applied this method of finite differences in designing the Linde (Unicorn Virtue) calendar, which was adopted in 665. The new calendar was an improvement over the previous ones in predicting the movements of the planets and in the placing of the long (30 days) and short months (29 days) as well as the intercalary months. To compensate for the extra days in a solar year of 365.2422 days and a lunar month of 29.5306 days, 1 intercalary month needs to be added every 3 or 4 years.

Li Chunfeng also earned a place in the history of *hunyi* (armillary spheres), predecessor to the telescope. His armillary sphere had three nests of concentric rings: the inner sighting tube ring, the intermediate nest, and the outer stationary nest. Li's innovation lies in the intermediate ring, which improved the observations of celestial bodies and allowed for finer accuracy.

Li Chunfeng wrote the treatises on astronomy, calendar, and portents in the official dynastic histories, the *Jinshu* (History of the Jin Dynasty) and *Suishu* (History of the Sui Dynasty), in addition to authoring another extant work, *Yisizhan* (Omen-taking, 645). Typical of astronomers in his time, Li Chunfeng could not avoid the moral and political responsibility of interpreting omens to the country, and included portent astrology and omen lore in his writings.

Li Chunfeng commented on the ten mathematical manuals that were officially designated for curriculum use both in Tang China and in Korea and Japan. These appear below with translated titles (Ho 1985): *Zhoubi suanjing* (Arithmetical Classic of the Gnomon and the Circular Paths of Heaven), *Jiuzhang suanjing* (Nine Chapters on the Mathematical Art), *Sunzi suanjing* (Mathematical Manual of Sunzi), *Haidao suanjing* (Sea Island Mathematical Manual), *Wucao suanjing* (Mathematical Manual of the Five Government Departments), *Xiahou Yang suanjing* (Mathematical Manual of Xiahou Yang), *Zhuishu* ("Stitching" Method), *Zhang Qiujian suanjing* (Mathematical Manual of Zhang Qiujian), *Wujing suanshu* (Arithmetic in the Five Classics), and *Jigu suanjing* (Continuation of Ancient Mathematics). *Zhuishu* is not extant and was substituted by *Shushu jiyi* (Memoir on Some Traditions of Mathematical Art).

Li Gao

Hong Wuli

Li Gao was born in 1180 in Zhending (now Zhengding County of Hebei Province) and died in 1251. His surname was Mingzhi, and Dongyuan the Old Man was his nickname. He was an exponent of one of the four major schools of the Jin-Yuan period.

After his mother died of an unknown disorder which was treated to no avail by unskilled practitioners, Li made up his mind to pursue medical studies. His tutor Zhang Yuansu, who advocated the revolutionary idea that "modern diseases cannot be cured by ancient prescriptions," taught him to probe for new ideas and prescriptions so as to free himself from the yoke of the ancient art of prescribing. He was conversant in the nature and properties of drugs and in their beneficial potentials. The recipes he formulated were all organized according to the theory of "king, minister, assistant, and attendant," commonly composed of 10 to 20 kinds of herbal drugs. In line with the classical theory, all the ingredients were closely related with both complementary and opposing relationships (Jiang 1963).

He emphasized the role of stomach *qi* during all seasons. *Qi* is the root of all body functions. The spleen and stomach are the roots of growth and metabolism; various disorders arise when their functions are jeopardized. He expounded the etiology and mechanism of disease due to endogenous pathogens (those coming from within), which are different from those caused by exogenous ones, and he stressed the importance of the spleen and stomach in the course of endogenous disorders. He criticized quacks that mix up disorders of different etiology and apply methods for exogenous ailments to tackle the problems of endogenous ones, with ensuing complications. Clinically, he stressed that the spleen and stomach should always be nourished so as to renew the body. He formulated a famous recipe, the *Buzhong Yiqi* (Benefiting-Interior Reinforcing-Qi) decoction, and the *Shengyang Yiwei* (Ascending Yang Replenishing-Stomach) decoction, which are both common remedies still applied today. Due to his emphasis on spleen and stomach, he was given the title of the head of an academic school, the Earth-Replenishing School (Li 1913). He was also a prolific writer. Among his works, the most famous ones include *Nei wai shang bien huo lun* (*Differentiation for Endogenous and Exogenous Disorders*), *Pi wei lun (On Spleen and Stomach), Yi xue fa ming* (Medical Inventions), *Dong yuan shi xiao fang* (*Dongyuan's Trial Effective Formularies*), *Lan shi mi cang* (*Clandestine Collections in Orchid Mansion*), *Huo fa ji yao* (*Essentials of Flexible Methods*), *Yao lei fa xiang* (*Pharmaceutical Normalcy*), *Yong yao xin fa* (*Mastery of Drug Application*), and *Shang han hui yao* (*Collected Essentials of Disease Due to Exogenous Cold*). In his later years, he passed his academic ideas and works on to his disciple Luo Tianyi (Taki 1956).

Li Shanlan

JEAN-CLAUDE MARTZLOFF

Li Shanlan. Fig. 1 Li Shanlan.

Li Shanlan (1811–1882) was a native of Haining, Zhejiang. Although he belonged to a moderately fortunate family and was given formal training in the classics, he never passed government examinations beyond the first level, and had to give up the dream of entering officialdom. Under difficult circumstances, he took refuge in Shanghai, a city newly opened to foreign trade as a consequence of the Opium War.

From 1852 to 1859, Li went into service with the London Missionary Society who employed him as a co-translator of all sorts of Western scientific works. Missionaries had an insufficient mastery of literary Chinese and for that reason they had to rely on Chinese co-workers, even though these, like Li Shanlan, generally had no knowledge of foreign languages. During this period, Li translated with Alexander Wylie (1815–1887) Joseph Edkins (a Protestant Missionary 1829–1890) and others the part of Euclid's *Elements* not yet translated into Chinese (Books 7–15), Augustus de Morgan's *Elements of Algebra* (1835), Elias Loomis's *Elements of Analytical Geometry and of Differential and Integral Calculus* (1851), John F. W. Herschel's *Outlines of Astronomy* (1849), and other manuals on mechanics and botany. But what made Li famous in the eyes of his contemporaries was not so much the numerous translations he was responsible for but his own mathematical works.

Contrary to what might be expected, Li's works were not based on new Western mathematics but on ancient Chinese conceptions, especially the positional algebra *tianyuan shu* developed five centuries earlier during the Song and Yuan dynasties. Li however did not stick slavishly to the venerable discoveries of his ancestors. Rather he used much ingenuity emulating Westerners and trying to beat them at their own game. Using ancient tools, he thus conducted research of his own into logarithms, infinite series, and combinatorics. In particular, he made extensive use of algebraic computations, analogical reasoning and inductive generalizations built on the knowledge of a few particular cases. But he never relied on hypothetical-deductive reasoning. One of his original results, which may be expressed as follows using modern symbolism, is:

$$\sum_{j=0}^{k} \binom{k}{j}^2 \binom{n+2k-j}{2k} = \binom{n+k}{k}^2,$$

where the $\binom{n}{p}$ represent the usual binomial coefficients occasionally appears in modern books.[1]

Owing to the generosity of Zeng Guofan (1811–1872), a famous general responsible for the suppression of the Taiping revolt, Li Shanlan's collected mathematical works were published in Nanking in 1867 under the title *Zeguxi zhai suanxue* (Mathematics from the Studio "Devoted to the Imitation of the Ancient Chinese Tradition").

The contents of the *Zeguxi zhai suanxue* collection are as follows:

A. Two prefaces
   1. Li Shanlan's preface, dated 1867, where he expresses his deep admiration for ancient Chinese mathematics and refers to himself as "Shanlan": "When ten years old, Shanlan found a copy of the Nine Chapters ....he read it and found that it was so easy that it necessitated no special study. But from this, he fell in love with mathematics *suan* [...] At the occasion of the provincial examinations, he found a copy of (Li Zhi's) *Ceyuan haijing* (Sea Mirror of Calculations Concerning Inscribed and Circumscribed

[1] Very interesting details (translated into English from the Hungarian original paper), about how this formula became known in Europe are stated precisely in Paul Erdos, ed. *Collected Papers of Paul Turan*. Akademiai Kiado, 1990. See Also J.-C. Martzloff. *A History of Chinese Mathematics*. Springer, 1997. 341.

Li Shanlan. Fig. 2 Alexander Wylie.

Circles) and of [Dai Zhen (1724–1777)'s] *Gougu geyuan ji* (Treatise on Cyclotomy by means of Right-Angled Triangles) (1755) [...]"

2. Preface by one of his (now unknown) disciples.

B. Thirteen treatises

1. *Fangyuan chanyou* (The Mysteries of the Square and Circle). The opening sentence starts by a proud assertion of what Li Shanlan considers an erroneous Western conception: "First, we must acknowledge the fact that what the Westerners call 'points', 'straight lines' and 'planes' cannot be dimensionless." Note that this offensive declaration must be taken *cum grano salis* because Li Shanlan was the translator of the *Elements* into Chinese. Then the treatise develops quadratures and developments into infinite series by submitting infinitesimals to all sorts of arithmetical operations and limiting processes. In this way, he obtains, for example, the following result:

$$\pi = 4 - 4\left(\frac{1}{3 \times 2} + \frac{1}{5 \times 4!!} + \frac{3!}{7 \times 6!!} + \frac{5!}{9 \times 8!!} + *\right)$$

where $4!! = 4 \times 2$, $6!! = 2 \times 4 \times 6, \ldots$ and where the factorial has the usual meaning.

2. *Hushi qimi* (The Mysteries of the Arc and Sagitta Unveiled). Developments into infinite series of trigonometric functions (sinus, tangent, secant...).
3. *Duishu tanyuan* (The Origin of Logarithms).
4. *Duoji bilei* (Accumulated "Heaps" Studied from an Analogical Point of View). Generalised Pascal's triangle with all sorts of finite summations. The term "heaps" used here refers to the fact that Li Shanlan visualised binomial and other combinatorial coefficients under the form of geometrical heaps of material objects such as small cubes or spheres analogous to marbles. Li Shanlan's formula occurs here.
5. *Siyuan jie* (An Explanation of the "Four Elements"). An interpretation of the meaning of Zhu Shijie's medieval algebra, developed in the famous *Siyuan yujian* [Mirror of the Four Elements] (1303).
6. *Linde shu jie* (An Explanation of the *Linde* Canon). The treatise contains an elucidation of this extremely difficult technical text and, in particular, of its non-linear interpolation formula. The term *Linde* is the name of a reign-period (664–666) of the Tang Emperor Gaozong. Its literal meaning is "unicorn virtue", a classical Chinese allusion to prosperity and happiness. Generally speaking, *shu* means "methods", "set of mechanical rules" or "algorithms" and *li* "mechanical rules for mathematical astronomy and calendrical calculations", but here they are interchangeable. *Linde shu* or *Linde li* means "*Linde* canon (of astronomical calculations)" and not merely "*Linde* calendrical calculations" as is often (and wrongly) said.
7. *Tuoyuan zhengshu jie* [An Explanation of the True *Shu* (here algorithms) of the Ellipse (lit. "flat circle")].
8. *Tuoyuan xinshu* (New *shu* for the ellipse)
9. *Tuoyuan shiyi* (Remaining Considerations on the Ellipse).
10. *Duishu jiantui bianfa shi* (Explanation of a Modified Method for the Calculation of Logarithms).
11. *Huoqi zhenjue* (True Tricks Concerning Fire Machines). This contains an explanation of the parabola in connection with the trajectory of projectiles.
12. *Jishu huiqiu* (The Reversion of Series). Given an infinite development, $y = f(x)$, find x in terms of y.
13. *Tiansuan huowen* (Queries on Chinese Mathematics).

In 1869, Li was appointed Professor of Mathematics at the newly created Tongwen guan, a college in Beijing devoted to the teaching of foreign languages, technology, and science. He based his lectures partly on Western mathematics and partly on Chinese mathematics, and remained in that post until his death. His works were much admired in China by mathematicians and non-mathematicians alike. They can be considered at the same time the most creative mathematics written

L

in China during the whole of the nineteenth century and the swan song of Chinese traditional mathematics.

Unsolved Problems

1. It is customary to refer to the above combinatorial formula as “Li Shanlan’s formula” in the same way as we refer to Pythagoras’ theorem, Bezout’s theorem and the like. Very often, however, these appellations are very loose and do not always adequately reflect historical reality. For example, Pythagoras’ theorem was not a “theorem” at first but rather something like an algorithm, and it was known long before Pythagoras.

   Thus, it may be that Li Shanlan’s formula was buried somewhere in the huge and not wholly explored treasure-house of nineteenth century mathematics, or in Japanese mathematics (*wasan*), where the occurrence of combinatorial formulae in various guises is not so infrequent.

   So we can ask ourselves if we can prove or disprove the statement: the appellation “Li Shanlan’s formula” is not a misnomer.
2. Is it possible to translate the *Zeguxi zhai suanxue* into a Western language?

   It most definitely is. Li Shanlan’s treatise is written in a crystal clear and beautiful sort of classical Chinese. Providing a translation, however, might be difficult, especially in view of the very special technical terminology he relied on. Concerning the importance of specific calculations in this work, the would-be translator would have to avoid any reference to “concrete mathematics” as Knuth would perhaps call these. But programs able to manipulate formal expressions and multi-precision arithmetic, like Maple, would help redoing the calculations mechanically, painlessly and exactly.

Li Shizhen

Fabrizio Pregadio

The great Chinese naturalist and pharmacologist Li Shizhen was born in 1518 near modern Qichun (Hubei). Born into a family of doctors, he concentrated on the study of medicine at an early age under the guidance of his father. His reputation as a physician soon reached the prince of Chu, who in 1543 entrusted him with medical and administrative responsibilities at his court in Wuchang. From 1544 to 1549 Li practiced at the Imperial Academy of Medicine (Taiyi Yuan) in Beijing. After that, he returned to his native village, where he worked as a doctor until his death in 1593.

The experience as a physician suggested to Li the need of a thorough revision of the traditional repositories of pharmaceutical knowledge (*bencao*). Earlier standard sources such as the work by Tang Shenwei had been made obsolete by the adoption of new drugs and prescriptions, along with errors in the identification and classification of some substances. Li apparently began to conceive the compilation of a definitive pharmacopoeia around 1552, and worked on this project for more than 25 years. He spent much of that time reviewing a massive amount of literature, and traveling extensively to collect specimens and recipes.

The result of these efforts represents the culmination of the literary tradition of Chinese pharmacology. Li Shizhen’s work, entitled *Bencao gangmu* (The Pharmacopoeia Arranged into Headings and Sub-Headings), contains 1,892 entries, classified into 16 main sections (e.g., Minerals, Trees, Reptiles) and 62 categories. The entries describe 275 minerals, 1,094 plants, 444 animals, and 79 miscellaneous substances (those in the sections Water, Fuel, and Earth). Li Shizhen himself contributed no less than 374 new entries.

Li classified the *materia medica* according to an essentially binomial system, describing species as variants of a genus. His work deals with minerals first, followed by plants, invertebrates, vertebrates, mammals, and humans. A typical entry is divided into sections concerned with nomenclature, places of occurrence, varieties, problems of identification, medical properties, uses, and prescriptions. The *Bencao gangmu* contains more than 11,000 recipes, about 8,000 of which were collected or devised by the author, and more than 1,000 illustrations. The sources, numbering about 1,000, consist of medical and pharmacological works, along with historical, literary, philosophical, and other texts. While Li – like most traditional pharmacologists before him – accepted the authority of the early, pre-Tang pharmacopoeias, he did not refrain from criticizing and correcting the views of later authors.

The manuscript of the *Bencao gangmu*, completed in 1578, went through several revisions until 1590, when Li took it to a Nanjing publisher for publication. It is uncertain whether the author was able to see his work printed before he died in 1593: recent research has suggested that printing may have not been completed until 1596 rather than 1593 as often indicated. The *Bencao gangmu* was re-edited several times in China and Japan. References in early sinological works reached the attention of eighteenth- and nineteenth-century Western scientists, including Carl von Linnée (Linnaeus) and Charles Darwin, who refer to it in their own works. (Editor's note: More detailed material can be found in Métailié 2001.)

Li Zhi (Li Ye)

Ho Peng Yoke

Considered by the historian of science George Sarton as essentially an algebraist, Li Zhi (1192–1279) was one of the greatest mathematicians of his time. He is known by some as Li Ye, a name that he was supposed to have taken at the later stage of his life to avoid the word *zhi* which was adopted by a member of the royalty. He used an algebraic process known as *tianyuanshu* (method of the celestial element) to set up equations of any degree. He was not the originator of this method, but it was through his writings that the *tianyuanshu* was handed down to later generations. It was introduced to Japan and had a profound influence on Japanese mathematics. Known as *tengenjitsu* to Japanese mathematicians, it enabled Seki Takakazu (also known as Seki Kowa, ca. 1642–1708) to develop a formula for infinite expansion, which is now arrived at using infinitesimal calculus. (See the article on Seki Kowa for a more complete description of the method.)

Li Zhi was born in Luancheng in modern Hebei province. He served the Jurchen government as a magistrate in Junzhou (in modern Henan province). In 1232 the Mongols captured Junzhou and Li Zhi made his escape taking refuge in various places and living as a recluse. He became a noted scholar in north China. Qubilai Qan intended to give him an official appointment, but he declined the offer. He read widely and was a voluminous writer. Unfortunately most of his books are lost. According to one source, before Li Zhi died he told his son Li Kexiu to burn all his writings except the *Ceyuan haijing* (Sea Mirror of Circular Measurements) which he wrote in 1248, saying that posterity might find it useful. Somehow, another mathematical text, the *Yigu yanduan* (New Steps in Calculation) which he wrote in 1259, also escaped the fire. It is only through these two works that we know about Li Zhi's contributions to mathematics.

