"Brahmagupta holds a remarkable place in the history of Eastern civilization." (Sachau 1971). Bhāskara II described Brahmagupta as *Gaṇakacakracūdāmani*, jewel among the circle of mathematicians.

Brahmagupta was born in AD 598 according to his own statement: "… when 550 years of the Śaka era had elapsed, Brahmagupta, son of Jisṇu, at the age of 30, composed the *Brāhmasphuṭasiddhānta* for the pleasure of good mathematicians and astronomers." Thus he was 30 years old in Śaka 550 or AD 628 when he wrote the *Brāhmasphuṭasiddhānta*. That he was still active in old age is clear from the title epoch of AD 665 used in another of his works called *Khaṇḍa-khādyaka*. Pṛthūdaka Svāmin, an ancient commentator on Brahmagupta, calls him Bhillamālācārya, which shows that he came from Bhillamāla. This place has been identified with the modern village Bhinmal near Mount Abu close to the Rajasthan–Gujarat border.

We have no knowledge of Brahmagupta's teachers, or of his education, but we know he studied the five traditional *Siddhāntas* on Indian astronomy. His sources also included the works of Āryabhaṭa I, Lāṭadeva, Pradyumna, Varāhamihira, Siṃha, Śrīṣeṇa, Vijayanandin, and Viṣṇucandra. He was, however, quite critical of most of these authors.

The *Brāhmasphuṭasiddhānta* is Brahmagupta's most important work. It is a standard treatise on ancient Indian astronomy, containing 24 chapters and a total of 1,008 verses in *āryā* meter. The *Brāhmasphuṭasiddhānta* claimed to be an improvement over the ancient work of the *Brahmapakṣa*, which did not yield accurate results. Brahmagupta used a great deal of originality in his revision. He examined and criticized the views of his predecessors, especially Āryabhaṭa I, and devoted two chapters to mathematics. There have been many commentators on this work. The earliest known was Balabhadra (eighth century AD), but his commentary is not extant.

Chapter 7 is on *Gaṇita* (Mathematics). It deals with elementary arithmetic, algebra, and geometry. The subject is presented under 28 topics of logistics (arithmetical operations) and determinations, including problems related to mixtures, plane figures, shadows, series, piles, and excavations. He wrote in a concise and understandable style, whether dealing with simple mathematics or complex geometry. In the treatment of surds, Brahamagupta is remarkably modern in outlook. The *Brāhmasphuṭasiddhānta* includes formulas for the rationalization of the denominator, as well as a marvelous piece of pure mathematics in the rule for the extraction of the square root of a surd. Still more remarkable algebraic contributions are contained in a chapter entitled *Kuṭṭaka*, which is a traditional name for indeterminate analysis of the first degree. The second order indeterminate equation

$$Nx^2 + c = y^2 \qquad (1)$$

is called *varga-prakṛti* (square nature). An important step towards the integral solutions of such equations is what is called Brahmagupta's Lemma in the history of mathematics. In modern symbology the Lemma is as follows:

> If (α, β) is a solution of (1) with $c = k$, and (α', β') is its solution with $c = k'$, then $(\alpha\beta' \pm \alpha'\beta, \beta\beta' \pm N\alpha\alpha')$ will be its solution with $c = kk'$.

This lemma not only helps in finding any number of solutions from just one solution, but it also helps in solving the most popular case of $c = 1$, provided we know a solution for $c = -1$, or ± 2 or ± 4.

In geometry, Brahamagupta's achievements were equally praiseworthy. He wrote a fine symmetric formula for the area of a cyclic quadrilateral, which appeared for the first time in the history of mathematics. Even more important are his expressions for the diagonals of a cyclic quadrilateral.

Brahmagupta's name has been immortalized by yet another achievement. A "Brahmaguptan quadrilateral" is a cyclic quadrilateral whose sides and diagonals are integral (or rational) and whose diagonals intersect orthogonally. He gave a simple rule for forming such figures in the *Brāhmasphuṭasiddhānta* (Chap. 7, verse 38): If a, b, c and α, β, γ are the sides (integral or rational) of two right-angled triangles (c and γ being hypotenuses), then $\alpha\gamma, b\gamma, c\alpha,$ and $c\beta$ are the required sides of a Brahamaguptan quadrilateral.

Prior to Brahmagupta, the usual method for computing the functional value intermediary between tabulated values was that of linear interpolation, which was based on the rule of proportions. He was the first to give second order interpolation formulas for equal as well as unequal tabulated argumental intervals. Mathematically, his rule is equivalent to the modern Newton–Stirling interpolation formula up to the second order.

The *Khaṇḍa-khādyaka* is a practical manual of Indian astronomy of the *Karaṇa* category. The author claims that it gives results useful in everyday life, birth, marriage, etc. quickly and simply, and is written for the benefit of students. The work consists of two parts called the *Pūrva* and the *Uttara*. The former comprises the first nine chapters and expounds the midnight system. The latter six chapters provide corrections and additions. This work has been studied by a great number of commentators, from Lalla in the eighth century to Āmarāja in the twelfth. It was translated into Arabic first by al-Fazārī (eighth century) and then by al-Bīrūnī.

Brahmagupta's genius made use of mathematics (traditional as well as that which he developed) in providing better astronomical methods. He used the theory of quadratic equations to solve problems in astronomy. He knew the sine and cosine rule of trigonometry for both plane and spherical triangles. He supplied standard tables of sines and versed sines.

The historian of science George Sarton called him "one of the greatest scientists of his race and the greatest of his time."

Bread in Africa

Diane Lyons, A. Catherine D'andrea

Bread is a dietary staple in north and northeastern Africa and is an important food for some Saharan and East African groups. African breads are baked, steamed, and sometimes fried to produce pancakes, flat breads, loaves or cakes using ovens, griddles, and moulds. Technical choice is associated with the baking properties of bread ingredients and should not be considered evolutionary stages.

B

Wheat and barley are Near Eastern cereals that were introduced into northeastern Africa in ancient times. Only Near Eastern cereals contain gluten, an elastic protein formed when their flours are mixed with liquid to produce dough. If yeast is added and ferments, it produces carbon dioxide gas which becomes trapped in the dough's elastic structure causing it to rise. Sourdough leavening is common in Africa and is produced with residue left in dough mixing containers or by adding dough saved from a previous batch. However, barley and many varieties of wheat (e.g., emmer wheat and at least one wild ancestor of wheat) form gluten with poor leavening capacities. These cereal flours still produce viscous dough suitable for shaping by hand, a prerequisite for baking on oven floors and walls. Light airy bread was possible only after bread wheat, a variety with superior leavening capabilities, was developed in southwest Asia probably during the fourth millennium BCE. Well-risen loaves are expensive because they require longer baking times, use more fuel and are only made for special occasions or commercially.

African cereals (sorghum, millets, teff) and other indigenous plants do not contain gluten and their flours are made into fermented batter or thick porridge and baked on griddles or in shallow earth depressions. Only sorghum flours will form dough suitable for baking in ovens.

Bread in Africa. Fig. 1 Place names mentioned in the text. Map by Kees de Ridder.

Early History

Bread baking often leaves little material evidence to track its antiquity. 18,000 years ago at Kubbaniya in Egypt, wild plants were made into a fine mush possibly to feed young children (Hillman 1989). Pot boiling was unknown at this time and plants may have been ground and baked in shallow earth depressions similar to those of the Tuareg (see later) (Close 1995). Ash bread is also common with nomadic people and leaves no evidence. Hunter-gatherers in southern Africa make “cakes” from ground corms of the iris family baked in hearth embers (Deacon 1984: 258), and nomadic pastoralists in northern Ethiopia make unleavened wheat bread by inserting a hot stone into small lumps of dough that are baked near the fire (Dufton 1970: 219–220).

Ancient Egypt

Emmer wheat and hulled barley were grown in the Nile Valley since the sixth millennium BCE (Murray 2000) and were used to make bread and beer in Dynastic Egypt. Bread baking practices are known from tomb paintings, miniature models of kitchens and bakeries, statuettes, texts, excavations of bakeries, oven installations, analyses of preserved bread loaves, and experimental studies (Samuel 2000). Caution is required in interpreting artistic renderings as “photographic” records, as images were intended for elite burials and likely do not provide details of the range of bread-baking practices. Most evidence indicates that grain was pounded in a mortar, ground into flour on a saddle quern (a simple stone mill used for grinding grain by hand), sieved through baskets, and then mixed with water or milk and sometimes dates, honey, eggs, butter, coriander, sesame seeds, or fruit (Samuel 2000; Wilson 1988). Bread may have been leavened, but this process is not required for bread making and chemical studies of preserved bread indicate that many were not fermented (Samuel 2000).

During the Old Kingdom (2686–2160 BCE) emmer wheat and barley flours were baked into bread in large conical molds called *bedja*. *Bedja* were stacked and preheated, filled with dough or batter, covered, set into depressions in the bakery floor, and banked with hot embers (Lehner 1997). Bread was also baked as hand-formed loaves in hearth ash, on griddles or preheated ceramic dishes. Small cylinder ovens about 30 cm high were heated with fuel fed through a door at the base. The top was covered and bread was baked on a shelf a third of the way up the interior (Wilson 1988). During Middle Kingdom times (2055–1650 BCE), bread was hand-formed, made in tall cylinder moulds, and baked on griddles or on open hearths (Samuel 2000: 565).

During the New Kingdom (1550–1069 BCE) emmer wheat predominated and bread was baked in tannur-type ovens that became the main domestic and temple bread-baking technology (Samuel 1999). Tannur first appear in southwest Asia in the late fourth millennium BCE (Van de Mieroop 1997: 156) and consist of a clay cylinder, sometimes set into a bench, with wood, cattle dung, or other fuel fed through an opening at the bottom. Dough is inserted through the top and is

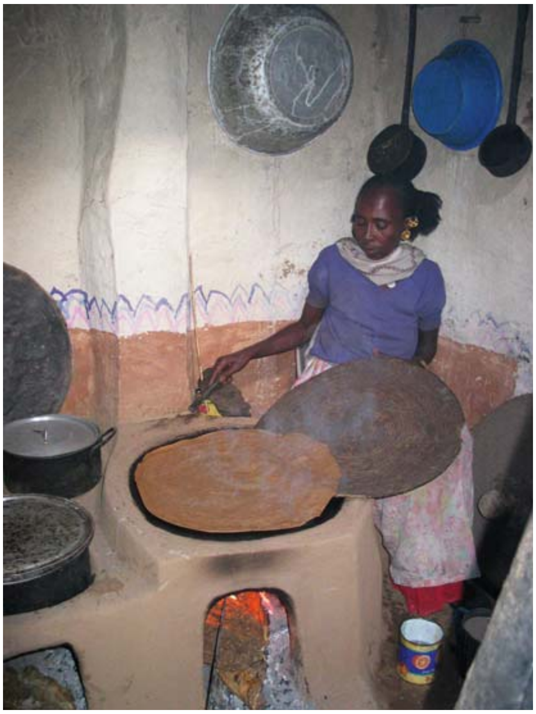
Bread in Africa. Fig. 3 "Sunny bread". Photo by Cathy D'Andrea.

pressed onto the hot interior walls to bake, although platters for large loaves may also have been baked in these ovens (Samuel 2000: 568). Long conical moulds were used for ritual purposes in the New Kingdom (Samuel 2000: 567) and a variety of hand-formed bread shapes were baked inside large commercial domed ovens. Some ovens were so large that the baker was held by his feet as he reached inside to position dough and retrieve baked bread (Wilson 1988: 55).

Major changes in bread making occurred during Greco-Roman times (332 BCE–AD 395) when free threshing wheat (durum and bread wheat) replaced emmer, and the saddle quern was replaced by the rotary quern (Samuel 2000). Small dome-shaped ovens are used to bake "sunny bread" (bread leavened in the sun) today near Luxor (Figs. 2 and 3).

Horn of Africa

The northern highlands of Ethiopia and Eritrea provide the only conditions for growing wheat in tropical Africa. Bread was a dietary staple by Aksumite times (300 BCE to AD 800) when huge quantities of bread were taxed from rural households (Kobischanov 1979). No definite bread ovens are known from the highlands,



Bread in Africa. Fig. 4 *Enjera* baking on *m'ogogo.* Photo by Diane Lyons.

but clay griddle fragments, dated to 500 BCE and similar to those used in domestic kitchens today, were found near Lake Tana along with the earliest evidence for tef, barley and emmer wheat in the region (Dombrowski 1971).

In northern Ethiopia and Eritrea, clay griddles (60 cm in diameter) called *mogogo* (Tigrinya) or *metad* (Amharic) are set atop a firebox made of upright, clay-covered stone slabs with an opening to the front for feeding fuel of cattle dung and small branches. In the central and southern highlands griddles are balanced on three stones set over a fire. Griddles are lightly lubricated with crushed oily seeds and dome-shaped lids are used to steam the bread (Lyons and D'Andrea 2003). *Enjera* or *taita*, spongy pancake bread made of teff, wheat, barley, and sorghum flours, is served with all meals (Fig. 4). Several varieties of slightly leavened and unleavened flat breads are made in the highlands and are differentiated by their thickness, ingredients and length of fermentation. In southwestern and central Ethiopia, similar pancakes and flatbreads are prepared from the fermented pseudostem of ensete (Smeds 1955: 24).

Somalian bread is similar to Ethiopian *enjera* but is made with sorghum flour batter poured onto a well-oiled griddle. Sweet *enjera*, and bread made with eggs are also produced. Thick sorghum dough is baked into flat bread on an oiled pan and Swahili sorghum bread is also consumed (see later) (Abdullahi 2001).

Bread in Africa. Fig. 5 *Kissra* baking. Photo by Catherine D'Andrea.

Sudan

Sudanese pancake bread called *kissra* is a staple made with fermented sorghum or finger millet batter on ceramic (now more commonly metal) griddles called *doka* heated atop three stone hearths (Dirar 1993: 171). At least 11 different types of Sudanese sorghum or sorghum-based breads are produced. Sudanese *doka* are similar to Ethiopian griddles, but were developed later *circa* AD 600 (Adams 1977; Shinnie and Shinnie 1978: 107). (Fig. 5). In Eastern Sudan thick sorghum porridge is baked into small flat bread called *hadib,* on the inner preheated walls of earthenware pots or metal petrol cans (Dirar 1993: 220).

Northern Africa

Wheat and barley have been grown in northern Africa since the mid- first millennium BCE, and sorghum and pearl millet were introduced into Libya during the early Islamic period (Pelling 2003). In the High Atlas Mountains of Morocco today, bread flours are made of wheat, barley, maize, millet and sometimes acorn (Balfet 1975; Bruneton 1975). Women make ovens (*afarnu*) by piling small stones 50 cm high and 80 cm diameter at the base and then coating the pile with thick clay (Bruneton 1975). After the clay dries, holes are cut at the top and base and the stones are carefully removed. The top opening draws a draft and fuel is fed through the bottom opening. Oven floors consist of flat stones resting on rock salt to retain heat. Once the oven is heated coals are swept to the side and dough is placed on the oven floor.

Different bread varieties include leavened wheaten bread for feast days and barley flour loaves for daily fare. Fast breads are baked from leavened dough in the embers or unleavened dough is baked on a hot stone plate or pottery sherd balanced on two stones over a fire (Bruneton 1975). Dough can be flavored with herbs, oil, garlic, onions, dill, sesame and aniseed (Balfet 1975; Bruneton 1975). Small domestic dome-shaped bread ovens are replacing traditional technologies in Morocco (Peña et al 2003).

In large villages in Tunisia leavened bread is made in commercial tannur-type ovens, and griddlecakes (*kesra*) are baked in a dish or on a metal plate. Griddle bread and pancake are sometimes stuffed with vegetables, meat and fruit, or a spicy sauce (Balfet 1975).

Sahara

Wheaten bread is common in the diet of the northern Tuareg and is baked in hearth ash, on a metal baking sheet or on the sides of an inverted metal pot heated over the fire (Nicholaisen 1963). However, millet flour is made into batter and baked in a preheated shallow depression in the ground. Fine sand and hot coals or a small fire is set over the top to bake the batter through (Gast, Marceau, and Adrian 1965; Nicholaisen 1963). The finished bread is washed, broken into pieces in a bowl, served with liquid butter and eaten with spoons. Some bread is made with millet flour, berry juice and special plants as a medicine for women. The flour is mixed with water into a solid "cake" and is baked like other millet bread (Nicholaisen 1963). Nomads in Sudan and Egypt use similar but larger earth "ovens", sometimes with floors of heated pebbles or pot sherds, to bake sorghum or millet flour bread (Dirar 1993: 218; Hobbs 1989).

East African Coast

Ovens called *mofa* occur in ninth century AD houses at Shanga on the Kenyan coast. *Mofa* were also used on some Arab dhows (Horton 1996: 46, 353). At Shanga, *mofa* consist of clay bowls set in floors that were possibly used to both bake bread and boil liquids (see Horton 1996: Plate 21). At the nearby site of Manda, *mofa* were made of clay cylinders with no base. These cylinders were approximately 40 cm in diameter and were constructed inside a pit (Chittick 1984: 153). The cylinder was then surrounded with soil and a fire was lit inside to heat the walls. Sorghum or millet flour dough was baked on the hot interior walls and such cakes were described by twelfth century Chinese traders as dietary staples (Horton 1996: 353). Horton (personal communication 2005) has observed that *mofa* are concentrated in northern coastal sites where sorghum is consumed and are much less common on southern coastal sites where rice is eaten. Although *mofa* are similar to tannur, Horton suggests that the technology is simple and could be a local invention.

West Africa

Bread was possibly made at Jenne-Jeno, Mali 2000 years ago from pearl millet and sorghum flours using earth depressions like those of the Tuareg (McIntosh 1995: 159–160). Medieval Arabic travelers observed bread made with unspecified tubers and millets in the eastern Sahara, Jenne, and Gao. These were consumed either as luxury items or cheap traveler's fare (Lewicki 1974: 46–47, 80), but baking technologies are not described. Today round clay griddles with four to six small bowls are used to fry fermented batter of pearl-millet flour into small cakes called *masa* or *marsa* in Ghana (Apentiik 1997) and Mali. Guinea millet is also made into fritters and cakes in northwestern Guinea (National Research Council 1996: 237).

Contemporary Issues

A recent advance in bread making technology is the introduction of electric mills that relieve women from the burden of grinding flour. Of considerable concern is the rapidly growing demand for Western white wheaten bread in Africa's urban centres. Methods are being developed to produce leavened bread with African cereals. Such projects are intended to protect African crop production and reduce reliance on imported wheat (National Research Council 1996).

Brewing in Africa

JOHN W. ARTHUR

Beer in Africa has been an important food staple since the Old Kingdom of Egypt (5400–5500 BP), from the site of Hierakonopolis (Geller 1992; Maksoud et al. 1994) and the New Kingdom of Egypt (1550–1070 BCE), to workmen's village sites at Amarna and Deir el-Medina (Samuel 1996). In many cultures of Africa, beer provides a substantial part of the diet, with one-eighth to one-third of grain crops being processed and consumed as beer (Platt 1964). Beer socially binds people together and serves to reinforce social hospitality, usually without aggressive behavior or addiction (Mandelbaum 1965). African societies use beer to indicate wealth and status, as a commodity of reciprocity, hospitality, and communality, as a payment of tribute to leaders, and as a vital food for the redistribution of wealth (Arthur 2003). In some cases, colonialism has dramatically changed the structure of beer and its ties to society. This paper reviews the importance of beer in Africa based on a number of ethnographic case studies.

Beer Production

The production of beer in Africa is usually under the domain of women. It requires a considerable amount of time-consuming labor. In most societies, producing beer is a multistep process. For the Mabaso women of South Africa or the Maale of southern Ethiopia, beer production can range from 5 to 12 days (Donham 1999: 153–155; Reusch 1988: 24). First, women let the grain sprout in a damp pot to produce a malt and then mix it with additional grains, and grind on a stone for hours. They bring large quantities of water from up to a mile away to mix with the ground grain and then boil the malt and flour in large pots. After boiling the mixture, women ferment the beer in large gourds or ceramic vessels. In Tanzania, the Haya make a beer using a combination of bananas and sorghum (Carlson 1990). They use ripe bananas because of their high sugar content, which assists in the fermentation process. The bananas are mashed with the help of dried grass, and then water is added in equal proportion to the banana liquid. After the water is added, dried sorghum is mixed into the water and banana solution and left to ferment for 24 h. In Ethiopia, the Gamo produce beer by two different methods (Arthur 2000). The highland Gamo produce beer by boiling water in a large ceramic cooking jar and then pouring the water over the wheat and barley flour and stirring it in a large serving bowl, where it is left to cool. It is then poured into a beer jar to ferment for 4 days. The second way to produce beer, which occurs in the lowland areas, is to combine and boil water and flour and then store this mixture in large beer jars for fermentation (Arthur 2000, 2002, 2003). In the majority of societies, women produce the beer, but once they produce it, it is used by many segments of society.

The Social Consumption of Beer

In Africa beer is consumed every day as a food product and beer also plays an essential role in the establishment of social obligations. The importance of communal consumption is one of the reasons people process their grains into beer rather than bread (Dietler 1990). Beer is often considered a food, rather than a beverage, and the consumption of beer adds considerably to their daily calories (Gardiner 1836: 266; Green 1999: 414; Haggblade 1992: 395; Karp 1980: 85; Moore and Vaughan 1994: 192; Richards 1939: 80; Saul 1981: 746–747). Beer may contribute to increasing caloric intake, but its symbolic role may be more important than its nutritional role. However, de Garine (1996: 215) argues that beer "may be richer in vitamins PP and

B-12, phosphorous and calcium than sorghum porridge, but it contains only half the calories, one-quarter of the proteins and no glucids" (Adrian and Sayerse 1954: 136; Pele and Le Berre 1966). For example, among the Koma of northern Cameroon, sorghum beer provides one-third the total energy consumed in a year and bonds age-sets and establishes a hierarchy between each one (de Garine 1996: 210). Among the Tiriki people of Kenya, beer is offered to visitors as a sign of friendship (Sangree 1962: 11), and the Baganda of Uganda use beer as a way to bond two men socially (Robbins 1979: 371). Beer acts as a social lubricant when the Tiriki and the Iteso people of Kenya men sit around communal beer pots everyday to discuss social issues, disputes, and tell stories (Karp 1980; Sangree 1962). The Haya of northwest Tanzania pay respect to fathers by offering them a gourd of banana beer, which must be done before others can be served (Carlson 1990). In addition, the Haya will offer a sacrifice of a gourd of beer to a father at the ancestral altar. The Kofyar of northern Nigeria conduct all aspects of their daily life around beer (Netting 1964). The Kofyar use beer as an award and as a punishment against not taking part in work parties, verbal or physical violence, disrespect of a clan member, or minor theft.

Beer as a Motivating Ingredient

In order to gather a work party, beer is essential; without beer, it is impossible to bring people together to cooperate on the task at hand. Work feasts are a type of commensal politics (Dietler 2001; Dietler and Herbich 2001), where people organize to work on a specific project and in return receive beer for their labor. Beer in work parties provides a social alliance between the work party sponsor and the people involved in the work party. Beer changes the context of the group, by becoming the "social focus" for all of the work party members, but also for people associated with the party members (Donham 1999: 155). Among the Konso of southern Ethiopia, the quality and quantity of beer is a motivational force in gathering people for a work party (Watson 1998: 148). If a person produces a high quality beer in sufficient quantities, then they can expect a range of 20–50 people to help them in the fields. There are a number of different types of Konso work parties, which involve fixed or volunteer groups, costing the sponsor approximately 50–150 Ethiopian birr (US $7.00–$21.00) depending on the size of the work party. Feasts also accompany work parties, as in Southern Africa, where leaders and wealthier commoners organize large work parties and then provide an abundance of beer (Crush 1992). The Pondo of South Africa rate their beer feasts higher than meat feasts, because beer makes the work seem more like a party (Hunter 1979: 89–90). Among the Kofyar of Nigeria, beer is the primary means for repaying voluntary labor to hoe and harvest agricultural fields and for building corrals and houses (Netting 1964). These examples demonstrate that beer is a motivating force for labor and beer also has a role to play in the formation of the elite.

The Social Hierarchy of Beer

The payment of tribute with beer indicates its economic and political importance. Although beer in Haya society is a secular refreshment, it has symbolic value since when Haya men make banana beer they must be sexually abstinent while brewing the beer (Carlson 1990: 298, 303–304). When the Haya produce beer, it is their obligation to pay their leader four or more gallons of banana beer. Beer, along with livestock, barkcloth, and iron products, are presented to leaders as tribute. They present the leader with special gourds of beer that have wrappings of banana fiber covering the gourds which are tied with twigs and leaves from a plant that symbolizes purity and strength. As with the offering of beer to the deceased father, the Haya king also offers a sacrifice to his ancestral altar for the welfare and fertility of his kingdom.

The Chagga leaders of Tanzania opened their houses and gave generous supplies of beer, which fulfilled their redistributive obligations and supported the warriors, who would fight on their behalf (Dietler 1990: 370–371; Gutmann 1926: 346). The Chagga leaders would collect this beer through either a tax that the people were happy to pay so that they might socialize with the leader or through a work party in which people would help cultivate his millet crop, which was used to make a beer feast. A sign of a good Buganda leader is the redistribution to the people in the form of "beer, meat, and politeness" (Mair 1934: 183). As with the Chagga, the Buganda leaders obtain their beer through a tribute system and beer also is used to settle disputes as fines (Robbins 1979: 371). Thus, the payment of beer forms a social, economic, and political reciprocal bond between commoners and leaders.

Brewing beer in association with slaughtering cattle among the Koma of Cameroon also provides a means to improve an individual's status (de Garine 1996: 208–210). The cattle dance ceremony celebrates the hard work and good qualities of a man's wife as being a good mother to their children. The ceremony in her honor is a redistribution feast that increases the husband's social status by distributing meat and beer to their kin and religious leaders. Once the husband has hosted up to seven ceremonies his status increases because he is knowledgeable about the secret rituals and places and can drink beer from his own pot without sharing.

Beer is associated with the wealthy, high-caste Gamo households (Arthur 2003). The political and religious aspects of Gamo life are under the authority of the *mala* caste. The production and consumption of beer occur at all political and religious ceremonies such as at initiation feasts for ritual-sacrificers (*halakas*), weddings, and at ceremonies celebrating saints' days. The *mala* ritual-sacrificers must demonstrate their generosity through beer feasts. The wealthiest *mala* are "caught" by the other *mala* members to become ritual-sacrificers (*halaka*) (Halperin and Olmstead 1976). If the people choose a person to become a ritual-sacrificer, his duties are to perform animal and beer sacrifices in which he prays for the health and fertility of his people, crops, and animals. Gamo ritual-sacrificers are always men, who must be circumcised, married, wealthy, and morally respected (Sperber 1975: 215). However, to become a ritual-sacrificer, a person has to perform two beer feasts (*perso oosha*), which include producing enough beer for the people who reside in his political region (*dere*) (Freeman 1997). This ritual-sacrificer must have enough farmland to provide for producing large amounts of beer and other types of high-status foods. This redistribution of wealth cannot be refused by the chosen ritual-sacrificer (Sperber 1975). He must organize two different feasts, one at his house and the other in the area of community gatherings (Freeman 1997). At both feasts, the participants must wait to start drinking until the *halaka*-to-be and the elder-sacrificer pour beer on the ground as an offering for the spirits. Each redistribution feast can comprise up to 300 people and requires 800 kg of wheat for beer production (Halperin and Olmstead 1976).

Thus, beer in African cultures is more than just a beverage; it is a critical component to the social, economic, and political structure of society (Carlson 1990; Netting 1964; Robbins 1979; Sangree 1962). People spend a considerable amount of their labor and time processing their crops into beer rather than bread because of the value of beer in establishing alliances. Beer binds these different groups together by providing a means of establishing reciprocity in the form of labor and social and economic coalitions. Furthermore, the importance of beer in the form of symbolic respect to the living and to ancestors exemplifies its significant role for the well being of societies (Arthur 2003).

Buddhism and Science

Somparn Promta

Buddhism is normally viewed as an atheist religion. Modern interpretations of the Buddhist teachings made by Buddhist scholars in Southeast Asia seem to bring Buddhism close to what is called 'science' in the modern world. That is, Buddhism is explored as a religion teaching that human life, the world, and the universe are the *Dhamma*, a Pali word containing complicated meanings. According to Buddhadasa, the most famous Thai Buddhist thinker, the Dhamma has four meanings (1) natural things, (2) natural laws, (3) human obligations to follow natural laws, and (4) the fruits gained from following the laws of nature. So human life, the world, and the universe, according to Buddhism, are natural things in themselves and they follow the certain laws of nature.

In Buddhist perspective, natural things and natural laws are not created by God or any other supernatural power. They exist naturally, meaning that the concept of creation is not necessary. However, Buddhism does not stress the philosophical arguments concerning the origin of the universe. The view of Buddhism on natural things and natural laws is practical in a sense that knowing what is the world *as we see now* should lead to a happy life. It should be noted that Buddhism believes that religious practice is closely connected to the laws of nature, so the learning of religious teachings in Buddhist perspective is learning the laws of nature.

In Buddhist texts, five laws of nature are mentioned (1) physical law, (2) biological law, (3) psychic law, (4) *kammic* law, and (5) moral law. The first two laws are believed by Buddhist scholars to be the same laws explored in physics, chemistry, and biology in modern Western science. Psychic laws could be partly compared to what are called psychological laws in Western psychology. However, there are some special contents in the Buddhist psychic laws not found in Western psychology. An example of these is the cultivation of the mind through meditation. Kammic laws are the laws concerning human actions. Buddhism believes that what we are is directly the result of what we do. We are born as a free entity to choose our future freely. Philosophically speaking, Buddhism believes that we are born with a free will. In this sense, we are solely responsible for whatever we have done. *Kamma* or *Karma* in Buddhist teaching, an action with intention and carrying moral value, is a secret power, like the field in physics, which dominates our life. Good Kamma determines a good life; bad Kamma determines a bad life. Moral laws are the laws that govern any events that cannot be classified under the first four laws. For example, Buddhism believes that the unjust or immoral structure of society is a bad thing. It is bad according to moral law. It is possible that individuals in society act well according to the law of Kamma, but they are good people in a bad society. The Buddha is well known as arguing against the caste system in ancient India. For him, it is possible that people of each class act well according to their class duties, but caste is still a bad thing, judging from moral law.

Looking through the Buddhist five laws of nature, we can see that the belief in nature is wider than the belief in nature found in science. In Western science, the laws of nature as found in physics, chemistry, and biology have nothing to do with social justice, fair distribution, or the violation of human rights. Science within this tradition has become something containing a narrow meaning. Science never questions how we can gain a happy life or a just society. Typical scientists seem to think that such a question should be considered outside the scientific community. It should be part of political science or political philosophy. The above tendency leads to the separation between 'knowledge' and 'value', and between 'nature' and 'human convention'. The Buddhist conception of natural laws does not make the same separation. For Buddhism, physical and biological laws are the beginning laws of nature to be explored. They are looked on as a means leading to some things more valuable.

Between human life and the physical world, Buddhism thinks the former is of more importance. However, as our life can never be separated from the world, the study of the physical world is accepted by Buddhism to be of some value as far as it is undertaken in balance with the study of human life. Furthermore, the study of the physical world must not be run separately from the study of society. If we are allowed to call the activities of exploring nature through the Buddhist five laws 'Buddhist science', what follows is that Buddhist science stresses the balance between three things: human life, society, and physical world.

The confrontation between modern science and Buddhism in the Buddhist countries such as Thailand seems to be best understood in the light of the Buddhist conception of nature as said above. In Thailand, where Theravada Buddhism plays the role of a national religion, the sale of GM food is allowed by law under the condition that the products must be declared to contain GM ingredients. Buddhism in Thailand does not raise moral questions about this, while Islam seems to doubt it. The recent study of the opinions of Buddhists concerning the issues of human cloning and stem cell research in Thailand declares that the Buddhists, compared to Christians and Muslims, can more easily accept human cloning and the use of stem cell for medical purposes if it is proved safe. This phenomenon can be understood if we are reminded that Buddhism is a religion free from religious dogmas. Like science, Buddhism believes in the natural creation of things. For Buddhism, anything allowed to happen in the world is 'natural'. So, Buddhists do not view human cloning as unnatural. On the contrary, it is 'natural' in a sense that it is allowed by the second law of the five laws. However, it should not be understood that Buddhism has nothing to question about these issues. These arguments essentially stem from the conception of balance between the five laws. Human cloning and stem cell research are viewed as activities run within the second law. So, it is not isolated from other laws.

Finally, Buddhist scientists in Buddhist countries like Thailand seem to feel that Buddhism and science are friendly. This feeling possibly stems from the picture of Buddhism in their minds. Buddhism as taught in the university classroom shares a lot with science. In chapters of high school Buddhism textbooks, the way the Buddha searches for knowledge is usually described in terms of scientific enquiries. The Buddha says that he did not create the truths he found after the process of study. They were naturally given. Anyone, according to the Buddhist perspective, can be a Buddha. The term 'Buddha' means the one who is enlightened. Enlightenment is nothing but the realization of natural laws. Knowledge in the Buddhist view is in the end the same thing as morality. We can easily find the balance between knowledge and value in Buddhist science.

Building Construction

Norbert E. Wilhelm

It is difficult to talk about the differences in Western and non-Western building technologies, as many approaches used today in this field were also used in western countries in the past. Some, such as mud technology, are currently being revived in Europe. A more appropriate expression might be indigenous or traditional technology.

Some basic approaches, such as the construction of walls out of stonemasonry, mud or branches plastered with mud can be found in many places in the world. It is not surprising that there is not so much basic difference, as the construction materials had to be found in the surroundings. What is amazing is to explore which quality or intelligence is presented in the specific adaptation to the climate and in resistance to disasters.

Traditional Construction Technologies are Still of Great Value

The fact that we now use other technologies does not mean that traditional knowledge was primitive.

Dealing with local material is more ecological, and these old technologies have no recycling problem.

Traditional technologies went through a long process of evolution, so they are in most cases the very best solution, taking into account what basic materials were available at any given place and time. They are well adapted to the local climate and are rather safe with regard to recurring local hazards. However this is only to the extent that was possible with the available materials and knowledge. The typical empirical way of improving the design could respond only to events with a reasonably short recurring period.

Modern technology has to an extent not yet proved its durability. We face problems, like corrosion in prestressed concrete bridges, whereas stone arch bridges survived for centuries without even regular maintenance or repairs. None of the modern bridges in steel or reinforced concrete would ever have such durability.

Many of these old building technologies still have a potential for improvements, if modern materials and knowledge could be added in a sensible way.

Today traditional building technology is for the poor; it is often the only one they can afford and handle. Unfortunately this gives it a bad image. It has become the technology of the lowest classes, seen as being primitive, in spite of all its values and potential.

Some famous architects have discovered the value of traditions and have gotten inspiration from local buildings. Considerable literature about vernacular architecture has emerged, praising the so-called *genius loci* (sense of place). An excellent collection which shows how people live is Oliver's *Dwellings* (2003). Unfortunately most literature looks purely at the architectural aspects, so that the engineering experience and the intelligent use of materials including their ecological aspects and their climatic adaptations is left out. This is what this article will concentrate on. One should not see the *genius loci* as something mystical; it is an experience that is presented by traditional buildings and it is important to document the technology in better detail, so that it does not get lost with the death of the last craftsmen.

Tradition Goes with Esthetics

Transport of nonlocal material was too expensive; this led to a rather great uniformity in a specific region. And as buildings and other constructions are unengineered, there is also not much variation in the structure. As a result, traditional buildings are rather uniform. The limitations given today by town planning regulations with regard to the size and often with the specification of certain exterior materials were more or less imposed by the limited resources for the old construction methods.

Limiting the variations of the buildings has a great esthetic advantage. Total uniformity is boring; too many differences in aspects and the missing of a common idea make the built environment chaotic. This is not surprising; all building was based on the variations of plants, landscape and textures of the available materials. The grain of a piece of wood never is uniform, but it follows a certain law, a certain pattern. No piece looks like the other, yet we still can say what type of wood it is. A landscape has its character, and a forest has its own appearance and mixture of trees. No person looks exactly like someone else. We are used to such variations generated by certain mechanisms and we appreciate them.

You can analyze this hypothesis when you visit a medieval town in Europe or if you walk through an old Indian city like the historic part of Ahmedabad, or an oasis in the desert. There are prevalent materials and variations of the design, based on traditions, limitations of the structural system and on what the owner could afford. Such an appearance corresponds to the older people's experience with their surroundings, and we find it pleasant. A similar homogeneity is difficult to achieve in today's architecture: normally, styles vary too much or completely new quarters or towns are too uniform.

Valuable Experience Is Conserved in Traditional Buildings

Our modern design work is to a very large extent based on mathematical models and calculations, which give reasonably reliable results for the dimensions and make nearly every shape possible. The old builders did not have such comfortable design tools. They were lucky if they could cope with the geometrical questions in the case of more complicated buildings. The construction of the building with regard to structural problems and in order to provide an optimal climate under the given conditions and restrictions was based on experience. That means testing at the scale of 1:1 at the real building. However, throughout history, traditional technologies were perfected bit by bit. The choice of material was limited to what could be found locally. So stones, mud, wood, and leaves are prevalent in construction technologies.

A limited range of materials is easier to handle in an improvement process. The results we can see today are quite intelligent and efficient. They represent the experience of hundreds or sometimes even thousands of years. For example in earthquakes, sometimes traditional buildings behave very well and are most efficiently designed, as one will see further below. What is not surprising, but really remarkable, is the climatic adaptation. If you follow the design criteria for comfort in a certain region, you end up normally with the traditional building layout and detailing (Koenigsberger 1973; Lippsmeier 1969).

However, there are several problems with traditional construction. As it is not based on theoretical models, average craftsmen and engineers do not really know why it works. So one has to follow the old rules, which get more and more lost. Only a few bright people brought the methods forward in the past. All the others were only followers.

The Major Construction Elements

There are many similarities between traditional construction technologies in non-Western countries and historical constructions in Europe. Either there was an exchange over wide distances in early times or the availability of material dictated similar solutions. Most likely both were true. However some tropical areas had their own specific solutions, manly dictated by the different climate and available materials.

Walls

Walls, the most important construction elements, are mainly of the following types:

a. Wattle and daub. The basic structure consists of wooden posts, normally directly put into the ground or in a simple foundation. In some regions the ends of the posts to be placed in the earth were slightly burnt until they developed a charcoal surface; that made them a bit more resistant to rot. A grid of smaller branches or bamboo, normally bound together by plant fibers, filled the space between the posts. The infill could also be of stronger horizontal branches and vertical hatch or wooden weaving. This wooden core was covered on both sides with mud. Sometimes fibers like short cut straw were added (Figs. 1 and 2).

This wall type is probably used the most in the world. The method of infill is also used for the typical European timber framework. One can achieve a very smooth surface if the last layer is reworked over and over without letting it dry until all shrinkage gaps are filled.

b. Mud formed in situ. Here the mud is mixed with water until it becomes workable. This is often done with the help of an ox walking in the mud. Then the mud pieces are placed one over the other while still wet and made smooth.

Building Construction. Fig. 1 Wattle and daub wall.

c. Sun dried mud bricks. After forming and drying bricks of wet mud, they are joined together with mud mortar.

d. Rammed earth. Here only slightly moistened and rather sandy soil is rammed in forms of varying sizes in layers. High buildings up to five storeys are built with this method. Well-known examples are the houses in Sanah, Yemen and the famous mosque in Mopti, Mali. In Europe large and high buildings still exist, made of rammed earth; it used to be a widespread method in Southern France.

In Afghanistan, one of the historical school buildings has a mixed wall construction, where the faces of the walls are made of mud bricks and the core of the walls is filled with rammed earth. Corners are made of burnt bricks in mud mortar. This two storey building in the center of Kabul is more than 100 years old and the walls are still sound (Figs. 3–5).

More about mud technologies (as well as their further development with lime or cement stabilizers)

Building Construction. Fig. 4 Old castle near Kabul Afghanistan (with rammed earth) (photo by the author).

Building Construction. Fig. 5 Detail of the rammed earth blocks (photo by the author).

can be found in Doat (1991), Minke (1999), and Niemeyer (1946).

e. Typical for many tropical hot and humid areas (where day and night temperatures vary only slightly) are light and easily ventilating walls. There the users can benefit from the slightest breeze. These walls are mostly made entirely of bamboo, but one can also find grass or palm leaves as cladding. Even entire structures of strong grass like reed existed where this grows close to swampy areas, for example in the Marshs (North of Basra) in Iraq (Thesinger 1967). They are bound together as in Thor Heyerdahl's famous boat Ra and can form quite sizable arch structures (Fig. 6).
f. A structurally interesting system concerns Chinese temples and other important historical buildings, where wooden columns (with infill or free standing) carry the roof. Such freestanding columns get their horizontal stiffness against wind mainly due to a high load from the roof. The horizontal load from the wind is related to the height of the structure, and adding vertical loads can increase the horizontal resistance. This is exactly the case, as the tiles of these Chinese roofs are embedded in a thick layer of special mortar. From below it looks like a full wooden roof. Leaving the mortar out would seriously harm the structural integrity. Unfortunately this strategy does not work in the case of earthquakes, as there the horizontal forces are related to the mass. So adding more weight in the roof does not help; old pagodas collapsed during earthquakes.

Building Construction. Fig. 6 Thor Heyerdahl's boat (exhibition in Tenerife, Spain). Similar technology is used in the swamps of Iraq for buildings (photo by the author).

Slabs

Slabs and flat roofs are normally supported by wooden beams with different infill materials. The major ones are:

a. Stones, which are then covered with mortar or mud. In this case, the beams have to be rather close together. Larger crossbeams can often support small secondary beams. This construction is rather typical for the east African coast with its Arabic influence.
b. Mud, reinforced by wooden branches. The construction usually starts with a mat (bamboo or similar), which prevents the mud from falling down. The branches, being fully embedded in the mud, act as a reinforcement, so that the distance between the beams can be larger upto about 45–60 cm (1.5–2 ft) (Fig. 7).
c. In Rajasthan, India, ceilings and roofs are made in stone-producing regions by placing a stronger stone as a beam and stone plates between those beams.

Roof Structures

In addition to slab roofs one can find the following basic roof structures:

Building Construction. Fig. 7 Roof structure (Dubai) beams, mats, and mud as topping (photo by the author).

Building Construction. Fig. 8 Support of a roof in China (photo by the author).

a. Wooden beam structures, where besides, the purlin[1] and rafter construction, we can mention some interesting other types. (1) In traditional Chinese roofs, the main load-bearing element consists of wooden beams arranged one on top of the other with small spaces in between. The top beams get shorter to follow the form of the gable. This makes larger spans possible without doing complicated latticework, although at the expense of more timber consumption (Fig. 8). (2) Some communities in Gujarat, India built conical roofs with small beams without intermediate support, which act like shells (see case study). Others build a wooden dome on a square house using strong branches (Figs. 9 and 10). (3) In Eastern Africa large roofs were built using tree type support systems. Now one can find this efficient system being revived in beach resorts at the Mombassa coast (Fig. 11).

[1] A purlin or purline is a piece of timber laid horizontally on the principal rafters of a roof to support the common rafters on which the roof covering is laid mostly using battens.

Building Construction. Fig. 9 Simple *Bungha* roof from the inside (photo by the author).

Building Construction. Fig. 10 A simple roof structure out of branches (Gujarat, India) (photo by the author).

b. Domes and vaults are often used in desert architecture. Most are made of mud bricks, as they have sufficient strength. The main problem in a dome and vault construction is to counterbalance the horizontal thrust. Heavy and sometimes inclined walls do this. If stones are used for domes, a good overlapping can take a lot of the horizontal tension. This is the case in many old mosques and temples (Fig. 12). Tension belts, which would be the best technical and scientific response to the problem, are not used to my knowledge. For vaults, only horizontal tension beams lead to an improvement. They can be found for example in old Ottoman buildings in the Balkans,

Building Construction. Fig. 11 Roof structure with tree-type supports (Beach Resort in Kenya) (photo by the author).

Building Construction. Fig. 12 Dome (Jumma Mosque, Ahmedabad). Ring forces balanced by overlapping; joints open where there is a little overlapping (photo by the author).

where wooden beams carry an intermediate floor under the vault. Removing such a floor with its beams could lead to collapse; even a replacement not respecting the invisible anchoring detail could have this effect. Interesting information on how to build domes and vaults without shuttering can be found in Doat (1991) and Minke (1999).

The above example as well as the Chinese roof (that stabilizes the wall columns by its weight) demonstrates how dangerous it could be to change traditional construction. One has either to follow the tradition strictly or one must fully understand how it works.

Roofing Material

Roofing material for waterproofing varies a lot.

a. Slab roofs (which are prevalent in dry climates) have mud layers for waterproofing. In some cases they are covered with an additional layer of bricks or clay floor tiles laid to slope. This makes their use as roof terraces more convenient. Normally they are only a mixture of mud and chaff. This cover is in some rare cases also used for sloped roofs.
b. Suitable leaves or grasses are very common covers for sloped roofs. There is the well-known thatch roof using various types of local grasses, some of them are more and some are less resistant. Palm branches are prepared by folding them in half, so that the stalk is one side and the whole piece can be bound to the substructure. This type of roof is called *macuti* in Eastern Africa. The pieces are laid with overlapping shingles. Rounder growing palm leaves are simply overlapped. All these roofs provide good ventilation and heat insulation which make the houses comfortable. However every three years or so thatch type roofing needs to be replaced, which is costly for the owners, and good material gets scarce in some regions.
c. Burnt clay tiles were common in some areas of India and for all official buildings in China, where they are normally glazed. As mentioned, in China, tiles are laid on top of a wooden structure in mortar. In India traditional country tiles were made of short conical pipes that were cut into halves. They are like all traditional tiles laid one on the bottom as a channel and one on top to cover the gap between the two bottom tiles. A more recent type has a U-section as a tapered channel and is laid in the same manner. People who could afford put several layers on the roof for better heat protection. The small gaps in such tiled roofs ensure good ventilation. Predominantly a layer of split bamboo supports the tiles. It is safer than the one batten per tile as we know it. In case an earthquake or high wind moves the tiles, they cannot fall down and cause harm. In some regions of India, one can also find such tiles laid in mud on simple thatched roofs (Figs. 13 and 14).

Building Construction. Fig. 13 Country tile roof (Gujarat, India). Split bamboo placed close together serves as battens (photo by the author).

Building Construction. Fig. 14 Country tile roof from inside (photo by the author).

Building Construction. Fig. 15 Roof with a stone slab (Rajasthan, India) (photo by the author).

d. Domes and vaults get a finishing by lime plaster. To make this watertight, the sand used must have different grains and some organic material added in order to increase the elasticity.
e. Regions with suitable stone plates have sloped roofs with overlapping stone slabs. (Fig. 15).

Earthquake Resistance

In many non-Western regions, earthquakes are a major natural hazard and all buildings are built to resist their forces.

It is not the earthquake that kills; it is the collapsing building. Traditional constructions have a remarkable earthquake resistance. Problems start when the traditional way of construction is modified. Craftspeople who execute the works cannot really design for earthquake resistance once traditional design is given up. The strength and the proper dimension of a structure were developed by experience, and this is also reflected in the features that may make a structure more earthquake resistant, even if they are not recognized as structural elements. Even builders might not know why there are certain elements, which users normally consider decoration, which often play a vital role in the buildings' strength.

An earthquake's actions can in a simplified way be understood as horizontal forces acting on the structure. They are more or less proportional to the mass of the structure concerned and are expressed as percentage of the gravity acceleration.

Various strategies deal with earthquake safety. Basically one can have (a) buildings that do not harm people when they collapse; (b) a construction that is light where earthquakes do not induce large forces; and (c) buildings can be strengthened in various ways to withstand earthquakes. Often a combination of those measures is used. One can also have a rather elastic and flexible structure, which reacts by deformation, but that is not the case in traditional buildings.

Traditional Japanese houses consist only of a light wooden structure and a sort of paper filling for the walls. As the structure is light, an earthquake will not introduce many forces and if it collapses, the walls are not seriously hurting users. This is an intelligent construction using strategies (a) and (b).

All types of thatched roofs (real thatch and covers from palm or banana leaves) always supported by a wooden structure, follow the same strategy. They are light and will not cause harm when the roof collapses. Even roof tiles did not result in serious injuries when falling down during earthquakes (or cyclones). As mentioned, in India, there were many pieces of split bamboo lying so close together that tiles could not fall through. However, when modern roof tiles were introduced, this feature was given up, as those new tiles only match well with single straight battens as support. Central Europe, where the design of modern tiles comes from, has not got serious earthquake problems, and there is always a ceiling under the roof. Introducing the same technology in earthquake-prone areas like northern India, where people normally cannot afford a cladding under the roof, was probably not a good idea. In the great Gujarat earthquake in 2001, falling tiles injured people, but practically nobody was killed. The death toll came mainly from collapsing slabs or slab roofs, especially when their supports failed.

To make the building itself resistant to prevailing earthquakes, following strategy (c) can be achieved in various ways. Rather resistant are wooden structures, filled with either woven mats or similar (which is the usual construction in the real tropics (see climatic adaptation), or with mud (mostly a wattle and daub type, see wall materials). Some latticework or diagonals increase the horizontal resistance. However, often the traditional joints are a weak point.

You often find this type of approach for the first floor of two storey houses. It has a long tradition in Muslim construction and can still be seen in old Turkish towns as well as in Kabul, Afghanistan. The first floor weight is more essential to the structure, as it contributes more to the internal forces, so it is wise to make it light.

A good way to reinforce masonry buildings against earthquake actions is to use horizontal bands with good tension strength. This is the recommended method for one and two storey buildings in many modern earthquake-related building design standards. Today, the bands are normally made of reinforced concrete. You will find similar bands in Turkey and in the Himalayan region of India etc., where houses are constructed of stones. These bands are however made of wood, a material that is relatively cheap and has good tension strength. There you find one piece of wood on either side of the wall, often interconnected in a form of a ladder by smaller batten type pieces. It looks and acts very similar to modern steel reinforcement in concrete beams. In the Himalayan region, people most likely discovered independently from the Arabic-influenced regions the positive effect of wooden beams in case of earthquakes. You can find buildings, mainly with dry masonry, which have wooden beams incorporated. They look very nice and can be considered as traditional decoration, but basically, they are reinforced against earthquakes.

Wattle and daub walls have also a rather high-tension strength, as the basic structure consists of wood. In addition, the walls are light and do not attract high horizontal forces.

Another way to increase the strength of a structure is to give it a suitable form. If you fold a piece of paper, the load bearing capacity becomes much greater compared to a flat piece. Round forms are very resistant and this is used in certain types of buildings. In Gujarat, India such a house type, called *bungha*, withstood the last heavy earthquake amazingly well (see the case study below).

A very simple and basic approach to make a wall itself earthquake resistant is to make it thicker. Assuming that the wall is sufficiently monolithic, one can assume that the resultant of the horizontal earthquake forces acts in the center of gravity of the wall, for a prismatic object that is the middle of the height. If the wall is wide enough in relation to the height, it cannot turn over. This is why huts (with light thatched roofs) and low stonewalls have no problems in earthquakes, even if they are only built with mud mortar. More effective are tapered walls with a wide base in the form of a retention wall or dam. This approach can still be found in earthquake-prone areas (Fig. 16).

In general, as one could see, traditional buildings were amazingly well adapted to earthquake hazards and this within a rather limited range of available local materials. Many problems started, when traditions were given up and westernized construction was imitated without designing the buildings for the prevalent hazards.

Building Construction. Fig. 16 Mud wall in a tapered form to withstand horizontal earthquake forces (Gujarat, India) (photo by the author).

Climatic Adaptation

For a good adaptation to the climate, the construction of a house plays a major role. Together with the architecture (Koenigsberger 1973; Lippsmeier 1969; Wilhelm 2000), which should deal with orientation, shadowing, openings, and spatial arrangements, the temperature and the air movement and the type of material used and its dimension also influence major components of comfort.

In desert conditions, thick and heavy walls provide a good phasing (time shifting of the temperature curve between outside and inside the building) and damping of the temperature. Mud and rubble stonewalls in the range of 30–45 cm (1–1.5 ft) as used in traditional constructions in such regions have a phasing of 12 h or so. This is how people can benefit from cool nights during the daytime. In the night they sleep outside or ventilate the room, if it is too hot from the heat stored during the day. A straw rich mud plaster normally increases the insulation and contributes to the damping effect. So the peak temperatures inside are lower than outside and closer to the average. In the desert environment, the rooms stays within comfortable conditions, whereas a prefabricated concrete building with thin elements as required for structural safety becomes too hot (Fathi 1986).

Building Construction. Fig. 17 Wind catcher tower (Dubai) (photo by the author).

In tropical conditions, light walls are traditional, which makes it possible to benefit from the slightest change of temperature. Weavings also let the air though, so that the users get more comfort through the air movement. All traditional houses in hot climates have openings near the roof or a roof that let the air pass through. In thatched or palm leaf roof covers this advantage is combined with good insulation properties so that the heat is kept out.

Ventilation can be further increased, if the floor is penetrable and put on stilts. Houses on the South East Asian islands with bamboo floors follow this strategy. A further improvement of the ventilation can come through a chimney effect. Raised gables in Bali, chimney-type additions on the center of the roof, wind towers in Arabia and holes on the top of domes are such devices (Fig. 17).

Example 1: Traditional Bunghas in the Semidesert of Kutch, Gujarat, and India

Probably the oldest types of houses in the semidesert of Kutch are called *bunghas*. They look very much like the well-known African round huts. They were considered rather backward and primitive type of construction. The big surprise was their amazingly good performance during the high magnitude earthquake in January 2001, where nearly 20,000 people died in the region.

Practically none of these buildings collapsed, except for those that were rotten, as the wooden roof structure and the walls had been weakened by termite attacks. Looking closer into the quality of the bunghas, one finds a very good adaptation to the desert climate with hot days and cool nights.

Building Construction. Fig. 18 Decorated *Bungha* (Gujarat, India) (photo by the author).

Building Construction. Fig. 19 Grain storage made of fiber-reinforced mud (Kutch, Gujarat, India) (photo by the author).

The bunghas are round structures, standing on platforms for better protection from the rain, which weakens the mud walls, as there are heavy rains from time to time. Several bunghas are placed together on this platform, forming the home of a large family. The houses with mud plaster are often nicely decorated and have furniture made of fiber-reinforced mud with a lot of decorations. The walls are in many cases made of wet mud pieces put in layers. In some cases sun dried mud bricks are used, fixed together with mud mortar (Figs. 18 and 19).

Another wall type consists of random rubble stone masonry, again fixed together with mud mortar. The fourth wall type found in some areas is the wattle and daub construction.

The wall thickness varies with the material. Wattle and daub is normally about 15 cm. This is the thickness that results from the material used and it is rather appropriate to provide a reasonable insulation and damping to cope with the high temperature differences between days and nights. The filling with branches, together with the mud layers on both sides, has rather good thermal properties. However from the point of view of building physics, a slightly thicker wall would be desirable.

The pure mud walls are about 30 cm thick, which ideally corresponds to the damping and insulation requirements. Mud mortar rubble stonewalls are generally 45 cm or 1.5 ft, which again corresponds ideally to the thermal requirements. The round form gives the walls a great stability, which explains the good performance of the bungha during the earthquake. The conical roofs are made of wooden rafters and covered with thatch. To interconnect the rafters, small branches or the core of palm leaves are used in small bunches that can easily be bent into horizontal rings. From the top, such a roof structure looks like a spider's web: the rafters go in a radial form from the center to the wall and their interconnections form concentric rings.

Many communities use a king post in the center of the room. They put a heavy beam on top of the wall about 1.80 m high, on which the king post ends. These people are sure that the king post is necessary, but other communities manage without it. They use a corner piece for each rafter to transmit the horizontal thrust of the conical roof to the walls that are acting as a tension ring. This interesting innovation takes longer to spread to the other communities living in the same region where bunghas are built (Figs. 20 and 21).

The roof cover is made of thatch, which has good insulation properties and at the same time lets air pass through and provides a good insulation for the buildings. Together with the good insulation and storage capacity of the walls the house is kept cool during the day and it is also comfortable in the cold nights in winter, which can reach zero degrees. Users are well aware of this and they call it a built-in air conditioning system. However they would like some improvements like better flooring and longer lasting roof materials.

Building Construction. Fig. 20 Old *Bungha* roof (Kutch, Gujarat, India). Large roof without king post and excellent decoration (photo by the author).

Building Construction. Fig. 21 Detail: corner element in a *Bungha* roof (photo by the author).

Example 2: The Afghan City House

Afghanistan has a harsh climate (hot summers, relatively cold winters and nights) and in addition there are earthquake hazards. Traditional housing is well adapted to those conditions. Whereas in villages, single storey mud or stone houses are prevalent, cities like Kabul have a long tradition of two storey buildings.

The plinth is built in random rubble stone dry masonry. This keeps the moisture from the soil out of the walls. In western technology the damp proof courses were only introduced in the beginning of the last century, normally as bitumen felt layers.

The ground flooring is laid on top of the so-called fox's dens. This is a system of ducts, which ventilate the space under the floor and is in some cases used as a heating system similar to the Roman holocausts (hollow floors and in some cases wall ducts, where fire was made for heating). Transverse main ducts connect both exterior plinth walls, so that the air can pass through. From this main duct secondary ducts run in a perpendicular direction. Then a layer of mud follows which carries the flooring, which is either made of brick or only mud. This construction keeps the floor dry. The ground floor walls are made of sun-dried mud bricks with a wall thickness of at least 30 cm (12 in.).

This corresponds ideally to the climatic requirements, as this wall has a high storage capacity and a phasing of up to 12 h. This room is cool on summer days (as it preserves the night temperature condition). A wooden framework with an infill of sun dried mud bricks forms the upper floor walls. These upper walls are only about 12 cm (5 in.) thick and have large windows. So the rooms in the upper floors pick up the outside conditions much faster, and one can choose the most comfortable room. The light walls, together with the wooden framework and a sort of batten as bracing against horizontal forces, make the building rather earthquake resistant.

The floor and the roof slab have wooden beams as load bearing structures at 45–60 cm apart (1.5–2 ft). As described earlier, there is a reinforced mud layer across the beams. To get the roof watertight, a layer of mud mixed with hacked straw is applied, which needs to be replaced every few years.

Some houses of this type are reported to be 200 years old and the technology is still used today. Those and more modern examples show the potential of mud houses.

Improving the traditional construction systems would be a real benefit for the poor, who mostly have only their labor to invest.

Cakravala Method

S. Raghavan

Let us consider the equations (i) $3x = 6$ and (ii) $5y = 2$ in the two variables x, y. We recognize at once the (integer) solution $x = 2$ for equation (i) and further note that there can be no y in the set **N**: = {1, 2, 3,...} of natural numbers which satisfies equation (ii), since the constant term 2 on the right-hand side of equation (ii) is not an integral *multiple* of (i.e., is not divisible by) the coefficient 5 of the variable y therein. Leaving these two simple examples of linear equations in a single variable, let us take up the following linear equation involving two variables x and y:

$$px - qy = m \qquad (1)$$

where the coefficients p, q and the constant term m belong to the ring **Z** of the usual integers....–3, –2, –1, 0, 1, 2, 3, ... Clearly, for (1) to have a solution $x = a$, $y = b$ with a, b in **Z**, it is necessary that any common divisor t of p and q (i.e. any t in **Z** dividing both p and q) must be a divisor of m as well. Thus the greatest common divisor (g.c.d. in brief) d of p and q denoted as (p, q) in symbols must also divide m. Now, a well-known algorithm of Euclid's for finding (in finitely many steps) the g.c.d. of any two given integers p, q enables us to write their g.c.d. d in the form $d = pa + qb$ with suitable a, b in **Z**, and we are led to the solution for (1) in integers $x = am/d$, $y = -bm/d$. We should not fail to mention that an alternative approach to solving (1) is to expand the rational number q/p (for $p \neq 0$) as a simple continued fraction. For example, if $p = 3$, $q = 11$ in (1), then $q/p = 11/3$ has the continued fraction expansion $(3{+}1)/(1{+}1/2)$ whose "penultimate convergent" $(3{+}1)/(1 = 4/1)$ solves this special case of (1) with $x = 4$, $y = 1$.

Solving linear equations such as (1) in 2 variables or in more variables often opens the door to cracking interesting puzzles or even settling serious problems! A clear description of the method of solving (1) is available in *Āryabhaṭīya*, a Sanskrit text of the (fifth or) sixth century AD. (According to Ian Pearce (2002), the mathematical part of *Āryabhaṭīya* covers arithmetic, algebra, plane trigonometry and spherical trigonometry and also contains continued fractions.) As observed by André Weil, this is also "the first ever explicit description" of the general solution in integers for (1) from anywhere, except China. In subsequent Sanskrit treatises, this method came to be known as the *kuttaka* (pulveriser) method, but it might not be fair to attribute the same with authority to Greek mathematicians granting the familiarity of Indian astronomers with developments in Greek mathematics until then. It is interesting to learn from Weil how, in utter disregard or (possible) ignorance of the remarkable application of the *kuttaka* in India and of the connection with the seventh book of Euclid's *Elementa*, Bachet ventured to insert (in the second edition of his book *Problèmes plaisants et délectables*) a strong claim to the *kuttaka* method as his own. Before attempting to say anything about the *cakravāla* method, let us see how the *kuttaka* method is applied.

Equation (1) can be rewritten as an (equivalent) "congruence" relation modulo the integer q, namely as $px \equiv m(\text{mod } q)$; we might recall here the customary notation, for a, b, c in **Z**, that $a \equiv b(\text{mod } c)$ exactly when c divides $a - b$. Whenever d, the g.c.d. of p and q divides m, we can find, by Euclid's algorithm, an integer x such that $px - m$ (equals qy and hence) is divisible by q, i.e., $px \equiv m \ (\text{mod } q)$. The *kuttaka* precisely enables one to find the form of the general solution of this congruence (whenever (p, q) divides m). Take, by way of an example, the congruence $3x \equiv 1$ (mod 7). Since the g.c.d. (3, 7) equals 1, the congruence is indeed solvable. Now $3 \times (-2) = -6 \equiv 1(\text{mod } 7)$ and so, on multiplying both sides of the congruence by –2, we get $-6x \equiv -2$ (mod 7) which is the same as $x \equiv 5$ (mod 7). The *kuttaka* thus tells us that any integer of the form $7n + 5$ for arbitrary n in **Z** satisfies the congruence $3x \equiv 1(\text{mod } 7)$.

From linear equations in x and y, let us move on to (much more non-trivial) equations of degree 2 in two variables, e.g. $x^2 - Ny^2 = 1$ for N in **N**. If $N = M^2$ with $M \in \mathbf{Z}$, the solution in integers x, y of this equation can be immediately found by factorising the left hand side and rewriting the equation as $(x + My)(x - My) = 1$ and hence as $(x + My) = (x - My) = \pm 1$. However, if $N = 2$ or any square-free integer (i.e. not divisible by the square of any prime number), then one could ask for all integers y such that $Ny^2 + 1$ is the square of an integer and, in other words, ask for solutions in integers x, y of

$$x^2 - Ny^2 = 1 \quad (2)$$

which indeed looks harder and is known as Pell's equation (ever since Euler attached Pell's name to it *by* mistake!).

For a while, let the square-free integer $N > 1$ be kept fixed in our general discussion and let, for any given integer m, the given triple $(x, y; m)$ stands for a solution in integers x, y of the more general diophantine equation

$$x^2 - Ny^2 = m \quad (3)$$

We can clearly identify, for any $t \neq 0$ in **Z**, the triple $(tx, ty; t^2m)$ with $(x, y; m)$.

Under the heading *Vargaprakrti*, (3) was investigated by the Indian mathematician Brahmagupta (seventh century AD) who used his *bhavana* rule to get non-trivial solutions for (2) in integers for several cases of N (and, in particular, for $N = 92$ or 83, solutions given by $(1151)^2 - 92 \times (120)^2 = 1$, $(82)^2 - 83 \times 9^2 = 1$. The *bhavana* (composition) rule gives, for two given triples $(x, y; m)$ and $(z, t; n)$, their product (or composite) $(x, y; m)(z, t; n)$ by the formula

$$(x, y; m)(z, t; n) := (xz \pm Nyt, xt \pm yz; mn) \quad (4)$$

Written in expanded form, this leads us to the composition formula

$$(x^2 - Ny^2)(z^2 - Nt^2) = (xz \pm Nyt)^2 - N(xt \pm yz)^2 \quad (5)$$

expressing, in modern parlance, the multiplicative property of the norm form $x^2 - Ny^2$ in two variables x and y.

The square-free integer N associated with the triple $(x, y; m)$ for (3) was referred to as the *gunaka* (or *prakrti)* and the integer m therein as *ksepa* (additive). Brahmagupta knew how composition of a triple $(x, y; m)$ with a triple $(p, q; 1)$ with the same *gunaka* N leads to a triple $(x', y'; m)$, while the product $(x, y; m)$ $(x, y; m)$ is again a triple $((x^2 + Ny^2)/m, 2xy/m; 1)$ provided $(x^2 + Ny^2)/m$ and $2xy/m$ are both in **Z**. For $m = -1$ or ± 2, composition of $(p, q; m)$ with itself leads to $(p^2 + Nq^2, 2pq; 1)$ or $((p^2 + Nq^2)/2, pq; 1)$, respectively. While the composition formula (5) occurs explicitly in Brahmagupta's work, special cases of the same for $N = 3$, $z = 5$, $t = 3$ may have been applied by Archimedes to obtain approximations to $\sqrt{3}$ by rational numbers, according to Weil.

We now give an example to see how the *bhavana* rule helps in solving (2). Let us take Brahmagupta's investigation of the case $N = 83$ itself. The natural number "closest" to the *vargamoola* (square root) $\sqrt{83}$ of 83 is 9 and the relation $9^2 - 83 \times 1^2 = -2$ is the same as the triple $(9, 1; -2)$ corresponding to the value 83 for N. Composing this triple with itself according to *bhavana* as in (4), we note that $((9 \times 9) + (83 \times 1 \times 1))^2 - 83((9 \times 1) + (9 \times 1))^2 = 4$, giving the "square" of $(9,1; -2)$ as $(164, 18; 4)$. On division throughout by 4, the last-mentioned triple leads exactly to $(82, 9; 1)$ which is a solution (as discovered by Brahmagupta) for (2) with $N = 83$. In H. T. Colebrook's book, *Algebra with Arithmetic and Mensuration, from the Sanscrit of Brahmegupta and Bháscara*, one can find an entire section dealing with Brahmagupta's investigations on *Vargaprakrti.* Brahmagupta could find extremely accurate values for $\sqrt{N}$ using his solutions for (2). According to Ian G. Pearce (2002), "this contribution is of huge interest as it is essentially the same method rediscovered and used by Newton and Raphson around 1690, which is known as the Newton–Raphson iterative method".

Despite Brahmagupta's admirable results, the general solution of (2) is still not at hand! The brilliant *cakravāla* (cyclic) method for the general solution of (2) has been located in the work of Bhaskara much later, around the twelfth century. Almost the same description of the *cakravāla* is provided in a commentary written around the eleventh century by "an otherwise unknown author" Jayadeva, leaving it open (for anyone) to identify the real inventor of the *cakravāla*. We shall now give a brief description of the method and an illustrative example.

The idea of the method is to start from a triple $(p_0, q_0; m_0)$ with "small" m_0 and use the *bhavana* to get a triple $(p_1, q_1; m_1)$ with m_1 "small" again and eventually, in finitely many steps, hit upon a triple $(u, v; r)$ with $r = 1$, -1, ± 2; for $r = 1$, (2) is solved with $x = u$, $y = v$ but in the three remaining cases of r, composition of $(u, v; r)$ with itself yields a solution for (2) as explained earlier (noting that the *gunaka* N is kept fixed all the while). For the triple $(p_0, q_0; m_0)$ at the start, p_0 is chosen such that p_0^2 is the square closest to N and q_0 is taken as 1 so that $m_0 = p_0^2 - N$. Next, the integer x_0 is chosen to satisfy the congruence $x_0 \equiv -p_0 (\text{mod } m_0)$ besides ensuring at the same time that $x_0^2 - N$ is "small" and in fact, more precisely, least in absolute value among all possible choices for x_0 with $x_0 \equiv -p_0 (\text{mod } m_0)$. Then the triple $(p_1, q_1; m_1)$ is defined as the composite

$$(p_0, q_0; m_0)(x_0, 1; x_0^2 - N) = \left(\frac{(p_0 x_0 . N)}{m_0}, \frac{(p_0 + x_0)}{m_0}; \frac{(x_0^2 - N)}{m_0} \right)$$

which is a genuine triple due to our congruence condition on x_0. If we note that $x_0^2 - N = m_0 m_1$, we may see that keeping $N - x_0^2$ "small" helps to keep also m_1 "small". The next step in the *cakravāla* is to find x_1 in **Z** so as to enable us to obtain the composite $(p_1, q_1; m_1)(x_1, 1; x_1^2 - N)$ is a genuine triple to be defined as $(p_2, q_2; m_2)$. Actually x_1 is to satisfy the congruence $q_1 x_1 \equiv -p_1 (\text{mod } m_1)$ as well as the condition that $x_1^2 - N$

is "small" (i.e. least in absolute value among possibilities for x_1 got by using *kuttaka*. Having got the triple $(p_2, q_2; m_2)$, one proceeds to find suitable x_1 (modulo m_2) to move on to a triple $(p_3, q_3; m_3)$ and eventually, as mentioned above to a solution of (2).

Example. For $N = 31$,we have $p_0 = 6$, $q_0 = 1$, $m_0 = 5$ giving us (in the terminology of Bhaskara) the (corresponding) auxiliary equation $31 \times 1^2 + 5 = 6^2$. Then by Bhaskara's lemma (i.e. indeed composing (6, 1; 5) with $(x_0, 1; x_0^2 - 31)$ so that $x_0 \equiv -6 \pmod 5$ and further the absolute value of $x_0^2 - 31$ is least (among all integers x_0 congruent to –6 modulo 5), we obtain $x_0 = 4$ and $(p_1, q_1; m_1) = (6,1; 5)(4,1, -15) = (11,2; -3)$. Next with the auxiliary equation $31 \times 2^2 - 3 = 11^2$, *kuttaka* is used to find x_1 with $2x_1 \equiv -11 \pmod 3$ and $x_1^2 - 31$ least (in absolute value), yielding $x_1 = 5$ and $(p_2, q_2; m_2) := (p_1, q_1; m_1)(5, 1; -6) = (-39, -7; 2)$. Since $m_2 = 2$, a shortcut via the *bhavana* is to define directly $(p_3, q_3; m_3) := (-39, -7; 2)(-39, -7; 2) = (-1{,}520, -273; 1)$, solving $x^2 - 31y^2 = 1$ at once. On the other hand, one could follow the general method indicated in the preceding paragraph to get $x_2 = 5$ and the triples $(-39, -7; 2)$ $(5, 1, -6) = (-206, -37; -3)$, $(-657, -119; 5)$, $(-1{,}520, -273; 1)$ in that order. Further iteration of the method not only yields more and more solutions for $x^2 - 31y^2 = 1$ but also reveals a "cyclic" pattern in the *additives* m_i (vindicating the chosen name *cakravāla*). Using familiar notation for periodic simple continued fractions for quadratic irrationalities (e.g. Davenport 1990: 104–105), we write $\sqrt{31} = \langle 5, \overline{1, 1, 3, 5, 3, 1, 1, 10} \rangle$ and the relevant *convergent* $\langle 5,1,1,3,5,3,1,1 \rangle = 1520/273$ got by omitting the *partial quotient* 10 from the *very first period* $\overline{1, 1, 3, 5, 3, 1, 1, 10}$ gives the same solution for (2) as above. Weil's own version of the *cakravāla* has the merit of not only totally dispensing with the use of *kuttaka* (in Bhaskara's exposition of the *cakravāla*) but also making the "cyclic" pattern in the occurrence of the *additives* m_i quite transparent and *in tune with* the phenomenon of *periodicity* in the continued fraction expansion for $\sqrt{N}$. Are not the triples (1,766,319,049, 226,153,980; 1) for $N = 61$ and (48,842, 5,967; 1) for $N = 67$ discovered and offered to us by Brahmagupta and Bhaskara masterpieces adorning the lustrous history of *cakravāla*?

To be fair though, one should recall Weil's remarks that a rigorous treatment as explained above for constructing the successive triples $(p_i, q_i; m_i)$ "may have been known to Indian mathematicians only experimentally and there is nothing to indicate whether they had proof for them, or even part of them" and again that "For the Indians, of course, the effectiveness of *cakravāla* could be no more than an experimental fact, based on their treatment of a great many special cases, some of them of considerable complexity and involving (to their delight, no doubt) quite large numbers. Fermat was the first to perceive the need for a general proof and Lagrange the first to publish one. Nevertheless, to have developed the *cakravāla* and to have applied it successfully to such difficult cases as $N = 61$ or $N = 67$ had been no mean achievement". Weil is unsparing as well in his critical analysis of Euler's contribution to the topic of "Pell's equation" in the form of drawing attention to the periodicity and "palindromic" property of the "partial quotients" in the continued fraction expansion for $\sqrt{N}$ or their use in solving "Pell's equation" with perhaps merely experimental evidence to back up his assertions. Although the "Cattle Problem of Archimedes" (Davenport 1990) is usually associated with Pell's equation, one learns from Weil that equations such as (2) "do occur in Diophantus…, but it is a rational solution that is asked for, even when accidentally a solution in integers is obtained…". A detailed discussion of Kronecker's interesting solution (using elliptic functions) for Pell's equation can be found in Siegel's section 27.1 (1963).

Calculus

K. V. Sarma

Calculus, both integral and differential, was known *to a limited extent* and used for specific purposes in India during early and medieval times, and is attested to by the works of Āryabhaṭa (b. 476), Brahmagupta (b. 598), Muñjāla (b. 932), Bhāskarācārya (b. 1114), Nārayāṇa Paṇḍita (1356), Nīlakaṇṭha Somayāji (b. 1444), and Jyeṣṭhadeva (ca. 1500–1610). In the same manner as Hindu geometry grew in response to the religious needs of designing sacrificial altars, it would seem that calculus too evolved when there was the need to ascertain favorable and unfavorable times for religious rites and rituals on the basis of the moments of the eclipses, conjunction of planets, and conjunction of planets and stars. Calculus did not evince further growth in India.

In order to determine the accurate motion of a planet at a particular moment (*tātkālika-gati*), Bhāskarācārya divides the day into a very large number of intervals of time units called *truṭi*, equal to 1/33750 of a second, and compares the successive positions of the planet, the motion during that very small unit of time being considered constant. He also suggests that the differential coefficient vanishes when the interval is diminished to the absolute minimum. He illustrates this by three examples.

Hindu ideas on infinitesimal integral calculus are shown in the methods employed and formulas arrived at for the calculation of the area of a circle, and the surface area and volume of a sphere, all of which are virtually the same as these derived by modern mathematics.

Two methods are adopted for finding the surface area of a sphere. One of them is to draw, from a point on the sphere taken as the pivot, a very large number of circles, parallel to each other and of small and equal interstices, and to slice the sphere at these circles. The sum of the areas of the strips peeled off each slice, the longest of them being at the equator, and the smallest, equal to zero, at the pivot and the bottom, would be equal to the surface area of the sphere. It is explained that when the breadth of the strips tends to zero, the total surface area could be obtained by the formula $4\pi^2$.

In the same manner, the volume of a sphere is equal to the sum of the numerous cones that would be formed with their bases on the surface of the sphere and their apexes being at the center of the sphere. When the number of cones is infinite, their bases could be taken as flat, and the volume of the cones could be calculated by the usual formula. From this postulate, the formula for the volume of the sphere is identified as $4/3\ \pi^3$. The several methods enunciated for the determination of the value of the circumference of a circle, involving the irrational quantity, π, as exposited in several works from Kerala, like the *Yuktibhāsā* of Jyeṣṭhadeva, also concern integral calculus.

Calendars in East Asia

Nakayama Shigeru

Successive attempts to improve a typical luni-solar calendrical system for reconciling two fundamentally incommensurable periods – the tropical year and the synodic month – were made throughout the history of Chinese and Japanese calendars until their replacement by the Gregorian solar calendar in modern times, the Japanese in 1883 and the Chinese in 1912.

The length of a synodic month varies between 29.0 and 30.1 days. The luni-solar calendar provided for "short" months of 29 days and "long" months of 30 days. Calendrical scientists attempted to arrange short and long months so that the moon's conjunction would take place on the first day of every month. The day notation of the lunar month represented the phase of the moon; for instance, the 15th day of the month was always a full moon, while the first day was a new moon.

In addition, the Chinese had an independent system of solar intervals (*qi*) for indicating seasonal changes, the most important phenomena in the regulation of agriculture. The tropical year was divided into 12 equal intervals of time, the element of a purely solar calendar. The middle point of each interval was called its *zhongqi* or interval center. The synodic month was always slightly shorter than an equal interval, and thus an interval center did not occur in certain months. Such months were designated as intercalary months, and in this way the sequence of synodic months was reconciled with the seasons of the tropical year. The year that included an intercalary month had 30 synodic months. This occurred roughly once every three years.

The Chinese calendar calculators were, however, not satisfied with providing a conventional calendar, in which the courses of the sun and moon were reconciled, merely for civil use; they also tried to include the anomalistic motions of the sun and moon.

Prior to the Tang period (roughly seventh to ninth centuries), a mean synodic month of approximately 29.5306 days was used for this purpose. Shortly before the Tang, however, a proposal was made to take anomalistic motions of the sun and moon into consideration in calendar making. Liu Zhuo (AD 544–610) used the term *dingshuo* (true synodic month) as opposed to the older concept of *pingshuo* (mean synodic month). During the Tang period the idea of the true synodic month was adopted in the official calendar in order to attain better agreement with the actual phases of the moon, and also for convenience in eclipse-prediction calculations.

Liu Zhuo also made the first recorded distinction between *dingqi* and *pingqi*. The former is the period of time for the sun to move through a 30° angle of the ecliptic (the band of the zodiac through which the sun apparently moves in its yearly course), which therefore varies in length in accordance with the anomalistic movement of the sun. The latter is the average length of time to move through a 30° angle. This concept, *dingqi*, however, was not actually adopted in the official calendar until the Qing period (the seventeenth century on).

Daily life is never affected by such small discrepancies in the calendar as those due to the anomalistic motions of the sun and moon. The astronomical attainments of the Chinese calendrical schemes went far beyond the concern of the common people. They included not only luni-solar phenomena but also the periodic motions of the five planets. They were called *li*, which corresponds to "ephemeris" as well as "calendar" in the narrow sense.

In the case of the Julian calendar reform data were doubtless gathered from prior calendars and not from actual observations. One recalls in this connection Lillius' effort in the Gregorian calendar reform to reduce the toil of observation and computation so as to provide an artificial system independent of astronomical tables and indeed of any link with actual celestial phenomena. The Western calendar was not, in terms of astronomical precision, overwhelmingly rigorous.

The difference of purpose between calendar-making in the West and East is clear. Whereas the Western calendar was divorced from the development of astronomical science, and aimed at schematic convenience for civil and religious proposes, the East Asian calendar, disregarding civil convenience, was an attempt to represent faithfully the movements of the heavenly bodies. It thus became much more complicated than its practical applications warranted. A sharp separation of scientific astronomy and civil calendar-making did not take place in traditional East Asia. Its scope was confined to the composition of a luni-solar ephemeris which stood or fell on the accuracy with which it could predict eclipses, which is the best way to check the validity of any luni-solar calendar. Analysis of planetary motions was rather ancillary to the main stream of Chinese calendar making.

Cosmological discussions often took place during the Han and Six Dynasties periods (second century BCE to sixth century AD), although they were discontinued soon after. In the Tang period the Chinese astronomers were no longer interested in this particular speculative pursuit. While occasional cosmological debates were found among philosophers, scientific cosmology was long set aside and forgotten in professional calendrical science circles until the time of the Jesuits' impact in the seventeenth century.

Perhaps the most striking thing about the recastings of the civil calendar in China was their frequency. In 2,000 years there were more than 50 revisions of the Chinese calendar, and then of the Japanese calendar, whereas in the West there was only one major reform, the Gregorian. Why were the Chinese so preoccupied with the calendar that they were driven to such repeated efforts? There were two major reasons, one political and the other technical.

Among the ancient Chinese the idea prevailed that a ruler received his mandate from heaven. In the early period, therefore, after important changes within individual reigns and always after important changes of dynasty, the new emperor was prompted to reform key institutions, especially the official calendar, in order to confirm the establishment of a "new order" which a new mandate implied. A new mandate meant a new disposition of celestial influences. The Han Emperor Wu (r. 1480–1487 BCE) was advised by his councilor to revise the calendar and change the color of ceremonial vestments, in order to make it clear that his rule was based on a true mandate. The result was the imperial edict by which the *Taichu* calendar was adopted.

This notion was responsible for the subsequent course of development of Chinese calendrical science. Calendrical science enjoyed governmental sponsorship throughout its history, and had more prestige than other branches of science; it was China's most genuine contribution to the exact sciences. The history of Chinese and traditional East Asian astronomy is, for the most part, the history of calendar-calculations.

In the course of time, however, the political importance of calendar reform dwindled. The restriction of calendar reform to change of dynasty was not strictly observed by the Northern Wei (fifth century AD) and succeeding northern dynasties. Some rulers unduly took advantage of calendar reform to gain or regain popular support. The calendrical significance and authority of calendar revision were thus largely lost. In the Tang dynasty, the motive for calendar reform became simply to correct disagreements of the calendar with observed celestial phenomena. Hence, reforms were carried out whenever a small error was found. This accounts for the frequent revisions in later phases.

Beyond the concern with timekeeping, the Chinese astronomers dealt mainly with apparent solar and lunar movements and eclipse prediction. The Chinese luni-solar calendar required revision whenever the discrepancy between calculation and observation became noticeable. For this purpose, the government founded the Office of Astronomy, and incumbent astronomers were responsible for the improvement of the calendar. The government enjoyed a monopoly on the regulation of time, which contributed to imperial control of daily life and which strengthened the central power and prestige at a sacrifice of civil convenience. People were forced, in matters of everyday life, to follow a calendar based on a complicated, “astronomically rigorous” and “state-authorized” ephemeris, which, unlike our solar calendar, could never be prepared by laymen, but depended on the skill of official astronomers.

Despite early recognition that a single perpetually valid calendrical scheme was impossible, the calendar calculators never tired of proposing revisions. Their incentive must be ultimately attributed to the rational desire to conform to the celestial order, a philosophical compulsion to accept the phenomena of the material sky as the most authentic reality. It was because of this orientation that calendar-making maintained its status as an integral part of Chinese science and learning for such a long time.

Modernization and Westernization

As the official calendar was quite an important part of the social system, westernization in modern times was first infiltrated through calendrical science.

Western astronomy had arrived in China with the Jesuits in the sixteenth century. Calendar-making was a vital function of the Chinese bureaucracy, and the Jesuits hoped that by demonstrating the superiority of Western astronomy they would succeed in persuading the bureaucratic elite that Western cultures and Christianity were superior. Astronomy was well suited to their purposes, not only because it was so important to the Chinese bureaucracy but because the phenomena with which it dealt possessed a universality that transcended East and West, and the objectivity of celestial phenomena did not permit much human manipulation. Furthermore, it was quantitatively precise. Thus, when the tally sheet was in, Chinese astronomers had to acknowledge that Western astronomy had superior features. All that the Jesuits made available from Western tradition, however, were peripheral data and methods of calculation. The structure, styles, and purposes of Chinese calendrical astronomy remained unchanged. As Xu Guangqi, a high Chinese official who collaborated with the Jesuit Matteo Ricci on several projects, put it, “We melted down their materials and poured them into the *Datong* (the traditional Chinese calendar then in use) mold.”

In Japan, the eighth Shogun Yoshimune (1644–1751) attempted to use this refurbished Chinese astronomy as the basis for calendrical reform, but he was effectively opposed by conservative court circles in Kyoto. The revision of Horeki that came into effect in 1754 was still modeled upon the traditional *Shoushi* calendar. Yoshimune’s desire was fully realized, however, in the Kansei revision of 1797.

After that, the scientific quality of the traditional luni-solar calendar was improved and perfected, but still the traditional mold was maintained throughout the Tokugawa period (1603–1867).

Despite the earlier recognition of Western superiority in science, a radical change of political institutions in Japan had to precede the official adoption of the Western Gregorian calendar in 1873. The decisive factor in the adoption of the Gregorian calendar was the high value the government placed on westernization. Many Japanese proposed a more reasonable solar calendar at the time of the reform, but the government preferred the Gregorian, despite its obvious shortcomings, because of diplomatic relations with the West.

With the establishment of the Republic of China in 1912, the Chinese luni-solar calendar was officially abolished.

To what extent the Gregorian calendar was observed among the populace is questionable, but after the second World War, it became firmly established in everyday life in East Asia.

Calendars in Egypt

Jehane Ragai, Gregg De Young

Neugebauer described the ancient Egyptian civil calendar as “the only intelligent calendar which ever existed in human history.” His statement can be appreciated by tracing the ancient Egyptians’ gradually developing sense of time from an initial awareness of the day to the full realization that the year had a constant length of 365 days. The introduction of the civil calendar, based on solar years as opposed to lunar years, resulted in the development of our present-day Gregorian calendar.

Humans first became conscious of the existence of the day through the regular reappearance of the sun after its disappearance the evening before. Observing the regular change of one crescent moon to the next, they became aware of the longer time unit of the month. The practical demands of temple administration led them to develop their ability to count and calculate and they realized that one lunar month was made up of 29 or 30 days.

With the advent of the agricultural civilization in the Nile Valley, the season, rather than the month, gained importance as a time unit, since the Nile flood was a regularly recurring phenomenon that had to be predicted with a certain degree of accuracy. The ancient Egyptians must soon have realized that a purely lunar calendar was not capable of adequately predicting such annual events. They hit upon another device by which the onset of the inundation could be determined. This was the heliacal rising of Sothis (Sirius, the brightest star in the sky) which coincided closely with the beginning of the annual flooding of the Nile. They observed that after a 70-day period of invisibility, Sothis could be seen again just before sunrise, and this first appearance was taken by the Egyptians to signal the beginning of the new year.

The Egyptians, having reckoned that there was a 365 day span between two successive heliacal risings of Sothis, initially resorted to a luni-stellar calendar which consisted of 12 lunar months totaling 354 days, to which an additional 13 intercalary month was added every few years to make up for the cumulative discrepancy arising from the 11 day difference between the lunar and stellar years. The rule of thumb used was that whenever Sothis rose during the last 11 days of the fourth month of the last season, the intercalary month should be added.

Such a solution was somewhat cumbersome, and although the luni-stellar calendar was used to determine religious festivals, a more practical calendar had to be introduced to meet the demands of the state administrative system. Around 4200 BCE, the Egyptians adopted a 365 day Civil Calendar which was divided into three seasons, each of four 30-day months. The year consisted of 12 months, each of which would count 30 days plus “five days upon the year.” Events were dated as occurring on the first, second, third… day of the first, second, third… month of the specific season.

The 365 day common year of the ancient Egyptians has also been called the “vague year” because its length fell short of the astronomical year by just over a quarter of a day each year. In Greek documents, the 12 months of this vague year are referred to by Greek names which originated from a cult connected with these months. These months are (1) Thoth, (2) Phasphi, (3) Altyr, (4) Choriak, (5) Tybi, (6) Mechir, (7) Phamenoth, (8) Pharmuthi, (9) Pachon, (10) Payni, (11) Epiphi, and (12) Mesori. These months are still preserved today in Egyptian folk tradition.

Each of these 30-day months was divided into three 10-day “weeks” or decans. Thus, there were 36 decans each year. The Egyptians defined each decan to begin when a particular star or constellation appeared on the horizon. The period of time between the appearance of one decan on the horizon and the next was defined to be an hour. From the surviving “diagonal calendar” examples, it is clear that the night was considered to contain only 12 h, rather than the 18 which might have been expected when we consider that we see approximately half the celestial sphere on any given night. The discrepancy seems to arise because the Egyptians did not include the period of twilight and the darkening of the sky as part of the night. Only the period of totally darkened sky corresponded to the term “night.”

The idea that the day also included 12 h seems to be developed merely in analogy with the night. These hours might be measured on a shadow clock, since the length of shadow cast by any object changes relative to the position of the sun in the heavens. The position does not just change over the course of the day, however, but also over the course of the year as the sun travels between the tropics. As a result, these shadow clocks do not give more than approximate seasonal hours. The use of clepsydra (water clocks), in which water escapes from a graduated container at a regular rate, may be closer to our modern concept of equal hours.

The Egyptian calendar constructors and time keepers did not go beyond the hour in measuring time. It is to the Baby-lonians, with their sexagesimal mathematical system, that we owe our modern concepts of 60 min in an hour and 60 s in a minute.

In time, the Egyptian 365 day calendar became completely out of step with the real tropical year, as it fell behind the latter by one day every 4 years. Thus, in

4 × 365 years, i.e., in 1460 years, the civil year would have lost a complete solar year and would again correspond with the seasons. This 1460 year period is generally referred to as the "Sothic Cycle" and reflects the fact that every 1460 years the so-called "heliacal rising of Sothis" fell on New Year's Day and thus marked the onset of a new Sothic period. The Egyptians seem not to have noticed the discrepancy between their civil calendar and the true solar year. If, at some point they did become aware of this difference, the strong conservative element in the culture apparently made them reluctant to make any amendment to their calendar.

In 238 BCE, King Ptolemy III made an unsuccessful attempt to correct the "vague year" by adding an extra day every 4 years. Modification of the ancient calendar only ensued two centuries later when, after Julius Caesar's conquest of Egypt in 46 BCE, he followed the advice of the famous Alexandrian astronomer, Sosigenes, and adopted a modification of the ancient civil calendar for the Roman Republic. Sosigenes suggested that the length of the year should be $365\frac{1}{4}$days; that there should be a 4-year cycle of 3 years of 365 days and a 40 year of 366 days; and that the year should begin on the first of January.

The Julian method of intercalation was not only convenient, it also provided a calendar whose year closely approximated the tropical year. Nevertheless, its deficiency appeared in time, making further reform imperative. The Julian Calendar, as we now call it, assumed the length of the year to be equal to 365.25 days, whereas the tropical year (defined as the passage of the sun from one equinox to the next) is nearly 365.2422 days. Thus, the error amounted to a gain of one whole day in 128 years. To deal with this problem, Pope Gregory XIII decreed that the 11 days, that had accumulated over the 16 centuries since the Julian Calendar had been introduced, should be removed from the calendar and that henceforward no century should be considered a leap year unless divisible by 400. This Gregorian Calendar, which we use today, can thus be seen to be based on the principle of the Civil Calendar of ancient Egypt.

Calendars in India

A. K. Chakravarty

Calendrical science developed in India in three distinct phases, and each phase influenced the succeeding one. The first phase produced the Vedic calendar, covering a period from an unknown antiquity to the Mauryan emperor Aśoka (ca. 300 BCE); the second had the Greco-Indian calendar for a short period between the post-Aśokan and post-Kuṣāṇa period (ca. AD 300). And the third produced the Siddhāntic calendar from the Gupta period (AD 319) which is still used in India today. All three phases are characterized by formulations of fitting a lunar year into a sidereal solar one by suitably intercalating lunations.

References to calendrical elements like lunation, intercalation, year, and solstice occur even in the earliest part of Vedic literature. A separate calendrical literature, deemed a part of the Vedas, was developed in a small text, *Vedāṅga Jyotiṣa*, but this text has not been fully deciphered yet. There are some astronomical statements in the text, and also in the earliest part of Vedic literature, which do not hold true in the latitude belt and in the time period when the Vedic Aryans are believed to have settled in India.

It is a separate course of study as to how and when the Vedic Indians obtained this calendar, but they adopted it without verifying it.

This calendar is based on the following imperfect parameters:

5 sidereal years = 1,830 days
62 lunations = 1,830 days
67 sidereal lunar months = 1,830 days

The star *beta Delphini* indicates the winter solstice (which was indeed the case around 1500 BCE) which is apparently a fixed point. The lunar orbit is divided into 27 equal arcs from *beta Delphini* each equal to 13°20′, called *nakṣatra*, the first arc named *Dhaniṣṭhā*. The arcs are named after a prominent star of the division. The theory is that if, in five years, two lunations are intercalated, then the lunar year will remain tied with the solar one. This period is called a 5-yearly cycle or *yuga*.

In practice, a cycle begins when the sun and the moon are in conjunction at *beta Delphini* (i.e., from the winter solstice). The first, second and fourth year each contain 12 new moon ending lunations. One lunation is intercalated at the middle of the third year and another at the end of the fifth. The second cycle then again begins from a similar new moon at winter, solstice.

This imperfect calendar was destined to collapse, as the succeeding cycles will begin from new moons shifted by some 4.5 days from the winter solstice at *beta Delphini* per cycle, accumulating to one lunation in six or seven cycles. However, the calendar did not collapse, and so the accumulated lunation was extra-calated, but we are not told in the text how this was done. Perhaps the rule is hidden in an obscure part of the text, and so we have to guess it.

A lunation is divided into thirty parts called *tithis*. Accordingly, 30 *tithis* = 1,830/62 days. The excess 30/62 of a *tithi* over a day is called an omitted *tithi*. A month's days are designated by the *tithi* of the day and not by ordinal numbers. The Jainas used this cycle in their calendar with a marginal change: that months were full-moon-ending and a cycle began from a full moon at summer solstice in the middle of the *Āśleṣā* division (180° away from *beta Delphini*).

Kautilya wrote a book entitled *Arthaśāstra* which is believed to reflect the social and administrative conventions of the Mauryan empire. This book, on the subject of measuring time, only reproduced the Jain school of the 5-yearly cycle. We are thus assured of its use until then.

The second phase of the Indian calendar began by the first century BCE after Śaka penetration into northwestern India.

The Śakas, a central Asian people, conquered Bactria in 123 BCE and established an era with epoch at 123 BCE, now called the Old Śaka Era. This epoch has variously been fixed at 88 BCE (Konow) and 110 BCE (Herzfeld), but, as M.N. Saha has shown, 123 BCE fits into all the circumstantial evidence.

The Śakas used the Greek calendar based on the Metonic cycle in their homeland. This was a nineteen year cycle at whose beginning and end the sun and moon are in the same relative position to each other. When they reached India they adopted Indian culture and Aryanized or Indianized the Greek calendar, producing a Greco-Indian calendar. It replaced the classical 5-yearly cycle and it circulated in India up to ca. AD 200. The Kuṣāṇas, another Śaka tribe, penetrated further inside India, adopting Indian culture and using this calendar. Kings of the Śaka and Kuṣāṇa dynasties left behind some inscriptions bearing dates. These always refer to an era, as in era of king Kaṇiṣka. Further, they contain a mysterious expression – *etaye purvam* – whose meaning has not been deciphered.

The Indian form of the calendar is that the months are full moon ending; the 19-year cycle begins from a full moon at the autumnal equinox in the month Kārtika; months are assigned Sanskrit or Sanskritized Greek names; and, in special cases, the day is designated by the moon's *nakṣatra* on that day. The Greek form is that days are designated by ordinal numbers and not by *tithis*, and intercalation is made at the middle of the year in Chaitra.

All these features are fully reflected in the inscriptions of the Kuṣāṇa kings. For example, present researches have shown that Kaṇiṣka established his era in AD 78 after deleting the 100th place in the old Śaka era for that year.

Now, 123 + 78 = 201 = 1, deleting the hundredth place. Hence, AD 78 = 1 Kaṇiṣka era (current) and 0 Kaṇiṣka era (elapsed).

We interpret *etaye purvam* as elapsed year, and accordingly the Julian equivalent of Kaṇiṣka era in these inscriptions is:

AD 78 = 0 Kaṇiṣka era.

The day of the month can also be identified with the *tithi* with tolerable accuracy. We have seen that the moon gains 12° over the sun per *tithi*. In case of new-moon-ending months, we should expect, on 20th Āṣāḍha:

Moon – sun = 20 × 12° = 240° (near about)
or sun = moon – 240°.

If the moon is near *Uttara Phalguni* (tropical longitude in AD 90 = 144°46′), we should have: sun = 144°46′ – 240° = 265° (say), so that the sun's position comes near the winter solstice, which cannot happen in Āṣāḍha. However, if the month is full-moon-ending, then the moon–sun = 5 × 12° = 60°, or sun = moon – 60° = 144°46′−60° = 85° (say), i.e., near the summer solstice, which indeed happens in Āṣāḍha.

If we compute the mean tropical longitude of the sun (L) and mean elongation of the moon in days (D), we get:

Date	L	D
June 21, AD 90	87°.16	4.81

These lunisolar positions are in complete agreement with the inscriptional dates. We may perhaps identify these dates as Julian equivalents of the inscriptional dates. Using this scale we can decipher all the other dates in the inscriptions of the Kuṣāṇa kings and use the same method to decipher the dates of the old Śaka Era.

This second phase was short-lived, but had far-reaching effects on the later Indian calendar. In fact, this was perhaps the most productive period in Indian calendrical history.

This Greco-Indian calendar was discontinued after the fall of the Kuṣāṇa empire.

In the third phase, the Indian calendar was thoroughly revised. New calendrical elements were introduced, new techniques in computational works were formulated, and the application of cycles for intercalation was abandoned. The new calendar that emerged is called the Siddhāntic calendar. This calendar was perfected by later Indian astronomers and is still used all over India with some marginal changes in some regions. In this phase the solar zodiac with 12 signs was introduced. The *nakṣatra* division was recast so that the first arc-division, renamed *Aśvinī*, began from the first sign *Meṣa* (Aries). This common point was the vernal equinox. By AD 550, the vernal equinox shifted to *zeta Piscium*, and this star (or a point very close to it) has since been the beginning of the Indian zodiac.

The new technique for computations was that an epoch, *Kaliyuga*, was formulated such that all the luminaries, like the sun, moon, and planets, were assumed to be in conjunction at the initial point of the zodiac at this epoch. Sidereal motions of the luminaries were so assigned that each of them made an integral number of revolutions in a period of 4,320,000 years (see Table 1).

Calendars in India. Table 1 In a period of 4,320,000 years

	Āryabhaṭa	***Sūryasiddānta***
Sidereal revolution of the sun	4,320,000	4,320,000
Sidereal revolution of the moon	57,753,336	57,753,336
Sidereal revolution of Jupiter	364,224	364,220
Total civil days	1,577,917,500	1,577,917,828
Intercalary lunations	1,593,336	1,593,336
Omitted *tithis*	25,082,580	25,082,252

Astronomical parameters in this phase were not uniform in different schools. We cite below some calendrical parameters from the Āryabhaṭian school (AD 476) and the *Sūryasiddhānta* school of the tenth century.

For any day in question, elapsed days from *Kali* are computed from the above figures, and from the rates of sidereal motion of the luminaries their positions are found in the zodiac. The epoch of *Kali* was computed by Bentley at 18th February, 3102 BCE midnight at Ujjain (longitude 75°45′ east). This date has been generally accepted by all astronomers.

Āryabhaṭa formulated corrections of mean motions of the luminaries, but such formulations are not found in earlier works. Our presumption is that only mean motions were considered in the pre-Āryabhaṭian period.

In this revised calendar, the luni-solar year begins from the new moon just preceding the sun's entry to the initial point in the spring month *Chaitra*. Now, 12 lunations fall short of 10.8 days from a sidereal year, and this accumulates to one lunation in 2 or 3 years. Whenever such an extra lunation forms, it is intercalated in the year; there is no role of any cycle here. This luni-solar year, with days designated by the *tithi* of the day, is used all over India for religious purposes.

A solar year is also devised beginning from the sun's entry into the first sign *Meṣa*, and is divided into 12 solar months, each month being the period the sun stays in a sign. Days of solar months are designated by ordinal numbers. The first month is *Vaiśākha*. Datings are recorded by luni-solar year in some regions, and by solar year elsewhere. The era generally used is the Kaṇiṣka era renamed the Śaka era.

In a year containing 12 lunations, the 12 new moons will, most generally, be distributed over the 12 signs, i.e., each sign will contain a new moon. However, in an intercalary year when 13 lunations are distributed over 12 signs, two new moons must occur in one sign, and in extreme cases, one sign may not contain any new moon at all. Such situations are natural phenomena and are no problem for astronomers.

Out of the 13 lunations occurring in an intercalated year, any one may be earmarked as the extra month. However, metaphysics has taken a toll here. As one sign will contain two new moons, so two lunations, one from each new moon, will occur in that sign. One lunation out of these two has to be selected as the intercalary one. Volumes of religious literature have been written, perhaps more voluminous than their astronomical counterparts, on which lunation is the proper one and which is the intercalary one. Similarly, when a sign becomes void of a new moon, religious literature is controversial as to which lunation is to be assigned to that sign. Almost every region of India has its own convention on these points.

Calendars in Islam

Mohammad Ilyas

Even the most ancient peoples considered the day the earliest unit of time-telling. However, the day is not convenient for long intervals of time. Even allowing for a primitive lifespan of 36 years, a person would live some 13,500 days, and it is very easy to lose track of some of those.

It seems natural to turn to the Earth's next most prominent body, the moon, for another unit. Here, the readymade period of the lunar phases provides the natural unit called the *lunar month*. The lunar month is approximately 29.5 days (more exactly 29.5306 or 29:12:2.8). In pre-agricultural times, the month provided a convenient and simple method for measuring moderately long periods of time. A lifetime of something like 400 months is a more convenient figure than 13,500 days. Lunar months united to the seasons, as they would have been initially, would produce some problems for a settled agricultural society, which is not the case for a hunting or herding society of nomads, who could wander more freely in search of grain or grass. Farmers not only had to stay where they were, but also needed to increase their chances of a good harvest by sowing at a proper time to take advantage of seasonal rains and seasonal warmth. Therefore, to keep the lunar months approximately seasonal, an intercalary month needed to be added in seven of each 19-year cycle (19 solar years = 235 lunar months, i.e. 19 lunar years of 12 months each, +7 lunar months). In due course, the practice of intercalation was gradually perfected; the intercalary months came to be added in the third, sixth, eighth, eleventh, fourteenth, seventeenth, and nineteenth year of each cycle, in a popular scheme which transformed the lunar calendar into a seasonal, or lunisolar calendar, in which a month remained in pace with the sun to within 20 days.

The lunisolar calendar practice was adopted by the Hebrews, Greeks, and Romans and remains in use in the Jewish, Hindu, and Chinese calendars of today. The early Christians continued to use the Jewish (lunisolar) calendar tied to the new moon for more than three centuries and established the day of Easter on that basis. On the other hand, the Roman Republic, which had also used a lunisolar calendar for a long period, moved to a purely solar calendar in 46 BCE as a result of abuse of power by Pontiffs in the matter of intercalation.

Julius Caesar decided to put an end to this chaotic situation by introducing the solar calendar system. In this transformation, 46 BCE was allowed to continue for 445 days (!) and came to be known as "The Year of Confusion", in effect the last one. The adopted solar calendar with a year length of 365.25 days became known as the Julian calendar.

The month, being tied to the moon, begins at a fixed phase in the lunar calendrical system. Since any phase will do, the month can begin at each full moon, the first quarter, etc. However, the obvious way is to begin each month with the new moon – on the evening when the growing crescent first becomes visible immediately after sunset. Practically all lunar calendars began their new months with the new visible crescent. Some modern users of the lunar calendar (the Chinese and Jews) have changed this to the astronomical new moon, i.e. the conjunction, while Muslims maintain the first visible phase of the new crescent as the beginning of a new month.

The Islamic calendar was both a religious as well as a civil calendar, necessary to determine periods of the annual month-long fast, pilgrimages, times of marriage and divorce, years of taxes on wealth for the needy, religious observances, and general and historical timekeeping.

In Arabia, the use of a lunar calendar is known to have existed from very early times. The original practice is believed to have been to use 12 lunar months to a year. On the pre-Islamic Arab calendar, the annual Pilgrimage (*Ḥajj*) to *Kaʿbah* in Mecca was a most significant and important event. Although the event of the pilgrimage to *Kaʿbah* was basically religious, it was also important for trade and business. When the *Ḥajj* was out of season, it created difficulties in procuring the crops and sacrificial animals for trade and use. To overcome this, the Arabs in Mecca are believed to have introduced a system of intercalation known as *al-Naasi*. A Meccan by the name of Qalmas is reported to be the first person assigned this task who, during each pilgrimage, would announce the dates for the coming years' *Ḥajj* and inform whether the intercalation was due for the coming *Ḥajj* season.

In addition to the month of *Dhu'l-Hijjah* (in which the pilgrimage is held), three other months (*Rajab*, *Shawwal*, and *Thu'I Qa'dah*) were sacred to the pre-Islamic Arabs. During these months, certain things, such as wars with opponents, were forbidden. In time, the practice of intercalation was much abused (as with the Roman calendar) thus affecting the sacred months and the related prohibitions by changing a sacred month into a non-sacred one.

The calendar in use in Medina (North of Mecca) remained in the original "twelve months to a year" form. The early Muslims continued to use the Meccan calendar while in Mecca, but shifted to the *Medinan* calendar after the Prophet Muḥammad and his companions migrated to Medina in AD 622. Following the conquest of Mecca in the eighth year of *Hijrah* (December AD 629), the Muslims continued to use the Medinan calendar, and the *Meccan* calendar ran parallel.

However, during the Prophet Muḥammad's last pilgrimage in the tenth year of *Hijrah* (AD 632), the Meccan practice of intercalation was abolished through a Quranic injunction, thus reverting the Arab-Islamic calendar to the simple "twelve months to a year" practice.

The Islamic calendar also required that the beginning of a month be based on the first sighting. This was particularly important for religious events like the beginning and end of the fasting month and the date of the pilgrimage to the *Kaᶜbah*.

There was no commonly accepted permanent calendar in pre-Islamic Arabia. Nevertheless, the custom of counting years was, in one form or another, prevalent among the Arabs and their neighbours. Opinions are divided as to the origin of this practice. According to Ibn al-Jazwī, it dates from the time when the children of the prophet Adam multiplied and spread on earth. In South Arabia, a calendar system originated in 115 or 109 BCE when the Himyarites adopted one using the regins of the Tubba as the epoch years of their era. The inhabitants of Sanaa (Yemen) also adopted a calendar, using the victory over the Yemen by the Abyssinians, and later, the Persian conquest.

The origin of a chronology of events in North Arabia may be traced as far back as the construction of the *Kaᶜbah* by the prophet Abraham and his son the prophet Ismail. The northern Arabians are also reported to have their famous battle days as marking epochs of eras. A local calendar is supposed to have existed in Medina also. Al-Masudi maintains that the people of Medina used the dates of their castles and palaces as their local calendar at the time of the prophet Muḥammad's migration, but others reject this, claiming the adoption of an era by the people of Medina to a month or two after the prophet's arrival, which continued until his death in AD 632. According to a widely held view, the *Hijrah* era was set up at the time of Caliph ᶜUmar ibn Khattab in AD 637/638, i.e. about 5 or 6 years after the introduction of the purely lunar calendar. After many consultations, the year of the prophet Muḥammad's *Hijrah* was accepted for the beginning of the Islamic (or *Hijrah*) calendar.

Based on scientific understanding, certain ground rules were laid down which form the part of *sharīᶜah* (the Islamic legal system) governing the calendar. Some of these were:

1. The length of a month should be 29 or 30 days.
2. The length of a year should be 354 or 355 days.
3. The maximum number of consecutive 30-day months is 4; the maximum number of consecutive 29-day months is 3.

4a. Each new month begins with the first light of the new crescent moon visible on the western horizon after sunset.
4b. One should try sighting the new moon on the 29th day of the month, but if it cannot be seen (even due to clouds), complete the month as of 30 days.
4c. The visual sighting report must be corroborated by a witness.
4d. The persons involved in the reporting must be reliable, adult, truthful, and sane, with good eyesight (implied). They are punished if proved to be purposely misleading.
4e. The visual sighting report should not conflict with basic scientific understanding and natural laws. Indeed, professional scientists' involvement is essential to ascertain the reliability of the reported sighting, and the scientific test would include a check on related parameters (e.g. the shape of the crescent, its position and altitude, time of observation, sky conditions).
4f. The sighting must be carried out in an organized way every month.

Sharīᶜah also allows for the correction of a mistake. If on the 28th day of an Islamic month, the new moon has been sighted, a correction will be made to the beginning of the month, since a month should have only 29 or 30 days. If the month concerned is *Ramaḍan* then an extra fast would have to be completed after Eid celebrations.

Clearly, earliest visibility of the new moon plays a very critical role in Islamic calendar regulation. The Islamic "State" placed special emphasis on astronomy research, and it became a standard element in formal religious and legal education. The early Muslim community, based under the clear skies of Arabia and assisted by State-sponsored research, had no serious problems in following these injunctions to regulate their calendar. Muslims contributed enormously to the development of the science of the new Moon's earliest visibility and its advance prediction for greatly varying geo-environmental situations. In this, they built upon the work of earlier researchers as well (e.g. Babylonians, Hindus, Jews). Besides the rigorous science, simple schemes were devised to construct long-term calendars especially to interconvert Islamic dates with Christian and other lunisolar calendrical dates. Based on technical information, one of the simple schemes (known as the schematic or *Istalahi* system) involved a cycle of 30 lunar years in which months approximately alternate between 29 and 30 days and 11 years consist of 355 days, the rest 354.

Backed by extensive research, Muslim scientists developed visibility tables and produced many reference works. All were well when astronomy and scientific endeavour were at their zenith in the Muslim lands.

Scientific interest in predicting the time of the first (earliest) new Moon sighting (for a clear sky) goes back to a period at least as early as the Babylonian era. Based on careful observational data, a simple criterion was developed and passed on to the Muslims through the Hindus, apparently with very little further improvement. This problem was thoroughly investigated by the early Muslim astronomers in the eight to tenth centuries AD and included such notable persons as Ḥabash al-Ḥāsib and al-Battānī. The physics-based system(s), developed up to the eleventh century, saw very little further development until more recent times, when improvements were made. There has also been a series of simpler criteria involving time difference (lag) between moonset and sunset and the "age" of the moon.

Calendars in Mesoamerica

Tom Jones

For many reasonably educated persons, the greatest single achievement of ancient Mesoamerica was the Maya calendar. In fact, a calendar was in use throughout Middle America, but it is its Maya form that has captured the world's imagination, the claim often being made that its accuracy exceeded that of the calendar in use in Europe at the time of the Conquest and, by some, even of that which we use today. While most of their neighbors kept account of time with three periods of differing numbers of days, the combinations of which formed a repeating calendar of 18,980 days, the Maya employed a mechanism that synchronized these same periods and others of their own making with a system that tracked cumulative time.

This cumulative record, or Long Count, expressed historical dates with five-place numbers that recorded days accumulated from an arbitrary zero-point which has been determined to correspond to August 13, 3114 BCE in our present Gregorian calendar. (The correlation of Maya dates to European are to the no-zero-year Gregorian calendar, employing Thompson's 1935 correlation of 584,285 days.) Accumulating 1-day (*k'in*), 20-day (*winal*), and 360-day (*tun*) periods, the Long Count employed a qualified vigesimal (20-base) place-number system – the qualification being an 18-base for the third place. The names and values of the Long Count places, from the unit up, were expressed in the writing system with distinct hieroglyphs for each order of magnitude (Fig. 1).

Thus, for example, a Long Count date with the numerical value of *9 bak'tunob, 8 k'atunob, 9 tunob, 13 winalob,* and *0 k'inob* records a day that was 1,357,100 days after August 13, 3114 BCE, which is to say March 26, 603. These values were communicated by positioning the numbers as prefixes or superfixes of the glyphs for the periods. The *-ob* inflection of Mayan nouns indicates plural. Because double digits are often required to express decimal equivalents of numbers in the places of the Maya system, Mayanists have adopted the convention of inserting periods between the places of Long Count dates. The above date, for example, is written 9.8.9.13.0. Though Maya historical dates that employed the Long Count were generally limited to five places, the calendrical system itself was open-ended

PLACE	NAME	DAYS	CALC	VALUE	GLYPHS
1	*K'in*	1 day	(1 X 1)	1 *K'in*	
2	*Winal*	20 days	(20 X 1)	20 *K'inob*	
3	*Tun*	360 days	(18 X 20)	18 *Winalob*	
4	*K'atun*	7200 days	(20 X 360)	20 *K'atunob*	
5	*Bak'tun*	144,000 days	(20 X 7200)	20 *Bak'tunob*	

Calendars in Mesoamerica. Fig. 1 The names and values of the Long Count places with their respective glyphs. [Drawings by the author]

and, when called upon to do so (as to meet mythological needs) could accommodate any number of places and express any full number of days. The greatest known to have survived is recorded at Coba as 13.13.13.13.13.13.13.13.13.13.13.13.13.13.0.0.0.0, which expressed in our decimal-system amounts to almost 22 quintillion tropical years!

Long Count dates were carved on monuments in the Maya heartland for over 600 years, the earliest known being 8.12.14.8.15 (8 July 292), the latest 10.4.0.0.0. (20 January 909). Moreover, the *Dresden Codex* records the much later date, 10.17.13.12.12 (29 October 1178). Though extensively used by the Maya, the Long Count was probably not their invention. Earlier Long Count dates have survived on several monuments on the southwestern Maya periphery – the earliest, 7.16.3.2.12 (7 December 36 BCE), at Chiapa de Corzo – in what was probably a proto-Zoquean (non-Mayan) speaking area.

The Maya coordinated this cumulative Long Count with the pan-Mesoamerican repeating calendar of 18,980 days. Known generally as the Calendar Round and called the *xiuhmolpilli* by the Aztecs and *hunab* by the Maya, this period consisted of three component cycles of 13, 20, and 365 days. The first two of these were a set of consecutive day-numbers (1–13) and a set of 20 day-names specific to each of some 60 language-groups within Mesoamerica (Fig. 2). The permutations of the 13 numbers and 20 names designated each passing day with a combination that repeated every 260 (13 × 20) days. This resulting 260-day period was termed the *tonalpohualli* by the Aztecs and is called the *tsolk'in* by Mayanists. Mesoamericans visualized this period as a four-sided cosmogram (Fig. 3) that can be described as a "Maltese" cross (the broad arms of which are identified in a counterclockwise order as East, North, West, and South) superimposed over a "St. Andrew's" cross (the narrow arms of which define the diagonal directions Northeast, Northwest, Southeast, and Southwest). The eight projecting arms of this scheme are each comprised of 13 days proceeding out from the center and 13 more returning, with the four outer edges of the "Maltese" arms also each contributing 13 to complete the round of 260 days. This 260-day *tonalpohualli* was the most significant aspect of the calendar for the daily life of the typical Mesoamerican. It formed the basis of numerous rituals, character evaluations, omens, and prognostications, traced out in Aztec, Mixtec, and Maya books.

While the 260-day ritual period seems to have been the result of the combination of a cultural fascination with the number 13 and a vigesimal counting system derived from the number of digits of the hands and feet, the 365-day period – the Maya *haab* or Aztec *xihuitl* – to which we now turn, was an attempt at a full-number approximation of the tropical year (of 365.2422 days, as calculated today). This "vague year" was achieved by a set of 18 named periods of 20 consecutively numbered days each, and five extra consecutively numbered terminal days (*Nemontemi* in Aztec, *Wayeb* in Maya) to total 365 days (18 × 20 + 5) (Fig. 4). Every day, then, could be expressed with a day-number, a day-name and a numbered position in one of the periods of the "vague year." The workings of this Calendar Round system are well illustrated by comparing the modes of expressing succeeding dates that include the five terminal days of the vague year in the Aztec *xiuhmolpilli* and Maya *hunab* (Fig. 5). The presence of these 5 days causes the position of any given *tsolk 'in* day to drop back by 5 days with each

successive vague year. Because 260 and 365 share a common denominator of 5, any specific combination of day-number, day-name, and vague year position repeats every 18,980 days (260 × 365 − 5 = 18,980), or about 13 days short of 52 tropical years. As with the Long Count, evidence for the origins of the Calendar Round lies beyond the western pale of the Maya, dating from as early as the sixth century BCE in the Zapotec region.

The *xiuhmolpilli* was of particular importance to the Aztecs, whose mythology claimed that the age in which they lived and in which the current Sun-God, *Tonatiuh*,

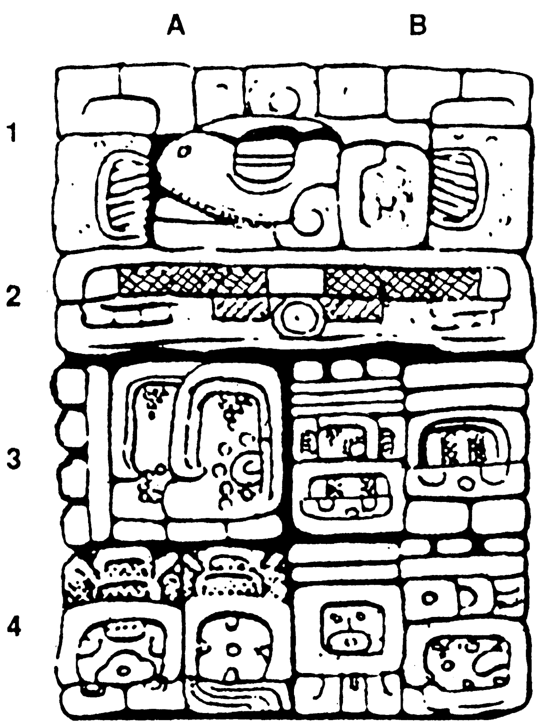
Calendars in Mesoamerica. Fig. 5 The succession of 25 Calender Round dates that pass through the five terminal days of the *xihuitl* of the Aztec *xiuhmolpilli* and the *haab* of the Maya hunab.

reigned was preceded by four earlier ages, each with its own sun and each of which had been destroyed in its own way – the first by devouring jaguars, the second by winds, the third by a rain of fire and the fourth by a world-flood. During this fifth era, under *Tonatiuh*, the future seems to have been doled out to the Aztecs one *xiuhmolpilli* at a time. Each successive *xiuhmolpilli* had to be freshly solicited by a great deal of bloodletting and an elaborate "New Fire" ceremony that was carried out during the five *Nemontemi* days of each 52 *xihuitl*. If, following the ceremony, the stars continued on their steady march across the midnight-sky of the last day of the *xiuhmolpilli* – presumably because the gods had found the ritual to their satisfaction – the people could be assured that another 52 "years" had been granted them.

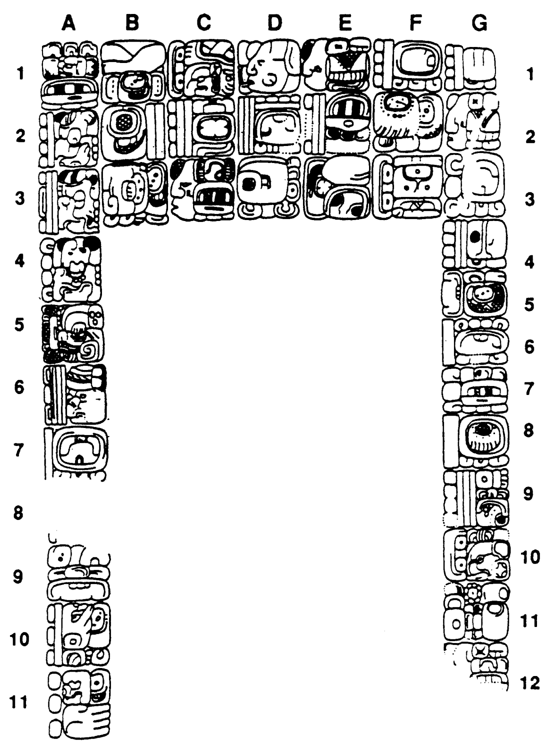
In the Maya region, this endlessly repeating pan-Mesoamerican cycle was synchronized with the accumulated days of the Long Count as the mathematical consequence of the arbitrary assignment of the Calendar Round date *4 ʻAhaw 8 Kumk'u* to the Long Count zero-date (13 August 3114 BCE). Written out in full and preceded by a distinctive hieroglyph that served to introduce them, dates so synchronized stood at the very beginning of the hieroglyphic texts on the carved monuments of Mayadom – whence their designation, Initial Series dates. To take an example, the Initial Series date on Quirigua Stela I (Fig. 6) – which reads in typical Maya fashion, from top-left to bottom-right, two columns at a time – displays a large initial series introductory glyph (ISIG) in the initial position (Al–B2) followed by the Long Count *9.18.10.0.0* (A3–A4) and the Calendar Round *10′ Ahaw 8 Sak* (B4), establishing a date corresponding to August 19, 800. (Glyphs are conventionally located by assigning upper-case letters to the columns of a text, numbers to its rows, and lower-case letters to divisions within the glyph-blocks and designating them in that order, as A3, C2a, F7b, etc. Number–values are dots for 1, bars for 5, and various special symbols for 0.

At times, supplementary to the Long Count and Calendar Round and inserted parenthetically between the *tsolk'in* and *haab* entries, were glyphs that recorded additional cycles of 7 or 9 days duration, as well as certain lunar information. Supplementing the cycles mentioned, the Maya tracked one of 819 days – a product of three basic periods (7 × 9 × 13) – relating it to a 4-day cycle (which the Aztecs also recognized) that linked each day with one of the four cardinal directions and associated colors (East, red; North, white; West, black; South, white). On Piedras Negras Stela 1 (Fig. 7), for example, the ISIG (A1) is followed by the Long Count *9.12.2.0.16* (A2–A6) and the *tsolk'in* position *5 Kib* (A7), while the *haab* position, *14 Yaxk'in*, does not appear until eight glyph-blocks later (C2). The intervening blocks include two that record the seventh position of the 9-day cycle (A8–A9), one that records the moon's age as 8 days (A10), another the moon's number as third in a set of six (A11), two that name the moon (B1–C1), and one that identifies it as a 31 month (B2). Following *14 Yaxk'in* are four noncalendrical glyphs (B3–E1) describing the event of the Initial Series date (July 7, 674).

When there was a need to record multiple dates, each new one (expressed as a Calendar Round date) was typically linked to its predecessor by what scholars call a Distance Number. The Distance Number employed



Calendars in Mesoamerica. Fig. 6 Quirigua, Stela I: hieroglyphic text with Initial Series date. [Drawing after Annie Hunter.] From *Biologia Centrali-Americana*, by Alfred P. Maudlsay, reprinted in 1974 by Milpatron publishing corp. used with permission of the publisher.



Calendars in Mesoamerica. Fig. 7 Piedras Negras, Stela 1: heiroglyphic text. [Drawing by John Montgomery.]

the same place system as the Long Count, but because the number of days to be recorded usually did not require all five places, they were entered in the reverse order of the Long Count – commencing with *k'inob* and proceeding only through those higher places necessary to record the distance. Thus on the Piedras Negras stela, following the initial event, come two glyphs that record the Distance Number *15 k'inob, 9 winalob*, and *12 tunob* (D2–E2), then two more that indicate an advance of that distance forward in time (D3–E3), and finally, two glyphs that record the Calendar Round date, *9 Chuwen 9 K'ank'in*. The calendrical mathematics are:

9.12. 2. 0. 16	*5 Kib*	*14 Yaxk'in*	(July 7, 674)
+12. 9. 15			
9. 12. 14. 10. 11	*9 Chuwen*	*9 K'ank'in*	(November 16, 686)

After two noncalendrical glyphs (F2–G2) that describe the event of the date so reached, come a second Distance Number, *5 k'inob* (F3), and the resulting third Calendar Round date, *1 Kib 14 K'ank'in* (G3–G4). The mathematics are:

9.12. 14. 10. 11	*9 Chuwen*	*9 K'ank'in*	(November 16, 686)
+5			
9. 12. 14. 10. 16	*1 Kib*	*14 K'an-k'in*	(November 21, 686)

This new date is followed by the single glyph that describes the event (G5). Then come the Distance Number, *5 k'inob, 2 winalob*, and *1 k'atun* (G6–G7), a fourth Calendar Round date, *5 Imix 19 Sak* (G8–G9), and fourth event (G10–G12). This final calculation is:

9. 12. 14. 10. 16	*1 Kib*	*14 K'ank'in*	(November 21, 686)
+1. 0. 2. 5.			
9. 13. 14. 13. 1	*1 Imix*	*19 Sak*	(September 23, 706)

As was the case for the second of these two monuments, the Maya often accompanied their calendrical entries with lunar data. From this propensity and from the structure of a Lunar Table in the *Dresden Codex*, it is clear that their concern was to anticipate eclipse-possible dates. Because eclipses (both lunar and solar) can only take place during a period of 18 days on either side of node-passage of the Moon over the path of the Sun, which occurs twice during a tropical year, the Maya grouped the months in semesters of six (and for corrective purposes, occasionally of five). In an attempt to approximate the Moon's 29.53059-day synodic period (as calculated today), they ascribed 29 and 30 days, alternately, to successive months, compensating for the gradual accumulation of excess time by introducing an extra 30-day month at predetermined intervals. One result was the *Dresden Codex* Lunar Table with its eclipse-period of 11,960 days, or just over 405 complete lunations. However, that excess time would be allowed to accumulate until after eight repetitions of the period (95,680 days), when the table could be adjusted to correspond more closely to the moon's position by subtracting 1 day. The mathematics behind this adjustment are: 29.53059 × 405 = 11,959.88895; 11,960 – 11,959.88895 = 0.11105; 11,960 × 8 = 95,680; 11,959.88895 × 8 = 95,679.116; 95,680 – 95,679.116 = 0.884, or 21.216 h. To further refine the Lunar Table's use, follow-up adjustments had to be made with succeeding repetitions of the cycle.

Though not central to the calendar itself, the planet Venus was nevertheless also a concern of Maya calendrical savants. Observations and calculations recorded in the inscribed monuments show that the Maya employed a 584-day period to predict culturally important points in the planet's synodic period. Both the Maya and the Aztecs assigned numerological significance to the correspondence between five of these Venus-periods and eight *haabs* (5 × 584 = 2,920; 8 × 365 = 2,920). Also, in the *Dresden Codex* is an elaborate table that consists of 13 sets of five periods of 584 days, or 37,960 days. Here again, because of the discrepancy between the full number 584 and the actual synodic period of Venus (583.97 days, by modern measurements) and because of the added cultural requirement that the first heliacal rising of the planet should occur on the *tsolk'in* date *1'Ahaw*, an adjustment like that in the Lunar Table had to be made after several runs of the Venus Table.

The Mesoamerican calendar, if by no means invented by the Maya, nevertheless reached its most elaborate form at their hands. Tracking basic periods of 4, 7, 9, 13, 20, 365, and 584 days and greater periods that were the products of various combinations or lowest common multiples thereof – 260(13 × 20), 819 (7 × 9 × 13), 2,920 (8 × 365; 5 × 584), 3,276 (4 × 7 × 9 × 13), 18,980 (13 × 20 × 365) and 37,960 (13 × 20 × 365 × 2 = 13 × 5 × 584) days – and groupings of months of alternately 29 and 30 days in duration, they synchronized them all with the cumulative and open-ended Long Count that recorded every passing day from its original *4 'Ahaw 8 Kumk'u* zero-point. Where the European calendar intercalated extra days as a device for keeping its dates in close harmony with the seasons (the vernal equinox, for example, occurring always on or about March 22), the Mesoamerican calendar, even in its most refined (Maya) mechanism, simply ground out the 1-day intervals of its several parts, accumulating or repeating them endlessly and without interruption, all of its components creeping gradually backwards through the seasons. It was thus impossible to identify a position in the tropical year by knowing a Calendar Round date. The first *4 'Ahaw 8 Kumk'u* fell on August 13, but the second fell 12 days earlier on August 1 and the third, 12 more on July 19. In the year 265, near the beginning of the Classic Period, after having returned to its original August 13 date 113 times, *4 'Ahaw 8 Kumk'u* fell on May 16, and by the close of the Classic in the late ninth century, it had fallen back to December 15.

However skillfully the Maya may have combined their astronomical observations with calendrical calculations to predict lunar and solar eclipse stations, heliacal risings and settings, conjunctions, stationary points, and retrograde motions of the five visible planets, the fact remains that, for all its reputation, the calendar itself was no more accurate than the 365-day calendar the ancient Egyptians adopted around 4250 BCE which was the product of twelve 30-day months (12 × 30 = 360), plus – like the Mesoamerican *xihuitl* or *haab* – 5 extra days. Indeed, it was an Egyptian mathematician, Sosigenes, who, recognizing the faults of the rigid 365-day year, persuaded Julius Caesar to adopt his scheme for reforming the Roman calendar in 45 BCE, by intercalating an extra day every fourth year into an otherwise 365-day year. However, it would be unhistorical to judge the Maya calendar by a standard set by the Egyptian, the Julian, or the later Gregorian calendar. The cultural need of the Egyptians was to anticipate (for agricultural reasons) the annual flooding of the Nile. That of the Julian reform was to ensure that the Roman solsticial festival *fors fortuna* would fall regularly on June 22. The Christians, in turn, adopted the Julian calendar in 325 at the Council of Nicaea from a need to establish predictable dates for Easter, which – for religious reasons – had to fall on the first Sunday following the first full moon after the vernal equinox. It was this same need that led Pope Gregory XIII to authorize a further reform of the Julian calendar in 1582.

However, the cultural needs met by the Mesoamerican calendar were of a numerological–astrological nature. Quite apart from the divinations of the purely numerical *tsolk'in*, the Maya assigned significance to astronomical predictions based upon complex multiples of their several whole-number cycles which were often linked to the actions of remote or fabled ancestors or mythological supernaturals or to multiples of the never whole-numbered synodic periods of the heavenly bodies. Contrived calendrical calculations into the remote past and distant future were made to establish mythological beginnings, regenerations, and calamities to come. Day-to-day events, even to the timing of military attacks or battles among themselves or surrender to the Spanish, seem to have fallen under this numerological spell. However closely the *Dresden* Venus Table may appear to approach a modern astronomical ephemeris of Venus, its purpose was to return the latter's heliacal rising to *1′Ahaw*, the birth date of the mythological Venus-associated hero, *Hunahpu* – irrespective of any temporary losses in accuracy its mechanisms may have produced. If the calendrical efforts of Mesoamericans can be described as an attempt to bring about a marriage between their whole-number numerology and their perceived rhythms of the Sun, Moon, planets, and stars, it was one in which it was the latter who were to love, honor, and obey. However, if the test of a good marriage is its durability, then the Mesoamerican calendar – particularly in its Maya form – was not only mathematically sophisticated, conceptually elegant, and visually beautiful, but a highly successful one as well.

Calendars in South America

R. Tom Zuidema

At the time of the Spanish conquest around the year 1530, the Incas had integrated different cultures, all belonging to Andean civilization, into a large empire, stretching from southern Colombia through Ecuador, Peru, and Bolivia, into northern Chile and Argentina. Much can be learned from the art of the Incas and their predecessors, including architecture, stone sculpture, pottery, and textiles. However, we have no access to written records as defined by western culture; understanding intellectual aspects of this civilization is almost exclusively dependent on what informants from Cuzco, the Inca capital in southern Peru, told the Spanish chroniclers. These were most impressed by Inca statecraft, although they were never present when it was still practiced. Their interpretation of Inca religion was heavily influenced by Christian opinions. Religion to them included memories of the Inca past and of state and private rituals related to, for instance, the calendrical organization of agriculture and llama husbandry. As Inca history is discussed in the article on Knowledge Systems of the Incas, this one concentrates on the calendar as it functioned in Cuzco.

Most of our information on the Inca calendar and related astronomical practices derives from only a few chroniclers: Juan de Betanzos [1551],[1] a soldier and the first chronicler to write on this subject in the context of a full account of Inca culture; an anonymous author [ca. 1565] with precise information on the integration of astronomical observations into the calendar; Cristóbal de Molina [1574], a priest with great knowledge of Inca rituals but excluding those for one-third of the year; and Bernabé Cobo [1653], a late Jesuit author who gave our most comprehensive description of Inca culture including the calendar for the whole year. His information probably derives from a now lost account by Juan Polo de Ondegardo [1559], whose own description of the calendar only survives in a much revised short version [1585] for use by Catholic priests. Later chroniclers and dictionaries mostly follow Polo's version and add little information toward a reconstruction of the original Inca calendar. This reconstruction provides very different results from the general picture that the chroniclers present us with.

All chroniclers conceive the Inca calendar as consisting of 12 months. Notwithstanding this agreement, there is much confusion about the nature of the months, their order, and their correspondence to Christian months. Some of this confusion may derive from much local variation among calendars in the empire, but most of the blame is due to Spanish misreporting on the Cuzco calendar itself. Betanzos, Polo, and Cobo describe a system of 12 "months" with a fixed position in the solar year. Molina speaks of "months" *and* "moons" and refers to rituals according to the phases of the moon for three times of the year, roughly corresponding to June, September, and January. Some modern scholars therefore argue that the whole calendar was lunar, but this was not the case (Ziólkowski and Sadowski 1992). On each of the three occasions important lunar rituals were celebrated after an independent solar observation had been made for that time of the year. We have no information on lunar rituals in Cuzco for other times of the year; we can only conclude that the integration of solar and lunar rituals in Peru was done in a way different from Western (Christian, Jewish) presuppositions in this respect.

There are various difficulties in accepting the Inca organization of months according to the Polo version of 1585. For instance, two names are taken together for one month that in other versions refer to separate months; in other calendars a name may be used as an alternative for either one or a next month. In some versions, a month name is suppressed for no apparent reason at all; months were said to be of rather different lengths, either longer or shorter than 30 or 31 days. And the anonymous chronicler mentions for two double-months that the moon observed in one month (either the first or the second) would always reach the other, leaving us to conclude that the fixed double-month was shorter than two movable synodic (lunar) months $(2 \times 29\frac{1}{2} = 59 \text{ days})$. Comparing the various descriptions of the Inca year, it becomes clear that originally it contained 13 and not 12 months and that each version suppressed one or another month name to accommodate this calendar to the Spanish one. It may have been a goal of Catholic missionaries fighting against "pagan" rituals, but there was also Inca consent, realizing the advantages of combining Inca and Catholic celebrations, first openly and later secretly.

From indications by Molina and Cobo we can conclude that the Inca calendar placed one month around the June solstice (21 June), celebrating *Inti Raymi* (feast of the sun), and two months, *Capac Raymi* (royal feast) and *Capac Raymi Camay Quilla* (royal feast, feast of the moon) around the December solstice, which honored the fact that in the southern hemisphere the sun is strongest then. For practical reasons, *Inti Raymi* may have been celebrated not on the days of the June solstice but within its month during the full moon either before or after in a given year. People took advantage of the dry season's clear skies when the moon shone the whole night.

During *Capac Raymi*, considerations were different. While the June solstice marked the middle of a month, the December solstice, six and a half Inca months apart, marked the date separating the two months of *Capac Raymi*. Moreover, these months fell in the middle of the rainy season when normally no good observations of the sun and the moon could be made. The month of *Capac Raymi Camay Quilla* was celebrated, first awaiting the new moon with some celebrations. The major celebrations came with the next full moon and took some 7 days. If the new moon arrived early after the solstice (December 21), all celebrations took some 22 (15 + 7) days; but if it was late, they could take up some 52 (30 + 15 + 7) days. Then the full moon

[1] In case of an old text, square brackets indicate the date of writing or first publication.

celebrations would not occur in *Camay Quilla* but extend into the next month. Although after those days the moon would still be visible late at night, no more attention would be paid. However, the day after these 52 days (February 13) was important for another reason. Then the sun in Cuzco – this city being $13\frac{1}{2}^{\circ}$ south of the equator and within the tropics – passes the zenith point in the sky at noon. Although the chroniclers were only vaguely aware of the importance of this event, Polo indicates that then a new year began, with people preparing for the coming harvest. The sun also passes the zenith 53 days before the December solstice, and we can assume that a similar calendrical calculation was made for this period. The anonymous chronicler considered it as one in which the moon of one month would always reach the other. Its beginning was celebrated with a feast, the *Itu*, which only Inca nobility could attend, and the last 6 days before the December solstice were also important for celebration. These days could begin with a full moon if the new moon had arrived late in this 53 day-period.

Apparently, the Incas divided the time from the first to the second passage of the sun through the zenith (107 days) into four months, of which the central ones of *Capac Raymi* were most important. The average length of the 13 months was about 28 days and as the connection to the length of a synodic month (29 days) was lost, there is no reason that the months could not be of various lengths as reported by the chroniclers. Having established the framework of the Inca calendar, an outline can be given of its ritual organization serving various, often contrasting, social needs.

The calendar organized, first, a multitude of sacrifices (llamas, guinea-pigs, birds, sometimes children) and offerings (mostly cultivated plants). The months were organized according to four seasons of three months and an independent month after the sun's second zenith passage. Sacrifices and offerings expressed the different seasonal concerns.

A quite different organization of the months attended more political interests in terms of tribute due by Inca and non-Inca subjects and of the large feasts of state presented by the king, queen, and high nobility. In this organization, months were brought together in groups of two and then of four. This organization cross cut the seasonal one but kept the same independent month. Our first chroniclers mention how tribute was brought to Cuzco every four months and how non-Inca nobles accompanying these deliveries stayed for the same time in town. Betanzos adds to this that services of labor and distribution of food, especially meat and cloth, followed the same schedule. At first, the colonial administration showed interest in adopting this schedule for its own needs, but after about 1570 it changed to the European custom of having tribute paid twice a year, around Christmas and St John (24 June), and chroniclers no longer paid attention to the earlier system.

I mentioned above the most important four month-period around the December solstice. In between the times of planting and harvest, this was a season when the fields needed less attention and when heavy rainfall made travel difficult. *Capac Raymi* and its preceding month were dedicated to the initiation rituals of noble boys, these being assisted by noble girls who had had their own rituals of first menstruation at other times of the year. In the lunar rituals of *Camay Quilla* and the following month, noble men and women pledged their allegiance to the king, and rains were ritually dismissed awaiting the ripening of the fruits. In the four months around planting, land was first prepared for cultivation, ploughed and planted, and then rituals followed to help the budding plants grow and attract rains. Again, the two central months were dedicated to state rituals. First, the king himself helped with the planting. Keen observations were made of sunset throughout the first month to have the various timings for planting and irrigation of different sorts of plants, at lower, warmer and higher, colder places well orchestrated. In the second month, dedicated to the moon, the queen, and women in general, "evil" and "illnesses" were ritually driven out of town in support of peace among people and of the growth of plants. Finally, the four months of harvest included the early harvest, the general harvest around Cuzco, the reception of foreign lords with their presents and the tribute of their people, and storage. Again the most important ceremonies occurred in the central months when first harvest was ritually brought into town and then the Inca himself ploughed, opening a new agricultural year, and ate with all nobles and foreign lords in the plaza.

Good descriptions of Andean rituals were also made for the central provinces around Lima, the vice royal capital in colonial times, and some of these ceremonies can be compared with Incaic ones in Cuzco. But when those other records became available in the early seventeenth century, more than 80 years had already passed after the Spaniards had arrived in the Andes. Much research still has to be carried out making those comparisons fruitful for a reconstruction of pre-Hispanic calendars in general.

Candraśekhara Sāmanta

K. V. Sarma

Candraśekhara Sāmanta (1835–1904) was a self-made astronomer who had the distinction of revising the traditional calendar of Orissa during the nineteenth century. He was a scion of a junior branch of the chiefs of the small estate of Khandapara and bore the title *Sāmanta* (Feudatory) on that account. His full traditional name was Sāmanta Śrī Candraśekhara Singh Harichandan Mohāpatra, and he was called locally Pathani Sāmanta. Young Candraśekhara had little modern education, but learned Sanskrit and astrology from his uncle, which he further developed by an intensive study of two of the authoritative texts of the times, the *Sūryasiddhānta*, and the *Siddhāntaśiromaṇi* of Bhāskarācārya. Exhibiting an uncanny interest in watching the skies, he became aware that the times of the rising and setting of the sun and moon and of the other celestial bodies were at variance with the times indicated in local almanacs arrived at by computation based on traditional texts. Often, when almanacs differed in their indication of times, and even of dates (*tithis*), there was confusion in the matter of fixing the days for domestic and social festivals and of sacred worship at temples like that of Lord Jagannātha at Puri.

Deeply religious and equipped with the fundamentals of traditional astronomy, Candraśekhara took it upon himself to remedy the prevailing state of affairs, and from the age of 23 he commenced watching the transit, conjunction, rising, and setting of the celestial bodies, and recorded his observations consistently and systematically. As aids to accuracy in observation, he designed, all by himself, several astronomical instruments which had been described in the *Sūryasiddhānta* and the *Siddhāntaśiromaṇi* and their commentaries. Among the instruments were an armillary sphere and a vertical wheel, which in modern terms served the purpose of the transit and alta-azimuth instruments. He also used the clepsydra (water clock) for measuring sidereal time. An instrument which he designed and used constantly for celestial observation in place of a telescope was a T-square frame which he called *mānayantra* (measuring instrument) with the main limb 24 digits and the crosspiece marked with notches and having holes at distances equal to the tangents of the angles formed at the free end of the main piece. He also designed an automatically revolving wheel (*svayam-vāhaka*), with spokes partly filled with mercury, which he also used to measure time. He effectively used the gnomon, which when fitted with a small mirror could be used at night for measuring time and angular distances.

Candraśekhara's observations, experiments, and recordings, on the basis of which he coined corrections to earlier enunciations and innovated new methodologies and practices, lasted 34 years. This enabled him to introduce reforms to all aspects of astronomical computation, which he set out in an extensive work, *Siddhāntadarpaṇa*, in 2,500 verses. This is an astronomical manual in five chapters, devoted, respectively, to Mean planets (*Madhyama-adhikāra*), True planets (*Sphuṭa-adhikāra*), Problems of Direction, Time and Place (*Tripraśna adhikāra*), Spherics (*Gola-adhikāra*), and Time and Appendices (*Kāla adhikāra* and *Pariśiṣṭa*). The main contributions of Candraśekhara include corrections to the sidereal periods of the star planets and to the main inclinations of the planetary orbits to the ecliptic (the band of the zodiac through which the sun apparently moves in its yearly course), identification, and evaluation of evection [solar perturbation of the lunar orbit], variation, and annual equation among the moon's inequalities, and horizontal parallax of the sun and the moon. Recognition and honors were late in coming when the Government of India conferred on him the title of *Mahāmahopādhyāya* (Scholar of scholars), the highest title for a Sanskritist.

Caraka

Guy Mazars

Caraka is the editor of a treatise of Āyurveda which bears his name, the *Carakasaṃhitā* or "Caraka's Compendium", a work with which classical Indian medicine really begins. The *Carakasaṃhitā* is supposed to contain the teaching of the sage Ātreya Punarvasu, recorded by one of his disciples, Agniveśa, and revised by Caraka. Ātreya and Agniveśa belong to the realm of legend, but Caraka is likely to have been a historical figure. Indeed, according to the Chinese version of a Buddhist text, translated from Sanskrit in the fifth century AD, a physician of the same name was practising at the court of the Scythian king Kaniṣka. Several scholars place this king at the end of the first or second century AD. Like Aśoka (264–227 BCE) some centuries earlier, Kaniṣka was well disposed towards Buddhism and protected it. During his reign, Indian culture underwent a great expansion. The redaction of the *Carakasaṃhitā* thus goes back to this period, if it is indeed the same Caraka.

However, the text which has come down to us is a composite work. It contains more recent portions added at the time of its revision by an author from Kashmir, Dṛḍhabala, who probably lived in the fifth century AD. But the core of its content is much older since Caraka himself had only reconstructed an already existing work, cited under the name of *Agniveśatantra*, the "Book of Agniveśa". At least one of the redactors of the "Compendium" was familiar with the diets and habits of peoples from different parts of the world. The *Carakasaṃhitā* was commented upon before the ninth century by Jejjaṭa, who may have been a Kashmirian or an inhabitant of Sindh. Then, in the eleventh century, Cakrapāṇidatta wrote a commentary called *Āyurvedadīpikā*, which has been preserved and edited. Cakrapāṇidatta was a native of Bengal, himself the author of the *Cikitsāsaṃgraha*, a well-known manual of therapeutics. He wrote other works, including the *Dravyaguṇasaṃgraha*, a short treatise of materia medica. According to the Arab bibliographer Ibn an-Nadīm, in his *Kitāb al-Fihrist* (Index of Arabic books, completed in 988 AD), a Persian version of the *Carakasaṃhitā* had been translated into Arabic by the time of the first 'Abbāsid caliphs (eighth century).

In its present form the *Carakasaṃhitā* consists of 120 chapters which are divided into eight parts (*sthāna*):

1. Thirty chapters in the *Sūtra* section dealing with various topics, including pharmacology, diet, some diseases and their treatments, physicians and quacks;
2. Eight chapters in the *Nidāna* section dealing with the causes of eight main diseases;
3. Eight chapters in the *Vimāna* section dealing with different topics such as "taste", logic, vessels, pathology and medical education;
4. Eight chapters in the *Śārīra* section dealing with embryology and anatomy, and on the connection between the body and the mind;
5. Twelve chapters in the *Indriya* section devoted to diagnosis and prognosis;
6. Thirty chapters in the *Cikitsā* section dealing with therapy;
7. Twelve chapters in the *Kalpa* section on pharmacy; and
8. Twelve chapters in the *Siddhi* section devoted to general therapy.

Cashewnut Processing on the Malabar Coast

K. T. Rammohan

The cashewnut processing industry on the Malabar Coast grew around the port towns of Quilon, Calicut and Mangalore, which had cashew-growing hinterlands. Cashew was not a systematically cultivated tree crop. In earlier days, poor people gathered the nuts, roasted them in mud pans, removed the shells by hand and sold the kernels in nearby markets. From the early decades of the twentieth century, trading companies from the West operating on the coast began to purchase shelled kernels from local people for export. After sun drying, cashew kernels were packed in mango wood cases lined with newspaper and shipped out, mainly to Marseilles and occasionally to London from where these would be re-exported. From the 1930s, with the emergence of the United States as a major buyer, the industry gained substantial momentum. To meet the increased demand, the trading companies resorted to the putting out system of production. The companies bought raw nuts locally (and also imported nuts from East Africa) and distributed these to people, who pan-roasted and returned the shelled kernels to the company. The kernels were dried, peeled, graded and packed at the company premises. Later, as the putting out system gave way to direct production by firms, factories where all the operations were undertaken emerged. The factories employed women and children of lower castes and outcastes who were paid very low wages. Over 90% of the workers were women. Men, again drawn from lower and depressed castes, were engaged primarily in roasting.

Cashewnut processing involved five principal operations: roasting, shelling, peeling, grading and packing. In the early factories roasting of nuts was done in the open air in iron pans. From 1932, iron pan roasting was replaced by drum roasting. Under the new method, an open-ended drum (rotary cylinder) was placed over a fire in a tilted position. Raw nuts were fed from one end, and roasted nuts were collected from the other. Each cylinder needed six persons to operate: the first person attended to the furnace, the second and third fed the raw nuts, the fourth rotated the cylinder, the fifth removed the roasted nuts, and the sixth sprayed water on the roasted nuts. The workers wrapped themselves in gunny bags to protect themselves from burns. By the mid-1930s, hot oil roasting replaced drum roasting. Here, raw nuts were roasted in a bath of cashew shell oil maintained at about 200°C. Due to the high temperature, the oil cells of the nuts broke, releasing their contents; and the nuts were then roasted to the desired degree. Cashewnut processing yields a by-product – cashewnut shell oil that has industrial and strategic uses. This could be extracted in full only in oil-bath plants. All these methods used cashewnut shells as fuel.

After roasting the nuts were shelled. This was the most arduous operation and had to be done in an uncomfortable squatting posture. Nuts were placed on a flat stone and were gently hammered with the help of small wooden mallets, to remove the shells. A high degree of skill was required to ensure that the kernels did not break. Peeling the skin off kernels was also a dexterous, repetitive and loathsome task. The kernels were then graded and packed.

C

Celestial Vault and Sphere

Cornelis Plug

The celestial vault is the apparent surface of the sky – both the night sky against which the stars appear to be placed and the blue expanse of the daytime sky.

The idea that the celestial vault, and particularly the daytime sky, is a physical cover of some kind is found in the cosmologies and myths of many cultures. Ethnic groups in northern Eurasia, for example, thought of the sky as a roof to protect the earth and life, and often described it as resting on a central pillar. In the hero tales of the Yakuts, the sky was said to be hemispherical, resting on the outer edge of the world. In the mythologies of Finland, Lapland and neighbouring regions, the celestial pole or the pole star was described as the "nail of the sky" which supports the celestial vault and around which it revolves. The Lapps, Finns, Yakuts, Japanese and Hebrews sometimes described the sky more specifically as a tent roof. The most popular conception of the sky in ancient Egypt was that of a blue water surface, a continuation of the sea or the Nile. Similar ideas were applied to the night sky. The Milky Way appeared to some as a stitched seam, and the stars as tiny holes in the fabric of the celestial vault.

In sub-Saharan Africa a widespread belief is that the daytime sky is a solid blue vault resting on the earth, on which the sun moves. During the night the sun is thought to return to the east either by passing under the earth (e.g. the Luyia of Kenya) or behind the solid sky (e.g. the Zulus of South Africa), in the latter case producing the stars by shining through small holes in the vault.

Although these speculations implied a fixed form for the sky, that form was seldom clearly defined. There was some debate among early astronomers in China on whether the celestial vault might be strongly flattened, perhaps even a plane parallel to the earth's surface. Thus the astronomical chapters of the official history of the Chin dynasty (AD 265–420), written in the seventh century under the supervision of Emperor Tai Zong, contain a discussion by the scholar Ge Hong (283–343) of the theory that the sun cannot be seen at night because it moves a great distance away from the earth. Ge Hong argued (Ho 1966: 57): "If it is said that the sun can no longer be seen because it has gone a very great distance from us, then when the sun sets, on its way towards the north, its size should diminish. But, on the contrary, the sun becomes larger at sunset". This refutation of the flattened vault theory did not originate in China. It was stated in similar words by the Greek astronomer Claudius Ptolemy in the *Almagest* (Book 1, Chapter 3), written around AD 142. The similarity of the wording leaves little doubt that intellectual contacts existed between China and the Middle East at the time.

The idea that the celestial vault is actually flattened has been ascribed to Empedocles, a Greek philosopher of the fifth century BCE. Ptolemy's refutation of the theory was later transmitted to Islamic scholars as part of the *Almagest*, and was slightly elaborated by the astronomer al-Farghānī in the ninth century. However, by this time most astronomers had long accepted that the celestial vault represents the upper half of an imaginary (or sometimes real) spherical surface, called the *celestial sphere* (or of a set of concentric celestial spheres). The other half of this sphere is below the horizon. The apparent positions, sizes and movements of the sun, moon, planets, comets and stars were described as if these bodies were situated on the inner surface of a real celestial sphere. Estimates of the sizes and separations between the celestial bodies were therefore expressed as lengths or distances on the celestial sphere, rather than in terms of angles. For example, Chinese observations of comets from the second century BCE to the nineteenth century were expressed in terms of the *zhi*, a length standardized as 311 mm in the ninth century. The *zhi* appears to have corresponded to an angle of a little less than 1°. Similarly, the Babylonian *ammat* (about 524 mm) represented either 2° or 2.5° at different times. And the Islamic *fitr* and *shibr* (spans later standardized as 152 and 178 mm, respectively) were equivalent to about 0.6° and 0.8°, respectively, in the astronomical work of Ibn Yūnus during the eleventh century. These lengths and angles seem to imply that the astronomers in each of the three cultures assumed that the imaginary sphere used to express their estimates had a radius of only some tens of metres. Numerous estimates of the perceived sizes of the sun and moon (usually seen as some 200–300 mm across) from classical to modern times in Europe support the same conclusion: there exists a universal tendency to describe perceived sizes and distances on the celestial vault as if the height of the sky is only a few tens of metres.

Although astronomers had long rejected the idea that the celestial bodies move along flattened trajectories, the Islamic physicist Ibn-al-Haytham pointed out in the eleventh century that the sky usually *appears* flattened. He explained this as an illusion created by our perception of distant objects towards the horizon, and the lack of such indicators of distance towards the sky. He furthermore used the flattened appearance of the celestial vault to explain the illusion that the sun and moon are enlarged near the horizon – an explanation that was transmitted to Western Europe during the thirteenth century and survived well into the twentieth century. Its importance lies in the fact that, for the first time, the perceived flattening of the celestial vault and the perceived enlargement of the horizon sun and moon were described as perceptual illusions (now studied by psychologists), rather than measurable phenomena to be studied by astronomers.

Ceramics, Mimbres

MICHELLE HEGMON

Mimbres pottery, made primarily in southwestern New Mexico between 750 and 1150 AD, is renowned for its spectacular, often naturalistic, black-on-white designs (Fig. 1). Although painted pottery is common in the archaeological record of the North American Southwest, Mimbres pottery stands out because of its elaborate representational designs, which depict everything from the ubiquitous rabbit to scenes of everyday life and apparently mythical creatures. Because of the pottery's beauty and appeal to collectors, many Mimbres archaeological sites have been destroyed by looters searching for pottery to sell, and irreplaceable information about the past has been lost.

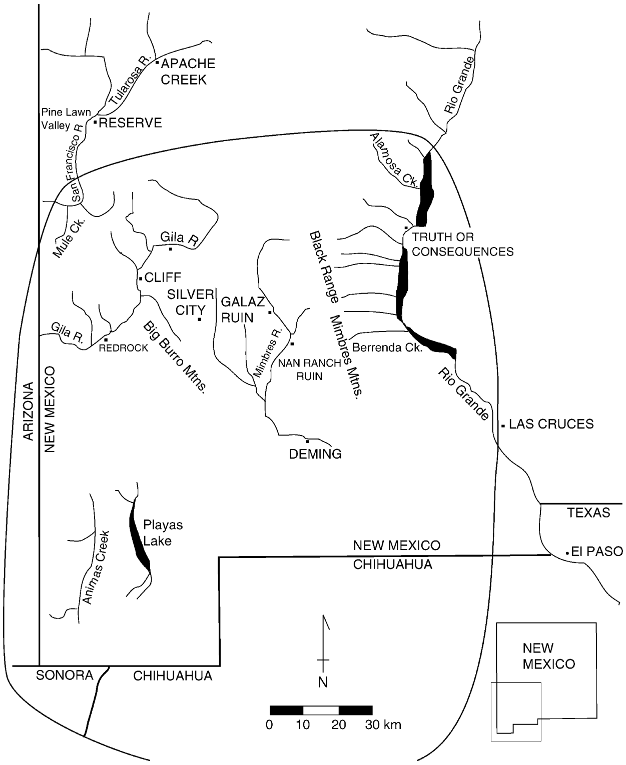
Mimbres, from the Spanish for "willows," is the name given to a small river in southwest New Mexico. The name came to be applied to the pottery found in archaeological sites along the river, and eventually to

Ceramics, Mimbres. Fig. 1 Classic Mimbres Black-on-white bowl from Ronnie Pueblo (Nelson 1999: 96–97). The bowl is part of the permanent collections of the Museum of Anthropology, Arizona State University.

the people who made the pottery. However, it is important to keep in mind that these are labels applied (mostly by people of European descent) to pre-Hispanic Native Americans. We do not know what the people called themselves, although we can be sure it was *not* Mimbres. In fact, recent approaches in archaeology have attempted to decouple pottery styles and cultural identity, and have challenged the extent to which the people who made the pottery we call Mimbres were united culturally, socially, or politically. They were maize farmers living in fairly simple hamlets and villages that housed from a few households to a few hundred people. They had no writing, draft animals, or metal tools. And while their social organization was elaborate in many ways, they did not have a well-developed political hierarchy or marked social inequalities. Syntheses of Mimbres archaeology include Anyon et al. (1981), LeBlanc (1983, 1989), Hegmon (2002), Hegmon et al. (1999), and Nelson (1999) and a recent issue of *Archaeology Southwest* (2003). Book-length treatments of Mimbres pottery, especially the designs, include Brody (1977, 2004), Brody et al. (1983), Brody and Swentzell (1996), Fewkes (1989), Kabotie (1982), LeBlanc (2004), Moulard (1984), and O'Bagy Davis (1995). In addition, reports on Mimbres sites include numerous pictures and analyses (e.g., Anyon and LeBlanc 1984; Cosgrove and Cosgrove 1932; Shafer 2003).

Situating the Pottery in Time and Place

The Mimbres region (Fig. 2) is part of the larger Mogollon archaeological culture area, which includes much of southern New Mexico and northern Chihuahua, as well as central Arizona. Mogollon pottery, made



Ceramics, Mimbres. Fig. 2 Map showing the Mimbres region in southwest New Mexico and surrounding states.

with iron-rich volcanic clays, is generally brown or red in color, while pottery made in the northern Southwest (what had been called the Anasazi area but is now more properly known as Ancestral Pueblo) is generally white or gray, sometimes with black designs. Because Mimbres pottery is black-on-white, it was initially thought to be northern in origin. However, it is now well known that Mimbres pottery is indeed a Mogollon brown ware, covered with a thin slip of white clay that provides a backdrop for the black designs. The local development of Mimbres pottery – from plain brown to red-on-brown to red-on-white and finally to black-on-white – is well understood and well dated (see especially Anyon et al. 1981; Scott 1983; Shafer and Brewington 1995; Shafer and Taylor 1986). Because the painting style changed fairly rapidly, archaeologists are able to date the pottery quite precisely. For example, Fig. 3 illustrates a bowl with a design that extends all the way to the rim and that has straight-line hachure with framing lines thicker than the hatch lines; these are both relatively early characteristics and together they indicate that this bowl should be classified as Early Style II (ca. AD 880–920; Shafer and Brewington 1995). Later designs (generally classified as Classic Mimbres Black-white or Style III, and illustrated in Figs. 1 and 4–7) have various kinds of rim framing lines. Scott (1983) illustrates the stylistic changes over time, and Shafer and Brewington (1995) present a detailed

microstyle chronology. Mimbres pottery includes various forms including storage and cooking jars as well as bowls. However, most of the painting and virtually all of the representational designs are found on bowls. Painted

pottery was most elaborate and probably most common during the Mimbres Classic Period (1000–1130 AD), and painted bowls at that time had an average volume of 2.2 l (based on data from the Galaz Ruin [Anyon and LeBlanc 1984: 169]).

Chemical and mineralogical analyses (summarized in Gilman et al. 1994) clearly indicate that Mimbres pottery was made in many locations and villages; it was not centrally produced. The elaborateness of the designs suggests that some may have been produced by specialists, but if this were the case they were likely part-time specialists. Recent calculations (LeBlanc 2004) suggest that all Mimbres black-on-white vessels could have been made by just a few potters, each making only 50–100 pieces annually. While most pottery makers and painters in the pre-Hispanic Southwest were probably women, several authors have suggested that at least some of the Mimbres designs were painted by men, because they depict rituals probably controlled by men (Brody 1977) and because the birth scenes are anatomically unusual (Hegmon and Trevathan 1996). The issue is controversial, and a clear resolution is unlikely.

Mimbres painted pottery is found in many contexts, including in trash middens, on living floors, and in burials, across the Mimbres region. Many burials – in simple pits in middens and under house floors – were interred with a bowl placed over the skull. Most of these bowls had a small hole carefully punched out of the base (see Figs. 3 and 6); these bowls are said to have been "killed," and some have speculated that the hole allowed the deceased's spirit to escape. Many of the bowls found in burials have wear patterns that indicated they had been used before they were interred (Bray 1982). It is possible that most individuals had a bowl that they used for eating and other purposes, and that bowl accompanied them into the grave.

The Designs

Before considering the designs and their analyses, two caveats should be noted. First, although many designs appear to be realistic, in that they accurately portray details such as the topknot on a Gambel's quail and the black tips on jackrabbit ears (Fig. 4) the corpus of designs as a whole should not be assumed to reflect Mimbres life accurately. Rather, the pre-Hispanic artists – for various aesthetic, cultural, and social reasons – *chose* to depict certain scenes in certain ways. The designs are representations of what people believed should be portrayed on pottery, and they should be interpreted from this perspective. Second, as Brody (2003) has emphasized, the designs were painted on hemispherical surfaces (i.e., the interior of bowls) that were often placed below the user and viewer's eye level; most reproductions do not convey the designs' three-dimensional aspect or use context.

Mimbres pottery designs have been the focus of much attention, by archaeologists, art historians, and the public (Brody 1977; Brody et al. 1983; Brody and Swentzell 1996; Moulard 1984), and much is known about what they depict. However, there is still a need for comprehensive quantitative analyses of the designs and their distribution, as I noted in my recent review (Hegmon 2002). Designs with representational elements (Figs. 1, 4, 6, and 7) are less common than those that are purely geometric (Figs. 3 and 5) (221 versus 494 in the Galaz Ruin collection [Anyon and LeBlanc 1984]). Most representational designs are depictions of animals native to the Mimbres region, some show scenes that include humans, and others depict apparently mythical creatures. Early Mimbres representational designs are similar to designs on pottery from the Hohokam region in southern Arizona, but by the Classic Period, the Mimbres style was unique.

Interpretations of the meanings of the designs are best made by considering their larger cultural context. Maize was a staple food in the Mimbres region, supplemented by other crops, wild plants, and meat from small animals such as rabbits, as well as occasional larger animals such as deer. In comparison, almost no maize or other plants are depicted on the pottery, and while there are many rabbit paintings (Fig. 4), there are few scenes (possibly only one in the known corpus) of rabbits being trapped or hunted. In contrast, quite a few paintings depict the hunting of larger animals, including bear and elk (Fig. 6). Taken together, these patterns support the argument that the paintings represent what people wanted to emphasize (i.e., hunting), not what they actually ate. One unpublished but widely cited analysis (LeBlanc 1977) found that bowls depicting certain animals were associated with certain villages or areas, suggesting the animals were relevant more to social identity (e.g., as clan symbols) than to food.

While many of the animals depicted on the bowls would have been local to the Mimbres region, a number of exotic and probably symbolically important species are also depicted. In many cases, biologists have been able to identify particular species because the Mimbres paintings include relevant details, such as fin and beak shapes. Macaws, particularly their red feathers, have great ritual significance to contemporary Southwestern Native Americans, and a few macaw skeletons have been found in archaeological sites in the Mimbres region and elsewhere in the Southwest, suggesting that this ritual significance extends far back in time. Parrot-like birds are occasionally depicted on Mimbres bowls, and analyses of their traits indicates that most are scarlet macaws, native to the lowlands of southern Mexico and central America, more than 1,000 miles from the Mimbres region (Creel and McKusick 1994). Similarly, analyses of the fish (and a possible whale) depicted on Mimbres pottery indicate that many are saltwater species, probably from the Gulf of California, approximately 640 km distant (Jett and Moyle 1986). Thus it is clear that the people who painted the Mimbres designs had knowledge of distant regions, either through travel or trade and interaction.

In the past two decades, archaeologists have devoted significant attention to understanding women and gender relations in the past. Mimbres paintings give particular insights (see Hays-Gilpin 2002) because some depict men and women engaged in various activities (almost all depictions of humans show them engaged in some activity; there are almost no simple portrait-like treatments). Some humans have clear sexual characteristics (breasts or penis), and inferences about styles of dress and body decoration associated with each sex make it possible to identify the sex or gender of many of the human figures (Munson 2000). For example, when string aprons (Fig. 7) are depicted on individuals with clear-cut sexual characteristics, they are always associated with females; thus, string aprons are interpreted as good indicators of gender (i.e., women). Drawing on this and similar analyses, Munson (2000) was able to conclude that there was a gendered division of labor in Mimbres society (men are more often associated with hunting, women with child care). However, there is at least one famous scene of a pregnant woman (seemingly triumphant) carrying a hunted antelope; this image graces the cover of a milestone volume on gender and archaeology (Gero and Conkey 1991). Furthermore, although more men than women are depicted engaged in apparently ceremonial activities, women are consistently shown handling ritually important parrot-like birds (often macaws) (see Fig. 7).

Contemporary artists often state that their art conveys meanings that cannot be put into words, and it is likely that the same applies to art of the past. It is also likely that Mimbres pottery painting – done by perhaps hundreds of artists over approximately four centuries – conveys a range of meanings. However, researchers have gained some insights into the general range of meanings associated with the pottery. Because the bowls are often found in burials, and some depict scenes from what appears to be the Puebloan World of the Dead, Brody and Swentzell suggest the images refer to "the unity of man and the cosmos, the living and the dead, and of the structures of harmony" (1996:38). Moulard (1984) similarly concluded that the designs symbolize transformations, such as from life to death or childhood to maturity.

Collections

Mimbres pottery – particularly pieces with representational designs – has long had great appeal to collectors. The result has been the destruction and desecration of Mimbres sites. The large site of Old Town is well known for looking like a mine field because it is so full of large holes, many made by backhoes and bulldozers. Galaz Ruin (Anyon and LeBlanc 1984), one of the largest Mimbres villages, no longer exists; it was completely removed by bulldozing. Much of this activity is illegal (i.e., it is illegal to disturb archaeological remains on public land, and it is illegal to disturb human remains even on private land), but law enforcement cannot always keep pace (Turnbow 2001). In an attempt to stop the destruction and preserve some of what remained of Mimbres archaeology, Steven LeBlanc formed the Mimbres Foundation in the 1970s, and today the Archaeological Conservancy undertakes similar activities on a much wider scale (LeBlanc 2003). Also, many responsible authors are today refusing to publish images of looted bowls so as not to increase their value (e.g., the second edition of Brody's *Mimbres Painted Pottery* [2004]), a strategy in line with the ethnical guidelines of the Society for American Archaeology. Thus the situation is improving, though destruction continues (Turnbow 2001).

The problem with collections is not simply private ownership of the remains of past Native American cultures. A more serious issue is that the demand for collections, and the high prices paid for Mimbres pottery on the art market, encourage the illegal looting of sites. And because many bowls are found in burials under house floors, the search for pottery results in the destruction of architecture and the desecration of burials. People who want to possess privately the beauty of a Mimbres bowl are advised to purchase some of the well-made replicas available from various sources, including Laurel and Paul Thornburg of Sonoita, AZ.

The End of the Mimbres Pottery Tradition

The style, color, and sizes of the pottery we know as Mimbres changed, more and less rapidly, during the entire period of its production, from at least 750–1150 AD. It became less common by AD 1150, and it was certainly no longer made by the end of the twelfth century. Instead, people in the Mimbres region began using and making an array of different kinds of pottery. An understanding of the end of this famous style provides insights into how archaeologists understand prehistoric peoples. Again, "Mimbres," is a Spanish word, a label we have applied to a river and a style of pottery, among other things. But the decline of the pottery does *not* mean the decline of a people. It simply is yet another example of a style change.

We know, through detailed studies of architecture and radiocarbon dates (Nelson and Hegmon 2001), that people continued to live in the Mimbres region during the time that Mimbres pottery became less common. So why did the style change? Mimbres pottery is unique in the Southwest, and it is reasonable to think that it meant something special to the people who made it. Mimbres villages were among the largest and most densely populated in the Southwest at the time (with the exception of the Hohokam area in southern Arizona). Life in these villages may have been fairly difficult; the Mimbres Classic period was a time of environmental degradation, and eventually drought and subsistence stress (Minnis 1985). The beauty of the pottery is not an indication of the ease of the artists' lives. Rather, Mimbres pottery, especially the elaborate Classic period paintings, may have been part of the tradition of living in large villages, including the hard times.

Beginning by 1130 AD, many people left the villages and resettled in small hamlets, a process known as regional reorganization (Hegmon et al. 1998; Nelson 1999). As people resettled, they developed new social networks and learned about new styles, which they eventually adopted as part of their changing social identities. The new generation chose to make new styles of pottery for new reasons.

Ceramics in Africa

Olivier P. Gosselain

Pottery making is a very ancient craft in Africa, as some of the oldest pottery remains known in the world were discovered on this continent. Dating from around 10,000 BCE – i.e., one or two millennia after the inception of the Jomon pottery in Japan – they were excavated in the Aïr Region of Niger (West Africa) (Haour 2003).

Despite its age, the craft is still alive in many parts of the continent. It has of course witnessed a lot of changes through the centuries, in regard to the forms, functions and decorations of the products, but also in terms of manufacturing techniques, scale of production or the social status of the potters. The last decades have been particularly significant, due to the massive introduction of plastic and metal containers, social and economic upheavals, the development of tourism and urban lifestyle, and the geographic extension of individual movements. In most places, ancient pottery functions such as cooking, handling, and serving have been abandoned, while new categories of products such as ornamental or commemorative vases and bibelots, flower pots, tiles, braziers or incense burners are booming. Water jars, however, continue to be massively produced as they provide the cheaper, or even the only way to keep cool water in rural areas.

Social Background

A comparison of several hundred ethnographic sources[1] indicates that at last four-fifths of the African potters working today are women, confirming the usual description of pottery making in Africa as a female activity. Male potters are also at work in various regions of the continent, where they either specialize in the making of particular vessels (big water jars, elite ware, and bottles) while women make the bulk of the production, produce the whole range of vessels in contexts where women are excluded from the craft, or work together with female relatives, carrying out specific operations such as clay extraction and transport, clay preparation, firing and, above all, plastic decoration (Schildkrout and Keim 1990).

The scale of production is highly variable, ranging from part-time, isolated artisans, whose products are essentially consumed locally, to full-time specialists working in workshops, whose vessels are distributed by middlemen in a 100–200 km radius. If men tend to be proportionally more frequent in the latter category, female potters are also associated with mass production, especially in West Africa.

In many instances, pottery making is open to anyone. All one has to find is someone who is willing to serve as a teacher. This means, in practice, having a close relative, friend or neighbor who engages in pottery making and does not mind spending time with someone who may subsequently become a competitor. But restrictions are also observed throughout the continent, which pertain to age, gender, geographical origin and, above all, socio-professional affiliation. For example, in many Sahelian societies, potters belong to caste-like subgroups such as blacksmiths, bards, tanners, weavers, woodcarvers, hunters, or jewelers (Da Silva Gaspar et al. 2005; Drost 1968; Frank 1998; Gallay et al. 1997; Gosselain 2001; Haaland 1978; Sterner and David 1991, 2003; Tamari 1997). The members of these endogamous specialist groups are associated with specific activities and duties, and distinguished from the remaining population. They are regarded with a mix of awe and contempt by nonspecialists, who often consider them "dirty" and "impure", and fear being harmed by their "power." Due to recent economic changes, however, caste-like structures may become permeable to other social groups in specific places.

Manufacturing Process

There are seven main stages of the pottery manufacturing process (1) clay extraction, (2) clay processing, (3) shaping, (4) decoration, (5) drying, (6) firing, and (7) postfiring. While most of these stages are mandatory, some – such as decoration and postfiring – are optional, although widely recorded across the continent (previous surveys of pottery chaines opératoires in Africa include Devisse 1984; Drost 1967; Gosselain 2002; Krause 1997; Livingstone Smith 1999, 2001b).

[1] Information examined in this article comes from two bodies of data. Since 1990, members of the *Ceramic & Society Project* developed at the University of Brussels, and its research associates have conducted fieldwork in Senegal, Gambia, Mali, Niger, Burkina Faso, Togo, Benin, Nigeria, Cameroon, Chad, and D.R. Congo, collecting information about some 1,000 potters in nearly 100 linguistic groups. The second body of data comes from a systematic perusal of the ethnographic and ethnoarchaeological literature devoted to pottery making in sub-Saharan Africa. These sources are of varying relevance and accuracy as they range from large-scale and detailed studies to more local/regional observations, or mentions in ethnographic monographs, administrative reports, and religious publications. Altogether, more than 700 sources have been processed, which relate to some 550 linguistic groups.

Clay Extraction

Available data indicate that most African potters collect their clay within a 3-km radius from the place where they live and/or practice the craft (see Gosselain 2002: 40–41). Those who exploit sources beyond this threshold generally use animals, cars, trucks, or pirogues (canoes) to carry the clay. Also, they often make stocks that last from several weeks to the whole potting season.

Four categories of extracting techniques are observed in Africa: surface collection, pit extraction, underground gallery, and underwater extraction.

In surface collection, the raw material is extracted on, or just below the surface, either on the ground (plain, fields, dried ponds, or riverbeds), a hill, or the wall of a slope or an embankment. After having eliminated the superficial organic and mineral layer, the potter extracts clay without really digging underground. The operation may be described as "peeling" a clay bed.

Pit extraction consists of digging the ground vertically or diagonally until an appropriate layer is reached. Most pits are some 1 or 2 m deep, and 2 or 3 m in diameter. But they may be as large as quarries, reaching some 15 m deep as in southeastern Nigeria (Nicklin 1979: 349). Variations are observed in the way potters exploit and manage these structures. For instance, some use them until the clay layer is completely exhausted, while others abandon the pit until a specific depth is reached, or as soon as it shows risks of collapsing.

Raw materials may also be extracted from galleries. This type of structure generally starts with the excavation of a vertical shaft. When the access shaft reaches the clay bed, the structure is extended horizontally (Livingstone Smith 2001b; Nwafor 1980; Schneider 1993). Galleries, like pits, are generally abandoned at the end of the potting season, but some may be used several years in a row. In the latter case, only the access shaft is re-excavated each year.

Finally, the rather uncommon technique of underwater extraction has been observed among the Tikar of Cameroon and Punu of Gabon (Gosselain 2002: 52–53). Here, artisans build two small dams in a river, bale out the water and dig the clay before the upstream dam gives way.

Usually, it is while performing other activities, and especially activities which force them to dig the ground (e.g., tending fields, building houses, and digging wells) or to frequent places such as riverbeds or swamps, that potters, members of their family, or any of their acquaintances may "discover" a new source and get the process leading to its possible exploitation under way.

A first requirement is that the clay must have the "right" physical properties; i.e., plasticity, texture, color, and even its taste and odor fit with the personal requirements of the potter (see also Barbour 1989; Brown 1989; Frank 1998; Trowell 1941: 61; Woods 1984: 305). If newly discovered clay is judged suitable, a second requirement is that it must be located nearby the potter's main occupational areas and/or working place. Since pottery making is usually subordinated to other activities, such as farming and domestic tasks, potters tend to restrict their investment in time and energy or, at least, to avoid scheduling conflicts between their different activities. Sources located nearby living or working sites, fields, rivers frequented for fishing, roads, or tracks, are therefore more likely than others to be selected and subjected to long-term exploitation. In fact, about 90% of the hundreds of sources that we visited in sub-Saharan Africa were situated nearby or within sites used primarily for other activities. Such a situation has an obvious impact on clay exploitation strategies. More importantly, it shows that clay extraction sites are not distributed randomly or according to a specific logic, but are an integral part of the overall territory frequented by both potters and nonpotters.

Finally, the selection and exploitation of clay sources are also surrounded by a series of rituals and taboos (Barley 1994; Berns 1993; Drost 1964; Gosselain 1999; Herbert 1993; Pinçon 1993). For instance, certain persons are systematically kept aside from the extraction site or the places were the potters store and manipulate the clay: men if the craft is practiced by women, women in other contexts, uninitiated people, members of other social groups than the potters, little girls or boys, pregnant women, menstruating women, twins, warriors, etc. Likewise, artisans must avoid doing particular things on the eve of extraction, during the trip to gather clay or at the site: e.g., having sexual intercourse, talking, singing, swearing, urinating, manipulating certain objects, eating particular food, etc. Rituals and sacrifices (i.e., food offering) may also be performed at the extraction site, a practice still widely recorded in Muslim societies.

Clay Processing

As in most places around the world, African potters never use the clay in its raw state but prepare it in one way or another. While processing practices are usually very simple, they may also involve complex combinations of techniques. These may be grouped into four main categories: pretreatments, removal of nonplastics, addition of nonplastics, and homogenization.

Pretreatments usually involve leaving the raw materials to dry, soak or sour for some hours, some days, some weeks, or even some months. Soaking is usually done in a pit, an old jar or a plastic container, and used when clay is extracted in a dry state. Its aim is to allow the material to regain its plasticity. If clay is already wet, the aim may be to give it a better workability through increasing the amount and distribution of water between particles and pores. A long soaking time may also help in increasing plasticity through pH alteration and the subsequent flocculation of clay particles, but such souring process seems quite rare among African potters.

When the clay is appropriately dried or soaked, a series of techniques may be used to remove undesirable nonplastics. The most common way is hand sorting, as potters always remove coarse impurities such as pebbles, roots, or leaves at some point during the process. But there are several other ways of controlling clay composition and texture. For example, potters may pound the clay with a stone or a wooden hammer on a stone, or they may simply pound it in a wooden mortar, grind it with lower and upper grinding stones, or grind it on a rock. Finally, nonplastics may be removed by sieving with baskets, pierced calabashes, or imported nylon meshes. Potters may also remove the coarser fraction of nonplastics by shaking the crushed raw materials in a calabash or by winnowing it with a winnowing basket or a calabash. A last technique, levigation, is quite rare in Africa. Here, the material is mixed with water until it reaches a colloidal state, the larger particles are retrieved at the bottom of the container, and the water is allowed to evaporate (David 1983; Gallay and Sauvain-Dugerdil 1981).

Generally called tempering, the addition of plastic or nonplastic elements to the clay may be done with a great variety of materials: another clay (or several clays), dust, organic rich earth (soil), mud, termite heap clay, sand, gravel, rocks (calcareous rocks, gneiss, schist, and asbestos), iron stone, grog (crushed, grounded, and/or sieved potsherds; Fig. 1 – by far the most common material), fired earth, ash, straw, cereal husks, grass, stems, bark, dung (horse, cow, goat, or donkey), shells, calcareous solution (grounded and sieved calcareous rock mixed with a large amount of water; Sall 2001), or bark decoction.

The last processing step generally consists in a thorough homogenization of the paste. This operation is mandatory in clay processing and has a determinant impact on clay workability. It may be done in different ways: kneading with the hands, trampling with the foot, or pounding with various kinds of tools and supports (the most current of which are mortars and pestles, lower and upper grinding stones, and handles of diverse farming tools). If one considers the different combinations of these four categories of treatments, as well as the diversity of behaviors, postures, and tools, there are probably hundreds of ways of preparing the clay.

Potters usually explain that they act the way they do because of “tradition” (i.e., the way they have been taught), but also because vessels made with a clay prepared differently would not survive the drying or firing stages, or would break during utilization. Such conceptions explain why some potters use different processing techniques according to the intended function of vessels, or according to vessel parts. Among the Koma-Gimbe of Cameroon, for example, potters simply pound the clay when making small vessels, but add sand when making large beer brewing jars. They explain that jars would crack when drying if

Ceramics in Africa. Fig. 1 Pounding sherds in wooden mortars for making grog. Note that tools and postures are identical to those used in the realm of food preparation (photo by Olivier Gosselain).

they did not do so (Livingstone Smith 2001b). Others examples of the use of different processing recipes have been collected elsewhere in Africa (Gallay and Sauvain-Dugerdil 1981; Herbich and Dietler 1991; Nicholson 1929; Tobert 1984; Trowell 1941). Most commonly, however, potters use the same preparation technique, whatever the intended function of the vessel.

Another factor that explains the local use of particular processing techniques is the existence of ties to techniques used in other realms of activity, such as food processing and agricultural practices. For instance, staple foods and clay may be prepared with the same tools and gestures, and according to the same recipes. In the Bariba village of Tourou (Benin), for example, potters pound the clay in a wooden mortar and separate the fine and coarse fraction by shaking the material in a calabash. Then, they pound the coarse fraction a second time, and let it soak in a jar placed in the sun. When the liquid is sufficiently thick, it is sieved through a pierced tin can and mixed with the fine fraction of the raw material. Potters explain that this mixture acts as “cement” and that the best millet porridge is obtained in a similar way. Similarly, the clay desalinization technique observed among certain Jola Kasa potters of Casamance echoes, the practices for agricultural land preparation in mangrove swamp zones (Sall 2001).

Symbolic or religious concerns may also influence clay-processing strategies. For example, some Boko potters of Benin take great care in extracting all rootlets from the raw material. This is because rootlets are used to prepare a medication that prevents potters from “swelling” when fashioning vessels. Some West African potters often recycle archaeological sherds into grog, as they consider this material to possess particular qualities because “ancestors knew how to make stronger pots,” or because “what has lain underground is stronger than what lies on the ground” (Da Silva Gaspar et al. 2005; Livingstone Smith 2001b). Another example comes from Tukulor potters of Senegal who stop putting dung in the clay when they settle in Soninke communities since the latter consider dung impure (Gelbert 2001).

Shaping

In most instances, shaping techniques may be divided into two specific operations that differentiate both in their purpose and the set of tools and gestures used to carry them: (1) roughing out and (2) preforming. During roughing out, potters transform a lump of clay and/or joint pieces of clay together in order to constitute a hollow volume – the rough shape – whose form, often cylindrical, has not yet reached that of the finished product. During preforming, potters give the hollow volume its final geometric characteristics through scraping and smoothing operations, with the help of a series of tools.

Wheel throwing – not considered here – is only documented in North Africa, where it has been practiced for centuries by male potters. South of the Sahara, only passing references are made to the use of wheel throwing by a few male potters in the Lower Congo area. The technique would have been introduced by Portuguese in the late seventeenth century (Vincentelli 2003: 44), but given the lack of precision, it is not clear whether it is still practiced as such by Kongo potters or has been modified.

Roughing Out

Techniques used in sub-Saharan Africa belongs to seven main categories (1) pounding in a concave form, (2) drawing of a ring-shaped lump, (3) superimposition and drawing of large rings, (4) molding (on concave or convex molds), (5) pinching, (6) drawing of a lump, and (7) coiling. As the last three techniques are widely documented outside Africa, only the first three will be considered here.

The pounding technique – also called “tamper and concave anvil technique” – consists of placing a lump or a pancake of clay on a mat-covered depression or a concave anvil made in wood, clay or stone, and beating it with the fist, a wooden pestle or, more generally, a stone or a clay tamper (Fig. 2). Continuing with rhythmic beating, the potter rapidly obtains a concave form that he/she turns continuously on the anvil or the depression while beating the clay. This technique is used throughout the Sahel, from Mali to Egypt (Drost 1967; Gosselain 2001; Huysecom 1992; Sterner and David 2003).

In the drawing of a ring-shaped lump, the potter fashion a ring of 20–60 cm in diameter with one or several slab(s) of clay, and pulls its wall up with the help of the fingers (Krause 1985; Lawton 1967; Livingstone Smith 1999, 2001b; Roy 1989). In most cases, the lower part of the vessel is fashioned later with coils or a pancake of clay, after the upper part has been preformed and is sufficiently dry to be put upside down. In a variant observed in western Cameroon, the bottom part is made before the upper one (Nyst 1996).

The superimposition and drawing of large rings is similar to the previous technique, except that the initial volume is made with two to eight crown-shaped rings of clay which are superimposed and carefully joined together. So far, the technique has only been recorded in the southeastern part of Central Africa, among several Bantu-speaking groups (Lorenz and Plesner 1989; de Maret and Bulckens 1978; Woods 1984).

The seven techniques mentioned above are seldom used as such by African potters. The shaping of medium to large vessels usually involves the combination of the last two of these techniques, with the consequence that a detailed comparison of actual shaping processes allows one to identify more than 50 variants across the continent.

Ceramics in Africa. Fig. 2 Shaping a vessel with the pounding technique, on a concave wooden anvil with a clay tamper (photo by Olivier Gosselain).

Compared to clay extraction and processing, the most striking aspect about the roughing out process is that it is based mainly on movements. While techniques such as molding and pounding require special tools and devices, it is especially the artisan's hands and fingers that are in action during the major part of the shaping process. The movements employed are also distinctive because of their relatively specialized character: few ties exist to other activities and only body postures (for example, working while standing bent over, seated with legs spread, or with one leg folded in front) find an echo in domains other than pottery making.

This preponderance of specialized gestures has been identified as a crucial factor for explaining the usual stability of shaping technique through time and space and its possible coincidence with major social boundaries such as language, socio-professional groupings, or political units (Gosselain 2000, 2002; Wallaert 1999). Their mastery involves a close interaction between two individuals and a training period that may span over several years, so that motor habits would be more resistant to change than other stages of the manufacturing process. Recent studies have showed, however, that borrowing processes also affect the shaping stage (Gelbert 2001; Sterner and David 2003). Another way of explaining stability in shaping techniques is that they are widely viewed by potters as an inheritance and a material correlate of social boundaries. Stability could thus be deliberately sought, as among the Songhay blacksmiths of Niger who acquired the molding technique from their Bella neighbors (considered as former slaves), but have chosen to pass on the pounding technique to their daughters, the later being regarded as the "true Songhay technique."

Preforming

This stage, which is carried out as a continuation of roughing out, consists of giving the just constituted hollow volume its final geometric characteristics. To this end, potters perform scraping and smoothing operations, with the help of a series of tools, which allow them to distort the wall of the vessel gradually to the desired curvature by applying pressure.

In order to round the body and make it bulge, potters scrape the outside and inside walls and modulate the pressure exercised on the tool, while supporting the wall with the other hand. Tools used for scraping the inside wall are generally round or spherical: rounded off pottery sherds, pieces of calabash, pods, large seeds, nuts, shells, or spoons. Moved horizontally or obliquely, they do not generate much displacement of clay since internal scraping aims essentially at modifying the shape of the body. Scraping and smoothing operations made on the outside wall, on the other hand, allow the potter to mask irregularities and to heighten the vessel through the displacement of a rather large amount of clay. Such operations are typically carried with flat and oblong tools such as flat sticks, spatulas, bones, blades, pods, shells, or corncobs.

Forming the neck may be done with different methods, either as a continuation of preforming the body or after having added one or several coil(s). A first method consists of bending the upper part of the wall through horizontal smoothing of the inside wall. In this case, the potter exercises increasing pressure on the smoothing tool, while supporting the wall with the other hand, until the appropriate curvature is reached. Another method consists of smoothing the outside wall of the vessel horizontally with a tool whose curvature

Ceramics in Africa. Fig. 3 Forming the neck and the lip of a vessel with the fingers. A constant pressure is exerted on the wall while the vessel is rotated slowly with the other hand (photo by Olivier Gosselain).

corresponds to that of the neck. Rounded off sherds or calabash pieces are typically used to that aim. A later method consists of pinching the rim between fingers (directly or with the help of a leaf, a rag, or a piece of leather) and rotating the vessel slowly with the other hand, while exerting a constant pressure on the rim and progressively tipping up the hand toward the exterior (Fig. 3).

Finally, lips may be formed through constant pressure between fingers – or with the help of any supple material – as in the neck-forming method described above. Depending on the position of fingers, the pressure exerted and the materials used, resulting lips may acquire a rounded or sharp profile, or bear a groove. The rim may also be shaped through smoothing with a flat or slightly concave tool such as a spatula, a stick, a bone, or the nervure (principal vein) of a large leaf. Here also, the potter usually rotates the vessel while exerting a constant pressure on the tool, placed perpendicularly on the rim. Instead of rotating the vessel, the tool may be displaced itself on the rim, especially when shaping the lip of large and heavy vessels. A last method consists of adding one or several coil(s) above the rim or on its side, and smoothing it with fingers or a supple material.

The very personal character of the preforming operations described above must be stressed. Minute variations in profiles – the shape of the neck, lip, handle, or base – are also likened to "signatures," which can be recognized as readily by eye as by touch (Gosselain 2002: 113, 115).