Consisting of 170 problems, the *Ceyuan haijing* begins with a diagram of a circle inscribed in a right-angled triangle. Diameters of the circle parallel to the vertical and horizontal sides of the triangle, and tangents to the circle parallel to these two sides of the triangle produced 15 different right-angled triangles of different sizes. Li Zhi worked out the relations between the sides of these triangles, and between the diameter of the circle and the parallel sides of two of the trapezia formed in the diagram. His understanding of the properties of the circle and the right-angled triangles enabled him to work out many of his problems with great ease. The same problem that his contemporary Qin Jiushao (ca. 1202–ca. 1261) solved with a tenth degree equation was handled by Li Zhi simply using a quartic equation instead.

The *Yigu yanduan* contains 64 problems involving mainly a square and a circle, with a few cases on two different circles, two different squares, and a circle together with either a rectangle or a trapezium. Again equations of higher degrees are used. This text stabilized the terminology used in Chinese mathematics about equations of higher degrees.

Līlāvatī

Takao Hayashi

The *Līlāvatī* is a Sanskrit work on arithmetic and mensuration (computational geometry) composed in or a little before AD 1150 by Bhāskara II, one of the greatest Indian mathematician–astronomers. The *Līlāvatī* is sometimes regarded as the first part of the *Siddhāntaśiromaṇi*, a masterpiece on *gaṇita* (mathematics) in its broad sense (including mathematical astronomy), the other parts being *Bījagaṇita*, *Grahagaṇitādhyāya* (Chapter on planetary computation) and *Golādhyāya* (Chapter on spherical astronomy), but in manuscripts the four parts have been handed down to us independently.

In medieval India, mathematics proper comprised two major fields, *pāṭīgaṇita* (mathematics of algorithm) and *bījagaṇita* ("mathematics of seeds" or algebra). The *Līlāvatī* is the most typical and the most influential work of *pāṭīgaṇita*. More than 600 manuscripts of the work have been reported so far and more than 30 extant commentaries attest that it was the most popular mathematical textbook in India used by a number of people on the entire subcontinent. Moreover, the work was translated not only into Indian languages of the North and of the South but also into Persian several times in the sixteenth and the seventeenth centuries, into English in the nineteenth century, and into Japanese in the twentieth century (Pingree 1970–94: A4, 299–308, and A5, 254–257).

The great popularity is due not only to the promotion of his works through a school (*maṭha*) established by his grandson, Caṅgadeva (Pingree 1970–94: A4, 299), but also to the elegant but plain Sanskrit and to the well-organized contents of the work itself. The *Līlāvatī* consists of about 270 verses of various meters for rules and examples and of prose paragraphs mainly for solutions of the examples: a rule is prescribed for a type of problem and it is usually followed by one or two examples, which in turn are followed by solutions. The sectioning of the book is not always clear but it seems reasonable to divide it in 14 chapters. The contents of each chapter are as follows:

1. Terminology (*paribhāṣā*): gives conversion ratios between various units for currency, weight, length, area, and capacity.
2. Determination of the places for numbers (*saṃkhyāsthānanirṇaya*): enumerates the names of the first 18 decimal places from *eka* (1) to *parārdha* (10^{17}). This is the Hindu traditional list that had been fixed in the time of Śrīdhara (eighth century AD) (Hayashi 1995: 64–70).
3. Eight elementary operations (*parikarmāṣṭaka*): prescribes rules for the eight operations (addition, subtraction, multiplication, division, square, square-root, cube, and cube-root) in three sections, namely, those for integers, for fractions, and for zero. The rules for integers are based on the place-value notation. For multiplication several additional rules are also given. The first four rules for zero are as follows ($a > 0$): $a + 0 = 0 + a = a$; $a - 0 = a$; $a \times 0 = 0 \times a = 0$, but, when other operations follow, the product, being called *khaguṇa* (a quantity that has zero as a multiplier), retains a besides the zero, and the zero is canceled if the succeeding operations contain zero as a divisor; and $0 \div a = 0$ and $a \div 0 =$ *khahara* (a quantity that has zero as a divisor). The rule, $0 - a = -a$, is not given here because negative numbers are avoided in *pāṭīgaṇita*; it is given in the *Bījagaṇita* of the same author. In that work, the infinity of the *khahara* is compared to that of God.
4. Miscellaneous (*prakīrṇaka*) operations: includes the rule of inverse operations, the optional-number computation (the rule of false position), the inequality computation (algorithms for two sets of algebraic normal forms), the square computation (three algorithms for the simultaneous indeterminate equations, $x^2 + y^2 - 1 = u^2$, $x^2 - y^2 - 1 = v^2$), the multiplier computation, the rule of three (which is essential for *pāṭīgaṇita* according to Bhākara II), the inverse rule of three, and barter. The "multiplier computation" was an algorithm for the equation, $x - \sqrt[a]{x} = b$ (the "multiplier" signifies a), which had been treated as one of the "class" (*jāti*) problems by Śrīdhara, by Mahāvīra, and by Śrīpati. Bhāskara II reduced several other "class" problems of similar types, which had been given different algorithms by his predecessors, to this type, and treated other "class" problems involving simple linear equations under the "optional-number computation."
5. Procedure for mixture (*miśraka-vyavahāra*): includes interest, investment, and proportional distribution of gain, filling a pond with water through several

pipes, buying and selling, equation of properties after the exchange of jewels, purity of gold, and combination.

6. Procedure for series (*śreḍhī-vyavahāra*): treats the sums of a natural series, of the sums of natural series, of a square series, and of a cubic series; the sum, the first term, etc. of an arithmetic progression; and the sum of a geometric progression.
7. Procedure for fields (*kṣetra-vyavahāra*): consists of four sections, namely, trilaterals, quadrilaterals, needle figures, and circle and sphere. The first section deals with the Pythagorean theorem and its application, rational right triangles, and the area, the perpendicular, etc. of a triangle. In the second section, besides the areas of equilateral, rectangular, and equiperpendicular quadrilaterals, Bhāskara II discusses in detail how to calculate the diagonals of an inscribed quadrilateral and criticizes Brahmagupta's method for its "heaviness" (*gurutva*). The third section, based on the property of similar triangles, deals with the lengths of various segments of a "needle figure" (*sūcī-kṣetra*), which is a trilateral formed by the base of a quadrilateral and by its flank sides extended to meet each other. In the fourth section, Bhāskara II employs the two approximations, 22/7 and 3927/1250, for π, and gives the formulas, $A = cd/4$, $S = 4A$ and $V = Sd/6$, for the area of a circle and the surface and the volume of a sphere, respectively, where d is the diameter and c the circumference. In his *Golādhyāya*, he criticizes Lalla's formula, $S = cA$, and derives his own for S and V by decomposing a sphere into a number of annuli in one place and into segments like orange peels in another in the former case, and into a number of pyramids in the latter (Hayashi 1997: 214–217). The same section also contains applications of the relationship, $a^2 = 4h(d\text{-}h)$, where a is a chord and h the corresponding "arrow" or the height, a list of the sides of inscribed regular polygons (up to a nonagon), and Bhāskara I's approximation formula for a chord, $a = (4db(c-b))/(5c^2/4-b(c-b))$, where b is the corresponding arc.

The next four chapters repeat traditional rules for three-dimensional figures.

8. Procedure for excavations (*khāta-vyavahāra*): deals with the volumes of excavations shaped like a rectangular solid, a truncated pyramid, a pyramid, and a cone.
9. Procedure for brick-piling (*citi-vyavahāra*): deals with the relationships of the volume, the height, the sectional area, and the number of the layers, of a wall made of bricks, the volume and the height of a constituent brick, and the number of the bricks.
10. Procedure for sawing (*krākacika-vyavahāra*): deals with the total area of the sections of a lumber cut by a saw, in order to evaluate the work of sawing.
11. Procedure for heaped-up grain (*rāśi-vyavahāra*): deals with the volumes of grain heaped up on the ground in the shape of a cone, heaped up against a flat wall, and heaped up inside and outside of a corner. The height of the heap is taken to be one-ninth, one-tenth, or one-eleventh of the circumference of the base according to whether the grain is fine or coarse.
12. Procedure for shadows (*chāyā-vyavahāra*): based on the property of similar triangles and on the Pythagorean theorem, deals with the shadows made by a gnomon; does not contain the calculation of the time of a day from the shadow of a gnomon, a calculation which was included in this "procedure" by Bhāskara II's predecessors.
13. Pulverizer (*kuṭṭaka*): deals with linear indeterminate equations of the type, $y = (ax + c)/b$. It is Bhāskara II who for the first time included a whole theory of the pulverizer in a book of *pāṭī*, although Mahāvīra had already treated it to some extent in his *pāṭī* book. This is because it requires neither algebraic symbolism nor "intelligence" (*mati*), which are essential for *bījagaṇita* or algebra according to Bhāskara II. He repeats the same rules for *kuṭṭaka*, together with several additional ones for negative coefficients, in his *Bījagaṇita*.
14. Chain of digits (*aṅka-pāśa*): treats permutations of the nine digits (excluding zero). An example for the last rule, for example, reads as follows: "How many varieties of numbers are there with digits placed in five places when their sum is thirteen? It should be told, if you know." This was an entirely new topic introduced by Bhāskara II, although a rule for calculating ${}_nC_r$ had traditionally been included in the chapter on "mixture" by Śrīdhara, Mahāvīra, Āryabhaṭa II, and Bhāskara II himself.

The above description of the *Līlāvatī* is based mainly on the Ānandāśrama edition, which differs from the Hoshiarpur edition in many respects: for example, the last mentioned topic, ${}_nC_r$, is placed at the end of the chapter on series in the Hoshiarpur edition (Hayashi 2002). It has been conjectured that those two editions represent the Northern and Southern recensions, respectively, but the history of transmission (including recensions) of the *Līlāvatī* is yet to be investigated on the basis of all the existing manuscripts.

Liu Hong

Jiang Xinoyuan

Liu Hong was a Chinese astronomer (AD 129–210), descended from the imperial family of the Eastern Han Dynasty. Liu Hong was very interested in astronomy from his childhood. About AD 160, he was assigned to be an officer of the Imperial Observatory. In this position, he participated in determining a series of astronomical dates. In AD 174–175, he offered *Qi Yao Shu* (The Art of Seven Planets) and its reformulated edition *Ba Yuan Shu* (The Art of Eight Elements) to the imperial government. The two works have been lost, but there are indications that they related to Buddhist astrology in Middle Asia. In AD 187–188, he composed the *Qian Xiang Li* (Qian Xiang Calendar), a work of traditional Chinese mathematical astronomy. The method to describe lunar motion in this work was so advanced that the imperial government adopted it immediately. In AD 206, he examined and approved the formal edition of *Qian Xiang Li*. This is one of the best calendars in ancient China. It used new data for the tropical year ($365\frac{145}{589}$ days) and the synodic month ($29\frac{773}{1457}$ days), calculated the advance of the lunar perigee, established the concept of the moon's path, and calculated the regression of node, established the first table of the lunar apparent motion in ancient China, and also made progress in the calculation of eclipses and planetary motion.

Logic

C. K. Raju

It is believed in the West that logic began with Aristotle and that logic is universal. The core of Western thought – including present-day formal mathematics and the philosophy of science – is premised on the belief that logical truths are universal, that they are necessary truths, and that logical deduction is certain and infallible. These beliefs about logic, however, are untenable, both historically and philosophically, in a larger picture which takes the rest of the world into account.

Philosophically, present-day formal logic, like the twelfth century BCE text, *Organon*, attributed to-Aristotle, supposes that deduction relates to two-valued logic. In such a logic, an affirmation A conjoined with its negation ($\sim A$) makes a contradictory pair, from which any conclusion B whatsoever can be validly inferred by the rule of inference known as *reductio ad absurdum*: ($A \wedge \sim A \Rightarrow B$), to put it symbolically, with "$\sim$" denoting "not," "$\wedge$" denoting "and," and "$\Rightarrow$" denoting the usual (material) implication. For example, A could be the proposition, "This pot is red," so that its negation $\sim A$ would be the proposition, "This pot is not red." From the contradictory pair ($A \wedge \sim A$), one can validly infer something completely unrelated like B: "The age of the cosmos is 8,000 years." Such proofs by contradiction are common in present-day mathematics. However, such a deduction would be invalid with a variety of logics that one can conceive of. The alleged certainty of deduction, therefore, rests on the belief that two-valued logic is universal or at least special in some way.

However, the various logics used for inference in India, prior to even the historical Aristotle, were neither two-valued nor even truth-functional. The *Dīgha Nikāya* provides an example. As the Buddha explains in the *Brahmajāla Sutta*, there are four alternatives:

1. The world is finite; this is one case.
2. The world is not finite; this is another case.
3. The world is both finite and infinite; this is the third case.
4. The world is neither finite nor infinite; this is the fourth case.
5. There are no other cases.

The semantic interpretation of the third case is that the world may be finite in one direction, but infinite in another. This presents no inherent absurdity, and could conceivably be in the nature of things.

The meaning of the fourth case, not so well brought out in the English translations of the *Dīgha Nikāya*, may be better understood as follows. Consider a person who refuses to take a position, and denies that he affirms any of the first three cases above. His position can only be described by the fourth case.

The need for such a fourth case is apparent from the thinking then prevalent. Likewise, the absence of any further cases is a reference to further negations used by pre-Buddhist thinkers like Sañjaya the Sceptic, who tried to wriggle out of even this fourth position, and whose comprehensive refusal to take any position whatsoever was described by the Buddha as being like the "wriggling of the eel."

These four cases are systematically used by later-day Buddhist thinkers like Nāgārjuna and Dinnāga who taught at the University of Nalanda. The latter developed a theory of (logical) quantifiers, "for all," "for some," etc., based on this sort of logic. From the perspective of present-day formalist treatments of logic, it should be noted that Buddhist logic is not multi-valued but is rather a quasi truth-functional logic.

The Jains had a related but different logic called the logic of *syādavāda* ("perhaps-ism"), based on the idea of *anekāntavāda* (no-one-point-of-view-ism). Attributed to Bhadrabāhu, instead of four alternatives, this logic has a sevenfold judgment (*saptabhangīnaya*) based on seven possible combinations of three primary values: *asti* (is), *nāsti* (is not), *avaktavya* (inexpressible), taken one, two, and three at a time.

Syad asti. ("Perhaps it is.")
Syad nāsti. ("Perhaps it is not.")
Syad asti nāsti ca. ("Perhaps it both is and is not.")
Syad avaktavya. ("Perhaps it is inexpressible.")
Syad asti ca avaktavya ca. ("Perhaps it is and is inexpressible.")
Syad nāsti ca avaktavya ca. ("Perhaps it is not and is inexpressible.")
Syad asti nāsti ca avaktavya ca. ("Perhaps it is, is not, and is inexpressible.")

Haldane sought to interpret the Jaina logic of *syādavāda* by temporalizing the three primary values. Consider an experiment in which a person is asked to judge whether or not a sensory stimulus, at the threshold of perception, is present. If this experiment is repeated several times, a person might in one case judge the stimulus as present, in another as absent, and may remain undecided sometimes. Combining these possible experimental outcomes in all possible ways gives us the seven different judgments used by *syādavāda*. Thus, it is quite possible that a person may, at one time say that a stimulus is present, but may, on a later repetition of the same experiment, say, about the same stimulus that it is absent, and on a third occasion say that he is unable to decide.

Haldane's interpretation of *syādavāda*, making it intelligible in a mundane context, seems, however, not to be correct. It is one thing to say, "This cat is now alive, and will be dead some time later." This is true of most known cats, and presents no difficulty: A is true at one time, and $\sim A$ is true at another time. However, it is altogether another thing to say, "This cat is both alive and dead at this moment of time." That sort of thing happens only to Schrödinger's famous cat (or its kittens). It is the latter sort of statement that is meant in Buddhist and Jaina logic, as is clear from the meaning explained by the Buddha. In fact, on Buddhist thought, as further elaborated by Nāgārjuna, a thing – anything – does not persist for more than an instant of time. Therefore, a statement about a cat, for instance, must refer to that cat at a given instant of time, for an identical cat does not exist at two different instants of time.

In terms of the present-day formal semantics of logical worlds, one might put things as follows. The different possibilities visualized in Buddhist and Jaina logic refer not to multiple logical worlds assigned to different instants of time, but to multiple logical worlds assigned to a single instant of time. In other words, Buddhist and Jaina logics relate to a world view in which time is perceived to have a nontrivial structure, an (atomic) instant of time is perceived not as a featureless geometrical point but as a microcosm. Hence, members of a contradictory pair can well be simultaneously true.

This can be understood at the mundane level as follows. Consider the statement, "This pot is both red and black." We could rewrite this, less informatively, as, “This pot is both red and not red.” Since earthen pots made by hand are rarely of a single color, this is a statement about a naturally prevailing state of affairs that is commonly observed. The statement, as framed, seems like a contradiction. But, it could be argued that this is an imprecise natural-language statement which should actually be written more carefully as, “This part of the pot is red, and that part of the pot is not red.”

However, such a reinterpretation raises some issues. First, there is the issue of the whole not being the sum of its parts. It is being assumed that the pot can be subdivided into parts. If the pot is physically shattered to carry out this subdivision, one can continue to speak of parts of the pot, but one cannot continue to speak of the pot. Therefore, the reinterpretation does not capture the exact sense of the natural-language statement. Thus, the idea of a thing being both true and false is not such an odd idea, and no catastrophic consequences need follow from it.