Another striking characteristic of the preforming stage is its permeability to innovation and outside influences. From simple widespread forms, artisans seem to be able easily to meet new requests (flowerpots, moneyboxes, stills, and incense holders) or to modernize the aspect of their products (Argenti 1999). This explains the current appearance of a new generation of flat-bottomed pots fitted with handles, faithful copies of the aluminum pans produced in urban environments. The realization of such products may allow a few individuals to position themselves as experts and agents of modernity.

Decoration

Plastic decorations – i.e., made when the clay is still wet – belong to four large categories (1) grooving, (2) incising, (3) impressing, and (4) appliqué.

Grooving consists of tracing lines or figures on the surface of the vessel with the fingers or various tools whose end(s) is/are rounded or sharp: sticks, stalks, thorns, ends of calabash scrapers, sharp stones, bones, shells, nails, bicycle spokes, bracelets (drawn on the surface), bundles of stalks or thorns held between finger or driven into a clay ball (Fig. 4), hair combs, and indented pieces of calabash, wood, plastic, or metal.

Incising is similar to grooving, except that the tools used have a sharp cutting edge so that clay surfaces are actually incised. Such tools include knives, spearheads, and scraps of metal.

Impressing is done with distinct tools and methods. The simplest is to press any kind of device or material (fingers, natural objects, sticks, combs or carefully designed wooden or iron stamps, as those used in the Inland Niger Delta; Gallay et al. 1998), in order to make a single impression that may be subsequently repeated on the surface. Another method consists of pressing while simultaneously rocking convex devices such as blades or indented combs and bracelets, so as to obtain zigzag-like rows of impressions. "Rouletting" is

Ceramics in Africa. Fig. 4 Decorating a vessel with a comb-like device (photo by Olivier Gosselain).

a third impressing method, done either with natural objects such as corn cobs, shells, fish vertebrae and various plant parts, or, more generally, with tools made by carving wood or twisting, knotting, braiding, coiling, or wrapping fiber strips or cords (see examples in Gosselain 2000; Soper 1985). Such tools and materials are rolled on the vessel's surface to impress regular patterns.

Appliqué comprises all types of clay elements added onto the surface: e.g., coils, buttons, spikes, and human or animal figures.

Besides plastic decoration, vessels may also be ornamented with painting and/or specific surface treatments. The most usual treatment consists of applying a slip made from iron-rich clays, crushed beforehand on a stone or in a mortar, and subsequently sieved and diluted in water. The application is made on a dried surface, directly with the hand or with a rag. In many instances, slipped surfaces are then carefully polished with round stones or strings of seeds (mostly from baobabs) or cowries. The resulting effect, after firing, is a dark red and shiny surface. Polishing may also be done on unslipped surfaces or with graphite, as among several South African populations (Bell and Calder 1998; Lawton 1967).

Painting occurs either before or after firing, the first being widespread on the continent, the second especially observed in South Africa or on modern ornamental vessels aimed at tourist or city markets. Prefiring painting is done with various mineral pigments diluted in water and occasionally mixed with gum Arabic, salt or sugar, all elements that are said to "strengthen" the adherence. The application is made with a feather, a millet ear, a stalk, or a stick with a crushed or rag-wrapped end. In southwestern Niger, Bella and Zarma potters use a blade for drawing thin lines and motifs (Fig. 5). Postfiring paintings are made with industrial paints and inks.

Regardless of the techniques, tools, and materials used, a striking feature of decoration is the casual way in which most potters talk about it. Decoration would be a matter of "simple embellishment," "like a hairstyle or clothes," the main function of which is to "attract the customer's eye." In some cases, even the esthetic function of decoration is questioned, as when potters explain that roulette impressions are simply a matter of modifying wall texture to prevent wares from being slippery (Bredwa-Mensah 1996; Priddy 1971).

This does not mean that artisans work with no references or precise rules. On the one hand, pottery decoration is generally only one realization among others in a much broader decorative system. For example, the existence of numerous parallels has been found between vessel ornamentation and tattooing or scarification (Barley 1994; David et al. 1988; Ritz 1989), and parallels also exist with architecture, certain technical devices such as cast iron ovens, or other containers (baskets, gourds, and aluminum pots). On the other hand, while decoration is obviously very susceptible to innovation (e.g., the current generalized use of letters of the alphabet in the painted decorations of West Africa), change is seen to particularly affect the components of decorations rather than their organization or "grammars." Some think that it would be at this second level that the symbolic function of decoration comes into play and that collective identities would express themselves (David et al. 1988).

Drying

A comparison of data indicates that there are no "rules" as regards drying modes and duration. For instance, some potters deem it necessary to place the wares in the

Ceramics in Africa. Fig. 5 Applying a mineral paint with the help of a blade (photo by Olivier Gosselain).

sun during the early stage of drying, while others take great care to shelter them during the first hours, the first days, or even the whole drying process. Similarly, some may wait several weeks or several months before firing the vessels, while others do it after 2 or 3 days. While drying periods are often shorter in the Sahel than in tropical areas, differences in practice appear to proceed essentially from personal conceptions and ways of scheduling manufacturing operations, rather than climatic variations or the chemical and physical characteristics of raw materials. Thus, potters who make vessels on demand or frequent weekly markets generally resort to short drying periods. If necessary, wares cracked from too fast a drying are simply repaired with fresh clay.

Such flexibility in drying procedures is due, in part, to the accommodating nature of the raw materials used in Africa. But it may be reinforced through the use of prefiring techniques that allow the gradual evaporation of residual water through preheating. For instance, pots may be placed around or above a cooking earth (Gosselain 2002: 145–146; Priddy 1971; Woods 1984), on glowing embers (Kanimba and Bellomo 1990; Mercader et al. 2000) or a rack-like structure below which a fire is kept going, as among several Kongo groups from Central Africa (de Maret 1974; Mpika 1986).

Firing

Although the emphasis will be put here on fuels and structures, several other aspects of firing may be taken into consideration, including the scheduling of firing events, the location of firing structures, the way vessels and fuel are positioned within the structure, the overall firing schedule (duration, refueling, way of assessing the degree of firing of the wares), or the identity of people taking part in the operation.

Fuel

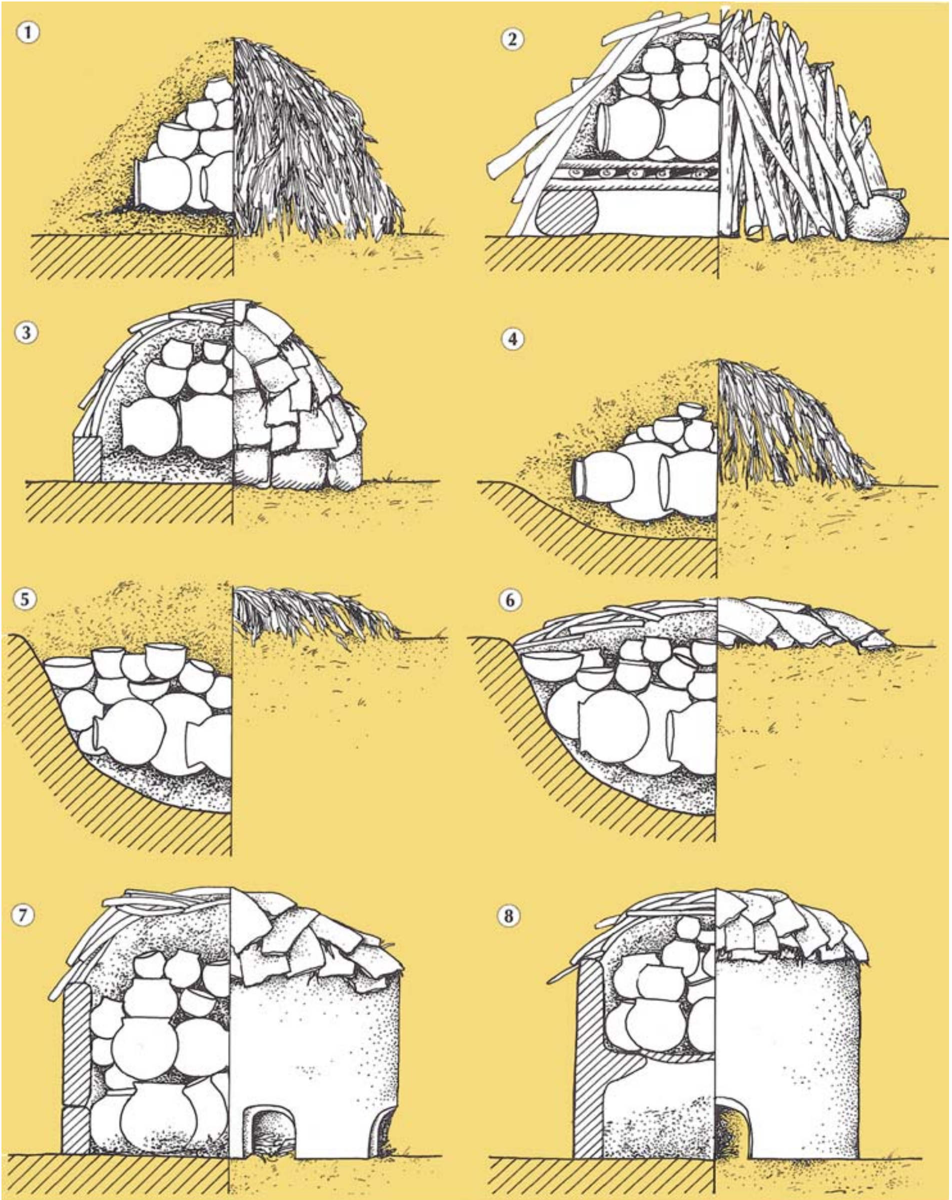
As summarized by Livingstone Smith (2001a: 993), almost everything that can be burned is used for firing pottery in Africa. Used independently or combined in various proportions, the materials may be grouped into three categories corresponding roughly to those made by the artisans themselves when asked about the nature of "appropriate" and "inappropriate" materials (1) manure – cows, donkeys, camels, or horses; (2) "light" fuels – dry grass or cereal stalks, cereal chaff, palm fronds, leaves, twigs, barks, or roots; and (3) "heavy" fuels – branches and logs from dozens of tree species.

Neither the firing structure nor the firing conditions possibly sought by potters seem to impose restrictions on the selection of fuel materials. With the notable exception of manure, whose combustion is slower, all the fuels used throughout Africa allow potters to obtain similar firing schedules and temperatures.

Structure

Eight firing structures are documented in Africa (see details in Drost 1967; Gosselain 2002: 153–162) (1) bonfire, (2) elevated bonfire, (3) bonfire with isolation, (4) depression, (5) pit, (6) pit with isolation, (7) oven, and (8) updraft kiln (Fig. 6).

The bonfire – also called "open firing" – is one of the simplest and most widespread technique in Africa. Pots are placed on a bed of fuel, at ground level, and covered with another layer of fuel. Those structures vary tremendously in dimension (50–250 cm in height and 50–700 cm in diameter), firing duration (from



Ceramics in Africa. Fig. 6 Firing structures used in Africa (1) bonfire, (2) elevated bonfire, (3) bonfire with isolation, (4) depression, (5) pit, (6) pit with isolation, (7) oven, and (8) updraft kiln (drawing by Yvette Paquay).

20 min to several hours), as well as the number of vessels fired at once (from 1 to 500). This number depends both on the stock of wares available at the moment of firing and on the personal conceptions of the potters. For example, some Gbaya potters from Cameroon deem it impossible to fire more that one to three vessels at once. They thus multiply firing sessions or construct several bonfires side by side.

Elevated bonfires have only been recorded so far in the Great Lakes region, among the Twa of Burundi and Rwanda and the Konjo of Uganda (Célis and Nzikobanyanka 1984). The technique consists of placing the vessels on an elevated bed of fuel constituted of a rack-like layer of branches placed on four or five big stones.

Bonfires with isolation differ from simple bonfires in that a layer of fireproof materials – sherds, old basins, and sheets metal – is placed either between the vessels and the upper layer of fuel or upon the whole structure. In the first case, the aim is to avoid color variations due to contacts between fuel and the surface of vessels; in the second, it is to protect the structure from the wind and keep the fuel in place.

Depressions are shallow excavations made in the ground (between 20 and 40 cm depth) in which vessels stand higher than ground level after having been placed on the bed of fuel. Their shape is circular, oval, or rectangular, with diameters (or sides) between 100 and 500 cm. As for the bonfire technique, important variations are observed in the number of wares fired at once and the duration of the firing. Variations also exist in the way vessels are positioned within the structure. For instance, while most potters place them horizontally or vertically, some place them upside down on the bed of fuel, in order to obtain a dark and shiny internal surface (Zaghawa of Sudan (Tobert 1984) or Hausa and Kanuri of Niger).

What differentiates pits from depressions is the fact that vessels stand below the ground surface after having been placed on a bed of fuel. Thus, their depth always exceeds 50 cm and may reach as much as 100–150 cm, for a diameter between 50 and 400 cm. Another difference pertains to the duration of the firing, often observed to be several hours long. In a variant observed among Bamileke fe'fe' from western Cameroon (Gosselain 2002) and Kongo Manyanga from Kongo (Mpika 1986), the wares are placed on a rack-like wooden structure standing above the pit and carefully tipped in the hole in the course of firing.

Pits with isolation resemble bonfires with isolation in that a layer of fireproof materials is placed either on the vessels or on the upper layer of fuel. This technique is often used in southern Africa (Lawton 1967; Krause 1985), but also in the Sahel area, from Senegal to Sudan. Here, firing is usually a whole night long, even though the fire actually burns for a few hours.

Ovens correspond to wall-enclosed firing structures within which fuel and vessels are put together. Such structures have only been documented in West Africa. Their walls are made of mud, with a height between 50 and 180 cm, and a diameter between 100 and 400 cm. One or several holes is/are made at the base of the wall, through which fuel is put in during firing. From 20 to 200 vessels are fired at once, which are piled and subsequently covered with fuel and/or a layer of sherds. Burning stalks or grasses are then put in the hole(s), either at the beginning or throughout the whole firing. A simpler oven technique, observed among some Yoruba of Nigeria (Fatunsin 1992: 39–40) and Bariba of Benin, consists of using a bottomless jar placed on mud bricks upon a small fire. Such technique is only used for firing small vessels.

Updraft kilns are even more rare than ovens, as they would be used in Nigeria only, among Nupe of Bida (Nicholson 1934; Vernon-Jackson 1960) and Yoruba of Abeokuta (Fatunsin 1992). The firing structure is also enclosed in a mud wall, but fuel is put in a distinct chamber and separated from the vessel with sherds or a perforated clay plate.

As stated above, measurements performed in the field show that the variety of fuels and structure used results, paradoxically, with a considerable homogeneity of firing conditions. Whether it is a question of temperature rise, temperatures reached, or the duration of exposure at temperature thresholds, each variant makes it possible to achieve the same global results (Livingstone Smith 2001a). This homogeneity in firing conditions is echoed by the way in which potters judge the degree of pottery firing; most of them interrupt the process or stop refueling when the wall of the pots becomes incandescent.

As regards relationships to other activities, certain similarities exist with cooking techniques (Gosselain 2002: 165). However, an activity such as metallurgy, a priori much closer, maintains no link with pottery making, even in societies where blacksmiths and female potters belong to the same endogamous subgroup. The fact that these two activities are practiced by different actors seems to present an obstacle to transfer. At the same time, firing is surrounded by a series of prescriptions and prohibitions, but these are less numerous than at other levels of the operating chain and do not seem to have much influence on the artisan's technical behavior. They mainly concern avoiding the situation in which badly intentioned people or those in impure states jeopardize the operation solely by their presence.

This worry stems from the generally public and collective character of the firing stage. In most regions of Africa, artisans habitually associate with relatives, friends, or neighbors for firing their wares. These associations have several advantages; they not only allow artisans to invest less effort in gathering fuel, organizing wares, or sharing in firing surveillance, but they also allow artisans to conform to a restrictive firing calendar (for example, weekly markets) when placements reserved for the operation are few in number.

Postfiring

In many regions of Africa, vessels receive a last treatment after firing, either when retrieved red hot from the fire or after having cooled off. These postfiring treatments, that aim at improving the physical characteristics and appearance of vessels, may be grouped into five categories (1) organic coating, (2) resin application, (3) smearing, (4) smoking, and (5) water sprinkling or soaking.

Organic coating is by far the most common treatment. It consists of coating the surface with an organic mixture made from the bark, fruits, leaves, branches, or root parts of several dozens of tree species, the most common of which are *Bridelia* *ferruginea*, *Bridelia micrantha*, *Parkia biglobosa*, *Parkia filicoidea*, *Diospyros mespiliformis*, *Ximenia americana*, *Pterocarpus angolensis*, and several species of *Acacia* and *Syzygium* (see details in Drost 1967: 174–182; Gosselain 2002: 184–190). After having been crushed, the part used is soaked in water for several minutes, several hours, or several days. It may be boiled (decoction), put into hot water (infusion), or kept at ambient temperature (maceration). As for the application, it is done by plunging the hot vessels in the mixture, sprinkling them with it, or smearing the surface with the help of a series of brush-like tools. Alternatively, cooled off vessels may be coated with the help of a rag. Besides having a decorative purpose, organic coatings are said to strengthen and waterproof the vessels.

Resin application is solely aimed at waterproofing the vessels. Here, the inside surface is coated with resin extracted from several tree species – e.g., *Canarium schweinfurthii*, *Copaifera demeusei* or *mildbraedii*, various *Acacia* species, *Euphorbia candelabrum*, *Dodonea viscosa*, and *Guizotia abyssinica* – either by melting it directly in the vessel or separately. In both cases, the vessel is rotated rapidly so as to ensure a homogeneous surface coating.

Other organic materials may also be smeared on the surface or cooked in the vessel in order to strengthen or waterproof them: leaves of *Ricinus communis* or *Sida rhombifolia*, oil or sap from *Raphia vinifera* or *Elaeis guineensis*, fruits, fibers, roots, cereal husks, milk, porridge, or cow dung (see examples and details in Gosselain 2002: 191–192).

Smoking aims at covering the vessel surface with wood tar in order to give it a black shiny aspect and, according to some potters, improve their strength and imperviousness. To that aim, vessels retrieved red hot from the fire are usually buried in organic materials such as grass, maize spaths, cereal husk or chaff, animal manure, fruit pods, bark or wood shavings (see examples in Gosselain 2002: 192–193). Another technique, observed in the Great Lakes region, consists of maintaining vessels above a fire made of grass, plantain leaves, or reeds (Trowell 1941).

Lastly, vessels may be plunged in, or sprinkled with, fresh water or boiling water (see examples in Gosselain 2002: 193). Here again, the aim would be to waterproof and strengthen the wares.

As with clay preparation or firing techniques, artisans generally have a very clear-cut opinion about the ingredients that it is advisable to select and the way to prepare them. These opinions are extremely divergent. In sub-Saharan Africa, about 50 plants are currently used for making organic coatings, as we have seen above, but few potters know about more than one and each potter believes there is no alternative to his or her choice. Similarly, those who prepare their coating in decoction or maceration form and apply them hot or cold consider it inconceivable to proceed otherwise. In reality, all choices are perfectly justified from the point of view of technical and esthetic aims. An analysis of the various fruits and barks used in certain zones of sub-Saharan Africa indeed reveals the presence of one same category of tannins, the procyanidins, which have excellent coloring and waterproofing properties (Dialo et al. 1995).

In general, the most striking aspect of the postfiring stage has to do with its numerous relationships to other spheres of activity. Thus, most of the plant types that artisans select are used for diet, leather dyes, fabrics or baskets, wall and pavement waterproofing and, above all, pharmacopoeia. This last domain is particularly interesting as the illnesses and injuries treated with the help of the same preparations that potters use are characterized especially by discharges (Gosselain 1999, 2002: 197–198, 210–211): various wounds, diarrhea, gonorrhea, hemorrhage, menorrhagia, ulcers, etc. Use of these preparations also appears during birth and circumcision rites. What we find at work, here, is simply the materialization of an extremely widespread association between pottery making and human beings (Barley 1994; David et al. 1988; Gosselain 2002: 205–208; Ritz 1989). And since treating a pot or treating a body are related activities from a symbolic point of view, a strong channeling of behaviors can occur when selecting ingredients or preparation modes.

This fact illustrates perfectly why a *chaîne opératoire* cannot be reduced to mere actions on matter. As stressed by Lemonier (1991) and several other scholars, techniques do not solely aim at transforming materials or acting upon the material world. They also respond to a series of social, political, economical, and symbolic concerns, whose components may be found at any level of the manufacturing process as we have seen throughout this article.

Ceramics in China

Jiazhi Li, P. L. Leung, K. N. Yu, R. Wu

China was one of the earliest countries that possessed pottery, and was also the country that invented porcelain. She has a unique and sustained history of technique development of 10,000 years. The entire development can be summarized by five milestones and three technological breakthroughs. The outstanding achievements in this development constituted an indispensable contribution to Chinese culture (Table 1 and Map1).

Five Milestones

The First Milestone: Appearance of Pottery in the Early Neolithic Age

According to archeological information, after the discovery of potteries of the Yangshao culture, the following were discovered:

- Those of the Hemudu culture in Yuyao, Zhejiang Province about 7,000 years ago
- Those of the Cishan culture and the Peiligang culture about 8,000 years ago
- Those of the Pengtoushan culture in Li County, Hunan Province and the Jiahu culture in Wuyang County, Henan Province about 9,000 years ago
- Those at the Yuchanyan site in Dao County, Hunan Province, the Xianrendong site in Wannian County, Jiangxi Province, and the Nanzhuangtou site in Xushui County, Hebei Province about 10,000 years ago

Neolithic period	**6500–1700 BCE**
Xia	2100–1600 BCE
Shang	1600–1100 BCE
Western Zhou	1100–771 BCE
Spring and autumn annals	770–476 BCE
Warring States	475–221 BCE
Qin	221–206 BCE
Han	206 BCE–AD 220
Three Kingdoms	220–280
Jin	265–420
Southern and northern	420–581
Sui	581–618
Tang	618–907
Five Dynasties and Ten Kingdoms	907–960
Sung	960–1279
Yuan	1279–1368
Ming dynasty	**1368–1643**
Hongwu	1368–1399
Jianwen	1399–1403
Yongle	1403–1424
Hongxi	1425–1426
Xuande	1426–1435
Zhentong	1436–1450
Jingtai	1450–1457
Tianshun	1457–1465
Chenghua	1465–1487
Hongzhi	1488–1505
Zhengde	1506–1521
Jiajing	1522–1566
Longqing	1567–1572
Wanli	1573–1619
Taichang	1620–1621
Tianqi	1621–1627
Chongzhen	1628–1643
Qing dynasty	**1644–1911**
Shunzi	1644–1661
Kangxi	1662–1722
Yongzheng	1723–1735
Qianlong	1736–1795
Jiaqing	1796–1820
Daoguang	1821–1850
Xianfeng	1851–1861
Tongzhi	1862–1874
Guangxu	1875–1908
Xuantong	1909–1911

The raw materials for early pottery were all obtained locally. In particular, a common feature for the pottery of about 10,000 years ago is that they were all coarse sandy pottery with coarse and loose textures, so most of them were only small shards when unearthed, and only very few whole pieces could be restored. Their firing temperatures were about 700°C. For examples, pottery from the Nanzhuangtou site in Xushui County contained big grains of hornblende and vermiculite (Fig. 1), and pottery from the Xianrendong site in Wannian County contained large grains of quartz, dickite, and muscovite (Fig. 2; Li et al. 1996). This also explained why the pots from the Nanzhuangton site contained more calcium oxide (lime, CaO) and magnesium oxide (MgO), and those from the Xianrendong site contained more silicon dioxide (SiO_2) and potassium oxide (K_2O). In this way, the amounts of calcium oxide and silicon dioxide can be used as characteristic constituents to differentiate between pots manufactured in the northern part and those manufactured in the southern part of China. The microstructure of the black pottery including charcoal from the Hemudu culture was rather peculiar (Li et al. 1978) and is shown in Fig. 3.

The Second Milestone: Successful Firing of Stamped Hard Pottery in the Late Neolithic Age and Appearance of Proto-Porcelain in the Shang–Zhou Dynasty

It is generally accepted that stamped hard pottery first appeared in the late Neolithic age about 4,000 years ago (which could be regarded as the Xia period according to dating results) and that proto-porcelains first appeared in the Shang dynasty. Stamped hard pottery had lower contents of iron oxide (Fe_2O_3) than general potteries. The firing temperature was above 1,000°C, and the maximum temperature could reach 1,200°C. Proto-porcelains had even lower iron oxide content; they were in general below 3%. The highest firing temperature reached 1,280°C. There were glaze layers of nonuniform thicknesses on the interior as well as the exterior surfaces of proto-porcelains. The glazed layer could be a green glaze with a grayish green or yellowish green color, or a yellow glaze with a greenish yellow or brownish yellow color. Generally speaking, the glaze was not tightly bonded to the body and could be easily delaminated. The glaze contains relatively high contents of calcium oxide, and is thus called *calcium glaze*. This kind of glaze is a unique high-temperature glaze created in China and is the earliest high-temperature glaze in the world (Fig. 4; Li et al. 1985).

The Third Milestone: Appearance of Green-Glazed Porcelain (Celadon) in Southern China in the Han–Jin Dynasty

The successful firing of the southern green-glaze porcelains, represented by the Yue wares in Zhejiang Province during the late East Han dynasty (AD 25–220), signified another leap in the development of ceramic technique in China. Porcelains first appeared in the world from this period.

Ceramics in China. Fig. 2 Microstructure (350×) of sandy pottery from the Xianrendong site in Wannian County, Jiangxi Province.

Ceramics in China. Fig. 3 Microstructure (165×) of black pottery including charcoal of the Hemudu culture in Yuyao, Zhejiang Province.

Ceramics in China. Fig. 4 Microstructure (140×) of an early proto-porcelain of Western Zhou dynasty from Jiang Shan, Zhejiang Province.

Porcelain differed from pottery in that the porcelain appeared to be stronger and more compact. Most were white; some had a grayish tint. Their cross-sections had a glass-phase luster and the thin layer was slightly translucent. They had relatively high contents of silicon dioxide and aluminum oxide (Al_2O_3) and smaller amounts of fluxing agents; they could be fired at higher temperatures and had higher strength. The porosity as well as the water absorption rate was very small. As regards their microstructure, they contained relatively larger amounts of glass phase as well as a certain amount of Mullite crystals. The quartz remnants were small and rounded. The appearance, chemical composition, physical properties, and the microstructure described above are the characteristics of porcelain. Yingxing Song (a famous scientist in the Ming dynasty) describes them as having the "…appearance of white flesh and jade skeleton" in his publication *Tian Gong Kai Wu* (Exploitation of the Works of Nature).

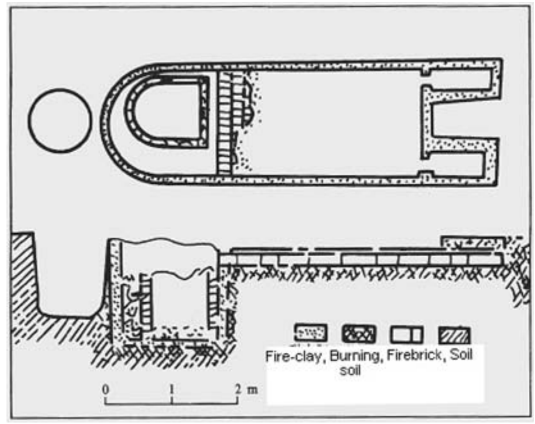
The success of green-glaze porcelains in southern China was primarily attributed to the rich reserve of China stone in the southern part of China. Since at that time only China stone was used as the raw material for porcelain, this led to the early quartz–muscovite series of porcelains with high silicon and low aluminum contents in southern China. The success of green-glaze porcelains could also be attributed to the techniques derived from extensive experience in firing the stamped hard pottery as well as the proto-porcelains.

We use as an example the shard from a green-glazed stamped *Ci Lei* (porcelain drinking vessel) unearthed from the Yue Kiln in Xiaoxiantan, Shangkyu, Zhejiang Province. The iron oxide and the titanium dioxide (TiO_2) contents in its body and glaze are relatively lower, and the titanium dioxide content in the glaze is particularly low. The firing temperature reached 1,300°C. The body contains relatively larger proportions of the glass-phase. The quartz remnants are small and uniform, while Mullite crystals are ubiquitous. The glaze layer contains extremely small amounts of bubbles and quartz remnants. The glaze layer is a rather thin transparent glass glaze. The anorthite crystallization layer is common at the body–glaze interface, which strengthened the bonding strength of the body and the glaze (Fig. 5). The water absorption rate of the body is only 0.28%, and the bending strength is as high as 71 MPa. Its chemical composition, microstructure, and physical properties perfectly satisfy the requirements for contemporary porcelains (Li et al. 1978).

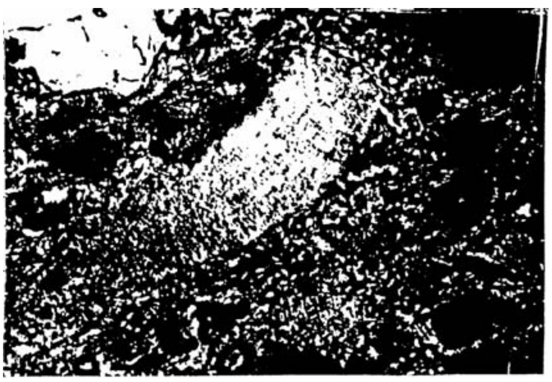
The Fourth Milestone: Breakthrough of White-Glazed Porcelain in Northern China in the Sui–Tang Dynasty

The breakthrough in white-glazed porcelain in northern China in the Sui–Tang dynasty (AD 589–907) was the result of the rich supplies of high-quality raw materials in northern China as well as experience over a long

Ceramics in China. Fig. 5 Microstructure (405×) of the glaze of a green-glazed porcelain from the Yue Kiln, Xiaoxiantan, Shangkyu, Zhejiang Province.



Ceramics in China. Fig. 7 Qichun relics of a Xing Kiln in the late Tang period.



Ceramics in China. Fig. 6 Kaolinite remnant in the body of a white-glazed porcelain of the Xing Kiln (350×).

period of time. Its occurrence was another leap forward in porcelain techniques in China, and made China the first country to possess white-glazed porcelains (Li et al. 1985).

The techniques required by the white-glazed porcelains of Xing, Gong, and Ding Kilns are summarized below.

Use of New Materials and Improvements in the Recipes for the Body and Glaze

All the bodies of white-glazed porcelains of the Xing, Gong, and Ding Kilns made use of secondary settled clay with higher contents of kaolinite or kaolin clay, so their bodies contained more than 30% of aluminum oxide. Figure 6 shows the microstructure of the body of a white-glazed porcelain of the Xing Kiln, in which a kaolinite remnant can be seen. Furthermore, feldspar was found in the recipes of the body of some white-glazed porcelains, and the potassium oxide content in these bodies could be above 5%. According to the silicon dioxide contents and α-quartz contents in the microstructure of the bodies, it can be inferred that the kaolin–quartz–feldspar porcelains emerged in the Sui and Tang periods in China. These were not found in the southern green-glazed porcelains. Even when kaolin clay started to be used for the Jingdezhen white-glazed porcelains during the late Song and early Yuan dynasties, these were only kaolin–quartz–muscovite porcelains. These two types of porcelain represented the two major white-glazed porcelain systems in northern and southern China. For some white-glazed porcelains of the Sui dynasty, the potassium oxide content far exceeds that of calcium oxide, the glaze of which is referred to as the alkali–calcium glaze. This is also never seen in the southern early green-glazed porcelains, and only starts to appear in the Jingdezhen sweet white-glazed porcelains during the Yongle period of the Ming dynasty and the Dehua white-glazed porcelains during the Qing dynasty.

Increase in the Firing Temperature and Improvement of the Kilns

The firing temperatures of white-glazed porcelains of the Xing, Gong, and Ding Kilns of the Tang dynasty reached 1,300°C, and some reached as high as 1,380°C. The increase of the firing temperature was certainly linked to the improvement of the kilns. The kilns used for the northern white-glazed porcelains in the Sui and Tang periods were up-draught Mantou kilns (Fig. 7). The improvements included big firing chambers, small kiln chambers, and double chimneys, which increased the drag force to enhance the firing temperature.

Use of Saggers and Improvement in Firing Techniques

The firing of Xing Kiln white-glazed porcelains during the late Sui and early Tang dynasties already made use of saggers (a sagger is a case made of fired clay in which porcelain and similar delicate items are enclosed while they are being fired in the kiln) for assembling and firing. The transition from open firing to firing in saggers was a breakthrough to enhance the quality of porcelains. This kiln was one of earliest ones which employed devices for firing in saggers, and possessed various saggers as well as various techniques according to the different forms of porcelains.

The Fifth Milestone: Time of Monochrome-Glazed, Polychrome-Painted, and Sculpted Porcelain from the Song to Qing Dynasty

All the famous porcelains from the Song dynasty to the Qing dynasty (AD 960–1911), such as the imperial wares, Ge wares, Jun wares, Ru wares, Yaozhou wares, Linru wares, Cizhou wares, Jizhou wares, Longquan wares, Jian wares, Changsha wares, Qionglai wares, Dehua wares, Yixing wares, and the later Jingdezhen wares, were all world famous for their monochrome-glazed porcelains, polychrome-painted porcelains, and sculpted porcelains. These porcelains illustrated the great achievements in the sciences, techniques, and arts needed for Chinese porcelains.

Starting from the late East Han dynasty, the Zhejiang Province had been firing celadon with iron oxide as the colorant. Until the South Song dynasty, the black body celadons manufactured in its imperial kiln and the Longquan kiln were crystallization-phase separation-crackle-glaze porcelains. These porcelains made use of the microcrystals of Anorthite and the immiscible liquid droplet separated from the glaze to enhance the jade-like appearance, and exploited the different expansion coefficients of the body and the glaze to generate cracks with different patterns and to become a unique world famous decoration. On the other hand, the white-body celadons were manufactured in the Longquan kiln in large numbers and were transported to different places in the world and have been collected by all major museums.

The celadons from the Ru Guan kiln and Linru kiln of Baofeng in Henan Province, as well as those of the Yaozhou kiln of Tongchuan in Shaanxi Province, also used iron oxide as the colorant. These porcelains also enjoyed a very good reputation in the world. The celadons from the Ru Guan kiln were particularly precious due to the short manufacturing periods and their small handed-down number.

Black-glazed porcelains emerged almost at the same time as the celadons. All the famous kilns in north and south China manufactured this kind of black-glazed porcelain from time to time, which used iron oxide as the main colorant. With the arrival of the Song dynasty, the techniques in manufacturing black-glazed porcelains had been significantly improved. The most unusual products included the hare's fur bowl of Jianyang, Fujian Province and the black-glazed bowl of Jizhou, Jiangxi Province. These developments were partially attributed to the habit of drinking tea at that time, and partially to the availability of the extremely complicated technology, which was unique in the world. The "hare's fur" was formed by crystallization and then phase separation (or direct phase separation), and then by recrystallization. Under different environments, products with different colors, such as the golden hare's fur and the silver hare's fur, can be formed (Chen et al. 1983a,b). Among these, the fur streaks of some will display different colors in the optical spectrum, which can interchange with each other when observed from different angles. This product is called *Hao Se Bian Yi* bowl (hare's fur bowl with alterable colors), which is a product of the science and technology that integrated the phase separation and crystallization in physical chemistry and thin-film interference or diffraction grating in physical optics. The Hao Se Bian Yi cup transported to Japan was called the *Yohen Temmoku* and was considered a national treasure.

The glaze of the Jun kiln in Yu County, Henan Province was a new product. It was a red glaze colored by copper compounds, or a multicolor glaze with nonuniform red patterns distributed on a bluish opalescent glaze surface with different tints. The blue Jun glaze was not colored by cobalt oxide, but was caused by the stronger scattering of the blue light with a shorter wavelength by the liquid droplet phase which fulfilled the size requirement for Rayleigh scattering. (Rayleigh scattering refers to the scattering of light off of the molecules of the air, and can be extended to scattering from particles up to about a tenth of the wavelength of the light. It is Rayleigh scattering off the molecules of the air which gives us the blue sky.) In other words, this was a kind of physical coloration. The copper-colored liquid phase droplets and cuprite formed the red patches, while the purple streaks were formed by the bluish polycrystals of chalcocite (Chen et al. 1983a,b). The phase separation of the Jun kiln glaze was a physicochemical process taking place within a range of chemical compositions and under the actions of the firing temperature, atmosphere, and time. Because of complicated factors, it was difficult to control the formation conditions, so the appearance of the products could not be controlled easily; this was referred to as furnace transmutation.

Starting from the white-glazed porcelain manufactured in the Five Dynasties to the bluish-white-glazed porcelains in the Song dynasty, Jingdezhen has been one of the greatest kiln sites in terms of quality, quantity, and impact. Before the Yuan dynasty and the early Ming dynasty, there had been ground-breaking developments in the techniques required for Jingdezhen porcelains. The white-glazed porcelains of Shu Fu (Center government in Yuan dynasty) and the sweet white-glazed porcelains of the Yongle period were not only superb in terms of the quality and appearance, but also provided sound techniques and physics foundations for the further manufacturing of monochrome-glazed porcelains and polychrome-painted porcelains. Starting from the Yuan dynasty, Jingdezhen started to fire the blue-and-white underglaze colored by cobalt oxide and the red underglaze colored by copper oxide (CuO), as well as the blue-and-red. This started the manufacture of products with polychrome high-temperature underglazed colorants. In particular, the blue-and-white porcelains were a unique long-lasting product with the largest sales in Jingdezhen. Furthermore, the different colors created by various metal oxides, such as iron, cobalt, copper, manganese, and their combinations, were the basis for the vibrant color-glazed porcelains from Jingdezhen. At the same time, overglazed painted porcelains started to emerge. When it came to the middle of the Ming dynasty, firing of the so-called *doucai* porcelains was successful, which incorporated the underglazed blue-and-white as well as overglazed paint. The best painted porcelains in the Ming dynasty were the doucai porcelains in the Cheunghua period, which were famous for their vibrant colors, white and moist appearance of the glaze, vivid patterns, and intricate skill work. They were collected in all major museums as well as by private collectors. In the Qing dynasty, there was another type of low-temperature overglazed painted porcelain called *wucai*. These were most famous during the Kangxi period. The subsequent *fencai* porcelains in the Yongzheng period also received great admiration.

After the Ming and Qing dynasties, major kilns all over China perished or stopped manufacturing, except that Jingdezhen kept firing its own colorful porcelains in large quantities and was able to imitate the products from other major kilns. In this way, Jingdezhen became the porcelain center in China and was nicknamed the "Porcelain City."

The Dehua kiln in Fujian Province, which was developed some time later than the Jingdezhen, was also world famous for its high-quality white-glazed porcelains and sculpted porcelains. The semitransparent bodies of Dehua white-glazed porcelains, due to the relatively larger proportion of glass and the very thin glaze layer, made the Duhua porcelains uniquely bright.

Before the emergence of the polychrome underglazed painted porcelains in Jingdezhen, the dark brown underglazed painted porcelains colored by iron minerals and those colored by copper materials had already appeared in the Changsha kiln in Hunan Province and the Qionglai kiln in Sichuan Province during the Tang dynasty. These successes had far-reaching influences on the painted porcelains in later generations. When it came to the Song dynasty, the painted porcelains manufactured by all the kilns in the Cizhou ware type in northern China reached another height. Since these were all folk kilns, the portrayed patterns were all derived from the daily lives of the general public, so the patterns had rich flavors of folk lives, which were in great contrast to those of the imperial wares with many more restrictions. These folk wares also created unique decorations which did not exist in the wares from other kilns.

From the proto-porcelains at the second milestone to the monochrome-glazed porcelains, polychrome-painted porcelains, and sculpted porcelains at the fifth milestone, porcelains dominated the history of Chinese ceramics. Interestingly, however, in Yixing, Jiangxu Province, which was also known as the *pottery city*, a world famous pottery called *Zisha pottery* (purple stone ware) has been manufactured since the Song dynasty.

Zisha pottery had many unique features. First, it was especially designed for tea drinkers. The most famous as well as the most manufactured products were teapots with various unique and beautiful forms. Second, it was derived from a unique raw material. The Yixing region is extremely rich in different kinds of Zisha minerals, which were used to produce Zisha pots with different colors. Third, most of the Zisha pottery were handmade, and made use of different tools in the manufacturing process, which fully reflected the wisdom and the skills of the pottery masters. Fourth, the decorations of the Zisha pots were unique in that they integrated the form, painting, poems, calligraphy, and seal cutting, and were thus very rich in Chinese culture characteristics. Starting from the Ming dynasty, there were great masters who made long-lasting famous pots. Therefore, Zisha pottery played a role in the fifth milestone.

When Chinese ceramic techniques developed into the fifth milestone, Chinese ceramics no longer referred to a single region or a particular monochrome-glazed porcelain. Instead, they included the monochrome-glazed porcelains, polychrome-painted porcelains, and sculpted porcelains from different kilns in both southern and northern China.

Three Technological Breakthroughs

The five milestones described above relied on continuous breakthroughs in firing techniques. The latter can be summarized as described below (Li 1978a,b).

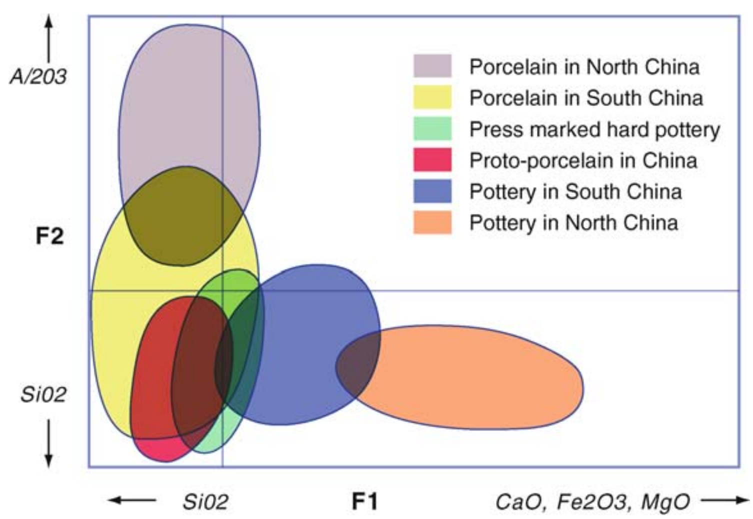
Selection and Refinery of Raw Materials

The raw materials of pottery in general, particularly the early ones, came from the local soil. Therefore, the soil around the residences of early people became the raw materials for firing their pots. Since most of these people resided near hills or close to water sources, the collected raw materials were, in general, soils containing different sand grains. Early pottery was mostly sandy, containing different types of sand grains with different sizes. Strictly speaking, these soils were not suitable for firing pots. After a relatively long period of time, the people became aware that some soils might be more suitable for firing, and they started to select these soils for their pots. In other words, the people started to select the soils locally and clay pottery appeared as a result. When the people discovered that using a particular clay could not satisfy the requirements for forming, drying, and firing, they added different sand grains, ashes of vegetation, and shells of corn, as well as ashes of shells, etc., to get pottery including sand, charcoal, or mussel. The black pottery including charcoal from Hemudu culture was a typical example (Fig. 3).

The raw materials for the stamped hard pottery, proto-porcelains, or even celadons and white-glazed porcelains were still selected locally. However, the people had higher standards for the suitable raw materials. This explained why the stamped hard pottery, proto-porcelains, and celadons were first successfully fired in some regions in southern China, while the white-glazed porcelains were first successfully fired in some regions in northern China. All in all, the raw materials derived from regions which were only suitable for particular types of ceramics.

Differences in raw materials will be reflected by the different chemical compositions of the ceramics. Principal component analyses have been performed on the chemical compositions of the bodies of 700 pieces of ancient ceramics spanning from the Neolithic Age to the Qing dynasty. The cumulative variance explained by the first three principal factors (F1, F2, F3) was more than 80%. Figure 8 shows the factor loadings of F1 and F2.

From Fig. 8, we can clearly see the changes in the chemical compositions of ceramics in southern China. During the development from the stamped hard pottery to the proto-porcelains and then to porcelains, the silicon dioxide in the bodies increased gradually while the fluxing agents calcium oxide, magnesium oxide, and particularly iron oxide decreased. The contents of aluminum oxide did not change much until after the Song dynasty when the aluminum oxide contents increased due to the use of kaolin clay. The chemical compositions of the ceramic bodies had overlaps, which demonstrated their close relationships. However, the ceramics from northern China did not have this pattern. The northern Chinese pottery came from an area with high fluxing agents and low silicon dioxide contents, while the porcelains were in an area with low fluxing agents and high aluminum oxide contents. This is explained by the use of clay which is more readily melted as the raw material for the former and the use of clay with kaolinite as the raw material for the latter. The two regions were well separated, which showed that they had no relationships with each other. The chemical compositions of the small number of stamped hard pottery and proto-porcelain unearthed in northern China did not show any transitional zone between the two regions, so no relationships between their chemical compositions can be inferred. It can be said that the development from pottery to porcelain took a different path in northern China. However, the development from pottery to porcelain together with continuous improvements in their quality was primarily attributed to the selection and refining of raw materials. The raw materials were the fundamental substances for firing the ceramics.



Ceramics in China. Fig. 8 The scatter plot of the F1 and F2 factors for the chemical composition of the bodies of Chinese ancient ceramics.

Improvements of Kilns and Increase in Firing Temperatures

According to the vast amount of experimental data obtained for firing temperatures from ancient ceramic shards, it can be concluded that there were two breakthroughs in firing temperature. The first one was realized for the firing of stamped hard pottery in the Shang and Zhou dynasties. The highest firing temperature of 1,000°C and the average value of 920°C for pots were increased to 1,200 and 1,080°C, respectively. The second one was realized for the firing of white-glazed porcelains in northern China in the Sui and Tong dynasties. The highest firing temperature of 1,280°C and the average value of 1,120°C for proto-porcelains were increased to 1,380 and 1,240°C, respectively, for white-glazed porcelains, the latter being the highest firing temperature for porcelains in the history of China. Table 2 summarizes the statistical data for the experimentally determined firing temperatures for pottery and porcelains.

From the archeological data for kilns, we can conclude that pottery from the early Neolithic Age might be fired without kilns, i.e., firing on the ground. Kilns were found from the Jiahu and Peiligang cultures. Kiln firing might have started later in southern China. After a long period of development and improvement, the dragon kiln and the chamber kiln with chimneys appeared during the Shang period in Zhejiang and Jiangxi Provinces. The stamped hard pottery and the proto-porcelain were fired in such kilns. The upward slope and the length of the dragon kilns, as well as the chimney of the chamber kilns, increased the drag force, thus enabling the rise in the firing temperature. This was the first breakthrough in the kiln structure, which facilitated the first breakthrough in raising the firing temperature.

In the Sui and Tang dynasties, big firing chambers, small kiln chambers, and multiple chimneys appeared in Hebei Province in northern China. As seen from the above, improvements in the kilns were closely related to the increase in firing temperatures.

Ceramics in China. Table 2 Changes in the firing temperature of ancient ceramics

Product	Sample number	Highest firing temperature (°C)	Average firing temperature (°C)
Pottery	15	1,000	920
Stamped hard pottery	55	1,200	1,080
Proto-porcelain	37	1,280	1,120
Porcelain	146	1,380	1,240

Invention and Development of Glaze

The earliest glaze which was transparent, bright, and which did not absorb water was the glaze for the proto-porcelains fired in the Shang dynasty more than 3,000 years ago. Therefore, glaze must have been created before the Shang dynasty.

It is well known that the proto-porcelains and the earliest porcelains were fired in southern China. Recently, a large amount of clay-glazed black pottery prior to the Shang period has been discovered in ancient kilns and tombs, and *Tao Yi* (pottery coat) has been discovered on the surface of colored pottery from the early Neolithic era in southern China. The creation and development of glazes in China can be divided into the following four stages, according to their chemical composition, microstructure, and appearance:

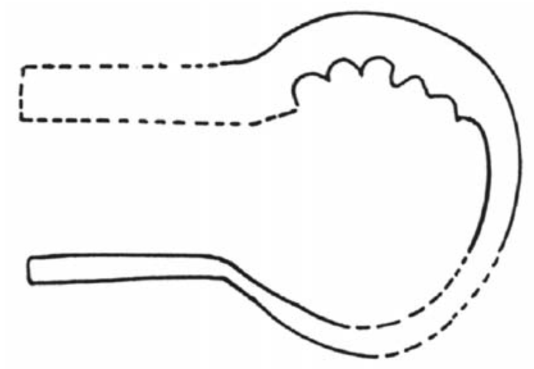
1. Breeding period of glaze – Shang dynasty
2. Formation period of glaze – Shang and Zhou dynasties
3. Mature period of glaze – Han, Jin, Sui, Tang, and Five Dynasties
4. Flourishing period of glaze – from the Song to Qing dynasties (Li 1983)

Similar to the five milestones, the three technological breakthroughs signified improvements and achievements during the 10,000 years of history from the Neolithic Age to the Qing dynasty.

Contribution to Chinese Culture

Chinese ceramics have a long history, rich technological and arts contents, and are highly acclaimed all over the world. The contribution of ceramics to Chinese culture can be briefly summarized:

1. The early pottery was based on very simple techniques. Pottery techniques were an integral part of Chinese culture. These techniques were made up by the three stages of raw material selection, forming of the wares and the firing of the pottery. The basic ideas behind the whole set of techniques developed more than 10,000 years ago; they have been used until now, and have laid the foundations of ceramic industries in later generations. With pottery cooking utensils, the people could enjoy cooked food, which enhanced their quality of life. This is important not only for the Chinese culture, but also for world culture.
2. The Chinese culture is one of the four ancient cultures in the world (China, India, Near East, and Greece) that has been sustained until today, with the development of Chinese ceramics as an example of its sustainability.
3. Pottery kilns appeared in the relics of Peiligang in Xinzheng (Fig. 9) and Jiahu in Wuyang in Henan



Ceramics in China. Fig. 9 Schematic diagram showing the relic pottery kiln T31 in the Peiligang in Xinzheng, Henan Province.

Ceramics in China. Fig. 10 Microstructure of a clay pottery of Peiligang in Xinzheng, Henan Province (70×).

Province about 8,000–9,000 years ago (Kaifeng 1978; Zhang 1999). These kilns proved that China was one of the first places to fire pottery in kilns. The appearance of kilns enabled the increase in the firing temperature (Table 3). This greatly enhanced the quality of the Peiligang pottery (Fig. 10) and at the same time enabled the first effective step in the history of high-temperature processes for mankind.

4. Slow wheel trimming for pottery appeared in the middle of the Yangshao culture, 4,000 years ago. Fast wheel trimming occurred during the Dawenkou culture. The fast wheel is also called the *potter's wheel*, which is the rudiment of the jolley (a mold to produce uniform hollow ware) used today. The fast wheel was a necessary requirement to throw as well as trim, and was instrumental in enhancing both the quality and the quantity of the products. The appearance of the fast wheel reflected the use of wheel shaft machines as well as the effects of inertia in manufacturing pottery, which inspired machining processes in later generations.
5. Early pottery contained certain amounts of sand grains with different sizes. Some of these sand grains occurred naturally in soils, while others were purposely added. The latter ones were referred to as *Chan He Liao*. For example, the burned vegetation found in Hemudu pottery was purposely added (Fig. 3; Li et al. 1978). These additions were used to mitigate the contraction of clay during drying and firing, which served the same purpose as the clinker (a hard brick used as a paving stone) does today.
6. Pottery can be both containers and tools. Earthen spinning wheels, net weights, pills, and casts have been found in many relic sites of the Neolithic

Ceramics in China. Table 3 Firing temperatures of some early porcelains from the Neolithic Age

Age, which were tools for textiles, fishing, and pottery manufacturing. Despite the very simple forms, these served as the first examples of using pottery as tools, and demonstrated that pottery was an indispensable material in human lives. In particular, the earthen pills and earthen net weights not only signified the exploitation of elastic stress and gravity machines in the manufacturing process, but they also illustrated that pottery needed chemical reactions, which were unlike stone wares which needed only physical processing. This was pioneering in the chemical industry.

7. Pottery was the earliest product integrating technology and arts. Colored pottery was discovered in Jiahu in Wuyang, Henan Province as well as in Hemudu, Yuyao, Zhejiang Province. Colored pottery and pottery statues were also found for the late Neolithic Age. These not only showed the artistic talents of the people, but also reflected their daily lives. For example, carved symbols were found on pottery from the relic site of Jiahu, which provided information on the emergence of Chinese words. Colored pottery was an ancestor to polychrome-painted porcelains in later generations; pottery statues were ancestors to sculpted porcelains.
8. The crucibles for alloy melting for bronze wares and the pottery moulds for casting illustrate the required skills for techniques. The emergence of pottery kilns and the attainment of higher firing temperatures as a result of the improvements in the kilns facilitated the development of bronze wares and thus the early arrival of the bronze-ware era. The early pottery marked the start of the Neolithic Age, but improvements and extended applications played an indispensable role in marking the end of the Neolithic Age and in marking an unacknowledged ceramic Age.
9. Porcelains are recognized as one of the greatest inventions in China. The manufacturing techniques of porcelain masters in different times were adopted by different countries in Europe and Asia, which had significant influence on the manufacture and the development of porcelains in certain countries in the world.
10. One of the main reasons that the Jingdezhen porcelains could survive and their quality improve was that the recipe contains kaolin clay and its percentage kept increasing. The good quality of the white-glazed porcelains from the Xing Kiln in northern China starting from the Tang dynasty was also attributed to kaolin clay. Firing of hard porcelains in Europe was also successful after the use of kaolin clay. China was the first country to discover kaolin clay. The terms *kaolin clay* and *kaolinite* were translated from Chinese.
11. The famous porcelains manufactured in various areas in China not only satisfied the needs of different people in China, but were also exported in large quantities or used as precious gifts. These exquisite porcelains, as part of Chinese culture, were thus dispersed to different areas in the world. This inspired their techniques and at the same time built the reputation of Chinese porcelains over the world.

Ceramics in Korea

Carolyn K. Koh Choo

Korean ceramics is a culture that has been close to the hearts and minds of Korean people throughout its history. In many parts of the country, one can still touch the centuries-old remnants of everyday bowls and dishes and even artistic masterpieces. For those who seek them out by research or consulting with experts and village elders, waste mounds of shards and dragon kilns are invariably found on sunny mountain slopes with flowing brook water nearby. Such artifacts reveal many details of the forming, designing, and firing methods of traditional Korean ceramics.

Today, Korean ceramics is enjoying an active phase of development. For the first time, all four major types of pottery – *togi*, celadon, *punch'ŏng*, and whiteware – are produced simultaneously in numerous studios. With the continued unearthing of kiln sites in major excavations have come new theories about the rise and development of Korean ceramics history. The overseas museum space dedicated to exhibiting ceramic art pieces has increased noticeably in the last decade. Special fairs, biennales, and competitions are held in many locations that attract both Korean and international audiences. The World Ceramic Biennale, held in 2005 for the third time in the greater area of Kwangju (near Seoul; this was the center of ceramic activities during the Chosŏn dynasty), is developing as an important event for ceramic arts and crafts.

Coming of Age for Korean Hard-Paste Porcelain

Among countless types of ceramic products that make ceramics culture ubiquitous, the position held by Korean porcelain and stoneware is due to their hard-paste raw material. Korea and China were the first countries to possess the know-how for using this material, readily available in nature, and obtaining the necessary firing power for its proper vitrification (forming a glassy or noncrystalline material). Although the dates are still being debated actively among ceramics scholars, a long tradition of making high-fired unglazed stoneware, called *togi,* enabled Korea to adopt porcelain technology from China sometime between the early ninth and late tenth centuries. The making of refined tea bowls must have been a strong motivation for the import of the technology because shards of such bowls are found in abundance in early kiln sites. The Japanese porcelain industry began only after many Korean potters were taken to Japan during the Hydeyoshi Invasion (1592–1598), which is also known as the Ceramics War or the Tea Bowl War.

While China and Japan benefited enormously from the export of their porcelain wares to Europe until the technology successfully developed there in the eighteenth century, Korea maintained its unique aesthetics that were appreciated mainly within East Asia. Never developing the overglaze that was so popular in Europe, Korea produced one major type at a time: *togi* up to the Unified Silla Kingdom (AD 668–935), celadon during the Koryŏ dynasty (AD 918–1392), and *punch'ŏng* and then more commonly whiteware during the Chosŏn dynasty (AD 1392–1910). Although several other types were also produced – including a substantial amount of white tea bowls in the initial stages of porcelain technology, a small amount of black temmoku-type, and a very small amount of ware known as Chosŏn celadon with white body and celadon type glaze – the linear sequential development of the four major types is undeniably the predominant feature of Korean ceramics history.

It is not surprising, therefore, that Korean ceramics remained largely unknown in the world, as attested by Bushell's report in his comprehensive 1896 book *Oriental Ceramic Art.* "Korea has been thoroughly explored during the last few years, and it is now known that no artistic pottery is produced there in the present day, and no indisputable evidence of any original skill in former times has been discovered." Within a decade of this report, an enormous amount of porcelain (including thousands of pieces in many shapes and types) was unearthed during the building of railroads. Many accolades were bestowed on Koryŏ *pisaek* celadon as early as the twelfth century. For example, a Song connoisseur, Taipyŏng Noin, said they were the "First Under Heaven" and a famous calligrapher envoy to Korea, Sŏh Keung, referred to the celadon as being very refined with workmanship surpassing that of the Yüeh kiln (in China). The isolation of Korea from development in other parts of the world resulted in the unique characteristics of simplicity and quietness that today are acclaimed as the quintessence of oriental spirit.

Togi Up to the United Silla Kingdom

The term *togi*, with a literal meaning of earthen or clay ware, is used inclusively for a wide variety of mostly unglazed earthenware or stoneware produced from the beginning of the Neolithic Age (ca. 6000–1000 BCE) through the Bronze and Iron ages (ca. 1000–0 BCE), the proto-Three Kingdoms period (ca. AD 0–300), the Three Kingdoms period (ca. AD 300–668; Koguryo in the north, Paekche in the southwest, and Silla in the southeast), and much of the Unified Silla Kingdom. On a much smaller scale, the production of *togi* continued during the Koryŏ and Chosŏn dynasties. One of the oldest Korean ceramic wares known today, a reddish comb-patterned jar with a pointed bottom, is carbon dated to 5770 BCE. Red and black (Fig. 1) pottery from the Bronze and Iron ages attest to the high level technology and aesthetics that the ceramics culture already obtained. These soft-textured wares were painted with iron pigments and burnished and most likely fired in an open pit.

By the end of the proto-Three Kingdoms period around the fourth century, two breakthroughs allowed the technology to become much more sophisticated and efficient. The potter's wheel was introduced and the knowledge of high firing power, originally developed

Ceramics in Korea. Fig. 1 Long-necked jar. Black pottery. Excavated at Koijeong-dong. Taejeon. Bronze age. National Museum of Korea, Seoul.

for bronze and iron casting, was applied to ceramics production. The type of dragon kilns and the method of reduction firing that Korea used continuously throughout its ceramics history were developed at this date. The *togi* fired in this way was highly vitrified and hard textured to the extent that it rings like porcelain when struck with the fingers. These wares were colored usually blue-gray or black-gray.

The first of these grayish stonewares is known as Kimhae ware after the southeastern area where they were first produced (Fig. 2). Kimhae prospered as an independent state known as Kaya until absorbed into Silla in the sixth century, and the highly vitrified *togi* characteristic of this area is also referred to as Kaya *togi*. Such ware became more refined and was produced in such vast amounts during the Three Kingdoms period and Unified Silla Kingdom that they are found in abundance even today.

The forms of the *togi* bowls and jars already possess the elements of beauty that characterize Korean ceramics in general, especially the slender gracious line of Koryŏ *maepyŏng* and the voluptuous roundness of Chosŏn whiteware jars. Both of these elements make the Kaya pedestalled jars, usually with lids, very attractive. The tall and short pedestals are basic components in much of the *togi* form. Shaped either as part of the whole ware or separately, they often have beautiful contours.

The naturalistic forms of humans, animals and birds, transportation means, and houses were favored motives both as shapes and as decorations. There were many varieties of warriors mounted on horses or carriages (Fig. 3). A roof end tile, in spite of its monstrous appearance, stimulates the feeling of warmth that is a

Kaesŏng is the capital city of the the Koryŏ dynasty (AD 918–1392), Kyŏngju that of the United Silla Kingdom (AD 668–935), and Seoul that of the Chosŏn dynasty (AD 1392–1910) as well as modern Korea.

Ceramics in Korea. Fig. 3 Ceremonial vessel in the shape of mounted figures. Excavated at Tomb 127 (the Gold Bell Tomb) in Nodong-dong, Kyŏngju. Three Kingdoms period (Silla). National Museum of Korea, Seoul.

hallmark of Korean ceramics (Fig. 4). A handsome inkstone is a forerunner of small equipment for calligraphy, which was made both in the Koryŏ and Chosŏn dynasties (Fig. 5). A Silla long-necked jar is decorated with many symbols of fertility and well being, such as figurines of a snake, a frog, a bird, a duck, a turtle, a woman playing a *kayakum* (a traditional musical instrument), and a man and a woman engaged in a sexual act.

The Unified Silla wares with lead and tricolored glazes of the Tang style are rare examples of low-firing glazes, because they were discontinued in the following Koryŏ dynasty (Figs. 6 and 7). Why Korea stopped this line of development and never adopted or developed the lead-containing materials for overglaze decoration that became so popular and profitable in China and Japan is one of the most interesting questions concerning the Korean ceramics industry.

Some later *togi* wares were glazed, often only partially, but this occurred due to ash falling on them unintentionally in the process of wood firing. Recent excavation of an eight to ninth century *togi* site at Kurimni in the southwestern area near the important celadon centers of Kangjin and Haenam offered some circumstantial evidence of glaze being intentionally applied. Such a suggestion is a topic of interest, because it raises the possibility that celadon technology might have arisen indigenously within Korea.

Celadon in the Koryŏ Dynasty

The appreciation of Korean ceramic art usually begins with numerous celadon masterpieces in the shape of *maepyŏng* vases, which inherited from the *togi* tradition the graceful elegant contours of the pedestalled jars and other vessels. This type developed widely and artistically with many variations in the shape and styles of decoration. The earlier ones decorated with only incised designs are often *pisaek* and beautiful. Many were decorated with inlaid designs of clouds and cranes (Fig. 8) and some rare pieces were painted with iron-black slip before the glazing (Fig. 9). The gourd-shaped ewer with decoration of copper red is a variation in shape (Fig. 10).

The love of naturalistic forms of plants, animals and birds was also inherited from the *togi* tradition. Notable among them are many water droppers, such as a child holding a bottle and a monkey holding a jar as big as itself (Fig. 11). A ewer in the shape of a dragon-headed tortoise seated on a lotus pedestal (Fig. 12) and an incense burner with the lid and feet in the form of lion figures (Fig. 13) are some of the celadon vessels with elaborate naturalistic forms.

Another form that was dominant in the Koryŏ dynasty was the tea bowl (Fig. 14), as the act of drinking tea was a highly valued means to clear one's mind for meditation in the Buddhist Koryŏ dynasty. The tea bowl shards excavated in the earliest porcelain kiln sites have a particular style of wide foot rim that resembles the sun's halo and is called that in Korean, *haemurigup*. The similarity in these foot rim styles, glaze colors, and general shapes of these wares with those found in Yüeh kiln is one of reasons to believe that the Korean porcelain technology was strongly influenced by the Chinese technology, or even that it was directly imported from China (Fig. 15).

Haemurigup tea bowls in recent excavations included surprisingly both celadon and whiteware. In particular, a series of excavations in Sŏri and Bangsandong in the 1980s and 1990s near Seoul showed that whiteware was just as important as celadon in the earliest stages of porcelain technology in Korea. During the latter part of its two-century long production, Sŏri produced only whiteware, and another nearby site of Chungamni also produced mainly whiteware during its entire existence.

Sŏri, Bangsandong, and Chungamni were among some 50 sites located inland in the western mid-section of the country, and they are now considered one of two distinct routes of technology transfer from China. The other route consists of a group of sites in the Kangjin area on the southwestern coast. These two different routes show several remarkable differences. Unlike in the inland kiln sites, only celadon is found in Kangjin. From the beginning, Kangjin kilns were constructed with mud and rock in a similar style to *togi* kilns, while kilns in inland sites were first constructed with bricks as in some Chinese kilns. Only later was the Kangjin type kiln of mud and rock introduced to some of the longer running inland sites such as Sŏri. Kangjin fired the wares in two steps – once before and again after glazing – while inland kilns fired wares in one step like the Chinese.

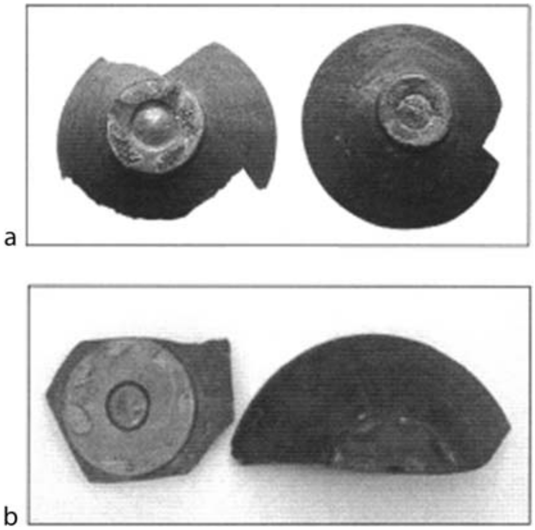
Ceramics in Korea. Fig. 13 Celadon incense burner with cover. The vessel has three lion-headed feet and decorated exterior with incised clouds. First half of the twelfth century. Height 17.5 cm. National Museum of Korea, Seoul.

By the middle of the eleventh century the inland kilns were mostly closed, while another center at Puan about 200 km north of Kangjin was newly established. The founding of Puan and closing of the inland kilns represented a new and indigenous phase of porcelain technology. In the two centers of Kangjin and Puan on the southwestern shore, porcelain production became highly centralized and reached a high technical and aesthetic level. Dedicating their efforts only to celadon rather than producing several styles, Koryŏ potters and their patrons made three original achievements in ceramic arts and crafts: *pisaek* glaze, the decorative technique of white and black inlay, and that of copper red.

Pisaek, represented by two different Chinese characters, mainly appears in a jade color and kingfisher's color (after the bird's blue-green plumage) in Korea, and as a secret color in China. In the Koryŏ *pisaek* celadon, the thin glaze blends with the body of the ware, revealing it just enough that the observer yearns

Ceramics in Korea. Fig. 14 Celadon bowl with inlay decoration. Mid twelfth century. Height 6.4 cm. National Museum of Korea, Seoul.



Ceramics in Korea. Fig. 15 (a) Whiteware shards with *haemurigup* foot rim, excavated in Sŏri, Korea. (b) Celadon shards with *haemurigup* foot rim, excavated in Yüeh, China.

to see more. Chung Yangmo, a leading historian of ceramic arts and former director of the Korean National Museum, likened the Korean celadon glaze to clear water flowing through brooks and streams in the mountains and valleys and to a partition screen made of ramie fabric.

The thin transparent glaze that showed off the celadon body in a harmonious way was ideal for underglaze decorative techniques. Perhaps such a success enabled and motivated Koryŏ and later Chosŏn potters to persist with only underglaze decorations. The first decorative effect was achieved simply by incising figures such as flowers and birds or making them stand out in relief. The second of the three achievements was made when the incised lines were filled with white or red (which turns into black when fired) clay material to contrast with the gray body color. Flying cranes among

Ceramics in Korea. Fig. 16 Celadon *maepyŏng*, decorated with black and white inlaid peony sprays and chrysanthemum scrolls and underglaze copper red. Mid twelfth century. Height 34.6 cm. National Museum of Korea, Seoul.

stylized clouds (Fig. 8), ducks playing underneath plants such as willow trees and reeds, and various renditions of lotus, chrysanthemum and peony flowers are some of the inlaid designs.

The third original achievement was the use of copper red, and this represented a technical challenge that required a good control of firing atmosphere and schedule. The volatile copper turns green when oxidized to its divalent state of cupric oxide (CuO). By the first half of the twelfth century, the subdued red from the reduced state of cuprous oxide (Cu_2O) and copper metal in colloidal state was used only sparingly in most cases to represent grapes (Fig. 10) and peony sprays (Fig. 16). It was used to outline lotus petals in gourd-shaped ewers and to cover the entire ware (Fig. 17).

Though the predominant wares were glazed gray-green or blue-green similar to *pisaek* celadon, some unusual glaze and decorative methods were produced. The entire body of *maepyŏng* (Fig. 9) is first coated with black pigment and decorated by brush painting with white slip before a clear glaze is applied. Another type is colored light brown, most likely to have been fired in an oxidizing atmosphere. Often it is brush painted with iron pigments and resembles Cizhou wares. Even a small amount of porcelain whiteware, in general much more vitrified than the whiteware

tea bowls of the earliest stage, was produced at Puan (Fig. 18).

Punch'ŏng and Whiteware in the Chosŏn Dynasty

Punch'ŏng grew directly out of inlaid celadon in the last decades of the Koryŏ dynasty when the government became too weak to keep the ceramics activities supervised and centralized. In the first two centuries of the Chosŏn dynasty *punch'ŏng* blossomed into a folk craft and art that was unique to Korea. Some of the earliest pieces are difficult to differentiate from heavily inlaid celadon. The white inlay material was eventually coated or brushed over the entire body surface before any further decoration was applied (Fig. 19). The name *punch'ŏng* was coined for this type of ware by Koh Yusŏp, a scholar of Korean ceramics in the first decades of the twentieth century, and was adapted from the longer term, *pun-ch'ang* (powder-decorated) *whe-ch'ŏng* (gray-blue) *sagi* (stoneware). The white slip was first used as a decorative medium easier to apply than white inlay, but eventually it became a means to make the wares appear whiter to meet the demand of royalty and officials who favored heavily the whiteware. The production of *punch'ŏng* came to an abrupt end after the Ceramics War. With so many potters taken to Japan, only the whiteware production was revived afterward in Korea.

Punch'ŏng is vigorous in form and decoration modes. Unlike celadon, it was produced in all parts of the country, and different styles reflected the people's daily lives, rooted deeply in the earth and other natural environments. The free-spirited spontaneous flow manifested in *punch'ŏng* led Koh Yusŏp to characterize Korean ceramics as made with "a plan without planning" and "technique without technicalities."

Celadon inlaying techniques became modified in many ways. The incision of designs was replaced by stamping with engraving tools or even with rope. Instead of filling individual incised lines or surfaces with inlay material, white slip was applied on the whole stamped body. When the body and the slip were leather dried, the surface was scraped off evenly with the stamped areas left with white inlay. In another modified method all the areas except those of such designs as flowers and plants were scraped off. Sometimes the scraped background was painted with iron-rich clay to contrast with the decorative area.

In more casually made wares, the only decorative element was white slip that was applied freely and unevenly with a large coarse brush. The abstraction of designs is bolder and more freely executed when they are brush painted with iron-rich pigment over white slip (Fig. 19). Those made in such styles in the area of Keryŏng Mountain became particularly popular with the Japanese.

Together with *punch'ŏng*, white porcelain replaced celadon as the dominant type in the Chosŏn dynasty. Chosŏn potters were able to produce much more vitrified whiteware than Koryŏ counterparts by adopting the two-step firing method that Kangjin and Puan had developed and used throughout their celadon production history. The adoption of Confucianism and its stern frugality from the Ming dynasty as the guiding principle of the new society to replace the Koryŏ life style of pleasure and luxury provided the crucial force for the ascent of the whiteware technology. The undecorated pure white was preferred, and the decoration was again limited to underglazing. The import of cobalt blue from China to produce white and blue represented the only innovative element in the new Chosŏn technology.

The raw material for Chosŏn whiteware was rediscovered in the area nearby Sŏri and Bangsandong, two centers where Koryŏ whitewares were produced at the beginning stage of porcelain technology centuries earlier. Except for the lower contents of iron and titanium oxide, it is basically the same porcelain stone that is used for celadon. This general area with plentiful raw material, Kwangju near the ruling center in Seoul, was soon established as the official kiln for producing high quality wares for the use at court. In much the same way as in Kangjin and Puan, the ceramics activity in Kwangju was supervised and centralized by court officials for nearly 500 years. So far some 285 sites have been discovered in this area, where the potters had to move to new sites approximately every 10 years in search of firing wood. Unlike celadon, the production of whiteware, however, was not restricted to this area and was produced all over the country.

The majority of Chosŏn whiteware was undecorated. As mentioned before, the colorful overglaze decoration was never developed and even the underglaze decoration with cobalt, iron, and copper oxides was sparingly used. However, the various shades of white for body and transparent glaze, combined with beautiful forms, resulted in some of the most appreciated masterpieces. The eighteenth century jar with globular body is representative of such pure white, imparting the feeling of abundance and warmth (Fig. 20). This particular form is made in diverse modifications and decorated with various designs and colors. The brush painting

with cobalt blue on a late seventeenth century or early eighteenth century globular jar is executed freely and boldly in the same characteristic manner as *punch'ŏng* wares (Fig. 21).

The cobalt blue decorated wares, made mostly for royal use, are usually refined and restrained. The cobalt pigment, imported and expensive, was usually used sparingly (Fig. 22). When its use became even more difficult after the war with Japan, iron pigment was substituted as the main pigment. It was used more freely and effectively in various styles of brush painting, some refined and some very daring (Fig. 23). The use of copper red, which became more liberal in the eighteenth and nineteenth centuries, produced various styles of jars, bottles, and water droppers that are very free-spirited (Fig. 24). In some rare pieces two of the three pigments are used in combination, and very rarely all three pigments are used, always very sparingly.

This short treatment of 8,000 years of Korean ceramics art and culture, linearly developing *togi*–celadon–*punch'ŏng*–whiteware as distinct phases of creative and original achievements, leaves many important stories untold. Many tea bowls of the Koryŏ and Chosŏn dynasty that became national treasures in Japan and the brown pottery known as *onggi*, which ranges from small boilers for herbal medicines to enormously large storage jars, are important examples that have been omitted altogether. The masterpieces and coarse everyday utensils are testimony not only to the availability of diverse materials and technical know-how of Korean potters and their clients, but also their creative spirits, their love of nature, and their dreams and ideals.

Ceramics: Maya Pottery

Sandra L. López Varela

A social analysis of pottery investigates how potters translated into clay the social values and representations of people's lives, simultaneously considering how these objects defined their being-in-the-world.

The Maya region is a vast terrain with varying geologies and topographies that provided the raw materials for many different recipes to make pots. A wide range of techniques deriving from the physical, chemical, and natural sciences is helping archaeologists to identify how potters chose to select raw materials. These were washed or levigated (made smooth) and nonplastic temper (to create hardness and elasticity) of certain grain sizes was added or mixed with other clays. Maya potters had a thorough knowledge of the different properties of the available natural resources, including their thermal behavior, to make a functional vessel. Natural resources were used to make pots to support numerous daily life activities, for everything from cuisine preferences to cave rituals.

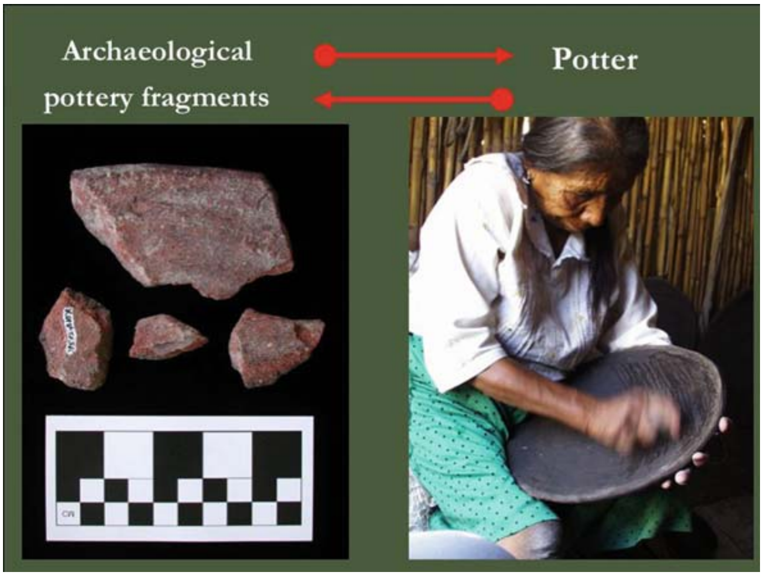
The natural and the social conditioned the making of Maya pottery (Fig. 1). In recent years, archaeologists have become interested in learning how social values are communicated through different kinds of objects and their uses (López Varela and Dore 2005). Throughout the history of humankind, people have used objects differently from their intended function. In the Maya region, pots painted with "Maya blue," a color created with palygorskite[1] were not a constant in every house (Arnold 2005a). Those who owned them expressed their social status and power with these vessels. When a cooking jar was placed in a burial site or a cave it extended its meaning beyond the domestic realm into that of the underworld. Learning about the physical and chemical properties of the clay bodies is important to determine the suitability of a vessel for cooking or storing different kinds of products. With this knowledge, archaeologists may distinguish if a vessel was used for its intended function or if it was used to signify, empower, embody, and/or engender the living spaces of those we now called "the Maya."

Analytical Approaches to the Study of Maya Pottery

Since the beginning of the twentieth century, archaeologists have studied pottery mostly to order archaeological remains in time and space so they can interpret past cultures. There are many reasons why pottery became the ideal data to reconstruct culture. Basically, pottery fragments can be arranged in a sequence of formal characteristics and styles called attributes. By determining the location of the pottery type in a stratigraphic column, the archaeologist dates a particular time and is able to produce a ceramic sequence. These goals conformed to cultural relativism, a scientific program established by Franz Boas, concerned with documenting culture-historical sequences and influences (Hodder 2004: 23).

Deriving from these goals, the type-variety system was introduced in 1960, as a systematic procedure from which to describe Maya pottery (Willey and Gifford 1960). To establish a type, the analyst takes into consideration decorative techniques and vessel form. When the analyst notes differences in ware, decorative techniques, vessel form, design, or temper, a variety of a type is established. The ware describes the paste composition (texture, temper, hardness, porosity, and color) and surface finish. When several types share the same ware, they form a ceramic group. Simultaneously, all of the known attributes are indicative of a particular class of pottery that was produced during a specific time interval known as the ceramic complex (Sabloff and Smith 1969: 77). By 1965, use of the "system," as colloquially referred to by its users, had created analytical and methodological problems that were revised during the Maya Ceramics Conference, held in Guatemala City (Willey et al. 1967). In 1969, Sabloff and Smith introduced a format to present the type descriptions of the Seibal pottery, similar to the one used in describing the ceramics from the Southwest of the United States (Colton and Hargrave 1937). For many analysts, the format, later extended in the Seibal monograph (Sabloff 1975), introduced a comparative framework for understanding pottery network distributions and extended the possibility to recognize new pottery attributes, leading to the establishment of new categories (e.g., Adams 1971; Kosakowsky 1987; López Varela 1989; Smith and Gifford 1966; Valdez 1987; Varela Torrecilla 1998). Each resulting monograph, presenting the description of the pottery and chronology, is to Maya pottery analysis like any

[1] Palygorskite is a fibrous clay mineral composed of two silica tetrahedral sheets and one aluminum and magnesium octahedral sheet that make up the 2:1 layer that occurs in strips. Palygorskite is most common in soils of arid regions.



Ceramics: Maya Pottery. Fig. 1 Learning how potters translated into clay the social values and representations of people's lives is a challenge for pottery analysis. Illustration by Sandra L. López Varela.

taxonomy book is to biology. The analyst learns the taxa by reading the descriptions of the pottery and looking at the illustrations reported in the monograph. The type-variety system has become a common artificial language for Maya ceramicists. The system provides artificial identities that are necessary for archaeologists to state what something is and what it is not; otherwise, there would be no process of communication for their results.

After World War II, the North American school of archaeology adopted the scientific method (Binford 1962), as a reaction to the tendency to describe artifacts and time, instead of investigating the processes that produced the differences between objects. This new way of doing science involved the testing of hypotheses, using technology and rigorous methods, such as statistics, that could produce a law, model, or theory that could adequately account for cultural phenomena. Both ruling schools of science were concerned with a search for objectivity, systematization, and the need to provide explanations of the observed phenomena. Their differences relied more in the incommensurable ways of seeing the world that has played a fundamental role in the making of science, as described by Kuhn (1996: 4).

The search for objectivity raised criticism of the failures of taxonomic systems to appraise the meaning of pottery (e.g., Dunnell 1971). Krieger (1944: 272), for example, suggested that objectivity may be reached if the researcher could base their definitions upon demonstrable historical factors not only on "the inclinations of the analyst or the niceties of descriptive orderliness." Later, Dunnell (1971: 116) specified that only "classes" of objects, not groups of objects, exist independently of time and space, that when provided with intentional definitions, together with the necessary and sufficient conditions for membership, these can be used to order real objects. Most of the debates were trapped in an endless circular discussion of subjectivity versus objectivity, as determining how many conditions are necessary and sufficient for membership in a class and the definition of what is a demonstrable historical factor are subjective decisions made by an analyst. If these analysts had observed the pottery under a polarized microscope their definitions of categories might have been very different, as the identified minerals composing the pottery would create a new group or taxa (Shanks and Hodder 1995: 9). Statistical methods, such as seriation,[2] were used to learn about the inherent space and time dimensionalities of Maya pottery (Henderson and Beaudry-Corbett 1993; López Varela 1989; Vallo 2002). The seriation method, however, is not an objective means for finding the life span of artifacts, as it orders the number of subjectively defined pottery attributes of the type-variety system.

Technology compelled the integration of physico-chemical or mineralogical analysis, aiming to reveal the provenience[3] and characterization of pottery, mainly

[2] Seriation is a relative dating technique based on the chronological ordering of a group of artifacts or assemblages, where the most similar are placed adjacent to each other in the series. Two types of seriation can be recognized, frequency seriation and contextual seriation.

[3] Also called provenance. The provenance is the source and ownership history of an archaeological find.

through instrumental neutron activation analysis (INAA) and X-ray diffraction (XRF) (Rice 1976: 542). Interest in understanding the craft specialization and technology of pottery was lost over the years, reinstating that the only use of artifacts is to construct and compare culture-histories by their ordering through a variety of methods (Rice et al. 2004). Based on this approach, results from instrumental techniques are far removed from the behavior of potters and from the society in which they live (Arnold 2005b: 15). Archaeologists use INAA, for example, to learn where pottery was made. Pottery is a complex mixture of raw materials often from disparate sources with clay and nonclay minerals mixed together in different forms and varying ways to produce a pottery fabric. Instrumental techniques are giving us information about the provenance of customarily 13–19 chemical elements in "pure" form (Kosakowsky et al. 1999; Neff et al. 1994, 1999). The given set is integrated by some of the most abundant chemical elements on earth. Absent from INAA results is silicium (Si, silicon in English) and aluminium (Al), the main components of silicate minerals and aluminium oxides that constitute the clay from which pottery is made. Contrary to Neff's (2005: 210) position, if we were to guide these studies from an anthropological perspective it would matter if we used chemical or mineralogical approaches to source determination or how many chemical elements of the periodic table would be measured. There is a substantial difference between learning about the technology from which pottery was made and defining the geological provenance of chemical elements.

Archaeologists have accepted the resulting data, under the strength of "scientific authority", without being able to interpret the nature of the data adequately or the problems regarding the analytical sensitivity, precision, and accuracy of physical or chemical techniques, including the preferential use of some laboratories (Bishop et al. 1990). Already, instrumental techniques have shown to have limitations in the study of Maya pottery. In the literature, we have already discussed the limitations of thermoluminescence technology for dating samples with a sedimentary origin (Wagner et al. 1999). In this case, the claim that the "system" is used as a quick and reliable method to compare and date pottery (Smith 1979) it proved to be an accurate description. In the field, the analyst is able to date any context, "good, fast, and cheap" with the type-variety system. Stemming from the inaccuracy of radiocarbon dated contexts (Hammond 1977) and the authority conveyed to instrumental techniques over other types of data, the Cuello data is a well-published example of the difficulties of timing archaeological findings (Andrews 1990; Andrews and Hammond 1990; Coe 1980; Joyce and Henderson 2001; López Varela 2005a).

Ethnoarchaeological studies have been crucial in leaning about pottery production. In fact, the concern of using instrumental techniques to define human behavior originates from analysts doing ethnoarchaeology (Arnold 1971, 2005b). For several decades, ethnoarchaeological studies have continued to address the transformation of human behavior as material culture to interpret the past (Arnold III 1991; Arnold 1971, 1978; Deal 1983, 1998). This comparative procedure allows the analyst to compare the archaeological and the living contexts. The making of Maya pottery in the past cannot be easily compared with a modern context. Indirectly, this idea suggests that people and their social values, concepts, representations, and symbols have remained unchanged (Hodder 1982: 16). The social logic of our actions, our being in the world, is embedded in history and tradition, so the detachment with the past is not absolute either. However, assuming that people can live unaffected for more than five hundred years of history entails some naïveté. Thus, the meaning of the past is created from our own experiences with the present (Thomas 1996).

Hermeneutic Relations with Maya Pottery

A social approach to the study of Maya pottery is concerned about investigating how material culture expresses the ways in which we conceptualize the relationships between others and ourselves. This new paradigm is interested in approaching the ways people have used objects or natural elements for daily life activities (Meskell and Preucel 2004). There is a genuine interest in learning about how individuals in a society communicate their particular values through objects and natural elements (Buchli 2004; Hodder 2004; Hoffman and Dobres 1999; Pfaffenberger 1999). Learning about the "social life of things" is a theoretical approach contributing to an understanding of the spatiality of objects, to the ways in which people organize living spaces and how these objects define their being-in-the-world (Tuan 1977; Low and Lawrence-Zúñiga).

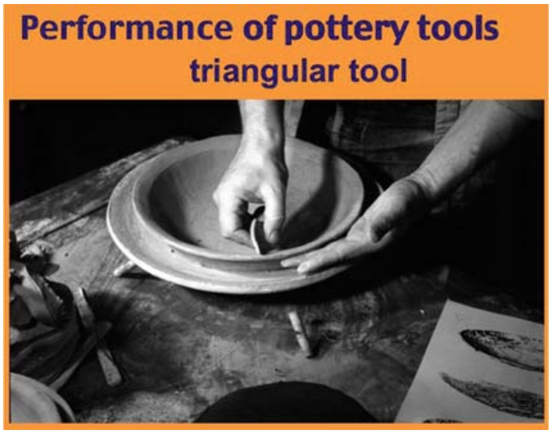
The social embedded in material culture communicates its materiality, but only if we are familiar with the meaning objects intend to convey. At the Institute of Archaeology at Belmopan, there is a distinctive piece of pottery, an orange, nonglazed piece recovered from Actun Chanona, a cave located at the base of the Sibun Gorge, Belize. This lion effigy bears a remarkable resemblance to those found in the Lion's Courtyard of the Alhambra in Granada, Spain. These lions conveyed the Quranic and Biblical images of paradise, a garden with four rivers, sprouting from the lions' mouth. All of these elements – water, plant fertility, directionality and the transition of humans into a paradisiacal world – were shared concepts with the Maya. Meaning does not reside in the object itself or in its immediate surroundings, but in the way that one makes sense of the object. Within this sense of materiality and agency it is essential to recognize that both elements, the social and the natural, are intertwined, both constructing individuals and the space they live in.

Materiality occurs in a time that results from our own lived experiences. Meaningful events and experiences construct our perception of time. Ceramic sequences, for example, are references for the archaeologist to measure time and are distant from the events that constructed peoples in the past. These sequences have constructed "Maya" time following a plot (Hodder 1995: 164) in which everything must have a beginning (Early Classic period), a climax (Late Classic period), and an end (Terminal Classic period). Over the last 40 years, analysts have struggled to define the pottery that characterized the Terminal Classic and the subsequent post-Classic period. Despite the observed persistence of pottery forms and wares from one period to the next, innovation and continuity have to be accommodated to the theories suggesting that a foreign population took over sites of the Maya Lowlands putting an end to Maya culture around AD 800 (Adams 1971; Sabloff 1973; Sabloff and Willey 1967). Over the course of new excavations, we have learned that fine paste pottery a considered trait of such population, was not exclusively made during the Terminal Classic, that alternative regions were producing the pottery, and that the pottery did not always display militaristic images (Bishop and Rands 1982; Foias and Bishop 2005; Lopiparo et al. 2005; López Varela 2005b; Rands 1987). The literary process has governed the ways analysts analyze pottery data. Instead of searching answers as to why new forms were introduced at a time of political turmoil, including environmental changes, analysts are more concerned about fitting innovation and continuity in pottery making as exceptions to the beginning–end cycle that ceramic complexes are forced to express.

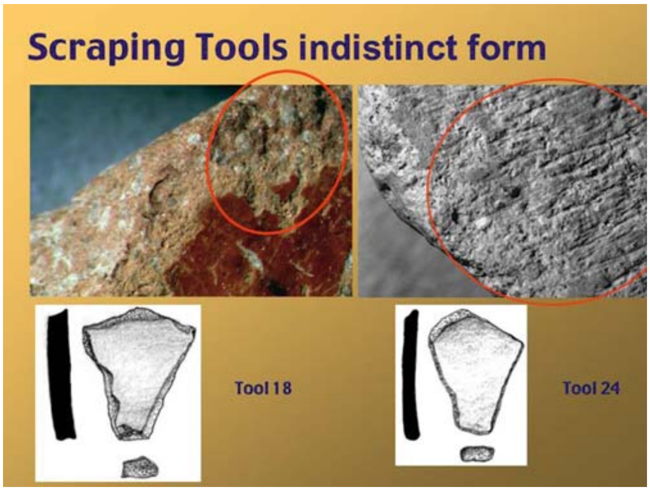
A Social Analysis of the Making of Maya Pottery

In recent years, archaeological research has provided further evidence of pottery making and tools (López Varela et al. 2001, 2002). Already, analysts have identified different kinds of firing features, ranging from open hearths to double-chamber kilns (Lopiparo et al. 2005; López Varela et al. 2001; Urban and Edward 2004). The seminal work of Anna O. Shepard (1956, 1964) stated the relevance of investigating the technological character of Maya pottery, but the number of such studies is very limited (e.g., Angelini 1998; Daszkiewicz et al. 1999; López Varela et al. 2002). Results deriving from these studies describe the sequence of steps by which natural resources were transformed into meaningful and functional objects. The chaîne opératoire (operational sequence) (Leroi-Gourhan 1943–1945), as an analytical concept, leads to an investigation of the decisions made by the producer, as to which resources to use and which form to make. The decisions made by Maya potters encountered recognition only recently in the archaeological record (López Varela et al. 2002). These decisions related to their selection of tools for the making of Late Classic vessels. Basically, potters chose to recycle broken pieces of pottery to make their tools for smoothing, scraping, incising, polishing, and boring. To make ceramic fragments suitable as tools, the edges need to be shaped; otherwise, it would be difficult to hold the piece with the fingers to perform a smoothing or scraping activity. Also, potters worked the edges of the sherds to create particular geometric forms and sizes. Selecting the shape of the pottery tool represents another choice to determine the effectiveness and performance of these implements. In the case of small tools, the angles allow reaching the joints quite easily, facilitating shaping, and retouching of the vessel. These shapes adapted to the pottery grammar of simple clean curvatures and preferable angles characteristic of the Late Classic vessel repertoire (Fig. 2) (López Varela et al. 2002).

Not all pottery fragments made useful tools. Potters intentionally selected broken pieces of pottery based on the characteristics of the fabric over hardness. Still, potters needed tools that could last to perform a particular task. Fragments were selected based on the texture properties of the fabric and the adhesive bond power of particles, as these affect resistance to abrasion (Fig. 3). Tools used for scraping characterized by a fabric containing angular, coarse, crystalline calcite, and rare grains of quartz, representing natural fine sand inclusions that facilitated its use in such activity. Also, most of these tools were made from jars that had a high



Ceramics: Maya Pottery. Fig. 2 Experimental use of a triangular tool. Photographs by Eric Mulder. Illustration by Sandra L. López Varela.



Ceramics: Maya Pottery. Fig. 3 Examples of scraping pottery tools. Photographs by Annelou van Gijn. Illustration by Sandra L. López Varela.

frequency distribution. Broken pieces of jars or bowls that could no longer be mended could be recycled to fabricate the necessary tool fairly quickly, according to our experimental studies (López Varela et al. 2002). Consequently, cost was a factor in the making of Maya pottery.

A social study of Maya pottery considers that the chemical and physical properties of the natural resources condition not only form and function, but also, the objectification of the social. For instance, vessels with a calcareous matrix (a substance containing calcium carbonate), according to chemical analyses, were not used in cooking or in any other activity that could involve their use in a fire atmosphere. Most of the pots with a calcareous matrix exhibited appliqués, slip clay, or paint (e.g., Hillbank Red or Saxche Orange Polychrome). On the contrary those vessels with a noncalcareous matrix and coarse crystalline calcite, added as temper, allowed their exposure to fire (Daszkiewicz et al. 1999). Most striated jars from the Formative to the post-Classic period have a noncalcareous matrix. We learned that potters changed their recipes to make pots, as certain jars of the Encanto Striated type contain aggregates of grog and clay in its noncalcareous matrix. Adding grog represents another choice the potter had to make either because it was necessary to recycle pottery against the lack of resources or the need for experimentation. There is evidence of the making of new recipes to make jars for post-Classic times, as the body shows large crushed particles of calcite that caused the jars of Piste Striated to bloat (Figs. 4 and 5).

To acquire their raw materials, Maya potters did not have to move a long distance. There is possible evidence that potters were quarrying in the surroundings of the pottery workshop found at K'axob (López Varela et al. 2001). In the surroundings of this workshop, nine roughly rectangular blocks of fine-grained consolidated sediment share physical attributes, such as texture, with Belize Red pottery, easily recognized by its thin walls and fine-grained but gritty paste composition. Their size and shape are ideal for tumpline (a band or strap strung across the forehead or chest to support a backpack) or canoe transport. Samples of Belize Red type, originating from excavations at Barton Ramie, showed that the gritty texture of Belize Red was attributable to fragments of pumice and volcanic glass and, to a lesser extent, grains of calcite (Gifford 1976: 255). The analyzed sample from K'axob is characterized by a noncalcareous matrix with grains of

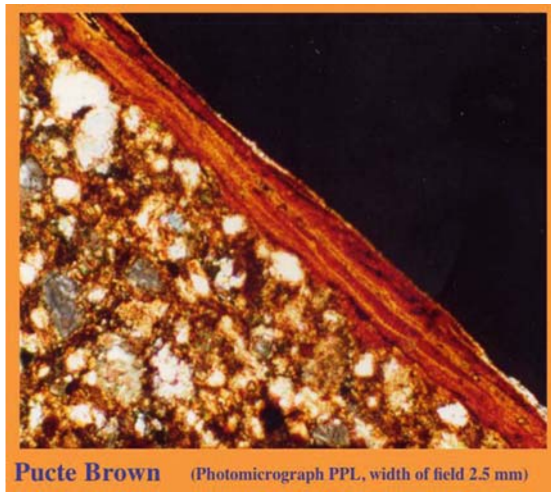
quartz and two aggregates of cryptocrystalline calcite. The composition is not common in the chemically analyzed samples. The making of Belize Red shows that potters accommodated the available natural resources to fulfill social demands (López Varela et al. 2001).

Maya potters received or provided stylistic and form conventions from and to a large-scale sphere of influence that includes, at various times, the Peten, Teotihuacan, the Usumacinta-Pasión regions, and the Yucatan. These pots represented individuals' thoughts and actions, like the making of the tripodal cylinder vessel of Early Classic times. The vessel form was used as far as Teotihuacan and has appeared in numerous contexts in the Maya region, unifying social or political values that are still being debated (Varela Torrecilla and Braswell 2003).

In the Maya region, social identity and power was displayed on painted vessels, such as those of the Saxche Orange Polychrome type. A calcareous matrix with rhombohedric carbonates of coarse silt and fine sand fraction characterizes the fabric. This fine texture provided relatively flat surfaces that could be smoothed with a pebble, for example. Most painted images are displayed on the outside surfaces of vases or the bottom of a dish. According to microprobe analysis, potters used brushes that facilitated the application of several coatings of slip (Daszkiewicz et al. 1999) (Fig. 6). Preparing the surfaces to display the images on a Saxche Orange Polychrome vessel, the potter applied a fine base layer of engobe,[4] then added a very thin iron-rich red slip. The black color of Actuncan Orange Polychrome contains both manganese and iron, contrasting with the red part that only contains iron.



Ceramics: Maya Pottery. Fig. 6 Micropobe Analysis of Pucte Brown pottery. Micrographs by Daszkiewick et al. (1999).

Manganese was also detected in the black paint of samples from Ixcanrio Orange Polychrome and Saxche Orange Polychrome. By controlling the original oxidizing and reducing atmosphere, the potter achieved both a red and a black color.

The Power of Knowledge

In writing about the social in the making of Maya pottery, it is of concern to me that the reader understands that those that made pots in the past had a thorough knowledge of what we now refer to as physical and chemical properties. The word technology may be inadequate to refer to the steps of how pottery was made in the Maya region. Reading the past in the realms of technology represents our ways of seeing the world, as its practice is implicated in acquiring and maintaining relations of power (Hoffman and Dobres 1999: 219). Technologies are media to express, materialize, and mediate social relations and world-views. The word technology is a representation of the current economic division of the world that situates the non-Western in a weak position against the powerful.

My search for social explanations must not be interpreted as an indigenous approach to archaeology. It does not represent the voices of Latin America. The on-going globalization of science, created by the dynamics of our own discipline, the belief that out there, in the external world, one can find indigenous archaeologies, is difficult to believe. Such a discourse is in itself another construct that supports the status quo of the powerful that inadvertently non-Western people continue to emphasize. Investigating the social aspects of pottery results from the long-time quest in archaeology of providing a human face to the pottery that we excavate.

[4] Engobe is liquid clay used to decorate a ceramic piece before it has been fired and usually applied before the piece has dried.

Ceramics: Olmec Pottery

Jeffrey Blomster

After 1200 BCE (years presented in this essay are uncalibrated), distinctive ceramic vessels – Olmec pottery – appeared at select sites across the vast region that anthropologists refer to as Mesoamerica (southern Mexico, Belize, Guatemala, and eastern Honduras; Fig. 1). While exchange and interaction between regions existed prior to this time, in the case of Olmec pottery, the ceramic vessels display a consistent iconography that often contrasts with local pottery traditions. The iconography exhibited on Olmec pottery may represent developing religious beliefs, cosmology and ideology, elements of which can be found in subsequent Mesoamerican groups. While features of the religion and cosmology existed prior to 1200 BCE, Olmec pottery synthesizes and abstracts these concepts on durable material. As such, understanding the origin and spread of Olmec pottery has important implications on the nature of Mesoamerican civilization.

In discussing Olmec pottery, the focus here is only on the earliest Olmec ceramic phase, which corresponds with the ascendance of the site of San Lorenzo from 1200 to 900 BCE – often referred to throughout Mesoamerica as the San Lorenzo Horizon.

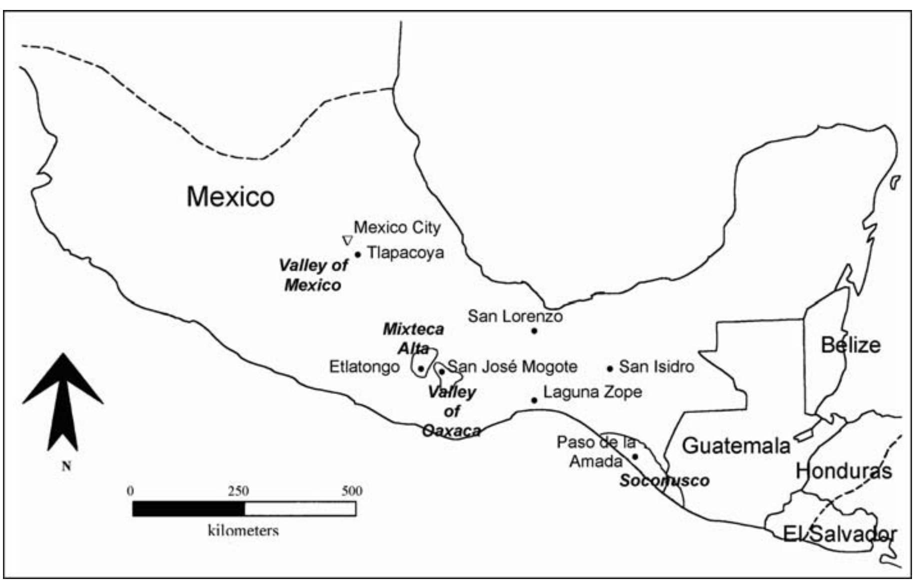
Mesoamerica Prior to 1200 BCE

For millennia after the adoption of agriculture, small villages – marked by very limited political organization and social differentiation – flourished throughout Mesoamerica. In the centuries before 1200 BCE, sociopolitical change began to occur. In the Soconusco region of coastal Chiapas, early chiefdoms of the so-called Mokaya people have been documented (Clark 1991; Clark and Pye 2000), where competing leaders vied for prestige and redistributed imported goods, such as obsidian (a volcanic glass). Each Mokaya chiefdom was centered on a main village, such as Paso de la Amada, where leaders lived in what were probably combinations of public structures and elite residences.

By 1200 BCE, chiefdoms also appear in the Valley of Oaxaca and the Nochixtlán Valley in modern Oaxaca state. In the Valley of Oaxaca, where most small villages covered only 2–5 ha, the village of San José Mogote had a 20 ha "downtown" area of public structures and higher status houses which contrasted slightly with normal houses in terms of quality of construction and plaster, and the occasional outbuilding or ramada (Flannery and Marcus 1994). Similar developments occurred to the northwest, where the site of Etlatongo became the head of a small chiefdom in the Nochixtlán Valley. Beyond Oaxaca, chiefdoms are evident at Basin of Mexico sites such as Tlapacoya and Tlatilco.

The Olmec and the San Lorenzo Horizon

Around 1200 BCE, all of the villages mentioned above exhibit a distinctive new style of ceramic vessels – Olmec pottery – that contrasts with local pottery traditions, which continued to be produced alongside Olmec pottery. While the origin of this pottery has been highly debated, the name applied to it – Olmec pottery,



Ceramics: Olmec Pottery. Fig. 1 Map of Mesoamerica, with modern national boundaries and Mexico City shown for reference. Important San Lorenzo Horizon sites from which Olmec pottery has been analyzed are indicated.

as well as the associated concept of Olmec style – has been criticized for linking this material with the archaeological Olmec people, who flourished at the Gulf Coast site of San Lorenzo, Veracruz, from 1200 BCE to 900 BCE (Blomster 1998; Coe 1968; Diehl 2004; Grove 1989). In this article, the terms Olmec style and Olmec pottery are used separate from the Gulf Coast Olmec, to indicate that the link between Olmec style material culture scattered across Mesoamerica and the Olmec people of the Gulf Coast is one that must be robustly documented rather than assumed. Much of the problem with incautious use of the terms “Olmec style” and “Olmec pottery” is that these concepts were created in the first half of the twentieth century by museum curators examining looted objects, lacking provenience, prior to the discovery and exploration of the archaeological Olmec (Blomster 1998, 2004; Grove 1996). Thus, many objects that have loosely been labeled “Olmec style” over the past 50 years have no actual correspondence with Gulf Coast Olmec material culture. To really discuss the Olmec style and Olmec pottery from a Gulf Coast perspective, objects from excavated and well-documented Olmec sites must be employed to define it, and then compared with the many disparate objects from throughout Mesoamerica that have been labeled as part of this style (Blomster 2002; Coe 1965).

The location of San Lorenzo, on an artificially modified salt dome above the surrounding floodplain, seems to have been an important reason for the growth of this center, which Cyphers (1996, 1997; Symonds et al. 2002) estimates as close to 500 ha – dwarfing all contemporaneous settlements in Mesoamerica. San Lorenzo is almost an island amongst various streams and rivers, with soils constantly replenished by the Coatzacoalcos River. The San Lorenzo Olmec appear to have exerted a tight control over their immediate hinterland, with secondary sites deployed throughout the landscape for controlling the flow of resources (Symonds 2000). Some archaeologists believe the Olmec at San Lorenzo represent a more complex form of political organization, perhaps an incipient state, while all other contemporaneous Mesoamerican regions featured chiefdoms. The debate over the sociopolitical organization of the Olmec has implications for their impact on other regions of Mesoamerica (see Note on Olmec interaction).

Olmec artists created the first monumental art in Mesoamerica, including multiton basalt colossal heads – representing Olmec rulers – and large, rectangular thrones for leaders. The Olmec style is different from other Mesoamerican art styles in formal qualities of shape, line, and space. This art is sculptural – made both in the round and in relief. In addition to the naturalistic imagery on monumental Olmec art there is iconographic or symbolic imagery that abstracts important concepts of Olmec religion, cosmology and ideology (Coe 1965; de la Fuente 1992). The sculptural nature of this style is expressed in pottery, where one of the important types (see below) features carved designs and symbols, some of which appear on monumental Olmec art.

Types of Olmec Pottery at San Lorenzo

In terms of Olmec pottery from San Lorenzo, four types have corresponding examples elsewhere in Mesoamerica (Fig. 2): Xochiltepec White, Conejo Orange-on-White, Calzadas Carved, and Limón Incised (Coe and Diehl 1980).

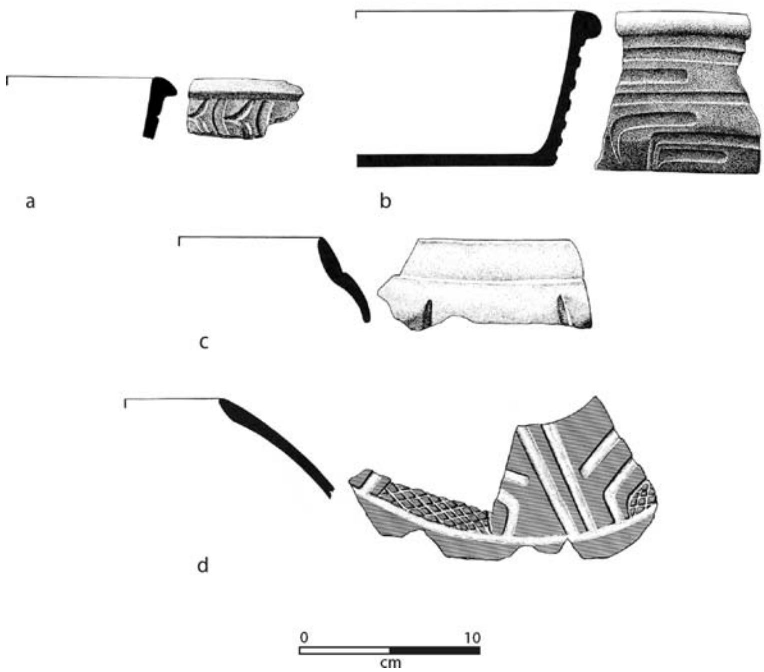
Xochiltepec White pottery is made of clay so low in iron that if fires pure white. In terms of vessel shape, this type is frequently expressed in effigy vessels that represent squashes, usually without additional decoration. Conejo Orange-on-White represents a related – and even scarcer – type (Coe and Diehl 1980: 179). It exhibits the same paste as Xochiltepec White, but has an orange slip, through which potters sometimes carved designs – contrasting the orange with the underlying white of the paste.

Calzadas Carved pottery exhibits distinctive carved Olmec-style symbols. Many of these stylized images contain elements of possible supernaturals referred to as the fire-serpent and were-jaguar, represented by what has been interpreted as flame eyebrows, crossed bands, opposed lines, and music brackets. Limón Incised pottery represents more abstract designs, which generally occur on the exterior of the vessel. Incised lines form curvilinear designs, emphasizing the *ilhuitl* or opposed volutes motif.

Olmec Pottery in Oaxaca

As my work has focused on Oaxaca state, I discuss primarily Olmec pottery present in San Lorenzo Horizon villages in the Valleys of Oaxaca (home of the Zapotec people) and Nochixtlán (home of the Mixtec people). Sherds – broken pottery vessel fragments – of Calzadas Carved and Xochiltepec White have been excavated in the large village of San José Mogote (Flannery 1968), as well as secondary sites such as Tierras Largas (Winter 1972), in the Valley of Oaxaca. Vessels that feature Olmec designs in Oaxaca, such as Leandro Gray and Delfina Gray (Fig. 3), have been interpreted as locally made without any priority by the Olmec in their creation (Flannery and Marcus 1994) – an example of a “peer polity” model (see Note). Accumulating evidence from both the Gulf Coast and Oaxaca, however, fail to support this position.

Excavations at Etlatongo, in the Nochixtlán Valley (Blomster 2004), recovered a large sample of Olmec pottery in an area once characterized as peripheral to the Valley of Oaxaca in terms of both sociopolitical



Ceramics: Olmec Pottery. Fig. 2 Types of Olmec pottery at San Lorenzo, with exterior shown to the right of the profile. (a, b) Calzadas Carved pottery. (c) Xochiltepec White pottery. (d) Conejo Orange-on-White. Adapted from Blomster, Neff and Glascock 2005: Fig. 2.

Ceramics: Olmec Pottery. Fig. 3 Examples of gray Calzadas Carved pottery from Oaxaca. Left, from San José Mogote; right, from Etlatongo. Photo by J. Blomster.

Ceramics: Olmec Pottery. Fig. 4 Cylindrical Calzadas Carved bowl excavated at Etlatongo but through compositional analysis determined to be an import from San Lorenzo. Photo by J. Blomster.

complexity and interaction (Marcus 1989). In addition to examples of Calzadas Carved (Fig. 4) and Xochiltepec White vessels, types of Olmec pottery that have not been published from the Valley of Oaxaca – Limón Incised and Conejo Orange-on-White (Fig. 5) – have also been recovered at Etlatongo. Thus, it appears that Etlatongo has a fuller suite of Olmec pottery types than the large chiefdom centered at San José Mogote.

Compositional Approaches to Olmec Pottery

The origin of Olmec pottery proved elusive through primarily stylistic analyses. If the peer polity model or "sister culture" model is correct, Olmec pottery made in Oaxaca should occur readily at San Lorenzo, while sites like San José Mogote should have little imported Olmec pottery. Oaxacan graywares – Leandro and Delfina Grays – have been interpreted as produced in

Ceramics: Olmec Pottery. Fig. 5 Conejo Orange-on-White vessel excavated at Etlatongo but through compositional analysis determined to be an import from San Lorenzo. Photo by J. Blomster.

the Valley of Oaxaca and exported to Tlapacoya and San Lorenzo (Flannery and Marcus 1994).

In order to determine more robustly the origin of Olmec pottery, chemical characterization techniques were used. Approximately 1,000 archaeological pottery and modern clay samples from the Gulf Coast, Oaxaca state, Chiapas and Central Mexico were subjected to Instrumental Neutron Activation Analysis (INAA) at the University of Missouri Research Reactor. This was a collaborative process, with specialists from both archaeology and compositional analysis contributing to the database and its analysis (Blomster et al. 2005; Neff and Glascock 2002). The INAA process determines the basic chemical composition of a sample through the measurement of various forms of radiation emitted as the radioactive isotopes in an irradiated sample decay. After counts of concentrations of 32 elements have been performed, the chemical data are then analyzed in order to recognize compositionally homogeneous groups within the sample; these groups represent geographically similar zones. Samples that fall within these groups originate from the same geologic zone, and are more similar to each other than samples from other zones.

Through INAA, it was possible to determine the compositional group and region of origin for 726 archaeological samples of Olmec pottery (Table 1). The results fundamentally change the way in which the production and distribution of Olmec pottery is modeled (Blomster et al. 2005).

The San Lorenzo Olmec produced both fine white paste pottery (Xochiltepec White and Conejo Orange-on-White) and decorated Olmec-style pottery (Calzadas Carved and Limón Incised) and exported them to other regional centers across Mesoamerica. Clays collected from various sites around San Lorenzo demonstrate the close chemical relationship between ancient Olmec pottery and modern clays in this region. Some Olmec pottery from other parts of Mesoamerica are in the same compositional group as those manufactured at San Lorenzo. Most regional centers produced local variants of Olmec pottery (Fig. 6), with much variation between regions.

Table 1 documents that the local variants of Olmec pottery were not exchanged between these villages. Of special interest is the data from San Lorenzo itself. A total of 203 archaeological pottery sherds were tested from San Lorenzo, and none of them comes from Oaxaca, or any other part of Mesoamerica. Calzadas Carved sherds found at San Lorenzo that appeared most

Ceramics: Olmec Pottery. Table 1 Regional Assignments for San Lorenzo Horizon Pottery (Adapted from Blomster, Neff and Glascock 2005: Table 2)

similar to "Oaxacan variants" (Flannery and Marcus 1994) were included in the sample to determine if Oaxacan villagers exported Delfina and Leandro Gray pottery to the Gulf Coast. Contradicting a central tenet of the peer-polity model, none of the locally produced Olmec-style pottery in the sample was exported to the Gulf Coast.

While it is possible that if every sample of Olmec pottery at San Lorenzo could be tested, a few may come from outside of the Gulf Coast, this does not impact the general findings of this study. The Olmec at San Lorenzo generally did not receive foreign-made variants of Olmec pottery; the Olmec were its primary exporters.

Olmec pottery and associated symbols were valued by elites at the largest chiefly centers in Mesoamerica. While regions outside of the Gulf Coast made their own unique innovations and contributions to local versions of Olmec pottery, it does not appear that these other regions contributed substantially to the assemblage of Olmec-style symbols employed beyond each region. The Olmec appear to have been the primary disseminators of this pottery, which often displays rich iconography. Furthermore, important villages in adjacent regions such as San José Mogote and Etlatongo received pottery from the more distant San Lorenzo rather than from each other. This attests to the high value that was placed on Gulf Coast produced Olmec pottery.

The Olmec interacted with groups across Mesoamerica that were already chiefdoms; both the Olmec and regional groups had various interests in this interaction. The symbols exhibited on Olmec pottery suggest the dissemination of elements of Olmec religion and cosmology, which may have been received and utilized in widely different manners based on the interests of regional leaders and negotiations between and within local populations. While investigators in the Mazatán region propose that this interaction transformed the local population from Mokaya to Olmec (Clark and Pye 2000), the impact in the Nochixtlán and Oaxaca Valleys appears to be substantially different and less profound. At Etlatongo, both imported and locally made Olmec pottery probably never exceeded 5–10% of the total ceramic assemblage (Blomster 2004). Access to foreign produced versus local imitation may reflect increasing differences in social status within Etlatongo society.

Note: The Debate on Olmec Interaction

Much of the debate over Olmec interaction revolves around two perspectives. The nuclear-linear or so-called "mother culture" school views the Olmec as a precocious group in terms of social complexity, synthesizing, and disseminating traits essential to all Mesoamerican societies. While Covarrubias (1957) proposed the Olmec created Mesoamerican civilization, modern proponents reject this idea, arguing that while the Olmec had achieved a different level of sociopolitical complexity than their contemporaries, they interacted with groups that already exhibited complexity (Diehl 2004). Due to the charged nature and contested meanings of the term "mother culture," scholars who explore Olmec influence in Mesoamerica attempt to move beyond this term by focusing on the actual impact of the Olmec outside of the Gulf Coast (Neff et al. 2006b).

The peer polity model or so-called "sister culture" school views the Gulf Coast Olmec as just one of many groups utilizing a shared symbol set with other regions of Mesoamerica, without any priority in developing these symbols or attainment of a greater level of social complexity (Flannery 1968; Flannery and Marcus 1994). Proponents of this perspective view the Olmec as a chiefdom, although the ongoing research at San Lorenzo (Symonds et al. 2002) demonstrates the more complex sociopolitical organization of the Olmec relative to contemporaneous groups.

Peer polity supporters (Flannery et al. 2005; Stoltman et al. 2005) banded together to contest the results of the INAA of Olmec pottery project, claiming a different approach to analyzing the ancient pottery – thin-section analysis (which looks at specific minerals in sherds) – contradicts the results of the INAA, viewing one method as superior to the other. The reality is these two methods complement each other. The conclusions of the Flannery and Stoltman group lack a substantive sample of local geology around San Lorenzo. Their claim, for example, that the volcanic materials in pottery excavated at San Lorenzo proves they are made in Oaxaca (Stoltman et al. 2005) founders on the fact that volcanic materials are also present in soils around San Lorenzo, as documented by petrographic analysis from the Cyphers project at San Lorenzo (Neff et al. 2006b). The INAA project (Blomster et al. 2005; Neff et al. 2006a) documents that the Gulf Coast Olmec produced and disseminated Olmec pottery. While this research contributes to a stimulating debate on Olmec interaction and contrasting scientific methods, basic questions about what the Olmec and the various groups received from this exchange await further exploration.

Ceramics in Southeast Asia

DAWN F. ROONEY

The mainland region of Southeast Asia has a rich, indigenous tradition of ancient ceramic production with centers in the modern nations of Cambodia, Lao People's Democratic Republic (Laos), Myanmar

(Burma), Thailand, and Vietnam. The main output was ware for domestic and ritualistic use and regional trade. The insular Southeast Asian region (Brunei, East Timor Indonesia, Malaysia, Philippines, Singapore) made only utilitarian earthenware such as cooking and storage vessels for foods and liquids. It did, though, import trade ceramics from the mainland, China, and Japan beginning in the fourteenth century.

By the second millennium BCE inhabitants of early rice-agriculture settlements in Southeast Asia were making similar types of red-slipped, painted, stamped, and cord-marked pottery. Roulette-made ware from India found in Java and Vietnam testify that trade contacts between India and Southeast Asia were established by the last century BCE.

Ban Chiang, Udon Thani Province, Northeastern Thailand, is a representative, prehistoric site for the region. Excavations of burials conducted between 1974 and 1986 yielded tons of shards. Various forms of vessels with geometric designs painted in red on a buff-colored body were made using the anvil and paddle technique. The site is dated from BCE 3600 to AD 200.

The prehistoric tradition of making indigenous pottery in Southeast Asia continued into the next period. Thousands of shards unearthed at Angkor Borei, Ta Keo Province, southern Cambodia, are typical pottery of the early historic period, particularly the spouted vessel (*kendi*) with a bulbous body and a spout on the side, which is a ubiquitous form at all early sites in Southeast Asia (Fig. 1).

The earliest transitions from low-fired, unglazed to high-fired glazed ware occurred in Cambodia and Myanmar between the eighth and ninth centuries AD.

Cambodia

Green-glazed roof tiles from temples of the Angkor Period (AD 802–1432) capital of Hariharalaya (now Roluos), built by King Indravarman I (r. AD 877–889), attest that the Khmers were making glazed stoneware by the late ninth century. Their repertoire expanded to include brown-glazed ware in the eleventh century. Ceramic production in Cambodia continued at least until the end of the thirteenth century. Although the Khmer Empire lasted for another 150 years, ceramics have not yet been positively attributed to the later period.

The first discovery of kilns producing Angkor Period ceramics was in the 1970s in Northeastern Thailand on the Khorat Plateau, an area that was part of the Khmer Empire between the eleventh and the thirteenth centuries. Kilns in Cambodia, however, were not confirmed until 1995.

Groslier proposed the first chronology for Khmer ceramics. He analyzed types of glazes on wares found in excavations in the mid-twentieth century at the Angkor Period Royal Palace compound and in a burial at Srah Srang, the royal bath. Brown published a later refinement of Groslier's chronology (1981).

Two extensive kiln sites have been identified in Buri Ram Province – Ban ("village") Kruat and Ban Baranae. The oval-shape, crossdraft kilns were built of clay slabs with two chambers and a chimney. Both made green- and brown-glazed ware.

Over 12 groups of kilns operating during the Angkor Period in Cambodia have been identified in Siem Reap, Banteay Meanchhey, and Kandal provinces. Anlong Thom, on the southern ridge of Phnom ("Mount") Kulen, 25 mile (40 km) northeast of Angkor, produced high-quality, green-glazed stoneware. The main shapes were architectural fixtures (tiles and finials), covered jars, and bowls (Fig. 2).

The iron-rich body of Khmer stoneware is gray with impurities. Larger vessels were coil-built; smaller ones

Ceramics in Southeast Asia. Fig. 2 Green-glazed roof tile. *L* = 7.5 in. (19 cm). Khmer. Tenth century.

Ceramics in Southeast Asia. Fig. 3 Brown-glazed storage jar. *Ht* = 26 in. (66 cm). Khmer. Twelfth century.

Ceramics in Southeast Asia. Fig. 4 Brown-glazed footed jar. *H* = 16 in. (40.6 cm). Khmer. Late eleventh century.

were thrown on a wheel. The glaze was either brown or green with fine-line cracks. Flaking of the glaze is a common defect. Decoration is always minimal and consists of repetitive geometric patterns encircling the neck, shoulder, or body (Fig. 3).

Some Khmer forms, uncommon in other ceramic traditions of Southeast Asia, may have metal prototypes. Examples are:

Ceramics in Southeast Asia. Fig. 5 Unglazed pipe. Stoneware. *L* = 3.5 in. (8.9 cm). Laotian. Seventeenth Century.

– A green-glazed cylindrical covered jar and a bowl with slightly flaring walls and unglazed firing scars around the lower body
– A brown-glazed flattened globular pot with a broad shoulder, a flat base, and a narrow mouth with a rolled rim
– A footed jar with a round body, a flat shoulder, tubular neck, flaring mouth with a flange, and a pedestal base
– Small pots with animal-shape (birds, elephants, rabbits) appendages (Fig. 4)

Laos

Excavations conducted at Sisattanak, near the modern capital of Vientiane in Lao People's Democratic Republic (Laos), in 1970 and 1989 identified a kiln site that operated between the fifteenth and seventeenth centuries based on radiocarbon dating of associated finds. Quantities of unglazed and brown-glazed stoneware shards and wasters were spread over a wide area. The shapes are utilitarian and include bowls, dishes, jars, and pipes (Fig. 5).

Myanmar (Burma)

Architectural plaques and tiles (unglazed and glazed) were used on temples at Bagan (formerly Pagan) in the eleventh century. Geometric tiles are square, round or octagonal and decorated with applied lotus leaves or a lozenge with a blue-green glaze and yellow and white accents. Pictorial plaques portray episodes from the Buddha's former lives (Fig. 6).

Myanmar archaeologists recently discovered hundreds of ancient kilns in Twante district, approximately 11 mile southwest of the capital, Yangon (formerly Rangoon). They produced only celadon and probably operated between the fifteenth and seventeenth centuries. Previously unidentifiable celadon found in burial sites in Indonesia, the Philippines, and Tak and Om Koi are now attributed to Myanmar.

Ceramics in Southeast Asia. Fig. 6 Glazed tiles at Naga-yon temple. Bagan, Myanmar. Eleventh Century.

Ceramics in Southeast Asia. Fig. 7 Excavated kiln at Twante, Myanmar. Fifteenth to seventeenth centuries.

Ceramics in Southeast Asia. Fig. 8 Celadon bowl (shard). Twante, Myanmar. Fifteenth to seventeenth centuries.

Two kilns were excavated in 1999. The characteristics are (1) oval-shape, (2) crossdraft, and (3) built of clay slabs on a slope with two chambers separated by a low wall and a chimney. An unusual feature of the Twante kilns is the remains of columns in the firing chamber, which were probably used to support a dome-shaped cover. The kiln dimensions are 39 × 16 ft (11.9 × 4.9 m). Tubular, clay supports were used to stack the ware. The body contains quartz, other silica, and a high concentration of iron. The characteristics after firing in a reducing atmosphere to a stoneware temperature are: a nonporous body and a wood-ash glaze with iron that produced a transparent, green color. Pooling of the glaze is common. Forms are medium-sized vessels that were hand-built or thrown on a potter's wheel. Typical shapes are simple bowls, dishes, and plates with minimal geometric decoration (Figs. 7 and 8).

Other known kiln sites in Myanmar include: Lagunbyee, a former Mon center, southwest of Bago (formerly Pegu) where remains of a brick, crossdraft kiln were discovered in 1987 and excavated in 1998–1999; the kiln is 120 × 70 ft (36.6 × 21.3 m) and provisionally dated between the eleventh and the thirteenth centuries. Ten kilns and firing supports have been discovered at Myaung-Mya, west of Yangon, near Bassein.

Although kilns have not been found, it is certain that distinctive earthenware with an orange body and an opaque white, vibrant red, or green glaze was made in Myanmar. A variation is a design painted in green under the white glaze (Fig. 9).

Thailand (Sawankhalok or Si Satchanalai Ware)

Three sources have enabled recent advances in our knowledge of ancient ceramic production in Thailand: underwater archaeology in the Gulf of Thailand where 130 shipwrecks have been reported; excavations of kilns at Sawankhalok and surveys in satellite areas – Phitsanulok, Suphan Buri, and Sing Buri; and ceramic finds in burials at Tak and Om Koi, western Thailand, near the Myanmar border. The quality of ware from the latter is extremely fine and the wide range includes ceramics from China, Vietnam, Thailand, Cambodia, and Myanmar.

Glazed architectural fixtures were made in the late thirteenth century for the temples of the burgeoning Kingdom of Sukhothai in north-central Thailand (279 mile (449 km) north of the modern capital of Bangkok). As the kingdom expanded, a second city developed at Si Satchanalai, 43 mile (69 km) north of Sukhothai, where kilns producing glazed ceramics were also set up. In the middle of the fourteenth century when Sukhothai became vassalage of the southern Kingdom of Ayutthaya, 49 mile (79 km) inland from the Gulf of Thailand the place name "Si Satchanalai" was changed to "Sawankhalok." Today, either name is acceptable when referring to the kiln site and the wares. The kilns continued to operate at least through the sixteenth century despite the shift in power.

The dates of operation for the two ceramic centers are not conclusively known. Evidence from shipwrecks

Ceramics in Southeast Asia. Fig. 9 Green and white earthenware shards. Myanmar. Fourteenth to sixteenth centuries.

Ceramics in Southeast Asia. Fig. 10 Excavated kiln at Ban Ko Noi. Sawankhalok, Thailand. Fourteenth to fifteenth centuries.

Ceramics in Southeast Asia. Fig. 11 Tubular support for celadon bowl; scar after firing. Sawankhalok, Thailand. Fifteenth century.

carrying ceramics found in the Gulf of Thailand reverses a previously held theory and confirms that the Sukhothai kilns began production later than those at Sawankhalok. During the peak period for the export of ceramics from north-central Thailand (fifteenth and early sixteenth centuries) an estimated 1,000 kilns were operating. Changes in social, economic, and political circumstances of the kingdom most likely impacted on the kilns, causing a gradual decline in ceramic production.

Some 800 kilns have been discovered in the modern village of Ban Ko Noi, 4 mile north of the old city wall on the banks of the Yom River. Ban Pa Yang, a smaller kiln site in the area, produced architectural fixtures, human and animal figures, and brown- and white-glazed trade ware.

Kiln technology at Sawankhalok evolved from a simple bank kiln for firing unglazed, low-fired ware to one constructed of clay slabs that was more sustainable and could hold larger vessels. Finally there was a crossdraft kiln built of prefired bricks. A typical kiln of the latter type is oval shape, crossdraft with a sloping chamber for the wares in the center, a recessed fire-box at one end, and a round chimney at the other. A typical kiln was 29 × 11 ft (8.8 × 3.4 m). For firing, a fixative was applied to the base of a vessel, which was then placed on top of a tubular clay support that was sunk into the sandy floor of the kiln. A black ring on the unglazed base resulted from the fixative of the vessel after firing (Figs. 10 and 11).

Green-Glazed Ware (Celadon)

Sawankhalok celadon is the most widely known product of the ancient Thai kilns. An iron-rich glaze was mixed with ash and fired in a reducing atmosphere. The thick, translucent glaze varies in color from a sea green to olive. Motifs incised in the center of plates and bowls, around the cavetto (a hollow or concave molding in the form of a quadrant) and rim, and on the exterior, drew inspiration from the regional flora, such as lotus and peony. Primary shapes are plates, bowls, bottles, kendis, and jarlets (a small, squat, rounded, or square jar with a small mouth) (Fig. 12).

Brown and White Ware

Sawankhalok kilns produced two other monochrome glazes – brown and white. A typical brown-glazed form is a jar with a tall body, a thick-rolled mouth rim and two handles. A combination of the two glazes on a single piece was a specialty of the export ware made at the Ban Pa Yang kilns (Fig. 13).

Exceptionally large water jars were also made (Fig. 14).

Architectural fixtures, such as tiles, were usually white-glazed (Fig. 15).

Ceramics in Southeast Asia. Fig. 12 Celadon plate. Diameter = 11 in. (28 cm). Sawankhalok. Fifteenth century.

Ceramics in Southeast Asia. Fig. 13 Brown-glazed jar. *H* = 5 in. (13 cm). Sawankhalok. Fifteenth century.

Ceramics in Southeast Asia. Fig. 14 Brown-glazed storage jar. *H* = 3 ft. Sawankhalok. Fifteenth century.

Ceramics in Southeast Asia. Fig. 15 White-glazed tile. *H* = 4 in. (10 cm). Sawankhalok. Fourteenth century.

Quantities of figures (animal and human) were made at Tukatha (Ban Pa Yang kiln site) for the religious and cult needs of the native inhabitants (Fig. 16).

Iron-Decorated Ware

A design was painted on the body with iron oxide; then a transparent clear glaze applied over it. Sometimes a slip was put on the body for a lighter color which created more contrast between the design and the background. Forms include plates, bowls, bottles, kendis, and architectural fixtures. A particular type of round covered box was produced prolifically for export. The body and cover of the box form a continuous line with modeled knob on the cover that is shaped like a lotus bud or in the form of a fruit stem (Fig. 17).

Thailand (Sukhothai Ware)

Two clusters of over 50 kilns have been identified at Sukhothai – one near Wat ("temple") Prah Phai Luang and another north of the city wall. The kiln shape and

Ceramics in Southeast Asia. Fig. 16 Brown-glazed chicken. $L = 3$ in. (7.6 cm). Sawankhalok. Fourteenth century.

Ceramics in Southeast Asia. Fig. 18 Disc firing support. Diameter = 4 in. (10 cm). Sukhothai. Fifteenth century.

Ceramics in Southeast Asia. Fig. 17 Underglaze glaze painted box with cover. Diameter = 4 in. (10 cm). Sawankhalok. Fifteenth to sixteenth centuries.

Ceramics in Southeast Asia. Fig. 19 Painted shard. Sukhothai. Fifteenth century.

construction are essentially the same as those at Sawankhalok except the Sukhothai kiln is narrower. The average dimensions are 29 × 8 ft. Plates and bowls were stacked for firing by placing one on top of the other separated by a disc-shaped clay support with spurs (usually five). A distinctive feature in the center of Sukhothai plates and bowls is five circular scars resulting from separating the disc after firing (Fig. 18).

Sukhothai kilns produced two types of ceramics – painted ware and a white-glazed ware. To achieve the former, a slip was applied to a dark body; next, a design was painted using iron oxide; then a thin, transparent glaze was applied. After firing, the texture of the gray body was coarse with visible white flecks of quartz; the color of the iron pigment varied from gray to olive, brown or black; and the glaze is often opaque, or milky in appearance with fine-line crazing and pin holes. A painted fish plate (average diameter = 10 in. (25 cm)) is characteristic of the Sukhothai kilns. The central motif is a single fish, painted in profile, and encircled by one or more rings. Other designs on plates, bowls, and a few bottles such as a single stemmed flower surrounded by leaves and a solar whorl and architectural forms were made at Sukhothai (Fig. 19).

Thailand (Suphan Buri Ware)

A complex of kilns at Ban Bang Pun in Suphan Buri Province, northwest of Ayutthaya, was discovered in the 1980s. The main output was unglazed stoneware footed jars, which were previously attributed to Sawankhalok or Sukhothai. Distinctive, repetitive bands of a leaf motif were stamped around the base of the neck and outer shoulder. The crossdraft, clay kilns were of a similar design to those at Kalong in northern Thailand.

Thailand (Phitsanulok and Nakorn Thai Ware)

Phitsanulok, a small state east of Sukhothai and controlled by the Sukhothai Kingdom in the thirteenth century, became a provincial capital of the Ayutthaya Kingdom in the fifteenth century. Excavations in 1984 at Ban Tao Hai ("village of the jar kilns") on the eastern bank of the Nan River, 2.5 mile (4 km) north of the modern town of Phitsanulok, revealed two brick, crossdraft kilns of the type developed at Ban Ko Noi with another estimated 40 kilns in the area. A typical jar is baluster-shaped with a flaring mouth and applied decoration. The kiln structure and the output suggest the site operated in the late fourteenth or early fifteenth century.

The identification of six kilns at Nakorn Thai, east of Phitsanuloke, indicates that it was also a production center for stoneware jars with dates of operation the same as the Phitsanulok kilns.

Ceramics in Southeast Asia. Fig. 20 Excavated kiln at Sankampaeng. Northern Thailand. Mid-fourteenth to mid-sixteenth centuries.

Ceramics in Southeast Asia. Fig. 21 Brown-glazed plate. Diameter = 9 in. (23 cm). Sankampaeng, Northern Thailand. Mid-fourteenth to mid-sixteenth centuries.

Thailand (Northern Thai Ware)

Lan Na, founded by King Mengrai in 1292, with a capital at Chiang Mai in Northern Thailand, was an extensive ceramic center making glazed stoneware for domestic and ritualistic needs between the mid-fourteenth and the mid-sixteenth centuries.

The northern kilns were dug from river banks, or made with clay slabs in-ground, or brick-constructed above ground. General characteristics are: small size, simple construction, and crossdraft with two chambers and a chimney. Plates, dishes, and bowls were stacked in the kilns lip to lip and base to base.

Kalong

Over 200 kilns are mid-way between Chiang Mai and Chiang Rai near the valley of the Lao River. Kalong kilns produced ware painted with iron oxide under the glaze in the style of those from north-central Thailand but with more flamboyant motifs executed with broader brush strokes. Dishes with an abstract leaf and flower design are typical. The Kalong kilns also made a fine, thinly potted ware covered with a soft rain-cloud gray glaze. Vases, bowls, bottles, and dishes comprise this group.

Sankampaeng, Phayao, Nan

Eighty-three kilns are located by the Ping River valley, approximately 15 mile (24 km) east of Chiang Mai. Average dimensions of a kiln are 10 × 4 ft (3 × 1.2 m). Plates and dishes (either painted or brown-glazed) with a central medallion of two fish are typical Sankampaeng ware. Celadon, painted ware, and two-color jars were also common (Figs. 20 and 21).

Kilns were reported at Phayao, in Cham Pawai district, near the remains of an ancient walled city, in the 1950s. The site is unexcavated but shards of celadon, brown-glaze, and two-glaze wares have been found. Stamped motifs and incising through a slip are distinctive characteristics of Phayao ware.

An extensive kiln site was found at Nan, western Thailand, in 1982. It produced painted ware (underglaze black) with a milky white glaze that was placed in a sagger (a box of baked fireproof clay used to protect pieces during firing) for protection during firing.

Phan

Twenty-seven brick kilns situated between Chiang Rai and Phayao are of the crossdraft type with the average dimensions of 20 × 11 ft (6 × 3.4 m). The Phan kilns only produced celadon. It is more carefully potted and more finely finished than other northern wares. The shapes include plates, bowls, jars, oil lamps, miniatures, elephants, and kendis. The sophistication and the narrow range of these wares suggest a slightly later date, perhaps from the mid-fifteenth to the mid-sixteenth century.

Thailand (Lamphun (Haripunjaya) Ware)

Although no kilns have been found, shards litter the area of Lamphun, the old Haripunjaya kingdom, and similar ones were found at Tak and Om Koi. These finds suggest a mid-fourteenth to mid-sixteenth century date. The finely textured body is either orange or brownish black. A typical form is a thinly potted, globular, long-necked bottle with a flat base, inlaid with slip, and either intricate white or black geometric motifs on the neck and body.

Thailand (Sing Buri or Maenam Noi Ware)

Excavations conducted in 1987 in Bang Rachan district of Sing Buri Province at the Tao Maenam Noi kiln site established the provenance of a class of brown-glazed storage jars previously believed to be Sukhothai. As the kilns are located near a temple, the ware is popularly called Wat ("temple") Phra Prang Pottery. The oval-shape, crossdraft, brick kiln measures 44 ft (13.4 m) long and is the largest one found so far in Thailand. Both unglazed and glazed ware was made, mostly storage jars but also unglazed kendis. A typical jar is heavily potted, with an ovoid body and a narrow neck with a rolled lip and partially covered with a brown glaze. These jars have been found in the cargo of a number of shipwrecks in the Gulf of Thailand dating to the late sixteenth or early seventeenth centuries (Fig. 22).

Ceramics in Southeast Asia. Fig. 22 Brown-glazed jar. *H* = 18 in. (45.7 cm). Sing Buri, Thailand. Late sixteenth to early seventeenth centuries.

Vietnam

The glazed ceramic tradition of Vietnam is unlike any other in Southeast Asia as it was strongly influenced throughout history by China, both technically and stylistically. Its development, forms, and motifs, therefore, are parallel approximately that of Chinese ceramics. Extensive excavations of burial grounds in the early twentieth century in Thanh-hoa Province, northern Vietnam, yielded quantities of ceramics dated between the tenth and the thirteenth or fourteenth centuries. Kilns near the modern city of Hanoi, the site of capitals of the Ly (AD 1009–1225) and the Tran (1225–1400) dynasties, were most likely the source of the Thanh-hoa ware. Vietnamese ceramics entered the export market in the fourteenth or early fifteenth century with painted ware in both underglaze blue and black. Despite the Chinese influence, some forms are distinctively Vietnamese. A storage container for lime to use for betel chewing is an example. The squat form has a small opening on the shoulder, a pedestal foot, and a "basket-like" handle with elaborate decoration. Ritualistic ceramics made in the late sixteenth or seventeenth century at kilns near Hanoi are distinguished by large altar vases and incense burners (Fig. 23).

Ceramics in Southeast Asia. Fig. 23 Green-glazed lime pot. *H* = 7 in. (18 cm). Vietnamese. Fifteenth to sixteenth centuries.

Chao Yuanfang

Fabrizio Pregadio

Virtually the only known detail of the life of Chao Yuanfang, Chinese physician and medical author, is that he was Medical Erudite (*taiyi boshi*) at the court of the Sui dynasty sometime between 605 and 616. In that position he supervised the compilation of the *Zhubing yuanhou lun* (Treatise on the Origin and Symptoms of Diseases), the first Chinese text comprehensively devoted to etiology and symptomatology. The work, which is integrally preserved, was submitted to the throne in 610.

The 50 chapters of the *Zhubing yuanhou lun* discuss more than 1,700 syndromes, classified into 67 categories of internal and external diseases. The final sections are concerned with gynecology, obstetrics, and pediatrics. A special feature of the text lies in its therapeutic methods. Rather than ingestion of drugs or acupuncture, Chao advocated a therapy based on such practices as diet and *daoyin* (a set of bodily postures, similar in some respects to Indian *hatha yoga*). The *Huangdi neijing* (Inner Canon of the Yellow Emperor) provides the broad theoretical foundation to Chao's work.

The *Zhubing yuanhou lun* exerted a remarkable influence on the history of Chinese medicine, as reflected for example in the *Qianjin yaofang*, written by Sun Simo. It was highly esteemed in Japan as well, where it inspired the classification of diseases in the earliest extant medical compilation, the *Ishinpō*.

Chemistry in China

Anthony R. Butler, Christopher Glidewell

Of all the sciences in antiquity chemistry was one of the least understood. Until people had some comprehension of chemical elements, compounds, atoms, molecules, ions, and bonding, they found it difficult to make much sense of the chemical processes occurring naturally. This does not mean that there is no real history of chemistry; it means only that we should assess the early chemical practitioners on the accuracy of their observations rather than that of their interpretations. The modern Chinese term for chemistry is *huaxue*, the study of change, and what the ancient Chinese did well was to note and describe the chemical changes which were observed when substances were mixed, heated, dissolved, or treated in some way. The fact that their interpretation may seem a little abstruse by modern standards does not detract from the worth of their observations.

Before chronicling chemistry in ancient China it is important to understand exactly what had stimulated an interest in chemical processes. The Daoist religion sought to lead its adepts into such a harmonious relationship with the world that they would escape the horrors of disease and the tragedy of death. It was not life after death but life without death, although the precise notion varied from age to age. Those who had discovered the *dao*, through meditation, study, forms of exercise, appropriate sexual activity, and purity of life, would retire to an isolated mountain retreat and there live in complete harmony with nature. They were called *xian* or "immortals," nearer to gods then men. The idea of longevity as a reward for the godly life is not unique to Daoism; similar notions occur in Judaism. In the genealogy of the patriarchs we read, "And Enoch walked with God after he begat Methuselah three hundred years and begat sons and daughters" (Gen. 5^{22}). However, what is special to Daoism is the use of drugs to acquire immortality.

Until the Song dynasty, Chinese drugs were grouped into three classes: superior drugs which allowed one to realize vital powers, medium drugs to enrich one's nature, and inferior drugs which cure disease. This particular classification is given in *Zhenghe bencao* (Herbal of the Zhenghe Era) and it is the superior drugs that became associated with the attainment of immortality. Initially the drugs were quite crude materials: minerals straight from the ground or dried herbs, but subsequent developments lead to the compounding of these "simples" to give "elixirs of immortality." It was in the preparation of elixirs that the ancient Chinese made their first chemical observations.

The preparation of elixirs was not an activity associated with a popular or debased version of Daoism and abhorred by the more sophisticated Daoist adepts. Although the importance of elixirs in Daoist practice varied somewhat from dynasty to dynasty it always played some part in the pursuit of the Daoist goal. Several emperors of ancient China expended considerable effort to obtain the elixir of life. Shihuangdi (259–210 BCE), of the Qin dynasty, equipped large expeditions under the command of Xu Fu and others to go abroad to uncover arcane secrets of preparing elixirs. Emperor Wu (156–87 BCE) appointed numerous magic specialists to high positions.

Two prominent components of Daoist elixirs were cinnabar (mercuric sulfide) and gold. The reasons for this selection are not difficult to appreciate. Cinnabar is bright red, reminiscent of healthy blood, and it was thought that the infusion into the body of extra healthy blood would enhance health and lifespan. The absence of understanding of chemical composition among the ancient Chinese meant that the physical appearance (i.e., the color) had greater significance than the obviously different chemical properties of cinnabar and blood. Gold was probably the most prized component of an elixir because it was obtained from the ground in an uncombined (and thus, uncorrupted) form and in the air it did not tarnish. If these attributes could be acquired by the human body then it would, indeed, last forever. One difficulty recognized by Chinese alchemists was that both cinnabar and gold are insoluble in water and, therefore, unlikely to be absorbed in the body. Much effort, therefore, was expended in devising methods of solubilizing both cinnabar and gold.

A manual in the Daoist Patrology (*Dao Cang*) entitled *Sanshi liu Shui Fa* describes the use of niter (potassium nitrate) in vinegar (dilute ethanoic acid) to bring numerous minerals, including cinnabar, into solution. In some cases there appears to be some confusion between solution and suspension; in other cases solution would occur in any aqueous solvent. However, in a few cases, particularly in the solubilization of cinnabar, some interesting chemistry is involved. A solution of pure niter in pure aqueous ethanoic acid has no effect on cinnabar but solubilization does occur if chloride ion is present as an impurity. This is probable as niter was obtained from marine sources. Thus the fanciful descriptions of Chinese alchemy may have a sound basis in chemistry if allowance is made for probable impurities. The same applies to an account in the *Sanshi liu Shui Fa* for the solubilization of gold where the required contaminant is iodate, a common impurity in crude niter deposits. The fact that these accounts of Chinese alchemical activity can be explained in modern chemical terms is evidence of the accuracy of the original observations.

Gold is not common in China and it was not regularly used as a form of currency. Because of the shortage of gold, much alchemical activity was directed at making gold from more commonly available materials. This appears, at first sight, to be identical with European alchemical activity but the motivation was completely different. In Europe it was, until fairly late in the thirteenth century, the pursuit of wealth; in China it was from earliest times the pursuit of immortality. Cinnabar was a popular material upon which to work (gold and cinnabar often occur together in the earth) and the *Gui Jia Wen* contains the lines:

> The span of life is up to me, not heaven.
>
> The reverted cinnabar becomes gold, and millions of years are mine.

In the most famous alchemical manual (the *Neipian* of the *Bao puzi*) the author, Ge Hong, gives a recipe for preparing gold from tin by heating with various forms of alum (potassium aluminum sulfate) on a horse dung fire. What was made was tin sulfide or mosaic gold, a yellow material which glitters just like gold. Present-day repetition of the procedure, using an electric furnace rather than a horse dung fire, confirms the production of tin sulfide.

The elixirs made from simples like cinnabar and gold contain, in general, so many components, some of which will contain impurities, that it is difficult to hazard a guess at what chemical changes are occurring. Picturesque titles were given to many elixirs. A mixture of calomel (mercuric chloride), cinnabar, sulfur, and realgar (arsenic sulfide) was known, according to the *Danjing Yaojue* of Sun Simo of the Tang dynasty, as Grand Unity Three Envoys Elixir. Needless to say, the elixirs did not have the required effect and their use in Daoist practice gradually died out, leaving only a memory of sustained but flawed chemical activity. There are just a few exceptions to this generalization of futility in Chinese alchemical activity, the most famous of which is the production of gunpowder, known originally as *huoyao* or “fire drug”. Niter and sulfur are mentioned in early *materia medicas*, including *Shennong Bencao Jing* from the Han. Possibly in pursuit of elixirs, they were mixed and inadvertently contaminated with carbonaceous materials, giving a material which burned very brightly. Careful adjustment of the proportions gave an explosive, used in China for firearms and civil engineering and for fireworks. The first printed recipe for gunpowder is given in a military manual, *Wujing zongyao* by Zeng Gongliang, printed in AD 1044. It was the optimized formula which traveled to Europe and had such a dramatic impact on the conduct of warfare. It is ironic that the most significant achievement of Chinese alchemists in their efforts to make elixirs of immortality was an instrument of warfare.

With a decline in interest in alchemy during the Yuan, Meng, and Qing dynasties, there was no emergence of modern chemistry from alchemical activity as there was in Europe. The advanced state of modern Chinese chemistry (epitomized by the laboratory synthesis of insulin in 1965) is due to the introduction of chemistry from the West during the nineteenth century, partly by missionaries and partly by young Chinese students studying in Europe and America. Among missionaries (although the term is not entirely appropriate) was John Fryer, the son of a poor English clergyman, who worked at the Kiangnan Arsenal translating manuals and textbooks for the Chinese government. Between 1867 and 1897 he acted as focal point for the propagation of western scientific ideas in China. Even during the political upheavals of the first part of this century, there was a general increase in Chinese scientific education, and a number of Western style scientific institutions, like the Peking Union Medical College, were established. In chemical research the dominant figure was Wu Xian. He completed his Ph.D. at Harvard Medical School in 1920 and returned to the Peking Union Medical School. By 1925 he was a full professor and initiated an extensive program of research into blood chemistry. Chemical research started elsewhere and, fueled by the innate talent of the Chinese people, it has grown, in spite of all the political upheavals of the Communist revolution and the downfall of Mao, to make China one of the leading nations in the world for chemical research.

C

Chen Yan

Hong Wuli

Chen Yan, a famous physician of the Southern Song Dynasty in the twelfth century, was born in Qingtian (now in Zhejiang Province), with Wuze as his surname and Hexi as his nickname. He was extraordinarily clever and proficient in prescription and pulse taking, as well as in treatment. It was said that he could prophesy the prognosis of incurable diseases. In 1161, he assembled a six-volume work of prescriptions, *Yi yuan zhi zhi* (Treatment Based on Etiology), with 81 categories which deals with the pulse and diagnosis of diseases, followed by their etiology, and the variorum of the *Canon of Pulsology*, all with relevant recipes. This work was never published.

Chen was especially interested in the study of pathogenesis. He claimed that the causes of all diseases could be divided into three categories; this was based on Zhang Zhongjing's hypothesis. Eventually, he compiled the *San yin ji yi bingzing zheng fang lun* (Discourses on the Manifestations and Recipes of Diseases of Three Pathogenic Categories) in 1174, in 18 volumes. He summarized all pathogens into three categories:

1. Endogenous emotional changes, the Seven Emotions (joy, anger, sadness, ratiocination, grief, apprehension, and fear), which originate from the internal viscera and affect the extremities.
2. Exogenous pathogenic factors, the Six Excesses (wind, cold, heat, damp, dry, and fire), which originate from the channels and affect the internal viscera.
3. Causes neither exogenous nor endogenous, which derive from immoderate food and drink, wounds, ulcers, and insect and beast bites. The etiological work exerted some influence on later generations.

Chen also summarized medical science in four Chinese characters, reading "title, substantial property application" claiming that all new commentaries on ancient classics could be categorized under four branches: sphygmology, manifestation, disease, and treatment. Hence, all medical students should recognize a disease on the basis of pulsology and make a diagnosis on the basis of manifestations.

In the years 1165–1173, he compiled the *Herbology of Compiled Categories* with subheadings based on the above-mentioned ideas. Though it was an anonymous compilation with a "Preface by Master Hexi," it was commonly believed to be Chen's.

Childbirth

Margarita A. Kay

The pelvic changes that evolved when hominids became upright walking creatures resulted ultimately in what is known as the "obstetrical dilemma" for humans. The woman's pelvic bones must not obstruct safe passage of the infant's head, and her soft vaginal tissue must be able to stretch to the maximum. Meanwhile, the baby must be mature enough to survive outside the woman's body but small enough to pass through her narrowed birth canal. Managing childbirth within these parameters developed throughout human history by means of observation, trial, and errors accommodated, however, by high fertility. Obstetrics conducted in hospitals is a recent biomedical specialty, and in the past decades, Western obstetrics has developed still more technologies. However, for non-Western mothers, little has changed in 2,500 years of written record. From that record, we can draw one of two opposing conclusions: first that childbirth customs are appropriate adaptations to biological needs; or, second, that high technology is always better than childbirth in a natural setting.

Some writers portrayed childbirth practices in non-Western societies as ideal, resulting in a quick and painless process. Men who were not allowed to observe births were told about them by informants who themselves also had been excluded from the birth scene. These writers believed that the non-Western woman just goes in the fields, gives birth, and returns to work in a few hours. Later, women anthropologists who observed non-Western births gave very different reports. Management of childbirth anywhere requires attention to the problems of safety, pain, fatigue, protracted labor, malposition of the fetus, delivery, expulsion of the placenta, and healing. Solutions to problems are mandated by the universal physiology of childbirth. In Western obstetrics, these problems of childbirth are managed with technological equipment; in non-Western societies, the same problems are managed with hands.

Childbirth is not only a biological occurrence; it is also a sociocultural event. Differences in the management of birth reflect different values and beliefs. In some cultures, myth is used to explain pregnancy and birth. Sometimes birthing is a private process, sometimes a communal event. How a society reacts to physiological processes and the extent to which there is contact with other cultures accounts in part for diversity in the ways of managing childbirth. Each birthing system relates to the place women hold in a community, the value given individual children in that community's social structure, how much medical care is available and how it is distributed, and the religious belief system that is in place. Thus childbirth practices develop within the context of each particular society.

Such cultural strictures determine, among other things, how the pregnant woman should behave, who should take care of her, how abnormalities are to be explained and how to prevent them, what, it is believed, causes labor, how it should be stimulated, where the birth should take place with which persons in attendance, and what should be done after birthing for mother and newborn. Descriptions of diverse birthing practices can be found in the writings of George Engelmann and Hermann Ploss, Max Bartels, and Paul Bartels. Birth customs are catalogued in the Outline of World Cultures. MacCormack and Kay edited anthologies detailing birth practices in mostly non-Western cultures. Following are illustrations of some of this diversity from East India, Japan, Malaysia, the Navajo Nation, Seriland of the northwest coast of Mexico, Guatemala, Mexico, Ireland, and Ibo and Bariba tribal homelands in Africa.

Many "normal" activities of women are proscribed during pregnancy with the view of preventing childbirth difficulties. Some of these prebirth customs, are considered adaptive by Western medicine. For example, pregnant American Indian women are urged to keep moving and working during pregnancy and to limit their intake of food. The goal is not to have too large an infant for easy delivery. In West Africa, on the contrary, women are fattened in order to make them desirable for marriage and childbearing. Each custom is beneficial: genetically, American Indian women tend to have very large infants, whereas the babies of African and African–American women are likely to be quite small.

The women themselves explain their customs only as "we have always done it that way." The outsider sees the rationale for many proscriptions deriving from principles of sympathetic magic, like affecting like. Ancient Mexicans and recent Navajo, for example, believe that weaving is dangerous during pregnancy because the umbilical cord will tie up the baby. This belief has a very long history. It is recorded as fact by ancient Greek authorities of Aristotle, Galen, and Soranus. Across Western and non-Western cultures, the woman and sometimes her mate are told to avoid certain foods and actions to prevent problems in birthing or abnormalities in the baby. Conversely, a woman's cravings for exotic foods must be satisfied or the baby will be marked. Some of the rules placed to solve birth problems may be seen in the belief system of the larger culture; for example, the *bidan kampung* (traditional midwives) of Muslim Malaysia consider the humoral system of Islam in selecting a western-facing direction (with modification for days of the week) to align the woman for birthing; west faces Mecca. For Navajo, on the other hand, it is vital that the mother's head *never* face west, for that is their direction for death. Women who are taught that congenital malformations are caused by unnatural phenomena wear amulets to protect the unborn child. Charms include medals, pictures, and prayers that represent their religion, iron filings, and pieces of crystal, coral, or jet. It could be said that magical thinking can also characterize high technological Western cultures, for childbirth outcomes cannot always be predicted. Rituals of testing are enacted to resolve anxiety of the unknown. Childbirth is feared to a certain extent by all people.

Non-Western women are given prenatal massages in many cultures, notably Japan and Mexico. The purpose of the massage is to fix the fetus in a position favorable for delivery. In some societies, the fetal position is also assisted by a belt around the woman's abdomen. The Japanese apply the maternal *obi* in a special ceremony in the fifth month of pregnancy. Mexican women wear a narrow red cord, which shows the ascent of the uterus. Traditional Navajo women maintain their custom of wearing a red belt woven with green figures, 5–6 inches in width, throughout pregnancy. This belt is later used during labor and delivery.

When a woman believes that her childbirth labor is starting, she takes herbal teas. Mexican women drink *té de manzanilla*, camomile tea, believing that if it is false labor, the tea will make the pains go away, and if it is true labor, the pains will come stronger and harder. This belief has pharmacological support. Navajo women use tea from a penstemon for the same purpose, or one from rabbitbrush. Ideally, the birth should be fast. Mexican and Guatemalan women are given the ancient Aztec herb *cihuapatli*, which has strong effects on the uterus. They are permitted little sleep but are encouraged to walk with their contractions to hasten delivery. When in pain they are allowed to scream, unlike West African Bariba and Ibo. The proud Bariba women attempt to deliver alone to conquer their fear. Traditional Navajo women were trained to make no sound in order to preserve the secrecy of the process and today are silent and motionless during labor.

Because childbirth is the obvious result of sex, women in societies that value female purity, innocence, and virginity have particular difficulties. Irish peasants hide their pregnancies as long as possible, and do not publicize births. Hindu women also do not advertise their condition, resulting in little attention to their prenatal health, and distressing labor. Following Biblical injunction, the laboring woman was expected to suffer, until in the mid-nineteenth century, Queen Victoria accepted the newly discovered anesthesia for her birthings.

In non-Western childbirth, a midwife conducts the birth process. She uses many ways to stimulate labor, from placing an amulet on the laboring woman or an axe under her bed, to giving herbal teas or some of the husband's semen for her to swallow. To lubricate the birth canal, she massages with whatever is typically available, such as lard, clarified butter (*ghee*) or cooking oil.

Posture during labor also varies. In many non-Western societies, the laboring woman is encouraged to keep an upright position, utilizing gravity to move the fetus in the birth canal. Anderson and Staugård summarized traditional birth positions of 22 tribes in Africa and found kneeling to be used in 12, squatting in ten, holding rope in seven, lying in six, and half sitting in five. These postures may relate to different pelvic dimensions; for example, women of Biafra commonly used the squatting position, which works best for women who have a short pelvic outlet. The 80,000 women who have had traditional genital surgery (female circumcision) present special challenges for safe delivery, because scar tissue does not stretch.

A common practice of American Indians has the woman in either a kneeling or squatting position, with one attendant supporting the woman from behind, pushing on the abdomen above the uterus, while another attendant is in front, pressing from below. The mother might be pulling on a rope during contractions. Or she might pull on a hammock, which is suspended above where she stands, as has been recorded for the Kalopalo Indians of Central Brazil. In the latter case, four attendants help the laboring woman, two pressing down on each shoulder, and two pressing on her feet to direct force during a contraction. Navajo women pull on the special red belt that they wore during pregnancy, looped over a beam in the ceiling. For the Seri, a hunting – gathering people of Sonora, Mexico, two women who are usually close relatives help with the birth. One assistant sits on the ground, her legs spread but her knees doubled under her, to make a lap for the parturient to sit on. The second assistant, also sitting on the ground but facing the laboring woman, holds her hands in position to receive the infant. The parturient and midwives often wait for hours in the described positions. To speed the labor, the parturient may be given tea from the roots of indigenous plants, or a concoction of alcohol, limes, cinnamon, and aspirin. The women often say that they do not want to marry because childbirth hurts too much. Women of the nearby agricultural Yaquis drink an infusion of the narcotic plant Datura for childbirth pain.

For difficult deliveries, Punjabi midwives straddle the chest of the laboring woman, pressing hard on the abdomen with their hands; or they push with the heels of their feet on the pubic bone.

In matrilineal societies such as the Navajo, the attendants are commonly women from the maternal side of the family. Patrilineal societies such as Egyptian or Japanese, where descent is traced through the father's line, require the presence of the husband's kin, to assure continuity of the line. The birthing woman is accompanied by her husband's mother, and goes to her mother-in-law's house to recuperate from the birth.

Delivery of the placenta (afterbirth) is a grave concern in all societies. The medical ethnobotany of every group contains a variety of plants to give the woman whose placenta is slow to separate. According to humoral doctrines which are prevalent in many non-Western cultures including India, China, Middle America, and Latin America, those herbs that acted on the uterus were categorized as "hot" and "dry," and many of the same plant genera are used crossculturally. A retained placenta is a most dreaded complication of birth: "anyone can deliver a baby but it is the placenta which kills" (Bariba). Once the midwife delivers the placenta, she disposes of it according to its meaning in her culture, respect as a spiritual entity or fear of its power. In Malaysia, the placenta is considered to be the fetus's semi-human sibling, and thus is washed and ceremonially buried, which is similarly done by Guatemalans and Seri.

Some of the materials used to act on the uterus, either to bring on menstruation, stimulate labor, hasten birth, or separate the placenta, have been subjected to phytochemical analysis. *Artemisia* species, the botanical name first given by the Greeks for their goddess of women, and used worldwide in Europe, the Middle East, China, Latin America, North America, and Mexico, contain estrogens, female hormones. *Matricaria*, named since Roman times from the Latin word for womb, relieves painful uterine cramps through its spasmolytic compounds. Analysis of other materials, such as the husband's semen, given to the laboring woman in some African cultures, shows that they are high in prostaglandins, chemical compounds used in biomedicine to initiate labor by causing the mouth of the uterus to begin opening.

Indian peoples of Mexico use plants passed down in oral history from Uto-Aztecan forbearers (such as *yyahautli*, marigold, to stimulate labor, and *toloache*, jimson weed, for labor pain) and also those learned from Europeans who came in the colonial period, coriander and rosemary, for their actions on the uterus. Hindu mothers are given Ayurvedic herbs, while Chinese herbs are used all over eastern Asia. Childbearing women take herbs for prenatal care, labor strength, and postpartum healing. The woman may drink the plant material in teas; it may be applied to her abdomen, inserted in her vagina, inhaled, or she may sit over infusions in vapor baths.

After the baby is born, the umbilical cord must be tied and cut, and again there are many practices to be followed. The cord is cut with a piece of sharp bamboo in Malaysia, a razor blade or broken glass in Ghana. It may be tied with hair, string, or animal tendon. The variety of dressings include pounded pottery, herbs, salt, ground shells, and ash, materials that can harbor bacilli causing neonatal tetanus. The cord remains may be buried in a place that is associated with the anticipated sex role behavior of the child. For example, a Navajo woman may bury her infant son's cord near the sheep corral and her infant daughter's cord near the weaving room. Mexican, Malaysian, and Japanese mothers kept each child's cord for the child's future welfare.

The immediate postpartum period lasts for 3 days in cultures predominately Christian, and 4 days in American Indian societies, the respective magic numbers for each. After giving birth, and for a period of time prescribed by the culture, 20 days for many American Indians, 40 days for traditional Jews, Christians, and Muslims, the woman is supposed to be confined to her home. It is believed that the woman is vulnerable, requiring protection during the entire postpartum period. Some Mexican patients still observe *la dieta* during which time baths, walking barefoot, and otherwise being subjected to cold are proscribed. This includes avoiding "cold" foods, foods that are believed to have a quality of chilling the body.

The newly delivered woman is healed with heat in many cultures. The Navajo woman may have heat applied by warming green cedar and holding it to the abdomen with her red sash. She is bathed on the fourth day after delivery, especially if she had a ceremonial Sing during her labor. Her lacerations are treated with a salve of baked cactus, or a fumigant treatment may be prepared by digging a hole and heating stones therein. Soranus described a similar fumigant 2,000 years ago. "Mother roasting," as it is called, is a therapy used by many societies in Southeast Asia, including Malaysian. A fire is maintained beside the delivered woman for a prescribed number of days. This "dries out" the womb. A ritual fire is kept burning in the dwelling of the Seri woman for 4 days following the birth, in this case for the infant's sake. Hot leaves are pressed on the Ibo mother's abdomen, immediately after birth. The *temascal* or sudatory was used by ancient Aztecs after childbirth, as well as by ancient Romans and is used by present day orthodox Jewish women after menstruation as well as after childbirth.

Sexual intercourse is not permitted anywhere until the puerperium, however defined, is over. Mexicans, like so many others, believe that intercourse when there is vaginal bleeding is abhorrent. The Navajo believe that even indirect contact with vaginal blood is very dangerous to the husband and anyone else. In many cultures, contact with blood was considered polluting to the individual and to the community. The woman could now be purified, by bath and by religious ceremony. Leviticus XII, 2 provides the Laws of Purification and Atonement for Jews, Christians, and Muslims. The postpartum bath is a Shinto rite of purification in Japan.

Non-Western Birth Today

It is estimated that worldwide, 80% of births are attended by Traditional Midwives, Traditional Birth Attendants, or simply female relatives. The status of the traditional midwife has varied through time and place. For some non-Western cultures, her status has been very low, for it is women's work, and deals with blood. With many ethnic groups in India, midwifery was looked upon as a most degrading occupation.

The traditional midwife is typically a woman who is respected in her community, nonliterate, postmenopausal, has herself borne children, and learned her craft as an apprentice to another woman. She is often looked down on by the Western medical community. Traditional midwives may get Western training to meet difficult births, although they may not always find such instruction useful. When Western technology is not available, the traditional midwife's birth skills may prove to be superior. It may be hoped that the Certified Nurse Midwives of each culture may bridge the birth customs of the non-Western traditional midwife with the practices of Western biomedicine.

Childbirth in India

Nitin Trasi

Obstetrics in Ancient India

The oldest sources of information about Indian culture are the four *Vedas*, sacred compositions probably compiled over several centuries during the second millennium BCE. The knowledge about Vedic medicine is contained mainly in the fourth and latest Veda, the *Atharva Veda*, and a related later work, the *Kauśika Sūtra*. Later, in the post-Vedic era, the ancient Indian system of medicine acquired the name *Āyurveda* (lit.: knowledge of life). The golden age of Indian medicine lasted almost 2,000 years, from about 1000 BCE to about AD 1000. The most famous works written at this time were the medical treatises known as the *Caraka Saṁhitā* and the *Śuśruta Saṁhitā*.

The art of obstetrics was well advanced in ancient India. Āyurveda had eight branches (*aśtānga āyurveda*), one of which was *Kaumārabhrtya* – gynecology, midwifery, and pediatrics. This included the classification of diseases of the female genital tract, including menstrual disturbances, and suggestions for treatment. It discussed the clinical course and various stages of labor, difficult labor (*mūḍagarbha*), the management of the puerperium (the period of confinement after labor), and miscarriage (*makkalla*). The different malpositions of the fetus were also known, and methods of treatment by version (the manual turning of the fetus to make delivery easier), embryotomy (an operation to destroy the fetus), forceps delivery, and even cesarean section were described (Keswani and Sharma 1972). In fact, the first mention of the obstetric forceps in world literature is to be found in the Vedas. It was called the *jugna ṣankhu*, and consisted of paired, semicircular-ended tongs, such as that used for holding hot utensils. It was probably used for extracting a dead and dismembered fetus from the mother's womb (Das 1929; Douglas and Stromme 1988: 367).

Caraka, the author of the *Caraka Saṁhitā*, was a famous physician. He is believed to have been the court-physician of the Buddhist king Kaniśka (AD 78–100), and attended on the king's wife as obstetrician during her difficult delivery (Saletore 1984: 300–301). The *Caraka Saṁhitā* lacked a detailed study of surgery, but was otherwise quite comprehensive.

Śuśruta was the most celebrated surgeon of ancient India. The *Śuśruta Saṁhitā* was originally written probably in the last centuries BCE, although some date it much earlier, even as far back as 1000 BCE. It is especially important from a surgical point of view. Śuśruta mentions as many as 121 instruments of various descriptions, made largely of steel. Alcohol in the form of medicated wines was used as a narcotic during and also after operations, and hot oils, tar, or caustics were used to stop bleeding. A drug called *Sammohinī* (producer of unconsciousness) was administered before major operations, and another drug, *Sanjīvanī* (restorer of life) was employed to resuscitate the patient after operation (Keswani 1961, 1967).

When delivery was impossible by natural means, the fetus – usually dead by then – was probably extracted using forceps; if necessary after dismemberment by embryotomy. Cesarean section, though mentioned in the literature, was not likely to have been a real choice. It had an extremely poor maternal outcome (almost 100% mortality) the world over until the twentieth century. In ancient India too, it was probably only performed on rare occasions on a dying mother (or one who had just died) in an attempt to save the baby. Embryotomy, on the other hand, seems to have been a well-known procedure, finding mention even in non-medical literature. The great monistic philosopher Ādi Śaṅkarācārya (AD 788?–820) refers to it, citing it as an example of human suffering even before life has begun.

> If, by chance, the child moves into a transverse position at the time of delivery, it is then turned out (extracted) forcibly, broken into pieces by instruments (*Prabhodasudhākara*, v. 10).

Charitable hospitals were established by many rulers, notably Rāhul, the son of the Buddha, and the famous Emperor Aśoka (ca. 273–232 BCE or 265–238 BCE).

The Populace

Although the art of obstetrics was well advanced in ancient India, most people probably had little access to it. Pregnancy and childbirth were generally managed at home, by practices based partly on experience and partly on cultural beliefs. Girls were customarily married off at a very young age, often even before they had attained puberty. Their obstetric career therefore began early, and they continued to bear as many offspring as their health would permit. The pregnant woman was subjected to many restrictions. The solar and lunar eclipses were believed to be especially inauspicious times for her, and she was forbidden from venturing out into the open at these times.

Childbirth was largely a domestic affair, the parturient woman being attended to by experienced elder ladies from her own and from her neighbors' families. The squatting position or the seated (kneeling) posture was often favored for childbirth, and even today many tribal societies in India prefer these positions. The vaginal canal was lubricated with clarified butter (*ghī*) and ghī was also fed to the mother in the belief that it would lubricate the birth canal. A normal delivery did not usually present too many problems, but there was no recourse when complications arose, and in such cases the baby was often lost, and at times the mother too. Unsanitary conditions and lack of proper training and knowledge contributed to a high maternal and fetal mortality. Neonatal tetanus was an important cause of infant mortality. Cow dung was believed to have purifying properties, and was commonly used to "purify" the floor of the house (Saletore 1943: 114). This could have been a contributory factor.

At some time, the system of the traditional birth attendant, the *dāi*, took root. These dāis were usually experienced elderly ladies who would provide their services for a modest fee. However, though experienced, the dāis had no scientific education or training. Even today, it is estimated that dāis conduct over 50% of births in rural India. However, since 1957, the dāis undergo scientific training, and dāi training is now an essential part of the maternal and child health program of the Indian government.

The Medieval Ages and Later

With the coming of the Muslim conquerors to India, from the tenth century onward, the golden age of Āyurveda began to decline. Some of the factors leading to the decline were want of patronage from the rulers, aversion of educated Hindus to contact with blood, pus and diseased persons, and absence of a system of regular education and training for practitioners. In the absence of professional standards, it became difficult to distinguish the genuine practitioners of Āyurveda (the vaidya's) from quacks. Medicine in India during the later medieval period was dominated by Persian and Arabic influences which introduced an amalgam of Greek and Persian medicine, known as the *Unānı system* of medicine.

From the 1800s until 1947, the British ruled over most of India (British India included what are now India, Pakistan, and Bangladesh). By then, both Āyurveda and the Unānı systems were unorganized, as they had not kept up with modern discoveries and research. Skills were passed by familial succession and not by institutionalized education, and the practitioners were for the most part uneducated and unwilling to incorporate the new knowledge and discoveries that were pouring in from the West.

The state of public health in India at the time was poor, and women and infants were the most neglected segments of society in matters of medical aid. Maternal mortality (maternal death during childbirth) and infant mortality were very high. Even when modern medical treatment was available, resistance to treatment by male physicians and the strict purdāh system prevalent among certain communities often ensured that women got little access to it. There were cases where women preferred to die in childbirth rather than submit to treatment by a male doctor (Kumar 1998).

Modern Obstetrics in India

The Portuguese first introduced modern Western medicine to India (Royal Hospital, Goa, 1510), but it was largely the British who later established and consolidated both its practice and its study in the subcontinent. Popularization of sound surgical practice led to great improvements in the health of the population. Specialization was introduced in Indian universities both in education and research, and India was kept abreast of all the major developments taking place in the fields of science and medicine all over the world. All-women managed hospitals were opened for women patients. In Bombay (now Mumbai), several hospitals for women were opened in the late 1800s; among them, the Cama Hospital (1886) and the Allbless Obstetric Hospital (1890) were entirely managed by women staff. Medical education was promoted among girls even at a time when this was not popular in Europe. Anandibai Joshee was the first Indian woman to go abroad for medical education. She obtained an American degree in 1886. Significantly, her MD Dissertation topic was "Obstetrics among the Aryan Hindoos" (Kumar 1998).

In the early twentieth century, several Indian obstetricians made valuable contributions in the field of obstetrics. Some of the pioneering Indian obstetricians were Dr. N. A. Purandare from Mumbai (1877–1964) and Rāo Sāhib Dr. Shivarao Trasi (1881–1954) from southern India. In 1929, Sir Kedarnath Das published his work on the history of the obstetric forceps, which is still considered a classic, and in which he described over 500 varieties of forceps and included over 2,000 references in ten different languages. Dr. V. N. Shirodkar (1899–1971) pioneered several new surgical techniques, the most famous of which was an operation for women suffering from repeated abortions. Other leading obstetricians were Dr. K. M. Masani (1903–1988), Dr. M. K. Krishna Menon (1908–1988), and Dr. B. N. Purandare (1911–1990), among many others.

In India today, women use both traditional and modern techniques, depending on their location and income. In remote rural areas, conditions are similar to what they were a hundred years ago, while women in the city have access to top hospitals and the best of equipment. Mortality statistics are still alarmingly high in certain parts of the country.

Chinese Science

Ho Peng Yoke

Scholars in the past found it difficult to focus their attention on Chinese science because in traditional China knowledge did not come under the same groupings as in the West. For example the Chinese pharmacopoeias included knowledge on natural history; the official dynastic histories, some Daoist writings, and the works of some great poets contain information on astronomy and alchemy, and compendia on military science mention meteorology and firearms together with magic and divination. It is true that there are some Chinese monographs on science and technology, such as the *Tiangong kaiwu* (Exploitations of the Work of Nature) and the *Jiuzhang suanshu* (Mathematical Manual of the Nine Sections). Nevertheless knowledge of traditional Chinese science exists mainly in the official dynastic histories, the compendia (*leishu*), the gazetteers, religious works like the *Daozang* (Daoist *Tripitaka*), the numerous book collections (*congshu*), and the general literature.

In sixteenth-century Europe, Francis Bacon (1561–1626), Jean Fernal (1497–1558), and Jerome Cardano (1501–1576) all made reference to three great inventions, namely the compass, the art of printing, and gunpowder. In the minds of many there was only some vague connection between China and these three inventions. Indeed, prior to the middle of the twentieth century the history of Chinese science received little attention both from inside and outside China. It gained recognition in the middle of the twentieth century when Joseph Needham launched his monumental work, *Science and Civilisation in China*. Needham did not pioneer the study of the history of Chinese science. Sinologists and scientists before him had written on acoustics, alchemy, architecture, astronomy, gunpowder, hydraulics, mathematics, and medicine in traditional China. However, Needham demonstrated the originality of many Chinese discoveries and inventions, including the "three great inventions" of Renaissance Europe, and made Chinese science a new discipline of study. Modern scholarship and recent archaeological discoveries have increased our understanding of Chinese science and helped in the reappraisal of some old interpretations.

Excavations carried out first at Anyang between 1928 and 1937 and again after 1950, followed by those done at Zhengzhou in Henan province, substantiated the existence of the Shang dynasty (sixteenth–eleventh centuries BCE) and brought to light many bronze artifacts, foundry sites, and proto-porcelain wares. At the ruins in Anyang the remains of the capital of the last Shang kings were found. This later period of the Shang dynasty is known as Yin (fourteenth–eleventh centuries BCE). Besides bronze artifacts, archaeologists uncovered gold, jade, pottery, and shell objects, wooden artifacts with traces of lacquer, traces of silk fabric, and even a chariot. The most important find, however, was the oracle bones, which were carapaces of a specie of tortoise or shoulder blades of buffaloes that bear inscriptions written by the people of Yin for divination purposes. They contain records of eclipses and novae, as well as names of stars and asterisms. They also show that the Yin people were already using a lunisolar calendar with 12 moons or lunar months in one year. Each month consisted of either 29 or 30 days each, and every 2 or 3 years there was one extra month, known as the intercalary month, added to the year. The numerals in the oracle bones were the earliest known Chinese numerals until the discovery of the inscriptions on the pottery at the ruins of Banpo, which dated back to about the year 3000 BCE. From the oracle bone numerals we know that the Yin people were already using a decimal system. We also find that the Yin people already had some knowledge of irrigation, agriculture, sericulture, and wine-making. For example, for tooth decay they used a character that included the character for "worms," suggesting that they had made an effort to attribute the problem to a cause. Chinese archaeologists have been quite active in recent years trying to re-establish the Xia dynasty. According to their tradition this dynasty existed for four centuries immediately before Shang, which itself lasted six centuries. Erlitou in Henan province, where bronze vessels dating back to the year 1700 BCE were recovered in 1971, is one of the more promising sites where they hope to discover epigraphical evidence to confirm the existence of that ancient dynasty.

Bronze vessels and pottery are some of the works of art characteristic of the Chinese. Shang bronzes show that the technique of bronze casting had already reached an advanced level. It was also in Shang China that the earliest proto-porcelain ware was discovered. It took the form of a wine container (*cun*), made of kaolin clay, with a yellowish green glaze on the surface about the mouth and a translucent deep green glaze on the inner and outer surfaces. The Western Zhou period (eleventh cenrury – 771 BCE) produced beautiful bronze vessels with inscriptions and proto-porcelain wares, some of which can be seen in many museums today.

In the Spring-and-Autumn period (722–481 BCE) two early texts, which Confucius (551–479 BCE) himself referred to, namely the *Shujing* (Book of Documents) and the *Shijing* (Book of Odes), were written. Both contain astronomical material from about the tenth to the fifth century BCE. The earliest sighting of Halley's comet in the year 613 BCE is recorded in the *Chunqiu* (Spring-and-Autumn Annals), which also contains references to solar and lunar eclipses, meteor streams, and other comets. The *Zhouli* (Records on the Rites of Zhou) informs us that the Zhou kings employed star clerks to observe astronomical and meteorological phenomena and to make astrological prognostications therefrom. The earliest star catalog is said to have been made by a court astronomer Wu Xian, of whom little is known. Two other catalogs were produced by Gan De and Shi Shen between 370 BCE and 270 BCE. The three original catalogs have long been lost. Some fragments claimed to be from the originals are quoted in many old astronomical writings. In the early fourth century Chen Zhuo (fl. ca. 310) constructed a star map supposedly based on such information.

Two weapons with iron plates taken from meteorite sources and dating back to the Western Zhou period were discovered in 1949. In 1976 a steel weapon of the sixth century BCE was excavated in Changsha, Hunan province, showing that by then China had already entered the Iron Age. Subsequently more iron artifacts of the fifth century BCE were found in Jiangsu and Henan provinces. It is interesting that although Europe knew about iron earlier, the Chinese came to know about the making of cast iron not later than the fifth century BCE, soon after iron was known to them. Another interesting technology developed by the Chinese of about that period is the breast-strap harness seen on the horses among the terra cotta warriors guarding the tomb of Qin Shihuangdi in Xian. Showing good understanding of the horse, this method was far superior to the throat-and-girth harness of the Roman chariot adopted in Europe in the early days. Some time between the years 600 and 1,000 the breast-strap technique went to Europe and evolved into the modern harness.

Between the sixth and the fourth centuries BCE the "Hundred Schools of Philosophical Teachings" flourished in China. Some of these schools played an important role in the development of science and technology in China. The philosopher Mozi (b. ca. 479 BCE) is remembered for his techniques of defense and for his knowledge of mechanics and optics embodied in his *Mojing* (The Canon of Mozi). Confucius is said to have edited the *Yijing* (Book of Changes), which contains one of the most subtle and influential methods of Chinese divination. In the past, especially in China, it was difficult to draw a sharp line of demarcation between science and divination. These two subjects were included within the term *shuxue* (mathematics). The writings of the Daoist philosophers and the Naturalists exerted a great influence on early Chinese science, and indeed they provided a set of natural laws that was supposed to be "universal", even more so than what modern scientists believe. Indeed the attempt to be too universal made it difficult for science in traditional China to separate itself from philosophy and to develop into modern science. The greatest name among the Naturalists was Zou Yan (fl. ca. 300 BCE) who lived in the eastern seaboard state of Qi (in modern Hebei province). He was the greatest exponent of the *yin* and *yang* theory and that of the *wuxing* in ancient China.

Traditional Chinese science was based on the philosophy of Harmony of Nature, in which heaven (*tian*), earth (*di*), and human beings (*ren*) were all mutually related. Attempts were made to develop a philosophy to explain everything – from astronomy to astrology, from mathematics to fortune-telling, from alchemy to magic, from philosophy to ethics, from politics to fine arts, and from medicine to music – in a common concept based on *qi*. The word *qi* has a wide range of meanings, which cannot be adequately covered by a single term in translation. Its modern meaning includes "air", "gas", "vapor", "steam", "weather", "trend", "demeanor", "manner", "temper", and a sort of life-giving force, reminding us of the Greek concepts of *pneuma* and *psyche*, the Hindu idea of *prāṇa*, and what modern scientists call "matter-energy".

From *qi* the two opposite and yet complementary cosmological forces *yin* and *yang* and the five *xings* were derived. *Yin* conveys the idea of darkness, the shady part of a mountain, coldness, cloudiness, rain, anything that is feminine, and so on. *Yang*, on the other hand, refers to brightness, the sunny side of a mountain, warmth, clear sky, sunshine, anything that is masculine, etc. The term *wuxing* was generally translated as "Five Elements". This gave rise to some confusion. When the Jesuits rendered the Four Elements of the ancient Greeks into Chinese they used the term *siyuan*, (four *yuans*), but when they translated the Chinese term *wuxing* they called it Five Elements. Unlike the Greek Elements (earth, air, fire, and water), the Chinese *xing*'s were not stationary but were in a state of constant motion rather than rest. They are Fire, Water, Wood, Metal, and Earth. There is an order of production or generation in which Fire produces Earth, Earth produces Metal, Metal produces Water, Water produces Wood, and Wood produces Fire. Then there is an order of conquest or destruction in which Fire conquers Metal, Metal conquers Wood, Wood conquers Earth, Earth conquers Water, and Water conquers Fire. In Chinese medicine for example, the *Huangdi neijing* divides different parts of the body into *yin* and *yang* and associates them with the five *xings*. For example, the heart, the small intestines and the tongue are associated with Fire, the kidneys and the ears with Water, the gall-bladder and the eyes with Wood, the lungs, the large intestines and the nose with Metal, and the stomach, the spleen and the mouth with Earth. The foundation of health, tranquility, and well-being rests on the perfect equilibrium and harmony of the two cosmological forces *yin* and *yang*, which continually ebb and flow. Everything is produced by union and perishes by decomposition. From the two orders of mutual production and mutual conquest the Chinese derived two principles, namely the "principle of control" and the "principle of masking". Any of the five *xings* that conquers another *xing* is controlled by the *xing* that conquers it. For example, Fire conquers Metal, but the process is controlled by Water. Any *xing* that conquers another *xing* is masked by a *xing* that produces the conquered *xing*, i.e., Fire conquers Metal, but Earth masks the effect.

Then comes the system of the *Yijing* (Book of Changes) with its 64 hexagrams said to be derived from the theory of *yin* and *yang* and that of the *wuxing*, although the system was sometimes used to support those two theories instead. Traditionally the origin of the system traced back to the eleventh century BCE when the sage father of the founder of the Zhou dynasty got inspiration from two mystical diagrams, the *Hetu* (River Diagram) and the *Luoshu* (*Luo* Chart). These two diagrams supposedly held the secrets of *yin* and *yang* as well as the *wuxing*. In the *Yijing* heaven and earth, thus *yang* and *yin*, originated from *Dao*. This term probably refers to natural order in this context but is opened to a broad range of diverse interpretations. The system of the *Yijing* was mainly employed for the purpose of divination. Besides divination it also found its use in the "explanation" of scientific phenomena, such as in astronomy and alchemy.

In traditional Chinese thought, divination and mathematics were inseparable. The word *shuxue*, the modern term for mathematics, was only first used in the modern sense in the last century when Li Shanlan (1811–1882) translated Western mathematical works into Chinese. Before then the same term in traditional China referred not only to divination and mathematics but also to astronomy and music. One is reminded of the word mathematics as defined by Boethius (480–524) to include arithmetic, geometry, astronomy, and music, which became the *quadrivium* in medieval Europe. In the eyes of traditional Chinese mathematicians, such as Liu Hui (fl. 263) and Qin Jiushao (1202–1262), divination was the loftiest form of *shuxue* while mathematics (in its modern sense) was only its common form. *Shu* was something that could be predicted by calculations, whether by means recognized by modern scholars as mathematics, such as finding the unknown number in a mathematical equation, or predicting rain in weather forecasts and telling the future using the system of the *Yijing*.

Buddhism and Daoism gradually gained ground over the Confucianists after Han China in the third century. A revival of learning during the time of Song China

(960–1279) saw the neo-Confucianists attempting to cover science, particularly cosmology, within their schools of philosophy. The most celebrated among them was Zhu Xi (1130–1200), who sought to explain everything, both natural and human, with *li* (Nature's pattern), *qi*, and *shu*, while Zhang Zai (1020–1077) applied the concept of *qi* to explain natural phenomena and moral issues. Then there was the *xiangshu* (numbers of the symbols of the *Yijing*) school that focused its attention on the elucidation, verification, and application of the system of the *Yijing*. The most famous member of the school was Shao Yong (1011–1077), who used the system to explain natural phenomena and human affairs and to work out past and future events. His new order of the 64 hexagrams was shown by Leibniz (1646–1716) to be similar to the arrangements using the binary notation. Although Zhu Xi's philosophy was adopted as state orthodoxy, it does not imply that it met no opposition. For example, a contemporary, Lu Xiangshan (1139–1192) developed the neo-Confucian school of Idealism or of the Mind, which was later further developed by the Ming philosopher Wang Shouren (1472–1529), who had a large following.

The earliest text on Chinese astronomy and mathematics is the *Zhoubi suanjing* (Mathematical Manual of Zhoubi), which Christopher Cullen showed recently to be a compilation of the first century. In 1973 many important discoveries were made in the excavation of a Western Han (206 BCE–AD 9) tomb in Mawangdui, Hunan province. They included a manuscript recording the ephemerides of Jupiter, Saturn, and Venus between the years 246 BCE and 177 BCE and a silk manuscript illustrating comets in various shapes. Astronomical instruments such as bronze clepsydrae and bronze sundials have also been discovered in other excavations.

The Commentary to the *Jiuzhang suanshu* (Nine Chapters on Mathematical Arts) by Liu Hui (fl. 263) was the most influential text in the history of Chinese mathematics. In 1983 the *Suanshushu* manuscript (Mathematics Book), written on bamboo strips, was discovered in an ancient tomb dating back to the second century BCE at an excavation carried out in Hubei province. A preliminary study shows some similarities between this manuscript and the *Jiuzhang suanshu*. Liu Hui also wrote another, but much shorter text, the *Haidao suanjing* (Sea Island Mathematical Manual), using the right-angled triangle to measure distance and height. Before the time of Liu Hui, around the year AD 190, Xu Yue wrote his *Shushu jiyi* (Recording Omitted Items in Mathematics). Between AD 280 and 473 the *Sunzi suanjing* (Mathematical Manual of Sunzi) appeared. Of all the problems it contains, the one that has aroused most attention among modern scholars is that of the Remainder Theorem. The problem is to find a number, which when divided by three leaves a remainder two, when divided by five leaves a remainder three, and when divided by seven leaves a remainder two. The required answer is 23. Actually this problem involves three indefinite simultaneous linear equations of one unknown, and there is an infinite number of answers of which the required answer is the smallest. Historians of mathematics study this purely as a case of the Remainder Theorem. However, a more important application of this problem was recently revealed. It was found to be the method adopted by Chinese astronomers up to the eighth century to calculate and construct new calendars.

Several other mathematical texts were written in the following three centuries. One must note the evaluation of the ratio of the circumference to the diameter of a circle made by Zu Congzhi (429–500) and his son Zu Keng. They gave three different values, of which the most accurate was $3.1415925 < \pi < 3.1415926$. The method used by Zu Congzhi was described in his book, the *Zuishu*, which unfortunately is already lost. Chinese mathematics reached its golden age of development in the twelfth and the thirteenth centuries. During the twelfth century, mathematicians like Liu Yi and others could solve cubic equations numerically. Their writings are no longer extant, but fortunately we have the works of four great thirteenth-century mathematicians, namely Qin Jiushao, Li Zhi (1192–1279), Yang Hui (fl. 1261–1275), and Zhu Shijie (fl. ca. 1280–1303). The study of numerical solutions of equations of higher degrees is yet another of the characteristics of Chinese mathematics. Li Zhi also had a great influence in the development of mathematics in Japan.