Second, how can we be sure that the apparent contradiction can always be resolved by suitably shattering the identity of the pot? Thus, a certain part of the shattered pot may continue to be both red and black, so one may want to divide the pot in a particular way. Now it may happen that, in a certain part of the pot, red and black are so entangled that it may not be clear how to separate them. The remedy obviously seems to be to make a finer division of the pot, and a still finer division, and so on, until the pot is suitably atomized. However, there is an assumption here. The assumption is that the entanglement and the resulting contradiction will somehow eventually resolve themselves with this process of reduction and that the entanglement cannot persist at the atomic level, where a thing either is, or is not. Apart from the fact that atoms are neither red nor black, there are several problems with such an assumption. For example, this assumption is contrary to what our most sophisticated theories of physics tell us. The behavior of physical systems at the atomic level is described by quantum mechanics, which tells us that there may exist entangled states that cannot be disentangled without fundamentally altering the system. The existence of such entangled states, incidentally, provides the hope today for future technology based on quantum computing, and it has various physically measurable consequences.

On the structured-time interpretation of quantum mechanics, these entangled states are interpreted to arise because time really has a microphysical structure (in the sense explained above, in the context of Buddhist and Jain logic) so that the logic of the microphysical world is quasi truth-functional. (In the structured-time interpretation of quantum mechanics, such a quasi truth-functional logic is related to the postulates of formal quantum mechanics.) To summarize, the logic of the empirical world may well be quasi truth-functional: i.e., we might have a situation where a proposition is both true and false at a single instant of time. Hence, we cannot automatically assume that the “contradictory” properties of a pot can be made to disappear by atomizing the identity of the pot.

Theoretically, from the viewpoint of present-day formal logic, one can conceive of an infinity of different logics, such as 2, 3,..., *n*-valued logics, or non-truth-functional logics. Among the infinity of logics that are available how can we be sure that two-valued truth-functional logic is the correct and universal choice? Suppose the choice is made culturally. That is, suppose we say that two-valued logic is what has been conventionally used in the West, and this is the logic that should be chosen since the West is culturally dominant. (A similar argument was given against intuitionists; it was argued that they were not adequately socially dominant among mathematicians, hence they were incorrect!) However, if such a weak argument is the ultimate basis of deduction, then deduction can at best give us a local cultural truth. On the other hand, suppose the choice is made empirically, then, as we have already seen above, we might end up with the logic of quantum mechanics, which need not be two-valued. Therefore, it is not clear that there is anyway the existing choice of logic in the West can be justified.

The possibility or necessity of determining logic empirically strikes at the root of another fundamental difference between Western and non-Western perceptions of logic. In the West, logical truths are regarded as necessarily true, and are privileged over empirical facts, regarded as being only contingently true. Present-day mathematical proof is required not to involve the empirical, since that would diminish the sureness attached to a mathematical theorem. Hence, also, the present-day belief in the philosophy of science, that when the conclusions of a physical theory are refuted by experiment it is the hypotheses that stand refuted, and not the process of inference which led from hypothesis to conclusion. (Here it is necessary to distinguish between validity and correctness. The point is that it is believed that no empirical fact can invalidate a correct mathematical proof.)

Therefore, even if one were to go about trying to settle the nature of logic empirically, this would have consequences which would be startling from a Western perspective. Empirical observations are fallible, and subject to revision. So if the nature of logic is decided empirically, logical truth would have to be regarded as more fallible than empirical truth: deduction would have to be regarded as more fallible than induction, since the nature of the logic used for deduction could only be decided inductively. This would stand much of Western thought on its head.

This would, however, leave much of non-Western thought unaffected. The belief that metaphysical (e.g., mathematical) truths are privileged over empirical truths is not necessarily shared by the non-West. In traditional Indian thought, for example, logical truths are ranked below empirical truths. Thus, the empirically manifest (*pratyakṣa*) is regarded the first *pramāṇa* (proof), and this is a means of proof accepted by all traditional Indian schools of thought, without any known exception. Inference (*anumāna*) or deduction is regarded like estimation as an inferior means of proof by the Lokāyata school and rejected, just as analogy is regarded as an inferior means of proof by Buddhists, and rejected in comparison with the empirically manifest and inference.

Thus, there appears to be no serious way out of this dilemma about the nature of logic, and most of Western thought would hence need to be reworked in the future to avoid this incorrect assumption that two-valued logic is somehow universal.

From a historical perspective we can understand how this Western myth about the universality of logic developed. The word "logic" derives from "logos" meaning "word" or "reason" – a term imbued with deep religious significance by the (Neoplatonist) philosophers of Alexandria, like Proclus, who refer to it as "divine." The reason for this, as stated by Plato, was that geometrical truths based on reason were thought to be eternal – like the soul, and unlike empirical things (like the body) that are by nature perishable. Proclus explains that mathematics derives from the Greek word *mathesiz*, meaning learning, so that mathematics is the science of learning. According to Socratic belief, all learning is recollection of knowledge already in the soul; hence it was thought that mathematics, since it embodies eternal truths, and stirs the soul reminding it of its past lives, thus justifies its name as "the science of learning" or the "science of the soul." This belief in eternal truths was also understood quite literally as implying a world which existed eternally, a subject on which Proclus wrote a book.

After the Christian church revised its doctrines of creation and apocalypse in the fourth century BCE, it found this belief in eternal truths, past lives, and an eternal world, implicit in mathematics and logic, contrary to the revised doctrines. The church viciously persecuted the philosophers of Alexandria, burning their books, smashing their temples, lynching them, and eventually making a law declaring a death penalty on them. The philosophers found a more congenial base in Jundishapur in Iran.

This religious significance of logic or reason, however, remained part of early Islamic rational theology (*aql-i-kalām*), and it received a big boost when the philosophers moved from Jundhishapur to the Bayt al-Hikmā (House of Wisdom) in Baghdad, with the support of Caliph al-Māmun. The belief in reason then acquired such force in Islam that even key opponents of the philosophers, like al-Ghazālī, conceded that God was bound by logic and could not create an illogical world or a world in which something might have contradictory properties.

Though incidental to al-Ghazālī's primary objective, this concession about logic marked a fundamental shift which has gone unnoticed. Plato and Proclus had thought that logical and mathematical truths were necessary truths in the sense that they were eternally true or true for all time. In al-Ghazālī's vision, Allah continuously created the world afresh each instant; therefore nothing could last eternally. With al-Ghazālī's concession that Allah could not create an illogical world, the notion of necessary truth acquired a new meaning. That is, al-Ghazālī regarded logical (and mathematical) truths as necessary truths in the sense that they were true in all conceivable worlds (that Allah could create), and not in the sense that logical truths were eternally true.

Western thought developed in European universities from the twelfth century BCE onwards under the influence of hundreds of Arabic texts translated into Latin. Particularly important were the texts written by al-Ghazālī's Islamic opponent Ibn Rushd (Averroes). For Ibn Rushd, the term "Aristotle" was a generic term for "the Greek sage," linked to the book called the *Theology of Aristotle*, one of the translations of the Baghdad House of Wisdom. Thus, for Ibn Rushd reason and religion continued together.

This Arabic knowledge flowing into Europe alarmed a section of the church and was regarded as spreading heresy at the time of the Crusades and Inquisition. Aquinas and the schoolmen undertook to make this knowledge theologically correct.

The first step in this process of theological purification was to deny any Arabic–Islamic contribution whatsoever in these eleventh century BCE Arabic texts, and to attribute wholesale to Aristotle, or some other Greek, the authorship of any desirable part of these works. (Theologically unacceptable parts were attributed to various others, like Plotinus.) Since the church could hardly acknowledge publicly that all its knowledge came from Islamic sources, so it had to be pretended that the heathen were mere carriers of what formerly was Western knowledge. The evidence linking these late and obviously accretive texts to the historical Aristotle is expectedly slight, and requires a giant leap of faith, but religious history is no stranger to such leaps of faith. This concocted story based on flimsy evidence has been uncritically accepted and repeated for centuries, but hardly stands up to the slightest critical scrutiny. In the process of denying the Arabic–Islamic contribution, the Indian contribution from the Nyāya school, which used a similar system of syllogisms (with two-valued logic), and was probably translated in the Bayt al-Hikmā, may also have been denied. The point here is not the priority for the syllogism – priority does not have the same importance in the non-West as it has in the West – the point is to understand the historical process by which the syllogism developed. In India, given the wide-ranging nonviolent debates between clashing traditions, it was important to evolve a systematics of argumentation. It is easier to believe that the syllogism developed in response to some such social need than to believe the tale that a single individual called Aristotle apparently created a complex theory *ex nihilo*.

Could the similarity between the Indian and the "Aristotelian" syllogism be due to transmission? Certainly, there were regular contacts between India and Greece from before the time of Aristotle, as recounted by Herodotus or as evidenced by Alexander's attempt to find the sea route to India after his army mutinied at the frontiers of India. Second, as a key beneficiary of Alexander's loot of Egyptian, Persian, and Babylonian books, Aristotle also had the benefit of access to a wide variety of world literature. Third, we know from the rock edicts of Aśoka the Great that he sent an envoy to Ptolemy II to teach righteousness (*Dhamma*) to the Alexandrians and Macedonians. Fourth, India had a roaring trade with Alexandria at the time of the Roman empire, and Roman historians complained that this trade was draining a major part of the surplus of the empire. Fifth, Augustine taunted the Alexandrian philosophers for being interested in "the mores and disciplines of Inde." So, transmission of knowledge between India and Alexandria certainly could have taken place (in either direction) over a wide-ranging period.

Whether such transmission involved the syllogism is another matter. It seems not to have been much used in Hellenic tradition. Therefore, it lacks credibility to imagine the pre-Hellenic existence of a syllogistic logic, from eleventh century BCE Arabic or later Byzantine Greek texts. The known facts are that the use of the syllogism among Arabs does not begin before the ninth century BCE, and among Europeans not before the twelfth century BCE; everything else is conjecture.

Apart from denying the slightest credit to the non-West in all the accumulated knowledge in the eleventh century Arab texts, the second step in the Christianization process of these texts was to revise the significance of logic and reason. Reason was no longer the window to the soul but was promoted in Christendom as a means of argument used to persuade the infidel who would not listen to arguments from the scriptures, but would accept arguments based on reason. Hence, reason (and the logic used by Aristotle) was declared to be "universal." It is in this way that it historically came to be believed in the West that logic began with Aristotle and is universal, although both beliefs are incorrect when a larger picture is taken into account.

In India itself, the Nyāya tradition was attacked by the Advaita Vedantist S'rīharṣa, in the ninth century BCE using arguments similar to those of Nāgārjuna. The Navya–Nyāya (new Nyāya) logic emerged subsequently.

Long Count

Vincent H. Malmström

One of the most original creations of pre-Columbian Mesoamerica was the so-called "Long Count," a system of recording events in time with unique precision. No parallel system existed in any other society until the Julian Day count was begun in Western Europe in 1582. Because it was most widely used by the Maya, its development was first credited to them, but subsequent research has shown that the earliest inscriptions which employed the Long Count not only lay well outside of the Maya core-area geographically, but also predated the rise of the Maya historically.

The Mesoamerican Long Count was a meshing of the two time-reckoning systems that had been already been in use in the region for about a millennium: a sacred almanac of 260 days and a secular calendar of 365 days. In both counts a vigesimal system was used to group the days into "bundles," for a total of 13 in the sacred almanac and a total of 18 in the secular calendar. The 5 remaining days in the latter count were considered "unlucky" or "worthless." The basic unit of the count was the day, or *kin*, in Maya. Twenty days constituted one *uinal*, and 18 uinals made up one *tun*, for a total of 360 days. (The *tun* was the only deviation the Maya allowed from a strictly vigesimal system, and was only employed in their count of days.) Twenty *tuns* comprised a *katun* (7,200 days) and 20 *katuns* constituted a *baktun* (144,000 days). The fundamental premise of the Long Count was that it recorded the number of days that had elapsed from a date in the distant past, which marked the beginning of the present cycle of the world. Because the Maya recorded their Long Count dates by enumerating, in order, the number of *baktuns*, *katuns*, *tuns*, *uinals*, and *kins* which had elapsed from that date, together with the number and name of the day in both the sacred almanac and secular calendar which it represented, any given day was identified by a minimum of nine elements. Thus, in the present convention for transcribing Long Count days, the first day of the Long Count was designated as 13.0.0.0.0. 4 Ahau 8 Cumku (Fig. 1).

Long Count. Fig. 1 One of the earliest Long Count inscriptions found to date is that recorded on Stela C, discovered by Mathew Stirling at Tres Zapotes in 1939. Although the top of the stela containing the *baktun* value was missing, it was located in 1969 and found to be a seven. In writing numerals, the Maya used a dot for values up to four and a bar to represent five; hence Stela C's *baktun* value was shown as two dots and one bar. In the photo above we see that the *katun* value has one dot and three bars equaling 16, the *tun* value has one dot and one bar totaling 6, the *uinal* value again has one dot and three bars representing 16, and the *kin* value near the bottom of the inscription contains three dots and three bars for a total of 18. Thus, the full numeric inscription was read as 7.16.6.16.18. and equates to 5 September 31(or 32 BCE). Stela C now reposes in the Museum of History and Archeology in Mexico City (photo by author).

Although many attempts were made to reconcile the Long Count with the Christian calendar, one of the first credible explanations was that offered by the American newspaper editor John Goodman in 1905. According to his calculations, the Maya had fixed the beginning of the present cycle of world as 11 August 3114 BCE – a date that accords with Julian Day number 584,283; hence, his correlation has been identified by that value. However, because Goodman was not an academic, little attention was paid to his findings until 1926 when a Mexican astronomer named Juan Martínez Hernández recalculated the beginning date of the Long Count as 12 August 3114 BCE, yielding an equivalent Julian Day number of 584,284. The following year, when the British archeologist J. Eric Sydney Thompson made his own attempt to reconcile the two calendars, he determined that the correct date should be 13 August 3114 BCE, for an equivalent Julian Day number of 584,285. Because all three of these correlations produced results within 2 days of each other and have subsequently been shown to accord most closely with known astronomical events, the so-called "Goodman–Martínez–Thompson" is now the accepted means of equating the Long Count with our own calendar. (It should be noted, however, that in 1935 Thompson revised his calculations and adopted Goodman's original formula of 584,283 instead; unfortunately, this "correction" served to confuse the correlation issue for an entire generation because it rendered all astronomical equivalencies impossible. Subsequently,

Long Count. Fig. 2 *Baktun* 7 inscriptions, which represent the earliest form of the Long Count, are all found in a restricted area stretching from the Pacific coast of Guatemala and Mexico across the Isthmus of Tehuantepec to the Gulf of Mexico. All of them are associated with early Olmec ceremonial centers (map by author).

Long Count. Fig. 3 Later examples of the Long Count, all dating to the so-called "Classic Period" (AD 250–900), occur only in areas occupied by the Maya. Apparently the Long Count neither reached other peoples in Mesoamerica nor, if it did, was adopted by them. Its presence among the Maya helps to explain their preeminence in pre-Columbian astronomic studies (map by author).

Malmström (1978, 1992), among others, has conclusively demonstrated that the 584,285 correlation is the only one which has astronomical validity.)

As early as 1930, the American mathematician John Teeple concluded that the Long Count had been devised on a date that the Maya recorded as 7.6.0.0.0. 11 Ahau 8 Cumku. Teeple had been struck by the fact that 73 cycles of the 260-day sacred almanac equated with 52 cycles of the 365-day secular calendar and that the day numbers and names of each count then came back into phase with each other. He believed that the Maya had also employed 73 cycles of larger intervals, such as *katuns*, in order to define longer spans of time, and that to fix the beginning of the present era of the world at an appropriately early date, they had projected their count backward for a total of 146 *katuns*, or 7 *baktuns* and 6 *katuns*. This meant that the Long Count had been originated on 18 September 236 BCE – a date that Thompson rejected as being too early because it assigned its creation to a people other than the Maya, who he championed.

In a paper published in 1978, Malmström, using a different premise – namely that the originator of the Long Count was bound by the recognition of the astronomical importance of 13th August as its initiating impulse – reached the same starting date for its origin as Teeple had done. Also in his paper he argued that, by using internal evidence contained in the Long Count, it is possible to establish both the beginning dates of the secular 365-day calendar and the sacred 260-day almanac as well. The former, he stated, was set in motion at the summer solstice around the year 1320 BCE, whereas the latter was initiated with the zenithal passage of the sun over Izapa in southernmost Mexico on 13 August about the year 1358 BCE. (Each of these dates may vary by as much as 4 years, due to the fact that the indigenous Mesoamerican calendars did not correct for leap years.) All of the earliest, or *baktun* 7, Long Count inscriptions have been discovered along an axis which extends from the Soconusco region of southern Mexico and adjacent Guatemala to central Chiapas into the Gulf coastal plain of Veracruz – an area which constituted the original homeland of the Zoque-speaking Olmec people (Figs. 2 and 3).

Lunar Lodges in Chinese Astronomy

F. Richard Stephenson

Probably during the first millennium BCE, Chinese astronomers grouped the stars visible from their country into about 280 small constellations, each containing an average of about five stars. Among these star groups, twenty-eight asterisms encircling the sky in the general vicinity of the celestial equator were regarded as of special significance. Although their general appearance was much similar to that of the other constellations, these select star groups, known as *xiu* (lunar lodges) came to be of great importance in astrology and positional astronomy. The expression *xiu* is the derivative of a term *su*, meaning, "to stay the night". Although many of the lunar lodges were not near the ecliptic, they represented the nightly resting places of the Moon in its monthly circuit across the sky. During the first millennium AD, the Chinese system of mapping the stars, together with its associated lunar lodges, spread to other areas of East Asia, notably Korea and Japan.

L

Just when the Chinese first divided the stars into groups is not known with any accuracy and this is also true of the *xiu*. A somewhat idealistic date for the origin of the lunar lodges can be deduced by considering precession of the equinoxes. Chinese astronomy is equatorial, rather than ecliptic, in character. Calculations reveal that in antiquity the mean great circle through the *xiu* was a significantly better approximation to the celestial equator than at present, with the best fit around 2500 BCE. Although attractive, such an artificial date has little to commend it. Several of the individual lunar lodges would still lie at a considerable distance from the mean circle, while there is no evidence of an advanced culture in China at such a remote period.

Direct historical evidence for the existence of the lunar lodges is lacking until about 3,000 years ago. The two earliest sources of information are quite diverse. Several of the ancient folk songs assembled in the *Shijing* (Book of Odes) – some probably dating from around 1000 BCE – allude to about ten star groups in total. Most of these constellations can be identified with lunar lodges as cited in later texts. Again, several bronze vessels which were cast at much the same period as the folk songs were composed are inscribed with the names of a few lunar lodges. It may thus be inferred that at least some of the *xiu* had acquired special significance

Lunar Lodges in Chinese Astronomy. Fig. 1 Laquer chest, with lid engraved with names of all 28 lunar lodges. The chest was discovered during excavations of a tomb dating from 433 BCE. (The chest is in Hubei Provincial Museum, Wuhan).

by early in the first millennium BCE. However, to encounter the earliest preserved list of all twenty-eight lunar lodges we have to move considerably forward in time.

A date of origin of the lunar lodges at least by the middle of the first millennium BCE was established as the result of a major archaeological discovery in 1978. In that year, a lacquer chest was unearthed from a tomb in Hubei province in Central China (see Fig. 1). This chest had been the property of a nobleman by the name of Yi who had died around 433 BCE, during the Warring States Period. On the lid of this chest are engraved the names of 28 constellations in a roughly circular pattern. In general, the various ideographs are identifiable with the names of the lunar lodges found in later lists, and are in the correct sequence. Of course, the existence of the 28 *xiu* as an entity could be much earlier, but at present we have no direct evidence to prove this.

Table 1 gives a standardized list (together with translations) of all 28 lunar lodges as found in texts of from the third century BCE onwards. In this table the *xiu* are numbered in their traditional order, commencing with *Xue* (located near the autumnal equinox in Virgo). In groups of seven, the lodges were traditionally associated with four mythical creatures: the first seven *xiu* with the Azure Dragon of the east, the next seven with the Dark Warrior of the north, the third seven with the White Tiger of the west and the last seven with the Red Bird of the south. Among the first seven lunar lodges, a few names relate to various features of the Dragon. However, the remaining *xiu* designations are little more than a random assemblage and in general they are much more mundane than the names of the Western zodiacal signs.

An early almanac known as the *Yueling* (monthly observances), probably dating from the Warring States Period (481–256 BCE), marks the passing months by the position of the Sun in various *xiu* as well as the culmination of certain lunar lodges at dawn and dusk. By at least the Former Han Dynasty (202 BCE–AD 9), a series of "determinative stars" (*chuxing*) – see Table 1 – were selected to specify right ascension. This coordinate was known as *ruxiudu* (degrees within a lodge). The meridian through each determinative star was adopted as the western boundary of a zone of right ascension bearing the same name as the lunar lodge itself. As a result, the term *xiu* came to mean both the asterism and the range of right ascension which it defined.

Commencing in the late second century BCE, several preserved lists give the equatorial extension of these zones in *du* ("degrees", of 365.25 to a circle.) Although the mean range in right ascension of each zone was 13°, the widths of individual *xiu* were far from regular. *Dongjing*, the widest lunar lodge, covered 33°, whereas *Zuixi* was only about 1° in extent. Table 1 gives the calculated widths during the Former Han Dynasty. As yet, the reason for this uneven spacing has not been fully explained. In some respects, the *xiu* resembled the Western zodiacal signs, which from ancient times were used to define celestial longitude. However, the signs of the zodiac were each 30° in extent and – unlike the lunar lodges – the effect of precession caused a gradual easterly displacement relative to the 12 constellations after which they were named.

For almost every solar eclipse occurring during the Former Han Dynasty, the official history of the period, the *Hanshu*, gives an estimate of the right ascension of the Sun to the nearest degree, followed by an astrological prognostication. Several later histories follow a similar practice. For instance, on a date equivalent to AD 120 January 18, the following entry is recorded in the *Houhanshu* ("History of the Later Han Dynasty"):

> The Sun was eclipsed. It was almost complete; on Earth it was like evening. (The Sun) was 11° in *Xunu* ("Maid"). The Female Ruler was upset by it; two years and three months later, Deng, the Empress Dowager, died.

At this date, the right ascension of ε Aqr, the determinative star of *Xunu* was 286° so that the estimated coordinate of the Sun would be 297°; this is in agreement with the computed right ascension of the Sun.

The lunar lodges were also used to specify the right ascensions of other star groups as well as the changing positions of the Moon and planets. The positions of temporary objects – meteors, comets, and novae or supernovae – were often described in this way. For

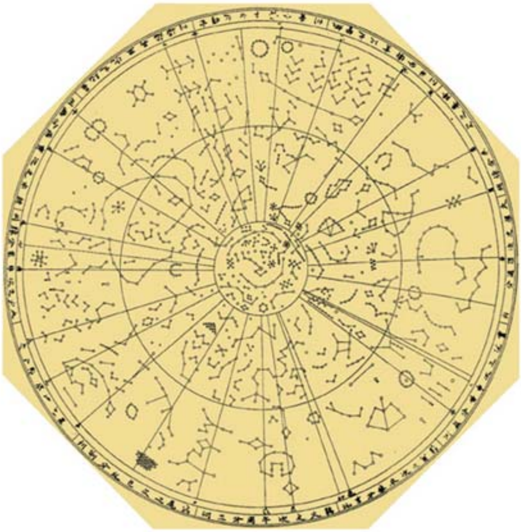
example, the passage of Halley's Comet in AD 66 through 8 lunar lodges between *Jianniu* and *Yi* is recorded in an early commentary on the *Houhanshu*.

Early measurements of the right ascension of Halley's Comet have proved of great importance in studying the orbit of the comet. For instance, at the very close approach of Halley's Comet to the Earth in AD 837, its position in the appropriate *xiu* was estimated to the nearest degree on several successive nights. At the time, the comet was moving rapidly across the sky at roughly 2°/h. The Chinese observations enable the date of perihelion to be estimated to the nearest 0.1 day. In AD 1006, the right ascension of a brilliant supernova was recorded as 3° in the lunar lodge *Di*. This and other contemporary observations have enabled the remnant to be convincingly identified.

The *Xingjing* (Star Manual), a star catalog which has been dated by astronomical computation to around 70 BCE, gives the earliest preserved measurements of north polar distance for the determinative stars of the *xiu*, as well as for many other stars. Individual results are typically quoted to the nearest 0.25° or 0.5°. Using these and similar measurements in later catalogs, together with several carefully executed star maps from around AD 1000 onwards, it is possible to identify the individual constituents of the *xiu* with stars listed in modern Western catalogs with considerable confidence. Certain lunar lodges, such as *Shen* (equivalent to the central portion of Orion), contain some very bright stars. Other *xiu*, such as *Yugui* (part of Cancer) consist of stars only barely visible to the unaided eye. Such marked differences are perhaps surprising, bearing in mind the importance of the lunar lodges. However, the brightness of a star was regarded as having little bearing on its astrological significance.

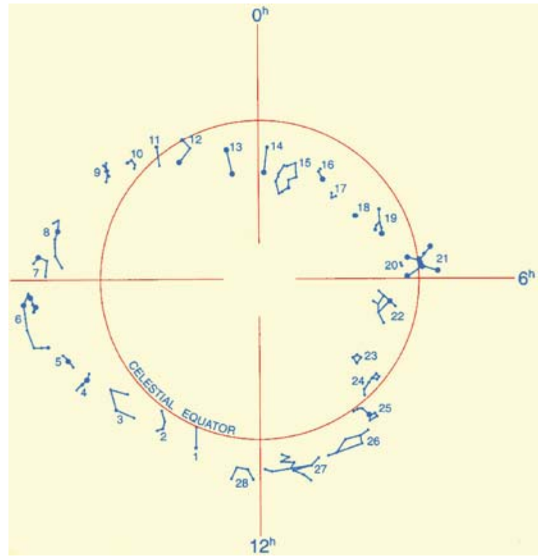
The earliest known chart of all 28 lunar lodge asterisms dates from around 25 BCE. This colorful representation is painted on the ceiling of a tomb which is located in the city of Xi'an and came to light in 1987. Many later star maps are extant – some displaying considerable detail and revealing much astronomical skill. These often depict the night sky on a circular plan (a polar projection) with the *xiu* boundaries shown as straight lines radiating from the north celestial pole at the center of the chart (see Fig. 2). Several illustrations of the lunar lodges have been found in tombs in recent decades. It is interesting to note that whereas Western representations of the zodiacal signs almost always use



Lunar Lodges in Chinese Astronomy. Fig. 2 Careful drawing of a Chinese star map dating from AD 1453. This was found in Longful Temple and is now in the Beijing Ancient Observatory. (Drawing: courtesy, Prof Pan Nai, Shanghai).

Lunar Lodges in Chinese Astronomy. Fig. 3 Chinese painting showing the 28 lunar lodges and 12 signs of the Western zodiac. This is painted on the ceiling of a tomb at Xuanhua, near Beijing, and dates from AD 1116. (Photo: Courtesy Prof Chen Meidong, Beijing).

the various symbols – e.g., a crab for Cancer, two fish for Pisces – Chinese illustrations of the *xiu* typically portray the outlines of the constellation patterns themselves (see Fig. 3). In artefacts of a nonastronomical nature, these illustrations are often quite stylised. For example, the blades of several well-preserved Korean swords are engraved with the configurations of all 28 *xiu*.



Lunar Lodges in Chinese Astronomy. Fig. 4 Celestial positions of the 28 lunar lodge asterisms. (This is my own illustration).

Individual determinative stars cover a wide range in declination: from around 0 up to some 30° (see Fig. 4). As a result, with the passage of time the differential effect of precession causes the widths of the *xiu* in right ascension to change somewhat. This effect has been most significant for *Zuixi*, historically the narrowest lunar lodge. In the Former Han Dynasty, it had a width of 1.2°. However, measurements made around AD 1280 by the great Yuan Dynasty astronomer Guo Shoujing reveal that by his time the width of *Zuixi* had decreased to almost zero. Over the next few centuries, *Zuixi* was tacitly assumed to be of zero width until the seventeenth century, by which time the calculated width was -0.4°! A well-preserved Japanese celestial globe of the time depicts only 27 lunar lodge boundaries.

Around AD 1650, the Jesuit Adam Schall von Bell, who was then Astronomer Royal of China, took the bold step of reversing the order of *Zuixi* and the adjacent lodge *Shen*, thus assigning a width of 11.4° to *Zuixi*. The revised width of *Shen* was now only 0.4°, but the effect of precession would gradually widen this lunar lodge with the passage of time. Jesuit missionaries, who made such a profound impression on Chinese astronomy in the seventeenth and eighteenth centuries, introduced improved techniques of measurement, as well as knowledge of the far southern stars which were invisible from China. However, they did not attempt to supplant the indigenous lunar lodge system (which was fundamentally equatorial) with the ecliptical scheme which was standard in the West.

Chinese astrography does not seem to have had any significant influence on cultures outside East Asia. In India, a parallel scheme to the *xiu* developed. Although there are similarities between the two systems, there are also marked differences. Vedic texts from at least as early as 1000 BCE list 27 or 28 *nakṣatra* (star groups in the path of the Moon). Like the Chinese lunar lodges, the *nakṣatra* had determinative stars (*yogatārā*). However, no measurements of the positions of the *yogatārā* can be traced until the fifth century AD. By this time, the *xiu* had already been established in China for many centuries. There is some evidence that a few of the *yogatārā* stars coincided with the Chinese *chuxing*. However, it has been shown that early Indian astronomers did not fully agree on which stars were regarded as *yogatārā*. In any event, most reference stars are quite distinct on the two schemes. The origin of the various similarities is presently unknown.

Today the lunar lodge system has been abandoned in East Asia – except at the popular level – in favor of Western techniques of specifying star positions.

Lunar Mansions in Indian Astronomy

K. V. Sarma

In Indian astronomy the 27 or 28 *nakṣatras* (constellations) with their *yogatārās* (junction stars), all situated in the zodiac, correspond to the lunar mansions called *xiu* in the East Asian and *manāzil* in the Islamic tradition. *Nakṣatra* (lit. *na-kṣatra*, non-moving, fixed; *nakta-tra*, 'guardian of the night'), meaning 'star', refers to the 27 asterisms or star groups that occur on or on the sides of the zodiac. It refers also to the 27 equal spaces into which the zodiac can be divided, each space being equal to: 360°/27 = 13°20′ or 800′, commencing from the First point of Meṣa, which is the starting point of the zodiac in Indian astronomy. Now, the zodiac is

divided into 12 equal parts, each being 30°, called 'sign' or *rāśi*, to accommodate the 12 solar months. Hence, each *rāśi* holds, inside it, two and a quarter *nakṣatra*-spaces, each distinguished by a prominent star which is called *yoga-tārā*.

Since the performance of rituals and sacrifices at specified times, days, seasons, and years was obligatory for the Vedic Indians, they were interested in the preparation of a workable calendar to be able to ascertain the specified times. This required the study of the motions of the sun and the moon, which moved along or near the zodiac. The fixed stars and constellations provided the astronomers with a stellar frame of reference against which they could follow and measure the movements of the sun, the moon, and the planets. Hence Indian astronomy identified and concentrated on the study, from very early times, of these stars only, to the exclusion of the general array of stars that stud the heavens. Thus the *nakṣatra* system of the Hindus came into being.

The *nakṣatras* had been identified even during the time of the *Ṛgveda,* though only those which were relevant to specific Vedic prayers were mentioned therein. In the *Yajurveda* and the *Atharvaveda*, however, all the *nakṣatras* were mentioned in the order in which they appear on the zodiac, since in those texts contexts required their mention in a row. In the *Yajurveda* literature, the several *nakṣatras* were assigned presiding deities, pictured as male or female or neuter, and the plurality specified. Legends have also been narrated to explain some of the characteristics of the *nakṣatras,* besides specifying them as benefic or malefic, which aspect was elaborated in later astrological literature.

Yogatārā (Junction star) is the cardinal star in a *nakṣatra* which is made up of several stars. Normally, the *Yogatārā* would be the brightest star in the group, and the zodiacal signs would mostly be named after that star. The several constellations of Hindu astronomy, the details regarding them, and their *Yogatārās* are listed in Table 1.

It is interesting that besides the above details, the work *Nakṣatra-kalpa,* an ancillary text of the *Atharvaveda,* also provides, among other things, the number of stars making up each constellation.

Lunar Mansions in Islam

PAUL KUNITZSCH

The old Arabs, before their acquaintance with Greek-based astronomy, had their own folk astronomy. They knew the fixed stars and used a number of stars and asterisms, the so-called *anwāʾ*, for orientation in nightly desert travels and for fixing seasons and predicting weather, especially rain. At an unknown time, and through unknown channels, they received from India the system of the 28 lunar mansions (*manāzil al-qamar*), stars or asterisms or spots in the sky, roughly along the ecliptic (the band of the zodiac through which the sun apparently moves in its yearly course), near which the moon was seen in the sky during its monthly revolution. Each mansion was identified with one of their *anwāʾ* stars or asterisms. The complete list is presented in Table 1.

Later, after the spread of Greek-based "scientific" astronomy in the Arabic–Islamic civilization, i.e., from the eighth century onward, astronomers knew about this system and gave exact identifications of the mansions' stars from among the 1,025 stars fixed up in the star catalogue in Ptolemy's *Almagest*. But the lunar mansions were not actually used by the Arabic–Islamic astronomers in their work. Their place was mostly in astrology. Here they were included in the numerous systems of divination, and in this context they were also borrowed into the Latin translations of Arabic astrological works, in Spain, in the late tenth century and, more often, in the twelfth and thirteenth centuries. Thus their corrupted, Latinized names are found throughout European astrological writings from that time on.

Luoxia Hong

JIANG XIAOYUAN

Luoxia Hong was a Chinese astronomer active in the Western Han Dynasty about 100 BCE. He came from southwest China as a folk astronomer. When the Emperor Wu (140–87 BCE) decided to draw up a new calendar, Luoxia Hong and more than 20 other astronomers were called together in the capital Chang'an. These folk and imperial astronomers put forward their plans for a new calendar. After comparing 18 plans, the emperor believed that the best one was put forward by Luoxia Hong and another astronomer Deng Ping. The new calendar was applied to the whole country in 104 BCE and called *Tai Chu Li* (Tai Chu

L

Calendar). This calendar became the standard model for nearly 2,000 years. It was a lunisolar calendar with the 19-year and 7-leap cycle, and included the calculation for the motion of the sun, moon, planets, and for eclipses. In fact it was a mathematical astronomy system. The emperor intended to confer an official position on Luoxia Hong to cite his achievements, but Luoxia refused it and preferred to live in seclusion.

Luoxia Hong made an equatorial armillary sphere to measure the data of his new calendar. He is one of the candidates for the inventor of this instrument.

Mādhava of Saṅgamagrāma

R. C. Gupta

During the Muslim rule in north India, there was a decline in Hindu culture. This adversely affected the creative spirit in indigenous art, literature, and science. Southern India was comparatively less affected, and traditional culture and the sciences flourished there. The followers of Āryabhaṭa I made enormous contributions to the development of mathematical sciences. It was a golden age of Indian mathematics.

Mādhava of Saṅgamagrāma, who flourished about AD 1400, was the first great astronomer and mathematician of the Late Āryabhaṭa school, which he in fact founded. Saṅgamagrāma has been identified as the modern Irinjalakkuda, a town near Cochin in Kerala State. Mādhava belonged to the Emprantiri subcaste group of Kerala Brahmins. We have no knowledge about his parents and teachers, or of the exact dates of his birth and death. Various dates ranging from AD 1336 to 1418 are used in his works. Hence the period of activity of his life has been roughly fixed from AD 1340 to 1425.