The Chinese emperor regarded calendar-making as one of his duties that came with the mandate bestowed upon him from Heaven. The Chinese calendar took into account the apparent cycle of the sun and the cycle of the moon, both of which cannot be expressed in an exact number of days. The astronomer responsible for constructing a lunisolar calendar had to make accurate observations of the sun, the moon, and the planets, but however accurate his observations, his calendar would eventually, in just a matter of decades, go out of step with observations. In 1972 archeologists working at the site of a Han tomb at Linyi in modern Shandong province, discovered a calendar for the year 134 BCE. Throughout the history of China no less than one hundred calendars had been constructed, not to mention other unofficial calendars sometimes used in certain regions. The most renowned among the Chinese calendars were the *Dayanli* calendar completed by the Tang Tantric monk Yixing (683–727) in 727 and the *Shoushili* calendar prepared under the Mongols by Guo Shoujing(1231–1316) in 1280. They used the method of differences in mathematics to make their calculations. Accurate and new astronomical observations had to be made for the purpose of calendar making. New astronomical instruments were constructed for this purpose. Yixing, for example had to construct his own armillary sphere. The Song dynasty (960–1279) is remembered for the several large armillary spheres made for this purpose. The most famous was that made by Su Song (1020–1101). It was an armillary sphere driven by a water wheel using the principle of escapement.

In the early stages medicine and magic were indistinguishable from each other, as both were practiced by the shamans (*wu*). Shamans and doctors were together referred to as *wuyi* (shamans and doctors). During the Spring-and-Autumn Period (722–480 BCE) there were signs that physicians and shamans had already parted company. There was the celebrated physician Qin Yueren, better known as Bian Que (fl. 501 BCE), who was the counterpart of Hippocrates (465–370 BCE) in China. He was already acquainted with the four important diagnostic procedures used in Chinese medicine: observing external signs (*wang*), listening to sounds (*wen*), asking the patient's history (*wen*), and feeling the pulse (*qie*). These are sometimes referred to as looking, listening, asking, and touching. The earliest Chinese medical writing known to us until recently is the *Huangdi neijing* (The Yellow Emperor's Manual of Corporeal Medicine). Consisting of two parts, the book appears to have been written by several earlier unknown authors but took its final form during the second century BCE. Between the winter of 1973 and the spring of 1974 some valuable medical writings were discovered during the excavations at Mawangdui near the city of Changsha in modem Hunan province. The tomb where these writings were found dated back to the year 168 BCE and hence the medical writings concerned must have belonged to an earlier date. These are the two most ancient Chinese medical writings extant.

The earliest Chinese pharmacopoeia that we have is the *Shennong bencaojing* (Pharmacopoeia of the Heavenly Husbandman). We do not know its exact authorship and neither are we certain about when it was written, although the date could not be later than the second century. It sets a tradition followed by a long series of succeeding pharmacopoeias over a period of more than a thousand years. It mentions the *yin* or *yang* property and the indications of each medicinal substance, noting that some combinations of two or more of them are either beneficial or counter-indicative. It divides all the 365 items of medicine that it contains into three categories. Those in the first category have the efficacy of nourishing or prolonging life; those in the second are, as a rule, nontoxic and can be used to restore the constitution of the patient; and those in the third are usually toxic or have side effects. The last category is used for combating diseases. Thus the *Shennong bencaojing* catered to the needs of both the physicians and the aspirants of longevity.

While the physicians had parted company with the shamans, some of the latter devoted their attention to prolonging the human life span. Some of the substances they ingested, such as mercuric sulfide, mica, licorice, and asparagus, are listed in the *Shennong bencaojing* pharmacopoeia. The search for the way to physical immortality probably began in China at least 2,500 years before our time. It is recorded that in the Warring States Period (480–221 BCE) someone presented an elixir to the prince Jingxiang wang in the State of Qu. Some modern writers attribute the first practice of alchemy in China to Zou Yan. Later on the story of the elixir told by the shamans got the fancy of the emperor Qin Shihuangdi, who made several attempts to procure an elixir for himself so that he could live and rule his empire to eternity. Another patron of the shamans was the emperor Han Wudi, who reigned about 133 BCE. It was then that the shamans talked about making gold as the first step toward the elixir. At about the same time, Liu An, the Prince of Huainan, compiled, with the help of a group of shamans and alchemists retained by him, the *Huainan wanbishu* (The Ten Thousand Infallible Arts of the Prince of Huainan). Tradition says that this book dealt mainly with alchemy, especially the making of gold, but unfortunately we no longer have the complete text, and the fragments of the book now left are only concerned with magic. In the following century Liu Xiang, who was said to have inherited this book, was commissioned by the emperor to make gold for the Treasury. His failure landed him in prison.

The earliest Daoist alchemical treatise that is still extant today was written by the alchemist Wei Boyang in the second century AD. Entitled *Cantongqi* (The Kinship of the Three), the text is very obscure, containing a number of alchemical terms with "hidden" meanings. The use of the system of the *Yijing* (Book of Changes) has contributed directly to the obscurity of the text of the *Cantongqi*. Alchemy gained popularity following the work of Wei Boyang. During the fourth century Ge Hong wrote his *Baopuzi neipian* (The Esoteric Chapters of the Solidarity Master), showing the great advancement made in alchemy since the time of Wei Boyang. Ge Hong was at the same time an accomplished physician. Other famous physicians who were also great alchemists after Ge Hong were Tao Hongjing (456–536), Sun Simo (?581–?682), and his disciple Meng Shen (621–718). For the next eight hundred years or so after Ge Hong, alchemy continued to flourish and many alchemical works were written. Most of these works are lost; those that survived are included in the present version of the *Daozang* (Daoist *Tripitaka*), a collection of 1464 Daoist works, only a small fraction of which deal with the subject of alchemy.

In many of their experiments the Chinese alchemists used the process of sublimation and of distillation. They often made use of the reaction-vessel, called *yaofu*. Many of the elixir recipes contained toxic ingredients such as mercury, arsenic, and lead. Hence such elixirs would be quite poisonous. Quite a number of Chinese emperors showed great interest in the elixir and some of them unwittingly perished. For example, the Jin emperor Aidi died in his very prime, aged only 25, as a result of his attempt to avoid growing old. The emperor Wenxuandi of Northern Qi, on the other hand, exercised more caution. When presented with the elixir he decided that the most opportune moment to test it would be on his death bed. At least three Tang emperors died as a result of taking the elixir. Political motives might be behind the early demise of some Chinese emperors, but the alchemists responsible were quickly punished for their failure. With the evidence so efficiently destroyed the full case is difficult to investigate.

There were probably many charlatans among the alchemists, who, when their elixirs brought about the early demise of unfortunate emperors, managed to escape before it became too late. However, there were also alchemists sincerely interested in their work who believed in the elixirs they made. So strong was their faith that many alchemists must themselves have fallen martyr to their own beliefs, or become victims to mistakes in following the obscure and contorted instructions of their predecessors. The most experienced or industrious experimenters were often the most enthusiastic believers, and in the end the surest victims. In this respect the elixir mania must have acted as an inhibiting factor to the progress of chemical knowledge in China.

Many Chinese alchemists were aware of the toxicity of their products. Some tried to neutralize the poison; some recommended only symptomatic treatment; some believed that the ill effects were only side effects associated with the elixir and as such should be completely ignored; some turned to the vegetable kingdom to look for suitable ingredients; and some turned away from the material elixir and practiced "physiological alchemy" (*neidan*) following a regime of meditation and breathing exercise. By the ninth century alchemy in China had already seen its best days. The alchemists gradually relied more and more on the vegetable kingdom for their raw material. Hence there was an alchemical work that included the term *bencao* (pharmacopoeia) in its title, namely the *Waidan bencao* (Pharmacopoeia of Operative Alchemy) by Cui Fang (fl. eleventh century). After the turn of the fourteenth century several books on elixir plants made their appearance. The Chinese alchemists seemed to have gone round one full circle back to the days of the ancient shamans. Alchemy merged again with the tradition of Chinese medicine set by the *Shennong bencaojing* pharmacopoeia.

Hence traditional Chinese medicine and alchemy arose from the same source. At first the shamans practiced both magic and medicine. About the sixth century BCE medicine and magic took different courses. Some shamans developed the art of prolonging human life and reached the conclusion that one had to make gold by artificial means as a first step to physical immortality. That was the beginning of alchemy. Alchemy maintained a close link with medicine, dealing only with different aspects of human life. Quite a number of alchemists were at the same time famous physicians, as in the case of Ge Hong, Tao Hongjing and Sun Simo. A preliminary study shows a close connection between alchemy and Chinese medicine in the similarities between the basic principles used in medical and elixir prescriptions. Medicine and alchemy borrowed from each other. For example, alchemical works are liberally quoted in the more important pharmacopoeias of later time such as in the *Bencao gangmu* (the Great Pharmacopoeia) written in 1596. Although the Chinese alchemists did not succeed in their quest for the elixir of immortality, they played a part as the iatrochemist in Chinese medicine. Another by-product of their experiments was that they stumbled upon gunpowder when some of them caused an accident when they did not exercise sufficient caution in using saltpeter and sulfur, allowing some carbon impurities to get in from the charcoal or wood that they used as fuel.

There was early intercultural transmission of scientific and technological knowledge between China and her neighbors, especially west Asia, before the Christian era. Buddhism first came to China in the second century. Scientific knowledge followed the wakes of missionary and pilgrimage activities. During the eighth century Indian monks and calendar experts, Nestorians, Arab merchants, Korean and Japanese students, and others lived together in the Tang capital Changan (modern Xian) which had a population estimated to be over one million. Mutual exchange of knowledge was inevitable. Muslim astronomers found employment in the astronomical bureau in thirteenth-century China and some Chinese astronomers could have been sent by Hulagu Khan to work in the observatory in Maragha under its director Naṣir al-Dīn al-Ṭūsī (1201–1273). The Renaissance in Europe was influenced in no small measure by Arabic and Indian learning, but Europe also acquired knowledge of Chinese science and technology through the Arabs and the invasion of the Mongols during the thirteenth century. Since the seventeenth century science in Europe has advanced by leaps and bounds while Chinese traditional science remained in a state of stagnation. Toward the end of the sixteenth century the Jesuits arrived in China, using science as a tool to promote their mission. Science from Europe, particularly mathematics and astronomy, demonstrated its superiority to traditional science. In the latter half of the nineteenth century modern science came to China from Europe and North America, and by the twentieth century China had joined the world in the common enterprise of modern science.

Cities and Towns in Ancient Israel (Bronze and Iron Ages)

Avraham Faust

Background

Many cities were uncovered in Bronze and Iron Age Israel, the vast majority of which were located on *tells* – artificial mounds created as a result of gradual human settlement activity. Notably, not every location is suitable for the emergence of a center, even of a local nature, and each site had advantages and disadvantages in relation to factors such as security, water supply, transportation (roads) and the availability of soils. Consequently, only several locations could, in antiquity, provide livelihood for a large population at any given region. This resulted with a repeating pattern in which the centers of many periods were continuously located one on top of the other, thus creating the famous *tells* which are so typical of the Middle Eastern landscape. Although in many instances extramural neighborhoods were built on the slopes of the tells (and in some rare instances cities were not built on tells), it is only in the later half of the first millennium BCE that the overall pattern changed; by then most *tells* were abandoned and cities were built practically everywhere. The gradual process of *tell* abandonment resulted from many factors, including changes in security conditions, increased population and improved technology, but this process lies outside the scope of the present discussion.

Notably, the towns (and *tells*) of ancient Israel were much smaller than their contemporaries in Mesopotamia and Syria. An average city of the Bronze and Iron Age covered some 3–5 ha (and sometimes even less); larger towns, in the scale of 7–12 ha, were also present. Towns of 20 ha, however, were exceptionally large, and megalopolis of 60 ha and more were extremely rare – very few such sites existed in the periods discussed here (e.g., Hazor in the Middle Bronze Age II and Late Bronze Age, and Jerusalem in the Iron Age II).

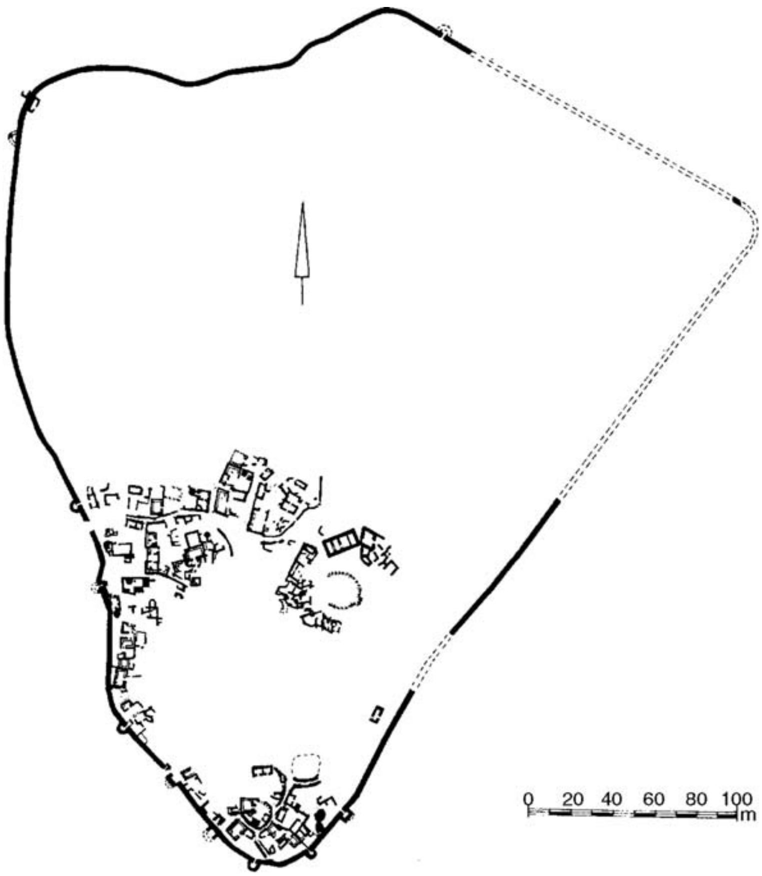
Defining a city is a complex enterprise. Within the scope of the preset paper, suffice it to note that the urban centers were much larger and more crowded then their rural contemporaries. Their inhabitants were of diverse backgrounds and occupations, and not all of them were engaged in agriculture. Social stratification is evident in practically all such sites, along with public buildings and royal construction activities (palaces, walls, storehouses, water system, etc.). These urban settlements served as political and economic centers for the villages that surrounded them, and probably also, during most periods, as centers of tax collection and as places of refuge in times of need.

History of Urbanization in Ancient Israel up to the Persian Period

Cities first appeared in ancient Israel around the transition to the third Millennium BCE (Early Bronze Age) (see Note 1). These first cities usually lie at the bottom of the tells, and in most cases not much is known for certain about their planning. It is mainly in the desert area, where the sites were not resettled in later periods, that we can discuss elements of city planning. ‘Arad, in southern Israel, is the best-known example of such sites (Fig. 1).

The site covers almost 10 ha, and seems to have been divided into several, public and residential, quarters. The former included several small temples and a modest palace. A large, but simple, water system into which rainwater were collected, was unearthed in the lowest part of the city. One should remember, however, that it is not certain whether ‘Arad is a representative of the Early Bronze Age urban phenomenon, as, due to its location on the desert fringe, it might have differed from the typical towns of the third millennium BCE.

The Early Bronze cities were gradually destroyed and abandoned toward the end of the millennium, and by the last two centuries of this millennium (the Intermediate Bronze Age) Cisjordan was devoid of any urban settlement.



Cities and Towns in Ancient Israel (Bronze and Iron Ages). Fig. 1 The Early Bronze Age city of ʻArad (based on Kempinski 1992a: 76; courtesy of the Israel Exploration Society).

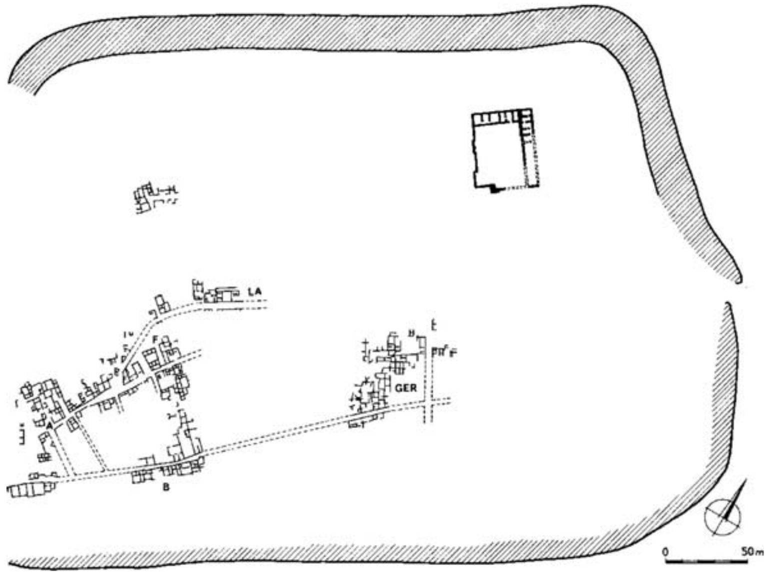
Urbanization resumed in the twentieth and nineteenth century BCE (Middle Bronze Age II; 2000–1550 BCE). New cities emerged throughout the country, with an emphasis on the lower regions. Port-cities were built for the first time. The largest Middle Bronze Age urban center was Hazor, which was apparently part of the Syrian system of city-states. Many sites were now surrounded with massive earth-works, whose purpose, however, is doubted since in many instances no city wall was unearthed on top of them. Some scholars have suggested that their construction, which required much labor but very few experts, served the local leaders as a substitute for the building of large and impressive city walls, as the latter would have required more experts which were not easily available for most rulers. Some towns show signs of planning, probably following a simple grid (Tell el ʻAjul) (Fig. 2).

While most characteristics of Middle Bronze Age culture continued during the Late Bronze Age (1550–1200 BCE), the number of towns declined, and they became smaller in size. Furthermore, hardly any settlement was fortified at the time (since the region was an Egyptian colony, the latter can probably be attributed to Egyptian policy).

Further decline occurred during the Iron Age I (1200–1000). The Egyptian domination over Canaan vanished, and many centers were destroyed or abandoned. Other towns, however, continued to exist, especially in the northern valleys, and a new wave of urbanization took place in the southern Coastal Plain, as a result of the arrival of the Sea Peoples (mainly the Philistines). The latter founded some new cities, for example in Ekron, covering relatively large areas.

Urbanization in many parts of the country was resumed on a larger scale only in tandem with the formation processes of the Israelite state, in the late eleventh and tenth centuries BCE, during the transition to the IAII (1000–586 BCE) (see Note 2). This urbanization probably involved, partially at least, forced settlement of population in urban centers.

The Iron Age II presents a settlement peak in the history of the region. Many urban centers were erected at the time throughout the country, with an emphasis on the highlands and the northern valleys. Excavations have uncovered various types of cities and a complex settlement hierarchy; from capitals, through administrative and regional centers of different sizes, to small field towns (in addition to rural settlements of course).



Cities and Towns in Ancient Israel (Bronze and Iron Ages). Fig. 2 The Middle Bronze Age II center of Tell el-'Ajul (based on Kempinski 1992b: 124; courtesy of the Israel Exploration Society).

The largest cities of the period were Samaria and Jerusalem, the capitals of the kingdoms of Israel and Judah (respectively). At its height the latter covered some 90–100 ha (including extramural neighborhoods) – larger than any other site in ancient Israel during the Bronze and Iron Ages. Also of significant size were several Philistine centers such as Ekron, Gath and Ashkelon.

Excavations have revealed clear evidence for socioeconomic stratification. Most of the population lived in small houses, which probably housed small nuclear families. The wealthy and some high officials were better off, and lived in large four room houses (see Note 3). In some settlements a form of a middle class is also identified. Palaces, which were identified in several cities, represent the upper part of the socioeconomic continuum, and this is where the royal family and the highest officials lived.

The Assyrian and (mainly) the Babylonian campaigns brought about large-scale destruction and population decline, and the number and size of towns decline dramatically. Urbanization in the Persian Period was more limited, and concentrated mainly in the Coastal Plain. Real large-scale urbanization re-emerged only in the Hellenistic period.

Iron Age Town-Planning

The Israelite towns of the Iron Age II (1000–586 BCE) have received a great deal of scholarly attention, resulting from the interest of scholars in this part of the biblical period, from its being a demographic peak in which more sites existed than ever before, and because the Iron Age II usually comprises the upper strata on the tells, therefore permitting large scale exposure, impossible for other periods.

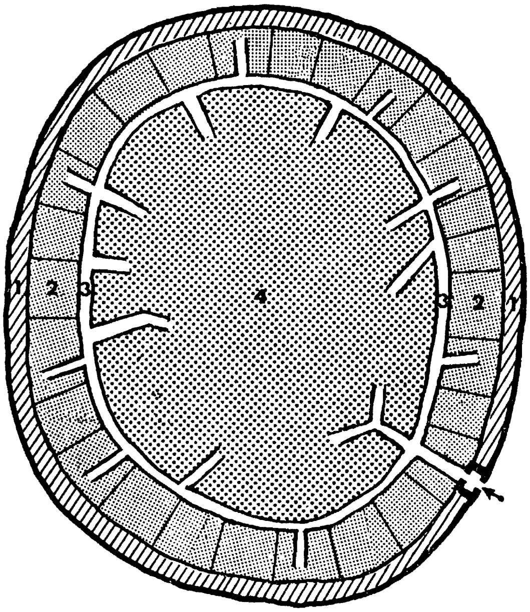
According to Yigal Shiloh's seminal study, the basic outline of the Israelite "town plan is clear: alongside the line of fortifications there is a belt of buildings bordered on the inner side by a ring road, running parallel to the fortifications, and separating these structures from the "core" of the city. The "core" itself was divided into many blocks of residential units of the four-room house type and its subtypes" (Shiloh 1978: 37–38) (Fig. 3).

Apparently, the outer belt was intersected by small alleys, separating the various houses, and leading to the city-wall, therefore enabling free access to the wall and to its casemate rooms (when these existed) (Fig. 4).

While some components of this plan can be found throughout the kingdoms of Israel and Judah, it is more typical of the Kingdom of Judah. In most cities in the kingdom of Israel (and probably also Philistia) a different planning prevailed. Here the city wall was accompanied by a road, and only inside this street were buildings built, divided into quarters by smaller streets.

Accessibility to the city wall seems to have been a major factor in Iron Age town-planning. A besieged city which fell to the enemy suffered a horrible fate, and both types of planning enabled the defenders easy and quick access to the city walls; through the small alleys in the "Judahite" plan, and from practically any place in the "Israelite" plan.

Another difference between Judah and Israel lies in the fact that most towns which were built according



Schematic model of the Israelite city, based on Tell Beit Mirsim, Tell en-Nasbeh, Beth Shemesh and Beer-sheba: 1. fortifications; 2. buildings of the outer belt; 3. ring road; 4. central core.

Cities and Towns in Ancient Israel (Bronze and Iron Ages). Fig. 3 A typical Israelite town (according to Shiloh 1978: 41; courtesy of the Israel Exploration Society).

to the latter plan were surrounded by a solid wall, while the "Judahite" plan is usually accompanied by a casemate wall. The alleys constructed in Judahite towns enabled the authorities not only access to the top of the wall, but also to some casemates, which could have been used for storage. The principle of accessibility to the city wall was adhered to in both plans, and it is likely that the reason for the adoption of different planning was due to space considerations. Larger cities could afford a massive wall, and a street that run along it. Smaller towns, in which space was scarce, tried to save as much area as possible; casemate walls were therefore built, and the ring-road was located inside the outer belt of houses (therefore reducing the space it consumed).

Another characteristics of the Iron Age city was a public quarter near the city gate. The impressive gate was usually accompanied by an open square, and near or around it were public structures, palaces, storehouses, barracks, water-systems, etc., as can be seen Beersheba, Tell en-Nasbeh, Beth-Shemesh, Jerusalem, Kinrot, Gezer, etc (see Note 4).

Furthermore, cosmological principles had also an influence on Israelite construction on all levels, from dwellings to cities. It seems that as part of their complex cosmology the Israelites regarded the east as the most auspicious direction, and the west as the most inauspicious one (like many other societies). Accordingly, they directed their structures in an easterly orientation whenever this was possible, and when this was not the case, they, at least, attempted to avoid the west. This was manifested also in city gates, and about 75% of those faced, roughly, the east. Following easterly orientation for dwellings in towns was difficult, and was carried out in the following manner (1) public buildings were adjacent to most of the Iron II city gates; (2) most city gates were oriented to the east.

The result was that no dwellings were built in the eastern part of the outer belt, and no dwellings in this belt were expected to face the west, therefore avoiding this inauspicious orientation. The same principle was followed also inside the ring-road, as in many cases houses were oriented toward small alleys (and avoided the main street when it was to their west).

The eastern orientation seems, therefore, to have been a major principle of town-planning, influencing not only the orientation of city-gates, but also of many dwellings and alleys.

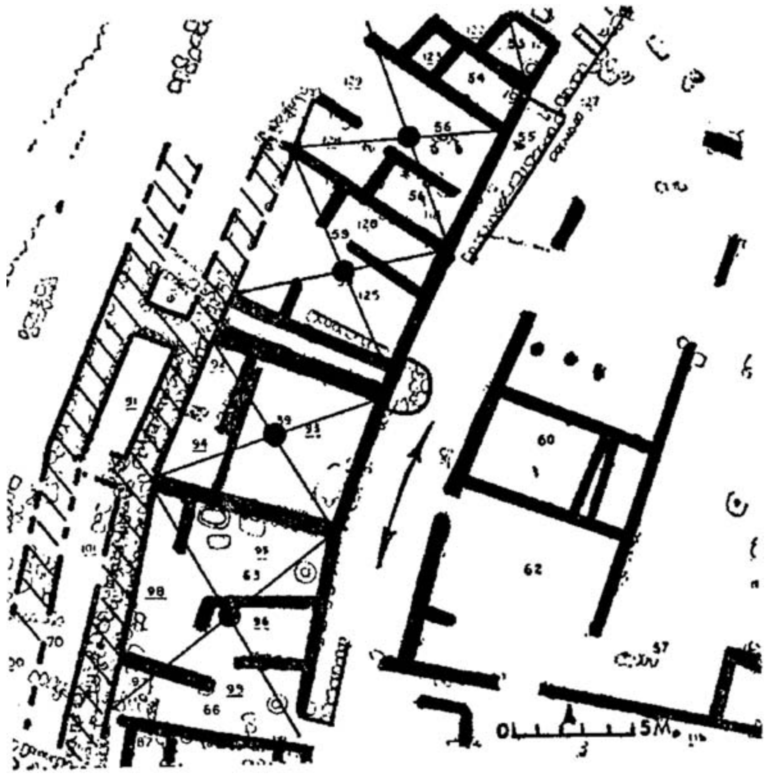
The town of Beersheba can serve as a good example of a planned settlement in the Iron Age (Fig. 5).

During the eighth century BCE Beersheba (stratum II) was a small but well-planned administrative center in the Negev. Its gate was in the southeastern part of the wall, facing this direction. Inside the gate, a small square was located, surrounded by pubic buildings of various sorts. The city wall was accompanied with a belt of houses, which used its casemates as their backrooms, and with a nicely built inner ring road that gave access to these houses. The outer belt of houses was intersected in various points by small corridors that connected the ring-road with the casemate walls, enabling easy access to the wall, and to some of its casemates. The inner part of the town – its core – was divided by smaller streets which cut through it, dividing it into blocks of houses.

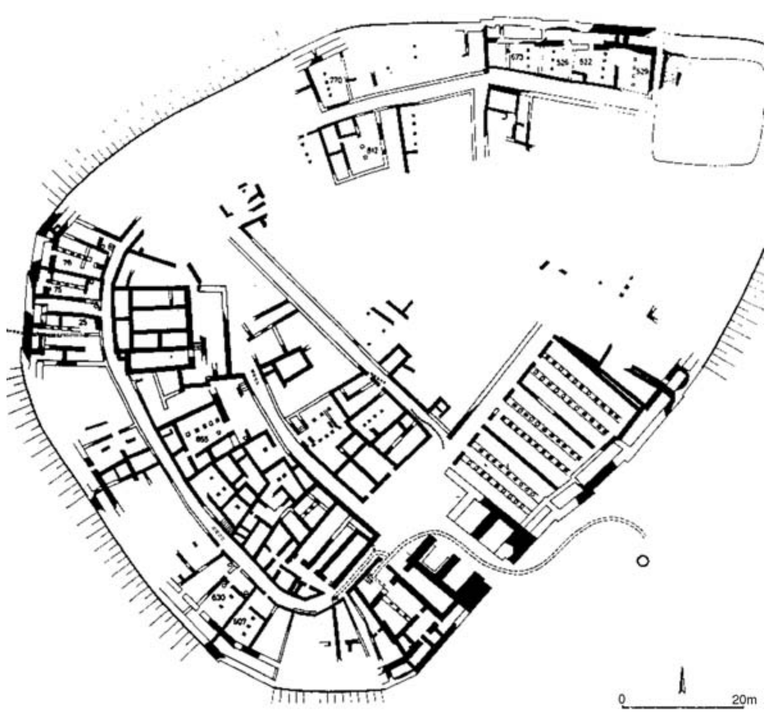
The eastern part of the outer belt of houses was composed by public buildings, and did not include any dwellings. The dwellings in this belt, therefore, were oriented to the south, east and north, but not to the west. Houses in the inner blocks were oriented toward the inner streets, usually avoiding the west. Adhering to the eastern orientation caused them, in some instances, to orient their backs to the main street, and to face small alleys.

Note 1

Notably, the emergence of towns was a long process, and it is not always easy to identify the exact point in time from which a settlement should be called a city. Some settlements were quite large and complex already in the last phase of the fourth millennium BCE (Early



Cities and Towns in Ancient Israel (Bronze and Iron Ages). Fig. 4 Part of Beth Shemesh city plan (based on Shiloh 1978: 40; courtesy of the Israel Exploration Society).



Cities and Towns in Ancient Israel (Bronze and Iron Ages). Fig. 5 General plan of Beer-Sheba (Singer-Avitz 1996: 168; courtesy of Prof. Ze’ev Herzog, Tel Aviv University).

Bronze Age I, traditionally regarded as a "proto-urban" period), and some have suggested that these were the first cities. Other scholars, however, had questioned the validity of the term "urban" not only for the centers of the third millennium BCE, but even to these of the later phases of the Bronze Age, suggesting that they were just complex villages. Most scholars, however, accept the traditional view, and regard these large settlements as cities.

Note 2

The late eleventh and early tenth centuries witnessed the gradual disappearance of rural settlements in most parts of ancient Israel. It is suggested that at least part of this process resulted from a policy of "forced settlement." The newly established Israelite monarchy transferred some of the population (especially in the newly conquered territories) to other/new settlements, and mainly to cities, in order to facilitate better control of the population, to lower costs, and to minimize the efforts involved in delivering sanctions, be it normative, remunerative or coercive, while maximizing its effectiveness.

Note 3

The term "four-room house" is a convention used to designate the typical Iron Age dwelling in ancient Israel whose ideal plan is composed of four main rooms. The "typical" house includes three parallel longitudinal spaces that are backed by a broad-room, with the entrance located at the central longitudinal space. The "rooms" are really spaces/areas and can be subdivided. There are subtypes of the "ideal" form, comprising three or two "spaces" and, in exceptional cases, even five "spaces." The high popularity of the four-room house was explained as either expressing its close relation with the Israelites (without elaborating the reasons for this relation) and/or its functional suitability to the needs of the Iron Age peasants, regardless of their ethnicity. Neither of these explanations, however, seem to account for the synchronic and diachronic dominance of the four-room house as a preferable architectural type in all levels of Iron Age settlement (from cities to hamlets; private dwellings and public buildings), all over the country (both in highlands and lowlands), for almost 600 years(!). It is likely that an adequate explanation for the unique phenomenon of the four-room house must relate to the ideological/cognitive realm, and to its place within the Israelite social and spiritual worlds.

Note 4

A typical public building in Iron Age towns is the "tripartite pillared building" (see Fig. 5, to the north of the gate). Such structures were discovered in many cities (especially near the city gate), but their interpretation varies greatly: the most common interpretation is that of a stable or a storehouse. In most instances, however, large quantities of "domestic" pottery (mainly bowls, jugs, juglets, cooking pots, and also storage jars) were found on the floors of these buildings. Since the finds do not easily fit with the above interpretations, some scholars have raised additional possibilities, including barracks, covered markets, customhouse, and a multipurpose public building which had many functions, including a shelter for the poor.

C

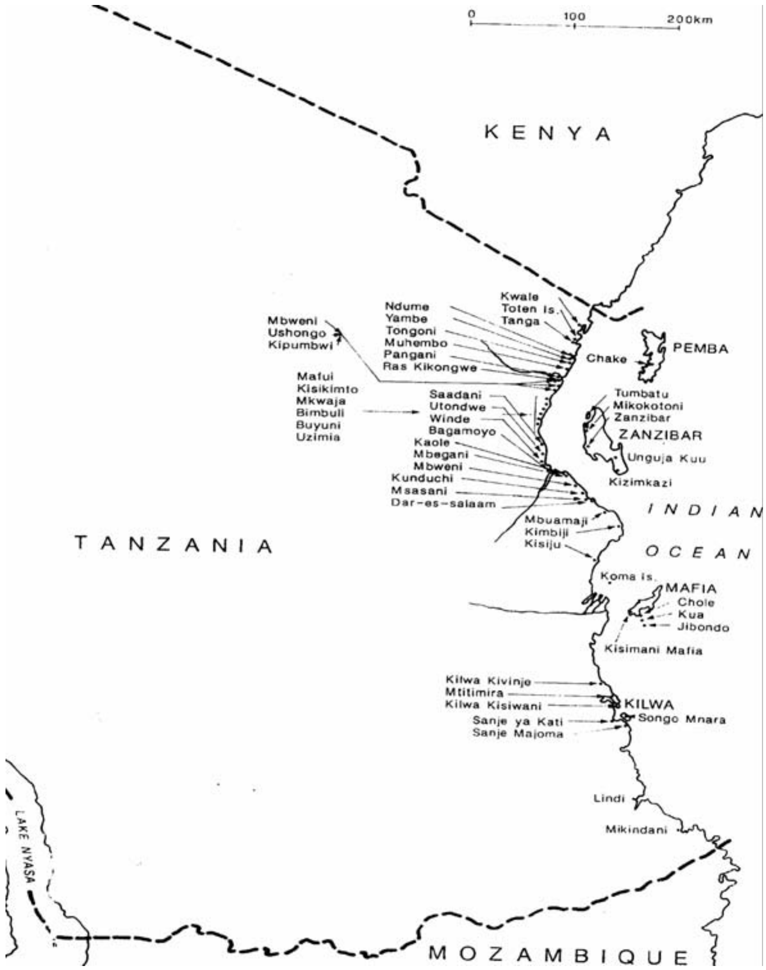
Cities and Towns in East Africa

Felix Chami

The towns of East Africa were built during two periods: pre-colonial and colonial. The former grew up along the coast, facilitating trade and communication between the rim of the Indian Ocean Seaboard and the interior of Africa. The towns, better known in history as Swahili City States, survived from about the beginning of the second millennium AD to about the 1890s. The latter were mostly new administrative centres established with the launch of German and British rule in East Africa from about the 1890s. Only a few settlements of the colonial period had a history predating the colonial era. Such towns include Mombasa, which is a Swahili town, and Mengo in Kampala, which was the seat for the Buganda Kingdom. This article examines the pre-colonial Swahili towns.

The Growth of the Swahili Towns

Swahili settlements spread all along the coast and islands of East Africa (Fig. 1). There were few



Cities and Towns in East Africa. Fig. 1 The Swahili towns on the Tanzanian coast. For the rest of East African coast see Horton and Middleton 2000: 6–7.

settlements before the Swahili towns of the thirteenth century, mostly built with mud and wattle. Concentration of these towns seems to have first occurred in the Mafia-Kilwa region on the coast of Southern Tanzania and on the Lamu Archipelago on the northern coast of Kenya. Individual settlements seem also to have flourished elsewhere on the coastal littoral and virtually on every island large enough to settle from Lamu archipelago to Madagascar. These early settlements are identified by archaeologists by remains there of early Islamic goods including Sassanian Islamic ware, Islamic copies of Chinese pottery and early Sgraffiato [decoration which is scratched through the clay surface coating to reveal the colour of the underlying clay].

Probably the largest earliest settlement of this period is that of Kilwa in Southern Tanzania (Figs. 2–4). The settlement seems to have become a larger centre by about AD 1000 when the earliest stone structures could have been built (Chittick 1974). Probably only a few stone structures would have been built then. The spectacular nature of Kilwa centre was the first to attract archaeologists in the1950s. Mortimer Wheeler led a team of researchers in 1955 to conduct a test excavation. This research paved the way to more intensive archaeological researches by Neville Chittick, not only in Kilwa but also in other Swahili towns (Chittick 1974, 1984).

Kilwa was large, the stone town itself estimated to have been about 50 hectares in the early period. This settlement must have controlled other larger settlements of the area more economically, as settlements of a similar nature existed on the islands of Mafia, off the Rufiji Delta, and on the nearby island of Songo Mnara. Other settlements of the period related to the development of Kilwa are found in Zanzibar and Pemba, the central coast of Tanzania, Comore and Northern Madagascar and on the northern coast of Mozambique and Zimbabwe. Archaeological work on sites located in those regions have yielded goods of exchange between these settlements, including coins, pottery and

Cities and Towns in East Africa. Fig. 2 The water facing side of Husuni Kubwa (Great Palace) in Kilwa Island.

Cities and Towns in East Africa. Fig. 3 Port of Kilwa with recent Portuguese to man fort.

Cities and Towns in East Africa. Fig. 4 Residential house around the Kilwa friday mosque.

stone vessels, suggesting that Kilwa was a centre with economic influence if not direct control of the peer settlements north and south.

The early towns of Lamu Archipelago were excavated later by Chittick (1984) and Horton (1996). Settlements like Gedi, Malindi, and Mombasa grew to compete with those to the north and even Kilwa at the time when Portuguese had entered the region. What is obvious in the archaeology of the coast of Eastern Africa is that the Swahili towns were related, and this is true whether or not Kilwa controlled affairs in the whole region between AD 1000 and about AD 1400.

In the later phase, from about AD 1300, or slightly earlier, larger Swahili towns were built by coral stones and lime mortar and roofed by mangrove poles, lime mortar and palm leaves. Archaeology also finds a profusion of many smaller settlements, which were built by mud and wattle; the larger settlements may also have had the majority of its population living in such simple houses (Horton 1996; Pradines 2002; Chami 2002). When Ibn Baṭṭūṭa visited the coast of East Africa in the AD 1330s, contrary to what archaeology suggests today, he did not see many stone houses even in larger towns such as Kilwa and Mombasa (Gibb 1939). Whether this was a personal bias against stone houses if he only saw simpler town places is not yet properly explained (see discussion by Sutton 1998).

It is also not quite certain whether each large Swahili town had its own trade and cultural link with foreign traders or if trade was only controlled by one or two larger towns which collected trade goods and distributed them to other towns. Ibn Baṭṭūṭa seems to have visited only two towns on the Swahili coast, Kilwa and Mombasa, suggesting that those were the larger ones. However, in the same time period a Chinese trip to East Africa led by Zheng He entered a town called ‘Malin’. Some scholars think this place was Malindi on the Kenya coast (Chittick 1975: 21; Wheatley 1975: 90–1); Fuwei (Fuwei 1996: 190) suggests that ‘Malin’ was Kilwa. A support for Fuwei comes from the fact that the wealthy clan at Kilwa at that time was known as Malindi and the most impressive tombs at the water front belong to this clan.

Probably each large town had its own trade abroad or a set of traders visiting particular ports in the Middle East and India. Archaeologists are now finding sites and many Swahili cultural materials in the Middle East, suggesting that the Swahili people sailed to those distant lands (Sutton 1998). It is likely that the profusion of foreign trade goods in all Swahili settlements could also suggest that individual towns engaged in long distant trade at least within the western Indian Ocean seaboard. This is testified by the fact that several towns are now known to have made their own coins and that when Vasco da Gama reached Northern Mozambique he had to get a person from Malindi, on the Kenya coast, to guide him to India. Probably the southern towns were not co-operating with the Portuguese.

The Origin of The Swahili Towns

Scholars had, up to the end of the twentieth century, debated the origin of the Swahili people and their stone town culture. Such debates revolved on the question of who the Swahili people were (Allen 1974, 1983; Nurse and Spear 1985; Pouwels 1987; Horton 1987; and Chami 1994, 1998). The original popular conception was that the Swahili people and their culture originated from the Middle East. These were alleged to have arrived in waves of immigration. Individuals in these waves founded settlements, which later grew into larger Swahili stone towns. Chittick (1974, 1975) used chronicles, particularly that of Kilwa, and archaeology to argue that the earliest immigrants could have arrived on the East African coast not earlier that the ninth century. This view suggested, therefore, that the Swahili people were originally Persians or Arabs who would later have mixed with Africans. Due to their alleged origin in the Muslim world the Swahili people were necessarily Muslims and people of towns.

Archaeologists such as Horton (1987), influenced by Allen (1983), suggested that the Swahili were people of Cushitic origin, from the northeast of Africa, who were originally pastoralists. The pastoralists, who are alleged to have ruled the Bantu speakers in a mythical land called Shunguaya, mixed with Bantu speakers, adopted Islam and spread to the rest of the coast and islands of East Africa. In this theory the Swahili people are seen as Africans who also mixed with the people of the Middle East in the process of adopting Islam and trade. This position was made more prominent in the 1990s (Horton 1990; Abungu 1994–1995; Sutton 1994–1995) in an attempt to quash the discovery that the Swahili people were Africans of Bantu origin, people of the general region of Eastern and Southern Africa who were agriculturalists and fishermen.

That the Swahili people did speak a Bantu language was a point recognised by linguists from the 1980s (Nurse and Spear 1985). Archaeologists had also established settlements of Early Iron Working people near the coast; scholars recognised that they were early Bantu speakers (Soper 1971; Phillipson 1977). Historians also recognised that the people reported by the Romans in the first centuries AD to have inhabited East Africa, then known as Azania, were agriculturalists and probably Bantu speaking (Casson 1989). In the early 1990s this author suggested that the cultural tradition found in the earliest Swahili settlements was culturally related to that of the Early Iron Working tradition (Chami 1994). In some cases settlements of the Early Iron Working people and those of the so-called early Swahili, termed by this author as Triangular Incised Ware tradition, were found in the same location. In some cases the later was found superimposed over the former in the offshore islands and on the coastal littoral of the central coast of Tanzania (Chami 1998, 1999a).

The evidence of cultural continuity from the time of Christ, through the mid-first millennium AD, to the time of the foundation of the Swahili towns in the early centuries of the second millennium AD, has now been recognised by many scholars (Kusimba 1999; Sinclair and Hakansson 2000; Spear 2000). Those who disagreed with the the first set of evidence for this continuity have now revised their ideas (Horton 1996; Horton and Middleton 2000; Sutton 1998). Archaeological findings now prove that the Swahili coast had been settled by an agricultural and trading population from the time of Pharaonic Egypt, 3000 BCE, through the Greaco-Roman period (Chami 2006). Whereas the former was of Neolithic tradition, the latter was an Early Iron Working culture. Throughout these periods the Indian Ocean, just like it was during the time of Islam, had brisk trade with communities of Asia, the Middle East and the Red Sea/Mediterranean worlds. Ceramics and beads as evidence of trade of all these pre-Islamic trading periods have now been recovered from the islands of Zanzibar, Mafia, Kilwa and Rufiji River (for conspectus see Chami 1999b, 2004, 2006).

The most recent thinking that the early Swahili people, or Zanj of the Arab documents, were Indonesians/Austronesians (Dick-Read 2005) is an attempt to disregard the archaeological, linguistic and historical data already established. For this recent thinking to be regarded as scientific at least a discussion of the previous thinking on the subject matter and its flaws should have be debated.

Some Cultural Aspects of the Swahili Towns

General Culture

The culture of the Swahili towns, as already suggested, is African with an infusion of Islamic traits. It is these infused Islamic traits such as religion, law, language, writing and costume which have made many students of the Swahili culture identify the people as Arabs. The people who had adopted this culture themselves wanted to be identified as Arabs or Persians. However, Ibn Baṭṭūṭa identified the people as 'Sawahil' and the earliest European visitors to the Swahili world, the Portuguese, identified the people as 'Moors' or 'Suaili' as opposed to Arabs.

De Barros, as Ibn Baṭṭūṭa did, also identified the Sultans of Kilwa as black people (Chittick 1975: 39). Barbosa, writing in about 1518, wrote, "Of the Moors there are some fair and some black, they are finely clad in many rich garments of gold and silk and cotton." To show that the Swahilis were different from Arabs, the Queen of Kilwa in the mid-eighteenth century wrote a letter calling home her people who had run away from the Arab/Omani domination of Kilwa to Mozambique. This was written in Kiswahili and not in Arabic; a Swahili letter suggesting that it was only the

Cities and Towns in East Africa. Fig. 5 Kilwa friday mosque.

Europeans/Christians who were in conflict with the Arabs, but not the African/Swahili people (Omar and Frankl 1994).

Religion

Most Swahili people are of the Sunni sect of Islam, which suggests an early link with Southern Arabia. Large mosques (Fig. 5) had been built with stones from AD 1300 or slightly earlier in every town of the Swahili coast. Some towns have several mosques, some being smaller for the purpose of a clan or a family. Kiblas/the north of these mosques were elaborately made; probably the one at Songo Mnara in Kilwa (Fig. 3) is the most elaborate of those seen by this author. One very unique religious aspect of the Swahili towns is that of making spectacular burials for the dead. The tombs, which most of them concentrate around the mosques, were built using stones and lime. Walls of some are more than two meters high with various decorative panels including impressed Chinese porcelain. Some tombs have high standing pillars some reaching up to six meters above the tomb.

These aspects of tombs are non-Islamic as they are found nowhere else in the Muslim world. Muslim burials are supposed to be made humbly and no materials or aspect of wealth are supposed to be involved. That these spectacular tombs are also found attached to houses or are located in compounds where people were living suggests that this is an African culture blended with Islam. I have noted elsewhere (Chami 2002) that the African tradition of wanting to live with the spirit of the dead in the same house/compound or within the settled landscape is the one portrayed in this context. Like the ancient Egyptian tradition, the spirit should not be abandoned in the wilderness away from human warmth and food. A failure to observe this rule was/is expected to bring bad omen to the family.

Writing and Arithmetic

Whatever type of pre-Islamic writing that could have existed on the coast of East Africa cannot be known for now. Early Islamic characters found on the Swahili settlements are Kuffic, the earliest known being of the eleventh century tomb of Kizimkazi in Zanzibar (Flury 1921). Later on Arabic scripts were used to write in the Swahili language. These can be seen in many tombs post dating AD 1300.

In daily counting the Swahili people mixed African and Arabic words. Counting may have followed Arabic languages in schools or official places, but in normal cases African counting was used. Today most counting words in Kiswahili are still African with the exception of a few numbers such as twenty, thirty, forty and fifty, which are in Arabic. Probably much more Arabic influence came after the rule of the Omanis from AD 1884.

Architecture

Garlake (Garlake 1966) studied the architecture of the Swahili towns; his interpretation of Swahili architecture has prevailed (Chittick 1984; Sutton 1998). As was noted with the tombs, the architecture of the Swahili buildings is of Western Indian Ocean Seaboard origin. It is the tradition that began and evolved within the region. The architecture is very much conditioned by available resources for building lime coral rubble which is made into walls with lime mortar and then plastered with the same mortar. Rarely were bricks and dressed stones (apart from porites) used. The only dressed stone used for door and window frames, mihrabs [a niche in the wall of a mosque or a room in the mosque that indicates the direction of Mecca] and lamp chambers was porite [coral]. This is a coral cut from underwater while fresh and it is dressed and decorated or inscribed while fresh.

For multi-storey houses floor slabs were made by arranging mangrove or other hard woods across. Lime mortar, sometimes mixed with coral rubble, was spread on top. Some houses, especially mosques, had moulded roofs with decorative arches, domes and vaults. Most houses must have been roofed by wood and palm/grass. Swahili houses had large verandas and corridors for relaxation and cooking. Carved panels decorated the doorframes.

Livelihood

Swahili people engaged in various economic activities. They are traditionally agricultural. They lived in mostly settled communities with vegetable gardens around their compounds and in areas a few hours' walk from towns. Allen (Allen 1983) characterized the Swahili as people who commute from town to the countryside for agricultural purposes. This has been the situation from ancient times. Crops cultivated include rice, millet, beans/peas, banana, coconut, sugar cane, spices and fruits such as mango and oranges. In recent history American crops such as maize, cassava, sweet potato and tobacco have been added to the list.

The Swahili people would have been mixed farmers who would also have domesticated chicken, cattle and ovicaprids (sheep and goats). These are well authenticated from archaeological records dating back to the early Swahili period. They also had dogs and cats and for the northern coast donkeys and camels. Due to environmental variability the northern part of the Swahili coast would have been more pastoral than the south because of the interaction that existed with the nomadic regions of Somalia and Northern Kenya.

Fishing must have dominated the activity of those living near the shore and on the island settlements as it secured the most reliable means of obtaining protein. They fished in the deep and shallower, waters and there is much evidence for times when they consumed a lot of shellfish probably suggesting difficult times (Msemwa 1994). There was also fresh water fishing. There are several large rivers entering the Swahili coast from the deep interior and also few lakes near the littoral which provided fish. Salting and drying fish facilitated transport to the deep interior.

Sailing, not only for fishing, but also for trade was probably the most prestigious activity of the Swahili man. Swahili towns consisted of people who had travelled far for the purpose of trade or prayers. There was a lot of intermarriage between communities. The Swahili people can therefore be seen as a maritime people. Goods to be exchanged with those arriving from abroad had to be collected from the south or interior of the region and this also involved distribution of those imported goods. So the Swahili towns were trade axes providing for the larger part of Eastern and Southern Africa.

Consequently the Swahili people were also involved in building sailing vessels. The Romans found the people of the Swahili coast already making sewn boats and also importing boats from abroad (Casson 1989). This technology grew tremendously and by the time of the stone towns the Swahili people must have been building large dhows used to cross the Indian Ocean to Arabia and India. In most of the Swahili towns today one can find at least one operating dhow/boat building yard, suggesting a continued tradition. Related to this technology was that of metal working, which has passed down since ancient times. This technology was necessary for cultivation and boat making, as wood had to be felled and worked.

Swahili Towns in Ruins

It was noted earlier that the realm of the Swahili culture is in the period between AD 1200 and 1500. After this heyday the Swahili culture entered into a deteriorating moment following the penetration of Europeans into East Africa. They wanted to conquer by destroying the large Swahili towns such as Kilwa and divert trade to the Atlantic Ocean towards Europe. The monopoly of trade was taken from the Swahili traders and put into the hands of European companies and later on, after 1800, into the hands of Oman Arabs and Indians. The Omanis came to East Africa to challenge the Portuguese. It was the Swahili rulers who invited the Omanis to use their Muslim responsibility to assist Muslim brethrens, but the Omanis did not leave after they accomplished the task. Only petty trade was left in the hands of the Swahili. In some towns trade was left to the Swahili people, but they had to cater for the masters of the new order.

In the new order, the Swahili towns, which had not given way to invaders before, were suppressed to the extent that they fell into ruins. This was necessary because other prosperous settlements, mostly controlled by the new Portuguese and Omani powers, emerged and it is here the new elite, whether foreign or local, would move (Chami et al. 2004). As Kilwa and other settlements of its type decayed, with only short periods of renewal, previously unknown towns emerged from about 1700. Such towns included Zanzibar, Bagamoyo and Kilwa Kivinje. Mombasa also grew substantially. These are towns founded by the enterprising British and German colonials. From the 1890s the new colonial towns such as Dar-es-Salaam, Nairobi and Kampala challenged these other towns. See (Chami et al. 2004) for an explanation of the fall and the rise of the Swahili towns.

C

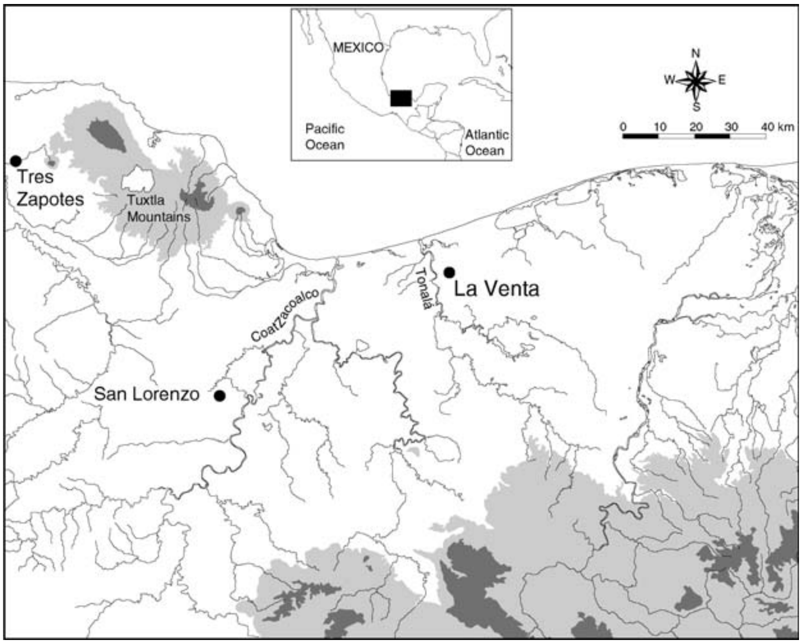
Cities and Towns of the Olmec

JOHN E. CLARK

Mesoamerica's first civilization arose about 3,400 years ago among the Olmecs of the tropical Gulf Coast lowlands of southern Mexico (Fig. 1). Olmec civilization lasted a thousand years and is recognized by its spectacular and unique art style manifested in colossal stone heads and thrones, figurines, carved pottery, and polished and incised jade objects. Among their many accomplishments, Olmecs created the first cities in North America. Many archeological sites are known for this culture, but only two were large and splendid enough to qualify as cities: San Lorenzo and La Venta. As capitals of dynastic societies and habitats of kings, some bureaucratic functions and services were unique to these cities, as evident in their palaces, thrones, royal tombs, ballcourts, temples, observatories, and state art. Scholars expect cities to accommodate 5,000 or more people. By the standards of function and size, San Lorenzo was Mesoamerica's first city. It enjoyed a meteoric but brief history and was succeeded in the same region by La Venta, the last Olmec city. For its part, La Venta represented the first mature manifestation of the quintessential Mesoamerican city, and it was a model of a sacred center copied by other peoples. Key issues in Olmec studies are the historic and formal relationships between San Lorenzo and La Venta. These are most easily appreciated by beginning with La Venta and tracing some of its features back to San Lorenzo.

The Last City, La Venta

La Venta was founded and built about 850 BCE on virgin soil in a special place: a long, 20 m high island in the middle of a vast swamp in western Tabasco, Mexico, just 15 km from the coast. La Venta was abandoned about 400 BCE and never reoccupied. This was a fortunate happenstance for investigators because the city has been preserved as the Olmecs left it



Cities and Towns of the Olmec. Fig. 1 Map of Mesoamerica showing the Olmec region and its principal sites.

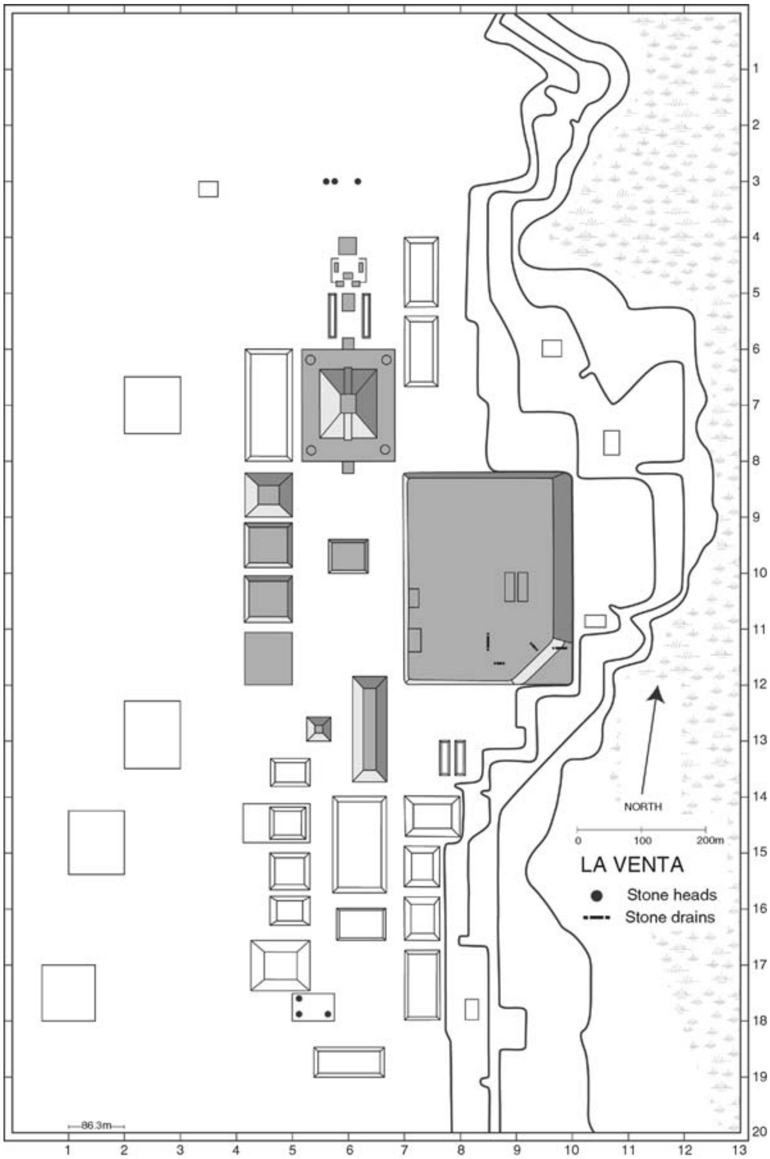
2,400 years ago. The map of the site in Fig. 2 indicates the probable early and final form of this city. At its founding, La Venta was laid out along the eastern edge of the island. This escarpment was cut and terraced to bring it into alignment with the principal axis of the ∴-shaped city. Some of the construction fill used to build the city may have come from these land modification operations.

La Venta was built to a rigid plan, in regular 86.6 m blocks, and along a centerline oriented 8° west of north. The original city center was 10 blocks long and 8 wide. Subsequent additions to the city respected the principal axis and measurement interval. Later mounds encroached on the original mounds in the north. The monumental city center eventually extended 1,482 m, or 17 blocks. Late in its history, stone monuments were set up as boundary markers. Three basalt colossal stone heads were placed at the northern end of the city, and they faced north. Three even larger sandstone heads near the southern end faced south. These monuments were placed 1,300 m or 15 blocks apart.

These building intervals, when translated into native Mesoamerican beliefs and practices, show that La Venta was built as a sacred center. The Olmecs measured this city with the 1.67 m fathom used by the later Aztecs and Maya; thus, the 86.6 m block represented 52 fathoms, the year count for the calendar round. Five such macrounits comprise the number of days in the sacred almanac (260), and seven (364) approximate the solar year. These calendar distances separate critical points in the arrangement of buildings at La Venta. For example, the original city was 10 blocks long, or 2 × 260. Later additions to the site extended it 7 blocks, or a solar year count. Other ritual counts are built into the placement of mounds and monuments. They demonstrate that La Venta was carefully planned and built with marvelous precision.

The city was partitioned and arranged according to function. The original layout shows a long, 6 ha plaza (2 × 4 blocks) with special architecture in each cardinal direction. The plaza was probably for public ceremonies and for viewing rituals performed on the platforms surrounding it. The plaza could have accommodated well over 100,000 standing spectators. Looking north, a spectator would see a 32 m high stepped pyramid made of nearly 100,000 m^3 of dirt and clay. A temple of perishable materials probably graced the top of this artificial mountain. The summit could be accessed from stairs on the south and north faces. The pyramid is the only promontory for over 100 km on this coastal plain and can be seen from over 10 km away. It would have been very impressive close-up in its final form. The pyramid was given a new clay skin several times during the city's history, each time making it slightly bigger and taller. The height of the original pyramid has not been determined.

East of the plaza lies a broad 8 ha platform or acropolis that required nearly twice as much earth and clay to build as the pyramid. This high platform was probably the royal compound: residence of the king, his courtiers, and servants. A ballcourt and an elaborate system of subterranean stone drains have been



Cities and Towns of the Olmec. Fig. 2 Map of La Venta, Tabasco, Mexico. The gray areas indicate the early part of the city.

identified there. In the block south of the plaza lies a long mound flanked on the west by a short pyramid. Together these constituted an astronomical observatory for monitoring the movements of the rising sun through the year, perhaps to coordinate the agricultural cycle and other state rituals. Looking to the west a spectator would see a string of low platforms and their perishable buildings, probably priests' residences or special temples. Axial symmetry is evident in the organization of the original city. Buildings on facing blocks around the plaza were complementary pairs: the pyramid and observatory formed a N–S pair, and the royal compound and priestly residences an E–W pair.

North of the pyramid block a compound was built 1/4 the scale of the rest of the original city. The main complex consisted of five low mounds surrounded by a 2 m high and rectangular palisade of upright, basalt pillars. Spectacular jade and serpentine offerings and royal tombs were found in this sector arrayed along the principal axis, and on both sides of it. Some individual offerings had more than 1,000 tons of serpentine. A pair of offerings depict the abstract face of the earth lord, each on top of 28 layers of carefully placed serpentine rubble. The two images look identical but are color coded to depict an east and west image of the same entity. All rock used in these offerings was imported from over 60 km away, so the massive offerings represented a tremendous burial of wealth. Another expense was the importation of tons of basalt for stone monuments and architectural enhancements.

These were brought in by canoe or raft from over 100 km of inland waterways. To date, 90 stone monuments and hundreds of 1-ton basalt pillars have been discovered in the city. Sculptures include colossal stone heads, thrones, full-figure images of kings, and low-relief carvings on flat slabs, or stelae. The latter depict gods or narrative scenes. The south side of the great pyramid had a line of six stelae facing the main plaza, three on each side of the stairs.

The mounds added to the southern end of the city later in its history are not as logically arranged as those of the original city. Presumably, they were for privileged personnel and state functionaries. With the exception of the six monuments used as boundary markers, large stone sculptures were confined to the northern part of the city, the domain of La Venta's lords and priests. The oldest buildings in the north were rebuilt or refurbished many times during their centuries of use.

In its final form the city center was about 58 ha in extent, and with its residential neighborhoods the whole city covered at least 200 ha. At its height, the city housed 3,000–5,000 people, with many more on small islands and river levees within 10 km of the city. The extent of the La Venta kingdom has not been determined, but the city was the royal capital for towns and villages located over 100 km distant. La Venta kings were depicted as corn gods, indicating that the city was governed by divine kings, or priest-kings. The institution of kingship became fundamental to Mesoamerica statecraft; its beginnings can be traced to San Lorenzo.

The First City, San Lorenzo

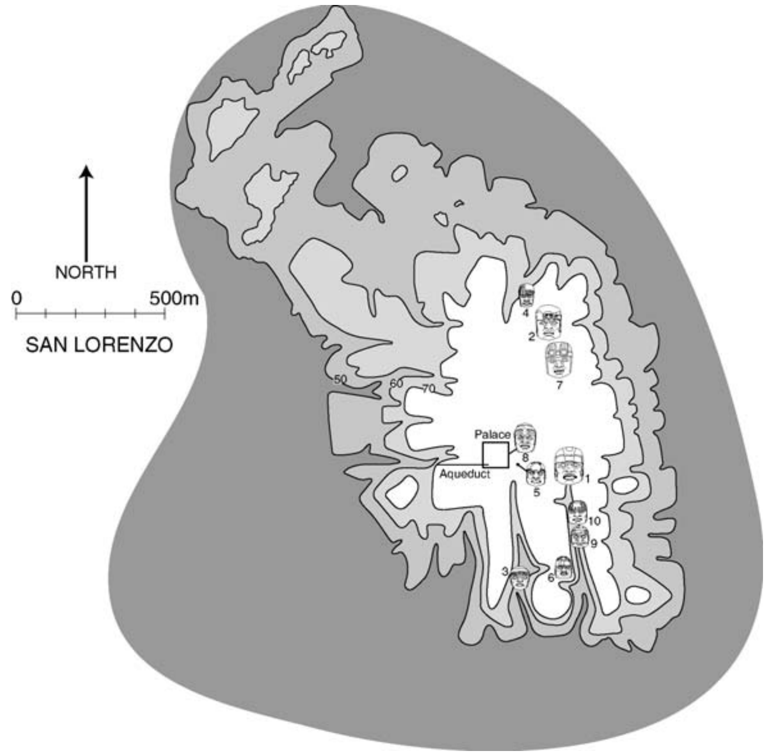
San Lorenzo was occupied off and on from 1750 BCE to AD 1100, but it only functioned as a city from 1300 to 1000 BCE, at which time it reached its maximum extent of 500 ha, over twice the size of La Venta in its prime. San Lorenzo collapsed about 1000 BCE, perhaps due to a shift in the course of the Coatzacoalcos River. The city is located 60 km from the coast and currently lies 7 km west of the meandering Coatzacoalcos, the second largest river in Mexico. Just over 3,000 years ago, this river ran on both sides of San Lorenzo, making the site an island and well positioned to control canoe traffic and commerce. The city core lay atop the summit of a 50 m high natural plateau nearly 60 ha in extent. The surface of the plateau was carved and stretched into a ⊥-shape, with the N–S crossbar being nearly twice as long (1,213 m) as the E–W axis (650 m). Elite houses, public buildings, and special stone statuary were confined to the top of the plateau, with residential terraces encircling the heights and spilling down and across the plain below. San Lorenzo was the capital of a region that extended 40 km up and down river. At least 7,000–10,000 people lived in the city in its heyday, with four times as many in subordinate communities and provinces.

Little is known of the layout of San Lorenzo because the city lies a meter or two beneath the current surface, so its format will only be revealed through excavation. The few mounds on the plateau postdate the Olmec occupation. A striking difference with La Venta is that early San Lorenzo lacked pyramids. Recent research discovered a palace with an inner courtyard; a colossal stone head and throne were on display there, demonstrating that stone monuments were associated with royal architecture and that some were buried in place. Plazas and temples have not yet been identified. Ballcourts are known at a junior center and may eventually be found at San Lorenzo.

Judging from the size and shape of the modified plateau top, and the first level of broad terraces below the summit, San Lorenzo was arranged in the same measurement increments as La Venta. The original cruciform of the plateau was 14 × 9 blocks. Another five blocks are evident in the descending terraces on the western and eastern extensions, making the planned city center a 14 block square, or two solar years on a side.

The shape of the plateau and alignments of stone heads and aqueducts demonstrate that the central part of San Lorenzo was rectangular and aligned to N–S and E–W axes, with the long axis 1° west of true north (Fig. 3). Both cardinal axes at San Lorenzo were important, but the axial symmetry of the city unfolds from the E–W centerline. When Olmecs built La Venta, they rotated the basic San Lorenzo plan 90° counter-clockwise so the most important cardinal direction became north instead of east. San Lorenzo was formally organized and zoned from the center of the plateau outward, and downslope. Residential status decreased as a function of distance from the center. The only palace identified so far was built near the western edge of the city's center (Fig. 3), opposite its placement at La Venta. The San Lorenzo palace was placed near a freshwater spring, and a 171 m long aqueduct ran west from its courtyard to the edge of the plateau. If the colossal stone heads were buried in palace courtyards, their distribution suggests that each king had his own palace and that these shifted during San Lorenzo's history from the west edge of the plateau to the east.

As at La Venta, much engineering and earth moving went into constructing San Lorenzo. The first task in building the city was to level the plateau and extend and straighten some of its edges. The eastern and southern faces appear to have been the most precisely cut, and even after nearly 3,000 years of erosion, their straight, perpendicular edges can be appreciated (Fig. 3). Ramps and causeways were created for hauling



Cities and Towns of the Olmec. Fig. 3 Map of San Lorenzo, Veracruz, Mexico, showing the distribution of colossal heads, the E Group palace, and long stone aqueduct. The heads are shown to scale relative to each other.

the colossal sculptures to the summit. A complex system of stone drains was also installed at their proper gradient.

Many specialized artists, artisans, and bureaucrats resided at San Lorenzo, and they were supported by food brought in from outlying settlements. The clearest evidence of subsidized citizens shows up in the site's 130 stone monuments imported from 60 km away, some of them weighing over 20 tons. The best known are thrones and colossal heads. The latter are thought to be realistic portraits of individual kings. Judging from similarities of facial features, at least three families appear represented in the San Lorenzo king list. These kings were depicted as warriors and heroes rather than gods, as became the subsequent practice at La Venta. Together, the San Lorenzo heads displayed the city's royal dynasty – the first in Mesoamerica. The artistry and labor evident in these monuments, and the organizational requirements for carving and dragging them through the jungle to the city, reveal the presence of other citizens: artisans, overseers, haulers, and probably slaves.

In summary, similarities between San Lorenzo and La Venta include their orientation, cruciform shapes, concentric zoning, size of city centers, standard block sizes, spacing by calendar distances, axial symmetry and complementarity, palaces, and abundant monuments of gods and kings. Significant differences are the presence of pyramids and special monumental architecture at La Venta and the emphasis on north as the sacred sector of the city, the place of the tallest pyramid. The small hamlet at San Lorenzo at 1750 BCE evolved in place into a glorious city in just four centuries. In contrast, La Venta was planned as a special city before the island was occupied. Many later Mesoamerican cities mimicked the formal layout of La Venta rather than that of San Lorenzo. The latter's contribution was getting kingship and city building started, not giving them their final form.

Cities and Towns in West Africa

Cris Beauchemin, Philippe Bocquier

West Africa, like most regions of the continent, is still largely rural. Even after decades of rapid urban growth and the emergence of cities of 1 million people or more, the majority of the population continues to live in rural areas. However, cities and towns generate higher revenues than the countryside. Urbanisation has brought major changes for both urban and rural dwellers. Large cities, which are often ports, are gateways to the rest of the world. The most traditional practices coexist with the most advanced technology and, in contrast to the negative image conveyed by media about the Developed World, Africans have shown a strong ability to adapt to the global world (see Fig. 1). That said development in West Africa is impeded by a number of problems. This article will address the endogenous and exogenous factors hampering urban development in West Africa. First, we will show that the (long) urban history of West Africa is the result both of indigenous and European influences. Then we will analyse recent urbanisation trends from a demographic point of view before examining the origin and reasons for urban development. Finally we will consider the issue of urban management. For the purposes of this article, "West Africa" is defined as the countries to the west of the line running from Lake Chad to the border between Nigeria and Cameroon.

Cities and Towns in West Africa. Fig. 1 Cotonou, Bénin. Tall, modern buildings are proudly erected next to very crowded places where the informal sector is blooming and yellow and green taxis are waiting clients to transport goods. Note the mobile phone antenna and the satellite dish on top of the blue building; all their offices are connected to the Internet. Some investors are less successful, as can be seen from the unfinished building on the right. © Franck Houndegla.

A Long but Little-Known Urban History

Urbanisation is not only a contemporary phenomenon in West Africa. Urban centres have developed in this region of the world for over 2,000 years (Coquery 1990). In the Middle Ages, some were very prosperous and were known by Europeans as great cultural and commercial places (Timbuktu, for instance). Some were even compared by travellers to European cities such as Amsterdam or Lisbon (Benin City in the seventeenth century).

Still, the history of West African towns and cities is still very incomplete, mainly because this is a new field of research. Urban Africa was only 'discovered' by historians in the late 1970s and until very recently there has been little interest in pre-colonial urbanism other than through the work of archaeologists (Anderson and Rathbone 2000). The scarcity of written sources and the fact that few stone monuments survive may explain why African urban history is still very incomplete. For a long time, towns and cities were only presented as colonial creations. Earlier settlements were not recognised as urban because their features were not similar to those of European towns and cities (often considered as a standard to define urban settlements): there were no stones used in architecture, an abundance of agriculture, and very low population density. But recent research has shown that West Africa has nurtured various forms of settlements quite distinct from simple villages long before the Europeans' arrival.

The first urban settlements in West Africa, as in the rest of the continent, were indigenous creations (Coquery 1990). The most ancient is Jenne-Jeno (distinct from Djenne), located in Middle-Niger, discovered by archaeologists in 1977[1]. It was probably created around 250 BCE, reached its peak between 750 and 1150, declined under Islamic influence and finally disappeared in the fifteenth century. Except for the fact that it had city walls, Jenne-Jeno did not look like a medieval European city. It was quite extended (40 hectares around the tenth century), as opposed to very dense European settlements of the same period. There were no monuments in the centre of the city (such as palaces, churches or markets always present in European towns and cities). And the

[1] For more information and to see pictures of the archaeological site, see: ►http://www.ruf.rice.edu/~anth/arch/brochure/

Cities and Towns in West Africa. Fig. 2 source: ►http://www.sum.uio.no/timbuktu/. The city of Timbuktu: a place of contact between the Sahara and Sub-saharan Africa.

buildings were made of adobe. But Jenne-Jeno was an important commercial centre for its region (fishing and agricultural products) and it was also probably one of the first places of the trans-Saharan trade (salt against copper in the fourth century).

Other towns and cities developed in this region of contact between the Sahara and the Savannah (Fig. 2), where international trade was possible. In the Middle Ages, the succession of great centralised states (ancient Ghana[2], Mali and Songhaï empires) contributed to the development of a network of towns and cities, among which Timbuktu, Djenne and Gao are the most famous. Following the trade Saharan routes, the Islamic and Arabic influences grew in the process of urbanisation. The introduction of Islam gave to the great cities mentioned above their monuments: Sudanese style mosques (Fig. 3). It also gave them a cultural aura (Timbuktu was a famous Islamic intellectual centre). And it played a role in matters of social organization; these cities were cosmopolitan places. Whatever the influence of Islam, their fame in the European Middle Ages is mainly due to the fact that they were the gold providers for the East through the trans-Saharan trade[3]. But they also played an important role in the economy and even in the urbanisation process of southern regions of West Africa. Stopover places, first created to facilitate the exportation of gold and other goods from coastal regions, progressively turned into real towns, such as Begho[4].

Cities and Towns in West Africa. Fig. 3 Djenné, Mali. This town exemplifies early urbanization in West Africa. Situated on the Bani River, Djenné dates back to 250 BCE In the thirteenth century, Djenné was an important market for trans-Saharan trade, particularly between North and West Africa. The most common items of exchange were gold, slaves and salt. Djenné also became an important center for Muslim learning during the seventeenth century. The city's mosque (at the rear of the Fig.) is the largest mud–brick building in the world. © IRD – Jacques Champaud.

Trade, through trans-Saharan routes, was a major factor of urbanisation in medieval West Africa. However it is worth noting that some great urban regions also developed in West Africa, even if they had weak connections with this trade system. It seems to be the case for the Hausa-speaking city-states, the Yoruba towns or the Ghanaian urban system. These urban regions have some common features. They started their development in the Middle Ages and were especially

[2] Ancient Ghana's territory is distinct from contemporary Ghana. It broadly covered the oriental Senegal and Mauritania, the occidental Mali and a part of the current Guinea. The creation date of the Ghana Empire is not precisely known, though an Arab writer mentions it in the eighth century. It finally disappeared in the twelfth century.

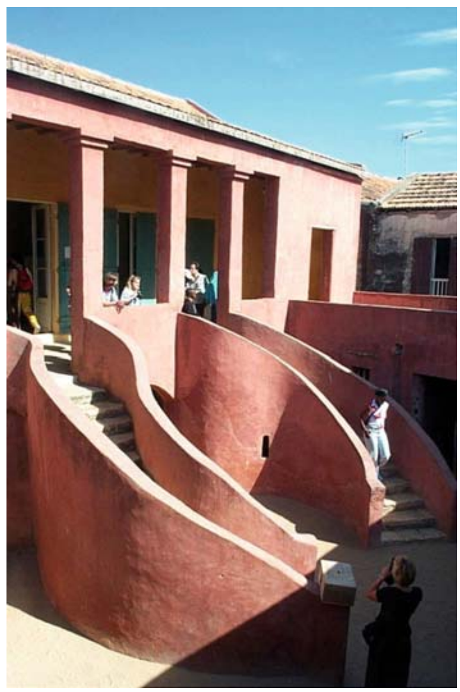
[3] See a map: ►http://www.metmuseum.org/toah/hd/gold/hg_d_gold_d1map.htm

[4] The Dioula merchants were also the actors through which the Sudanese-style mosques spread all over West Africa.

prosperous between the fifteenth and the eighteenth century (their respective peak periods are however not totally contemporaneous). In contrast with the Middle Niger cities, the towns of each of these regions emerged without a centralised state. They shared a common culture (language, religion, social organisation) but they were in competition, and sometimes at war, each one of them trying to extend its influence on the surrounding countries (Fig. 4). Whereas the Middle Niger cities were mainly turned towards international trade, the towns and cities of the Hausa, Yoruba and Ghanaian regions were first engaged in regional trade. Agriculture was sufficiently intensive to produce enough surplus to feed an important urban population. In Ghana for instance, around 30% of the population lived in urban areas and 70% of the urbanites (merchants, craftsmen, the nobility and their families) bought their food in markets (Coquery-Vidrovitch 1993). The rural people were under the domination of urban power; they were sometimes forced to leave their villages in order to settle in the towns (Yoruba region) and also paid important taxes. In the Ghanaian region, rural taxes represented between a quarter and a half of peasants' earnings (Coquery-Vidrovitch 1993). Some cities of these three regions remained famous: Kano and Katsina in the Hausa region, Great Accra in Ghana, Benin City, Old Oyo or Ife in the Yoruba area. They have been described by the first Europeans who arrived in West Africa (Iberian sailors) in the fifteenth century. Till the eighteenth century, Ghanaian and Yoruba towns and cities[5] benefited from the new forms of trade introduced by Europeans. But the launching of the slave trade disrupted these urban networks.

The first European settlements in West Africa were not towns: they were only isolated forts on the coast, whose purpose was to resupply the shipping expeditions. They progressively turned into trading posts and finally into small towns when the slave trade was introduced in the eighteenth century (Fig. 5). Gorée, Saint-Louis or Ouidah, for example, were central places at this time. They were inhabited not only by Europeans but also by African people. And a kind of local bourgeoisie, with a Creole culture, appeared. The overseas trade acted as a new vector of indigenous urbanisation on the coast and also in the hinterland. New states, engaged in the slave trade, emerged and gave birth to new capital cities (kingdoms of Porto Novo and Abomey, Ashanti Empire). For instance, Kumassi, the Ashanti capital city, was a center of the slave economy, but it was also a trade centre for kola nuts, which were exported to the north. It was the heart of a dense road network, quite far from the coast, in

Cities and Towns in West Africa. Fig. 4 Source: ►http://www.uni.edu/gai/Nigeria/Pictures/kano.html. Kano, Nigeria. The old-walled section of Kano is nearly 1000 years old and is enclosed by a mud wall. Located on the edge of the Sahel, Kano is a Muslim city, one of the oldest in West Africa. Kano was the centre of a prosperous Hausa city-state in the seventeenth century, when the Songhaï Empire declined. Under the Sokoto Empire (nineteenth century), it became a very important place of textile production in West Africa. At the end of the nineteenth century, half of the West Sudanese population was dressed with loincloths from Kano.



Cities and Towns in West Africa. Fig. 5 Source: ►http://www.globalgeografia.com/album/senegal/goree.jpg. Gorée, Senegal. This building, built around 1780, may have been the last slaves' house in Goree. The first ones dated back to 1536, built by the Portuguese, first Europeans to set foot on the island in 1444.

[5] Hausa city-states were less influenced because they were far from the coast.

order to escape a too strong European influence. There were 77 neighbourhoods (around 13,000 inhabitants in 1870) separated by large and rectilinear avenues. It remains today an important city in Ghana.

The abolition of slavery, declared in 1815 in all European countries, appears as a shock in African urban history. The cities whose prosperity relied on the Atlantic slave trade declined. New settlements were created to welcome freed slaves from the United States (Monrovia) or from the British territories (Freetown). Some existing towns turned the end of the Atlantic trade to their advantage by using for their own development the workforce of the slaves. For instance, Kano became a great centre of textile production in West Africa (Fig. 4). In 1894, there were 100,000 inhabitants, 50% of whom were slaves. During the nineteenth century, various urban centres emerged as commercial places and/or as capital cities for new West African states (Sikasso, capital city of Kenedougou; Sokoto, capital city of the Fulbe Empire...).

To sum up, it should be clear that the urban history of West Africa started before European colonisation. First contacts with Europeans, from the fifteenth to the nineteenth century, had an impact on the urbanisation process, but they did not totally drive it. When Europeans started to colonise West Africa, they created new cities, mainly ports (e.g., Dakar, Abidjan, Cotonou, Conakry...) and crossroads places (e.g., Bamako) aimed at facilitating natural resources exportation (see Map 1). They also took advantage of the existing urban networks. Indigenous towns and cities happened to be excellent places for the political and economic control of the territories. Colonisation seriously boosted the urbanisation process by creating new urban activities. Labour migration was an important factor in urban development in colonial times when workers were needed for public infrastructure (airstrips, railways and ports), administration (soldiers, clerks) or various private services (maids, etc.). Migration flows to urban centres continued after independence. In sum, colonisation acted as a starter for urban development on a larger scale[6].

Recent Urban Trends in West Africa: Rapid Demographic Change

In terms of the contemporary urbanisation process, West Africa is at once lagging behind (with the exception of Nigeria, it remains one of the least urbanised regions of the world) and at the forefront of change (the region had one of the highest urban growth rates of the second half of the twentieth century). Urban growth has not been linear: after a peak in the 1960s (9.3% per year for West Africa as a whole), it reached a low of 5.6% in 1990–2000 (Fig. 3), and the region remains predominantly rural (see End Notes 1. Definitions and Measures Vagaries). Migration is usually seen as the main contributing factor in the growth of towns and cities. According to a 1988 UN report, almost all governments of developing countries believed that internal rural-to-urban migration was the dominant factor contributing to the growth of cities (United Nations 1998). But urban growth can be generated by any of three mechanisms: natural growth, reclassification and migration. All these components follow a specific pattern in the context of West Africa.

Cities and Towns in West Africa. Fig. 6 A street restaurant in Dakar, Senegal. Women prepare and sell traditional dishes (rice on the left and vegetables on the right). © IRD – Michel Dukhan.

Natural urban growth (i.e., the surplus of births over deaths) in West Africa remains one of the highest in the world: 2.7% annually, versus 1.9% for the developing world as a whole (PRB 2001). (Natural growth rates are nevertheless lower in urban than in rural areas, since mortality and fertility have declined faster in towns and cities than in the countryside). This is one reason why urban growth remains so high in this region compared to the rest of the world. A United Nations study has shown that the contribution of natural growth to urban growth is much higher in Africa than in other parts of the world. On the African continent, natural growth accounted for 75% of urban growth in the 1980s, compared with a share of only 50% in Asia, excluding China (Chen, Valente et al. 1998).

Another feature of urban growth specific to West Africa is the importance of reclassification. Reclassified

[6] Bairoch (1985) estimates that the urbanisation level in Africa as a whole was 5% in 1900, 12% in 1950, and 28% in 1980.

settlements are those that cross a population threshold (10,000 inhabitants in the GEOPOLIS database used in this article; see End Note 1), beyond which they are considered urban instead of rural. These newly-urban settlements contribute to urban population growth, even though their population may not have moved. In Africa as a whole, between 1950 and 1980, the share of reclassification in urban population growth was 26.4%. This means that, in 1980, more than one new African urban dweller in four lived in an agglomeration that had been classified as rural in the previous 30 years. This rate was only 13.4% worldwide, excluding China and Korea for which reliable data are not available (Moriconi-Ebrard 1994). Thus, urban growth in Africa, much more than in the other continents, is due to the proliferation of new small urban centres that had previously been considered rural (see End Note 2. The Urban Future: Mega-Cities or Small Towns?).

Considering the foregoing arguments, the role of migration in urban growth seems to be less important than is commonly assumed. The process of urbanisation, from a demographic point of view, is more complex than a simple rush of migrants from rural to urban areas. Furthermore, the contribution of migration and reclassification to urban growth appears to be decreasing. Indeed, according to the GEOPOLIS database, two-thirds of urban growth in West Africa was due to migration and reclassification in the 1960s, versus only one-third in the 1990s (Bocquier and Traoré 2000). This result is consistent with several other studies (Arnaud 1998; Chen, Valente et al. 1998). To what factor can this change be attributed?

One reason is mathematical. Urban growth due to migration automatically falls as the urban population increases in relation to the rural population, simply because the rural population who could potentially leave their villages becomes smaller. When the majority of people live in villages, net out-migration (i.e., a negative migratory balance) from a rural area means, for the same volume of migrants, a higher net in-migration rate towards urban areas. As the respective proportions of the rural and urban populations balance out, the number of migrants who contribute to urban growth decreases, even though the probability of out-migration from rural areas may remain the same. This is what happens in developed countries; when more than 60% of the population lives in urban areas, urban growth by immigration from rural areas is necessarily low. But is this mathematical equation sufficient to explain the decline in urban growth in the 1980s and 1990s in Africa, where the level of urbanisation is only around 30%?

In fact, the decreasing role of migration in urban growth is largely due to new migratory trends. In sub-Saharan Africa as a whole, several recent sources indicate that rural out-migration has not only subsided, but that its counter-stream (i.e. urban out-migration) has increased. West Africa offers interesting examples in this regard. Côte d'Ivoire, for instance, experienced a migratory reversal between the mid-1980s and the late 1990s[7]; urban-to-rural migration exceeded the opposite flow, causing the level of urbanisation to decline (Beauchemin 2002b). Even though the counter-urbanisation process is still marginal in Africa at national level (Zambia is the only other country where this trend has been identified), many countries are experiencing a decrease in rural-to-urban migration to some extent. A West African network of national migration surveys revealed that secondary towns in seven countries (Burkina Faso, Côte d'Ivoire, Guinea, Mali, Mauritania, Niger and Senegal) recorded a net loss of migrants between 1988 and 1992 (Bocquier and Traoré 2000). Some larger cities are also affected by a decline in migration; Accra, capital city of Ghana, apparently saw significant net out-migration in the mid 1980s (Simon 1997); and Abidjan had no migratory growth between 1988 and 1992, excluding international flows (Beauchemin 2001). Economic decline appears a pervasive explanation for the slowing of urban growth and change in migratory trends. Despite these new migratory patterns, in most West African countries, the urban population continues to grow faster than the rural population. However, due to the slowdown in urban growth, the rural way of life could well remain predominant in West Africa for a long time to come (Bocquier 2003).

The Economic Roots of Urban Development

Although urbanisation is commonly associated with a gradual reallocation of labour from agriculture to industry, which is what happened in the industrialised world in the nineteenth century (Bairoch 1985), urban in-migration in West Africa occurred (and continues to occur) without industrial development. In addition, African countries witnessed a massive migration of the rural population to urban areas despite rising levels of urban unemployment and underemployment (Todaro 1997).

These apparent contradictions in migration and urbanisation were initially attributed to irrational behaviour. A better explanation was found in the concept of economic dualism between the formal and informal urban sectors, first introduced by Lewis (1954) and extended by Todaro (1976). In contrast to the formal sector (geared towards capital-intensive, large-scale modern production), the informal sector is a traditional, unregistered, subsistence sector geared towards labour-intensive, small-scale production. How-

[7] Internal migration has probably evolved since then, due to civil war.

ever, the spectrum of informal activities ranges from the so far predominantly downmarket informal sector to an upmarket informal sector (see Figs. 8 and 7), which is closer to small and medium business type activity, even though it does not comply fully with tax and social security regulations. The existence of the informal sector explains why rural-to-urban migration has persisted—leading to rapid urban growth—despite limited absorption capacity in the urban formal employment sector (see End Note 3. Migration, Urbanisation and Development; A Controversial Issue). Although sometimes discouraged by public authorities because of its illegality and suspected tax evasion, most researchers now recognise that the informal sector has economic advantages; it absorbs surplus labour and provides a safety net in a context of high unemployment and poverty (Becker, Hamer et al. 1994; Snrech 1994). In fact, the sector employs the majority of urban workers and serves the purpose of receiving and integrating migrants and providing them with minimum subsistence. However, this pattern has evolved in the last two decades as a result of the economic crisis.

Since the 1970s, West Africa, still mostly dependent on commodity exports (coffee, cocoa, bananas, petroleum, etc.), has suffered from falling prices on international markets. West African countries first delayed the crisis by maintaining public expenditure. But, as debt became unsustainable, structural adjustment programmes (SAPs) imposed by international organisations and donors focussed on reducing public expenditure via privatisation and staff redundancies (Duruflé 1988; Becker et al. 1994). Employment surveys conducted in 2001–2002 showed that public sector employment in seven West African capital cities was 8% on average, with a higher-than-average rate in Niamey (15%) and Ouagadougou (13%), which is still rather low considering that these cities concentrate most of the public sector activities (AFRISTAT 2005). In the 1990s, urban unemployment reached unprecedented levels, in particular among educated people looking for jobs in the formal sector (Lachaud 1994; Charmes 1996; Bocquier and LeGrand 1998). In 2001–2002, in Cotonou, Bamako and Lome unemployment was relatively low (5% to 8%) compared with Dakar (12%), Niamey (13%), Abidjan (14%) and Ouagadougou (15%) (AFRISTAT 2005). These figures, computed using the ILO's standard measure of unemployment, would be much higher if they included discouraged unemployed city dwellers (i.e. non-working people who have stopped looking for a job after unsuccessful attempts) and 'underemployed' people. Gugler generally defines 'underemployment' as the underutilisation of labour. This occurs when workers are so numerous that at all times a substantial proportion is employed part-time. It is linked to the economic role of solidarity groups that continue to employ all their members rather than laying them off when there is insufficient work to keep them fully occupied (Gugler 1982). As most workers turned to the informal sector, the crisis caused the informalisation of the urban economy. In West African capital cities (Cotonou, Bamako, Lome, Dakar, Niamey, Abidjan and Ouagadougou), about 75% of employment is informal, with little variation (plus or minus 5%) between countries. However, the informal sector itself suffered from worsening economic conditions. Demand from urban households plummeted as standards of living deteriorated. In 2001–2002, more than 55% of workers earned less than the official minimum hourly wage, and average monthly household income ranged from $30 to $70 (i.e. $10 a month per urban dweller on average) across the seven capital cities listed above. Less income in the informal sector is shared by more people as competition was heightened by the arrival of those left out of the formal economy (Arnaud 1998). Urban poverty has increased dramatically in West African towns and cities. Even though the recession affected both urban and rural areas in West Africa, urbanites seem to have suffered more hardship than their rural counterparts. Jamal and Weeks calculated that, in the 1970s and 1980s, the rural–urban income gap in many African countries either disappeared or shifted in favour of the farmers (Jamal and Weeks 1993). The fall in real urban incomes has generated a new urban poor population, who are forced to adopt survival strategies. Households diversify their sources of income; previously non-working members, mainly women, enter the petty commodity sector, and wage earners take on supplementary cash-earning activities. They reduce their expenditure by developing subsistence agriculture within and around the urban area (see Fig. 9), and by adjusting their housing arrangements (some move towards less expensive districts, while others rent out a part of their house). Another coping strategy is to strengthen and adapt rural–urban ties, which includes returning to rural homes. This often involves changes in household composition. Adult members are sent to villages to diversify income in order to cope better with economic hazards, some children are sent back to rural areas where schools are cheaper, while foster children are sent back to their original households (Beauchemin and Bocquier 2004, Potts 1997). These strategies are not marginal and explain why urban out-migration has increased significantly in West Africa.

Household coping strategies would appear to be effective in adapting to the deteriorating urban economy. In West Africa, no riots broke out in response to the implementation of structural adjustment. However, in this context of rising poverty, social and ethnic tensions have been exacerbated in some countries[8]. In other countries, remittances from international migrants might have acted as safety valves. For instance, Senegalese and Malian emigrants are known to play an important role in both rural and urban development in their home countries (Tall 1994; Gueye 2002; Bertrand 1994).

Construction of Towns and Cities

The physical appearance of West African cities and towns is mostly the result of a recent and rapid pace of growth, which public authorities, despite their intentions, have been unable to control. Almost everywhere, governments nationalised land after independence, and public authorities were supposed to become the main—if not the only—actor in urban development. They did indeed draw plans and build housing units to supply demand from urban residents. However, the supply of public housing has only ever met a small proportion of needs, and the dwellings or serviced plots made available are not affordable for the lowest income groups. How did the others—in fact the majority—find accommodation? They relied on the informal sector, by buying a plot from a holder of customary tenure rights and building their own houses, or by renting a place in an unauthorised neighbourhood (Durand-Lasserve 1986; Rakodi 1997).

Cities and Towns in West Africa. Fig. 9 In a context of growing poverty, urban households turn to agriculture within and around urban areas in order to reduce their expenditures. Here, the Figure also shows the progressive building process in West Africa. Construction is usually incremental due to the underdeveloped nature of the housing finance system sector. Therefore, people build as they get money. © IRD – Philippe Haeringer.