There is no doubt that Mādhava was an extraordinarily brilliant man. He used his talent and sharp intelligence to acquire knowledge by private study, and could thus overcome the difficulty of finding a good Guru because of his inferior status in the dominant Namputiri Brahminic community. He was a self-taught genius and not a gifted pupil. He was generally referred to as *Golavid* (Master of Spherics) by subsequent scholars and followers of his School, such as Nīlakaṅṭa Somayāji (AD 1444–1545) and Acyuta Piṣāraṭi (AD 1550–1621).

Mādhava wrote all his works in Sanskrit, the classical language of India. One of his earliest works is the *Candra-Vākyāni* (Moon Sentences). This was composed as a revision of Kerala's ancient traditional astronomical work attributed to Vararuci, who lived 1,000 years earlier. The *Candra-Vākyāni* gives 248 mnemonic phrases regarding the longitudinal position of the moon for each of the 248 days which comprise a period of nine anomalistic months.

The *Sphuṭacandrāpti* (Computation of True Moon) contains 51 verses and is a work of the *Karaṇa* category. A *Karaṇa* is a handbook on practical astronomy. In this one, he provides an ingenious method for finding the true position of the moon.

Mādhava's *Veṇvāaroha* (Bamboo Climbing) is an elaboration of his *Sphuṭacandrāpti* and consists of 74 verses. In this work the author created a facile procedure to find the true lunar positions at intervals of about half an hour. It is dated as AD 1403, and is the most popular astronomical work of Mādhava. Acyuta Piṣāraṭi wrote a Malayalam commentary on it.

A recently identified astronomical work of Mādhava is *Agaṇita-grahacāra.* It is an extensive work on planetary computations using somewhat novel methodologies. It is a treatise of the *Karaṇa* category and must have been composed just after AD 1418 which is the latest date mentioned.

Among other unpublished works of Mādhava there are two short astronomical tracts. One is the *Madhyamānayanaprakāra* (Method for Computing Mean Positions) which is extant in a unique manuscript at the India Office Library. The other is *Lagnaprakaraṇa,* of which at least three manuscripts exist in South India. This work deals with computations of ascendents.

It is possible that Mādhava composed a work on *Golavāda* (Spherics) which earned him the appellation *Golavid.* But the reported manuscript from a private collection has been eaten by white ants. Mādhava was also the author of a number of stray or free verses which have been cited by later authors and commentators.

Scientific Contributions

The traditional "moon sentences" of Vararuci (fourth century), used in Kerala, gave daily longitudes of the moon only up to minutes of the arc or angle. Mādhava computed more sophisticated moon sentences which expressed the longitudes correctly up to seconds. By making use of the popular system of alphabetic numerals, called the *Kaṭapayādi Nyāya,* these mnemonic phrases were made short and aphoristic. Mādhava also provided a value of π using a system of word numerals (*bhūta-saṁkhyās*).

The knowledge of an accurate value of π enabled Mādhava to obtain a better value of the traditional

Sinus Totus (Total Sine, or radius). Mādhava's sine table is quite precise and accurate. He may have used traditional methods for getting the table or the newly discovered power-series expanion of sine (see below). For computing sine for the argument intermediary between any two tabulated angles, he knew a formula which is equivalent to the modern Taylor series approximation up to the second order. Higher interpolation based on second order finite differences had been known in India since the time of Brahmagupta (seventh century AD).

For computing π to any desired degree of accuracy, Mādhava discovered a number of series including the one $/4 = 1 - 1/3 + 1/5 - 1/7...$, often called the Leibniz series after the German mathematician G.W. Leibniz.

Another formula perhaps known to Mādhava is now called the Gregory Series, after the Scottish mathematician James Gregory (1638–1675). The Indian proof is found in the *Yuktibhāṣā* (AD sixteenth century) and other works.

One of Mādhava's major achievements was the discovery of the power-series expansions of sine and cosine, and which are equivalent to

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + ...,$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + ...,$$

The two Sanskrit verses which embody the method of computing sine based on power-series up to x^{11} are quoted by Nīlakaṇṭha in his commentary on the *Āryabhaṭīya* (II, 17b).

In this connection it is relevant to discuss a small tract called *Mahājyānayana-prakāra* (Method for the Computation of the Great Sines). It gives the power-series methods for computing *Mahājyās* (Great Sines). Unfortunately there is no mention of an author's name in it, although Mādhava's rule for computing sines up to x^{11} is mentioned. Sarma attributed the tract to Mādhava, but Gold and Pingree consider it to be the work of his follower(s). Perhaps Mādhava explained his theory during lectures to his pupils, whose lecture notes may be the basis of the above tract.

Magic and Science

KAREN LOUISE JOLLY

The concepts "magic" and "science" are products of Euro-American history; thus their use in other regions of the globe, from the colonial era to modern anthropological studies, is intertwined with Western intellectual history. Consequently, understanding the meaning of, and relationship between, magic and science in the context of western notions of rationality is essential when examining phenomena in non-Western societies placed in these categories. Magic and science are, in essence, labels used to exclude and include according to an intellectual value system rooted in European history. They are part of the cultural baggage taken abroad by Euro-American travelers, and used to identify "otherness" in foreign cultures. In non-Western cultures, similar practices of "magic" were not necessarily excluded or marginalized by the growth of science as they were in the West.

The European evolution of these two words from the classical (Greco-Roman) era to the twentieth century shows a growing gap between magic as occult or hidden knowledge on the one hand, and science and religion as public knowledge on the other. Increasingly in the European intellectual tradition, science was defined in narrower ways while pushing magic out of the realm of knowledge. This contributed to an evolutionary paradigm applied by Westerners to non-Western societies, of progress from magic to religion to science, a model now called into question by modern anthropologists. Because of this conceptual evolution in the intellectual history of Europe, "magic" and "science" can be used in a number of senses in modern

English usage (see the *Oxford English Dictionary*). The gradual transformation of the word science as a distinctive rationality valued above and against magic is part of a uniquely European duality not generally found in non-Western societies, where magic can exist side-by-side with science and religion.

History of the Terms in the Western Intellectual Tradition

European intellectual history is full of self-imposed oppositions: temporal–spiritual, natural–supernatural, pagan–Christian, devil–God, magic–religion, and magic–science. All of these are subject to a moral scale of Good versus Evil, a distinction in Western thought that has its roots in the Judeo–Christian monotheistic system positing a single, omnipotent, all-good Deity. This way of thinking is very different from, for example, the Chinese world view embodied in *Yin* and *Yang*, opposites that create balance (positive–negative, active–passive forces) without the identification of Evil versus Good. Thus, the Western dualities are not, as some westerners visiting other cultures have assumed, universals found in all cultures; rather, they are a particular product of the belief systems and intellectual history of Europe.

Nonetheless, despite these polar oppositions in European thought, changes in definitions over time caused overlaps and gray areas. Thus magic, as the opposite of religion or science, has a history that complicates the way the word is used at different times and places by different classes of people. The self-defined shape of European history is one of progress from magic to religion to science: from root definitions in classical culture (Greco-Roman), through the medieval magical and religious mentality, through major religious and intellectual changes (renaissances) in the medieval and early modern world, to the development of science as a separate discipline in the modern world. At the same time, this chronological picture is muddied by the slippery definition of magic as it changes in relation to the growth of religion and science. Throughout the development of these distinctions, from the fourteenth through the nineteenth and twentieth centuries, Europeans and Americans went abroad and applied these differing notions to the peoples they met.

The root meaning of magic contains a sense of exclusion found throughout the history of the term: in the Roman world, the Latin *magia,* derived from *magi* (Persian astrologers like the Magi of the Christmas story), implied a foreigner, even when the practitioner was a Roman. This was someone who possessed secret and powerful knowledge both feared and respected, displayed in the ability to manipulate unseen or spiritual agencies, in such arts as divination, astrology, curses, oracles, and amulets to ward off evil (Luck 1985). Thus the word magic has at its root a sense of marginality in its otherness and its paranormal, unknown, and supernatural associations, but also a strong sense of power held exclusively and secretly by the *magus.* The root word for science, on the other hand, is more normative: *scientia* includes knowledge, art, or skill. It derives from the Greek heritage a strong sense of human rationality, but comes to include divinely revealed knowledge as well in the Christian era (from ca. 200).

In the progress model, the magic of the European past is associated with the medieval period (ca. 500–1350), in contrast to the rationality of the Renaissance (fourteenth and fifteenth centuries) and Enlightenment (eighteenth century) intellectual revolutions. "Medieval" thinking has earned the label "magic" from later generations on several grounds. The medieval otherworldly emphasis and reliance on divine revelation led to a lack of distinction between natural and supernatural and contributed to an allegorical way of thinking about nature, so that objects such as a flower and events such as storms or illnesses were read as divine messages. Medieval thinking rested on a belief in a wonder-working, ever-present God and also a magic-working evil presence in the devil; sometimes the miracles of God's saints and the tricks of the devil appear similar in method in the eyes of later thinkers (Flint 1991; Thomas 1971). Specifically, the belief in supernatural powers in words is found in both Germanic animism (worship of nature spirits) and the Christian tradition: in Germanic animism charms (ritual words and actions) invoke the inherent virtues of a plant. In the Christian Eucharist, bread and wine are changed into flesh and blood through prayer. The two were joined in Christianized folk medicine in the production of charms using Christian prayers as the powerful words (Jolly in Neusner et al. 1989). To Protestants (after the sixteenth century) and anthropologists (late nineteenth century), these practices are all magical in their manipulation of nature through word-magic (as opposed to true religious prayer as supplicatory). Yet to the medieval mind, magic was defined by *who* – God or the Devil – not by *how* – supplication versus manipulation. Thus medieval thinking was rejected as backward by later rationalists and was used to describe cultures that had not advanced out of magical or superstitious thinking.

Religion, in the history of European "progress," moves away from magical thinking and opens the door for rationalism. The tradition of logic and deductive reasoning dates back to the Greeks and partially survived into the Middle Ages through Roman-Christian church leaders and thinkers; the recovery of Aristotle through Arab sources in the twelfth century helped spur a renaissance in learning among medieval scholars so that human reason was placed alongside divine revelation as a way of knowing truth. This interest in the potential of human reason to understand things in conjunction with divinely revealed knowledge cleared a space for reason to function independently over the succeeding centuries. The separation of natural from supernatural, and reason from revelation, allowed thinkers to focus on the human study of natural phenomena. Magic in this context became things not in the category of the divine (miracles) and not subject to human reason either: black magic associated with the devil and witches, such as curses and evil spells, or the low magic of ignorant persons based on false reasoning, such as herbal charms and love potions. High, white magic was associated with the intelligentsia of the high Middle Ages and Renaissance (twelfth through fifteenth centuries). These early scientists dabbled in the occult, a gray area in between divine knowledge and human reason: occult phenomena were insensible (not subject to human sense perception), such as magnetism, gravity, or the pull of the stars, but might be intelligible (something to be reasoned about); these occult phenomena, classified as "natural magic," became the sciences of astrology, astral medicine, and alchemy, for example.

In the Scientific Revolution, science became a separate, and increasingly higher, discipline from religion; it came to mean exclusively the human (versus divine) study of natural (versus supernatural) phenomena. This secularization of knowledge was the product of the Italian Renaissance of the fourteenth and fifteenth centuries and the Enlightenment of the seventeenth and eighteenth centuries. Simultaneously, Protestant ethical values contributed to this process a utilitarian view of the created order that effectively circumscribed religion into a rational system: God made the world to work by certain laws that humans could understand and systematize (Tambiah 1990). Human study could produce a true understanding of reality independent of divine insight. Magic was now clearly marked as something not rational: it could be proven to be a hoax (prestidigitation or sleight-of-hand), and was relegated to the entertainment industry where it could be enjoyed as an illusion, a deception that could be scientifically explained. As science became the religion of the modern west, magic was being exorcised from modern consciousness not as demonic but as irrational and backward.

This simple pattern of progress from magic to religion to science is misleading in two ways: it is anachronistic in applying later definitions of magic back on to earlier periods where the word had different meanings, and it does not take into account the overlaps and continuities whereby magic survives alongside religion and well into science. For example, the Scientific Revolution is compromised by intellectual dabbling in the occult: the great shift from a geocentric worldview (earth at the center) to heliocentric (sun at the center) was founded not just on forward-looking developments in mathematics and astronomy but was motivated by a backward-looking interest in a supposedly Egyptian magical tradition, Hermeticism (Tambiah 1990). Differences of class in relation to conceptions of magic further complicate this picture of Euro-American intellectual history: the older ways of folk belief, in medicine for example, as a viable, not magical, method of manipulating nature or spiritual agencies was retained among many classes long after the religious authorities or the intellectual elite had dispensed with it, and in some cases had begun investigating it as witchcraft (antireligion) or fraud (unscientific). All of these divergent attitudes toward magic were carried abroad by Europeans and Americans: magic as demonic, evil, and fearful; magic as medieval or backward; magic as unscientific, irrational, or uncivilized; but always as something "other."

Modern ethnography, the study of cultures, is a product of this western history and its intellectual legacy of magic versus religion or science. The earliest ethnographers were explorers and missionaries, some of whom made an effort to observe and document these "new" peoples. The paradigm of progress some missionaries used in meeting nonurban, preliterate peoples was to categorize them as children needing to be fostered into adulthood; other colonizers used a model to exploit the "Indians" as subhuman slaves. For the missionaries, conversion was one step in the maturing process necessary for the native peoples to reach the "level" of civilization mastered by the Europeans.

Modern anthropology attempted to break with the religiously biased view of these missionaries and take an objective observer stance which was, none the less, still colored by an evolutionary model of progress from magic to religion to science (Herbert 1991). This model is clearly evident in the works of early nineteenth-century founders Edward Tylor and Sir James Frazer and into the twentieth century in Jacob Bronowski and Bronislaw Malinowski (Tambiah 1990). The anthropological definition focused on magic as unscientific manipulations of nature or supernatural forces and classified it according to its false premises (imitative magic, contagious magic, sympathetic magic). These notions of magic were assumed as a universally valid construct applicable cross culturally. Consequently, observed peoples were placed into the spectrum of development from magic to science. This model is the subject of debate in late twentieth-century anthropological scholarship, by such authors as Francis Hsu and Stanley Tambiah, who question whether the European concept of magic can be used accurately to classify a set of phenomena in a non-European culture.

Indigenous Views in Non-Western Societies

In Western thought, then, magic has become something marginal, separate from or opposite to a mainstream tradition of religion or science. Non-Western practices of magic seen in their own cultural context are not the opposite of religion or science, but are complementary to their political, social, religious orders; magic is not the "other" in their worldview, but is part of the norm. Magical practices in non-Western societies can function as part of their cultural identity, alongside scientific development or as a subgroup of religion. In many parts of the world, syncretism is more prominent as a response to alternate worldviews, resulting in coexisting modes of rationality rather than competing ones.

The ancient civilizations of Asia offer examples of traditions developing their own modes of rationality with different dynamics than the European model, between the spheres of religion, science, and magic. In China, the traditions are as complex and overlapping as they are in Europe: ancestor-worship, Confucianism, Daoism, and Buddhism as belief-systems evolved and interacted amid the simultaneous development of science and technology. These belief-systems cannot be easily categorized as religion, philosophy, or magic along Western lines. The Buddhist emphasis on the world as illusory and the Daoist focus on metaphysics lent themselves more readily to practices resembling magic in a Western sense (appeals to supernatural aid, fortune-telling), as did ancestor worship. Confucianism, on the other hand, has both religious and philosophical elements; its concern with the social and political world resembles more the secular humanism of the western tradition. All of these coexist as alternate, and sometimes complementary, modes of rationality in China.

Similarly in the Chinese world, science and technology do not necessarily replace magico-religious belief: villagers' responses to crisis (for example, a plague) incorporate both medicinal remedies such as serums proven through experimentation in the Western scientific tradition, and rituals seeking to appease the gods. While Westerners would be under some pressure to justify such magical practices with some rational or pseudoscientific explanation, the Chinese do not feel compelled to argue about where or how the practice fits into some duality of true or false, natural or supernatural, orthodox or heretical, scientific or magical. Ancestor worship and recourse to geomancers (practitioners of *feng shui,* the art of finding spiritually correct locations for buildings) and fortune tellers (Daoist priests or other spiritualists) continue in twentieth-century China and in Chinese communities in the West without shame or apology (Hsu 1983).

Elsewhere in Asia, "magic" continues as part of mainstream culture because it is closely linked with cultural identity. In Korea, female shamans perform ritual cures and exorcisms (*kut*) as part of the uniquely Korean fabric of life, alongside imported traditions from China and the West; in this way shaman practice is part of a unique Korean identity (Kendall 1985). Shintoism in Japan, like ancestor-worship in China, is part of the Japanese cultural heritage embedded in everyday life, so much so that it easily accommodated an incoming religious system such as Buddhism or the development of science and technology, with which it has no reason to quarrel. Thus, syncretism, rather than opposing dualities, is a common pattern in the dynamics of magic, science, and religion in Asian cultures.

In many of the ancient near eastern and south Asian cultures, practices resembling magic (fortune-telling, amulets, and sorcery) form a subgroup of either religion or science/medicine. Magicians in India, for example, are closely linked with the religious traditions of Hinduism, Buddhism, and Islam. Indian thought emphasizes the illusory nature of the physical world; religious masters (gurus, yogi, and other mendicants) are able to manipulate the natural world precisely because they have reached a state of enlightenment where the world is truly an illusion to them. Likewise street magicians and stage entertainers practice "deceptions" (sawing people, producing trees from a basket, pulling an egg or a bird out of a bag, making ropes rise) that echo Hindu or Islamic stories and thus embody certain truths about the world as a wondrous, deceptive, and illusory place that one looks *through* to find meaning. Although such street magicians are a separate, low (Muslim) caste in India, they are a prominent part of India's cultural landscape, popular as reflections of Indian values (Seigel 1991).