As in other sub-Saharan African countries, in West Africa there are overlapping land tenure systems. Although the law imposed public control over land, the customary system has survived informally. Theoretically, in that system, land cannot be owned as private property. It is vested in a community (usually a lineage whose ancestors settled on the land), and administered by the head of the group. In that system, unused land can be allocated to a non-member of the group, especially if he needs it to survive. In that case, in the traditional system, only a token payment to the land chief is required. This is not a sale since the land remains theoretically inalienable. However, in urban areas, as pressures intensify, traditional payments are moving closer to real land prices. Since the 1960s, in all cities, customary authorities have informally sold (i.e. without transfer of title) land for urban development. Since the occupants have no title, public authorities can always contest the use to which the land is put. Until the late 1970s, informal settlements were demolished. Then policies switched to regularisation and upgrading programmes; titles or occupancy licences were delivered to the previously unauthorised occupants and infrastructure was installed (Amis 1989). All in all, states now tolerate informal settlements because they meet popular demand. Building a house is for most households the only source and accessible investment while bank savings are unreliable and poorly profitable. The informal land tenure system has thus become

[8] On the conflict in Côte d'Ivoire, see Beauchemin 2005.

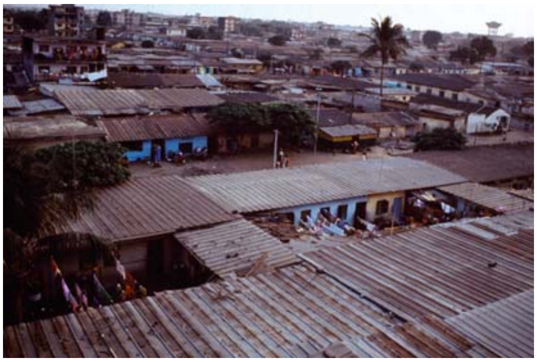
more secure. In 2001–2002, between 50 and 85% of self-declared landowners in seven West African capital cities possessed a land title (AFRISTAT 2005). The urban structure of unauthorised neighbourhoods is also quite similar to that of regular districts; landowners, intermediaries and buyers are adopting urban and architectural standards likely to facilitate subsequent regularization (see Fig. 10).

In West African cities, the majority of houses in both the formal and informal sectors have been built on an individual rather than mass production basis. The typical West African housing unit is the compound house (see Fig. 11). This type of accommodation houses 85% of the population in Abidjan (Côte d'Ivoire) and Bamako (Mali) and three-quarters of households in Accra (Ghana). Even in informal areas, urbanites do not build their own houses; artisan builders are commissioned (Coquery 1990). Construction is usually incremental, mainly due to the lack of title and an underdeveloped housing finance sector (see Fig. 9). According to needs and means, houses are extended horizontally (by filling empty spaces with new rooms, such as by reducing courtyards to corridors) or vertically (by adding more storeys). Most compound houses are permanent structures, built of cement breezeblocks with corrugated iron roofs. Mostly built for rental, compounds usually accommodate several families and various socio-economic and ethnic groups, enabling a mix of the city's population groups and cultures (see Fig. 12). Compared with other cities in the developing world, including the rest of sub-Saharan Africa, most West African cities do not appear to be very segregated, either socially or ethnically.

Cities and Towns in West Africa. Fig. 10 Dakar, Senegal. This neighbourhood is next to the airport area (rear of the Fig.). It was officially declared unsuitable for building development by the Senegalese government. However, this land was sold for construction by customary authorities of the *Lebou* (a local ethnic group). The quality of the houses shows quite well that unauthorized areas do not necessarily become slums. Nowadays, this type of neighbourhood is often regularized after construction (informal owners finally obtain titles from the public authorities). © IRD – Michel Dukhan.

The informal nature of land distribution and housing production has led to under-serviced urban development. There is no legislation governing construction in unplanned housing areas, and consequently there is no tax on the capital gain on land sales and no obligation to service land prior to sale. As for housing, publicly provided services and infrastructure have lagged far behind needs. As a result, a large share of the urban

C



Cities and Towns in West Africa. Fig. 11 Abidjan, Côte d'Ivoire. Except in the downtown center and in some upper-class districts, the city skyline is very low and horizontal. 85% of the Abidjan population lives in compounds such as this. Several households surround the courtyard, usually the center of the plot. Each living unit normally comprises one room or two rooms of approximately 10 m^2, one which is used as a bedroom and the other a sitting room. Three rooms is the maximum number of rooms for this type of housing and that is very rare. Courtyards are progressively filled with new constructions. At the rear, owners have started to build additional storeys. © IRD – Philippe Haeringer.

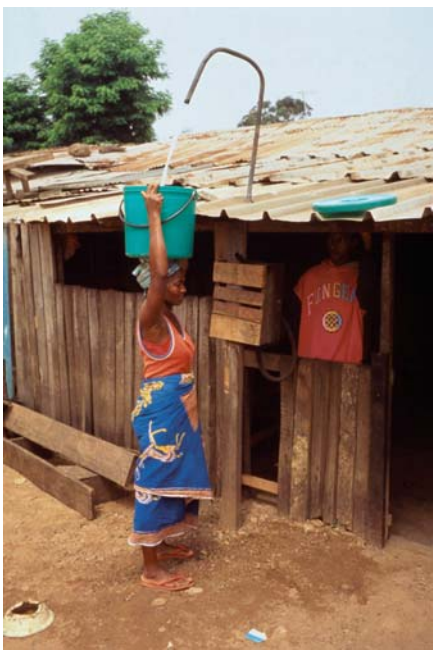
Cities and Towns in West Africa. Fig. 12 Abidjan, Côte d'Ivoire. Courtyards are used for domestic activities and sometimes for economic activities. Here, women sort candies they are going to sell in the street and at the markets. On the right front, notice the collective place dedicated to the dishes and the washing. Barrels (red and blue, on the left rear) indicate that there is no tap water in the compound. Women are in charge of getting the water. © IRD – Philippe Haeringer.

population does not have access to basic services. Access to water, vital for health, is a concern for much of the urban population (see Fig. 13); in 2001–2002, only 43% of all households had access to tap water in the seven capital cities cited above, with the proportion ranging from about one-quarter in Lome, Bamako and Niamey to 41% in Cotonou, 50% in Abidjan and 68% in Dakar (AFRISTAT 2005).

In response to service shortages, urban dwellers have adopted a range of alternative strategies. In Pikine, the largest suburb of Dakar, by taking advantage of political clientelism, residents in the unauthorised area have obtained as many facilities (schools, health centres, water points) as their counterparts in the formal area. For urban dwellers, political pressure has become a potentially powerful lever since decentralisation in the mid-1980s. Do-it-yourself is another strategy; illegal hook-ups to electricity may be a way to access power (Marlard et al. 1999). Informal economic activities have also emerged to compensate for the inadequacy of the public service system. Many people rely on private vendors instead of collecting and queuing themselves for water although prices are more expensive than for public supplies (see Fig. 14). Collective taxis and private minibuses (*gbaka* in Abidjan, *cars rapides* in Dakar, etc.) serve the neighbourhoods with terraced roads bypassed by public transport systems and are usually less expensive (see Fig. 15). A large proportion of the residents of unauthorised neighbourhoods thus have access, to some extent, to the highest-priority services. The situation is nevertheless not very satisfactory. Poor sanitation is a major health issue, water that is expensive and remote encourages drinking of non-potable water, and unregulated transport is dangerous. Furthermore, the privatisation of urban services, in line with structural adjustment recommendations, has worsened the situation since the mid-1980s (Stren and White 1989).

In a nutshell, West African cities and towns face the same problems as other developing regions in terms of access to services and housing. However, due to the informal land tenure and housing systems, squatting[9] and slums are much less extensive than in Asia and Latin America (Peil 1976; Konadu-Agyemang 1991). A regional study found that 'only' (*sic*) 15 to 25% of urban residents lived in precarious housing (shanty towns), a similar proportion in planned districts, and the remainder, i.e. the majority, in structured, albeit informal, neighbourhoods. However, the fact remains that in the poorest neighbourhoods, living conditions are so bad that infant and child mortality rates are sometimes higher than in rural areas (United Nations human settlements programme 2003; National Research Council 2003).

Urbanisation is known to be historically associated with development. In the past, when the developed world



Cities and Towns in West Africa. Fig. 13 San Pedro, Côte d'Ivoire. A woman buys water from a neighbour who is equipped with running water. The scene takes place in the Bardo, the largest informal settlement in Côte d'Ivoire; 90 000 people (about to thirds of the town population) lived there in 1998. San Pedro is the perfect example of the urban planning failure in West Africa. It is a new town, created in 1968 to be the exportation (cocoa, wood, etc.) port of the southwest of Côte d'Ivoire. From the beginning, the Bardo, the unplanned part of the city, started to grow faster than the authorized part. © IRD – Philippe Haeringer.

Cities and Towns in West Africa. Fig. 14 Mopti, Mali. A water street vendor. © IRD – Sophie Martin.

[9] A distinction must be made between squatting (deliberately building on land without permission and against the owner's wishes) and unauthorised settlement (building in areas where the government has not given permission to build, but where customary owners can sell plots for construction).

Cities and Towns in West Africa. Fig. 15 Dakar, Senegal. The official public transport system is not sufficient to serve the whole agglomeration and is too expensive for a large part of the population. Private mini-buses, the so-called 'cars rapides' in Dakar (it means fast buses), compensate for this inadequacy. But since the material is old, they are not always secure and contribute a lot to pollution. © IRD – Michel Dukhan.

experienced its transition from a predominantly rural-agricultural economy to an urban-industrialized one, urban growth was the highest where economic growth was fast. The urbanisation process in sub-Saharan Africa differs to some extent from the process experienced by contemporary developed nations at a comparable stage in their development (Njoh 2003). There is nevertheless a consensus nowadays to recognize that the level of urbanisation (percent urban population) is correlated to various development indicators, such as the GDP per capita or the Human Development Index (Davis and Henderson 2003; Njoh 2003). Therefore recent slow-down trends of urban growth, especially where migratory reversal occurred, may be worrying in terms of development. Actually, these trends reveal a polymorphous crisis, i.e. both a crisis of urban management (unsolved problems of housing, services, infrastructure, etc.) and a crisis of the urban economy (increasing unemployment, insufficient income, high cost of living, etc.). From a global point of view, the peripheral position of the West African countries in the world economy appears to be the main reason for their lagging urbanisation (Simon 1997). West African countries are still excluded from the more profitable production sectors. Their economies are still highly dependent on raw materials and from this end they are not able to control the world markets. In this context, West African states remain highly dependant upon international aid. As a consequence, conditions imposed by the financial institutions weigh heavily on national economic and urban policies. Urban management issues are thus more and more delegated to (new) municipalities, which dispose of fewer means. Public services are often privatized, but the poorest do not have necessarily better access to them. Drastic reductions in public expenditure prevent states to invest in infrastructure (electricity, roads, etc.) that are recognized to be necessary for the population's wellbeing and for the enterprises' prosperity. West African states have to reconcile on one hand the conditions that will allow private informal and formal enterprise to expand in towns and cities in order to generate wealth and employment and on the other hand extend basic services in order to guarantee a better health and education for the poor.

Note 1 Inconsistent Definitions and Measures Vagaries

What is rural? What is urban? There is no global standard to define the line between urban and rural settlements. This issue is not specific to West Africa, but it is particularly relevant there because of frequent discrepancies. For instance, in Côte d'ivoire, the official definition published in 1975, based on population and activity criteria, has never been used in practice (a list of cities has been established without regard for the official definition) (Dureau, 1987). Furthermore, there are often inconsistencies between national official definitions and definitions published in UN reports (practically the only comprehensive source of international urban data available). In the UN's Statistical Yearbooks, definitions are not stated for some countries, even though this information is available in national reports (e.g., Benin, Burkina Faso and Guinea). Definitions for other countries (e.g., Côte d'ivoire, Mauritania and Niger) are even in contradiction with national definitions. Obtaining information on the definition of urban settlements in West Africa is in itself a challenge. In any case, one observation can be made: the definition of 'urban area' varies from one country to another, and can also vary over time, which makes geographical and chronological comparisons problematic. As a result, most publications on urban trends based on UN data are flawed by the inconsistency of definitions (Bocquier 2003).

In order to draw a more accurate figure of urban trends in the world, Moriconi-Ebrard (1994) has created an urban database based on a standardised definition: in GEOPOLIS, settlements with a population over 10,000 are considered urban, regardless of country and period (from 1950 to now). This new definition could have a major impact on national figures. However, in the case of West Africa, using a standardized definition does not produce a very different figure of urban trends on the regional scale. The level of urbanisation measured by official definitions appears to have been slightly overestimated, but trends remain similar. The pace of urbanisation in West Africa slowed sharply in the 1980s and 1990s.

Urban studies in West Africa are not only flawed by definition problems. They are seriously hampered by a lack of reliable and up-to-date demographic data. Census data are the principal sources of information on urbanisation. But censuses tend to be conducted only once a decade and then take several years to be analysed and published. In Africa, deadlines are often delayed due to financial, political or security reasons, so that recent data are rarely available. As a result, figures shown in UN publications are often estimates. Because of the poor quality of available data and an inappropriate projection method (Bocquier 2005), estimates for West African countries in the 1980s and 1990s have overrated urbanisation levels. To conclude, statistics on urban trends should be used with caution!

Note 2 The Urban Future: Mega-Cities or Small Towns?

Contrary to popular perception, most urban dwellers in Africa do not live in the slums of mega-cities. In fact, most African cities are small by international standards. Lagos in Nigeria is the only sub-Saharan African urban agglomeration to be included in the UN list of the 30 largest urban agglomerations in the world. Urban systems in Africa, and more specifically in West Africa, are quite different from those in Latin America or Asia. There are no major metropolises (with the exception of Lagos), but many small and medium-sized towns (as a result of the reclassification process). It is precisely because large cities play a less clear-cut role in urban dynamics than in other parts of the developing world that this is such a controversial topic among academics.

Some authors stress and decry the high degree of primacy, where a large proportion of the urban population lives in a single city. This view is widely shared by policymakers who are concerned by the growth of large cities and who claim to have developed policies to reduce migration to cities (United Nations 1998). Some African cities do clearly predominate in national urban systems (e.g. three-quarters of the urban population of Guinea were living in Conakry in 1994, according to UN data) and have seen spectacular growth, especially in the 1970s (e.g. Abidjan grew by more than 10.3% per year between 1965 and 1975, a record rate of urban growth). Furthermore, several studies have shown an increasing concentration of the urban population in the main cities in recent decades; urban systems seem to have evolved from undersized to oversized capital cities as compared to the world average (Bocquier, Traoré, 2000).

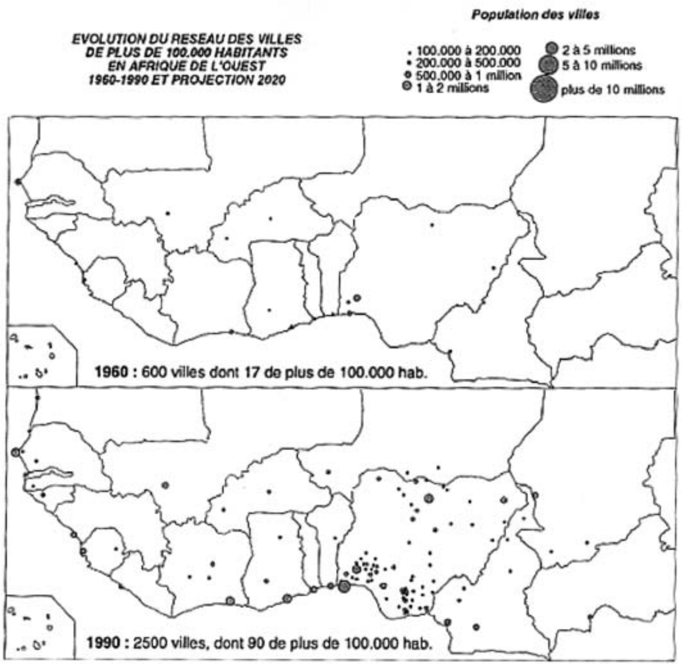
Conversely, some authors argue that urban growth in West Africa is largely due to the development of small and intermediate towns. Using other data sources or other calculation methods, they show that primacy is no greater than in other regions of the world and that it has not increased over time (Cour and Snrech, 1998; Bocquier, 2003). Indeed, in most countries, the principal city's share of the total urban population has not changed much since the 1950s. For instance, Dureau (1987) has shown that Abidjan has concentrated about 40% of the urban population of Côte d'Ivoire since 1936 and that, even when the city saw spectacular growth (1965–1975), 49% of new urban dwellers settled in secondary towns. In fact, in the mid-1980s, West African small and medium-sized towns became a separate subject of research (Hardoy and Satterthwaite 1986; Baker 1990; Dubresson 1996). Several studies stressed the importance of their development. In West African countries, the number of small towns (settlements with a population of 5,000 to 20,000) rose from 150 in 1960 to 400 in 1980 (Giraut and MoriconiEbrard 1991) (see map 1).

What is the urban future? Projections are always hypothetical, especially when they are related to such controversial issues (Bocquier 2005). Nevertheless, a consensus is emerging. Despite popular perceptions to the contrary, West African people will not all be living in mega-cities in the near future. Primacy may increase in some countries, but it may result from regional integration. Cities like Dakar, Abidjan and Lagos are highly cosmopolitan and their share in the urban population would be more accurately assessed at the regional level (West Africa) than at the national level. In any case, small and medium-sized towns will continue to appear (through reclassification) and grow.

Note 3 Migration, Urbanisation and Development: A Controversial Issue

Does rural-to-urban migration (and the resulting urbanisation) favour economic development? This question, which is a matter of policy concern in West Africa is also vigorously debated by scholars. Broadly speaking, there are two main contrasting viewpoints.

An anti-migration viewpoint is that rural-to-urban migration is excessive and should be curbed because it leads to a "less than optimal allocation of labour between the rural and the urban sectors" (Gugler 1982). On the one hand, it exacerbates unemployment and underemployment in African cities. On the other hand, it reduces potential agricultural output, by depriving the rural population of its more innovative and able-bodied members. Furthermore, rural-to-urban migration is criticised as the primary contributor to the uncontrolled expansion of urban areas (Bairoch 1985). Finally, rural-to-urban migration increases the cost of providing for the country's population in two ways. Firstly, new infrastructure is required by the migrants, and amenities (housing, transport, garbage and sewage disposal, etc.) are more expensive in cities or towns than in rural



Cities and Towns in West Africa. Map. 1 Evolution of the West African urban system (1960–1990). 1960: 600 towns and cities, 17 have more than 100000 inhabitants. 1990: 2500 towns and cities, 90 have more than 100000 inhabitants. Source : ►http://www.urbanisme.equipement.gouv.fr/cdu/datas/docs/ouvr16/2020_p1.htm. These maps show the proliferation of towns in West Africa during the second half of the XX[th] century. Most of the larger towns and cities were developed under colonial rule and were founded in coastal regions and along rivers.

areas, where they may not be needed at all (Gugler 1982). Secondly, urban job creation is generally more costly than rural job creation, because most jobs in the industrial sector require substantial complementary resource inputs. For these reasons, rural-to-urban migration is seen "both as a symptom of and a contributor to African underdevelopment" (Todaro 1997). This view is largely shared by policymakers (United Nations 1998).

Taking the opposite point of view, pro-migration authors argue that it is completely inappropriate to regard migration as an undesirable force, which needs to be suppressed (Amis 1989). On the urban side, authors acknowledge that substantial unemployment and severe underemployment characterise most large African cities today, but they point out that, on average, migrants must be better off in urban places, otherwise rural out-migration flows would slow (Becker, Hamer et al. 1994). On the rural side, they argue that there is no labour shortage since emigration has not prevented the rural population from increasing far more rapidly than it has ever increased in the developed countries (except in the United States). On the contrary, rural out-migration is seen as a way of alleviating human pressure on natural resources. In addition, they contend that urbanisation stimulates agricultural activities, since it creates a market for specialised food production with high added value (market gardening and poultry farming). Apart from the impact on rural areas, migration and urbanisation are seen as key components of the development process. Authors argue that, for several reasons, increased urbanisation raises per capita income and other measures of economic welfare. First, when driven by rural-to-urban migration, urbanisation tends to move workers from agriculture to more productive occupations (e.g. urban services, commerce, and manufacturing sectors). Second, urbanisation offers the cost-reducing advantages of economies of agglomeration and economies of scale and proximity as well as numerous economic and social externalities (e.g. skilled workers, cheap transport, amenities, etc.). Finally, urbanisation also contributes to development in more subtle ways. For example, it may lead to lower levels of fertility and mortality, as individuals benefit from improved access to health care. Theory apart, Becker et al. (1994) stress that, from a macro-economic point of view, while less than a third of Africa's population lives in cities or towns, these centres generate over half of the continent's gross domestic product (GDP).

To conclude, one is tempted to agree with Portès, who takes the view that "internal migration and urban growth are intrinsically neither good nor bad. Such assessments depend upon the specific social context, and in particular, on the point of view one adopts with respect to the different classes and institutional actors. A case can be made that, in the short run at least, the present trends of rural–urban migration and urban concentration are functional for a wide assortment of groups" (Portès 1985).

C

City Planning in Ancient India

PAUL GREGORY

As the birthplace of Indian culture, the towns of the Indus Valley represent an important and rich source of information concerning urban development in the Indian subcontinent. The Indus River is one of the largest and most important rivers in south central Asia. From its source in the Himalayan Mountains to its terminus in the Indian Ocean it traverses a course of over 2,000 miles. For millennia it has been an essential route for travel, trade, and communication and has been the source of much of India's agricultural production. The valley which surrounds the Indus River has witnessed the birth, growth, and death of many cities.

Excavations of Indus towns have demonstrated the most ancient town planning in the world. The grid pattern (straight streets intersecting other straight streets at right angles) is among the most common and universal types of town planning. The discovery and excavation of the most famous of these sites, Mohenjo-daro, by Sir John Marshall (1931) and Ernst Mackey (1938) supported the contention of Dan Stanislovski (1946) that the development of the grid pattern in western societies – Greece, Rome, and Europe in the Middle Ages – can be linked directly to the development of town planning in the Indus valley.

A recent excavation on the Western plains of the Indus – the Rahman Dheri site – reveals a town plan from the early Indus period. This site comprises an area of roughly 22 ha and could have been home to 10,000–14,000 people. Radio carbon-dating of artifacts places development somewhere in the first half of the fourth millennium BCE. Rahman Dheri is built in the classic grid pattern. It is rectangular in shape surrounded by an immense wall and bisected by a major traffic artery which runs roughly southeast to northwest. Perpendicular to this road exists a pattern of regularly occurring laneways which appear to create individual dwelling lots.

The successor to the plan of Rahman Dheri is thought to be the Surkotada site in Kutch which dates to ca. 2500–2000 BCE. Though smaller in scale than its predecessor the Surkotada site is built along the same grid pattern as Rahman Dheri. This settlement was enclosed by a stone rubble and brick fortifications. This produced two separate areas each of roughly 60 m^2.

Similar to Surkotada, only on a larger scale, the Kalibangan site was completely surrounded by an enormous rampart. This site, about 200 km to the southeast of Hirappa on the banks of the (now dry) Ghaggar river, was composed of two mounds. The smaller mound, named the citadel, was to the west and was roughly 240 m by 120 m. The larger mound, named the lower city, was to the east and measured 360 m by 240 m. The lower city demonstrates the grid plan divided into blocks of which the east–west side was roughly 40 m in width. The width of lanes and streets in the lower city ranges from 1.8 to 7.2 m. Interestingly each lane or street is some multiple of 1.8 m. This site is thought to date to the early Indus period, roughly 3000 BCE.

The evolution of Indus town planning reached its zenith at Mohenjo-daro. The town is geographically located on a floodplain of the Indus river; the city occupies about 1 km^2 – over five times larger than Kalabangan. The basic grid of Mohenjo-daro is about 180 m^2, subdivided into 16 sections of about 40 m^2. Mohenjo-daro existed from ca. 2500 to 2000 BCE. During this time it bore the brunt of often severe flooding, and as a result the original grid plan was often modified and transformed. The city itself was originally planned in the same way as Kalabangan: an oblong walled city divided into a citadel and a downtown area divided by an open space. Similar to its predecessor communities, the town plan of Mohenjo-daro indicates the same parallel grid street structure that has come to characterize urban planning in this region at this time.

As this brief history of the evolution of town planning in the Indus river valley demonstrates the grid pattern was commonplace. The importance of the Indus river valley communities to the historical development of culture and civilization in the Indian subcontinent and the East is well known. Stanisloski has suggested that the grid pattern form of town planning has its roots in the Indus valley. Parallel developments in Nepal, Sri Lanka (formerly Ceylon), Burma, Korea, Vietnam, and China also indicate how widespread the influence of the Indus river valleys communities were. It is suggested that this form of town planning was taken up by the Greeks, Romans, and other Western Europeans and eventually became a standard form of urban organization in Europe and the New World.

Excavations at and along the Indus River valley reveal cities strikingly similar in topography to contemporary Western European and North American cities. While some may suggest that the grid pattern evolved in a happenstance fashion without benefit of central planning or administration, substantial evidence exists to support the opposite point of view. First, the grid pattern can be seen in a variety of towns all along the Indus river, which existed and flourished over a several thousand year period. Second, the similarity between these towns and the general division between a lower city area suggests the development of town planning conventions as early as 2500 BCE. Third, there is a remarkable mathematical symmetry in Kalabangan where lanes and streets (which range from 1.8 to 7.2 m in width) all occur in multiples of 1.8 m.

The contribution of this historic period to the development of Western cities should not be underestimated. Much of what we take to be enlightened urban planning was considered over four thousand years ago by planners in south eastern Asia.

City Planning: Aztec City Planning

Michael E. Smith

The Aztecs were the most urbanized of the ancient civilizations of Mesoamerica. The last in a long line of urban societies, they selected principles of city planning from an ancient Mesoamerican heritage and adapted these to their needs. Most Aztec urban centers were modest settlements best called towns, but the central capital Tenochtitlan was a huge metropolis of a different order.

Most Aztec towns were founded between AD 1100 and 1350 when the Aztec peoples immigrated into the central Mexican highlands. They established new settlements and dynasties leading to a system of autonomous city-states. The construction of a royal palace marked the official founding of a new city or town, most of them city-state capitals. In 1430, three Aztec peoples – the Mexica, Acolhua, and Tepanecs – formed a tributary empire, known as the Triple Alliance or the Aztec Empire. Two of their capitals, Tenochtitlan (Mexica) and Texcoco (Acolhua), became the preeminent cities of the Valley of Mexico. By the time Spanish conquerors arrived in 1519 this empire had conquered much of Mesoamerica, and Tenochtitlan had grown into a city of 200,000.

One of the remarkable features of Aztec urban planning is the extent to which basic buildings and

planning principles were standardized among cities throughout central Mexico. This standardization long preceded the formation and expansion of the Aztec empire, and its explanation probably lies in the common cultural origins of the Aztec peoples, coupled with processes of interaction that kept the rulers and nobility of the Aztec city-states in constant contact with one another. This uniformity in urban planning contrasts strongly with other Mesoamerican cultures, such as the Classic Maya, the Olmec, or the Zapotec, whose individual cities show far greater variation in architecture and urban layout.

Historical Development of Planning Principles

The Aztecs drew upon several ancient historical traditions to select principles of urban planning for their cities and towns. Not surprisingly, the two major Aztec urban types – city-state capitals and Tenochtitlan – had somewhat different historical legacies. In this section I outline 17 principles of urban planning employed in central Mexico, grouped into four historical categories based upon their historical origins: ancient Mesoamerican principles, Teotihuacan innovations, Tula innovations, and Aztec innovations. Table 1 lists these principles and their use in Aztec towns and in Tenochtitlan.

Ancient Mesoamerican Principles of Urban Planning

The Aztecs drew on ancient Mesoamerican principles of urban planning in the design of their cities. Five such principles can be identified for the pre-Aztec cities of Mesoamerica, including those of the Classic Maya lowlands, Oaxaca, and other regions (for Mesoamerican architecture and cities, see Hardoy 1968).

1. *The Inventory of Public Architecture.* A basic set of public buildings was used in most ancient Mesoamerican urban centers: large temple-pyramids, smaller temples, royal palaces, ballcourts, and a suite of less-common special purpose buildings that included council halls, sweatbaths, schools, and other structures.
2. *The Urban Epicenter.* Public architecture in Mesoamerican cities tended to be concentrated spatially in a central zone, called the urban epicenter. The locations and orientations of individual buildings often suggest coordination and planning, although strict formal patterns, such as orthogonal layouts, were rare.
3. *The Central Public Plaza.* The basic unit of urban planning was the public plaza, an open rectangular space whose sides were taken up with public buildings. Large cities with multiple concentrations of public buildings often had multiple public plazas of different sizes.
4. *Astronomical Orientations of Buildings.* The ancient Mesoamerican peoples were accomplished astronomers, and key public buildings were often aligned with significant astronomical phenomena, such as the direction of sunrise on the solstice. There is a general tendency for urban epicenters to be aligned roughly to the cardinal directions (most

typically several degrees east of north), a pattern that may also have derived from astronomical considerations (Aveni 2001).

5. *Unplanned Residential Zones.* Most urban housing was located outside of the urban epicenter. Individual houses typically show little or no evidence that their locations, forms or orientations were coordinated or planned by central authorities.

Teotihuacan Innovations

With a population of around 150,000 inhabitants, the huge metropolis Teotihuacan was the largest city in Mesoamerica (and one of the largest anywhere in the world) during the Classic period (ca. AD 150–650). Teotihuacan dominated central Mexico politically, and its economic and cultural influence extended to all corners of Mesoamerica. In its form and size, Teotihuacan was utterly unique in Mesoamerica, and only the later Aztec imperial capital Tenochtitlan can be said to resemble Teotihuacan at all (Cowgill 1997; Millon 1992). Six innovations in urban planning can be identified at Teotihuacan.

6. *The Huge Size of the City.* With an extent of over 20 km^2 and its huge population, Teotihuacan was a city of a different scale from anything seen previously in Mesoamerica (Fig. 1).
7. *Massive Scale of the Main Temples.* Although not the tallest pyramids in ancient Mesoamerica, Teotihuacan's "Pyramid of the Sun" and "Pyramid of the Moon" are among the most massive in volume.
8. *Orthogonal Planning of the Entire City.* The principle of orthogonal city planning was quite rare in ancient Mesoamerica, found only at Teotihuacan, Tenochtitlan, and perhaps Tula. Teotihuacan is remarkable for the consistency of orientation of its buildings.
9. *Layout Dominated by a Central Avenue.* The so-called "Street of the Dead" is a central avenue several km in length that forms the central axis for the layout of Teotihuacan (Fig. 1). This use of a dominant central avenue is not found elsewhere in Mesoamerica.
10. *Lack of a Central Public Plaza.* There is a moderately sized open plaza at the north end of the Street of the Dead, but this plaza differs from typical Mesoamerican central public plazas in several key respects: it is small in relation to the size of the city; only a few of the central public buildings are adjacent to the plaza; and it is not centrally located within the city. Instead, the Street of the Dead at Teotihuacan can be considered a functional analogue of the Mesoamerican central public plaza in terms of urban layout and planning. The major public buildings were arranged along this feature, which gave form to the entire plan of the city.
11. *Standardized Housing.* One of the most remarkable urban features of Teotihuacan was the highly standardized form of commoner housing, the apartment compound. There were more than 2,000 apartment compounds in the city, all aligned to its orthogonal grid.

Tula Innovations

Tula, the next large political capital in central Mexico after Teotihuacan, drew on the layout of Teotihuacan for inspiration in urban planning. Although the rulers of Tula returned to the older Mesoamerican pattern of urban layout around a large public plaza, they employed several of the Teotihuacan innovations (nos. 6, 7, and perhaps 8). Although not as large as Teotihuacan, Tula was much larger than its central Mexican contemporaries, and one of the largest cities in

City Planning: Aztec City Planning. Fig. 2 Reconstruction of the epicenter of Tula. Modified after Mastache et al. (2002: 90).

Mesoamerica during the Epiclassic and Early Postclassic periods, ca. AD 800–1200 (Mastache et al. 2002). Three urban planning innovations can be identified for Tula.

12. *Formalization of the Epicenter.* The public plaza at Tula established an orientation that was used for all of the buildings in the urban epicenter (Fig. 2). This shows a higher level of coordination and formalization than was typical of other Mesoamerican urban epicenters. The Aztecs later adopted this principle for their urban epicenters.
13. *The Largest Temple on the East Side of the Plaza.* At Tula, the largest pyramid, Temple C, is located on the east side of the central public plaza, a pattern also used by the Aztecs.
14. *Circular Quetzalcoatl Temples.* The cult of Quetzalcoatl, the feathered serpent, spread throughout Mesoamerica in the Epiclassic and Early Postclassic periods. In Postclassic times, circular temples were dedicated to Quetzalcoatl's avatar, the wind god Ehecatl (Pollock 1936). At Tula, a circular temple was built at the El Corral locality, a concentration of public architecture outside of the main urban epicenter.

Aztec Innovations

The rulers of Aztec city-states drew primarily upon general Mesoamerican planning principles and Toltec innovations when they laid out their towns. The rulers of Tenochtitlan, on the other hand, emphasized these principles to a lesser extent, preferring planning principles from Teotihuacan. Three innovations can be identified for Aztec cities.

15. *Twin-Temple Pyramids.* Several of the earliest Aztec cities (e.g., Tenayuca and Teopanzolco) used a new form of pyramid with two temples on top and two stairways (Fig. 3). By the Late Aztec period, this form had fallen out of fashion except at the central temples of Tenochtitlan and Tlatelolco.

City Planning: Aztec City Planning. Fig. 3 Aztec twin-temple pyramid at Teopanzolco. Photograph by Michael E. Smith.

16. *Multiple Small Altars.* One of the notable attributes of Aztec cities is the prevalence of small platforms or altars throughout the urban epicenter (Fig. 4). These were often located within the public plazas, and some altars were adjacent to large pyramids.
17. *Walled Ceremonial Precinct.* The central religious architecture at Tenochtitlan was concentrated within a walled compound called the "Sacred Precinct". Although some authors have suggested that this was a regular feature of Aztec cities, Tenochtitlan is in fact the only example with a well-documented walled precinct.

These seventeen principles are listed in Table 1.

City Planning: Aztec City Planning. Fig. 5 Construction stages of the twin-temple pyramid at Tenayuca. From Smith (*The Aztecs* 2003: Fig. 2.8); based upon (Marquina 1951: 169).

Urban Architecture

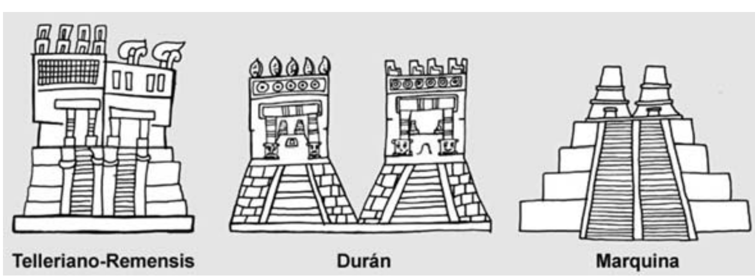
In addition to their use of ancient Mesoamerican traditions of urban planning, the Aztecs also made use of Mesoamerican patterns of monumental architecture. The basic religious structures were temple-pyramids, typically rebuilt and expanded by successive kings. When archaeologists excavate into a Mesoamerican pyramid, they typically find the buried remains of one or more earlier construction stages (Fig. 5). This continual rebuilding of temples in the same location was related to notions of sacred space and the importance of continuity with the past. In addition to temple-pyramids, the Aztecs also used the basic Mesoamerican architectural inventory of palaces, ballcourts, altars, and commoner houses.

Twin-Temple Pyramids

This innovative form of temple-pyramid is found at only five Aztec cities. Two of the major political capitals of the Early Aztec period – Tenayuca and Teopanzolco – employed large twin-temple pyramids for their central state temples (Fig. 3). Excavation of the Tenayuca pyramid revealed a series of enlargements and expansions (Fig. 5), all employing the double temple design. By the Late Aztec period, this style had fallen out of fashion at most Aztec cities, whose main pyramids had only a single temple. But the Mexica peoples at the twin cities of Tenochtitlan and Tlatelolco revived this form for their central pyramids. At the well-known Templo Mayor of Tenochtitlan, the temples were dedicated to Tlaloc (an ancient central Mexican fertility god) and Huitzilopochtli (patron god of the Mexica with associations of warfare and sacrifice). This structure is known both from excavations (Matos Moctezuma 1988) and from pictorial sources (Fig. 6) .

Single-Temple Pyramids

The single-temple pyramid was the standard form of temple throughout most of Mesoamerican history. The extent of its use during the Early Aztec period is hard to judge, but by Late Aztec times this form dominated Aztec cities, serving as both their central temples and as subsidiary temples (Fig. 7).



City Planning: Aztec City Planning. Fig. 6 Native drawings of the Templo Mayor of Tenochtitlan. From Smith ("A Quarter-Century of Aztec Studies" 2003).

Circular Pyramids

Many Aztec cities and towns had circular pyramids dedicated to the wind god, Ehecatl (Fig. 8). These temples were rarely if ever located in central positions in Aztec cities. In some cases (e.g., Tlatelolco and Tenochtitlan) these temples were located within the urban epicenter but somewhat apart from the central twin-temple pyramid (Guilliem Arroyo 1999). In other cases (e.g., Huexotla, Zultepec, and perhaps Calixtlahuaca) the circular temples were located far from the urban epicenter, as at the earlier city of Tula.

Ballcourts

Only a few Aztec ballcourts have been located, but given the prominence of ballcourts and the ballgame in Aztec codices (Nicholson and Quiñones Keber 1991) (Fig. 9), it is likely that these features were integral parts of most city layouts. The restored ballcourt at Coatetelco (Fig. 10) is probably typical of Aztec ballcourts; see also Matos Moctezuma (2001). The Aztecs played a version of the Mesoamerican ballgame, a public performance using a rubber ball that combined sport, ritual, and politics in poorly understood ways.

City Planning: Aztec City Planning. Fig. 7 Small single-temple pyramid at Calixtlahuaca. Photograph by Michael E. Smith.

City Planning: Aztec City Planning. Fig. 8 Circular temple at Tlatelolco. Photograph by Michael E. Smith.

Palaces

Aztec palaces, unlike those of the Classic Maya, were highly standardized in layout. They contained a central courtyard with a single entrance. The courtyard was enclosed by raised platforms, on top of which were arranged a series of rooms, halls, altars, and other features (Figs. 11 and 12). This standard plan was followed for a whole range of palaces, from the sumptuous royal palaces of Tenochtitlan and Texcoco to the modest residences of provincial nobles (Smith *The Aztecs* 2003: 139–146; Evans 1991).

Special-Purpose Buildings

A variety of specialized buildings are known from archaeology and documentary sources. Written sources mention two types of schools, but none have been excavated. Special buildings for elite warriors have been excavated adjacent to the Templo Mayor of Tenochtitlan and in a rock-cut chamber at the hilltop ceremonial precinct of Malinalco (Fig. 13).

Altars and Small Platforms

Among the more intriguing and poorly understood features of Aztec cities are small altars and platforms that typically occur in multiple groups (Fig. 4). There were evidently numerous categories of such altars, dedicated to diverse deities and with a variety of uses in ritual and performance. Two specific functional types have been identified so far: platforms that supported skull racks (for the display of the skulls of sacrificial victims), and altars dedicated to the curing principles of the *tzitzimime* deities (Fig. 14) (Klein 2000). The Aztecs even journeyed to Tula to build a small altar in front of Temple C, perhaps symbolically to convert the ancient structure into an Aztec temple.

Commoner Housing

Two patterns of commoner housing have been identified at Aztec cities. At Tenochtitlan and other cities in the Valley of Mexico, house compounds enclosed by low walls was the norm (Evans 1988; Calnek 1974). These compounds contained a number of structures and rooms arranged around an open work area (Fig. 15). In the provinces, in contrast, commoners lived in individual adobe houses (Smith et al. 1999). Although often arranged into groups around a central patio, these house groups were never enclosed with walls (Fig. 16). Commoner housing exhibited considerably more variation within and between cities than was found in the palaces of the nobility.

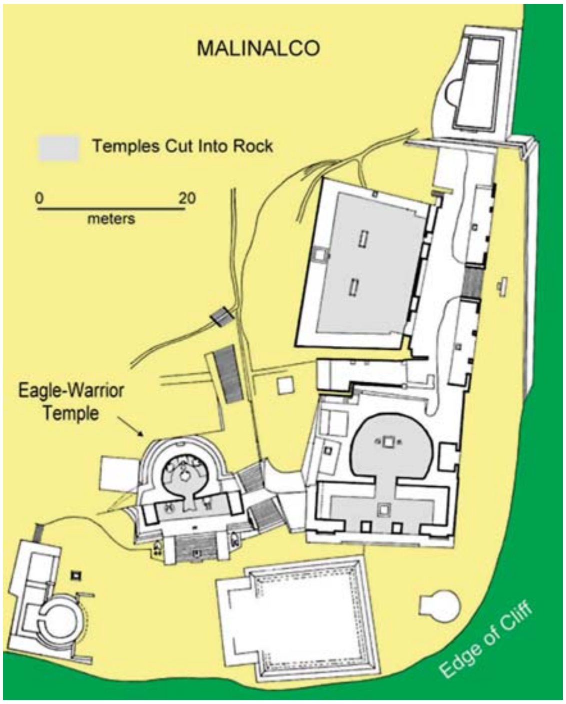
Categories of City

City-State Capitals

As noted above, the designers of Aztec cities and towns drew upon the principle of the formalized urban epicenter as articulated at the ancient city of Tula (Fig. 17). The city of Coatetelco in Morelos (Arana Alvarez 1984) illustrates this pattern (Fig. 18). The central pyramid lies on the east side of the plaza (as at Tula), with the ballcourt opposite. Five small altars or platforms, attached to the exterior wall of the ballcourt, extend into the plaza. The buildings on the north and south sides of the plaza were only partially excavated and their functions are not known. The formal, planned central plazas of Aztec towns are clear even in the overgrown mounds at unexcavated urban sites such as Coatlan Viejo (Fig. 19). Although it is possible that the planned layout of the epicenters and their consistent orientations just east of north related to cosmological principles, there is no concrete evidence to support this interpretation.



City Planning: Aztec City Planning. Fig. 13 Map of the hilltop ceremonial zone of Malinalco. From Smith (*The Aztecs* 2003: Fig. 7.5); based originally upon Marquina (1951).

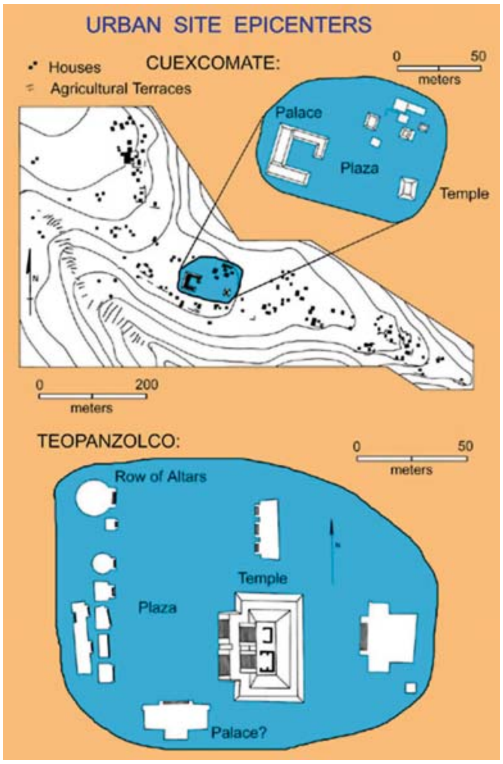
City Planning: Aztec City Planning. Fig. 16 Commoner houses excavated by the author at Yautepec. Photograph by Michael E. Smith.

Outside of the epicenter, the residential zones of Aztec towns exhibited little evidence for planning or coordination. Although only one Aztec town – Cuexcomate – has been mapped in its entirely (Fig. 17, top), residential excavations in other cities and towns are consistent with this interpretation of unplanned residential areas (Smith et al. 1999).

A related type of settlement was the hilltop ceremonial zone, found in a number of Aztec city-states. The rituals carried out at these locations were typically political ceremonies linked to both agricultural fertility and the religious legitimation of kings and dynasties. The best known examples are Cerro Tlaloc in the Valley of Mexico, Malinalco in the State of Mexico (Fig. 13), and Tepozteco in Morelos.

Tenochtitlan

When the Mexica peoples constructed Tenochtitlan on an island in Lake Texcoco in the early fourteenth century (the official date for the founding of the city is AD 1325), they drew more inspiration from Teotihuacan and Tula than from the standard Aztec urban plan already established at many towns in central Mexico (Table 1). The use of orthogonal planning is one of the remarkable features of the imperial capital (Fig. 20). Although few explicit articulations of urban planning concepts have survived, three factors were most likely responsible for creating the form of Tenochtitlan: the city's island location, imperial ideology, and cosmological principles. Most of Tenochtitlan's 13.5 km^2 were reclaimed from Lake Texcoco. Spanish observers were struck by the great number of canals in the city, which they likened to Venice. The canals were used as transportation arteries and for agricultural purposes. Raised fields or *chinampas*, an extremely productive method of farming, were built to cultivate reclaimed swampy land in the outer neighborhoods of the city (Calnek 1972). Families living on their individual small plots worked these fields (Fig. 15). As the city expanded, many of these rectilinear chinampas were converted into dry land, contributing to the orthogonal plan of the city.



City Planning: Aztec City Planning. Fig. 17 Definitions of urban epicenters of Cuexcomate and Teopanzolco. Modified after Smith (2004: Fig. 2).

Tenochtitlan's orthogonal layout is seen in the major avenues radiating out from a central ceremonial precinct in the cardinal directions (Fig. 20). The avenues divided Tenochtitlan into four quarters, each with its own smaller ceremonial precinct. Outside of the chinampa areas, houses were packed tightly together. The city of Tlatelolco, with its own impressive epicenter (Fig. 8), was originally a separate town but was later incorporated into Tenochtitlan (González Rul 1998). By drawing on the orthogonal layout of Teotihuacan (Fig. 1), the Mexican rulers proclaimed Tenochtitlan's continuity with the past and its legitimacy as the imperial capital of central Mexico (Umberger 1987).

Cosmological principles also contributed to the form and layout of the capital. The largest structure, the Templo Mayor (Fig. 6), was viewed as the symbolic center of the Aztec empire (Carrasco 1999; López Luján 1994), and it was the setting for elaborate state ceremonies including human sacrifices. The Templo Mayor was built in alignment with sunrise on a key holy day (Aveni 2001), and the entire layout of Tenochtitlan can be viewed as an extension of the sacred orientation of the central temple.

In sum, the planners who laid out Tenochtitlan made radical breaks with past Aztec (and Mesoamerican) norms in two ways. First, they filled the central plaza with buildings. In place of an open plaza is the sacred precinct, a large walled compound packed with temple-pyramids, altars, priests' residences, and other sacred buildings (Fig. 21). The palaces of the Mexica kings

were arranged around the outer walls of the precinct. The sacred precinct occupies the place of the public plaza in other Aztec (and Mesoamerican) cities. Second, the imposition of a common grid over the entire city was a radical practice that expressed the power of the rulers to shape their city and differentiate it from other Aztec cities. The orthogonal layout also exemplified continuity with Teotihuacan and resonated with ancient Mesoamerican cosmological principles of the importance of the cardinal directions.

City Planning: Inca City Planning

Jean-Pierre Protzen

Although the Incas were not great city builders, they redesigned their capital, Cuzco, on a grand scale, and founded numerous new settlements. Ollantaytambo is one such new town. Because it has what "may be the oldest continuously occupied dwellings in South America" (Kubler 1975), and because many parts of the town are well preserved, it would seem the perfect object for the study of the town planning principles of the Incas.

Ollantaytambo is located about 90 km to the northwest of Cuzco at the confluence of the Urubamba and the Patakancha rivers. It is built on a narrow, gently sloping bench of artificially leveled ground squeezed in between Cerro Pinkuylluna to the east and the Patakancha river to the west. It is carefully sited so as not to occupy prime agricultural land, yet to provide easy access to the terraced fields to the north and the south. The glacier-fed Patakancha provides an ample water supply for both agricultural and domestic uses. Tucked in between the high mountains at the mouth of the Patakancha valley, the town is well protected from the fierce afternoon winds which often sweep through the broader Urubamba valley.

The town was laid out on a regular grid, trapezoidal in shape, of four longitudinal and seven transversal streets. The transverse streets, oriented at 110.5° east of magnetic north, are perfectly parallel to each other, suggesting that the Inca were knowledgeable about geometry, and that they had a method of surveying to lay out the streets.

In the time of the Incas, there was a large plaza in the middle of the town. On its north and south sides it was bordered by great halls, long buildings with many openings toward the plaza. If what Garcilaso de la Vega tells us about Cuzco holds for Ollantaytambo, then the plaza was the theater for ceremonies and festivities, and the great halls were the place where the revelers withdrew to pursue their activities on rainy days (Garcilaso de la Vega lib. VII, cap. X; 1976: II,108).

The fifth transverse street manifestly divided Ollantaytambo into two parts with distinct architectural features: the street facing walls in the southern half of town were built of cut and fitted stones, whereas in the northern half they were built of unworked field stones. The blocks in the southern half show a rigorously repetitive block design of two walled-in habitation compounds, called *kancha*, arranged back to back, that is not reflected in the northern half. Cobo stated:

> The Incas imposed in all their kingdom the same division in which the city of Cuzco was divided, Hanan Cuzco and Hurin Cuzco; cutting each town and lordship into two parts or factions called hanansaya and hurinsaya, which means "the upper district" and "the lower district," or the part or faction from above and the faction from below;… (Cobo lib. XII, cap. XXIV; 1964: II,112).

This division, which is a social one and probably has ancient Andean roots, was used by the Incas to control, administer, and inspire their subjects (Cobo lib. XII, cap. XXIV; 1964: II,112). The two moieties were essentially equal, and each was governed by its own leader, with the *hanan* leader having first rank. It is possible, but not demonstrated, that the architectural division observed at Ollantaytambo is a referent to this social division.

Because of the rigor and clarity with which the town of Ollantaytambo has been laid out, one might be tempted to interpret it as an exemplar of Inca town planning. A comparison from a formal point of view with other Inca sites, however, does not sustain this proposition. Outside Ollantaytambo regular grids are only found at Chucuito, on Lake Titicaca, and Calca. The Chucuito grid too is trapezoidal in shape, and that of Calca appears to be strictly orthogonal. It is not known with certainty whether the Chucuito grid is of Inca origin. Calca, on the other hand, is known to have been established by Waskhar, the twelfth Inca. Whether or not the blocks in these two sites were occupied by kancha is not known. Cuzco, the navel of the Inca empire, shows an ordered street pattern, but the grid and the block sizes are not as regular and uniform as those of Ollantaytambo. At least some blocks in Cuzco were built up with compounds very similar to the kancha at Ollantaytambo. Huánuco Pampa, a large administrative center in the central highlands, lacks a regular street pattern, and although there are discernible town blocks, they are quite irregular in size and shape. Many kancha-like compounds are scattered throughout the site, but their design is quite varied and irregular, and the compounds do not define blocks or streets. At Patallaqta, some 20 km downstream from Ollantaytambo, the kancha design is prominently in view. There are two arrangements of kancha; one consists of two kancha, back to back, similar to Ollantaytambo, except that it is not walled in; the other is made of four smaller kancha. Even though the kancha are not walled in, their groupings nevertheless define town blocks and streets. Tambo Colorado, an administrative center in the coastal valley of Pisco, has neatly rectangular compounds, but the center is not built on a grid pattern of streets, and the compounds only remotely recall the kancha design. The only feature common to the sites discussed above appears to be a plaza. At Huánuco Pampa the plaza is huge; it measures about $540 \times 370\ m^2$, is surrounded by buildings on all sides, and is dominated by what must be the largest remaining *usnu*, a ceremonial platform. Two great halls face the plaza on its east side. The plaza, *Hawkaypata*, in Cuzco was also quite large, about $200 \times 250\ m^2$. It too had an usnu, and was bordered with great halls on its north and east sides. Tambo Colorado's trapezoidal plaza is surrounded by buildings on three sides and has an usnu on its fourth side, but no great halls face it. Whether the plaza at Ollantaytambo had an usnu is not established. Thus, if the plaza is a recurrent element of Inca settlements, its configuration is by no means standard.

If no specific town planning rules seem to emerge from the comparison of different Inca settlements with Ollantaytambo, it stands to reason that Ollantaytambo is not representative of Inca town planning. It has been said that the Incas laid out their new settlement in the image of their capital, Cuzco. However, a comparison of the various plans analyzed above does not fare much better; there are no more similarities between Cuzco and the other sites than there are between them and Ollantaytambo. Rowe suggested that Cuzco was laid out in the shape of a Puma. Neither of the plans reviewed can be made to fit this shape. Perhaps similarities between Cuzco and other sites should not be searched for the physical form, but instead, as Gasparini and Margolies (1980) suggested, "in the meaning and the functions of the form." They argue that, if one makes abstraction of the physical form, one will note that certain elements are "repeated with considerable insistence." They list the division into *hanan* and *hurin*, a principal and a secondary plaza, the great halls on the plaza, the *usnu*, the *inkawasi* (house of the Inca), the *aqllawasi* (house of the Chosen Women), the temple of the sun, and the storehouses. In light of the difficulties of attributing specific functions to particular ruins, and the uncertainties regarding a physical referent for the division into *hanan* and *hurin* discussed above, the effort to establish similarities among settlement patterns, and to derive planning canons, is considerably weakened.

The Spanish chronicler Bernabe Cobo described an elaborate set of about 40 lines, called *zeq'e*, radiating out in all directions from the Qorikancha, the holiest of all Inca shrines, in Cuzco. Along each line were arranged a number of sacred places and objects. Each line was the responsibility of a specific royal family of Cuzco. The families were in charge of officiating at the shrines in their care and of providing the appropriate sacrifices on the designated days. Although Tom Zuidema (1964) argued that the zeq'e influenced the plan of Cuzco, and perhaps of other Inca settlements, it is obvious that the radiality of the zeq'e did not affect the city's layout which is orthogonal in its core. As John Hyslop (1990) noted, "it is still uncertain to what degree the Incas are actually portraying zeque systems (even) in radial layouts, or just the principles and spatial relationships found in the system."

Another reason why it may be difficult to extract generally applicable town planning rules is that the various settlements served different functions and were used in different ways. Ollantaytambo, Machu Picchu, and Patallacta discussed above were royal estates, that is the private property distinct and apart from state property, of the ninth Inca Pachakuti, and Calca was an estate of the Inca Waskhar. Cuzco, on the other hand was the all important capital of the Inca Empire, whereas Huánuco Pampa, like Tambo Colorado, was a regional administrative center in a newly conquered territory. The different types of settlements may have operated and functioned along different lines, such that any comparison may be spurious. Little is known about life in Inca settlements. Of Cuzco, Pedro Sancho de la Hoz, Francisco Pizzaro's personal secretary, wrote that it "was so large and so beautiful that it would be worthy of being seen even in Spain," and he added that it was "full of palaces of the lords, for in it there lived no poor people." What Sancho described referred probably only to the core of the city, for it is known that there were people from every corner of the empire also living in Cuzco. Of life in Cusco Protzen and Rowe (1994) wrote:

> Street life was probably limited to the movement of people from one place to another, with a stop perhaps for a bit of gossip, or to fetch water from the canals. There was no mercantile activity in the streets and there were no storefronts. Most residential and religious compounds [or *kancha*] were surrounded by walls with only one doorway giving access to the street. Supplies for sustenance of daily life were delivered directly from the state warehouses to the compounds. All production, weaving, wood and metal working, pottery, brewing, baking, and so forth was carried out within the compounds. On official occasions, civil or religious, the street scene may have been animated by parades and processions: the Inca being carried around town in his litter with the requisite entourage of nobles and bodyguards; the arrival of a dignitary from the provinces accompanied by llama trains loaded with gifts of all kinds; the triumphant return of a war party, with soldiers displaying their loot and parading prisoners; or a solemn religious procession, with priests in colorful attire carrying idols and other paraphernalia.

It is not known to what extent what happened in Cuzco can be extrapolated to other Inca towns. There are very few eyewitness accounts of life in other places of the Inca Empire. Little is known about the organization, function, and operation of royal estates. However, as in the case of Ollantaytambo, one can assume that there was a royal residence for the Inca and his immediate entourage, that there were accommodations for the accompanying nobility and administrators, and that there were quarters for the servants. Yet, the layout of the settlement, its size and its architecture, suggest that it was more than just a rural retreat with its requisite appendices. It has the character of an agglomeration in which a population of perhaps a thousand people was permanently settled.

Discovering general planning principles may be, at least in part, also complicated because the principles, whatever they were, may have been altered to fit the specific features of a site and its topography.

In Cuzco, in spite of colonial modifications, the major features of the Inca plan can still be appreciated. The grid-like street pattern was squeezed and bent into the neck of land between the Watanay and the Tulumayo rivers to conform to the Puma shape. At Patallaqta the street pattern also is grid-like, yet it is shifted and broken to fit the crescent-shaped plateau on which it is built. At Machu Picchu, where the terrain is much more accidented, or broken, than at Patallaqta, the intent of an orthogonal layout can still be detected. Alleyways and staircases generally cross at right angles. The modifications brought to the layout are subtle adaptations to the specific topography. Streets and alleyways, like the terraces, follow the contour lines, and staircases follow the terrain's fall lines. The town occupies two natural ridges, and is completely split into two sectors by a plaza which is molded into the saddle between the ridges. The kancha are squeezed, stretched, and distorted to fit the available space on the terraces, as they do at Wiñay Wayna, about an hour from Machu Picchu.

One of the most striking site planning efforts, and some of the most spectacular adaptations of building forms to suit the particular terrain, are seen at Phuyupatamarka. The buildings literally grow out of the bedrock and espouse the terrain to become one with the site; the man-made world again is inseparable from the natural world.

Today's tourists, arriving at Machu Picchu by train and bus, miss one of the most important features of Inca site planning; they are deprived of the dramatic encounter with the site the ancient traveler experienced when coming through the gate of Intipunku. That encounter involves a succession of open spaces that are scaled from the vast horizons of the Andes to the intimate courtyard in town, strung together by narrow passages over precipitous cliffs, steep staircases, alleyways, and gates. Along this pathway the site is veiled and unveiled in a sequence of vistas that reveal the lay of the land and the setting of the town, and attract attention to details of nature or architecture framed by narrow passages or gates.

The gate of Intipunku affords a distant view of Machu Picchu, still too far away to discern individual architectural features, but close enough to grasp its general layout, and to appreciate its scenic setting and subtle incorporation into the majestic landscape. When one descends the trail from Intipunku, Machu Picchu disappears from view completely only to reappear in a succession of mere glimpses. Only when one rounds the bend in the trail, just below the so-called Watchman's House, does the site reveal itself again in its entire splendor, spread out immediately at one's feet with the sugar loaf peak of Wayna Picchu looming over it. Continuing down the stairway toward the main gate, most of the site vanishes again, and it is not until the very last step before the gate that Wayna Picchu is unveiled again in a dramatic view, perfectly framed by the gate.

Moving on through the site, one's view is alternatingly constrained by high walls bordering the alleyways and broadened as one emerges onto a staircase, a terrace, or an open space. There is a progression from the open and public spaces through narrow alleyways and gates to the enclosed and private spaces. At many junctures, one's attention is drawn to important features in the landscape. Sometimes this is achieved by narrowing one's field of vision, sometimes by widening it. The windows of the Temple of the Three Windows concentrate the view upon the half dome of Putukusi to the east and to the west the plaza, defined by the temple and the two buildings which flank it, opens wide to a sweeping view of the snow-capped Cordillera Vilcabamba and its many sacred peaks.

Machu Picchu is not unique in this; orientations upon features in the landscape are rather common in Inca architecture and can be observed at many other sites.

The rigid street grid of Ollantaytambo was by no means the norm for Inca settlements. Where regularity in the layout of the streets is found, it is probably a by-product of the rectangular design of the kancha, and not so much a reflection of the intent to parcel out the land in a grid. In accidented terrain the kancha and the building forms were "deformed" and modified to adapt to the topography, rather than made to conform to an abstract principle. While some commonalities and the repetition of certain elements can be observed at various sites, there is simply not enough empirical evidence available to induce a set of formal town planning rules by which, if they existed, the Incas laid out their settlements. It may be that the incorporation of views and the orientation on architectural and landscape features was the all-pervasive site and town planning criterion. To support this hypothesis, if it is at all tenable, many more sites will need to be analyzed dynamically; that is, as one moves through the sites rather than by merely investigating their plans.

City Planning: Maya City Planning

Rubén G. Mendoza

Much of ancient Maya civilization flourished in the period from AD 250 to 900 in the area encompassing the whole of Mexico's Yucatan Peninsula, the Mexican states of Chiapas and Tabasco, and the countries of Belize, Guatemala, western Honduras, and El Salvador. During the course of nearly twenty centuries of development, the distinctive architectural styles of the Maya heartland evolved and collapsed. As with other aspects of the Native American legacy, ancient Maya architecture was once seen as far too sophisticated to have been the product of aboriginal genius, and was long credited to Old World voyagers ranging from Egyptians to Israelites, and from white men or Danes to "great white Jewish Toltec Vikings" (Silverberg 1968).

As scholarly knowledge of Maya architecture, settlement patterns, and city planning has grown exponentially over the course of the last 60 years, so too has our respect and admiration for this ancient American tradition (Morley 1983). Until quite recently, scholars perpetuated the belief that the Maya had neither a literate tradition or history, nor true cities or political economies. They often typecast Maya architecture as inferior, because it did not employ the "true" arch in the Roman sense. And they were unable to demonstrate that Maya centers were planned and constructed under the direction of professional architects with drafted plans. Given the geomantic principles, astronomical alignments, and geometric sophistication inherent in Maya cities, it would be more difficult to demonstrate that the Maya had no such architects or recorded plans. This review will begin with an overview of the role of astronomy, cosmology, and geomancy in Maya architectonic arrangements, and then move to a broader consideration of the question of site planning in the ancient Maya heartland.

Maya Architecture, Sculptural Programs, and Cosmology

Archaeologist and architectural historian H. E. D. Pollock has defined ten primary architectural and planning styles for the lowland Maya heartland. To these may be added another four highland Maya areas that I believe may be distinguished for the Quichean highlands of southern Guatemala, the Cotzu-malhuapan Pacific coastal tradition, the Middle Classic (AD 400–650) styles of Kaminaljuyu and vicinity, and the hybrid regional developments of the present-day state of El Salvador.

Where the Maya lowlands are concerned, Pollock describes the influence of environment and topography on planning and architectural layout:

> The flood plains of Copan and Quirigua; the flat or gently sloping banks of the Pasion River; the steeply rising hills along the Usumacinta River; the mountainous shelf of Palenque and alluvial plain of Comalcalco; the low, wet, but often sharply broken terrain of the Peten; southern Campeche; and southern Quintana Roo; the savannas, valleys, and hills of the Chenes and Puuc regions; and the flat northern Yucatan plain all offered different opportunities and challenges to the ancient builder.

Custom was mediated by local and regional environmental conditions and the adaptive traditions which arose from them. Clearly, civil planning developed well beyond the purely "organic" (Andrews 1974) organization of monuments oriented to topographic and natural features of the immediate environment. Even in the earliest periods of Maya city planning, cosmological, astronomical, ritual, genealogical, and dynastic variables were integrated into site plans and construction programs. Plans were formulated in terms of multiple variables, not the least of which were the mechanistic dimensions of astronomical and cosmological cycles and dimensions, and the organic or topographic, and natural or practical realities of urban planning.

The period immediately preceding the Classic period was a time of great dynamism. According to archaeologist C. Bruce Hunter, "between 600 BCE and AD 250 great activity in city planning was taking place all over Mesoamerica. Cultural areas were defined, ceremonial complexes in the heart of the cities were constructed, and trade routes and luxury goods fostered trade competition between regions." Many of the greatest urban centers were built at this time. By the end of the Preclassic era – ca. AD 100 – Tikal and Uaxactun in the Peten lowlands and Cerros and Cuello in Belize had added to the architectural traditions of the era. The ancient cities of Dzibilchaltun in the northern lowlands, El Mirador in the southern lowlands, and Kaminaljuyu in the Guatemalan highlands defined the ceremonial construction for each of these subregions.

On the basis of recent glyphic transcriptions, we can now say that the iconography and architectural order inherent in the earliest city planning incorporated cosmological, dynastic, ritual, architectonic, and geomantic principles used in the organization of sacred geography and the built environment. My own study of the sculptural program embodied in the architecture and planning of the rock-cut temples of Malinalco, Mexico, and Carolyn Tate's more recent architectural survey of the ancient Maya center of Yaxchilan provides compelling evidence for Mesoamerican site plans based on pre-Columbian solar configurations or cosmograms, as well as the use and deployment of solstice-based axial alignments in city planning (Mendoza 1975; Tate 1992).

Geomancy and Maya City Planning

Geomancy, referred to as "mystical ecology" and as cosmological ecology or sacred geography, was the ancient Chinese practice of situating burials, monuments, and entire towns on the basis of cosmological principles. Because ancient Chinese scholars documented this practice so extensively, it is largely identified with Chinese civilization, although recent studies make clear the use of geomancy in ancient Mesoamerica (Freedman 1969).

Much of the divinatory practice embodied in geomancy is particularly relevant to Mesoamerican, and specifically Maya, city plans. According to John

Carlson, geomancy is “a divinatory art involving the interpretation of local topographical features for the purpose of properly locating and orienting the constructions of man – be they graves, houses, or entire cities.” However, Carlson has redefined geomancy as a:

> profound system of thought, deeply rooted in ancient and fundamental oriental philosophy and involving perception of the dynamic balance of the controlling forces of nature. It is the system in which man divines his own place in relation to the play of these forces, and it is the mechanism by which he can influence them in order to re-establish equilibrium when imbalance is perceived (Carlson 1981).

Maya city centers all provide archaeological evidence for the interpretation that plans were based on cosmological and geomantic models; however, few such sites have been examined with such principles in mind. Recent studies, such as those of William Rust (1992), Jeremy Sabloff and Gair Tourtellot (1992), Wendy Ashmore (1992), Robert Sharer (1990, 1992), and Carolyn Tate (1992), make clear the ancient Olmec connection to Maya ceremonial and settlement planning, the influence of changing economic and demographic patterns on planning, the icons of power, divinity, and divine mandates invoked through creation myths and expressed through architectural vocabularies and sculptural programs, the concentric patterning of civil monuments, and the deployment of solar cosmograms in site planning, respectively. We shall examine one site in detail.

Yaxchilan

The site of Yaxchilan, Chiapas, which overlooks the Usumacinta River separating Mexico from Guatemala, is one site that has been examined from the perspective of world plan as embodied in city plan. The site underwent dramatic transformations in construction during the reigns of Shield Jaguar, his father Bird Jaguar III, and his grandfather. The site was altered to establish “specific axes of solstitial orientation for architecture depending on the function of the building or space or the message of its sculptural program, and was conceived to define ritual areas used by particular rulers” (Tate 1992). Yaxchilan was constructed on an elongated shelf and used terraces, tiers, and elevated plaza-platforms within the context of a larger acropolis-centered pattern. Yaxchilan also incorporated a series of hills into the larger plan of the site, and was situated in a position providing the only unobstructed vantage point from which to observe solstice alignments between major buildings and prominent mountain peaks – serving as clefts in the horizon and as points of astronomical reference. Other recent observations document that major buildings at Yaxchilan were devoted to rites of passage – particularly those pertaining to dynastic accession, succession, calendrically based Period Endings, and to the capture and sacrifice of living kings. Such monument are oriented with respect to the eastern horizon and the summer solstice, whereas funerary chambers and obituary monuments and stelae are oriented along solstitial axes pertaining to the winter solstice at 118° east of magnetic north. Several of the obituary monuments and funerary shrines in question are aligned to 115°–116°, as opposed to the more exacting 118° east of magnetic north; apparently so as to allow for the use of doorways with half-quatrefoil overhead jambs to provide for architectural-solar hierophanies, or light and shadow patterns serving to record the passage of summer and winter solstice events. Such information provides a direct correspondence with ancient Maya identifications of the summer solstice with royal and/or divine renewal and the planet Venus, and the cosmological association of the southern horizon with caverns as the portals to the underworld, the moon, and the land of the dead. The fact that Yaxchilan’s southern precinct skirts the mouths of two prominent caves is cosmologically significant. According to Carolyn Tate, the caves “must have played a role in Bird Jaguar’s decisions on how to shape the ritual landscape” (Tate 1992).

Major buildings, monumental stelae, altars, and ritual markers from Yaxchilan all bear orientations that speak to political and ritual events. Buildings were aligned horizontally, and “situated from high to low vertically” (Tate 1992). By employing “alignments of stelae that conceptually linked the reigns of successive rulers,” the architects and planners coordinated the organization of the royal house of that era.

Recent studies at the sites of Tikal and Quirigua (Guatemala), Cerros (Belize), and Kohunlich (Mexico) provide dramatic examples of the means by which Maya world view and the realm of the supernatural were incorporated into city planning in a manner reminiscent of Christian, Muslim, Buddhist, and Hindu towns and cities of the Old World. While the sites of Cerros and Kohunlich provide architectural arrangements centered on monumental depictions of solar, lunar, terrestrial, and venusian cosmograms, the sites of Tikal and Quirigua incorporate these same dimensions in addition to those iconographic vocabularies and Twin Pyramid groups and precincts intended to symbolize the Classic Maya conception of the cosmos. Maya city planning has only recently undergone scrutiny with an eye to the larger mechanistic and organic dimensions and concepts of time and space inherent in Maya planning and design of the built environment. Wendy Ashmore has recently identified what she deems the five principle components of the Maya pattern pertaining to Tikal and related sites, these are (1) north–south axial arrangements, (2) complementary and paired functions of buildings centered along the main axes that serve to demarcate supernatural and celestial from underworld or terrestrial dimensions, (3) subsidiary eastern and western monumental arrangements within precincts providing for a triangulation with monuments located on the northern perimeter of individual precincts – and identified with the celestial vault and the cosmic tree of the north, (4) ball courts as transitional zones between north and south, and (5) the construction of causeways and paved roads linking precincts into a symbolically coherent cosmogram. To this listing I would add specific buildings that embody solar cosmograms and cosmic templates, as well as sculptural programs and iconographic vocabularies deployed across whole sites to imbue them with a sacred geography and cosmological ecology (Mendoza 1977). We can no longer assume that the Maya built in a random and largely organic fashion – by accretion and accommodation as opposed to design and structure. Primitivist and eurocentric portrayals of the ancient Maya have eroded in recent years under the onslaught of a new world order reinterpreted on the basis of surviving hieroglyphic stairways, monumental texts, commemorative stelae, funerary shrines, frescoed murals, painted ceramics replete with textual information, and pre-Columbian and contact period codical documents and screenfold books. These sources are now providing a revolutionary perspective on the Maya (Schele and Freidel 1990).

Clocks: Astronomical Clocks in China

Christopher Cullen

Timekeeping was a necessary preoccupation of the Chinese imperial state from its inception in the third century BCE. It was essential to the effective performance of ritual, which required the selection of auspicious hours as well as days, and to the proper interpretation of the astrological portents carefully recorded by the Astronomical Bureau. In addition it underpinned the fine tuning of increasingly elaborate systems of mathematical astronomy. The earliest devices used by astronomers were simple outflow or inflow waterclocks (clepsydras), which depended on the flow of water from a vessel to a small orifice. A graduated float indicated the time elapsed. Several later sources mention the Han dynasty scholar Zhang Heng (AD 78–139) as having succeeded in rotating an armillary sphere by means of "flowing water" so that it kept time with the heavens.

More detailed accounts survive of a similar project under the Tang dynasty in the eighth century AD, when the Buddhist monk Yixing and his colleague Liang

Lingzan made a water-powered armillary sphere, which incorporated jack-work to announce the hours and quarters by bells and drums. In neither case we have enough data to begin to reconstruct the mechanism involved. However, in AD 1086 the high official and scholar Su Song was commissioned to construct an astronomical timekeeper which was to be much more complex than any of its predecessors, and a detailed illustrated description of this device has come down to us in his monograph entitled *Xin yixiang fa yao* (Description of a New Astronomical Instrument or New Design for an Armillary Clock).

From this book we learn that the device Su Song constructed was in effect a clock-tower more than 10-m high, surmounted by a great bronze armillary sphere automatically rotated, with a rotating celestial globe in an inner chamber. On the front of the tower was a complex array of jacks and annunciators to mark the passage of time. The mechanism which turned the shafts was based on a great water-driven scoop wheel, with a weighbridge and trip-lever movement which allowed the wheel to advance one step each time a standard weight of water had run from a constant-head tank. This happened once every hundredth of a day, about 15 min, so that the correspondence with the heavens was somewhat jerkily maintained. While the utility of this device to astronomers can only have been moderate, its possession must have been seen as a considerable enhancement to imperial prestige. Su Song's tower fell out of use when the capital fell to invaders in AD 1126.

Clocks and Watches

Donald R. Hill

There was a long tradition in the Hellenistic world for the construction of large water clocks. Vitruvius, writing in the first century BCE, mentions the water clocks constructed by an Alexandrian engineer called Ctesibius (ca. 300 BCE) which incorporated gearing, automata, and audible time signals. The Alexandrian writer Hero, who flourished around AD 60, is known to have written a book on water clocks. The Byzantine historian Procopius described a monumental water clock constructed at Gaza in the sixth century AD. It is almost certain that the inspiration for the construction of water clocks in the Islamic world came from this Hellenistic tradition.

Islam

Monumental water clocks are described in detail in two Arabic treatises. Al-Jazarī in his machine book *Kitāb fī maʿrifat al-ḥiyal al-handasiyya* (The Book of Knowledge of Ingenious Mechanical Devices), completed in Diyar Bakr in 1206, describes two such machines. Riḍwān ibn al-Saʿātī, in his treatise *Kitāb ʿamal al-sāʿāt wa ʻl-ʿamal biha* (Book on the Construction of Clocks and on Their Use) dated 1203, describes the water clock built by his father Muhammad at the Jayrun gate in Damascus. It fell into disrepair after Muhammad's death and was restored to working condition under his son's supervision. It was a large construction, having a timber working face about 4.73 m wide by 2.78 high, built into the front of a masonry structure. The clock had several design defects which undoubtedly caused the breakdown that Riḍwān undertook to repair. Moreover, Riḍwān himself was not an engineer and his description, though containing some valuable information, omits to deal with some important constructional details.

Al-Jazarī's two clocks, on the other hand, were manufactured and constructed in a very workmanlike manner. Although very similar in principle to al-Saʿati's they did not incorporate any design defects. The first and larger of the two was described in such careful detail that it was possible to construct a full-size working facsimile from al-Jazarī's instructions and illustrations for the World of Islam Festival, in the London Science Museum in 1976.

The working face of the clock consisted of a screen of bronze or wood about 225 cm high by 135 cm wide set in the front wall of a roofless wooden house which contained the machinery. At the top of the screen was a zodiac circle about 120 cm in diameter, its rim divided into the 12 signs. It rotated at constant speed throughout the day. Below this circle were the time-signaling automata which were activated at each hour. (The clock worked on "unequal" hours: i.e., the hours of daylight or darkness were divided by 12 to give hours that varied in length from day to day.) These included doors that opened, falcons that dropped balls on to cymbals and the figures of five musicians – two drummers, two trumpeters, and a cymbalist. The musicians were operated by the discharge of water from an orifice, whereas all the other automata were operated by a heavy float that descended at constant speed in a reservoir. A cord tied to a ring at the top of the float led to a system of pulleys that activated various tripping mechanisms.

The speed of descent of the float was controlled by very ingenious water machinery that included a feedback control system and a flow regulator, the latter for varying the rate of discharge daily in order to produce the "unequal" hours. The same system was used by Riḍwān and both writers attribute its invention to Archimedes. There is a treatise that exists only in Arabic and is attributed to Archimedes. The treatise almost certainly contains Hellenistic, Byzantine, and Islamic material but its first two chapters describe water machinery that is essentially the same as that used by Riḍwān and al-Jazarī. There is every likelihood that these chapters were indeed the work of Archimedes.

Al-Jazarī's book also contains descriptions of four other water clocks, two of which embody the principle of the closed-loop, and four candle-clocks which, on a small scale, are as impressive from an engineering point of view as the water clocks.

Other Arabic works add to our knowledge of Islamic hydraulic timekeeping. A certain Ibn Jalaf or Ibn Khalaf al-Murādī worked in Andalusia in the eleventh century. Unfortunately, the unique manuscript of his treatise on machines is badly defaced, but it is possible to determine the essential details of the automata and water clocks that are described in it. The most important feature that they incorporate is complex gear-trains which include segmental gears (i.e., gears in which one of the wheels has teeth only on part of its perimeter, a device that makes intermittent action possible).

Al-Khāzini's justly famous book on physics, *Kitāb Mīzān al-Ḥikma* (Book of the Balance of Wisdom) was completed in 1121–1122. In the eighth treatise two steelyard clepsydras are described. On the short arm of the beam was a vessel that discharged water at a constant speed from a narrow orifice. Two sliding weights were suspended to the long arm, which was graduated into scales. At a given moment the weights could be moved to bring the beam into balance and the time could then be read off from the scales.

A number of noteworthy references to water clocks can be found scattered among the works of Arabic writers. For example, we read of one such device in the works of the Anadusian poet ʿAbbās ibn Firnās (d. 887). Two water clocks were constructed by the famous astronomer al-Zarqallu in 1085 on the banks of the river Tagus at Toledo. The remains of two large water clocks still exist in Fez, Morocco. One of these is in the street opposite the Bu'ananiyye Madrasa and was built in 1357. According to the historian of Fez, Al-Jazna'ī in *Zahrat al-Ās*, at each hour pellets fell onto a gong and a pair of door leaves opened. The door openings and the brackets for the gongs still exist. A second clock was constructed in 1361. It had an astrolabic dial and it also released pellets and had doors that opened. It is in the minaret of the Qarawiyyīn mosque. The doors and the dial still survive, but in neither of the Fez clocks does any trace of the water-machinery remain. Another North African water clock, in Tlemcen, was mentioned by Abū Zakariyyā Yaḥyā ibn Khaldūn in *Bughyat al-ruwwād*.

In 1276–1277 a work entitled *Libros del Saber de Astronomia* was produced in Castilian under the sponsorship of Alfonso X of Castile. This consists of various works that are either translations or paraphrases of Arabic originals. It includes five timepieces, one of which is of significance in the history of horology. This consisted of a large drum made of walnut or jujube wood tightly assembled and sealed with wax or resin. The interior of the drum was divided into 12 compartments, with small holes between the compartments through which mercury flowed. Enough mercury was enclosed to fill just half the compartments. The drum was mounted on the same axle as a large wheel powered by a weight-drive wound around the wheel. Also on the axle was a pinion with six teeth that meshed with 36 oaken teeth on the rim of an astrolabe dial. The mercury drum and pinion made a complete revolution every 4 hours and the astrolabe dial made a complete revolution in 24 hours.

This type of timepiece had been known in Islam since the eleventh century.

China

The commonest method of timekeeping in China, for many centuries, was the inflow clepsydra. In its simplest form this consisted of two vessels: a reservoir and a receiver below it. The reservoir had an overflow pipe near its top and an orifice in its underside. The water supply ran into the reservoir and the overflow pipe ensured that the water level remained constant. The rate of flow from the orifice into the receiver was therefore also constant as was the rise of the water in the receiver. A float in the receiver was used to activate various time-recording mechanisms.

The inflow clepsydra was used extensively in China from the Han period (202 BCE to AD 221) onwards. Two main types were developed. The first type involved the introduction of one or more compensating tanks between reservoir and receiver. At each successive stage the retardation of flow due to diminishing pressure head was more and more fully compensated. The introduction of at least one compensating tank can be dated to the second century AD. As many as six tanks are known to have been used. In the second type an overflow or constant head tank was placed in the series, a practice that began in the middle of the sixth century AD. There can be no doubt that this type of water clock was widely used in China throughout the medieval period.

The most notable achievement of Chinese horologists was the clock described by Su Song in *Xīn yixiang fa yao* (New Design for an Armillary Clock or Description of a New Astronomical Instrument) begun in 1088 and completed in AD 1094. This was a monumental clock, 30–40 ft (9–12 m) in height, having a rotating armillary sphere and celestial globe, together with numerous jack-work figures with both audible and visible effects. These devices were driven, through a complex system of gearing, by a water-wheel 11 ft (3.35 m) in diameter carrying 36 scoops on its perimeter. Water stored in an upper reservoir was delivered to a constant-level tank by a siphon, whence it was discharged on to the scoops of the wheel, each of which had a capacity of 0.2 ft^3 (.6 cm). The wheel was provided with a very ingenious escapement system, in essence two steelyards upon each of which the scoops acted in turn. When a scoop was full, its weight overcame the balancing system and it fell freely for a given distance until checked, without recoil, by a locking device. The next scoop then came under the delivery jet and the cycle repeated itself. There is no evidence that the system of escapement used in Su Song's clock was ever transmitted westward.

The mechanical clock was invented in western Europe toward the end of the thirteenth century. Almost certainly its inventor came from the ranks of the makers of water clocks. The verge escapement made the mechanical clock possible, but all its other features – weight-drive, automata, gear-trains, and segmental gears – were present in Islamic water clocks. It is highly probable that these ideas were transmitted from Islam to the European makers of water clocks. An Islamic influence on the genesis of the mechanical clock may therefore be postulated.

Several of Taqī al-Dīn's writings are concerned with timekeeping, and one of these, *Al-kawākib al-darriyya fī al-binkāmāt al-dawriyya* (The Brightest Stars for the Construction of Mechanical Clocks), written about 973/1565, has been edited with Turkish and English translations.

In this he described the construction of a weight-driven clock with verge-and-foliot (an early form of balance) escapement, a striking train of gears, an alarm, and a representation of the moon's phases. He also described the manufacture of a spring-driven clock with a fuzee [a conical pulley or wheel] escapement. He mentions several mechanisms invented by himself, including, for example, a new system for the striking train of a clock. He is known to have constructed an observatory clock and mentions elsewhere in his writings the use of the pocket watch in Turkey. This is a surprisingly early reference to the use of watches in Turkey; the manufacture of watches began in Germany about 1525 and in England about 1580.

Taqī al-Dīn's descriptions are lucid with clear illustrations, showing that he had mastered the art of horology. Clockmaking did not, however, become a viable indigenous industry and Turkey was soon being supplied with cheap clocks from Europe. Taqī al-Dīn himself commented on the low price of these European clocks, which entered Turkey, he said, from Holland, France, Hungary, and Germany.

Coir in India: History of Technology

K. T. Rammohan

Coir, a natural fibre used extensively to make brush, spin yarn, twist rope, and weave carpets, is obtained from coconut. The coconut tree (*Cocus nucifera*) grows in many tropical countries but chiefly in India, Thailand, Sri Lanka and the Philippines. Within India it grows best on the southwest coast of Malabar, especially in the state of Kerala. Europeans and Arabs used to refer to it as the Indian Nut. One of the earliest references to its production in Kerala appears in a temple inscription of tenth century, which refers to the fruit as *tengai* and lists it as a major source of revenue to the temple. *Ten* means the south, probably indicating its arrival from South Sea Islands and/or Sri Lanka by the sea. While there is inscriptional evidence of coconut groves from this period, really large-scale cultivation – turning almost the whole region into a vast coconut grove – begins from the sixteenth century. For the people of Kerala, the coconut tree is what the reindeer is to the Eskimos; it fulfils many needs.

The coconut tree with its long trunk – very rarely branched – stands tall on sandy tracts adjoining the sea and backwaters. It yields fruits – coconuts – about three-quarters the size of a football. These are green on the outside when tender, turning into brown as the coconut ripens. Coconuts are usually plucked by a male worker climbing up the tree using a loop grip-chord at the ankles. Sometimes, to ease labour, a single bamboo (*Dendrocalamus strictus* or 'male bamboo') is leaned against the tree and used to gain the first long ascent from the ground – the branches extending from the nodes of the bamboo serving as steps – while the rest of the climb is completed using the loop grip-chord. On reaching the top, the climber cuts off bunches of coconuts with a knife and drops these to the ground. The nuts are picked from the ground, collected and carried in bamboo and reed baskets, mostly by women.

Only male workers of specific castes group engage in plucking coconuts. Usually they do not take up other work. The collecting women could be of any caste and are not restricted solely to this activity. Even today the wages of the climber and the collectors are paid partly in coconut. Over the past two decades semi-mechanical devices for tree climbing have been introduced but these have not gained popularity as experienced climbers do the job much faster.

A hard shell with an outer cover of fibrous mass protects the coconut kernel. The coconut is first removed of its husk with an iron spike or a knife. To obtain the kernel the inner shell is cracked, yielding two, fairly hemispherical pieces, brown on the outside and white inside. The coconut kernel is an important component of the everyday diet of the people of Kerala and is their chief source of oil for cooking and anointment. It is the coconut husk obtained while cutting up the coconut for kernel that yields fibre. Coir is thus the product of a by-product obtained in coconut cultivation.

Yet, of the several industries associated with the coconut tree in Kerala, the coir industry is the most important in terms of employment and investment. The use of Malabar coir yarn and rope for maritime purposes internationally has a history that may be traced to the thirteenth century or even earlier. Coir yarn was used to stitch together the planks of a ship and ropes were used to tie the sails to the mast. Coir ropes were also used in fishing. Weaving of coir matting or carpets on the Malabar Coast dates back to the nineteenth century. For the poor in Europe, coir matting substituted for expensive carpets, while for the rich it served as an underlay for expensive carpets. Coir fibre was used in upholstery and in making brush mats. While coir yarn was widely used locally for agricultural purposes, mat and matting were woven primarily for the world market.

Initially, coir fibre and yarn were exported from Kerala to Great Britain where these were woven into brush mat and matting. As coir fibre is bulky, transport over long distances was uneconomical. Baling presses could not gain wide acceptance because baled fibre was hard to tease. From the mid-nineteenth century, carpet weaving factories were set up in Kerala's port towns, initially under the initiative of British capital and subsequently by local entrepreneurs – although

Coir in India: History of Technology. Defibering.

export of fibre and yarn and its processing elsewhere continued. The expansion of the coir matting industry and the consequent rise in demand for raw material yarn prompted changes in the scale and technology of spinning. Unlike weaving, which was conducted in factories spinning was household production. It continues to be so even today.

To produce fibre, the coconut husks are first treated in saline water (retting) and the fibrous mass removed from its semi-hard shell by hand (ripping). That is beaten with a rod to yield tufts of fibre (defibering), and finally cleaned by throwing up in the air. The husks are carried by big, country canoes along canals to the backwater for saline water soaking. To soak the husk, a big, circular net of coir is stretched across the water surface and stacked with husks. A worker standing on the backwater bank throws husks into the net. Workers standing waist-deep in the backwater arrange the husks in layers, one over another, in the net. Usually, 10,000 husks are stacked in a net. The stacked husks are covered with plaited coconut leaves and tied together on the top, crisscrossed with coir strings. The husk mass is then punted to the interior of the backwater and covered with mud and stones dug out from the backwater bed. The plaited coconut leaf cover and mud ensure that the husks do not dry up in the sun. As the husks absorb water, since they are burdened with heavy stones, the husk mass sinks a little. To distinguish between husk mass sunk by different owners, small metal discs bearing the initials of the owner or a number code are inserted into the husk mass.

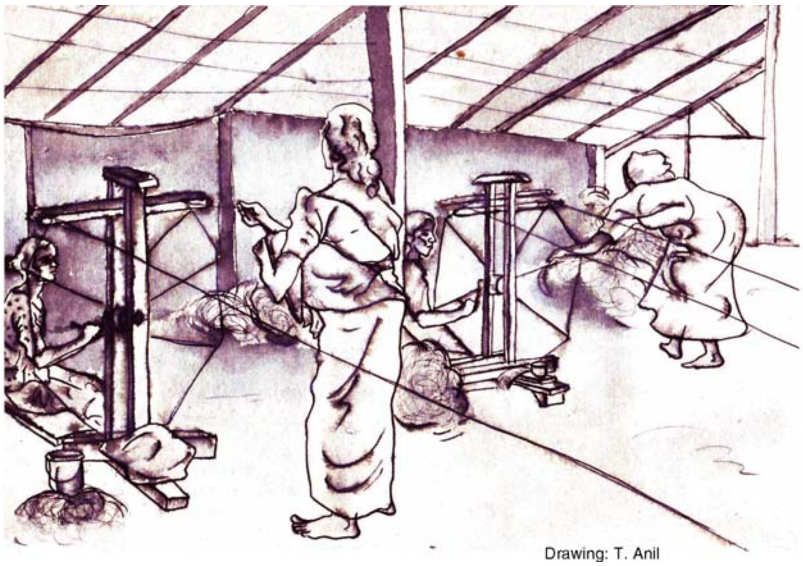
The husk mass remains in water for a period ranging from six to eight months or even more. Flushing washes away tannin and facilitates bacterial action that decomposes the fibre-binding pectin. Salinity lends strength to the fibre. The husk mass becomes heavy after retting and has to be brought back to the backwater bank in a canoe. Workers standing waist-deep in the backwater untie the retted husk mass and throw the husks into the canoe. The retted husks are unloaded at the defibering sites that are usually located on the bank. Women workers carry these as head load to the work spot. Male workers, usually drawn from subordinate caste groups, do the entire retting operation.

In certain parts of Kerala retting is carried out by burying the husks under the beach sand. Retting in small ponds in the homestead is also in vogue. Unlike backwater retting, which is a male preserve, women undertake retting in beach sand and ponds. The defibering mills that have been built in the past few years do away with the retting operation and defiber the green husks. The fibre so produced has to be soaked for a few days in saline water later. Even then, its quality is inferior to that produced by retting.

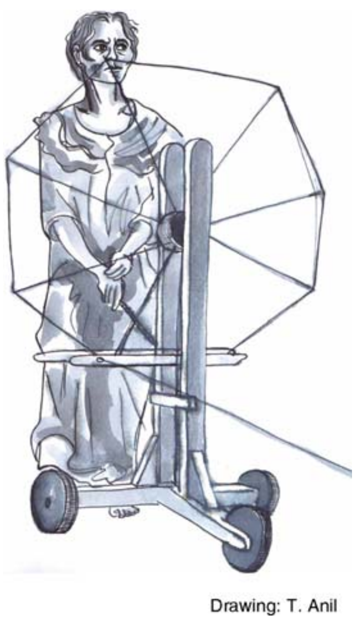
Defibering or separating fibre from the retted husk is done entirely by women, mostly of subordinate caste groups. The worker squats on the ground and rips off with her hand the loosened fibrous mass from its semi-hard shell. She then places the fibrous mass on a flat stone or wood and gently beats it with a small iron or metallic rod. A few beatings and the black, retted husk turns into a tuft of golden brown fibre.

A large quantity of fibre dust or pith is produced in defibering. Accumulated pith makes small hills on the backwater side. This is occasionally removed and used as a saline input or as ash in coconut groves and vegetable gardens. More recently pith has been put to new uses. It is baled into pith bricks for use in indoor gardening or into pith logs to block soil erosion. Like other coir products these also enjoy global demand.

Defibering work is backbreaking. The long working hours, continuous exposure to sun and rain, the uncomfortable squatting posture, contact with fibre particles and dust, and lack of a balanced diet because of the very low wages often cause women's health to deteriorate. There had been attempts to mechanise the defibering operation beginning from the nineteenth century, but these were given up as employing labour was cheaper and capable of producing better quality fibre as compared to the mechanical process. Attempts at mechanisation occurring in the latter half of the twentieth century were defeated by workers who were faced with the threat of unemployment. Over the past decade, however, defibering mills that can process large quantities of raw husks have been established.



Coir in India: History of Technology. Spinning.



Coir in India: History of Technology.

As with defibering, only women workers and mostly of subordinate castes spin coir yarn. Traditionally the fibre was spun into yarn by rolling between the palms. With the expansion in international demand for coir carpets and therefore for yarn for weaving in the mid-nineteenth century, spinning wheels were introduced. A woman worker – most often a child or an old woman – rotates the fixed wheel while two other women workers walk backwards feeding fibre and drawing out a strand of yarn. The workers then walk forward, twisting the two strands into one by pushing a moveable wheel and by running a triangular wedge. The spun yarn is counted and bundled and delivered in the market or sent to the weaving site by country canoes, carts, and trucks.

Spinning is laborious. By the end of the workday, a spinner, walking forward and backward between the two spinning wheels, would have covered a distance of about 8 km. The spinners often tend to develop body disorders, especially the outward curving of their feet from walking backwards. For centuries, the low wages of spinners has been a disincentive to entrepreneurs in experimenting with mechanised processes. During the past decade, coir workers' cooperatives have sought to increase productivity and reduce labour by introducing electrically operated spinning wheels. These have not been very successful. The yarn tends to break too often in mechanised spinning and the final output is not of a quality that matches the yarn spun on hand-rotated wheels.

Spinning yarn by rolling it between the palms still continues in parts of Kerala. Rope making is also done by hand. One end of the yarn is tied to a coconut tree and the other end passed through the eye of a coconut shell. A small stick is then tied to the other end and briskly rotated. This draws the yarn and gives it a hard twist. After toughening each yarn, these are plaited to make rope. Depending on the strength required, four or more yarns may be plaited.

Certain kinds of coir yarn are used in agriculture, packing, and house construction. Certain other kinds are raw material for weaving carpets. Traditionally, entirely and even today, mostly, coir yarn is woven into matting on wooden handlooms. In contrast with defibering and spinning done only by women, weaving is exclusively male labour. While a mat is woven on relatively small looms worked by a single worker, matting is made in large looms with six to eight persons working in unison. Power looms have led to a substantial rise in productivity and a widened range of products – sometimes in combination with jute and latex – but some of the designs may be worked only on handlooms.