The interconnection of belief, science, and magic is also seen in Islamic culture. Medieval Islam fostered scientific, technological, and medical research because of their belief in a monotheistic Deity who made all things rational for humans to study (a view that eventually sparked medieval European science). Yet Islam also has magical–mystical subgroups, some of whom were condemned by Islamic law: their explorations of astronomy have astrological connections, as in Europe; their mathematical concepts have occult meaning to some; Sufi mystics distanced themselves from the Islamic intellectual heritage and sought knowledge through other, spiritual or interior, means. While these branches of Hinduism, Buddhism, or Islam may be minority groups, they are not marginal to their own cultures. Rather, they form an important extension of mainstream ideas that influences the whole culture, although not without conflict.

Societies in Africa, the Pacific, and Southeast Asia that did not have the urban, literate characteristics of these older civilizations provide clear examples of how poorly the conceptual dichotomy of magic versus science works as a model for understanding cultures where so-called magical practices are part of the norm. In Mali (Africa), the *Sundiata,* a twentieth-century version of an oral tradition dating back to the thirteenth century, speaks of the war magic used by Malian sorcerers to make a tribe successful so that others feared them; their magic oracles dispensed wisdom for successful living, a combination of prophecy and character insight. Likewise, many Pacific island cultures practiced a kind of potent magic in love, war, and healing that relied on a sorcerer's ability to conjure nature and spirits.

These practices encompass both white and black magic in the European paradigm, to both heal and curse; such mastery is always dangerous to the practitioner because of the power of the sources he or she is using. In New Caledonia (Melanesia), sorcerers concoct love potions; in Samoa (Polynesia), chants ward off a headache caused by a god. In Pohnpei (Micronesia), tribal groups employ sorcery to win a war, calling on ghosts or natural forces such as tides; during the Spanish occupation, they used both the borrowed technology of guns and their own tradition of sorcery to hold off attacks (Hanlon 1992). Marquesans (in French Polynesia) also practiced a kind of war "magic" closely linked to their tribal identity: chants of power specific to their people and location used words ritually to invoke natural/supernatural forces to aid them in battle. The concept of *mana* in Polynesian cultures embodies this sense of powerful forces that can be channeled through words and actions, and is a more authentic construct for understanding their practices than is "magic."

Such beliefs and practices, prior to European contact, were part of political and social value systems; the practitioners were feared for their power, but were not marginal to an intellectual belief system, as they became in European culture. The retention of these beliefs in the power of the old ways after contact, sometimes in defiance of, and sometimes integrated with, Western beliefs, is a form of cultural resistance and identity.

Many non-Western cultures, confronted with the European intruder, perceived the actions of the newcomer in terms of their own construct of supernatural or occult power. For example, in the Americas, native American Indians identified literate Europeans (mostly missionaries) as shamans, and their books as tools for manipulating natural/supernatural forces. Literacy was a powerful form of knowledge to acquire, and therefore was classified with other powerful forms of knowledge in their culture held by their shamans (magic and magicians to the Europeans). Thus literacy, and the Christian religion wound around it, was incorporated into the native belief system (Axtell 1988). Indeed, in the same way that the taking of photographs was feared by some groups as a type of sorcery for capturing their souls, so too the writing down of history and ethnographic observations (by Westerners) is sometimes perceived as a kind of sorcery: the power of shaping and defining cultural identity past and present.

Just as the magic-religion divide is indistinct, so too the magic-science line is easily crossed. Westerners cast doubt on the ancient Polynesians' ability to navigate the Pacific to reach new islands such as the Hawaii chain without the technological tools used by Europeans to accomplish such tasks. New research and recreated voyages, however, confirm the knowledge of wind, sky, and water, and the skills of navigation contained in the remnants of Polynesian chants and other oral traditions, usually categorized as magico-religious rituals. This ambiguous line between magic and science is also visible in modern globalized medical practices that incorporate both Western medical techniques and traditional medicine from non-Western societies. The Chinese practice of acupuncture, once viewed in the United States as magic or pseudoscience, is now being mainstreamed into American medicine in lieu of drugs. In Java, a doctor claims the ability to produce heat and electricity from his own body for healing purposes and he documents this ability using the Western scientific mode of proof (experimentation, repeatability), performing spontaneous combustion on video (*Ring of Fire*). Such global syncretism is increasing rather than decreasing, blurring the distinctions between magic and science as defined in European intellectual history.

Traditionally, then, magic has been defined in opposition to science or religion in Western intellectual development. However, such practices in non-Western cultures that appear to resemble this category or are similar to practices Westerners label magic, may not in those cultures have been defined as a class in opposition to some concept of religion or science. The realization that "one man's religion (or science) is another man's magic" is leading to redefinitions of these terms and the development of meanings and categories unique to each cultural context.

Magic Squares in China

Ho Peng Yoke

By modern definition a magic square is an arrangement of numbers in a square whereby the sum of the numbers in every individual row, in every individual column and in each of the two diagonals of the square is identical. Figs. 1 and 2 are examples of magic squares. In Fig. 1 all rows, columns and diagonals add up to the sum 15 and in Fig. 2 they add up to 34.

4	9	5	16
14	7	11	2
15	6	10	3
1	12	8	13

Magic Squares in China. Fig. 2 Magic square of 34.

Each number occupies a cell. There are 9 cells in Fig. 1 and 16 cells in Fig. 2. Figure 1 is known as a 3 × 3 magic square or a magic square of the order 3; similarly Fig. 2 is a 4 × 4 magic square or a magic square of the order 4. Methods for constructing these two magic squares as well as some magic squares of higher orders are given in the *Xugu zheqi suanfa* (Continuation of Ancient Mathematical Methods for Elucidating the Strange), composed in 1275 by Yang Hui. Numbers can also be arranged to form a circle or even a cube that shares some of the properties of the magic square. Nowadays all these come under the heading "number theory" or even "mathematical recreation" in libraries. However, the word "magic" in the magic square has lost some of its original meaning.

Chinese magic squares have attracted the attention of modern mathematicians and historians of science. Studies by modern scholars have brought forth many interesting results, but how and why certain Chinese magic squares were constructed cannot be fully understood if one approaches the subject entirely from the standpoint of modern mathematics. The modern Chinese equivalent of the term "mathematics" is *shuxue*, but prior to the middle of the nineteenth century the same term had a much wider meaning, embracing mathematics, philosophy, astrology, and divination. Studies from the angle of modern mathematics have recently been supplemented by investigations from a different perspective.

The first-century book *Da-Dai Liji* (Record of Rites by the Elder Dai), contains the following arrangement of numbers:

2,9,4 7,5,3 6,1,8.

This set of numbers also occurs in a probably earlier mathematical text, the *Shushu jiyi* (Memoir on Some Traditions of Mathematical Art), said to be written in the year 190 BCE by Xu Yue. This is the earliest magic square on record. It was used mainly in astrology and divination. Then during the twelfth century one of Zhu Xi's (1130–1220) disciples Cai Yuanding (1145–1198) identified the Bright Hall and the Nine-palace arrangement as the legendary Luoshu chart mentioned in ancient texts. Together with another legendary chart, the Hetu River Diagram, the riddles of the universe were supposed to be embodied therein. Hence the two charts were used to interpret not only natural phenomena, but also philosophy and human behavior. They even found their use in Daoist ceremony and magic. Numerology played a profound role in Chinese magic squares. The occurrence of certain numbers, e.g., 5, 9, 25, 49, 50, and 64 in Chinese magic squares is significant. All these were closely associated with the Hetu and Luoshu charts and with the *Yijing* (I Ching, The Book of Changes).

Yang Hui's *Xugu zheqi suanfa* is the earliest and best source for Chinese magic squares. The methods of construction of some of the larger magic squares remind us of the foot movements of the Daoists performing ceremonies and magic. About three decades later Ding Yidong wrote his *Dayan suoyin* which contains a number of magic squares and magic circles constructed on a similar basis. Then in about the year 1593 Chen Dawei collected a number of magic squares in his *Suanfa tongzong* (Systematic Treatise on Arithmetic) without involving himself with the theoretical aspect of the subject. In 1661 Fang Zhongtong (1633–1698) wrote the *Shuduyan,* which contains magic circles, cubes, and spheres, besides magic squares. Next comes Zhang Chao's (b. 1650) *Xinzhai zazu* (Miscellanea of Zhang Xinzhai), which includes a Supplement to the magic squares of Cheng Dawei's work. The last description of magic squares by a traditional Chinese scholar came in the latter part of the nineteenth century when Bao Qishou wrote his *Binaishanfang ji* (Collections of Writings in the Binai Mountain Studies).

The Luoshu chart magic square probably first went to India and then to the Arab countries, where other magic squares were later developed in their individual ways. From the Arab countries magic squares were said to be first brought to Europe by a Byzantine, Manuel Moschopoulos (fl. ca. 1295–1316). Transmission of knowledge between China and her western neighbors was seldom unidirectional. In 1956 a thirteenth-century 6 × 6 Muslim magic square was excavated near the city of Xi'an. Magic squares even had a role to play in trade between China and the Arab countries in the past. In 1906 when Queen Mary of the British Empire visited Hyderabad in India she was presented with a Chinese porcelain plate decorated with Arabic inscriptions and a magic square. This plate is now preserved at the Victoria and Albert Museum in South Kensington. It was manufactured in the eighteenth century at the world renowned Chinese kiln center, Jingdezhen. It was used originally by the Muslims as a medicine bowl, so that the inscriptions were taken from the *Qu'rān,* and the magic square was believed to possess powerful virtues for protecting life, healing the sick, and bringing about a comfortable delivery when a pregnant woman sat on it. Other specimens of Chinese porcelain plates bearing magic squares in a corrupted form are among the collections of museums and private collectors today.

Magic Squares in Indian Mathematics

Takao Hayashi

The oldest datable magic square in India occurs in Varāhamihira's encyclopedic work on divination, *Bṛhatsaṃhitā* (ca. AD 550). He utilized a modified magic square of order four in order to prescribe combinations and quantities of ingredients of perfume. It consists of two sets of the natural numbers 1–8, and its constant sum (p) is 18. It is, so to speak, pan-diagonal, that is, not only the two main diagonals but also all "broken" diagonals have the same constant sum. Utpala, the commentator (AD 967), also points out many other quadruplets that have the same sum.

One of the four candidates for Varāhamihira's original square, with a rotation of 90°, coincides with the famous Islamic square, which al-Bīrūnī and al-Zinjānī frequently used as a basic pattern for talismans.

Varāhamihira called his square *kacchapuṭa* (the carapace of a turtle?), which reminds one of the title of a book on magic, *Kakṣapuṭa* (date unknown). The book contains a method for constructing a magic square of order four when a constant sum (p) is given. It also contains a square having the sum 100, which is attributed to Nāgārjuna.

In his medical work, *Siddhayoga* (ca. AD 900), Vṛnda prescribed a magic square of order three to be employed by a woman in labor in order to have an easy delivery. Its sum is 30. This is the first datable instance of a magic square of order three in India, although there is a legend that a Garga, who may or may not be the author of the *Gargasaṃhitā* (ca. first century BCE or AD), recommended magic squares of order three in order to pacify the *navagraha* (nine planets).

The famous Jaina magic square, which is incised on the entrance of a Jaina temple, Jinanātha, in Khajuraho, is assignable to the twelfth or the thirteenth century on a paleographical basis. It is pan-diagonal. Several Jaina hymns that teach how to make magic squares have been handed down, but their dates are uncertain.

As far as is known, Ṭhakkura Pherū, a Jaina scholar, is the first in India who treated magic squares in a mathematical work. His *Gaṇitasāra* (ca. AD 1315) contains a small section on magic squares that consists of nine verses. He gives a square of order four, and alludes to its rearrangement; classifies magic squares (*jaṃta* = Sanskrit *yantra*) into three (odd, even, and evenly odd) according to the order (n), i.e., the number of cells (*kuṭṭha* = Sanskrit *koṣṭha*) on a side of the square; gives a square of order six; and prescribes one method each for constructing even and odd squares.

The method for even squares divides the square into component squares of order four, and puts the numbers into cells according to the pattern of a standard square

M

of order four. That for odd squares first places in the central column the arithmetical progression whose first term and common difference are unity and (n + 1), respectively; and then, starting from the numbers in the central column and proceeding by knight move, successively increases the number by n. The square thus obtained is the same as the one obtained by the so-called diagonal method (cf. Fig. 21).

Nārāyaṇa wrote a comprehensive work on mathematics entitled *Gaṇitakaumudī* (AD 1356). Its last chapter, called *bhadra-gaṇita* (Mathematics of Magic Squares), comprises 55 verses for rules and 17 verses for examples, and is devoted exclusively to magic squares and derivative magic figures *(upabhadra)* of various shapes (cf. Figs. 22–23).

The topics treated are: definitions of technical terms; determination of the mathematical progressions

to be used in magic squares by means of *kuṭṭaka*, i.e., indeterminate equations of the first degree; how to make a square of order four by *turagagati* (horse move); the number of pan-diagonal magic squares of order four, 384, including every variation made by rotation and inversion.

Then Nārāyaṇa gives three general methods for constructing a square having any optional order (n) and constant sum (p) when a standard square of the same order is known – (1) by means of an arithmetical progression having an appropriate first term (a) and common difference (d), (2) by means of n sets of arithmetical progressions whose common differences are all unity, and (3) by adding an appropriate number (t) to every term of the standard square.

Nārāyaṇa next explains two methods each for constructing *sama-garbha* (even-womb) or evenly even, *viṣama* (odd-womb) or evenly odd, and odd squares when the sum is given. The two methods for

the first kind are (1) by folding two preliminary squares *karasaṃpuṭa-vat* (just like the folding of two hands), and (2) by arranging numbers in the component squares of order four according to the pattern of a standard square. For the second kind they are (1) by putting numbers zigzag in the square and (2) by transposing certain numbers in the natural square. These two methods are not completely mechanical, and require *mati* (intelligence). The methods for the third kind are (1) by folding two preliminary squares just as in the case of the first kind and (2) by starting from the central cell of any side of the square and proceeding diagonally.

In the last section Nārāyaṇa gives a number of examples for two kinds of derivative magic figures, *saṃkīrṇa* (miscellaneous) and maṇḍala (circular). Both

kinds are made by rearranging ordinary magic squares. In his encyclopedic work on Hindu Law, *Smṛtitattva* (ca. AD 1500), Laghunandana gives a method for making squares of order four having any optional sum that is determined according to the purpose (see Table 1).

Significant scholarly work has been done on the importance of magic squares both mathematically and philosophically. Cammann and Roşu both discuss the significance of magic squares in Indian thought and compare Indian, Islamic, and Chinese magic squares.

Magic Squares in Indian Mathematics. Table 1 Purposes of magic squares of order four

Sum (p)	**Purpose**
20	To neutralize poison
28	To protect crops from insects
32	To accelerate delivery
34	To protect travelers
50	To exorcise evil spirits
64	To protect warriors
72	For women having no children
84	To soothe crying children

Hayashi discusses the magic squares of Varāhamihira, of Pherū, and of Nārāyana, providing the first modern translations of their works on magic squares. Datta and Singh's posthumous work, revised by K. S. Shukla, mainly treats Nārāyana's magic squares. Kusuba provides an English translation with mathematical commentary, as well as an edition of the Sanskrit text, of Nārāyaṇa's work on magic squares. Singh gives an English translation of the entire *Gaṇita-kaumudi* including the chapter on magic squares.

Magic Squares in Islamic Mathematics

JACQUES SESIANO

One of the most impressive achievements in Islamic mathematics is the development of general methods for constructing magic squares. A magic square of order n is a square divided into n^2 cells in which different natural numbers (mostly the n^2 first naturals) must be arranged in such a way that the same sum appears in each of the rows, columns, and two main diagonals. If, in addition to this basic property, the square remains magic when the borders are successively removed, we speak of a "bordered square." If the sum in any pair of complementary diagonals (i.e., pairs of parallel diagonals lying on each side of a main diagonal and having together n cells) shows the constant sum, the square is called "pandiagonal."

Squares are usually divided into three categories: odd-order squares ($n = 2k + 1$, k natural), evenly even squares ($n = 4k$), and evenly odd squares ($n = 4k + 2$). There are general methods for constructing squares of any order from one of these three categories. Except for the smallest possible order, $n = 3$, there are numerous possibilities of forming magic squares of any given order. There may be, however, some limitations concerning additional magical properties; for instance, there are no pandiagonal squares of evenly odd order.

Information about the beginning of Islamic research on magic squares is lacking. It may have been connected with the introduction of chess into Persia in early Islamic times. Initially, the problem was a purely mathematical one; thus, the Arabic ancient designation for magic squares is *wafq al-a'dād* (harmonious disposition of the numbers). We know that treatises were written in the ninth century, but the earliest extant ones date back to the tenth century. It appears that, by that time, the science of magic squares was already established. Not only was the construction of a magic square, simple or bordered, explained for various orders, but also several additional conditions or refinements were considered. For example, the construction of "composite squares" was well known: if $n = r \times s$, with $r, s \geq 3$, one may fill successively, according to a magical arrangement for the order r, r^2 subsquares of order s (Fig. 1). Another contemporary achievement was the construction of bordered squares in which the even numbers are separated from the odd ones (Fig. 2).

Treatises explaining general constructions were common in the eleventh and twelfth centuries. They also explain how to construct a magic square for a given sum, or for a word of n letters or n words to be put in the first row, since a number among the units, the tens, the hundreds, and one thousand is associated with

each of the 28 Arabic letters. The words occurring in the first row are either proper names or words of a religious nature (Fig. 3; the five words correspond to the numbers 81, 7, 116, 66, and 80). Pandiagonal squares are constructed in various ways for evenly even orders, but incompletely for odd orders (the method fails for certain orders).

From the thirteenth century on, magic squares become more and more associated with magic and divinatory purposes. Consequently, some texts merely picture squares and mention their attributes. Some others, though, keep the general theory alive, mostly to enable the reader to construct amulets by himself.

Interest in magic squares in Europe first arose toward the end of the Middle Ages, when two sets of squares associated with the seven planets were learned of through astrological and magic texts (whence the name), but without any information on their construction. Thus, the entire theory had to be built anew, and it is only in very recent times that the extent of Islamic research has come to light. It should also be remarked that the methods of construction spread eastward around the twelfth century toward India and China.

Magic Squares in Japanese Mathematics

Yoshimasa Michiwaki

The study of Magic Squares in Japan began in the beginning of the Kan-ei period (1624–1643) with the import of *Suan fa tong zog* published in 1592 by Chen Dawei of China. Almost all the famous *wasan* (Japanese mathematics) experts, such as Takakazu Seki (or Seki Kowa, ca. 1642–1708) studied squares. On a smaller scale, the study has continued, and we have gained some new insights lately.

The study of squares concerns itself with some aspects of combinatorial mathematics, so some of its general methods are applied as well. For example, some parts of perfect 5 × 5 squares are made by the "Knight Jump Arrangement". The study of compositions, which was started by a Russian scholar, is limited to perfect 4 × 4 squares, but the method was also applied to 8 × 8 squares, as in the study by Motoaki Abe. Rakuho Abe obtained a fantastic result of irregular, perfect 7 × 7 squares. This is shown below:

16	24	20	17	37	14	47
23	28	48	1	38	6	31
39	7	45	9	42	18	15
40	4	29	25	21	46	10
35	32	8	41	5	43	11
19	44	12	49	2	22	27
3	36	13	33	30	26	34

An irregular, perfect 7 × 7 square.

In this the total of the diagonal or pandiagonal numbers is 175; the total of the four corner numbers (16 + 47 + 34 + 3) is 100; the total of the numbers around the centers (9 + 21 + 41 + 29) is 100; and the total of the middle numbers of the four sides (17 + 10 + 33 + 40) is also 100.

In the middle of the Heian period, i.e., in 970, Tamenori Minamoto edited *Kuchi-zusami* for the education of young nobility. In the 12th chapter we find this sentence: 4 and 2 make a shoulder, left 3 and right 7, legs are 6 and 8, head 9, body 5, tail is 1:

4	9	2
3	5	7
8	1	6

The legs, head, and tail seem to be those of some animal (a tortoise?), and maybe they suggest the arrangement of numerals. We are not sure how

Minamoto came by this knowledge of squares, but the 3 × 3 square in *Kuchi-zusami* is the oldest record as far as we know.

A book by Yūeki Andō (1624–1704), a clansman of Aizu, is the first in the world in which the author explains a general way to make squares by increasing from 3 × 3 to 30 × 30 squares (see Table 1).

Magic Squares in Japanese Mathematics. Table 1 A general way to make squares

A

7	4	1
8	5	2
9	6	3

B

2	9	6
3	5	7
4	1	8

C

4	9	2
3	5	7
8	1	6

D

12	19	8
9	13	17
18	7	14

For example, if we exchange positions in square A so that 1 ↔ 6, 3 ↔ 8, 9 ↔ 4, and 2 ↔ 7, we get square B. Then the four corners are all even numbers. If we then turn these four corner numbers 90° clockwise, we get square C.

21	16	11	6	1
22	17	12	7	2
23	18	13	8	3
24	19	14	9	4
25	20	15	10	5

5 × 5 square, with a 3 × 3 square inside.

In the 5 × 5 square like the figure shown above, the thick-lined square is a 3 × 3 square. Change it into D of Table 1. Next, work on the four corners of the outside square, and exchange positions in the following manner: 1 ↔ 15, 5 ↔ 23, 25 ↔ 11, and 21 ↔ 3. Do not turn the four corner numbers, because they are odd numbers. You will complete the work by putting D, the 3 × 3 square, inside it.

Takakazu Seki commented on the general way of making squares in the books, *Hōjin-no-hō* and *Ensan-no-hō*, written in the third year of the Tenwa period (1683). He divided them into odd-celled squares and two types of even-celled squares. Squares by Katahiro Takebe (1664–1739) are introduced in Volume 4 of the *Ichigen Kappō*, written by Shukei Irie.

In 3 × 3 squares, put the numerals in order, turn the center joined by both diagonals, lines, and rows 45° leftward. Then turn the center of the lines and rows 180°:

7	4	1
8	5	2
9	6	3

⟶

4	1	2
7	5	3
8	9	6

⟶

4	9	2
3	5	7
8	1	6

Yoshisuke Matsunaga (1692–1744), a pupil of Seki's pupil, wrote *Hōjin-Shin-jutsu*. There are also studies by Yoshihiro Kurushima (d. 1757), and by Naonobu Ajima (1732–1798). The question on step children is in *Jingōki* by Mitsuyoshi Yoshida. The question is close to that of Joseph's problem in the West.

Shūtarō Teramura (1902–1980) studied how many "parent–child" squares could be made in all, and in 1926 he made 605 squares. Following are some examples.

In the first, the parent square is a perfect 8 × 8 square. The child one (between thick lines) is a perfect 4 × 4 square (shown below):

2	29	51	48	1	30	52	47
56	43	5	26	55	44	6	25
15	20	62	33	16	19	61	34
57	38	12	23	58	37	11	24
4	31	49	46	3	32	50	45
54	41	7	28	53	42	8	27
13	18	64	35	14	17	63	36
59	40	10	21	60	39	9	22

A parent–child square, 8 × 8, with a 4 × 4 square inside.

In another example, the parent square is also a perfect 8 × 8 square, and the child one (upper-middle part) is a perfect 4 × 4 square, as shown below:

2	29	51	48	1	30	52	47
56	43	5	26	55	44	6	25
13	18	64	35	14	17	63	36
59	40	10	21	60	39	9	22
4	31	49	46	3	32	50	45
54	41	7	28	53	42	8	27
15	20	60	33	16	19	61	34
57	38	12	23	58	37	11	24

A parent–child square.

To make a perfect 4 × 4 square, choose optional numbers for x, y, z, u, and t. $X = x + y + z + u$. Make the square as follows:

x	y	z	u
$z - t$	$u + t$	$x - t$	$y + t$
$1/2X - z$	$1/2X - u$	$1/2X - x$	$1/2X - y$
$1/2X - x + t$	$1/2X - y - t$	$1/2X - z + t$	$1/2X - u - t$

To make perfect 8 × 8 squares, choose optional numbers for a, b, and c, and construct the square as in Table 2.

In an N square, in which a line has n divisions, and which consists of n^2 numerals, the total of the vertical and horizontal lines should be the same as that of both diagonals. This square is a Magic Square, and if each sum of the numbers of all the parallel lines is the same, the square is a Perfect Magic Square. The study of Michiwaki and Moriyama (1963) tells how to make it.

Magic Squares in Japanese Mathematics. Table 2 Making perfect 8 × 8 squares

a	b	c	d	e	f	g	h
$c+x$	$d-x$	$e+x$	$f-x$	$g+x$	$h-x$	$a+x$	$b-x$
$e+y$	$f-y$	$g+y$	$h-y$	$a+y$	$b-y$	$c+y$	$d-y$
$f-y$	$h+x$	$a-x$	$b+x$	$c-x$	$d+x$	$e-x$	$f+x$

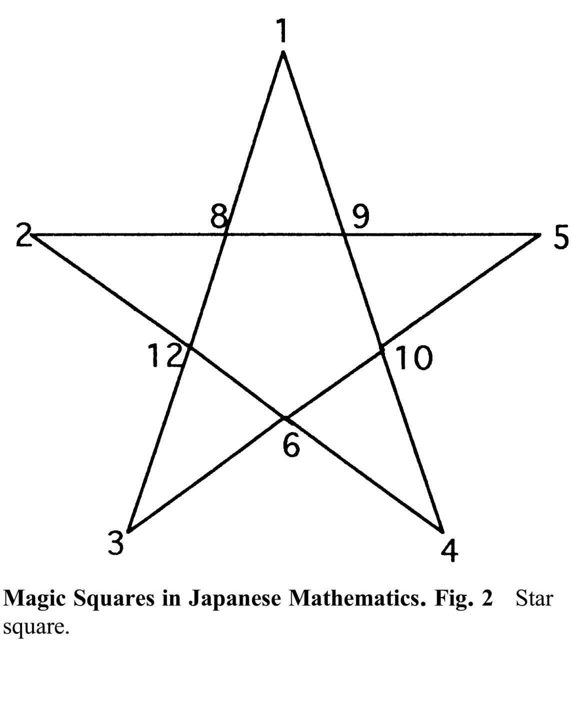
Magic Squares in Japanese Mathematics. Fig. 1 Circular square.



Magic Squares in Japanese Mathematics. Fig. 2 Star square.

There are also many special squares. The best examples of circular squares are introduced in Takakazu Seki's *Hōjin-no-hō* and *Ensan-no-hō* (see Fig. 1).

Star squares were studied by Shigematsu Urata and Rakuhō Abe in 1955 (see Fig. 2).

The first cubic square in Japan was introduced as "cubic design" in *Rakusho-kikan* by Yoshizane Tanaka (1651–1719). In it, he piled up the following 4 × 4 squares in order:

(1)

14	54	43	19
59	3	30	38
22	46	51	11
35	27	6	62

(2)

20	44	53	13
37	29	4	60
12	52	45	21
61	5	28	36

(3)

33	25	8	64
24	48	49	9
57	1	32	40
16	56	41	17

(4)

63	7	26	34
10	50	47	23
39	31	2	58
18	42	55	15

Arata Sakai started the study of perfect 4 × 4 cubic squares in 1938, and Shigematsu Urata completed it in 1948. Motoaki Abe made a 5 × 5 cubic square in the latter part of the Taishō period. A 7 × 7 cubic square was made by Motoaki Abe and Shōji Shimada.

In 1948 Rakuhō Abe made a perfect 6 × 6 cubic square with a plane 6 × 6 square as its base, but the diagonal total was not regular. Michiwaki and Moriyama studied the way to make special perfect 9 × 9 cubic squares, and the way to count their numbers.

Magnetism in Chinese Culture

CHEN CHENG-YIH (JOSEPH)

In Chinese civilization, the *ci-shi* (lodestones) and their ability to attract iron are mentioned in a number of Zhou period Classics. It is stated in the *Shanhai Jing* (Classic of the Mountains and Rivers) that lodestones are found at *ao-ze.* A remark in the *Guan Zi* (Book of Master Guan) indicates that the finding of lodestones was once viewed by ancient prospectors as an indication for the possible presence of other mineral deposits. Both the *Gui Gu Zi* (Book of the Devil Valley Master) of the fourth century BCE and *Lushi Chun Qiu* (Master Lu's Spring–Autumn Annals) of 239 BCE mention that the lodestone attracts iron.

The attractive interaction between the lodestone and iron was interpreted as being caused by *xiang gan* (mutual influence), a sympathetic response between two interacting entities. Wang Chong, in the *Lun Heng* (Discourse Weighed in Balance) of AD 82 offers the interpretation that some items attract others, while some cannot, because their *qi* is different and consequently they cannot mutually influence one another. The character *qi* literally means vapor or breath. In the course of time, it took on a number of proto-scientific significances: the basic constituent entity of all things in nature and the media of the *yinyang* interactions. There are a number of scholars who translate *qi* as "energy," "field," or "matter-energy," but in ancient times, the concepts of energy and field were not yet explicitly developed. *Qi*, as it is given in the Chinese texts, is not identified by its intrinsic properties, but by its general relationship with others. Though the pattern relationship is identifiable with certain aspects of the modern concept of energy, field, or matter-energy, it is better to preserve the term *qi* and not to translate it.

A later account (AD 300) by Guo Pu also comments on the role of *qi* in such interactions.

The lodestone draws iron, and amber collects mustard-seeds. [Since] their *qi* are invisibly interconnected and their measures are silently met, the mutual influence between them consequently occurred.

Such a view of interaction at a distance involving *qi* is compatible with modern views.

The strength of such attractive interactions was later discussed in terms of the weight of iron pieces or the number of needles that the lodestone was capable of supporting.

Tao Hong Jing stated in the *Ming Yi Bie Lu* (Informal Records of Famous Physicians) that some "[lodestones] could suspend a chain of more than ten needles".

Based on such quantitative measures of the attractive power, lodestones were graded as follows:

> A piece of genuine lodestone is called the *yan nian sha* if it is capable of attracting, on its four sides, one catty of iron piece (the equal weight of the lodestone); called the *ji cai shi* if it is capable of attracting, on its four sides, eight ounces weight of iron piece; and called simply the *ci shi* if it is capable of attracting, on its four sides, four ounces of iron piece *(Lei Gong Pao Zhilun)*.

M

The directional property of lodestones was probably first used in the *sinan* ceremony, a practice evolved directly from the tradition of using a gnomon and the positions of the sun and stars to determine the time and directions. The term *sinan* means "south verification" or "south controller." The discovery of lodestone's south pointing property led naturally to its association with the term *sinan* and the *sinan* (south verification) devices. However, early mentions of the *sinan* devices provide little information on their construction. In the *Gui Gu Zi* there is mention of the fact that when the Zheng people engage in collecting jade, they always carry with them a *sinan* to avoid being lost.

The device described by Wang Chong has been widely considered to be the earliest form of the magnetic compass.

The Chinese literature of the period ranging from the Han to the Tang dynasties provides a number of hints that, by the first century AD, the fact that the directive property of the lodestone could be transferred to small pieces of iron was discovered, and by the seventh century AD, the magnetized needle began to appear in certain compasses, replacing lodestones for greater precision. But the records are not sufficiently specific to provide a definitive account of these developments. Explicit descriptions of magnetic properties and compass construction are found in the work of the Song dynasty.

Properties of magnetized needles are discussed in the work of Shen Gua (1029–1093). We have from his *Meng Xi Bi Tan* (Meng Xi Essays) of 1086, the following description of declination:

> *Fang Jia uses the lodestone to rub the point of a needle*;
> *The needle is then able to point to the south*.
> *It does not, however, point directly at the south*,
> *It always inclines slightly to the east*.

Following this description is the passage on the needle supporting methods:

> [The needle] can be supported by making it float on the surface of water, but it is rather unsteady. It may be balanced on the finger-nail, or on the rim of a cup, so that it can turn more easily, but such supports being hard and smooth [mean it] is liable to fall off. The best way of supporting the needle is by suspension. The method uses a single cocoon fiber of new silk to suspend the needle. By attaching silk to the center of needle with a piece of wax the size of a mustard-seed and hanging in a windless place, the needle will then always point to the south undisturbed.

He discusses three types of needle-supporting methods: floating, pivot, and suspension. For the study of magnetic properties, Shen Gua preferred the suspension method using a silk thread. The other two methods of supporting the needle, by floating it on the water surface and by pivoting it on a hard smooth surface, correspond to those used in the wet and dry compass, respectively.

Shen Gua's work also discusses magnetic polarity. He noticed that some needles pointed north and some south. He believed that different natures caused this, just as animals shed at different seasons.

An important discussion of the magnetic compass is found in the *Wujing Zongyao* (Collection of the Most Important Military Techniques) of AD 1044.

> When troops encountered gloomy weather or dark night, and could not distinguish the directions, they would let an old horse in the front lead them, or else they would make use of the south-pointing carriage, or the south-pointing fish to identify the directions. Now the carriage method has not been handed down. In the (south-pointing) fish method, a thin leaf of iron is cut into the shape of a fish two inches long and half an inch broad, having a pointed head and tail. It is then heated in a charcoal fire until it becomes thoroughly red-hot, taken out by the head with iron tongs, and placed so that its tail is in the *zi* direction (due north). In this position, it is quenched with water in a basin, so that its tail is submerged for several tenths of a inch. It is then kept in a *miqi* (tightly closed box). To use it, a small bowl filled with water is set up in a windless place, and the fish is laid as flat as possible upon the water surface so that it floats, whereupon its head will point in the *wu* direction (south).

The passage not only provides a clear discussion on the construction of a compass, but also reveals a different method for magnetizing iron pieces. Thus no later than the early Song dynasty (960–1279), two methods of magnetizing were known. Other than rubbing with the lodestone, an iron piece could also be magnetized by quenching it from red heat through the Curie point, held in a north–south direction (in the magnetic field) of the earth. The discovery of the thermoremanence phenomena was of great scientific significance. Since the earth's magnetic field is relatively weak and the soft iron does not retain its magnetism long, questions were raised as to whether such magnetized iron could function satisfactorily as a compass. Recent archaeological evidence revealed a long history of steel development in China, beginning from the later part of the spring-autumn period of the Zhou dynasty. By the second century BCE, two methods for steel production from pig iron were developed, one by the puddling of molten iron and the other by decarbonization of cast iron in the solid state without the formation of graphite. Thus, good steel and steel needles were certainly available in the early Song dynasty.

An important use of the compass is in navigation. Clear and accurately datable statements on such a use are found in the *Pingzhou KeTan* (Pingzhou Table Talk) of 1119, when the author says that ships' pilots look at a south-pointing needle or sample of the mud collected from the sea bottom to determine their whereabouts in dark weather. This is confirmed in other books of the period.

Based on these statements and other sources, Needham has concluded that "description of the use of the compass for navigation on Chinese ships antedates the first knowledge of this technique in Europe by just under a century, but there are indications that it was used for this purpose in China somewhat earlier."