C

Colonial Medicine in India

Ranès C. Chakravorty

Ancient India

The Indian subcontinent was well inhabited by the first millennium BCE. The inhabited territory extended west into areas that today are in Pakistan and Afghanistan. These ancient Indians had a well-developed system of medicine termed Āyurveda (The Science of Life). Ayurvedic physicians practiced medicine and to a lesser extent, surgery. The system and its practitioners were held in high regard and Indian physicians are known to have been in the courts of the Muslim rulers. Some of the Ayurvedic texts were translated into Arabic early in the history of Islam.

The basic thrust of Colonialism is to exploit the colonized for the benefit of the colonizers. Usually after a long period of colonization the two groups come to a situation of better parity. Both these phenomena are well illustrated in the colonization of India.

Muslim Invasion

From the early eighth century, India was invaded by the Muslim kings ruling in the west across the Himalayas. Initially these Muslim pockets were small and often short-lived. By the twelfth century, a Muslim kingdom had been established in Delhi, though the ruler(s) recognized their western center outside India as the capital. By the thirteenth century Muslim occupation in India had become permanent, and ultimately the Muslim rulers assimilated into the Indian culture. The Turk, Babur, established his capital in Delhi in 1526, though it was not until his grandson, Akbar (1556–1605) ruled, that the Mughals considered themselves Indians. The Muslims had brought with them the Islamic system of medicine, Unani or Tibbi, based largely on translations of Greek

Medicine. However, Āyurveda was also in use, not only in the Hindu population, but also among the Muslims.

With the arrival of the Europeans, European physicians also practiced in India though in small numbers. From the time of Shahjehan, Akbar's grandson, some European physicians are known to have practiced in royal courts. Thus, Niccolo Manucci (1639–1717) was an artilleryman to Shah Jahan's eldest son Dara Shukoh. He later took up the profession of medicine (even though untrained) and practiced both professions (!) in various royal courts. Manucci's memoirs name some other European physicians practicing in India. François Bernier, a Frenchman with a medical degree from Montpellier, served Dara Shukoh and later his brother, the Mughal emperor Aurangzeb (Majumdar et al. 1994).

European Colonization

Portuguese

From the middle of the sixteenth century, European nations turned their eyes eastward for territorial expansion and trade. The Muslims had established themselves in the Middle East from today's Syria southwards to Egypt and across North Africa to the southern half of Spain. Trade with India and further East had become dangerous and expensive. There was also the need to spread Christianity.

The first to arrive in India was the Portuguese Vasco da Gama who landed at Calicut (now Kozhikhode) in southwest India on 20 May 1498. By 1510 the Portuguese had an established presence in Goa on the west coast. Goa remained a Portuguese possession until 1949 when it joined the Republic of India. In the 450 years of its association with Portugal, Goa became a medical center of sorts. It had the oldest European-style hospital and medical school in the East.

The Royal Hospital was started in 1510 and by about 1546 western medicine was being taught. The Hospital was fully supported by the Portuguese rulers and was a showpiece in its time. The continuing rivalry between the Dutch and the Portuguese, however, caused a decline in Goa's prosperity and the Hospital started to decline by the mid-seventeenth century. In order to have a cadre of assistant physicians, non-Portuguese natives were taught the rudiments of medicine.

Some Portuguese physicians and apothecaries traveled to Goa and some even stayed behind. The most prominent among them was Garcia d'Orta. A converted Jew, Garcia d'Orta was born to Jewish parents who had been expelled from Spain in 1492. They were converted to Catholicism but were always looked down upon. D'Orta studied medicine in Spanish universities and returned to Portugal in 1523. He then joined the faculty at the medical school in Lisbon. In 1534 he left for Goa with his friend, who was to become the Governor-General of Goa and the Portuguese territories in India.

D'Orta became a very successful practitioner, not only for the rich Portuguese in Goa, but also for the rulers of neighboring Hindu and Muslim kingdoms. (Other Portuguese physicians also became court physicians and many rich Indians came to Goa for treatment.) D'Orta is remembered today for his book *Coloquios dos Simples e Drogas da India* – an Indian materia medica, which was published in 1563, in the first printing press in India. The book gained great renown and was very popular in Europe. D'Orta died in 1568, probably quite poor as the Catholic hierarchy had turned against him. His bones were burnt at an auto-da-fe in the cathedral in Goa some years after his death. D'Orta remains the first author of a western-style medical book from India.

A woman medical doctor, Dona Juliana, came to Goa and later on moved to the court of the Great Mughal Akbar. Nicolau Manucci, mentioned above, came and practiced in Goa for a short while but was then thrown out by the authorities.

Around 1842 a formal medical school, Escola Medico-Cirurgica de Nova Goa was established in Goa. The number of graduates (strictly limited to Christians) from this school was never very high, though many of them went on to achieve professional distinction in Goa, in India and in the Portuguese territories elsewhere (Pandya 1982). The school was discontinued at the time of Goa's admission to the Republic of India.

Following the Portuguese, the French, the Dutch, and the Danes established trading centers in India. The latter two countries had undistinguished and short stays in India. The French remained in Chandernagore, Pondicherry, Mahe, Yaman, and Karikal, all isolated enclaves until Indian independence in 1947. During this period they had no significant medical establishments either as medical schools or hospitals.

British

Starting with small trading posts in the seventeenth century, the British ultimately occupied all of the Indian subcontinent and the history of colonial medicine in India is almost exclusively that of the development of medicine during British rule (1857–1947).

Medical practices under the British will be described in two phases. The first was under the East India Company, the next under the British crown as a part of the Empire.

Phase 1: The East India Company

The East India Company was a profit-making body administered by local administrators in India. In theory the Board of Governors in England were responsible for the supervision with some generally minimal oversight by the British Parliament. Under the Company, fortune making and profiteering were rampant and generally tolerated. Only a very few people were ever brought to justice in the courts or impeached in the Parliament. The entire western-style medical setup was for the British, largely the armed forces; the native population depended upon the indigenous medical systems.

Each ship coming to India had a (naval) surgeon on board.[1] They sometimes deserted (often without punishment when captured), settled as surgeons to the trading settlements on land and not infrequently fought as soldiers in the many and frequent battles between the British, the French (the Carnatic and Mysore Wars),[2] and the native Indians.

While a number of the naval surgeons were of great service to the British, two are of special interest, signifying different aspects of the duties of the navy surgeon. William Hamilton of Dalziel in Scotland is hardly remembered today Fig. 1. However his epitaph (still to be seen in the graveyard of St John's Church in Kolkata, India) states "…his Memory ought to be dear to this Nation for the Credit he gained ye English in curing FERRUKSEER the present king of Indostan… by which he made his own name famous at the court of that great monarch; and without doubt will perpetuate his Memory in Great Britain as well as in all other Nations of Europe." Hamilton was apparently trained as a surgeon and did not have a university degree in medicine. He was attached to the small Company trading post in Calcutta. The Company had been trying to get a *firman* or permit to carry on trading with the local populace under advantageous terms and lowered customs duties. The Company sent a delegation to the Surman Embassy to the court of Farrukhshiyar, the reigning Mughal monarch in Delhi. On arrival at Delhi, the delegation found that Farrukhshiyar was seriously ill with infected lymph nodes in the groin. He had been treated by the court (native) physicians unsuccessfully. Hamilton treated the emperor (apparently lancing the boils) which resulted in rapid recovery. The emperor also had an anal fistula that Hamilton successfully treated.

Colonial Medicine in India. Fig. 1 The tombstone and epitah (in English and Arabic) of William Hamilton in St. John's church, Kolkata, India (Photograph by author).

The grateful monarch issued a firman in favor of the British, munificently rewarded the young surgeon, and wanted him permanently in his employ. Hamilton died soon thereafter and was buried in the Company cemetery in Fort William, Calcutta (Wilson 1911).

John Zephania Holwell (1711–1798) was quite a different type of physician. Born to well-established parents (his father was a timber merchant in London) Holwell studied in England and Holland and trained as a surgeon in Guy's Hospital, London. He came to India in 1732 and to Calcutta, which had the most important British factory in India, in 1736.

In 1756 the British settlement in Calcutta was attacked by Siraj-ud-Dowlah, the ruler of Bengal. The Governor left the Fort with all the ladies and most of the men for a safe refuge on the river Ganges. Holwell remained as the governor of the fort, put up a stiff fight, was defeated and captured. He with the 156 other captives was put in a small chamber termed the "Black Hole." Only 23 survived the night (Holwell's description of this event has been seriously criticized. Probably the numbers reported were exaggerated though the confinement did happen. A monument erected by Holwell to recall the event was later removed but can still be seen at the back of St John's Church.)

Holwell became the temporary Governor of Bengal after Robert Clive's return to England and finally returned to England in 1761. He wrote a number of books on his experience, knew a number of languages including Arabic, and was one of the first to study Hindu antiquities.

Phase 2: The British Raj

In 1857, there was a revolt by some of the Indian regiments and Indian rulers against the East India Company. Known variously as the Sepoy Mutiny

[1] The training and career of a naval surgeon of the times are well detailed in *The Adventures of Roderick Random* (1748) by Tobias Smollett (1721–1778) who was himself a physician trained at the University of Aberdeen.

[2] The Carnatic and Mysore Wars were fought in the latter half of the eighteenth century by the British against the Marathas, rulers of Mysore, and the French to establish British power in southern India.

(by the British) and the First War of Independence (by the Indians) the immediate result of this conflict (which the British won) was the takeover of the Indian territories by the British Government. The Government sent representatives of the Crown (Governor Generals) to rule over the Indian territories.

Even though the Government was mainly geared to British interests, there was some beginning interchange between the Indians (mainly the Hindus) and the British rulers. Calcutta remained the capital and the seat of government (until 1911) so most of the action occurred there (Bala 1991; Arnold 2000).

With the establishment of the Raj, the early British officials were very interested in native customs and learning. In 1776, (Sir) William Jones, a superb linguist, and a Judge of the Calcutta High Court, established the Royal Asiatic Society of Bengal with the support of the Government specifically for oriental studies and research. Both he, Warren Hastings, and other high-ranking officials encouraged the study of the Indian systems, and this helped establish the Calcutta Madrassah for the study of Arabic and Persian and the Sanskrit Colleges of Calcutta and Benares for the study of Arabic (Majumdar et al. 1979).

Because of the lack of practitioners trained in Western medicine, the local British physicians would train their assistants for 1 or 2 years and then certify them as being capable of practicing western medicine independently. In order to increase the number of better-trained medical practitioners and the number of assistants to the European physicians, the Government started a Native Medical Institution in 1824 in Calcutta (and later in Bombay) mainly to produce assistants, dressers, etc. Auxiliary Medical sections were also established at the Sanskrit College in Calcutta where Āyurveda was taught together with some western medicine. (A hospital with 30 beds was started for these students in 1830.) At the Calcutta Madrassah, rudiments of western medicine were taught together with Unani or Tibbi – the Arabic medical system. The western system had a therapeutic armamentarium that was possibly inferior to the native systems. Its nosology (classification of diseases) was different but not much better; the main difference was in the study of human anatomy by dissection and surgery (without anesthesia).

A Bengal Medical Service had been started in 1763 – similar provincial services started in Madras and Bombay. Membership was limited to the British for many years and when Indians started to be admitted to the Indian Medical Service they were usually assistant or subassistant surgeons. Created to serve the needs of the Empire, the IMS had a prime responsibility to the armed forces and military matters; service to civilians was secondary.

Arrangements for the institutionalized treatment of the employees of the East India Company and the soldiers and sailors had existed from the beginning at the three main British centers – Calcutta, Madras, and Bombay. Madras had a hospital since 1664. A hospital for Europeans was started near St John's Church in Calcutta in 1707. In 1768 a General Hospital for other Europeans (including indigents) and visiting European sailors was started in Calcutta. This Presidency General Hospital still exists.

Lord William Bentinck was the Governor-General from 1828 to 1835. He was convinced that education was to be Europeanized. In 1835 the Native Medical Institution and the medical sections of the Sanskrit College and Calcutta Madrassah were abolished. The Bengal Medical College was opened in Calcutta with three British and one Indian faculty (Anon 1935). The Indian, Madhusudan Gupta had been a student (and later a teacher) of the Vaidyaka Sreni or medical section of the Sanskrit College. A remarkable person in all respects, Gupta initiated cadaver dissection in 1836 (Chakravorty 1997) Fig. 2. In 1857, with the establishment of the University of Calcutta, the College changed its name to the Calcutta Medical College. The Madras Medical College also started in 1835. Amongst other achievements, this institution was the first to formally train women in medicine. The Grant Medical College of Bombay was started in 1845.

Colonial Medicine in India. Fig. 2 Painting by Madhusudan Gupta by Mrs. Belnos in the Anatomy Department, Medical College, Kolkata, India (Photograph by author).

Women

The first special attention paid to native women by the British physicians followed a law enacted in Britain. From 1805 to 1833 and again from 1868 to 1880, venereally infected prostitutes and soldiers were kept in "lock hospitals." Christian women missionaries from the west played a large role in looking upon native women's health, although the main object was probably conversion to Christianity (Balfour 1929). The first was Clara Swain, who in 1869 established the American Methodist Episcopalian Mission in Bareilly. Here she also trained Indian women in nursing and midwifery. Many women missionaries came from Great Britain, Canada, and the United States to render service to native women and men.

Ida Scudder, an alumna of Cornell University Medical School, opened a medical college and hospital for women in Vellore, Madras Province. In 1945 the college was opened to men also. Today it is the biggest Christian hospital in the world and one of the best-teaching institutions in the country. India was a haven for women medical graduates from the British Isles. They had problems in being accepted in Great Britain but had much better opportunities in India.

A specialized case was that of Lady Dufferin's Fund (Lal 1994). Initiated by the wife of the Viceroy, Lord Dufferin, this organization collected donations to start hospitals for women and train nurses and midwives. Though always short of funds, the Fund played a significant role in women's health care. It also helped establish the Lady Hardinge Medical College for Women in Delhi in 1916.

As in all other countries, women had difficulty in receiving formal education in medicine. Among the first woman physicians of India was the English woman (Dame), Mary Scharlieb who was the wife of a prominent lawyer of Madras. Her husband's family was well known to the Governor and the Superintendent of the General Hospital in Madras. She first took courses in midwifery but later with three other Anglo-Indian ladies was allowed to attend classes and sit for the final Licentiate examination in 1878. Of her colleagues, Dora White became a physician to the Nizam's Government in Hyderabad and D'Abreu (who had come to Madras as she had not obtained admission in Calcutta) became a medical missionary. She later returned to England and became very well known as a physician.

The first Indian woman to graduate was Kadambini (Basu) Ganguli (1861–1923). She was the first woman to get the Bachelor's degree at Calcutta University (together with Bidhumukhi Bose). She obtained her licentiate from Calcutta University in 1886. Later she went to Great Britain and obtained degrees from Glasgow and Edinburgh. She was a very successful practitioner of medicine, obstetrics and gynecology, and surgery.

Anand(a)ibai Joshi of Pune graduated from the Women's Medical College of Pennsylvania in 1886. She returned to practice in India in charge of the Female Ward of the Civil Hospital in Kolhapur, Maharastra, but died of tuberculosis soon thereafter.

Diseases, Public Health, and Research

India has its own spectrum of diseases, many of which were unknown to westerners. I will discuss only three of the most devastating.

Malaria had been a devastating disease in India and the countries around the Mediterranean for centuries. Because of the lethality of malarial fever, the British Indian authorities had established a Fever Commission (of which Madhusudan Gupta – see above) was a member. Later "Burdwan fever" – a malignant febrile illness, generated a great deal of discussion, without any effective resolution of its nature and treatment. The use of Jesuit's Bark, Cinchona (quinine), was known and in fact had been used by Ayurvedic physicians since 1860. However it was not until Ronald Ross (1857–1932) working in the Presidency General Hospital in Calcutta established the life cycle of the malarial parasite in the mosquito that the disease was finally understood. Born in India and educated in England, Ross joined the Indian Medical Service in 1881. He was awarded the Nobel Prize in 1902. He left India for England in 1901 and died there in 1932.

In 1859, the prevalence of infectious diseases and a high mortality amongst Europeans in India had resulted in the formation of a Royal Sanitary Commission with Dr John Snow (who had written the book *On the Mode of Communication of Cholera* in 1855) as its chairman. In 1863 a Commission was setup to inquire into the Cholera Epidemic of 1861 in Northern India. With Robert Koch's identification of the causative organism in the water of a reservoir in Calcutta in 1884, the possibility of controlling cholera through sanitary measures became practicable. (Koch became a Nobel Laureate in 1905.)

Smallpox had been a devastating disease all across the world for centuries. Variolation – the introduction of live smallpox from a patient to a healthy person by scarification had been used for immunization for centuries. The Indian Medical Service accepted and used this method till the discovery of vaccination (the introduction of cow pox by scarification) by Edward Jenner (1749–1823) in 1796. Both variolation and vaccination were used in India for immunization for a while until the Smallpox Commission in 1850 stated that the latter was superior and safer than the former.

Research

Though Ronald Ross was the physician to get the highest accolades, the members of the Indian Medical Service carried on investigations into common local diseases. In later years some Indians (outside the IMS) also became well known for their research findings. Thus Sir U. N. Brahmachari discovered the cure for Kala-Azar (Leishmaniasis), and Sir K. N. Das was a pioneer obstetrician who wrote a classic text on the discovery, development, and use of the obstetric forceps.

In the 190 years of British occupation of India, the relationship between the colonizer and the colonized had equalized considerably. In 1887, Dr R. G. Kar and colleagues started the Carmichael Medical College as the first non-Government Medical College in the country. Today the R. G. Kar Medical College is one of the prime teaching and research institutions in the country. In the earlier half of the twentieth century, the medical programs in the country were more and more in the hands of the Indians, though postgraduate education abroad, especially in the British Isles was almost mandated for a teaching position and even for successful private practice. Indian physicians today occupy many prestigious chairs outside India, especially in English-speaking countries. This is one of the legacies of colonial medicine in India.

Colonialism and Medicine in the Malay Peninsula

Hairudin Bin Harun

The history of British medicine in the Malay Peninsula is synonymous with the history of tropical medicine. It is also a history of colonial medicine, which is a chapter of the history of British colonialism and imperialism in the East.

Three factors were crucial in determining the outcome of the struggles by colonial powers to expand and consolidate their empires in the East: sea-power, colonial settlers, and diseases. The nation that controlled the sea could occupy distant lands with ease. If there were conflict, sea-power enabled a colonial nation to intercept and prevent vital supplies from reaching rival colonies. Colonial settlers were important for political and economic reasons. A claim for the motherland could easily be made over an area well settled with colonial immigrants. Economic exploitation and control could be established by a network of colonial settlements, which also functioned as buffers against economic challenge and security threats from natives or rival powers. Finally, disease was of immense importance in moderating colonial expansion. Diseases could exact a heavy toll on the army, officials, colonial settlers, and their laborers or slaves. Malaria and yellow fever reportedly wiped out some of the British colonies in the tropics and Africa.

British colonial rule over the Malay Peninsula and Borneo Island (now Malaysia) lasted for more than a century. Their use of medicine as a strategic, diplomatic, and political tool to enhance their grip on the indige nous people and resources of the Malay Peninsula is well-documented. Medicine was also an instrument of colonial conscience, one aspect of which was the call to discharge "the white man's burden," including the task of "civilizing" the natives. In the Peninsula this entailed, among other things, the aggressive promotion of tropical medicine, and it contributed to Malayan negative perceptions of colonial medicine. Indeed, colonial medicine came to be perceived as a ruthless campaign to stamp out their traditional medicine.

In spite of that, colonial medicine could still claim success among the colonial laborers and urban dwellers, although among the natives and villagers the campaign seemed to have failed. There are several reasons for this. One was the preexistence of an elaborate traditional medical system. Second, the natives enjoyed better health than the imported colonial laborers, and even the colonial masters, many of whom were afflicted either with beriberi or malaria. Third, local traditional medicine was far more effective in treating some forms of tropical diseases.

The effectiveness of Malay medicine, however, was generally overlooked. It was difficult for colonials to accept that a primitive medical tradition could be equal to or better than colonial medicine. The official attitude further institutionalized such prejudices, as Malay medicine was officially perceived with contempt.

Since the beginning of British colonialism in the Malay Peninsula, combating tropical diseases was a priority. Initially, it was important to the officials and indentured colonial laborers, and it assumed a strategic and political dimension.

If one were to put a date on the genesis of British colonialism in the Malay Peninsula, it is likely to be 1786. This was when the East India Company took possession of Penang from the Sultan of Kedah. By 1830 the Company had added Singapore and Malacca to its inventory list, and by 1895, four of the richest Malay states in the Peninsula were under British influence. Throughout the period, the number of Britons sent to the area increased tremendously. The Peninsula's climate and geography, however, were harsh, and many of the early colonialists succumbed either to the heat or diseases. The large-scale importation of foreign indentured laborers, known then as *coolies*, was a significant feature of the period. They were crucial for economic and political reasons, but they were also decimated by diseases, especially malaria and beriberi. The result was a loss of productivity and a forced suspension of many economic projects. Thus, disease, or its absence, among officials, settlers, and coolies acquired an economic imperative; while health or the lack of it among natives acquired a strategic and political dimension.

During the colonial period, the course of events in the Peninsula was inevitably intertwined with that in England. The 1870s saw the emergence of a new political figure in Britain, Joseph Chamberlain (1836–1914). In 1893 he was appointed Secretary of State for the Colonies. He reorganized the Office from an ill-equipped, almost forgotten, department to one of the best around. Indeed, colonial appointments before he took office were seen as more akin to polite exile than glamorous jobs. Chamberlain changed that. He was able to infuse a new attitude, as well as a new policy, so that the colonial jobs gained the same respectability as home appointments.

As far as the history of colonial medicine is concerned, Chamberlain's most significant political act was his appointment of Dr Patrick Manson (1844–1922) as the Medical Advisor to the Colonial Office. Dr Manson was then the most distinguished authority in tropical medicine, which was then a marginal subject within mainstream medicine. The main concern of British medicine was the diseases of Europe, not of the tropics, and health policy was geared to serve home needs and rarely those of the colonies. Under Chamberlain, with Manson as the medical advisor, there was a reorientation of policy and priorities. The medical problems and health policies of the colonies were given serious attention. Soon Chamberlain's name became synonymous not only with the development of British colonialism but also with the development of tropical medicine. Indeed, under his stewardship, Britain's colonial fortune took a positive turn; so too did the health of Britons and the state of medicine in the colonies.

Chamberlain was forthright about the fact that British lives were more important to him than native lives. The participation of his ministry in the development of British tropical medicine was solely to ensure their welfare. The welfare of the natives was looked upon only in terms of Britain colonial interests, if ever. This policy was reflected in the establishment of the London School of Tropical Medicine in 1899. Its purpose was to foster research and development of the "new" British tropical medicine. The school was backed up by a number of research stations in the colonies, the biggest and most important of which was the Kuala Lumpur Pathological Institute, located in the Federated Malay States (British Malaya). The Institute was formed a year after the London School. Indeed, the rapid development of British tropical medicine in the early part of the century owed much to the linkages of the London School with the Kuala Lumpur Institute.

The Institute's founder was Sir Frank Swettenham (1851–1945), a charismatic colonial official who knew a lot about colonial and local politics but next to nothing about medicine. Swettenham's tenure coincided with the period of intensive colonial economic activities in the Malay States. These were sustained mainly by the extensive importation of coolies from abroad, particularly from China and India. As indicated earlier, this importation was important for both economic and political reasons. It showed the native Malays that the British could easily handle any boycott by local labor; but the importation soon hit a snag. Many of them were decimated by unknown diseases, one of which was later identified as beriberi.

Owing to the epidemic, the local colonial administration was burdened by thousands of sickly and unproductive coolies. A search for a beriberi cure was imperative. Swettenham had come to know about the interest at the Colonial Office regarding tropical diseases, and about the plan to set up a school of tropical medicine in London, but he also knew that the

School's priority was research on tropical diseases afflicting European communities in the tropics. In the Peninsula, however, beriberi was a non-European disease. Swettenham was aware that it was extremely difficult, if not impossible, to persuade the Colonial Office to allow it to devote a portion of its research time and money to beriberi. It was at this stage that he toyed with the idea of a local institution modeled after the school, which would facilitate the search for beriberi's cure.

In London, luck seemed to be on his side. Swettenham's plan for a local medical research institute was received positively. It was seen as simply the compliance of a colonial official to London's policy on tropical medicine. Such plans from distant colonies normally received an impersonal go-ahead signed routinely by nameless individuals on behalf of the Secretary. Instead, Swettenham's plan came to the attention of Chamberlain, who personally signed the authorization papers for the Institute. At home, Swettenham did not bother to wait for the official go-ahead; he had made arrangements to set up the Institute even before Chamberlain had signed the order.

Perhaps owing to the excellent staff, the Institute lived up to its expectation. It was able to come up with the cure for several tropical diseases, including beriberi. The riddle to the latter was conclusively resolved exactly 9 years after the founding of the Institute. Thus it succeeded in alleviating the colonial authorities from one of the major causes of the local economic and social problems. The Institute was a bastion of colonial medicine, and far removed from the practices of traditional medicine. Notwithstanding that, some of the major breakthroughs of the Institute were affected directly or indirectly by the latter. For instance, in the search for the cure of beriberi the Institute's scientists looked to traditional cures for clues, and indeed found a lead in Malay medical practices. Colonial pharmacologists examined and benefited greatly from the Malay materia medica, particularly in the search for new drugs and alkaloids. Institute authorities still were extremely reluctant to acknowledge any hint of contribution by native medicine, especially in advancing tropical medicine.

To understand the events that followed, it is necessary to take a brief look at the prevailing colonial health policy, particularly with regard to the natives. There were several discernible phases. The initial phase placed the emphasis on the health of the officials and laborers with no regard to the natives. The second phase involved the missionary zeal to promote colonial medicine among the natives and other non-European inhabitants of the colonies. The *Ordinance to Provide for the Registration of Medical Practitioners in the Colony* (1905) was passed to control the practice of medicine, by stipulating minimum qualifications for those who wanted to practice medicine in the Malay States. On the face of it, the Ordinance seemed to spell a blow to traditional medical practitioners, particularly the natives and the Chinese, but interestingly, the Ordinance carried with it an exclusion clause:

> Nothing contained in this Ordinance shall be construed to prohibit or prevent the practice of *native* systems of therapeutics according to Indian, Chinese or other Asiatic method.

Throughout the British rule the native Malays relied extensively on traditional medical systems for their medical needs. The backbone of the traditional system was the medicine man, *bomor*, or *pawang*. They did almost everything, from preparing herbal medicines, setting dislocated bones, and delivering babies, to variolation and minor surgery like circumcision. Occasionally, Europeans sought treatment from the *bomor* and claimed that they were cured of their ailments by the Malay medicine man.

Evidently, colonial medical officials were intrigued by the ability of the native Malays to live a healthy life in the tropical climate. Many noticed that the native Malay view of nature was totally different from theirs. Nature or the land was treated by the Malays with respect, regarded more as a living or spiritual being than a thing, and more like a member of their family than an artifact of convenience. The Malays maintained a relationship with their land in what one would describe now as balanced ecological relationship. In fact, the need to seek harmony and equilibrium was central to their view of disease and health. Nature was multidimensional and hierarchical, having both a metaphysical and physical dimension – reflecting the spiritual and physical constitution of man. Their doctrine of diseases and health reflected the belief that health was a manifestation of the harmony of human's inner constitution and nature's constitution; disease was the result of a lack of harmony.

The complexities and intricacies of the Malay medical doctrines were left much to themselves. Occasionally they became objects of anthropological curiosity by colonial scholars. However, this attention was academic; no medical officials or policy makers seemed interested in knowing more about Malay medicine or the Malay medical system. It was not until the later stage, the missionary zeal phase, that they began to take notice of Malay medicine. At this stage, however, Malay medicine was seen more as a rival than a complement.

The effort to introduce colonial medicine to the Malays was apparently a frustrating task to the majority of the colonial officials. Frequently, they expressed their frustrations at what they alleged was the Malays' indifference to "superior medical treatments." For instance, the Colonial Resident Councillor of a Malay State remarked:

> If a Malay thinks he is going to be kept in a hospital, he will not apply for medicine as an outdoor patient and will prefer to remain in his own house and be treated by a Malay doctor on simple herbs, together with a judicious supply of still simpler incantations. (Harun, 1989)

The Colonial authorities also took active steps to restrict the practice of Malay medicine men. This perhaps can be best seen in the checking of the traditional inoculation or variolation practice. Variolation was widely practiced whenever smallpox broke out in a village. It involved the direct inoculation of smallpox virus treated with certain medicinal herbs. Colonial doctors described it as "a barbarous practice," and the practice was targeted for curtailment. In 1905, when smallpox broke out in the eastern Malay state of Kelantan, the Government enforced a law banning variolations. In their place, they introduced large-scale vaccinations. The authorities also recruited some traditional inoculators as "assistant vaccinators," although the actual task of vaccination was undertaken by the colonial medical department.

To the Malays, the inoculation rituals sanctioned by their traditional culture were much preferable to vaccination. Their acceptance of colonial medicine lagged behind official expectation. In fact, the authorities noted a decrease in the number of natives seeking medical treatment at colonial clinics. They realized that the campaign to promote colonial medicine among the Malays would fail unless their confidence was won over.

The new campaign strategy perhaps can be best seen in the work of Dr Gimlette. He was a colonial medical officer best known for his sympathetic and detailed study of Malay medicine which was originally part of the new campaign. By the time he finished, it had taken an unexpected form. For all practical purposes, it had become a crusade for the preservation of Malay medicine. Gimlette, probably to the displeasure of his superiors, openly urged the colonial authorities to soften their attitudes toward the *bomors*. Indeed he argued that "it would be unfair to damn him [the *bomor*] as an accursed sorcerer who poisons honest folk to gain his private ends." Gimlette even drew parallels between the practice of colonial doctors and that of the medicine man:

> It is too much to say that the work of the bomor in clinical medicine is merely fanciful; he endeavors to prepare a *penawar*, that is to say a "neutraliser," for every kind of poisonous principle; this idea of neutralization distinctly anticipates modern science. His knowledge of local materia medica is often profound, and after all, some of his theories as to the etiology of tropical diseases are conceptions now known to modern science in the form of animal parasites (protozoa, spirochaetes, etc.), which are invisible except under high powers of microscope.

Gimlette also claimed that Malays knew mosquitoes were the cause of malaria, evidently earlier than Manson. According to Gimlette, Malays' apparent resistance to malaria was largely owing to their knowledge of mosquitoes. For instance, the Malay traditional ritual of smoking their homes and villages through the burning of *padi* (paddy) straw during harvest season effectively expelled mosquitoes in their homes or in the surrounding area. Malays also bred fish in their *padi* fields during the flooding period. This practice was akin to a form of biological control of pests, since the fish preyed on small organisms and thus destroyed all the mosquito larvae breeding in the *padi* fields. The Malays also practiced selective clearing of jungles as another form of mosquito control. Gimlette was convinced that the secret of Malays' resistance to malaria or "harmony" with mosquitoes, lay in their practice of such rituals.

It is not known what the actual reaction to Gimlette's views was, particularly within the colonial medical establishment. It is likely that his views would have caused some uneasiness among officialdom. Gimlette assigned a common level of legitimacy to Malay medicine and colonial medicine. It is interesting to note that soon after the publication of his book on *Malay Poison*, Gimlette retired in 1921 from the Colonial medical service. He returned to England and embarked on a project to compile a dictionary of Malay folk medicine. Because of ill health, the project was not completed. However, his friends, Thomson and Skeat, took over the project and completed the manuscript, which was posthumously published in 1934 as the *Dictionary of Malayan Medicine*.

The official version of the development of colonial or tropical medicine was no different from the history of medicine. The motives were Hippocratic idealism and the fanatical dictum that there should be no mention of nonscientific or nonmodern contributions to the development of modern medicine. Understandably, the Malay's contribution to the development of colonial medicine in the Peninsula was largely ignored.

The prevailing colonial view stereotyped native medicine as nothing more than primitive panaceas or "snake-oil cures." However, studies like Dr Gimlette's challenged established prejudices and institutionalized misconceptions. They established that native medicine was a storehouse of perennial wisdom, and collection of empirical observations of scientific significance. Still, Malay medicine was often referred to contemptuously in colonial discourse.

No branch of modern science can be said to have developed almost exclusively under colonial ideological and political impetus than tropical medicine.

Colonialism and Science

Michael Adas

From the very first decades, scientific advances played essential roles in European overseas expansion. Improved astronomical instruments and calculations and an array of new navigational devices and cartographic techniques made the Portuguese voyages into the uncharted South Atlantic possible. Subsequent voyages of exploration and (for the Europeans) discovery led to further refinements of both instruments and navigational data and stimulated the introduction of ever more sophisticated ways of measuring time, distance, and location. Scientific curiosity was among the main motives of Europeans who planned or led expeditions of discovery and conquest. Astronomers and cartographers often sailed with explorers and merchants for the express purposes of testing new instruments, taking astronomical or meteorological readings from distant latitudes, and charting regions that had hitherto been unknown to the Europeans. The application of the data gathered on these voyages to improving maps, to compiling more accurate navigational charts, and to devising new instruments greatly enhanced European advantages over other peoples in navigation, trade, and warfare by sea.

As European armies and administrators advanced inland, first in the Americas and the outlying island of Africa and Asia and later throughout the globe, botanists and geologists followed, collecting "exotic" specimens to carry home to the gardens and cabinets of their rulers and national scientific societies. European savants examined and classified the bewildering mass of information and objects that flowed in from the rest of the globe, and struggled to fit it into the preexpansion world picture; or, more commonly, used it to build a new vision of both the earth and the cosmos. A host of self-appointed, usually amateur, ethnologists also reported extensively on the diverse peoples and cultures they encountered overseas. Their observations became the basis for elaborate, allegedly scientific, and invariably hierarchical classifications of human types. These classifications in turn provided evidence to support highly contentious theories regarding the relationships among human groups, usually termed races, and between humans and other species, particularly different varieties of apes.

Both in Europe itself and increasingly (but on a much reduced scale) in colonial enclaves overseas, scientific institutions – such as the Hortus Botanicus in Leiden, Kew in London, and the Sibpur botanical gardens in Calcutta – served as clearing houses for flora and fauna collected from around the globe and focal points for taxonomic inquiries and experimentation in procreation and hybridization. The elected members of Europe's scientific societies, most notably London's Royal Institution and the Académie des Sciences in Paris, provided the backing to mount scientific expeditions, certified that what were regarded as scientific procedures had been followed by the explorer or naturalist in question, and made the findings of overseas investigations available to the educated public of their respective nations and the European scientific community as a whole.

From the outset the scientific side of the process of European overseas expansion was all but monopolized by one of a number of approaches to the natural world that had jostled for supremacy in the medieval era and coexisted in the West since ancient times. The predominance of what recent scholars have characterized as the Baconian or mechanistic strain of scientific thinking in European colonial enterprises was of special importance. It meant that other options, such as the organic approach to nature and the cosmos, which might have been more compatible with and accommodating toward non-Western epistemologies, were excluded or relegated to marginal roles in this critical area of interaction between European and non-Western peoples and cultures.

The key attributes of the dominant Baconian or mechanistic strain of Western science rendered European colonial observers and policy-makers particularly unreceptive to non-Western ways of thinking about and interacting with the natural world. The underlying assumptions of the Baconian approach also strengthened the resolve of those among the colonizers who were ironically the most concerned with the well-being of the subjugated peoples to impose Western epistemological presuppositions and standards and procedures of investigation on colonized peoples. Though there were important differences among those scientists who adhered to the Baconian mode, it is possible to distil a number of key attributes that most colonial theorists and administrators would have agreed characterized the proper, or Western, approach to scientific thinking. Though developed in the West and shown by recent research to have been vitally affected by the social and cultural milieux in which it arose, the science carried overseas by European colonizers was seen to be value neutral, objective in its procedures, privileging abstraction and reason, empirically grounded, and somehow transcending time and space and thus universally valid. These attributes gave the practitioners and advocates of Western science confidence that the spread of this epistemology – and the institutions and procedures associated with it – to the rest of the peoples of the globe was both beneficial and inevitable.

This view is, of course, still held today by many scientists as well as development specialists, social theorists, and assorted intellectuals with an interest in the so-called Third World. Its champions among the colonizers viewed the diffusion of Western science as part of a larger campaign to rationalize the world and conversely to banish what they viewed as superstitious or subjective, intuitively oriented epistemologies. Although only the most reflective and outspoken colonial observers would have acknowledged it, Western science was also aggressively expansive and intolerant of rival non-Western epistemologies – just as it had been of alternatives in Europe itself. By the early nineteenth century, it was also inextricably linked to the great technological advances that drove the Industrial Revolution, and the market-oriented, fossil fuel intensive, interdependent global order that was associated with the resultant transformation of the West. Thus, the Western scientific approach proved to be quite compatible with prevailing Western hegemonic ideologies, such as the *mission civilisatrice*.

Despite attempts to develop general paradigms for the diffusion under the aegis of European colonial domination of Western science, its role in the process of colonization and its impact on non-Western peoples and cultures varied widely by time and place. Important differences can be seen, for example, in the scientific fields and types of investigations that were prominently associated with overseas colonization before and after the Industrial Revolution. In the early centuries of exploration European scientists overseas were mainly preoccupied with astronomy, zoology, and botany. As Western Europe's need for markets and raw materials grew with the spread of industrialization, fields like meteorology, geology, chemistry, and applied mathematics became increasingly integral to the colonial enterprise. As European colonizers came to administer much of Africa and Asia directly, more sophisticated techniques of surveying, codifying, and statistical gathering became essential for activities as diverse as revenue collection and the formulation of legal codes. Recent scholarship has also shown that the relationships between colony and metropolis in terms of scientific investigation and exchange also shifted dramatically after World War I. These transformations were accelerated in the interwar years and after World War II by the process of decolonization, and a concomitant shift from an emphasis on extraction to a fixation with the rhetoric of development, which became enshrined in modernization theory after 1945.

The process by which Western science was diffused and its impact on overseas societies also differed greatly depending on the timing and nature of European interaction with non-Western cultures, the colonizers' assumptions about the level of sophistication of indigenous epistemologies and material cultures, and the actual attainments of colonized peoples in science and technology. The process of Western scientific diffusion, for example, in settlement colonies such as Australia and Canada, that had relatively small and scattered autochthonous populations, followed a very different course than in densely populated areas, such as South Asia and China, where small communities of European administrators, missionaries, and merchants encountered highly developed scientific and technological traditions with ancient links to their own.

Even within the different types of colonial societies there were critical variations. Thus, for example, the New World colonies in both Latin and North America, which were the first areas of extensive European conquest and large-scale settlement, were the sites of significant scientific investigations and developed their own scientific societies as early as the eighteenth century. By contrast, Australia and New Zealand were not settled until the following century and were not integrated into the scientific networks of their European metropolis, Great Britain, until the late 1800s. In addition, from as early as the late seventeenth century, the pursuit of science was stunted in much of Latin America, as compared to Canada and the United States, due to Spain's long political and economic decline and its increasing marginalization as a center of scientific learning.

None the less, in all of the settlement colonies, indigenous learning, and epistemologies were pushed to the periphery. Ethnologists studied "aboriginal" beliefs and traditions for their folkloric or antiquarian value, not because they had anything to teach the colonizers about the ecology or topography of the lands they occupied, much less because they might stimulate major modifications in European understandings of the natural world. The research agendas of all of the settlement colonies were also largely dictated by the savants of scientific societies and institutions of higher learning in Europe itself. Though the size and the close links of the elite in the United States to Europe made original work by colonial scientists, such as Benjamin Franklin, more likely than in other settlement areas, until the early twentieth century settler colonists were primarily engaged in applied field research, heavily focused on the collection of local flora and fauna samples. Much of this work was directly linked to efforts to uncover and extract the great natural wealth of settlement areas. The empirical findings of New World botanists, geologists, or ethnologists, who were often merely temporarily transplanted Europeans, were mainly funneled to scientists in European centers for interpretation and theoretical elaboration.

After about 1900, scientific connections between European centers and settlement areas – both those still formally colonized and those, such as the United States, long independent – were radically transformed. Dominions, such as Canada and Australia, were accepted as partners, rather than assistants, in international scientific inquiry. The settlement areas more generally emerged as important centers of scientific research and theoretical innovation in their own right – as evidenced, for example, in Frederick Banting's discovery of insulin in Canada and Macfarlane Burnet's work on immunology in Australia. This was particularly true of the United States, where the already substantial growth of an internationally recognized scientific community early in the twentieth century was greatly accelerated in the 1930s by the forced migration of leading scientists from Europe, such as Albert Einstein. By the 1940s, this former colony and settlement area had taken the lead in many areas of scientific endeavor, from the most abstract theory to applied research.

In comparison with the tropical dependencies, where small numbers of Europeans ruled large and ancient African or Asian societies, the diffusion of Western science to the settlement areas met with little serious resistance. To begin with, the transfer was overwhelmingly to settler populations of European origins and heritage. This meant, on the one hand, that questions of racial ability with regard to the development of scientific communities and institutions in colonized areas did not arise, even though the arrogance of metropolitan savants was often a source of considerable discomfort for the colonials. On the other hand, because the dominant settlers despised and marginalized or discarded altogether the epistemologies of the indigenous peoples, there were no alternative thought systems or ways of doing to rival or provide foci of resistance to hegemonic Western scientific approaches.

Scientific friction between metropolis and settlement colony arose from personal and institutional rivalries, but scientists in both locales shared epistemologies, methodologies, and presuppositions about the place of humans in the natural order. Local resistance came not from subjugated indigenous peoples defending their own, very different traditions, but from the poorly (or un)educated majority of the settler population. The latter were not so much opposed as indifferent to the endeavors of a rather isolated scientific elite, whose labors appeared to be wasted unless they could be turned to some immediate practical advantage. Thus, the key challenge for the scientific communities in the settler colonies was expanding popular understanding of and approval for scientific research, and winning government funding for scientific institutions and projects. Evidence of practical application was key to success in these endeavors, and thus a premium was placed on applied research, at least until the middle of the twentieth century.

The linkages between science and colonization in nonsettler areas of Africa, Asia, and Oceania, where small numbers of Europeans dominated large and diverse colonized populations, were markedly different than in Australia or the United States. Here it is important to distinguish between areas that the Europeans conquered outright and ruled directly, such as India and much of sub-Saharan Africa and Southeast Asia, and those they dominated indirectly or "informally" through military threats and periodic interventions, economic influence, and the manipulation of indigenous leaders. The latter areas would include most of the Islamic Middle East, Persia/Iran, China, Siam/Thailand, and Japan – until it became a Western-style scientific and technological power in its own right in the early twentieth century. Even within these two general categories of nonsettlers, critical distinctions need to be taken into account. Colonial policies regarding the diffusion of scientific learning and investigation, for example, were quite different in British India or French Indochina than in most of sub-Saharan Africa or the islands of the Pacific, even though all of these areas were formally colonized. Within the indirectly controlled areas in the informal spheres of influence, the European approach to Islamic societies in scientific matters differed in important respects from their interaction with China, Japan, or Thailand.

In some ways the diffusion of Western science in some formally colonized areas like India shared more with informally controlled areas, particularly China and the Islamic Middle East, than with Africa or the Pacific, which were ruled directly. In India, China, and the Middle East, the European colonizers recognized not only that the indigenous peoples had produced ancient and sophisticated civilizations – which usually meant that they had certain key attributes, including writing, specialized elites and cities – but that they had long nurtured scientific traditions of their own. Informed European observers even acknowledged that the West owed a large debt to Islamic peoples both for the recovery of much of classical Greek learning that had been "lost" to European civilization after the fall of Rome, and for original scientific advances made by Muslim peoples and transmitted to Europe through Arab and Jewish scholars in Spain and Italy. A handful of European observers also recognized that Islamic civilization had served as a vital conduit of scientific learning and inventions from civilizations further east, particularly India and China.

Recognition of the earlier scientific achievements of selected non-Western peoples informed the attitudes of European colonizers towards the diffusion of science in the societies so designated in important ways. In the early centuries of European overseas expansion, it fed mutual curiosity and ongoing interchange. The first Jesuit missionaries in China, for example, evinced a strong interest in Chinese astronomy, chemistry, and medical techniques. In India, Portuguese and later Dutch merchants and officials routinely consulted Indian physicians well into the eighteenth century. European physicians not only studied the prescriptions and techniques of Indian *vaidas* and *hakims*; they readily conceded the superiority of indigenous specialists in treating tropical diseases.

By the early decades of the eighteenth century, most European observers had concluded that even the most advanced, non-Western scientific traditions were hopelessly outdated and encrusted with superstition and quackery. If it survived at all, recognition of non-Western achievements was focused on the distant past. In the accounts of European authors who concerned themselves with matters scientific or technological, the stagnation of Indian or Chinese learning, in stark contrast to the ever-changing and highly progressive advance of Western knowledge, was a constant refrain. In areas that escaped direct colonization, particularly China and Japan, scientific knowledge and technological expertise had been and remained the most effective ways for gaining access to Asian rulers and impressing Asian elites with the efficacy of Western ways, which seemed otherwise dubious, if not crude. None the less, the sense that peoples like the Chinese and Japanese had long been civilized and had once excelled in science and technology deeply affected the educational policies pursued by Christian missionaries, when they were permitted to proselytize in these areas, and the trading policies and diplomatic exchanges of the great powers. Japan as a whole closed in on itself after 1600, but Dutch traders at Deshima continued to make the latest European scientific treatises available to an emerging Japanese literati. Christian educators in China frequently pushed advanced training in the sciences (particularly medical) and mathematics. By the late-nineteenth century, regionally based segments of the Chinese scholar-gentry were avidly importing Western technologies in "self-strengthening" campaigns designed to ward off the imperialists' partition of the Middle Kingdom.

From the mid-nineteenth century similar patterns of diffusion can be found in other non-Western areas, which the Europeans regarded as long civilized but where they increasingly exercised informal sway. French missionaries strove to impress their Lebanese students with the superiority of Western scientific learning, while Siamese rulers strove to educate an elite corps in the engineering skills of the West. Because their own scientific traditions shared much with those of the Europeans – not the least a common, extensive borrowing from the ancient Greeks – the approach of the Muslim peoples of the eastern Mediterranean to these interchanges was somewhat different from that of the Siamese or, most critically, the Chinese. Having given so much to the West in the sciences, Arab and Turkic reformers could claim that it was in no way demeaning for Muslim peoples to borrow back in order to catch up to their European rivals. Though not all accepted this argument, it made the introduction of Western scientific learning palatable for those who supported advocates of forced "modernization," such as Muḥammad ʿAlī in Egypt and the Ottoman ruler Mahmūd II. Unable to make a convincing argument for such historical precedents, the Confucian literati of China vehemently resisted the introduction of Western learning or reluctantly conceded its necessity in the name of China's survival.

Although similar tensions were present in formally colonized areas that had longstanding scientific traditions, such as India, decisions about how much and what sort of Western scientific and technological diffusion should occur were taken out of the hands of the indigenous peoples. Colonization resulted in a growing influx of European scientists, engineers, and medical practitioners, and a great expansion in their activities and influence. The collection of flora and fauna that antedated colonial rule continued and in

C

some respects expanded, but trained scientists and technicians were now employed by colonial administrations for massive and systematic geological and land tenure surveying operations. Statisticians oversaw census counts; botanists tested new plant varieties in state supported gardens; and hydrologists directed the overhaul and expansion of irrigation systems. As these activities suggest and scholars from formerly colonized areas have recently argued, science was a central pillar of the European colonial order.

Colonial science was also field-oriented, overwhelmingly applied, and devoted primarily to enhancing efforts to maximize the extractive potential of conquered areas. Its diffusion to the colonized peoples was consciously channeled and often constricted out of security concerns or fears of future economic competition. Rather than an abstract, objective and dispassionate concomitant of colonial expansion, Western science was the linchpin of rationalizing offensives that sought to reshape the thinking of colonized peoples, reconfigure the spatial relationships in colonized areas, and remake institutional frameworks and social relations in ways that accorded with Western epistemologies and presuppositions about the logical order of things.

Much of the literature on the diffusion of Western science in the colonial empires has concentrated on the biographies and activities of European scientists and on the policies pursued by European colonial administrators. As a consequence the varied and critical roles played by the colonized peoples in the dissemination of Western scientific learning and techniques have been obscured. At a range of levels, their contributions were essential. In the era when naturalists were dominant, the collection and identification of specimens would have been difficult, if not impossible, without Javanese or Indian guides and assistants, and villagers who were vital repositories of local knowledge about animal life or the rain forest. Working in the celebrated miniaturist tradition that peaked under the Mughals, Indian artists sketched flora and fauna in the field and often illustrated the published collections on these subjects that remain standard references to the present day.

As the grip of colonial administrations tightened from the middle of the nineteenth century, subjugated peoples found new ways to become involved in the scientific enterprises that buttressed the new order. Indian surveyors, engineers, and medical practitioners served in colonial administrations both in South Asia and British colonies in Africa and Southeast Asia. Indian chemists, physicists, and biologists worked for British firms, traveled to Europe for advanced study or to take up research positions, and increasingly taught in one of a growing number of universities in India itself. Indian doctors and surveyors set up private practice in colonial towns.

The assumption of many of these roles depended on the spread of higher educational opportunities open to Indians in the sciences and mathematics. The very existence and steady expansion of these opportunities underscores a vital difference between India and most of the other colonized areas. Here again, the colonizers' recognition of precolonial scientific attainments proved critical. The work of Sir William Jones and other "Orientalists" in the late-eighteenth and early nineteenth centuries left little doubt that ancient Indian civilizations had excelled in many of the sciences and mathematics. Though increasingly disdainful of these achievements and impressed with contemporary Indian backwardness in matters scientific and technological, key colonial officials who strove to reform Indian society premised their educational initiatives on the assumption that Indians could master the most advanced Western scientific learning and mathematical techniques. This assumption and the policy decisions regarding higher education that followed gave Western-educated Indians much greater agency in the process of the diffusion of Western science than was enjoyed by any other colonized people. By the last decades of the nineteenth century, racist objections to these policies were raised by both prominent officials and private individuals. However, the path breaking work done by such Indians scientists as Ray and Bose made a shambles of the racists' aspersions, and bolstered the demands of Indian nationalists for greater opportunities in higher education, particularly in the Western sciences.

With the partial exception of colonies like French Indochina and the Netherlands Indies, opportunities for advanced training in the Western sciences in much of the rest of Asia, sub-Saharan Africa, and the Pacific islands were minimal or nonexistent. In these areas, scientific work was the monopoly of the European colonizers. As in settlement areas, such as Australia and the United States, indigenous epistemologies and local knowledge were dismissed as irrational, ignorant, and superstition-bound. These might be studied in order to understand the "native mind" to control the colonial populace better. However, they had nothing to contribute to Western scientific learning or methodology. Thus, in most nonsettler colonies, which the Europeans deemed devoid of scientific traditions of their own, racist assumptions regarding the mental capacity of the indigenous peoples insured that little or no advanced training in science or mathematics was available. These policies in turn left most colonized peoples ill-prepared for a postcolonial world where Western scientific knowledge and skills have proved vital for successful economic competition, development planning, and many aspects of intellectual discourse.

The colonizers' disdain for indigenous epistemologies and approaches to the natural world has also obscured a number of other important patterns involving the interaction of science and colonialism. However extensive or limited the volume of Western science diffused to different colonies, in all there was a persistence of indigenous scientific thinking and practices. In some cases the colonizers themselves were complicit in this process, as when the British made use of Indian *hakims* and *vaidas* in their campaigns to eradicate epidemic diseases, such as smallpox and cholera in India, or when merchants or officials in Africa resorted to local cures for snakebite or dysentery. In some colonies, most notably India but also in Kenya, Senegal, Indonesia, and other areas, the defense of indigenous epistemologies and procedures was explicitly linked to the nationalist assault on the European colonizers. In the thinking of visionary leaders, such as Mohandas Gandhi, the restoration and reworking of these traditions posed what well may be viable alternatives to the approaches to economic and social development championed by the industrial West.

In virtually all of the formerly colonized societies, non-Western approaches to science in areas as diverse as medical practice, preservation of soil fertility, and care for the emotionally disturbed have persisted. In view of the clear limits in terms of resource exhaustion, environmental degradation, and social inequity of both major Western development alternatives – market-capitalist and socialist command economy – this persistence may ultimately prove critical. It may be that the predominant direction of scientific diffusion will be reversed; that approaches to work, resource use, social organization, and economic well-being pioneered by Gandhi and other non-Western thinkers will have much to offer the beleaguered societies of the postindustrial world.

Colonialism and Science in Africa

Gloria T. Emeagwali

By 1914, most of the African continent had been subordinated to colonial rule, with 36% of African territory seized by the French, 30% by the British, and the remaining 34% dominated by Belgium, Germany, Italy and Portugal. This of course was not done without bloodshed. Millions of Africans died in the process of resistance against the invasion of the continent, waging guerrilla warfare for as many as 30 years in some cases. Colonialism was essentially a process of administration which denied Africans political and economic autonomy while subordinating them to the dictates of an evolving global capitalist ethic and world market controlled by a Euro-American elite. Indigenous science and technology were adversely affected by it. Ironically though, institutions such as the British Imperial Institute, through its Scientific and Technical Department, actually aided in the transfer of existing scientific and technical know-how from the colonies to the metropole.

One of the major effects of colonialism was the subordination of science and science education to the logic of colonial production and class structures. Science and technology development in most cases ceased to emanate from the womb of African civilization and indigenous problem-solving and experimentation. A new set of norms, values and relations of production was introduced and superimposed on existing precapitalist structures. In so far as colonialism was an exploitative system geared toward the redeployment of resources in the form of mineral and agricultural wealth, from the periphery to the center, it necessarily led to the destabilization of existing processes of accumulation of knowledge and technique. Colonial capitalism was geared primarily toward the export of surplus from the continent, and colonial education was to focus primarily on the creation of a new collaborative, nonthreatening elite supportive of the colonial agenda and committed to the running of the colonial (and neo-colonial) machine. It was less geared to innovation and creativity than to servile complicity.

References to glass-making and iron fabrication may illustrate the extent to which indigenous capability was undermined. As a consequence of the relatively cheap glass products from Europe dumped on the Nigerian market, indigenous glass producers ceased to produce glass from local raw materials such as silica and potash and proceeded to simply re-smelt and refashion imported European glass objects. In the case of iron there was a deliberate attempt to undermine indigenous initiative by the introduction of the “scrap iron policy” whereby metal designed as “scrap” was imported into the region from Britain. It has been argued that this policy was a deliberate attempt on the part of the British to replace iron products with those from European factories. The policy succeeded in strangulating the local metallurgical industry and arrested the further development of indigenous technology in this field.

The Scientific and Technical Department of the British Imperial Institute, located in London, was aimed at the acquisition of knowledge with respect to various indigenous technologies through experimental research, technical trials, and commercial valuation from within the vast colonial domain, including African colonies. The Institute consisted of a series of well-equipped research laboratories, and a supporting staff of trained scientists and researchers kept active in the analysis of natural and manufactured products from the colonies. Specific attention was placed on medicinal plants and it was explicitly stated that the numerous plants held in high repute as medicinal agents in the colonies should be investigated both as regards their active ingredients and their medicinal value. The above guidelines led to experimentation on *Khaya senegalensis* and a variety of Guinea corn, amongst others, plants held in high repute by indigenous experts. Traditional medicinal knowledge, integrated into the British scientific laboratory, was in fact a contributing factor in pharmaceutical development in the metropolitan center in the first three decades of the twentieth century. Research activity was not confined to medicinal plants, however, and one of the areas of investigative research was textile, specifically silk. Loni or Boko silk from Bauchi, Nigeria was one of those products analyzed. An up-to-date display of the various research findings was kept in the Galleries of the British Imperial Institute, London, and was of particular interest to merchants and industrialists on the look out for new products. Details were provided on application to the Commercial Information Office of the Institute or other authorized officers.

It is clear therefore that colonialism had far reaching implications for both the colony and the metropole. It weakened indigenous African capability with respect to experimentation, problem-solving and the creation of indigenous utilitarian objects and processes. At the same time though it facilitated the transfer of knowledge from Africa and other colonial dependencies while leaving in return an education system more geared to the reproduction of Christian religious norms and values and alienation than the further development of scientific and technological capability.

Colonialism and Science in the Americas

Ubiratan D'Ambrosio

When the Europeans arrived with Christopher Columbus, they found that the set of explanations and dealings with natural realities that constituted the scientific knowledge of the peoples of the newly found lands absolutely novel. They marveled at the constructions, urban organization, clothing, and ornamentation of these peoples, mistakenly called Indians. To explain and understand what they were witnessing, European knowledge was not appropriate. The surprise was total.

Viking traders, and probably some other European, Asian, and African navigators, had previously visited these lands. There is evidence of this in or about the tenth century, but the records of these visits did not reach what we call the official literature.

The Portuguese were the most advanced people in Europe in navigational knowledge. People interested in navigation would study at the court of King Dom Joào II, in Lisbon, and frequent the entourage of the Infante Henrique, his son in charge of the navigation projects. Astronomers, ship builders, and pilots from all over the world were there. Among them was Martin Behaim, who, upon returning home to Nürnberg in 1490, was asked by his city authorities to produce a report on his studies abroad. He presented this in the form of a model of the Earth: a globe which he called the *Erdapfel*. There, between Europe, Asia, and Africa, shown in a detailed picture, lay a vast mass of water.

Surely views like this convinced Christopher Columbus, also a student in the court of Dom Joào II, of the possibility of reaching Cipangu and the domains of Grand Kahn. He convinced the King and Queen of Spain, Fernando and Isabel, who financed a fleet of three ships, which left Palos, near Seville, on 3 August 1492. On 12 October 1492 they landed on an island called Guanahani in the language of its inhabitants. They did not recognize where they had landed; Columbus and the others believed they had reached Asia. The early days of the conquest and first encounters with the natives are related in descriptions of the conquest, by Columbus himself and by other chroniclers.

What the Spaniards encountered, as far as science and technology are concerned, is described in the article on "Americas: Native American Science" in this encyclopaedia. The centuries preceding the arrival of Columbus saw a political process very similar to the one which took place in Europe in the Middle Ages, when principalities and other smaller domains were uniting into larger organizations such as kingdoms and nations. The Spanish conquerors were able to destroy the emergent power elites and replace them with the power of the conqueror, based on a well-balanced State-Church structure controlling the means of production.

In Central America there was a tax system based on collecting products, while in the Inca Empire tax was paid in labor. We can identify something that approaches private property and commerce in the Aztec model, while among the Incas the State is all powerful in the economy. Recent research reveals important commercial development in the coastal area of Peru and the beginnings of economic uses of sea resources. Although by and large the economic practices are similar to those in Europe, there is no indication at all of something that resembles capitalism. Maybe these are examples of noncapitalist economies. It is important to note the relatively low use of technology in agriculture. For example, they had no plowing devices and practically no fertilizers. Thus, production relied more on human factors, such as a more attractive division of lands with well-coordinated forms of cooperation and control of distribution, than on the intensive use of technology. At the same time, a considerable intervention of the state in major infrastructures such as irrigation and roads, associated with a rather efficient tributary system, indicate economic models which differ from those in the Old World (Europe and Asia). This is an important area of scholarship.

This was the situation the conquerors encountered when they met the highland civilizations. Before that two of colonial settlements had been created in the Dominican Republic: Isabela in 1494, and Santo Domingo in 1496. In the beginnings of this process, with agriculture depending on Indian slave labor, local tribes were exhausted. This caused slave-hunting expeditions to the other islands of the Caribbean. To the South, the arrival of the Portuguese Pedro Alvares Cabral in Brazil led to an exploratory mission by Amerigo Vespucci, in 1501, under the Portuguese crown. The establishment of colonial settlements waited until 1532, when Martim Affonso de Sousa founded Sào Vicente in coastal Brazil. In 1534 the Portuguese king divided Brazil into large areas, the *capitanias*, mostly coinciding with the current coastal states of Brazil, and with the right of property to be inherited. This family distribution of the lands of Brazil established much of the style of land possession in the Portuguese colony.

Meanwhile, the search for slaves led the Spaniards to found Puerto Rico in 1508, Jamaica in 1509 and Havana in 1511. From there to Florida was a small step for Juan Ponce de León in 1513. The exploration of the coast of the Gulf of Mexico by Alonso de Pineda was completed in 1519. Also, Vasco Nuñez de Balboa led the remnants of the failed expeditions of Alonso de Ojeda and Diego de Nicuesa to Colombia and Panama to the Pacific Ocean and the founding of Panama in 1519. From there the exploration of the Central America and Mexico and incursions to South America were obvious steps. Founding several cities, the conquerors approached the heart of the Aztec and Inca empires.

The recognition of high civilizations in the region approached by the Spaniards led to political, religious, and philosophical disputes. Under instructions by the King of Spain to establish trading relations, Hernán Cortés contacted the Aztec King Moctezuma. Attracted by the richness of the Aztecs, Cortés joined with peoples conquered by the Aztecs against Moctezuma, and ingeniously used Aztec mythology as a war strategy to defeat him. Cortés completed the conquest of the region and established the Kingdom of New Spain. In 1539, he was recalled to Spain, leaving behind an empire stretching from the northern part of South America to the southern part of the United States, up to the Colorado River.

The successes in Central America led to efforts to conquer South America. In 1530 Francisco Pizarro reached Peru and won over the Inca Atahuallpa, who was killed after being baptized. Resistance to the conquerors lasted until 1572, with a prolonged siege of Cuzco, the old Inca capital, ending with the capture and beheading of the last Inca, Topa Amaru. From Peru, the conquest was carried on to the South and North. Founding of the cities of Quito (1534), Lima (1535), Buenos Aires (1536), Asunción (1537), Santa Fé de Bogotá (1538), Santiago de Chile (1541), Potosí (1545), La Paz (1549), and Caracas (1562) completed the period called "the Conquest." All of Latin America, with the exception of the Amazon Basin, was in the hands of the Spanish and the Portuguese. Attempts by the French and the Dutch to conquer regions in Brazil did not succeed.

In the colonial times that followed, we see the exploitation of the lands and resources and of the peoples of the conquered regions. The colonizers brought with them traditional European agricultural and mining techniques with which they exploited the native production, mainly in metallurgy. The colonizers changed the means of production. This was done to a great extent indirectly. The native religions were simply destroyed. Food habits were also considerably modified. Wheat, rice, coffee, citrus, sugar cane, and bananas were all grown for export. This had severe consequences for the nutrition of the natives. Famine, never known in pre-Columbian times, became a major concern for Latin America. Urbanization, again following the styles of Europe, led to the development of architectural styles unsuitable to the weather and geological conditions of the conquered lands. This can be traced to the current inadequacy of the cities in the face of natural disasters such as earthquakes, floods, and high winds.

In the sciences in general, Latin America was the recipient and not the producer of scientific advances. The peripheral status of the countries was maintained throughout independence. Indeed, the colonial style and submission of the native population, with land distribution determined by the conquerors and colonizers, was kept after independence. Independence was for the *criollos*, never for the native populations, throughout the three Americas. Even after independence, education was modeled on the former imperial system.

Colonial science, considered as contributing to the mainstream of scientific development, is at best very modest. It is very important to recognize isolated cases, but they do not add to universal scientific development. Native contributions are almost exclusively in medicine, particularly in pharmacology.

The development of Native American science and philosophy was interrupted with the conquest and colonization. Remnants of pre-Columbian forms of knowledge are limited, and research today only begins to reveal their depths.

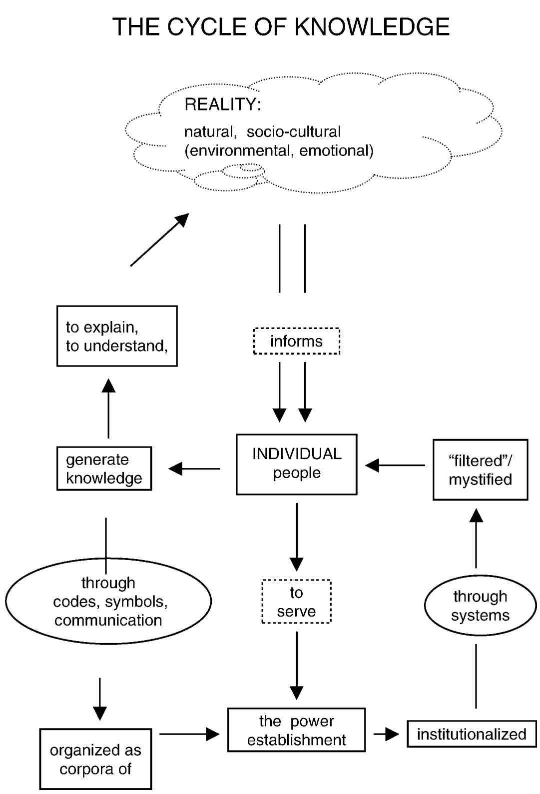
An explanatory note: this article is a critical appraisal of science, technology, and society in the Americas. It deals primarily with the social support for science, technology, and mathematics in colonial Latin America. Other forms of knowledge come naturally in the exposition. They are mutually interdependent and cannot be separated. The frequent references to mathematics reflect the perception that modern science relies, after the success of Newton's *Principia*, on Mathematics. Hence, there is sometimes a confusion between science and mathematics, as well as between science and technology. Most of the times we refer only to science, but the reflections imply technology and mathematics. This is characteristic of the research program, which underlies this paper, called Ethnoscience or Ethnomathematics.

Every culture generates knowledge as a response to mystical, environmental, and economic demands. The major challenge is to understand the human condition, which aims for survival and transcendence. Survival of the individual and of the species depends on the encounter with nature as a whole, which includes others of the same species capable of cooperation for procreation. The encounter is in the moment, is present. Transcendence results from backing survival by searching the past, trying to understand birth and creation, and by probing into the future, questioning death and posthumous influences, and this determines behavior.

Individual knowledge, as well as behavior, is the response to these drives, which implies gregariousness. Individuals are organized in groups, in the broad sense, as families, tribes, communities, and societies in general, and develop communications strategies. These strategies allow for exchanging individual knowledge and generating group knowledge, and agreeing on compatible behavior. The culture of a group may be defined as shared knowledge and compatible behavior of the group.

How is knowledge shared and how is behavior made compatible? In other words, how are they generated, intellectually and socially organized, and diffused? These questions are closely related and schematized in Fig. 1.

Science, as well as language, religion, arts, astronomy, mathematics, and techniques, are corpora of knowledge that have been generated, organized and diffused in a particular context, with specific motivations. Eventually, the corpora of knowledge become unsatisfactory and subject to criticism and revision. This



Colonialism and Science in the Americas. Fig. 1 The Cycle of Knowledge.

may be the result of internal cultural factors, or, what is very common throughout the history of mankind, as a result of exposure to other cultures. Both the internal and external factors are present in cultural dynamics.

Science in History

The great navigations since the sixteenth century mutually exposed forms of scientific knowledge from different cultural environments. The several ethnosciences involved in the encounters, which obviously include European science, have been subjected to great changes as a result. Ethnosciences, as a research program, focuses on corpora of knowledge established as systems of explanations and ways of doing, which have been accumulated, through generations, in specific cultural environments. This program, typically interdisciplinary, brings together and interrelates results from the cognitive sciences, epistemology, history, sociology, and education. An essential component is the recognition that science and mathematics are intellectual constructs of mankind, in response to the needs of survival and transcendence.

The need for an intellectual framework to organize the corresponding systems of explanations and codes, norms and practices gave rise to many aspects of science and Mathematics (D'Ambrosio 1994). In this research program, particular attention is given to those dimensions of knowledge which bear some relation to what became known as science and mathematics in European civilization after the fifteenth century.

Today, many of the weather explanations and predictions, agricultural practices, culinary, production systems and commerce, dressing and institutional codes, such as the legal system, processes of cure, languages, religion, philosophy, which, as a complex, constitute science, come from the European tradition developed in the Middle Ages and the Renaissance. They were imposed, after the sixteenth century, to much of the world, in the processes of conquest and colonialism. But we see, all over the world, extant practices performed in various levels of intensity and in very distinctive ways. These practices, which have their origins in native communities, have been, and continue to be, significantly modified as a result of mutual exposition of cultural forms. For example, it is common to see indigenous peoples in the Americas using Indo-Arabic numerals, but performing the operations from bottom to top, explaining that this is the way trees grow. In the more advanced nations, it is not difficult to identify the influence of this mutual exposition in priorities and even styles of scientific action.

Priorities and styles of intellectual action are the substrata upon which new knowledge is built. Thus, new knowledge reflects the individual and cultural history of the agent, and reveals the diversity of extant cultures. This is the essence of a multicultural historiography, which is the framework in which we discuss the history of science in Latin America. A new educational posture depends on a new historical attitude which recognizes the contribution of past cultures in building up the modern world and modern thought, and which avoids omissions and errors of the past treatment of cultural differences.

We easily identify two categories of scientific knowledge (1) academic science, sometimes called formal or scholarly science, generated by a restricted professional community, organized as specialties or disciplines, according to a convenient epistemology, and shared with peers through an elaborated language, and diffused through strictly controlled institutions, academic or governmental and (2) traditional science, also called cultural science, popular science, practical science, street science, resulting from everyday practices and common knowledge.

These names are challenged. Many scholars do not agree with using the word "science" with a qualification, reserving the word only for the former and using simply "traditions" for the latter. The main distinction refers to criteria of rigor and truth and to the nature, domain and breadth of its pursuits. Science is subjected to a concept of truth supported by criteria of rigor, and organized in disciplines. The criteria of rigor, hence the concept of scientific truth, are changeable in the light of new evidence. In other words, permanence is not strict in science, which led to scientific evolution or revolutions. This is the main issue behind the Popper–Kuhn controversy. In the traditions the focus of concern and the methods are, necessarily, holistic. Traditions reveal, sometimes explicitly, mystical features, characteristic of revealed truth, giving a sense of permanence to their fundamental principles. Thus, scientific knowledge tends to be skeptical, while traditional knowledge is more prone to fundamentalism.

Indeed, sciences and traditions are closely related and influence each other. Skepticism and fundamentalism are the consequences of the resistance to recognize the mutual influence. The Ethnoscience Program is the recognition of this mutual influence. Its main objective is to understand, through a concept of cultural dynamics, this influence.

For example, pre-Columbian cultures had different styles of doing their measurements and computations, and these practices are still prevalent in some native communities (Closs 1986). Most Amazonian tribes have counting systems that go, "one, two, three, four, and many." And that is all, since with these numbers they can satisfy all their needs (do Salvador 1965: 89–90). We also see important ways of dealing with pottery, tapestry, and everyday knowledge with strong mathematics characteristics in several cultures. The people from these cultures have no problems at all in assimilating the current European number system and deal perfectly well with counting, measurement, and money when trading with individuals of European culture demands it. Land measurement, as practiced by peasants in Latin America, comes from ancient geometry transmitted to medieval surveyors since land property and measurement (geo-metry) is strange to pre-Columbian cultures.

The high prestige of science comes mainly from its recognition as the basic intellectual instrument of progress. Modern technology depends on science and the instruments of validation in social, economic, and political affairs, mainly through storing and handling data, are based on science and mathematics. Particularly important in this respect is statistics, which brings to science an aura of essentiality in modern society. There is a general feeling that there are practically no limits to what can be explained by science. Many of the applications which give science such a prestigious position are part of various forms of cultural conflict (D'Ambrosio 2000).

Some Remarks on Historiography

History, as a major academic discipline, carries with it an intrinsic bias which makes it difficult to explain the ever-present process of cultural dynamics which permeates the evolution of mankind. This paves the way for paternalism and arrogance, for intolerance and intransigence. This interferes with the understanding, by a cultural group, of the processes of building up cultural realities which respond to the need for survival and transcendence of another cultural group.

This is seen in the encounter of the two worlds, Europe and America, in the processes of conquest and colonialism. The origin of the interference may be related to distinct views of nature. A scientific conceptualization, which resulted from the medieval intertwining of Judaic, Christian, and Greco-Arabic thought in Europe, led man to look at nature and at the universe as an inexhaustible source of richness and to exploit these resources with a mandatory drive toward power and possession, ignoring native cultural, economical, spiritual, and social diversities. Man was created, in the Biblical tradition, to obey the Creator and to be the master of all the creatures.

In the history of science, these biases have been methodological, as well as ideological. The fact that to pursue historical analyses one talks about the sciences, such as physics, chemistry, or mathematics, as distinct from religion, art, or politics, is an obstacle to understanding the processes of evolution of ideas and methods, of reflection and action, which underlie man's struggle to find explanations and to understand and cope with his environment, as well as to find means of conviviality with nature.

One of the main difficulties in doing the history of science in Latin America concerns the chronological division. In what follows, geographical divisions and historical periods are defined according to the general chronology associated with the conquest and colonization of the Americas.

Geographic divisions are defined following the administrative organization in Viceroyalties (1) New Spain (roughly what is today Mexico, Guatemala and upper Central America) (2) New Granada (roughly what is today southern Central America, Costa Rica, Panama, Colombia, Venezuela, Ecuador); (3) Peru (roughly what is today Peru and Bolivia); (4) La Plata (roughly what is today Chile, Paraguay, Argentina, and Uruguay); and the lately created Viceroyalty of (5) Brazil, under the Portuguese crown. Since the independence movements, which began early in the nineteenth century, the cultural map has remained roughly the same.

With respect to periods, it is misleading to adopt, for the New World, the same division as in the history of science in Europe. I propose five major periods:

1. Pre-Columbian era
2. Conquest and early colonial times
3. Established colonies
4. The rise of independent countries
5. The twentieth century (which will not be dealt with in this essay)

These periods reflect the established societies before the conquest, the emerging classes of Creoles, the definition of production and political systems, and international geopolitics, which have, mainly in the twentieth century, major influences in the sciences and technology in Latin America. Of course, there are specificities. While recognizing important attempts of French and Dutch settlements in the Americas, the main colonial role was played by Spain, Portugal, and England. It is important to understand the different styles of these three colonial empires.

Portugal, since its early consolidation as a kingdom, in the thirteenth century, recognized the Atlantic as its essential link to its commercial interests. The limited means of production led Portugal to develop a potent scientific and technological establishment focused on the navigations. The European navigators of the end of the fifteenth and early sixteenth centuries reached all of America, Africa, India, and China. In the case of Africa and in Asia, there had been previous contacts with civilizations which had many encounters among themselves and with Europeans. Thus the encounters of the fifteenth and early sixteenth centuries were amplifications and deepenings. Meeting the "new," the unknown, the unexpected, was experienced by Columbus and the Spaniards, in 1492 and in the subsequent voyages to the New World.

Visions of the World

Earlier contacts with the Americas are known, but the motivations and behavior of earlier navigators was completely different from the Spanish and Portuguese, and afterward the English, French, and Dutch.[1]

The influence of the navigators and chroniclers, particularly Portuguese, in building up the mode of thought which underlies modern European science is noticeable. In the words of Joaquim Barradas de Carvalho, "the authors of the Portuguese literature of the navigation made possible the Galileos and the Descartes" (Carvalho 1983: 13), essentially through the development of "objective and serene curiosity, rigorous observations and creative experimentation" (Correia 1940: 468).

Particularly important as chronicles are the *Crónica dos feitos de Guiné* of Gomes Eanes de Zurara (1453) and the *Esmeraldo de situ orbis*, by Duarte Pacheco Pereira, written between 1505 and 1508. These, particularly the latter, are probably the earliest major scientific works reporting on what was observed and experimented in the newly "discovered" environments.

The voyages themselves allowed a broader view of the world. For the Portuguese, to venture into the Southern Hemisphere demanded two major enterprises: the construction of the caravel, an extremely versatile ship built by the Portuguese in the fifteenth century as the result of a remarkable engineering project[2]; and novel navigation techniques, relying on tables constructed from systematic recorded observation carried on by the commanders of those ships. As the first European looking at "different skies," they were responsible for recording what they saw. The contributions of Gil Eanes crossing the Bojador Cape in 1434, Nuno Tristão reaching in 1443 the coast of Mauritania, and the major achievement of Diogo Cão crossing the Equator line in 1483, all paved the way for Bartolomeo Dias to cross the Cape of Hope in 1488 and for Vasco da Gama to reach Calicut in India, in 1498. Together with Columbus reaching the Western lands in 1492, the vision of the World changed. All lands and peoples were within the reach of the navigators. It was the beginning of a new phase in the history of mankind.

Conquest and Early Colonial Times

America, and to some extent Africa, were more surprising to Europeans than the lands which had been reached before by land routes, in the so-called Old Continent. Particularly, America showed peoples with new systems of explanation, of rituals and of societal arrangement. Reflections on natural philosophy or the physical sciences, particularly astronomy, were part of the overall "Cosmo" vision of the pre-Columbian civilizations.

The scientific establishment and native scientists, surely present in the society of the conquered cultures, were not recognized as such by the conquerors. One of the earliest registers of these cultures, Fray Bernardino de Sahagún (1499–1590) writes that "The reader will rightfully be bored in reading this Book Seven, [which treats astrology and natural philosophy which the naturals of this New Spain have reached]… trying only to know and to write what they understood in the matter of astrology and natural philosophy, what is very little and very low" (Sahagún 1989: 478). This important report explains much of the flora and fauna, as well as the medicinal properties of herbs of Nueva España. But he does not give any credit to indigenous formal structured knowledge. This is typical of what might be called an epistemological obstacle of the encounter.

In the vision of the conquered, a great impression was caused by the arms, tools, and equipment in general, as seen in pictures, for example in the *Codice Florentino*. Much research is needed on the science of the encounter. But this needs a new historiography, since names and facts, on which current history of science heavily rely, were not a concern in the registry of these cultures. A history "from below," which might throw some light on the modes of explanation and of understanding reality in cultures, has not been common in the history of science.

Mexico, in itself, has a very rich colonial history. Developments in Central and South America reveal the important and strategic position of Mexico in the New World.

To acquire fluency in the language of the conquered peoples was a priority. Grammars are a major contribution to this. As early as 1547, Fray Andrés de Olmos (ca. 1485–1571) published the *Arte de la Lengua Mexicana*. Fray Domingos de S. Thomas (ca. 1505–1570) published in 1560 the *Grammatica o Arte de la Lengua General de los Indios de los Reynos de Peru*. The need for this understanding of the culture of the conquered, where much of the mining was taking place, is also seen in numeracy. A description of the number system of the Aztecs was written by Juan Diaz Freyle: *Sumario compendioso de las quentas de plata y oro que en los reinos del Pirú son necessarias a los mercaderes y todo genero de tratantes. Con algunas reglas tocantes al arithmética.* Printed in Mexico in 1556, this is the first arithmetic book printed in the New World. This is a clear indicator that the successful elimination of basic communicative instruments supporting the means of production and the religion of the conquered, such as language and numeracy, had to be mastered by the conqueror. Soon after the consolidation of the conquest, this book disappeared from circulation and Aztec arithmetic was replaced by the Spanish system; the Spanish language also became dominant.

Printing of scientific books in Mexico reveal the intellectual atmosphere of Nueva España. Alfonso [Gutierrez] de la Veracruz published, in 1954, *Recognitio Summularum* and *Dialectica Resolutio*, and, in 1557, *Phisica Speculatio*. The first book contains an exposition on Aristotle's theory of syllogisms, including modal logic, and the second contains Aristotle's "Categories," with commentary, and includes numerous examples drawn from geometry, such as parallel lines, triangles, and the incommensurability of the diagonal of the square.[3]

It is interesting to observe that the registration of space location did not have the same importance as language and numeracy. Maps, essential in European actions, were not known in these cultures, while time measurement was done with remarkable precision. This has much to do with the differences in what I call Cosmo vision.[4]

Although different production systems and societal organization prevailed in the Atlantic Coast, under Portuguese rule, efforts to master the language were also important. In 1595, José de Anchieta S. J. (1534–1597), published the *Arte de Grammatica da Lingoa Mais Usada na Costa do Brasil*, and in 1640, when Spanish interests grew in the Eastern South America, mainly focused on the Jesuitic Missions in Paraguay, Antonio Ruiz de Montoya S. J. (1585–1652) published the *Arte y Bocabvlario de la Lengva Gvarani.*

In early colonial times, the Spanish and the Portuguese tried to establish schools, mostly run by Catholic religious orders. The effort to impose the language of the conqueror was responsible for considerable advances in linguistics. The demand for science and mathematics was essentially for economic purposes related to trade, but there was also an interest in science and mathematics related to astronomical observations. Reliance on indigenous knowledge was limited, but there was some interest in the nature of native knowledge. The *Historia Natural y Moral de las Indias*, published in Seville in 1590 by Joseph de Acosta S. J. (1540–1600),

[3] I owe this information to Bruce S. Burdick.

[4] An important study of these differences is Fernando Flores Mirador: *Tierra firme antecipada. El descubriiento de América y las raices arcaicas de Occidente* (to appear), Lund, 2003.

is representative of the trend to write comprehensive studies of society, history, religion and science.

Already in the first century after the conquest, there were practical books published in Mexico, such as the *Arte menor de arithmetica,* by Pedro de Paz, in 1623, and *Arte menor de arithmética y modo de formar campos,* de Atanasio Reaton, in 1649. It is also to be noticed the book *Nuevas proposiciones geométricas,* written by Juan de Porres Osorio, in Mexico.

There are some sources for the history of the natural and the health sciences in the general books of the chroniclers. In the conquest, there was a high level of scientific curiosity to observe and understand new diseases and new cures. Indeed, Felipe II (1527–1598), of Spain, sent his personal physician, Francisco Hernandez (ca. 1514–1597), to Mexico, to learn and record new practices and drugs which might be useful in improving health care in the cities. Unfortunately, all of his manuscripts were destroyed in a fire at the Escorial Library.

It is important to remember that social medicine was more developed in Portugal and Spain, as well as in England, than in the rest of Europe. Upon the arrival of ships to and from the New World, it was necessary to provide medical care for the travelers, in many cases subjected to new and unknown diseases. The *Santas Casas* (holy houses), founded in Lisbon in 1498, were built with this purpose. In 1543, Bras Cubas founded a *Santa Casa* in Santos, near São Vicente, one of the earliest urban settlements in the Portuguese colonies, founded by Martim Afonso de Souza. Soon there was concern about creating formal medical classes in the colonies. In 1653, a Chair of Medicine was established in Nueva Granada, in the Colegio Mayor de Nuestra Señora del Rosario, in Bogota. This lasted until 1865 and was replaced by the Facultad de Medicina de la Universidad Nacional, in 1867.[5]

Astronomy was a major area of interest in Latin America in the seventeenth century. There are important discussions on the meaning of comets. Many of the interpretations related to the purpose of such strange phenomena: to convey divine messages to mankind. Surely, these were searches for scientific explanations. Several polemical exchanges of letters and papers are known from these times, with important epistemological arguments. The figure of Don Carlos de Sigüenza y Góngora (1645–1700), of Mexico, towers. His works focus on astronomical observations and calculations. His most important book, considered one of the most important works of Latin American science, is *Libra astronómica y filosófica,* written in 1690. In it, Sigüenza y Góngora refutes prevailing astrological arguments about comets.

In Brazil, research on comets was also of major importance. We can see the same tone of the reflections of Sigüenza y Góngora in the work of Valentin Stancel S. J. (1621–1705), a Jesuit mathematician from Prague who lived in Brazil from 1663 until his death. His astronomical measurements are mentioned in Newton's *Principia.* A polemic, which includes another Jesuit, Antonio Vieira S. J. (1608–1697), reveals how important was the discussion about the nature of comets in building up modern scientific ideas.

In the Viceroyalty of Peru, we have the same concerns. The first to be recognized as a mathematician in Peru was Francisco Ruiz Lozano (1607–1677), who wrote *Tratado de los Cometas,* essentially a treatise of medieval mathematics explaining the phenomenon.

The Established Colonies

The death of Carlos II (1661–1700), of Spain, resulted in a turbulent period in Europe, known as the War of the Succession of Spain (1701–1714). An important consequence was the intellectual movement known as the Enlightenment [*Ilustración*], which had important consequences for the Americas, mainly the intellectual revival, which began in Spain under Carlos III (1716–1788) and in Portugal under José I (1714–1777) and his strong minister, the Marquis of Pombal (1699–1782) (Maxwell 1995).

Religious orders were not immune to the new ideas coming from Europe, and several descriptive treatises of the world were written. A general geography of the continent, the *Geographia Histórica de la América y de las Islas Adyacentes, y de las Tierras Arcticas y Antárcticas, y Islas de los Mares del Norte y del Sur*, authored by Pedro Murillo Velarde S. J. (1693–1753), was published in Madrid, in 1752, as volume IX of a monumental 10-volume *Geographia Histórica del Mundo.* This important and comprehensive presentation of the New World is a remarkable source of the history of the development of the colonies, revealing the political struggles and cultural differences.

As a result of the War of the Succession of Spain, relations with other European nations were intensified, and, as a consequence, a number of foreign scientific expeditions, with mixed scientific and commercial interests, came to the region during the eighteenth century (Weinberg 2000: 497–515). This contributed to shaping scientific development in Latin America. Great repercussions were caused by the scientific expeditions of Amedée Frézier (1682–1773), published in 1716 as *Relación del viaje por el mar del Sur a las costas del Chile y del Perú realizada durante los años 1712, 1713 y 1714,* and of Charles Marie de la Condamine (1701–1774), whose main results were

5 A detailed history of this chair of medicine is the book by Emilio Quevedo and Camilo Duque, *História de Cátedra de Medicina, 1653–1865*, Centro Editorial de la Universidad del Rosario, Bogota, 2003.

published as *Relation abrégé d'un voyage fait dans l'intérieur de l'Amerique méridionale*. Alejandro Malaspina (1754–1809) organized one of the most important expeditions. In 5 years, they visited practically all the Spanish possessions and collected precious materials.

A good number of expatriates and Creoles played an important role in creating a scientific atmosphere in the colonies. As a result of the emergence of modern science, following the publication of Newton's *Principia*, mathematics was central in the emerging scientific community. A number of intellectuals, well versed in a variety of areas of knowledge, were responsible for introducing mathematics to the colonies. These include Juan Alsina and Pedro Cerviño in Buenos Aires, who lectured on infinitesimal calculus, mechanics and trigonometry. In Peru, Cosme Bueno (1711–1798), Gabriel Moreno (1735–1809) and Joaquín Gregorio Paredes (1778–1839) are best known. In Brazil, José Fernandes Pinto Alpoim (1695–1765) wrote two books, *Exame de Artilheiros* (1744) and *Exame de Bombeiros* (1748); both focused on what we might call military mathematics, and both were written in the form of questions and answers.[6]

A distinguished figure from the period is José Celestino Mutis (1732–1808), who was responsible for an unpublished translation of Newton, but also for the introduction of modern mathematics in Colombia, mainly relying on the books by Christian Wolff. He was the founder of the *Observatorio de Bogotá* in 1803. His most distinguished disciple, Francisco José Caldas (1771–1816), became the director of the Observatory. Caldas was deeply involved in the Independence War and was shot by the Spaniards.

In Chile, the Universidad Real de San Felipe, which was inaugurated in 1747 in Santiago, was provided with a "catedra" of Mathematics. Fray Ignacio León de Garavito, a self-instructed Creole mathematician, was responsible for this chair.

Again we have to mention Mexico, where the most important developments of mathematics in Latin America at that time, took place. In the first half of the eighteenth century a number of textbooks on geometry, arithmetic, and astronomy were in use in Mexico, written by local scholars. These were mostly minor scientific works. In the second part of the century, there were publications with more scientific value. Particularly notable are the *Lecciones matemáticas* of José Ignacio Bartolache, published in 1769. In 1772, an unkown person built a "calculating wheel," capable of performing the four basic operations for numbers up to 10^8 digits. Also in 1772, Benito Bails published the *Elementos de matemáticas*, which treated infinitesimal calculus and analytic geometry.

A special kind of applied mathematics was developed, stimulated by the complexity of problems related to water and to mining. These two constitute the most important problems in the technological development of the country. "Subterraneous geometry" became a major theme in Mexican science. The needs of mining led to the creation of mining schools, such as the Real Seminário de Minería, founded in Mexico City by the Spanish mineralogist Fausto de Elhuyar in 1792. Particularly important were the efforts for urbanization, which took place in all the colonies (Catalá 1994). The book *Comentarios a las Ordenanzas de Minas*, by Francisco Javier Gamboa, published in 1761, is most representative of these developments.

Let us move to the South. In Guatemala, which included Costa Rica, the most renowned scholar was José Antonio Liendo y Goicoechea (1735–1814). He taught at the Universidad de San Carlos de Guatemala. This had already become a very important academic center after a new plan of studies published in 1785, written in Latin in the form of 25 theses, under the title *Temas de Filosofia Racional y de Filosofia Mecánica de los sentidos, de acuerdo con los usos de la Física; y de otros tópicos físico-teológicos según el pensamiento de los modernos para ser defendidos en esta Real y Pontificia Academia Guatemalteca de San Carlos*…. This was, essentially, a medieval proposition. Goicoechea was responsible for modernizing this plan of studies, incorporating experimental physics into the project, and introducing modern mathematics based on the texts of Christian Wolff.

Independence: The Basin Metaphor

The independence of the Viceroyalties of Nueva España, Nueva Granada, Peru, La Plata, and Brazil was achieved in the first quarter of the nineteenth century. The political division in countries, following independence, was practically the same as today. The pattern of cultural dynamics since colonial times did not change much, except for the fact that other empires replaced Spain and Portugal as central nations.

There is no way to deny that (Western) science and mathematics are essential in the modern world. Public opinion is ready to support investment in scientific and mathematical research in spite of being absolutely unable to guess what kind of research is being supported. For example, peers and society in general regard those that get good grades in mathematics as potential geniuses, while those that do not do well in mathematics are regarded as potentially stupid. Socially, this has been instrumental in the selection of the elite. The attitude regarding sciences in general is not different. The

[6] Brazil was different from the Spanish colonies; she did not have presses. These two books, although written in Brazil, focusing on Brazilian interests, were printed, in Portuguese, in Spain and Portugal.

appropriation, by larger strata of society, of scientific and mathematical terminology and even results, is reprehended and even derided. Those who do well in the arts or in sports, but fail in mathematics, are considered less intelligent. The references to "hard sciences" subtly reveal contempt for the humanities and social sciences. The best illustration of this is what became known as the "Science Wars," exposed by Alan Sokal's hoax.[7]

Let me introduce some concepts and reflections that result from what is now called Social Studies of Science or Science Policy. This is basically the study of the politics of scientific development, the backbone of funding agencies. It is very interesting to analyze the substitution of the colonial discourse by the discourse of aid – both multilateral, like UNESCO, and bilateral, like ORSTOM, the British Council and others. The nature of the deprived populations in colonial times and after independence, following WWII, did not change. Neither did basic needs. But the strategies to keep them as faithful consumers had to change.[8] But let us not deviate from the main objective of this paper, which is the production of scientific and mathematical knowledge.

When deciding on investments in science and technology, it is natural to expect social benefits. These investments have been substantial, both through funding agencies, either governmental or through aiding agencies, either bi- or multilateral. The outcomes in the so-called Third World have not been encouraging, as recently mentioned by the Director-General of UNESCO. "The gap between rich and poor countries is a gap of knowledge," said Federico Mayor (1994). Over 80% of the benefits of scientific and technological research are available only to the populations of the First World. But the gap between central nations and peripheral nations in the production of scientific knowledge is widening. Scientific productivity is related to the cultural atmosphere and self-esteem. Evidence from research shows that both individual and social creativity are enhanced by self-esteem. Self-esteem can hardly prevail among a population deprived of its history.

The most efficient strategy to consolidate colonial control was to deprive the conquered peoples of their systems of explanation and the instruments for survival and transcendence. This was achieved with a subtle deprivation of the history of the conquered and the production of a history "favorable" to the conqueror. This prevailed after independence. Today, Cardinal Richelieu and D'Artagnan are themes of history and literature in former colonies. Hernán Cortez is better known than Montezuma. Local heroes are ignored or labeled as evil criminals. For example, in Brazilian history books, Zumbi (1655–1695) was regarded as an outlaw and although recognized, more recently, as a hero, the space reserved to him in books and classes is negligible.[9]

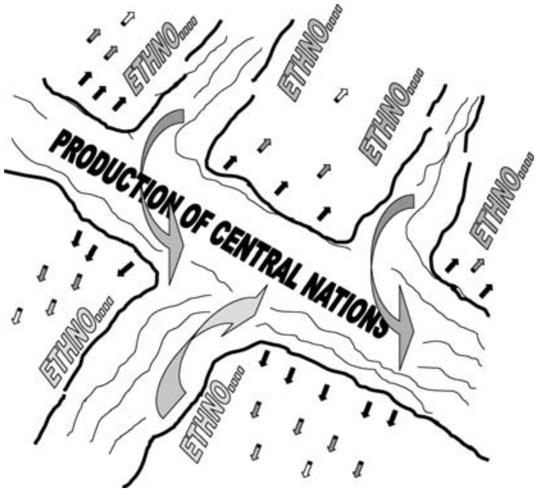
We may consider, as it is frequent in discussions of policy, especially in the United Nations and other national and international agencies, the production of scientific, technological, and mathematical knowledge as something measurable. Scientometrics relies on several indicators and the studies of quantitative history allow us to speak of the central nations as those who produce new knowledge, and the peripheral nations as those who absorb new knowledge. Production and absorption of knowledge are clearly distinguishable. The sad situation is that the peripheral nations have been slow in absorbing new knowledge. The lack of infrastructure acts as a barrier for this process (D'Ambrosio 1975: 94). The Basin Metaphor helps us to understand the process. The main producers of knowledge (Central Nations) are represented by the main stream. Water always fertilizes their margins. They will produce their effect in the margins of the tributaries (Peripheral Nations) much later, when the waters have already flown along the stream (thus producing the gap or obsolescence of knowledge). The water (knowledge) does not flow upstream of the tributaries (Fig. 2).