Needham is also of the view that "Chinese sailors remained faithful to the floating-compass for many centuries. Although the dry pivoted compass had been described early in the twelfth century AD, it did not become common on Chinese vessels until it was reintroduced from the West in the sixteenth century by the Dutch and Portuguese by way of Japan. Associated then with it was the compass-card (the windrose attached to the magnet) which had probably been an Italian invention at the beginning of the fourteenth

Magnetism in Chinese Culture. Fig. 1 Clay figurine with a dry-pivoted compass in its arm unearthed in 1985 from the tomb of Zhu Jinan.

century." The European mariner's compass is characterized by sixteen compass points in contrast to the 24 of the Chinese compass. The discovery of the clay depiction of a dry-pivoted compass in the tomb of Zhu Jinan (1140–1197) in 1985 raised a number of pertinent questions. The compass depicted in the arm of the two clay figurines unearthed from the tomb has 16, not 24, compass-points. Since the tomb was sealed in 1198, the compass depicted here could not have been influenced by those reintroduced from the West.

Both the dry-pivoted and floating compass were used in Chinese ships. The choice was often based on accuracy. It should be noted that, though the gyroscope was invented in China around the first century BCE by Ding Huan, no known reference to its use in connection with the mariner's compass is available.

Magnetism in Mesoamerica

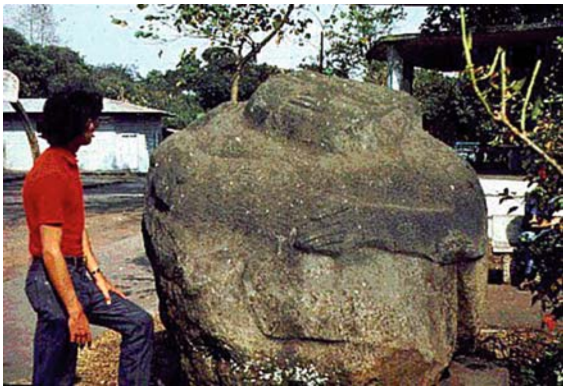
Vincent H. Malmström

That the pre-Columbian peoples of Mesoamerica were familiar with the property of magnetism has been suggested by several researchers, among them the geographer Robert Fuson and the anthropologist Michael Coe. Indeed, a flattened oblong piece of hematite discovered during Coe's excavation of the Olmec site of San Lorenzo in southern Veracruz state in 1966 has been thoroughly examined by John Carlson, who suggests that it probably was fashioned for use as a compass. (In tests, however, it never aligned more closely than about 35° with the Earth's magnetic field.) In 1975, a basaltic sculpture at the site of Izapa, on the Pacific coastal plain of Mexico near the Guatemalan border, was found to possess a strong magnetic field. Variously described as being the representation of either a frog (Norman 1976) or a turtle's head (Malmström 1976), it has a

Magnetism in Mesoamerica. Fig. 1 The black volcanic sands of the beaches near Izapa are the nesting place of a deep-carapaced black turtle that migrates between the Guatemalan coast and the Galápagos Islands. Perhaps local fishermen associated magnetism with the homing instinct of these creatures. Interestingly, the Chinese also associated turtles with magnetism, using the term "black turtle rock" for basalt and making their early compasses in the shape of turtles. (Photo by the author.)

north-seeking pole in its snout and a south-seeking pole at the back of its head. The discovery led the latter researcher to speculate that the stone's carver may have associated the property of magnetism with the homing instinct of the turtle. Because it was the only magnetic object found at the site, critics of the notion that it was a human artifact argued that it may have been struck by lightning and its magnetic field had been induced in that manner (Fig. 1).

However, in 1979, several additional magnetic sculptures were discovered in the Pacific coastal plain of Guatemala, including seven which now repose in the central plaza of the town of La Democracia, and two more which were identified at the nearby sugar plantation of El Baúl. Those at La Democracia are extremely crude depictions of human beings, and, because of their rotundity, have been termed the "Fat Boys" by archaeologists. When an entire body is depicted, the two magnetic poles are usually found on either side of the navel; when only a head is portrayed, the two magnetic poles are almost invariably centered on the right temple (Fig. 2).



Magnetism in Mesoamerica. Fig. 2 In the sculptures known as the "Fat Boys," magnetism appears to have been associated with certain qualities of the human being. We can only speculate that when the magnetic pole was located at the navel, it may have symbolized the life force, or the continuity of life, whereas when it was located in the right temple, it may have represented consciousness, memory, or intellect. (Photo by the author.)

The sculptures at El Baúl include a rampant jaguar, with magnetic poles in each upraised paw, and a tablet showing two men seated on a bench with their arms folded over their chests. This single block of stone has four magnetic poles, one north-seeking pole between each of the men's folded arms and one south-seeking pole below each man in the space beneath the bench. In 1983 a small humanoid sculpture in the plaza of Tuxtla Chica, Mexico, just back of Izapa, was found to be magnetic in the right side of its head. Clearly, the patterns of polarity discerned suggest a conscious intent on the part of the sculptors to fashion their carvings around a known center of magnetic attraction, for in none of the stones has any inset of foreign material been made. That such recurring patterns could have been the result of random lightning strikes must also be ruled out. Because the "Fat Boys" are considered to date from 1500 to 2000 BCE, it is possible that these sculptures represent the oldest known magnetic artifacts in the world. But to what use, other than art and magic, this knowledge was put, we have no answer as yet (Fig. 3).

Magnetism in Mesoamerica. Fig. 3 Because all evidence of magnetism in Mesoamerica is associated with basaltic sculptures whose size prohibited their movement on more than a local scale, the knowledge of this property apparently was limited to a small area of volcanism on the Pacific coastal plain of southernmost Mexico and adjacent Guatemala. (Map by the author.)

Mahādeva

K. V. Sarma

Mahādeva (ca. 1275–1350) composed the extensive set of planetary tables, *Mahādevī*, named after him and dated 28th March, 1316. He belonged to a family of astronomers and in his work *Grahasiddhi* describes himself as the son of the astrologer Paraśurāma, son of Padmanābha, son of Mādhava, son of Bhogadeva of the Gautamagotra, a follower of *Sāmaveda* and a performer of sacrifices. The planetary tables contained in the *Mahādevī*, prepared for facilitating the computation of the daily almanac, were extremely popular in the Gujarat and Rajasthan regions, and numerous manuscripts of the work have been located in these places. While the basic text was restricted to 43 verses, the author himself wrote a set of instructions for using the tables, called *Grahasiddhi*, which also were extensively used. The popularity of *Mahādevī* is also attested to by the several commentaries that were written on the work, including that of Nṛsiṃha (1528), Dhanarāja (1635) and Mādhava, and a host of anonymous commentators.

Mahādeva is a synonym of Śiva, one of the trinities of Hinduism, and so formed one of the words commonly used to name Hindus. There are several astronomers of medieval India who bore the name Mahādeva. Among these are: Mahādeva, younger brother of Viṭṭhala, from Gujarat, author of *Tithicakranirṇaya*, also called *Tithinirṇaya, Tithiratna,* and *Mahādevasiddhānta*; Mahādeva, author of *Jātakāpaddhati*, called also *Mahādevapaddhati* after his name; Mahādeva, son of Luṇiga and author of commentaries on the *Cintāmaṇisāraṇikā* of Daśabala and the *Jyotiṣaratnamālā* of Śrīpati; Mahādeva of the Kauṇḍinyagotra, son of Bopadeva, and author of *Kāmadhenu* called also *Tithikāmadhenu*; Mahādeva, son of Kahnaji Vaidya, author of *Muhūrta-dīpaka* in 57 verses, written in 1640, *Praśnapradīpa* called also *Praśnaratna* (1647), *Bhāveśaphalapradīpa* (1647), *Kālanirṇayasiddhānta* (1652), and a commentary on his own *Muhūrtadīpaka* (1661); Mahādeva Pāṭhaka (1842–1899), son of Revāśaṅkara, and author of *Varṣadīpaka*, called also *Varśadīpikā* (1861), *Jātakatattva*, written in 1872, *Pitṛ mārgapradīpa* in 57 verses (1874), *Varṣapaddhati*, a compilation (1874), and *Āśubodhajyotiṣa.*

Mahāvīra

R. C. Gupta

The Rāṣtrakūṭa dynasty of the medieval period was founded in the Deccan, South India, by Dantidurga about the middle of the eighth century AD. A king of this dynasty named Amoghavarṣa ruled from AD 815 to 877. The long period of his rule is known for its material prosperity, political stability, and academic fertility. He was rich, powerful, and peace-loving, and he patronized art and learning.

In the later part of Amoghavarṣa's reign there lived a great mathematician named Mahāvīrācārya. Mahāvīra was a Digambara Jaina and wrote an extensive Sanskrit treatise called *Gaṇitasāra saṅgraha* (Compendium of the Essence of Mathematics) about AD 850. It is devoted to elementary topics in arithmetic, algebra, geometry, mensuration, etc. The work is important because it is a collection summarizing elementary mathematics of his time and providing a rich source of information on ancient Indian mathematics. It is written in the style of a textbook and was used as one for centuries in all of South India. Its importance is greater still because the *Pāṭīgaṇita* of Śrīdhara (ca. AD 750), written in the same style as the *Gaṇitasāra saṅgraha*, is not extant in full.

Mahāvīra shows sufficient originality not only in presenting older material lucidly, but also in introducing several new topics. A commentary called *Bālabodha* in Kannada was written by Daivajña Vallabha. A Sanskrit commentary was composed by Varadarāja. Dates for these two commentators are not known, nor are their works available in print. There were other translations in the eleventh century and in 1842.

The nine chapters of the *Gaṇitasāra saṅgraha* are as follows:

1. Terminology (70 verses)
2. Arithmetical operations (115 verses)
3. Operations involving fractions (140 verses)
4. Miscellaneous operations (72 verses)
5. Rule of three (43 verses)
6. Mixed operations (337 1/2 verses)
7. Geometry and mensuration (232 1/2 verses)
8. Excavations (68 1/2 verses)
9. Shadows (52 1/2 verses)

The total number of verses, 1,131, shows that the book is quite comprehensive. Another noteworthy feature is that the Jaina tradition of Indian mathematics is also preserved within the scope of the *Gaṇitasāra saṅgraha*.

The authorship of the astronomical work *Jyotiṣ-apaṭala* is also ascribed to Mahāvīra. Some manuscripts of this title are mentioned in the *Jina-ratna-kośa* and the *New Catalogus Catalogorum*, but no author is mentioned. Another work attributed to him is *Chattisu*, but this is also a sort of elaboration of part of the *Gaṇitasāra saṅgraha* made by Mādhavacandra Traividya (about AD 1000). Whatever the case, the reputation of Mahāvīra relies solely on his *magnum opus*.

During ancient times, unit fractions were considered quite important. There are some interesting results in the *Gaṇitasāra saṅgraha* on this topic. One rule gives a practical method for expressing any given fraction as a sum of unit fractions. Let p/q be the given fraction (p being less than q). We add a suitable integer x to q such that $(q + x)$ become exactly divisible by p, say, r times. Then Mahāvīra's rule is

$$\frac{p}{q} = \frac{1}{r} + \frac{x}{(r \times q)}.$$

Mahāvīra made a very significant remark in connection with the square-root of a negative number. He said "A negative number is non-square by its nature, whence there is no (real) square-root from it."

This remark is the first clear recognition of the imaginary quantities in mathematics which had to wait for several more centuries for their formal definition.

Mahāvīra was one of the earliest Indian mathematicians to deal with the lowest common multiple which he calls *niruddha*. It was evolved to simplify operations with fractions.

Arithmetical and geometrical progressions were already handled earlier. An extensive treatment is available in the *Gaṇitasāra saṅgraha*. In the absence of modern theories of logarithms and equations, problems were solved by methods of trial and repetition.

Mahāvīra seemed to be expert in handling all sorts of equations reducible to quadratic forms and gave a variety of examples of them.

In mensurational problems in geometry, Mahāvīra usually gave two rules: one for rough and the other for better or accurate results. He dealt with all the usual plane figures. For π, he conformed to the Jaina values 3 (rough), and $\sqrt{10}$ (better). He was the first Indian to deal with mensuration related to an ellipse which he calls *āyata-vṛtta* (elongated circle), but his rules are approximate.

For an ellipse of semimajor and semiminor axes his "accurate" results are:

$$\text{Area} = b\sqrt{(4a^2 + 6b^2)},$$

$$\text{Perimeter} = \sqrt{(16a^2 + 24b^2)}.$$

For the exact rectification of the ellipse, one had to wait for about 800 years to acquire the powerful tool of calculus. In this situation Mahāvīra's first attempt is to be appreciated.

Regarding the volume of a sphere of radius r, Mahāvīra gave the formula

$$v = \frac{9}{2}r^3,$$

which was the practical rule of Jaina tradition. He gave another rule for the purpose, but it gives a better result only with an emendment of the text. For the curved surface of a spherical segment, his rule has been newly interpreted to yield the formula

$$S = \pi r^2 \theta \sin\theta,$$

where θ is the semiangle subtended by a diameter of the base of the segment at the center of the sphere. This peculiar formula gives quite a good result in all practical cases (i.e., for θ up to 60°). The modern exact formula is $2\pi r^2(1 - \cos\theta)$. For the volume of frustum-like solids, Mahāvīra gave a generalization of Brahmagupta's rule based on the theory of averages.

In the end we mention Mahāvīra's extensive contribution to the formation of rational figures. He calls a triangle or quadrilateral *janya* (generated) when its sides, altitudes, and other important measures can be expressed in terms of rational numbers.

Mahendra Sūri

K. V. Sarma

Mahendra Sūri, Jain astronomer, and pupil of Madana Sūri, was a protégé of the progressive minded Sultan Fīrūz Shāh Tuglaq, who ruled in Delhi from AD 1351 to 1388. The Sultan was one of the pioneers of the cultural exchange between Hindus and Muslims and was much interested in astronomy. His most important contribution in this field was the introduction of the astrolabe into India from the Islamic world. He induced Mahendra Sūri to study the astrolabe and familiarize Indian astronomers with the instrument through the Sanskrit language. This persuasion resulted in Mahendra Sūri's writing the *Yantrarāja* (King of Instruments), in 1370, the first work written in Sanskrit on the astrolabe.

The *Yantrarāja* sets out in five chapters the theory of the astrolabe, the construction of the instrument with its several planes and designs, and lines, circles, and other markings to be made on the planes while making the instrument and graduating it for making observations and recordings. It is to be noted that Mahendra Sūri first describes the ordinary astrolabe, which he calls *saumya-yantra* (northern instrument), wherein the astrolabe is projected from the south pole, and then the *yāmya-yantra* (southern instrument), where the instrument is projected from the north pole. He then introduces a *miśra* (mixed) instrument, which he calls *phaoñīndra-yantra* (the serpentine instrument), wherein the two types are combined.

The commentary on the *Yantrarāja* by the author's pupil, Malayendu Sūri (fl. 1377) explains the practical application of the instrument for taking readings. He also provides tables of the latitudes of about 75 cities in and outside India, and also one for 32 fixed stars. In this connection the commentator says that the Muslims have recorded more than 1,022 stars, but that he has selected only 32, being those required for practical use in Indian astronomy and astrology. There is still another commentary on the work, which is more elaborate than that of Malayendu Sūri, written by Gopīrāja about AD 1540, which is still in manuscript form.

Makaranda

K. V. Sarma

M

Makaranda was a resident of Kāśī (or Benares, Varanasi). In AD 1478 he wrote an extensive astronomical manual with the title *Makaranda*. This was doubly significant, first because the title was reminiscent of his own name, and, second because it called the computed result obtained *makaranda* (honey), and gave the several astronomical terms names of parts of plants, such as *guccha* (flower cluster), *kanda* (bulb), *vallī* and *latā* (creeper), and the like. Makaranda based his work on the parameters of and practices prescribed by the modern *Sūryasiddhānta*, to which he added certain corrections to insure greater accuracy, and provided a number of astronomical tables for ease in computing the daily almanac.

Makaranda's tables, which are often long and extend to several centuries, involved much labor and ingenuity in their preparation. They cover such subjects as *tithi* (lunar day, five tables), *nakṣatras* (asterisms, four tables), *yogas* (complementary positions of the sun and the moon, three tables), *saṇkrāntis* (entry of the sun into the zodiacal signs, three tables), mean motion of planets and their anomalies (11 tables), length of daylight on different days (one table), weekdays (two tables), and eclipses and allied matter (ten tables).

In order to render the work of the user easier, Makaranda provides, in certain cases, two sets of tables, one for single years and the other for groups of years, all from the epoch date of the commencement of Śaka year 1400 (AD 1478). Thus, when calculations are made for a date which is several years after the epoch, multiples of the group-years can be skipped, just taking note of the readings for the number of group-years skipped and applying the same to the relevant year of the current group. In the case of *tithis* the group is taken as 16 years; for *nakṣatras* and *yogas*, it is nearly 600 years, from AD 1478 to 2054, in 24 year periods. For the precession of the equinoxes, it is nearly 100 years, from AD 1758 to 1838, in 20-year periods, and for *saṇkrāntis* for 400 years, from AD 1478 to 1877, in 57-year periods.

Makaranda's tables were widely used in the entire northern belt of India, comprised of Gujarat, Rajasthan, Uttar Pradesh, Bihar, and Bengal, as attested by the profusion of manuscripts of the work found in this region. The work has also been commented on by several authors, from Ḍhuṇḍirāja (fl. 1590), through Purusottama Bhatta (fl. 1610), Divākara (fl. 1606), and Kṛpakara Miśra (fl. 1815), to Nīlāmbara Jhā (b. 1823). The *Siddhāntasudhā* of Paramānanda Ṭhakkura is based on the work of Makaranda.