The water of the tributaries fertilizes their margins, and also adds and contributes to the volume of water of the main stream. For example, expropriation of "popular" knowledge – so common in the pharmaceutical industry – and cooptation strategies, particularly the brain drain, encourage this. A strict school system was

[7] See the issue devoted to the theme "Science Wars" in *Social Text*, 46–47, Spring/Summer 1996. The issue has very interesting papers. Regrettably, attention was given only to the hoax of Alan Sokal. As a consequence there was a renewal of attacks on Afrocentrism, warnings against a "new dark age of irrationalism" and other controversial disputes going on in the academic world. All this, that might be interpreted as a form of intellectual fundamentalism, is nothing but a defensive posture against the challenge of the current epistemological order.

[8] These topics have in the postwar period drawn much attention and generated important studies whose results throw some light on the production of scientific knowledge throughout history. Particularly interesting is the historiography adopted by Harold Dorn in his exciting book, *The Geography of Science*, Baltimore: The Johns Hopkins University Press, 1991.

[9] Zumbi is the leader of the "Quilombo dos Palmares," a republic created by runaway slaves in the Northeast of Brazil, which lasted for about 100 years. It was destroyed in the late seventeenth century. But other such republics lasted and some were contacted only recently. Their economy and production systems, particularly agriculture and mining, are as yet to be studied. See more on the communities of runaway slaves in the Americas in Richard Price, org., *Marron Societies: Rebel Slave Communities in the Americas*, 2 vols. Baltimore: The Johns Hopkins University Press, 1972.



Colonialism and Science in the Americas. Fig. 2 The Basin Metaphor.

responsible for this strategy in colonial times. This is manifest in the emigration of academics and, worst, in the subordination of laboratories and research institutions of the peripheral nations to the priorities of their major homologues in the central nations (D'Ambrosio 1979: 223–229). This strategy plays out, for example, in the valuation of foreign academic degrees over local degrees. Now, it is quite revealing to see the efforts to entice research institutions in the peripheral nations to join major biotechnology research plans.

The cooptation of scientists in the periphery is normally done by sending experts, in many cases scientists with high reputations, to the periphery for short visits and conferences, by offering fellowships, by giving stipends higher than the current national salaries, by sending equipment (in many cases obsolete or already heavily used) and offering international travel to seminars and congresses. This is true in academics and, in the more developed peripheral nations, also in industry. Particularly in mathematics, we have numerous examples of such practices in the postwar period. The presence of monies of the US Army, Navy, and Air Force research agencies, as well as of the NSF, the CNRS, the British Council, the DAAD and other agencies, following the pattern mentioned above, is remarkable.

These cases have not been studied in detail as yet. They have the common feature of producing human resources and results without any analysis of the capability of the peripheral countries to absorb and to make these resources and results useful for their needs. Normally this is the result of a lack of qualitative directives in science policy of the peripheral nations. Practically every scientific development plan in the periphery is a program entirely based on quantitative goals. The World Bank, the UNDP and other financing agencies rely on, indeed stimulate, plans based on quantitative goals. Clearly, they are easier to check. But the benefits for the poor populations of the peripheral nations are practically nil.

In the basin metaphor, the sources of the rivers, both the main stream and the tributaries, correspond to ethnomathematical knowledge. Ethnomathematical knowledge, like the waters, flows fertilizing the margins of the tributary and eventually mixes in a major stream, contributing to this flow. Waters of the main stream do not go upstream through the tributaries.

The notion of progress carried on by the main stream will benefit the margins of the tributary after a long way through difficult land paths – which correspond to the acquisition of knowledge from other sociocultural and environmental sources. The needs of the margins – peripheral cultures – are met by the water of the tributaries, and only later receive the benefits coming from the main stream. But these can be useful only if the grounds are fertile. To make them fertile requires long, deep, and very complex educational reforms.

In this metaphor, an alternative to main stream and tributaries would be to have a large lake, where all the sources contribute equally to the main body of water. Each source produces according to its environmental history and all the waters of the lake fertilize all the margins. The creation of the great lake – the deterioration of the current world order – is identified with a sensible globalization, leading to a new planetary order.

Developments in the Newly Independent Countries

The independence of Guatemala, in 1821, decreased the influence of Mexico in Central and South America. The establishment of new universities and the renewal of old ones, immediately preceding and after independence, generated open attitudes with respect to sources of knowledge on which to build up the newly established countries of Latin America. Formerly restricted to an almost exclusivity of influences coming from Spain and Portugal, the new countries attracted considerable attention from the rest of Europe, and a new wave of scientific expeditions came to South America. They had great influence in creating new intellectual climates throughout the region. This new source is seen very strongly in the building of large and diversified libraries, both public and private, and the acquisition of modern literature.

In Costa Rica, colonial authorities established the Casa de Enseñanza de Santo Tomas in 1814, in which the most influential teacher was Rafael Francisco Osejo, born in 1780. In 1830, he wrote *Lecciones de aritmética*, written in the form of questions and answers, a common feature in that period, as shown above when referring to Alpoim in Brazil. In 1843 the Casa de Enseñanza was transformed into the Universidad de Santo Tomas, where courses in Engineering were established. But there were no courses in pure sciences and mathematics.

Colombia soon attracted foreign mathematicians. The Frenchman Bergeron introduced Descriptive Geometry in the country, and the Italian Agustín Codazzi (1793–1859) was influential in creating the Colegio Militar. Lino Pombo (1797–1862), who was particularly influential in founding the Academia de Matematicas de Venezuela, wrote a complete course of mathematics.

In Brazil, the transfer of the royal family of Portugal, who were escaping the Napoleonic invasion, in 1808, was decisive in changing cultural life in the colony. The Portuguese court settled in Rio de Janeiro, where it was necessary to create an infrastructure to run, from a colonial town, the vast Kingdom of Portugal. They founded a major Library and an Escola Militar (Military School), the first institution of higher learning in the colony. Both were influential in the development of mathematics in Brazil. In the school, a doctorate in mathematics was established and a number of theses were submitted and defended (da Silva 1992). Translation of the textbooks of Lacroix, of Legendre and others, were quite important in generating what we might call a mathematical style in Brazil.

Particularly interesting is the case of Joaquim Gomes de Souza (1829–1863), known as "Souzinha," the first Brazilian mathematician to appear in Europe. He presented his results in the Académie des Sciences de Paris and in the Royal Society. Only short notices of the papers were given,[10] and they were posthumously published as *Mélanges du Calcul Intégral*, as an independent printing by Brockhaus of Leipzig in 1889. This work, dealing mainly with partial differential equations, is permeated by very interesting historical and philosophical remarks, revealing access to the most important literature then available. This was possible due to the existence of important private collections in Maranhão, his home state in the Northeast.

Argentina, independent since 1816, experienced a remarkable intellectual development. In 1822, the ephemeral Sociedad de Ciencias Físicas y Matemáticas was founded in Buenos Aires (Nicolau 1996). There was an emergence of private libraries. Particularly important is the private library of Bernardino Speluzzi (1835–1898), which listed the main works of Newton, D'Alembert, Euler, Laplace, Carnot, and several other modern classics. Another intellectual, Valentin Balbin (1851–1901), while Rector of the National College of Buenos Aires proposed a new study plan, in 1896, which included history of mathematics as a distinct discipline. This is probably the first formal interest in the History of Mathematics in South America, which eventually led to an important school of History of Science in Argentina.

In Peru, there was an interest in Statistics, beginning with the book *Ensayo de estadística completa de los ramos económico-políticos de la provincia de Azángaro…* by José Domingos Choquechuanca (1789–1858), published in 1833.

In Chile, the Universidad de Chile was created in 1842, with a Faculty of Physical and Mathematical Sciences. A most distinguished member of the Faculty was Ramón Picarte, a lawyer, who had his paper, "La división reducida a una adición," accepted and published by the Academy of Sciences of Paris in 1859.[11] Much emphasis was given to teacher training. An agreement with the government of Germany provided the pedagogical support to reform education in the country. Fifteen German mathematicians, most with a doctorate, immigrated to Chile in 1889.

The influence of Auguste Comte (1798–1857) toward the end of the century was very important in all of Latin America, particularly in Mexico and in Brazil. Although the main reason was the demand of the emerging political elites to build up the ideological framework of the new countries, Comtian ideas influenced a considerable development of mathematics and the Sciences in general.[12]

Conquest and colonization had an enormous influence on the course of development of civilization. The chroniclers of the conquest tell of different ways of explaining the cosmos and the creation and of dealing with the surrounding environment. Religious systems, political structures, architecture and urban arrangements, sciences and values were, in a few decades, suppressed and replaced by those of the conqueror. A few remnants of the original behavior of these cultures were and still are outlawed or treated as folklore. But they surely integrate the cultural memory of the peoples descending from the conquered. Much of these behaviors are easily recognized in everyday life.

Mathematics, as an human endeavor, is not different. This is one focal point of the research program known as Ethnomathematics, which deals with the generation, the intellectual and social organization and the diffusion of different ways, styles, modes (*tics*) of explanation, understanding, learning, coping with and

[10] *Comptes-Rendus de l'Académie des Sciences de Paris*, tomes XL, p. 1310, and XLI, p. 100 and *Proceedings of the Royal Society*, 1856, pp.146–149. It is quite interesting to read the referee's reports and the reaction of Gomes de Souza to the fact that Liouville did not give an appraisal of the paper, according to Gomes de Souza, because of "la petite jalousie." A thorough study of the scientific works of Gomes de Souza has still not been done.

[11] I did not have personal access to these papers and to the records of Picarte's presence in Paris.

[12] See the important doctoral dissertation of Circe Mary Silva da Silva, Positivismus und Mathematikunterrichte: Portugiesche und franzsische Einflüsse in Brasilien im 19. Jahrundert, IDM, Bielefeld, 1991.

probing beyond (*mathema*) the immediate natural and sociocultural environment (*ethno*). This clearly results from the mutual exposition of different cultures and the dynamics of this process is a major problem we face in doing the history of ideas in every region of this world.

The conquest paved the way to colonization. In the Americas, the early colonizers, the Spanish and the Portuguese, paved the way for the French, the English and the Dutch colonizer and later on for Africans, Europeans, and Asiatic immigrants. With them came new forms of coping with the environment, of dealing with daily life, and new ways of explanations and learning. The result was the emergence of a synthesis of different forms of knowing and explaining which were generated by and available to the different communities, to workers and to the people. We recognize the emergence of new religions, cuisine, music, arts, and languages, particularly in the Americas – the Creoles. All of these interrelated as a synthesis of the cultural forms of the ancestors.

Science and Mathematics, as cultural forms, are not different. The emergence of new cultural behavior is another focal point of the research programs known as Ethnosciences and Ethnomathematics.

Particularly in the Americas, the variety and peculiarity of the expositions of cultures and the specificity of the population migrations reveal an effort of the colonizer to transfer, with minor adaptations, the forms of social, economical and political organization and administration prevailing in the metropoles, including schooling and scholarship (academies, universities, monasteries). The new institutions in the Americas were based on the styles prevailing in the metropoles, mostly under the influence, and even control, of religious orders.

All this, which took place during most of the sixteenth, seventeenth, and eighteenth centuries, occurred while new philosophical ideas, new sciences, new ways of production and new political arrangements were flourishing in Europe. The cultural artifacts produced in Europe were assimilated in the Americas under specific, mostly precarious, conditions. There is a clear coexistence of cultural goods, particularly knowledge, produced in the Americas and abroad. The former were consumed mostly by the lower strata of society, the people and workers, and the latter by the domineering classes. These boundaries are not clearly defined and the mutual influences of the resulting intellectual productions are evident.

This poses the following *basic question*: What are the relations between the producers and consumers of cultural goods?

This guides my proposal for the historiography of science and mathematics and what I have called "the Basin Metaphor." Although this is a question affecting the relations between academia and society in general, hence between the ruling elites and the population as a whole, it is particularly important for understanding the role of intellectuality in the colonial era. Thus ethnoscience and ethnomathematics are fundamental instruments of historical analysis (D'Ambrosio 1995; 1996).

Curiously enough, the main factor influencing the consumption of what we might call academic science and mathematics produced in an alien cultural environment – sometimes inside the same country – depend basically on what the "outsiders" – that is, the people, not learned in science and mathematics – have to say about science and mathematics. This factor has not been given attention in the prevailing historiographies (D'Ambrosio 1993). This broader look, suggested by new historical scholarship, comes under severe attack, in what became to be known as the Science Wars (D'Ambrosio 2000). My proposal incorporates to the History of science and Mathematics, in an essential way, the views of aliens, in the sense of strangers to the specific knowledge fields or strange to the cultural environment, about science and Mathematics.

Colonialism and Science in India

DEEPAK KUMAR

Colonization was not merely a political phenomenon; it had far-reaching economic and cultural ramifications. It was an exercise in power, control, and domination. Scientific and technological changes greatly facilitated this progress. Techno-science and colonialism are closely linked and to some extent share a cause and effect relationship. In recent years a good deal of work has been done on the nature, course, and consequence of this relationship in different geographical and culture areas. Some scholars see in it utilitarian and developmental images; many others find it utterly exploitative, while some prefer to opt for a middle path and emphasize both the regenerative and retrogressive aspects of the science and colonization nexus. So the debate continues, and several works have appeared with case studies on Africa, Latin America, and Asia. India, being a prime example of classic colonization, has also received considerable attention.

The fact that India has a very long techno-scientific tradition and a rich cultural heritage is fairly well known. It was, however, during the seventeenth to eighteenth centuries, the post-Renaissance epoch (that of Descartes and Newton) that Europe began to outdistance India in scientific and material advancement. The rise of modern science in Europe profoundly disturbed the balance of scientific development among traditional societies. It is also possible that the various sciences and technologies were on a decline in India around 1790. There was definitely no "conscious" spirit of technological innovation and scientific enquiry to match the spirit of Europe. The result was colonization.

The advancing European trading companies became deeply involved in political and military rivalries, culminating in the establishment of the British paramountcy over the Indian sub-continent. A new empire was in the making. The colonizers were out to collect the maximum possible information about India, its people and resources. They reported what was best in India's technological traditions, what was best in India's natural resources, and what could be most advantageous for their employers. The English East India Company, for its part, was quick to realize that the whole physical basis of its governance was dependent upon the geographical, geological, and botanical knowledge of the areas being conquered. The colonizers fully recognized the role and importance of science in empire building.

The most interesting feature of this early phase of colonial science lies in its highly individualistic character. State followed the trade, and certain individuals on the spot would largely determine what was advantageous for both. These colonial scientists would try their hands at several fields simultaneously, and were in fact botanist, geologist, zoologist, physicist, chemist, geographer, and educator – all rolled into one. As data gatherers they had no peers, but for analysis and recognition, they had to depend upon the metropolitan scientific culture whose offshoots they were and from which they drew sustenance. The colonial government quickly patronized geographical, geological, and botanical surveys; after all these were of direct and substantial economic and military advantage. Medical or zoological research did not hold such promises. Research in physics and chemistry was simply out of the question, for there were no laboratories, equipment, or specialized training. The reigning spirit remained that of exploration. Systematization or analysis of its results had to wait for some time, but then, even disjointed and often haphazard studies served some purpose.

Other positive achievements were the establishment of scientific bodies and museums. Pre-British India never had anything like as scientific society, not to say a journal, which could provide some sort of a platform for scientific workers. William Jones was the first to realize this and founded the Asiatic Society in Calcutta in 1784. This society soon became the focal point of all scientific activities in India. It was followed by the Madras Literary and Scientific Society (1805), the Agricultural and Horticultural Society of India (1817), Calcutta Medical and Physical Society (1823), and the Bombay Branch of the Royal Asiatic Society (1829). Trigonometrical and topographical surveys were organized under the Great Trigonometrical Survey of India (1818), and a Geological Survey was established in 1851. Scientific research thus for a long time remained an exclusive governmental exercise, and this largely determined the nature and scope of scientific research in India. Colonial science primarily implied “natural history” and its star (if not sole) attraction was the exploitation of natural resources. It was basically plantation research with emphasis on experimental farms, the introduction of new varieties, and the various problems of cash crops. Next came surveys in geology and meteorology. Another major area of concern was health. The survival of the army, the planters, and other colonizers was at stake. The importance of medical research was always recognized, but the quantum of emphasis varied from time to time. In any case, however, research was not to be a curiosity-oriented affair. Financial considerations were invariably there. The colonial administrators consistently held that scientists in India should leave pure science to Britain and apply themselves only to the applications of science. They would goad the various organizations to work along only economically beneficial lines. Colonial researchers often found themselves unable to distinguish between basic and applied research. This was particularly true of the geologists and the botanists. Their problem was how to discover “the profitable mean course” in which scientific research, having a general bearing, would at the same time solve the local problems of immediate economic value. The dilemma was fairly acute.

In the field of education, science was unfortunately never given a high priority. In 1835 Thomas Macaulay not only succeeded in making a foreign language, English, the medium of instruction, but his personal distaste for science led to a curriculum which was purely literary. A few medical and engineering colleges were opened, but they were meant largely to supply assistant surgeons, hospital assistants, overseers, etc. What India got was some sort of a hybrid emerging out of a careless fusion between literary and technical education. What is more, adoption of English as the sole medium of instruction in science rather hampered its percolation to the lower classes. Colonial education widened the social gulf and accentuated the age-old divide. Even in government institutions, growth was kept under a self-regulatory check. The Tokyo Engineering College was established in 1873, much later than the Engineering College at Roorkee, and by 1903 it had a staff of 24 professors, 24 assistant professors, and 22 lecturers. The Massachusetts Institute of Technology was established in 1865 and by 1908 it had 306 teachers. And Roorkee, even after 100 years of its existence (i.e., in 1947), had only three professors, six assistant professors, and 12 lecturers.

Colonialism involved not only exploration and classification but also coding and decoding cultures. Its cultural projects showed deeper penetration and greater resilience than its economic forays. With the help of schools, universities, textbooks, museums, exhibitions, newspapers, etc. local discourse was influenced and colonized. Modernity was presented as a colonial import and not something intrinsic to humanity’s rational nature. Colonial rule, with its sharp tools, dissected and bared differences and was not inclined to synthesize. Colonialism usually stalls the possibilities of exchange and prefers one-way traffic. One may talk of transfer – transfer of knowledge, systems, or technologies – but it was a transfer restricted or guided to achieve certain determined objectives. As education and awareness grew, several Indians participated in the official scientific associations and institutions, but very often they searched for a distinct identity and established institutions, scholarships, and facilities of their own.

In the first half of the nineteenth century, Bal Gangadhar Shastri and Hari Keshavji Pathare in Bombay, Master Ramchandra in Delhi, Shamhaji Bapu and Onkar Bhatt Joshi in Central Provinces, and Aukhoy Kumar Dutt in Calcutta worked for the popularization of modern science in Indian languages. In 1864 Syed Ahmed founded the Aligarh scientific Society and called for the introduction of technology to industrial and agricultural production. Four years later Syed Imdad Ali founded the Bihar Scientific Society. These societies did not live long. In 1876 Mahendra Lal Sarkar established the Indian Association for Cultivation of Science. This was completely under Indian management and without any government aid or patronage. Sarkar’s scheme was very ambitious. It aimed not only at original investigations but at science popularization as well. It gradually developed into an important center for research in optics, acoustics, scattering of light, magnetism, etc. In Bombay, Jamshedji Tata drew up a similar scheme for higher scientific education and research. This was opposed by the then Governer-General, Lord Curzon. Yet it finally led to the establishment of the Indian Institute of Science at Bangalore in 1909. There was thus greater awareness by the turn of the century.

In the first quarter of the twentieth century, those who put India on the scientific map of the world were J. C. Bose, who studied the molecular phenomenon produced by electricity on living and nonliving substances, Ramanujan, a mathematical genius, and P. C. Ray who analyzed a number of rare Indian minerals to discover in them some of the missing elements in Mendeleef’s Periodic Table. C. V. Raman’s research on the scattering of light later won him the Nobel Prize in 1930 and gave the name to Raman spectroscopy. Meghnad Saha pioneered the field of astrophysics, while S. N. Bose’s collaboration with Einstein led to what is known as the Bose–Einstein equation. These were great sparks, individual and sometimes lonely, yet imbued with both scientific and national spirit. They thought over what role science and technology would play in building modern India, and they dreamt of freedom. The colonial government was aware of its limitations and discomfiture, and gradually permitted greater indigenization of its scientific institutions and cadre. In the wake of the First World War the government realized that India must become more self-reliant scientifically and industrially. It appointed an industrial commission in 1916 to examine steps that might be taken to lessen India's scientific and industrial dependence on Britain. However, few of the Commission's recommendations were actually implemented. Discontent continued to grow. India's national leaders appreciated the importance of science and technology in national reconstruction and worked closely with the scientific talent of the time. A National Planning Committee was formed in 1937 for this purpose, in which several leading Indian scientists and technologists participated. In 1942, the Council for Scientific and Industrial Research was established. The end of colonial science was pretty near. With the A. V. Hill Report in 1944 on Scientific Research in India, the curtain dropped.

The foregoing analysis illustrates that in a colonial situation field sciences may have been developed through imported scientists as an economic necessity, but little fundamental research was possible. A few colonial scientists made important contributions that no doubt enriched science in general, but their activities hardly succeeded in introducing science to the Indian people or in ameliorating their condition. Colonial science did, on the whole, support and help sustain exploitation and underdevelopment.

Colonialism and Science in the Malay World

Hairudin B. Harun

By the sixteenth century, the legends of the Golden Chersonese, about the distant land having more gold and exotic treasures than people, were well established among the sea going nations of Europe. Legend had it that the Golden Chersonese was geographically located midway between India and China. The Golden Chersonese description apparently fit the Malay Peninsula very well. Indeed, it came to be known among the early Europeans by that very name until it was replaced by another, Malacca. By whatever name the Peninsula was known, it was a major focal point of Eastern trade. Indeed, Malacca – actually a tiny coastal city-port situated in the middle of the Malay Peninsula – was not only a commercial Mecca, but also a cultural center and meeting point for the major civilizations of the time.

In 1575, Louis De Roy, writing on the virtues of the new knowledge and inventions spurned by the Renaissance spirit, made a special note about the meeting of Magellan and the King of Malacca. According to De Roy, the meeting was made possible by the new knowledge of the seas and the use of the magnetic compass for navigation. Malacca, to the Europeans then, as not just a reference to the city-port but rather to the whole Malay Archipelago, including the Peninsula and Islands of Indonesia that were under Malaccan rule. By the time De Roy's article was published. Malacca had actually been under the annexation of Portugal for 65 years, since the Portuguese defeated the Malays in 1511. Some scholars have suggested that the downfall of Malacca also marked the decline of Eastern scientific and technological superiority *vis-à-vis* the European. Others have cautioned against making simplistic conclusions, pointing out that the reasons for the downfall of Malacca were far more complex than those that have been suggested.

The Portuguese ruled Malacca until the mid-seventeenth century. In 1614 the Dutch successfully wrested Malacca from the Portuguese. By the mid-eighteenth century Dutch power in the Malay Archipelago declined, giving way to the British. The British were relatively latecomers to the region, but they were none the less regarded as the best prepared – intellectually, militarily and economically – among the colonizers of the region. They were poised for a long stay.

There were two major factors that were crucial to the expansion and consolidation of the Crown's influence: the colonial economy and the health of officials, colonialists, and *coolies* (colonial laborers). In the early phase of British colonialism, spices, timber, and other agricultural products were the backbone of the colonial economy. Knowledge of economically and medicinally useful plants of the East was indispensable both for the sustenance of the economy and the maintenance of health. This knowledge was to be found in the new discipline of plant science, later known as *economic botany*, and much later as *agricultural science*.

The cultivation of spice trees, and the transfer of economic plants like rubber trees from the Amazon to the Malay Peninsula, was some of the colonial activities made possible by the new plant science and its scientific institutions. Indeed, apart from medicine, no branch of science was regarded as so crucial to the sustenance of colonialism as economic botany. Before the advent of synthetic drugs, herbs and plants were the main source of medicines. For instance, quinine, an extract from the chichona tree that grew wildly in the Peruvian jungle, was extensively used to cure malarial fever. Hence, knowledge of the indigenous plants was important not only for economic reasons, but tot health as well. Health and diseases also assumed an economic and political significance. They were moderating factors in the colonial expansion and exploitation of the East, especially in the tropics. Tropical diseases like malaria were a menace to the health of colonial officials and then laborers. Indeed, malaria reportedly wiped out some of the remote British colonies and military bases and was blamed for slowing down colonial campaigns in the Far East and Africa. In the following discussion we will see how the development and history of British colonialism and science in the Malay Archipelago became intertwined.

Botany and British Colonialism

As early as the seventeenth century there were attempts to grow exotic and foreign food crops away from their natural habitats. The first attempt to grow pineapples in England was reportedly made during the reign of Charles II (1660–1685). The colonization of the New World and later, Asia, led to the introduction of many new crops to Britain. Maize, a staple crop of the Native

Americans, which yields ten times more than wheat, was among the crops that revolutionized European tastebuds. Another imported high yielding crop, that reportedly saved Ireland from starvation, was the potato. However, there were still many food crops that resisted local cultivation and therefore had to be brought over from the colonies. Supply was notoriously irregular and rarely adequate to meet demands. It was not until the nineteenth century that supply became more reliable. This reliability owed much to the active colonization of new fertile lands in the East and the new discipline of economic botany.

In the nineteenth century, the political ideology of the times, the botanic gardens, and the colonial office functioned as an integrated framework, enforcing an economic structure whereby the East became the producer of raw materials for the West's industries. Indeed, this framework was a characteristic description of colonialism which involved, among other things, the establishment of plantations and the large-scale cultivation of economic plants, and the systematic transfer of economic plants from an area less productive or less conducive (either politically, economically, or scientifically) to a more productive and conducive one. Colonialism also entailed the need to coordinate and transfer labor from one colony to another in order to ensure the viability of a plantation or an agroeconomic project. Underwriting the success of the colonial plantations and agriculture-based economic projects were the many research oriented botanic gardens established throughout the colonies. The most prominent of these botanic gardens were the Calcutta Garden in India, the Peradeniya Gardens in Ceylon (Sri Lanka), and the Penang, Malacca, and Singapore Gardens in the Malay Peninsula, known then as *British Malaya*.

The Royal Botanic Gardens at Kew in London was the center for scientific research and coordination of the work of the botanic stations in the colonies. Kew's role was very well illustrated in the case of the discovery and cultivation of the cinchona tree – the medicinal tree from which the malarial medicine, quinine, was extracted. The discovery of cinchona involved a large army of field workers and researchers collecting and gathering seemingly irrelevant bits of information and materials, from every remote corner of the British Empire and beyond. The information and materials were sent to Kew for analysis. The discovery and eventual successful extraction of quinine, which turned out to be the most potent antidote for malaria, was a credit to Kew and its network of botanic gardens in the colonies. Indeed, quinine was not just an important scientific discovery; it also had important demographic and political effects. Through the control of malaria it saved the lives of countless colonial officials and their *coolies* (laborers) and made possible the large-scale colonial exploration and exploitation of Africa and the Far East.

Colonial Botany in the Malay Peninsula

Colonial botany came to the shores of the Malay Peninsula in the year 1822 with the establishment of the botanic garden in Singapore by Sir Stamford Raffles. The staff of the botanic garden was instrumental in overseeing the introduction and improvement of spice cultivation in the Straits Settlements. Indeed, in the Malay Peninsula *botany* was almost indistinguishable from *economy*. Whether the relationship between botany and colonial economy in the colonies had any influence in the formalization of economic botany back in the motherland is a difficult question to answer with certainty; but what is certain is that the colonial economy benefited much from the knowledge and expertise provided by economic botany.

Back in Britain, botany was given a boost following several developments, one of which was the appointment in 1841 of Joseph Hooker (1817–1911), far more widely known as a colonialist than as a botanist, as head of the Royal Botanic Garden at Kew. Kew was responsible for coordinating and supervising all the scientific research on economic plants and agriculture within the British colonial empire. It was under Kew's supervision that in 1858 new botanic gardens were established in Singapore superseding the one established by Raffles. In 1887 botanic gardens were also established in Penang followed soon after by another in Malacca.

Nowhere is the importance of Kew to British colonialism so clear as in the case of the transfer of the wild Brazilian rubber plant from Latin America to the Malay Peninsula. Initially, various species of wild rubber seeds were collected from the Amazon jungle and sent to Kew Gardens for study and analysis. Eventually a species, *Hevea brasiliensis*, was identified as promising and was transferred to the botanic gardens in Singapore. Under the supervision of the Singapore gardens which H. N. Ridley headed, politically backed by the colonial office, and heavily financed by the Crown companies, experimental plantations were set up in various parts of the Malay Peninsula. The plantations turned out to be experimentally successful and, as anticipated, destined to become commercially successful too. At the turn of the twentieth century, with the advent of motor vehicles industry in Europe and America, rubber became one of the most important raw materials for the new industry. Rubber planting indeed became one of the most profitable colonial commercial ventures. Most importantly, rubber could only be found in abundant quantity and of high quality within the British Empire.

The transfer, identification, and eventual cultivation of economic plants would not have been successful without colonial botany equally recording a success in another related activity: taxonomical works. Indeed, one of the main tasks of the botanic gardens was taxonomical work closely associated with identifying economically and medically useful plants. The varieties of plant life in the tropics became a testing ground for the new system of classification. In the Malay Peninsula, the colonial taxonomical campaigns of identifying and naming tropical plants soon turned out to be an enormous task that almost overwhelmed the colonial scientists and their machinery. The variation of plant life in the tropics rendered it practically impossible for their taxonomists and the new taxonomy to start fresh from scratch. However, starting from scratch was the last thing that they had to do. Long before the arrival of the British, the natives had already classified most of the plants, especially the economically useful ones. More often than not, all the colonial taxonomist had to do was to refer to the local taxonomy and be creative. They eventually discovered that the local folk taxonomy was almost encyclopedic, encompassing the encounter of many generations of indigenous wisdom with the local flora.

Colonial Botany and Malay Ethnobotany

The encounter of the colonialists with Malay ethnobotany probably went as far back as the arrival of the first Europeans to the area. Tome' Pires, a Portuguese scholar and explorer, who visited Malacca during the Portuguese rule, noted the existence of a botanical tradition among the Malays. The Malay botanical tradition was described as being composed of a complex system of plant taxonomy and knowledge as well as the cultural–educational rituals associated with teaching and imparting the knowledge to successive generations.

The majority of the colonial botanists, with very few exceptions, were genuinely intrigued by the sophistication and mechanics of Malay plant taxonomy. They seemed to agree that the Malay taxonomy was much more than a fanciful accidental uttering of a primitive tribe oblivious to any sense of rationality or systematic thinking. In fact, in many ways it was comparable to the modern colonial system.

In the colonial scientific taxonomy, plants having the same kind of flower and fruit but which differ in details of size, shape, and color of the flowers, fruits, or leaves constituted a *genus*. A specific name came after the generic name either as an adjective qualifying it or as noun in the genitive case if the species was in honor of some person.

Colonial botanists noted that Malay folk taxonomy, on the other hand, was based on either the use or morphological characteristics of the plants, or at times both. Most economically useful plants were classified by their use, whilst medically useful plants and others were often classified by the morphology of their niche, leaves, fruits, or flowers. What was found as a pleasant surprise to many of the colonial botanists was the discovery that in many instances the colonial scientific taxonomy and Malay taxonomy shared common grounds. There were also considerable numbers of Malay taxonomical names that found no equivalents whatsoever with the colonial names. Names like *kedundung*, *Tinjau Belukar*, and *Puding* were morphological names referring to the chief characteristics of the respective plant. They could be either a reference to their growth habit, shape of leaves, flowers, fruits, or combinations of any of those. They did not correspond neatly to the modern colonial taxonomy. However, in spite of that, Malay ethnotaxonomy was a tremendous aid to the colonial reclassification of plants in the tropical Peninsula to modern taxonomy.

Many of the taxonomical and other scientific findings were published in the *Kew Bulletin*. The Bulletin was not only important academically, but it was also a medium of communication and instruction between Kew and the imperial network of botanic stations. It played the dual role of a scientific medium and a channel for colonial interests, reflecting faithfully the nature of colonial scientific activities.

Colonial scientific activities in the Malay Peninsula, especially the botanical and the taxonomical exercises, were not just scientific per se; they were first and foremost an integral part of the colonial activity to sustain British colonialism. In short, they were by and for colonialism.

Combinatorics in Indian Mathematics

Takao Hayashi

Having prescribed the rule

$$C_n^r = \prod_{k=1}^{r} \frac{n-k+1}{k}$$

for the number of combinations of r things taken at a time from n things, Bhāskara II (AD 1150) remarked:

> This [rule] has been handed down [to us] as a general [method], being employed [for their own purposes] by the experts [of specific fields of study], namely, for the tabular presentation of possible meters in metrics, for the number of ways of opening ventilating holes, etc., and the diagram called Partial Meru in arts and crafts, and for the varieties of tastes in medicine. [But], for fear of prolixity, they are not explained here (*Līlāvatī* 113–114).

It is impossible to tell exactly when and by whom this rule was formulated, but from ancient times Indian peoples have had a keen interest in arranging things in order in various aspects of human life, and in theorizing in various areas of study.

The *Bhagavatī*, one of the 12 canonical books of the Jainas, counts by enumeration the number of all the possible cases when one person, two persons, three persons, etc., are distributed in the seven nether worlds.

Most books of Sanskrit and Prakrit prosody, such as the *Chandaḥsūtra* of Piṅgala (ca. AD 200?), *Vṛttajātisamuccaya* of Virahāṅka (between the sixth and the eighth centuries), *Jayadevacchandaḥ* of Jayadeva (before AD 900), *Chando'nuśāsana* of Jayakīrti (ca. AD 1000), *Vṛttaratnākara* of Kedāra (before AD 1000). *Chando'nuśāsana* of Hemacandra (ca. AD 1150), etc., devote one of their chapters (usually the last one) to "six kinds of ascertainment" (*ṣaṭpratyaya*), namely:

1. Spread (*prastāra*), to spread a list of all the possible variations of a given type of meter consisting of short and long syllables according to a certain method.
2. Lost (*naṣṭa*), to find out a lost variation when its serial number in the list is given.
3. Mentioned (*uddiṣṭa*), to calculate the serial number in the list when a particular variation is mentioned.
4. Short- (and-long-) calculation (*laghukriyā*/*galakriyā*), to calculate the number of the variations in the list that have a given number of short or long syllables (for this purpose, a diagram called the Mount Meru-like spread (*meruprastāra*), equivalent to the so-called Pascal's triangle, is constructed).
5. Number (*saṃkhyā*), to calculate the number of all the variations in the list.
6. Way (*adhvan*/*adhvayoga*), to calculate the space of writing materials required for writing down the list.

A chapter on prosody in the *Nāṭyaśāstra* of Bharata (before AD 600), a dramaturgical work, and one in the *Agnipurāṇa* (ca. AD 800), a work on sacred traditions, also contain a section on these topics.

Four out of the six kinds of ascertainment, namely: spread, lost, mentioned, and number, were applied to the melody (combinations of seven notes) and the rhythm (combinations of a half, one, two, and three beats) in Indian music (Śārṅgadeva's *Saṅgītaratnākara*, ca. AD 1250), for which a diagram called Partial Meru (*khaṇḍameru*) was employed. This was also the case with the combinations of five subcategories taken severally from five categories of "carelessness" (*pramāda*) when they contain different numbers of subcategories, in Jaina philosophy (Nemicandra's *Gommaṭasāra*, ca. AD 980).

Medical treatises such as the *Carakasaṃhitā* (ca. AD 100) and *Suśrutasaṃhitā* (ca. AD 200) treated combinations of the six basic tastes (*rasa*), and of the three humors (*doṣa*) of the body. Varāhamihira dealt with the problem of combinations of nine and sixteen basic perfumes in the *Bṛhatsaṃhitā* (ca. AD 550).

Indian mathematicians prior to Bhāskara, too, are known to have been interested in these problems of combinatorics. Brahmagupta devoted one whole chapter consisting of 19 (or 20) stanzas of his astronomical work, *Brāhmasphuṭasiddhānta* (AD 628), for combinatorics related to Sanskrit prosody. The problem of tastes was taken up by the mathematician Śrīdhara in his *Pāṭīgaṇita* (ca. AD 750). Mahāvīra treated the six kinds of ascertainment of Sanskrit prosody as well as tastes in his mathematical treatise, *Gaṇitasārasamgraha* (ca. AD 850).

In addition to the traditional rule for combination mentioned above, Bhāskara gave six rules for permutations concerning sequences of numerical figures in a chapter called "nets of numbers" (*aṅkapāśa*) of his famous *Līlāvatī*. However, it is Nārāyaṇa who for the first time treated various problems of permutation and combination, including the system of "spread-lost-mentioned," of different areas systematically from the viewpoint of mathematics with the help of variously defined sequences of numerals. Chapter 13 entitled "nets of numbers" of his mathematical treatise, *Gaṇitakaumudī* (AD 1356), consists of about 100 stanzas for rules of combinatorics and 45 for examples.

Combinatorics in Islam

Ahmed Djebbar

Among the factors which influenced mathematics in Arab-Islamic civilization was a cultural life which fostered, particularly between the ninth and twelfth centuries, rich interaction between the different intellectual activities of the time.

Taken in a general sense as a study of configurations in one-, two-, or three-dimensional spaces, combinatory analysis had its beginnings in early studies in music, chemistry, astrology, and especially in metrics and Arabic linguistics. From the ninth century on combinatory processes asserted themselves in truly mathematical disciplines like algebra, astronomy, and trigonometry.

Combinatory Practices in Nonmathematical Fields

In music, many works contain a study of the combinations of sounds and rhythms, for example, the *Rasāʾil* (Epistles) of the Ikhwān al-ṣafāʾ (Brethren of Purity, tenth century) and the *Kitāb al-mūsīqā al-kabīr* (Great Book on Music) of al-Fārābī (ninth century). In the field of chemistry, as early as the eighth century, Jābīr ibn Ḥayyān introduced combinatory arguments in his theory of balance, which was based on the principle that everything is a combination of numbers. Jābir goes so far as to identify the language, i.e., the combination of words, in chemistry which he considers to be a morphology of metals.

In astronomical astrology, the conjunctions of the seven planets known at that time played an important role in predicting events. One needed to know the number of conjunctions which corresponded with the number of combinations of seven elements two times 2, three times 3…seven times 7. There was a great need to construct configurations by manipulating numbers or letters. Many mathematicians worked on this problem trying to invent processes of construction and new types of magic squares, for example, Thābit ibn Qurra (d. 901), Abū'l-Wafāʾ (d. 997), Ibn al-Haytham, Ibn Munʿim (d. 1228), and Ibn al-Bannāʾ (d. 1321).

In the field of Arabic poetry, it was al-Khalīl ibn Aḥmad (d. 791) who originated research on meter. He began by deriving a superficial structure of Arabic verse (which also serves for prose). Then he derived an underlying structure based on ten measures which, in combination, provided the five fundamental meters. In turn, these meters provided other meters to Arabic poetry thanks to a purely combinatory operation, circular permutation.

In the field of Arabic prose, there is even more interesting information about combinatory practices. As early as the eighth century, al-Khalīl undertook an analysis of the structures of the Arabic language and attempted to develop a theory based on the results of his investigations by studying the constitution of the roots of the language from the 28 letters of the alphabet, and then the composition of words from those roots. To that end, he calculated combinations, without repetitions, of letters two by two, three by three, four by four, and five by five, in order to determine the numbers of roots of two to five letters in the language. The results of his calculations, without any explanation, appear in his book *Kitab al-ʿayn*. After him, a long tradition was established in this field, but the combinatory aspects have not been systematically studied.

That being said, the examples cited above are really too sparse and isolated to prove any continuity in combinatory practices. In particular, we have not yet found anything which demonstrates the beginning of the mathematization of these combinatory practices in the Muslim East or in Andalusia before the twelfth century.

Combinatory Practices in Mathematics

Combinatory practices in the field of mathematics prior to the twelfth century were relatively modest and concerned only two disciplines, astronomy and algebra.

In astronomy, for example, there is the book of Thābit ibn Qurra, *Al-shakl al-Qaṭṭāʿ*, in which combinations occur, two by two, in six sizes occurring in the formula fixed for the secant figure. In his book, *Maqālīd ʿilm al-hay'a* (Keys to the Science of Astronomy), al-Bīrūnī also uses small combinatory results for the purpose of determining the unknown elements of a spheric triangle as a function of the known elements.

In algebra, there are two works which contain certain aspects of combinatorics. The first, the *Kitāb al-ṭarāʾif fi'l-ḥisāb* (Book of Rare Things in the Art of Calculation) by Abū Kāmil (d. 930), deals with the resolution of certain systems of indeterminate equations, stated in the form of problems of birds, the aim being to enumerate, for each system, all the possible solutions. The second work is the *Kitāb al-Bāhir* by as-Samaw'al (d. 1175) on algebra, its objects and its instruments.

We have, as yet, no way of proving that these combinatory practices from within the mathematical tradition gave rise to any real research in the field between the ninth and the twelfth centuries, and in instances where research did occur, we do not know the results. In any case, it was not the combinatory elements encountered in mathematical problems which inspired the mathematicians of the Maghreb who became involved in combinatorics. It was the tradition of linguistics and lexicography which was the basis of their research.

Ibn Munʿim

The oldest mathematical work from the Maghreb which deals with combinatory problems is the *Fiqh al-ḥisāb* of Ibn Munʿim, a scholar originally from Andalusia, living in Marrakesh in the Almohad era. To our knowledge, his book was the first in the entire history of mathematics to have devoted a whole chapter to this type of problem and to have stated them and solved them according to a common procedure.

Combinatorics After the Thirteenth Century

In the second half of the thirteenth century or the beginning of the fourteenth, another Maghrebin mathematician, Ibn al-Bannāʾ, took up some of the results of Ibn Munʿim in at least two of his works, the *Rafʿ al-ḥijāb* and the *Tanbīh al-albāb*. In the latter work, he notes only a table of combinations from Ibn Munʿim without giving exact references, but he explicitly lays claim to the demonstration of a result long attributed to Pascal (d. 1662) which gives C_n^p as a function of C_n^{p-1}, thus allowing the calculation of the combinations two times 2, three times 3, etc., of a certain number of objects, using the arithmetical formula:

$$C_n^p = \frac{n(n-1)\cdots(n-p+1)}{1\cdot 2\cdot 3\cdots p\cdot(p-1)}$$

which today takes the form of

$$C_n^p = \frac{n!}{p!(n-p)!}.$$

In the same spirit, he deduced the expression of arrangements without repetition of a certain number of objects, after having calculated the number of their permutations.

It is important to point out that, at the same time, in the East, the mathematician al-Fārisī (d. 1321) identified the values of the different combinations of the elements of the arithmetic triangle of al-Karajī and used them to establish a theorem of the theory of numbers such that one can determine the number of divisors belonging to a certain whole. Unfortunately, we do not know if this contribution of al-Fārisī spread throughout the East nor can we affirm that it was known in the Muslim West.

However that may be, we can discern two significant processes from Maghrebian writings after Ibn Munᶜim. First, there occurred the extension of the field of application of formulas and of combinatory reasoning. This field was no longer concerned just with the elements of an alphabet, since that became an abstract model operating in different mathematical fields: in astronomy, with the reformulation and enumeration of compound ratios occurring in spheric trigonometry; in geometry, with the classification of figures and the enumeration of all the equations one can deduce; and finally in algebra, with the enumeration of systems of equations (the work of Ibn Haydūr (d. 1413) and of equations of a certain degree greater than three (the work of the Egyptian Ibn alMajdī, d. 1447, in his commentary on the *Talkhīṣ* (Summary) of Ibn al-Bannā˒).

In the second place, there was a taking account of enumeration in general, in very different fields not always related to mathematics. The most typical case is that of Ibn al-Bannā˒, who devoted part of his work *Tanbīh al-albāb* to these types of problems: the enumeration of different cases of possible inheritances when the heirs are *n* boys and *p* girls, the enumeration of prayers to be said according to the exigencies of Malekite ritual in order to compensate for having forgotten other prayers, and the enumeration of all the possible readings of the same sentence according to the rules of Arabic grammar.

The presence of the same combinatory vocabulary in the works of different authors and the fact that none of them laid explicit claim to their results reinforces the characters of continuity of combinatory practices, a continuity made possible, probably, by the persistence of this new chapter in the teaching of certain professors of that time.

However, if to our eyes this new material and these new instruments seem objectively to be of a piece, we do not know to what degree those who contributed to their formulation were conscious of them or what importance they held in *their* eyes.

The reasons for this are to be found in several places at once: the state of the society itself and the nature of its activities and preoccupations which did not allow for the significant development of combinatorics; the absence of local or regional institutions responsible for renewing programs and imposing, and then perpetuating, the teaching of new ideas; and the imprint of certain specialists whose authority influenced at certain moments the content of scientific teaching, fixing it or simplifying (or deleting) certain theoretical developments and certain chapters. At least that is what Ibn al-Bannā˒ implies in his *Rafᶜ al-ḥijāb* and what Ibn Khaldūn confirms in his *Muqaddima* (Prolegomena), writing about the abandonment of theoretical problems and the perpetration of a more utilitarian mathematics.

Comets and Meteors in the Islamic World

David Cook

Comets and meteors in the classical Muslim world were viewed through the prism of Ptolemaic science as anomalies that broke the rules governing the fixed stars and the seven orbiting planets visible to the naked eye. For this reason, comets and meteors were viewed as portents and frequently noted in the history books and commented upon by the population viewing them. Rulers saw them as negative omens and feared the appearance of comets, while revolutionaries used the awe and terror engendered in the common people to foment change.

The terms used in the Arabic and Persian books are difficult to define with precision. All the most common terms for comets – *najm dhū dhū'aba/dhūa'ib/dhanab* (a star with a lock, locks or a tail) or *kawkab* (a star or a planet) with the same group of suffixes – indicate an association with the fixed or orbiting stars and not an independent existence. Frequently other terms are used that have even less precision, such as *nayzak* (a spear), a "sword" in the sky or other terms (among the

Christian sources, a "cross" for example). But at all times the comet attracted attention because it was sharply differentiated from the fixed stars and the orbiting planets, and merits notice in early books of astronomical folklore (e.g., al-Thaqafī [d. 1012]: 36–37). It seems that many nonscholarly observers of comets believed that they were seeing the selfsame comet that returned on a regular basis.

More scholarly writers were puzzled by the appearance of comets, but they relied upon the classical heritage to explain them. An example of this tendency is the famous Spanish Muslim scholar Ibn Rushd (d. 1198), who wrote that the Greeks and the Romans saw comets as unstable parts of the orbiting planets, and that the "tail" was just the light that appeared as a tail to the eye (Ibn Rushd: 43). Others saw the tail as an integral part of the comet, however. Ibn Rushd further cites Hippocrates and his disciples who stated that the "tail" of the comet was the result of the vapors that were pulled by the sun as it passed by. However, Ibn Rushd was critical of theories proposed by Democritus that comets occurred at the time of planetary conjunctions or were related in some way to the planets (a view he ascribed to the Romans, unnamed). He responded to Hippocrates by stating that if the tail of the comet was the result of vapors, then the comet should be seen with a tail sometimes and without it at other times (Ibn Rushd: 44–45).

Ibn Rushd also pointed out that it was fallacious to state that comets only appeared from the north, and cited personal observation to refute this claim. He stated categorically that comets were not to be grouped with the other stars at all. In the end he proposed that both the comet and the tail were burning with flame, and that the comet interacted with the effluvium, which created the illusion of a long tail (Ibn Rushd: 47–48). In conclusion, similar to popular observers of comets, Ibn Rushd noted that they portend high winds and dryness. Not everyone, however, considered comets to be ill omened. For example, "Ṣāliḥ…al-Wāsiṭī said: Ghazwān told me: A comet rose and so my father sent me to Ziyād b. al-Rabīa to ask him [about it]. He said: Say to him that this comet rises every thirty years and when it rises that year will be fruitful, and it was as he said" (Bahshal: 173, cited in Cook 1999).

There are a large number of observations located in Muslim texts, primarily in Arabic and Persian. Cook (1999) and Rada (1999) have gathered most of the relevant material; however, new comets and meteors continue to be found, and there are great many subsections of Muslim literature that have yet to be surveyed for comets and meteors. The information contained in these observations is eclectic in nature. On occasion it is highly precise in terms of times, dates and angles of observation, but for the most part it is casual and anecdotal, often related to the ominous nature of the comet's appearance. All of the appearances of Halley's Comet (appearing approximately every 71–74 years) can be reconstructed after the 684 appearance, with the exception of the 1,301 appearance, can be attested from Muslim sources.

However, it is not until the 837 appearance of Halley's Comet that we find regular notices in the Arabic language historical materials concerning comets. Prior to this time a great many of the appearances are to be found in problematic materials (apocalyptic, literary) or are indistinct either as to the date and time of the sighting and often as to the phenomenon being witnessed. From 837 the quality of the material is considerably higher, and the dates are often exact with sufficient details that the historian can identify the orbit of the comet. For example, in 905, "a star with locks appeared in Capricorn, toward the north, near Ursa [Minor or Major]" (Cook 1999: 139). Gradually measurements in degrees appear inside the texts. In 947, "there appeared in the heavens a star with a tail whose length was about four degrees on Friday night, August 29, in the year 947 and it disappeared after ten days from its appearance" (Cook 1999: 141). Many other sightings are available. However the quality of the material drops off sharply after 1400, and it is difficult to find precise astronomical descriptions of comets in the Persian historical materials (with the exception of the text published by Kennedy). After the 1830s Arabic historians ceased to note the appearance of comets.

Meteors are a completely different matter from comets, and need to be divided into two groups: meteor showers observed in the heavens and meteorites that have fallen to the earth, often with a substantial impact. In contradistinction to comets, the appearance of meteors is attested in the *Qur'ān* and received an accepted place within the framework of popular Muslim cosmology. *Qur'ān* 72 records that *jinn* (beings made of fire) used to sit on *shihāb*s (meteors) and listen to heavenly conversations (cf. also *Qur'ān* 15: 18, 37: 10). God would periodically throw them down and this action generated the appearance of fireballs (Ṭabarī XXIX: 110–111). This view of the heavens is in close accord with other popular beliefs, such as the belief that the Milky Way galaxy was the sweat of a snake that supported the Throne of God (al-Suyūṭī: 32–33), and is not mentioned in the more scientific discussions.

Falling stars and meteor showers are attested regularly from approximately the beginning of the ninth century, just as with the comets above. But the earliest attestation of an actual meteorite in the Muslim sources is from 852, when "Ṭāhir b. 'Abdallāh [ruler of eastern Persia] sent a stone which fell from the heavens in the region of Tabaristan [northern Iran] to al-Mutawakkil [the caliph]. Its weight was 840 *dirhems* (approximately 253 kg), and they said that its fall was heard at a distance of four leagues, and that it came down to earth in five pieces" (al-Ḥarīrī, I: 181). From this point onward meteorites are regularly recorded in the sources, and are often related to the appearance of meteor showers. Usually the sound of the entry of the meteorite into the atmosphere is described as that of loud thunder, and often columns of light or a flash are mentioned as well. Earthquakes are noted to have followed these events after a short time.

Of course, the only meteorites that received close attention were those that fell upon inhabited areas. Meteorites are said to have fallen on Qayrawan (Tunisia) in 951–952, in Aleppo (1025), in the Yemen (1084, 1154, 1384), Tripoli (1117) and a number of other places. In 1110–1111 a meteorite hit Lake Van (today in eastern Turkey) and emptied the lake and killed all of the fish in it (Matthew of Edessa: 206–207). However, as with the materials on comets, there are few records of meteor showers or meteorites in the extensive Mamluk historical literature (1250–1517) or the Persian history books. Peripheral regions of the Muslim world, such as Morocco, Yemen, India, and Jirba (today in Tunisia), continued to note large numbers of meteorites until the end of the seventeenth century after which it is difficult to find any notices of their appearance.

The Muslim materials on comets and meteors are abundant and have yet to be thoroughly researched. It seems reasonably clear that as long as comets were viewed as portents they merited mention, but meteor showers and meteorites were of lesser import. Gary Kronk in his authoritative *Cometography* has commented on the importance of the Muslim astronomical materials, which have served as a corrective for the lack of European materials during this period, and can be usefully compared with the plethora of Chinese and East Asian observations.

Compass

Julian A. Smith

The origin of the magnetic compass is obscure. Medieval and Renaissance European compasses have been analyzed in detail, but until recently little work has been done on their history in non-Western cultures. Most modern accounts place the birth of the magnetic compass in ancient China, but its inventors are unknown, its development unclear, and historians are divided over whether its later appearance in the West was independent, or borrowed from China through overland or Arabic maritime intermediaries.

The Chinese compass seems to have been derived from a "south controlling spoon" (*si nan shao*) carved from lodestone (magnetite) and used in the early diviners' boards the Han Dynasty (202 BCE–AD 220). Just as in ancient Greece, Chinese philosophers were first aware of magnetic attraction; the ability of the lodestone to pick up iron was mentioned in the *Lü Shi Chun Qiu* (Master Lu's Spring and Autumn Annals, third century BCE), the *Lun Heng* (Discourses Weighed in the Balance, AD 83), and a host of other Chinese annals between the third century BCE and the sixth century AD. The discovery of magnetic directivity (the tendency of magnets to point north and south) made the lodestone particularly important in geomancy and divination. Historian Joseph Needham argued that this was known publicly by the first century AD, and may have been a secret of court magicians as early as the second century BCE.

Between the first and sixth centuries AD, Chinese scholars discovered that magnetic directivity could be induced in small iron needles by stroking them on lodestones. These needles, when floated in bowls of water (sometimes hidden inside carved wooden fish), would then guide Chinese navigators by pointing to the north and south; these early "wet compasses" were the first type. The second variety, a "dry compass" consisting of a needle mounted on a pivot (often concealed inside a wooden turtle), was developed much later (early twelfth century). Chinese encyclopaedias such as the *Taiping Yulan* (Taiping Reign-Period Imperial Encyclopaedia) also mention "dry" compasses made by suspending a magnetic needle on a silk thread.

Chinese physicists may also have been first in discovering magnetic declination. The fact that the compass does not point exactly to the geographic north, but rather to the magnetic north a few degrees away, was mentioned in philosopher Shen Gua's *Meng Qi Bi Than* (Dream Pool Essays) in 1088 AD. He says the compass needle "always inclines slightly to the east." Knowledge of this effect was extremely important for ocean navigation. Chinese knowledge of declination goes back to the late Tang period (eighth–ninth centuries AD).

The development of the magnetic compass in India is highly uncertain. According to some scholars, the compass is mentioned in fourth century AD Tamil nautical books; moreover, its early name of *maccha-yantra* (fish machine) suggests a possible Chinese origin. In its Indian form, the wet compass often consisted of a fish-shaped magnet, floated in a bowl filled with oil.

The earliest references to the magnetic compass in Europe appear in the grammatical and philosophical treatises *De Nominibus Utensilium* and *De Naturis Rerum* of English monk Alexander Neckam (1157–1217), French poet Guyot de Provins' (fl. 1184–1210) *La Bible*, and the *Historia Orientalis seu Hierosolymitana* of French preacher Jacques de Vitry (ca. 1165–1240). Based on these sources, historians have dated the European appearance of both dry and wet compasses to the middle of the twelfth century.

Among Arabic sources, the earliest descriptions of the magnetic compass occur in the thirteenth century. A Persian collection of stories, the *Jāmiʿ al-Ḥikāyāt* (ca. 1232) of Muḥammad al-ʿAwfī says that sailors navigate using a piece of iron rubbed by a magnet, and the 1282 lapidary of Bailak al-Qabajaqi, the *Kanz al-Tijar*, mentions a wet compass seen in 1242. Some of these early treatises discuss the use of fish-shaped compass needles among Islamic navigators in the Indian Ocean, suggesting a possible borrowing from Indian sailors; but it is also possible that Arabs got the compass from Europeans (scholars arguing this hypothesis often point out the Arabic word for compass, *al-kunbas*, appears to come from Italian roots). Much more research needs to be done before this argument can be settled.

Computation: Chinese Counting Rods

Lam Lay Yong

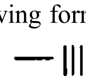
The basic questions in the study of arithmetic in any civilization are: how did the people add, subtract, multiply, and divide, and what were the notations and media that were used to perform these operations.

The ancient Chinese used bamboo sticks or animal bones to count. The first five numbers were tallies in the following form:

The representations for six, seven, eight, and nine were as follows:

The horizontal rod represented the quantity five.

It is easy to imagine how these rod numerals were handled for the addition or subtraction of small numbers such as two plus five or nine minus two. In the case of the addition of, for example, six and seven, the three vertical rods were grouped together and the two horizontal rods representing two fives were replaced by a single rod positioned horizontally to the left of the three vertical rods. The sum, thirteen, was expressed in the following form:



In this manner, a place value notation was created; the tens' place was to the left of the units' place. The nine numerals that could occupy this place were similar in idea to the nine numerals shown above but had a significant difference: the vertical rods were turned into horizontal ones and the horizontal rods were turned into vertical ones. They were of the following form:

The notion of place values was then extended to express larger numbers. The first set of nine numerals occupied positions whose place values were units, hundreds, ten thousands, and so forth; the second set of nine numerals occupied positions whose place values were tens, thousands, hundred thousands, and so on. For example, the rod numeral for thirty six thousand one hundred and eighty-seven appeared as

and the rod numeral for thirty thousand one hundred and eighty-seven appeared as

which revealed that the thousands' place was empty.

Any number, however large, thus could be represented by the rod numeral system, which used a place value notation with ten as base. The rod numeral system was essentially a computing mechanism; the results of the calculation were recorded in the written numbers.

The rods were used for reckoning in the fifth century BCE. According to *Qian Han shu* (Standard History of the Western Han Dynasty), they were cylindrical bamboo sticks, 0.1 *cun* (approximately 0.231 cm) in diameter and 6 *cun* long. They were carried in a hexagonal bundle made up of 271 pieces. Computation was performed on a flat surface such as a table or a mat. By the sixth century AD, the rods were shorter in length and square in cross-section. During the Tang Dynasty (AD 618–907), it was quite common for officials, astronomers, engineers, mathematicians, and others to carry their bundles of rods wherever they went. Besides animal bones and wood, the rods could be carved from horn, ivory, or jade.

Sun Zi suanjing (The Mathematical Classic of Sun Zi) written aiiiuiul AD 400 is the earliest existing work to have a description of the rod numerals. It also gives detailed descriptions of how multiplication and division were performed. The step-by-step procedures are the same as the earliest known methods of multiplication and division using Hindu–Arabic numerals, which were described by Muḥammad ibn Mūsā al-Khwārizmī in his book on arithmetic and by Abū al-Ḥasan Aḥmad ibn Ibrāhīm al-Uqlīdisī in *Kitāb al-Fuṣul fī al-Ḥisāb al-Hindī*. This fact together with other evidence supports the thesis that the Hindu–Arabic numeral system has its origins in the Chinese rod numeral system.

Just as the Hindu–Arabic numeral system provided the mainstay and impetus for the growth and development of our arithmetic and algebra, the rod numeral system provided the same support for the development of mathematics in ancient and medieval China.

The process of division with rod numerals resulted in an important notation for the expression of a fraction. For example, the notation for four-fifths is

This is the same as the notation for the common fraction in Hindu–Arabic numerals which also originated from the earliest method of division with numerals. The use of this notation enabled an extensive study on operations with fractions – a subject with which other ancient civilizations had difficulties that were frequently insurmountable.

With the concept of the rod numeral system ingrained in their minds and using the rods as the medium of expression, the ancient Chinese developed arithmetic and algebra. The problems in *Jiu zhang suan shu* (Nine Chapters on the Mathematical Art) (ca. AD 100) show that they were able to solve problems involving fractions, the Rule of Three, proportion, areas and volumes, square roots and cube roots, the Rule of False Position, sets of simultaneous linear equations, and negative numbers.

For numerous centuries the rod numeral system played a dual role: in calculation and in the development of mathematics. It aided the progress of the Chinese civilization till the Ming Dynasty (1368–1644) when it was gradually replaced by the abacus as an instrument for computation. Mathematics flourished from the firm foundation depicted in *Jiu zhang suan shu* and reached its peak in the thirteenth century. When the rod numerals became outmoded and fell into disuse, mathematics also underwent its period of decline and transition.

Computing Science in Ancient India

SUBHASH KAK

India's romance with numbers can be seen in the mention of large numbers up to 10^{19} in the Black Yajurveda. The sources for mathematical computing in India in the early phase are the Vedic books including the Brāhmana texts, the *Śulbasūtras* (texts on altar geometry), *Jyotisha* (astronomy), the *Chandahśāstra* (Pingala's book on prosody), Pānini's grammar, the *Nātya Śāstra* (Bharata Muni's text on music, drama, and dance), and nonmathematical texts such as the *Mahābhārata* and diverse *śāstras* (scientific and philosophical texts).

The Indian approach to the world was classificatory and computational. In astronomy, an attempt was made to reconcile the motions of the sun, the moon, and the planets that required periodic corrections. In grammar, the most economical rules for different constructions were sought. Not only the sign for zero, but also the binary number system, infinity and its operations, the ideas of metarules, algebraic transformation, recursion, hashing, mathematical logic, formal grammars, and high level language description arose first in India.

The *Śulbasūtras*

The *Śulbasūtras* belong to the *Vedāngas*, or supplementary texts of the Vedas that deal with construction of geometric altars. Their contents, written in the condensed *sūtra* style, cover geometrical propositions and problems related to rectilinear figures and their combinations and transformations, squaring the circle, as well as arithmetical and algebraic solutions to these problems. The root *śulb* means measurement, and the word *śulba* means a cord, rope, or string.

The extant *Śulbasūtras* belong to the schools of the Yajurveda. The most important *Śulba* texts are the ones by Baudhāyana, Āpastamba, Kātyāyana, and Mānava. They have been generally assigned to the period 800–500 BCE of which Baudhāyana's text is the oldest. Baudhāyana begins with units of linear measurement and then presents the geometry of rectilinear figures, triangles, and circles, and their transformations from one type to another using differences and combinations of areas. Approximations to the square root of 2 and to π are given next.

In the methods of constructing squares and rectangles, several examples of Pythagorean triples are provided. It is clear from the constructions that both the algebraic and the geometric aspects of what we call the Pythagorean theorem were known. Several geometric constructions in these texts are based on algebraic solutions of simultaneous equations of linear and quadratic types. It appears that geometric techniques were often used to solve algebraic problems.

Jyotisha

Recent researches have established that the altar geometry of the *Śulbas* was used to represent astronomical facts related to the knowledge of the lunar and the solar years. The solution to these problems involved solution to indeterminate linear equations. Lagadha's *Vedānga Jyotisha* (1300 BCE), a book on the motions of the sun and the moon, presupposes knowledge of such equations.

Pānini's Grammar

Pānini's *Ashtādhyāyī*, "The Eight Chapters" (fifth century BCE), provides 4,000 rules that describe the Sanskrit of his day completely. The great variety of linguistic ideas used in the text mirrors the complexity of cognitive relationships that is the secret of its power and success. It is remarkable that Pānini set out to describe the entire grammar in terms of a finite number of rules. Scholars have shown that the grammar of Pānini represents a universal grammatical and computing system.

The *Ashtādhyāyī* ostensibly deals with the Sanskrit language. However, it presents the framework for a universal grammar that can apply to any language. Two important early commentaries on this grammar are by Kātyāyana and Patanjali. Bhartrihari examined its philosophical basis in an important work in the fifth century AD.

Pānini's grammar begins with metarules, or rules about rules using a special technical language, or metalanguage. Several sections follow on how to generate words and sentences starting from roots, as well as rules on transformation of structure. The last part of the grammar is a one-directional string of rules, where a given rule in the sequence ignores all rules that follow. Pānini also uses recursion by allowing elements of earlier rules to recur in later rules. This anticipates in form and spirit by more than 2,500 years the idea of a computer program.

In Pānini's system, a finite set of rules is enough to generate an infinity of sentences. The algebraic structure of Pānini's rules was not appreciated in the West until about 50 years ago when Noam Chomsky proposed a similar generative structure. Before this, in the nineteenth century, Pānini's analysis of roots and suffixes and his recognition of ablaut led to the founding of the subjects of comparative and historical linguistics.

Pānini took the idea of action as defined by the verb and developed a comprehensive theory by providing a context for action in terms of its relations to agents and situations. This theory is called the *kāraka* theory. These *kārakas* are:

1. That which is fixed when departure takes place
2. The recipient of the object
3. The instrument, or the main cause of the effect
4. The basis, or location
5. What the agent seeks to attain, deed, object
6. The agent

These *kārakas* do not always correspond to the nature of action; therefore, the *kāraka* theory is only a *via media* between grammar and reality. It is general enough to subsume a large number of cases, and where not directly applicable, the essence of the action/transaction can still be cast in the *kāraka* mold. To do this, Pānini requires that the intent of the speaker be considered. Rather than a structure based on conventions regarding how to string together words, Pānini's system is based on meaning.

Chhandahśāstra and *Nātya Śāstra*

The *Chhandahśāstra* of Pingala (400 BCE according to tradition) describes the binary number system. The idea of mathematical zero is also implicit in some of Pānini's rules. The *Nātya Śāstra* presents important results on permutations and combinations. Further results are to be found in later books on musicology such as the *Brihaddeśi* and the *Sangīta-Ratnākara*.

The Siddhāntic Age

Āryabhaṭa (born 476) presented the first general solution to the linear indeterminate equation using the method of *kuttaka*. Brahmagupta (seventh century) solved the quadratic indeterminate equation $Nx^2 + 1 = y^2$. Brahmagupta's expressions for the diagonals of a cyclid quadrilateral are considered most extraordinary.

Virahānka (eight century) gave an explicit rule for what we call the Fibonacci sequence. Vīrasena (ninth century) knew the logarithm to base 2 and its properties. Jayadeva of the same period developed the *chakravāla* (cyclic) method which, according to Hankel, is the "finest thing achieved in the theory of numbers before Lagrange (18th century)." Bhāskara (born 1114) made further advances to trigonometry and analysis.

Navya Nyāya

Navya Nyāya (New Logic) began in Mithila under the leadership of Gangeśa Upādhyāya (twelfth century). The scholars of this school developed an elaborate technical vocabulary and logical apparatus that came to be used by philosophers and writers on law, poetics, aesthetics, and ritualistic liturgy. In their technique of analyzing knowledge, judgmental knowledge was analyzed into three kinds of epistemological entities in their interrelations: "qualifiers"; "qualificandum," or that which must be qualified; and "relatedness." Further abstract entities used were qualifierness, qualificandumness, and relatedness. The knowledge expressed by the judgment "This is a blue pot" may then be analyzed into the following form:

> The knowledge that has a qualificandumness in what is denoted by 'this' is conditioned by a qualifierness in blue and also conditioned by another qualifierness in potness.

At its zenith during the time of Raghunātha (1475–1550), this school developed a methodology for a precise semantic analysis of language. Its formulations are equivalent to mathematical logic.

Kerala Mathematicians

The Kerala school of mathematics flourished during 1200–1600 in South India. One of its great figures, Mādhava (ca. 1340–1425), also provided methods to estimate the motions of the planets. He gave power series expansions for trigonometric functions, and for π correct to 11 decimal places.

A very prolific scholar who wrote several books on astronomy, Nīlakanṭha (ca. 1444–1545), found the correct formulation for the equation of the center of the planets and his model is nearly a true heliocentric model of the solar system. In it, the planets go in eccentric orbits around the mean Sun, which in turn goes around the Earth. He also improved upon the power series techniques of Mādhava.

These mathematicians made truly fundamental advances in analysis including infinite series and calculus. Almeida and his collaborators have suggested that Jesuit missionaries brought this work to Europe and it may have provided the spark for the European mathematical revolution.

Conics

Jan P. Hogendijk

The theory of conic sections was discovered in Greece around 350 BCE. The most comprehensive ancient treatise on the subject was the *Conics* of Apollonius of Perga (fl. ca. 200 BCE). This treatise consisted of eight Books, of which only the first four have come down to us in Greek. Apollonius considered an arbitrary cone with a circular base, whose apex is an arbitrary point not in the plane of the base. He obtained the conic sections as intersections of this cone by a plane not through the apex. Apollonius distinguished three types of conic sections: the ellipse, the parabola, and the hyperbola.

The story of the translation of the *Conics* into Arabic is interesting, because it shows the difficulty of translating a technical mathematical text. The first Arabic geometers with an interest in the *Conics* were the three Banū Mūsā ("sons of Mūsā," fl. ca. AD 830). At first they possessed only one poor Greek manuscript, containing the first seven Books, and they were unable to understand the very technical contents. Then one of the brothers, al-Ḥasan, decided to develop the theory of the ellipse as the intersection of a cylinder and a plane. He believed that the cylinder was easier than the cone, and he hoped that the theory might be more accessible this way. Al-Ḥasan wrote a book on his discoveries, entitled *Al-shakl al-mudawwar al-mustaṭīl* (The Rounded Elongated Figure). This work is lost.

After the death of al-Ḥasan, his brother Aḥmad obtained a second manuscript of the first four Books of the *Conics* in Syria, together with the commentary of Eutocius of Ascalon (ca. AD 500). This manuscript was much better than the other one, and with the help of the book of his deceased brother, Aḥmad was able to make sense of the contents of the Greek text. He then inserted cross-references in the Greek in order to make the text more comprehensible. Now that he understood the first four Books, Aḥmad was able to make sense of Books V–VII on the basis of the other manuscript. He then had the Books translated: Books I–IV by Hilāl al-Ḥimṣī, Books V–VII by Thābit ibn Qurra. Aḥmad supervised and corrected the translation. Thus Aḥmad ibn Mūsā and Thābit rescued one of the most interesting mathematical works of antiquity, namely Books V–VII of the *Conics*. Book VIII of the *Conics* seems to have been lost altogether. It was reconstructed around 1000 by Ibn al-Haytham, and around 1700 by Edmund Halley.

By the ninth century, geometers in the Arabic tradition had already written treatises on conic sections. Thābit ibn Qurra authored a work on plane sections of a cylinder, which is extant. A popular subject was the determination of the surface areas of segments of conic sections and the volumes of solids obtained by revolving a segment of a conic section about one line (such as the axis or the base). The Arabic geometers knew that Archimedes had solved this problem for the parabola, but they did not know his method of solution. The treatises on this subject by Thābit ibn Qurra, and by the tenth-century mathematicians al-Qūhi and Ibn al-Haytham, are among the highlights of Arabic mathematics.

The Arabic geometers applied conic sections in the solution of a group of problems (trisection of the angle, construction of two mean proportionals, construction of the regular heptagon, etc.) which could not be solved by means of ruler and compass. In the tenth century AD, most geometers in Iraq and Iran considered straight

C

lines, circles, and conic sections the only legitimate means of construction in geometry. The reason was that these objects belonged to fixed (immovable) geometry (*al-handasa al-thābita*), whereas all other curves and instruments were believed to be created by motions and instruments, which did not belong to mathematics but to mechanics.

Conics were also used in the solution of the "Problem of Alhazen" (named after al-Ḥasan ibn al-Haytham, mentioned above). In this problem, the positions of the eye, the object, and a convex or concave spherical, cylindrical, or conical mirror are given. One asks for the points of the mirror at which the object is reflected to the eye. Ibn al-Haytham constructed these points of reflection, and he showed that the object is reflected at no more than four points on the mirror. His solution is very intelligent but also extremely complicated, and several seventeenth-century European mathematicians complained about its difficulty. Earlier, the solution had been simplified by al-Muʾtaman ibn Hūd, the king of Zaragoza (d. 1085), but this simplification was unknown in Christian Europe.

In the tenth century, al-ʿAlāʾ ibn Sahl studied reflection in parabolic lenses (which had been studied before) and refraction in hyperbolic lenses (this topic was new). He showed that rays parallel to the axis are refracted to one of the foci of the hyperbola. The reasoning implies knowledge of what we now call Snell's law of refraction, but it is unclear how al-ʿAlā discovered this law.

An important field of application of conic sections was the theory of cubic equations. A cubic equation is an equation of the form $x^3 + ax^2 + bx + c = 0$, for a, b, c given numbers. The Arabic geometers were unable to solve this equation algebraically, i.e., to say, by expressing the root x in terms of a, b, and c. However, they learned to solve it geometrically. The history of the theory is connected with a certain division of a line segment mentioned by Archimedes in Proposition 4 of Book II of *On the Sphere and Cylinder*. Archimedes used the divided line segment but he did not show how it could be divided. In the ninth century, al-Māhānī showed that the division of the line segment, which Archimedes uses, depends on a cubic equation of the form $x^3 + c = ax^2$ (a and c are positive). However, he was unable to solve this equation. Abū Jaʿfar al-Khāzin (tenth century) knew the work of al-Māhānī and also a commentary by Eutocius of Ascalon (ca. AD 500), who shows how the line segment can be divided by means of conic sections. Apparently, Abū Jaʿfar realized that one could use Eutocius' construction using conic sections to find the root x of the equation $x^3 + c = ax^2$ to which al-Māhānī had reduced the problem. Soon other Arabic geometers discovered that conic sections could also be used to solve other "types" of cubic equations. (Because they only worked with positive coefficients, they distinguished different types of equations, e.g., $x^3 + c = ax^2$ is of a type different from $x^3 + ax^2 = c$, etc.) In the eleventh century, ʻUmar al-Khayyām gave in his *Algebra* a geometric solution (by means of conic sections) of all types of cubic equations. His theory was considerably improved by Sharaf al-Dīn al-Ṭūsī around 1200.

The Arabic mathematicians developed an instrument, the perfect compass, with which conic sections could be drawn, but this does not seem to have been much used and no examples have survived. Ibn al-Haytham used conic sections for mosaic constructions.

Consciousness in Ancient India

Subhash Kak

The Vedic texts from ancient India (approx. 3000–1000 BCE) claim to be *ātmavidyā*, "science of self" or "consciousness science." The most ancient of these is the cryptic *Ṛgveda*. But prose commentaries, called the *Brāhmanas* and the *Upanishads* that appeared in the centuries following the *Vedas*, provide a framework to decode its narrative, establishing its central concern with consciousness.

Until recently, the question of consciousness was considered to lie outside of the scope of science and, consequently, the Indian texts on the subject were not properly examined. Scientific attitudes toward consciousness have changed due to the recent advances in neuroscience and because modern physics and computer science must confront the question of the observer.

In the Vedic view, reality is unitary at the deepest level since otherwise there would be chaos. This reality is called *Brahman* (neuter gender). Brahman engenders and, paradoxically, transcends the mind/matter split. It is identical to consciousness at the cosmic scale and it informs individual minds. Turning focus to the very nature of the mind provides insight about consciousness.

Limitations of Language

Since language is linear, whereas the unfolding of the universe takes place in a multitude of dimensions, language is limited in its ability to describe reality. Because of this limitation, reality can only be experienced and never described fully. All descriptions of the universe lead to logical paradox, and Brahman is the category transcending all oppositions. Vedic ritual is a symbolic retelling of this worldview.

Knowledge is classified in two ways: the higher or unified, and the lower or dual. The higher knowledge concerns the perceiving subject (consciousness), whereas the lower knowledge concerns objects. The higher knowledge can be arrived at only through intuition and meditation on the paradoxes of the outer world. The lower knowledge is analytical and it represents standard sciences (*śāstra*) with its many branches. In addition, *darśana* represents philosophy where the problem of self is taken together with some aspect of outer reality. There is a complementarity between the higher and the lower, each being necessary to define the other. This complementarity mirrors the one between mind and body.

Recursive Reality and Mind

The Vedic texts present a tripartite and recursive view of the world. The universe, viewed as three regions of earth, space, and sky, is mirrored in the physical body, the breath (*prāna*), and mind. This connection is a consequence of a binding (*bandhu*) between various inner and outer phenomena.

The universe is understood to be a living organism and therefore subject to cycles of life and death. The universe evolves according to cosmic law. Since it cannot arise out of nothing, the universe must be infinitely old. Since it must evolve, there are cycles of chaos and order or creation and destruction.

In the Vedic discourse, the cognitive centers are called the *devas*, deities or gods, or luminous loci. Thus the *Atharvaveda* calls the human body the city of the *devas*. Each *deva* reflects primordial consciousness and one can access the mystery of consciousness through any of these.

Mind in Indian Philosophy (*Darśana*)

The six systems of Indian philosophy are paired together in three complementary groups: logic (*Nyāya*) and physics (*Vaiśeshika*); cosmology (*Sāmkhya*) and psychology (*Yoga*); and language (*Mimāmsā*) and reality (*Vedānta*). Although these philosophical schools were formalized in the post-Vedic age, we find the basis of these ideas in the Vedic texts. In each of these, the question of the experiencing self is included.

The objective of the Nyāya is *anvīkshiki*, or critical inquiry. Its beginnings go into the Vedic period, but its first systematic elucidation is given by Gautama in his *Nyāya Sūtra* (third century BCE). The text begins with the nature of doubt and the means of proof, considering the nature of self, body, senses and their objects, cognition, and mind. The Nyāya is also called *pramāna śāstra* or the science of correct knowledge. Knowing is based on four conditions:

1. The subject or the *pramātri*
2. The object or the *prameya* to which the process of cognition is directed
3. The cognition or the *pramiti*
4. The nature of knowledge or the *pramāna*

Gautama mentions that four factors are involved in direct perception: the senses (*indriyas*), their objects (*artha*), the contact of the senses and the objects (*sannikarsha*), and the cognition produced by this contact (*jnāna*). The five sense organs – eye, ear, nose, tongue, and skin – have the five elements – light, ether, earth, water, and air – as their field, with corresponding qualities of color, sound, smell, taste, and touch.

Manas or mind mediates between the self and the senses. When the *manas* is in contact with one sense organ, it cannot be so with another. It is therefore said to be atomic in dimension. It is because of the nature of the mind that our experiences are essentially linear, although the quick succession of impressions may give the appearance of simultaneity.

Objects have qualities which do not have their own existence. The color and class associated with an object are secondary to the substance. According to Gautama, direct perception is inexpressible. Things are not perceived as bearing a name. The conception of an object on hearing a name is not direct perception but verbal cognition.

According to the atomic doctrine of Vaiśeshika ascribed to Kanāda, there are nine classes of substances: ether, space, and time that are continuous; four elementary substances (or particles) called earth, air, water, and fire that are atomic; and two kinds of mind, one omnipresent and another which is the individual. The conscious subject is separate from the material reality but he is, nevertheless, able to direct its evolution.

The Sāmkhya and the Yoga systems take the mind as consisting of five components: *manas*, *ahamkāra*, *chitta*, *buddhi*, and *ātman*. *Manas* is the lower mind which collects sense impressions. *Ahamkāra* is the sense of I-ness that associates some perceptions to a

C

subjective and personal experience. Once sensory impressions have been related to I-ness by *ahamkāra*, their evaluation and resulting decisions are arrived at by *buddhi*, the intellect. *Chitta* is the memory bank of the mind. These memories constitute the foundation on which the rest of the mind operates. But *chitta* is not merely a passive instrument. The organization of the new impressions throws up instinctual or primitive urges which create different emotional states. This mental complex surrounds the innermost aspect of consciousness, which is *ātman*, the self.

Yoga psychology of Patanjali is a very sophisticated description of the nature of the human mind and its capacity. It makes a distinction between memory, states of awareness, and the fundamental entity of consciousness. It puts the analytical searchlight on mind processes with clarity and originality.

Mīmāmsā and Vedānta consider the analysis of language and reality, respectively. Mīmāmsā ideas became a part of the grammatical tradition and Vedānta became a vehicle to consider consciousness in the most abstract sense.

Parallels with Cognitive Science

There are intriguing parallels between the insights of the early Vedic theory of consciousness and those of quantum mechanics and neuroscience. To express Vedic ideas in modern terms, one might say that individual minds emerge out of the reflection that the brain provides to the underlying illuminating consciousness. Therefore, senses of awareness, such as vision and hearing, may be separated from the person who obtains this awareness.

The human brain represents the clearest structure to focus the self, which is why humans are able to perform in ways that other animals cannot. Self-awareness is an emergent phenomenon which is grounded on the self and the associations stored in the brain.

From a modern scientific viewpoint, living systems are dynamic structures, defined by their interaction with their environment. Living systems may also be defined recursively in terms of living subsystems. Thus, for ants, one may consider their society, an ant colony, as a living superorganism; in turn, the ant's subsystems are also living. Such a recursive definition appears basic to all life. Machines, on the other hand, are based on networking of elements that create a well-defined computing procedure, but they lack a recursive self-definition.

The Vedic system, which was an earlier attempt to unify knowledge, was confronted by paradoxes similar to that of contemporary science. It is noteworthy that Schrödinger, the co-creator of quantum theory, admitted to having been inspired by the Vedic texts. According to his biographer Walter Moore, there is a clear continuity between Schrödinger's understanding of Vedānta and his research:

> The unity and continuity of Vedanta are reflected in the unity and continuity of wave mechanics. In 1925, the world view of physics was a model of a great machine composed of separable interacting material particles. During the next few years, Schrödinger and Heisenberg and their followers created a universe based on superimposed inseparable waves of probability amplitudes. This new view would be entirely consistent with the Vedantic concept of All in One (Moore 1989: 173).

The similarity between the Vedic system and quantum mechanics and the fact that quantum mechanical models of consciousness are being attempted leads us to ask how far the Vedic thinkers took their classificatory models of consciousness. We find both hierarchical and distributed cognitive centers listed in the Vedic texts.

Further Universal Categories

If the categories of the mind arise from pattern recognition of shadow mental images, then how are these categories associated with a single "agent," and how does the mind bootstrap these shadow categories to find the nature of reality?

These questions are examined in the later Vedic tradition both within the frameworks of Vaishnavism and Shaivism. Of the latter tradition, the later Kashmir Shaivism of Vasugupta (AD 800) has in recent years received considerable attention (Shiva is the name for the absolute consciousness).

According to Sāmkhya, reality may be represented in terms of 25 categories. These categories form the substratum of the classification in Kashmir Shaivism. The Sāmkhya categories are:

1. Five elements of materiality, represented by earth, water, fire, air, and ether
2. Five subtle elements, represented by smell, taste, form, touch, and sound
3. Five organs of action, represented by reproduction, excretion, locomotion, grasping, and speech
4. Five organs of cognition, related to smell, taste, vision, touch, and hearing
5. Three internal organs, mind, ego, and intellect
6. Inherent nature (*prakriti*) and consciousness (*purusha*)

These categories define the structure of the physical world and of agents and their minds.

Kashmir Shaivism enumerates further characteristics of consciousness:

7. Sheaths or limitations of consciousness, being time (*kāla*), space (*niyati*), selectivity (*rāga*), awareness (*vidyā*), creativity (*kalā*), and self-forgetting (*māyā*)
8. Five principles of the universal experience, which are correlation in the universal experience (*sadvidyā*, *śuddhavidyā*), identification of the universal (*īśvara*), the principle of being (*sādākhya*), the principle of negation and potentialization (*śakti*), and pure awareness by itself (*śiva*)

The first 25 categories relate to an everyday classification of reality. The next 11 categories characterize different aspects of consciousness that are to be understood in a sense different to that of mental capacities (categories 21–23). One of these mental capacities is akin to artificial intelligence, which is geared to finding patterns and deciding between hypotheses. On the other hand, categories 26–36 deal with interrelationships in space and time between these patterns and deeper levels of comprehension and awareness.

Deterministic science cannot explain free will. If consciousness is seen as emerging from the ground of the classical world, then scientific laws again remain incomplete. On the other hand, we do not know why the brain-machine has awareness whereas computers never will. Nor do we understand the mechanisms behind psychoneuroimmunology or the astonishing abilities of savants.

The Indian approaches to consciousness seem to have anticipated many difficulties of contemporary science. The classificatory systems developed in the Indian tradition define categories, such as that of universal experience, that can be seen to explain the "complementary" nature of human experience. These categories clearly assign a central role to selectivity, or context, and change. The Vedic system takes the mind to be emergent on the ground of the brain, but this emergence is contingent on the principle of consciousness.

The ancient Indian texts of consciousness were long limited to philosophical analysis alone, remaining an unexplored frontier in the history of science. Further advances in a scientific understanding of mind will lead to a better appreciation of these texts.

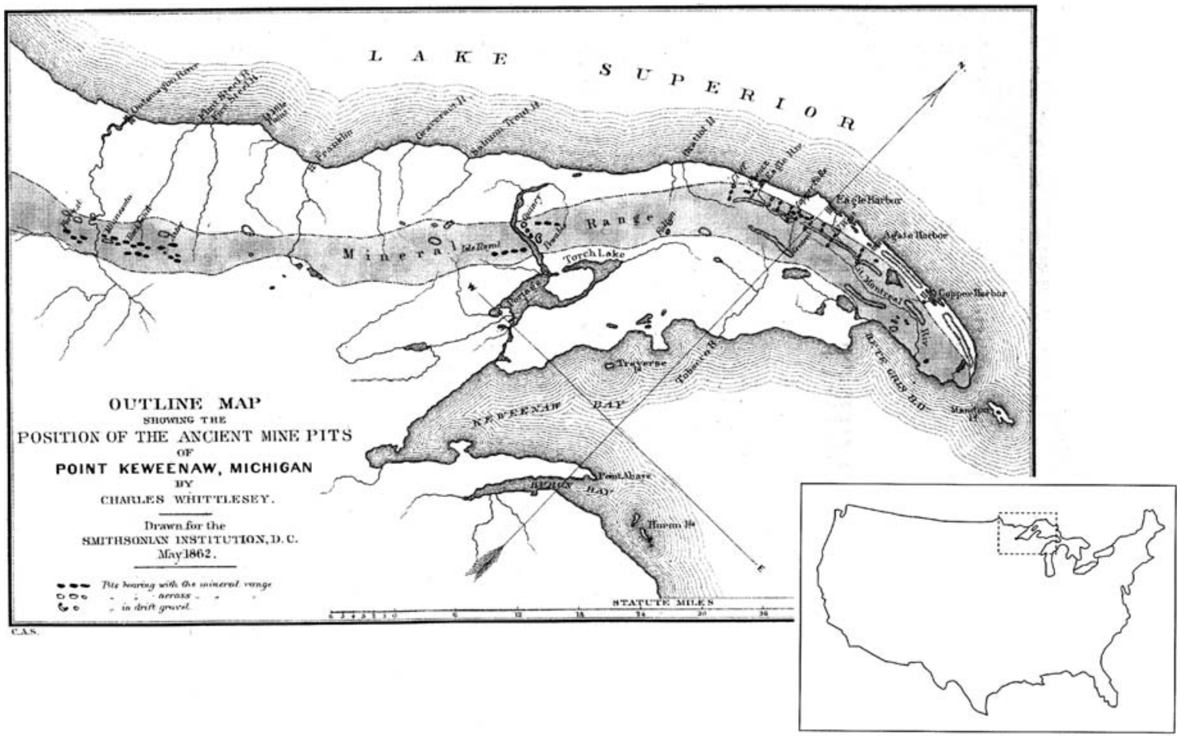
Copper Mining in the Great Lakes (USA)

SUSAN R. MARTIN

The roots of indigenous metal mining are ancient in eastern North America. Evidence for early metal mining in North America comes from the copper-bearing regions of the western Lake Superior Basin in the central part of the continent. Here are to be found veins of elemental copper dispersed within sandstone and basalt bedrock, lying relatively close to the surface. In addition, pieces of loose elemental copper lie scattered in the glacial drift that is to be found in many streambeds and riverbanks. These pieces of useable copper and their parent veins were discovered and exploited by Native American people as early as 7,000 years ago. Though the first metalworking technologies of North America derived from the same technologies that people worldwide universally applied to reducing and using stone for tools, this long tradition of using copper for tools and ornaments is the product of native North American ingenuity. Moreover, the traces of this industry of copper mining and working (spoil piles, pits, discarded hammers, and other tools) were visible to the first capitalist American mining entrepreneurs of the Lake Superior basin who established their own mines on the same old ground that had proved itself first via native mining efforts (Foster and Whitney 1850). Archaeological research in the Lake Superior Basin and other copper-bearing areas documents the long-standing importance of copper technologies in the lifeways and practices of the indigenous people of the continent (Fig. 1).



Copper Mining in the Great Lakes (USA). Fig. 1 Map of the keweenaw Peninsula, Lake Superior, USA, indicating locations of prehistoric copper mining pits. Source: Whittlesey 1863.

The bedrock geological history of the Lake Superior region is fairly well understood (LaBerge 1994); its basement of pre-Cambrian bedrock, part of the Canadian Shield, is very ancient. The deposition took place around 1,100 million years ago (MYA), initiated by a period of roughly 25 million years during which a series of enormous movements of magma broke through a cross-continental rift and laid down some 200 extensive lava flows. This activity was intermittent, and followed by long periods of erosion and sedimentary deposition. The resulting strata are deformed by faulting and subsidence to a broad syncline that underlies Lake Superior and its drainage basin.

Gases trapped in the cooling lava, especially at the tops of flows, created porous structures in which later precipitation of minerals took place. Fissures in the lava and interspersed sedimentary rocks provided places where deposition of elemental copper occurred. The copper itself “was likely leached from volcanic rocks deep within the rift by hydrothermal solutions and was then deposited in these same rocks at relatively shallow levels closer to the surface. The timing of the widespread deposition of copper postdated the formation of the bedrock strata by about 20–30 million years and occurred from about 1,067 to about 1,047 MYA” (Martin 1999: 27–28). The result of this activity comprises the largest body of elemental copper known on earth, and its relatively shallow and accessible position allowed people to recover it. The copper-bearing strata outcrop in a narrow band about 3–6 km wide lying in a southwest to northeast direction along the Keweenaw Peninsula and Isle Royale on the western shores of Lake Superior; the beds also outcrop at the northern and eastern shores of the lake, and extend, deeply buried, further to the west into Minnesota. In other areas, native (elemental) copper is a common though irregular constituent of copper ore deposits in Tennessee, Georgia, New Jersey, Nova Scotia, and elsewhere (Levine 1999).

The Lake Superior deposits are quite variable in actual copper content and in form. In sedimentary bedrock deposits, the copper is finely dispersed; in the basalt bedrock the copper is more likely to be found in fissures, veins or nodules of varying sizes. Masses of copper weighing several thousand kilograms were occasionally encountered. The most useful deposits for prehistoric people were of two kinds: thin veins that yielded sheets of copper, or fist-sized nodules of copper. Reducing very large pieces to useable sizes was somewhat beyond the reach of native technologies, but smaller pieces of both kinds could be rendered into tools and useful objects relatively easily. Useful nodules were sometimes found as constituents of the local late Pleistocene glacial drift or in redeposited gravel banks along streams and rivers. This copper-bearing drift is also widely dispersed across the central portions of the North American continent, where glacial ice flows carried copper and other detritus far from their points of geological origin.

The simplest and least-effort way to acquire copper in elemental form was to search and dig through the many beds of glacial drift in the rivers and streams surrounding the Lake Superior and adjacent regions. Based upon the many pitted areas observed and mapped by Whittlesey during the mid-nineteenth century (Whittlesey 1863), these beds of glacial drift were systematically explored for copper nodules. The glacial drift with copper as a constituent was/is widespread across the central part of North America (Salisbury 1885), and occurred south and west of Lake Superior as far as Iowa and the Dakotas.

In addition to such areas, the bedrock veins were also systematically visited and mined over many thousands of years. Finding the buried veins was a simple matter of being observant. In the western Lake Superior basin, the veins of metal are visible in some surface basalt bedrock outcrops, particularly those that were scoured by glacial action. In other areas, erosion and water action revealed buried veins and nodules. In still others, companion minerals marked the probable occurrence of copper veins. Mining pits on Isle Royale investigated by the University of Michigan in the early 1960s dated to ca. 2470 BCE ± 150 radiocarbon years (Fitting 1975: 238). The early geologists Foster and Whitney described the pattern of such mining pits on the south shore of Lake Superior; observing that along “a distance of nearly 30 miles, there is almost a continuous line of ancient pits along the middle range of the trap (sic), though they are not exclusively confined to it” (Foster and Whitney 1850: 161). The typical pit was rather shallow and followed the course of a vein of copper in a small-scale simple excavation. Alvinus Wood described one that he observed during his excavations on the Keweenaw Peninsula in the late nineteenth century. “It was shown to be 14 ft. deep, having been filled up by the sliding-in of material composed largely of broken rock, taken out in sinking the ancient shaft, and left near its mouth” (Wood 1907: 288). According to Wood, the pit measured about 7 ft. in diameter. In scale, these pits were most comparable to quarrying a face of exposed rock, similar to the mining of flint that had been done for millennia, as opposed to the burrowing or tunneling more typical of recent hard rock mining.

The ancient mining was done with stone hammers that people used to crush the bedrock surrounding a copper-bearing vein. The hammers were, for the most part, unaltered impromptu tools found in the local glacial gravel. Mining pits are sometimes most readily identified by the appearance of many of these expended (shattered) hammers. The hammers were of various sizes and materials; most were of basalt or gabbro and weighed about 2–4 kg, although larger ones were also used, especially early in the mining sequence. Some of the hammers had minor surface modifications, such as a partial or full groove pecked into the circumference to allow a withe or handle to be attached. Pry bars of wood or copper were probably also used to loosen the copper within the vein, and there is some suggestion, especially borrowed from other primitive mining locations around the world, that fire might have been used to weaken the trap rock so that freeing the copper took less mechanical effort. Experimental work on Lake Superior prehistoric mining methods demonstrated, however, that such methods did not measurably improve the efficiency of removing copper (Bastian 1963). Additional artifacts, including copper tools, wooden bowls, wooden ladders, paddles, and other accoutrements of mining were reported to be found in the mining pits investigated by Whittlesey (1863). The size of the mining pits and their conformation suggests that one or two persons could work comfortably within a pit, and experiments showed that ca. a cubic foot of trap rock per hour could be removed from a pit face simply by stone hammering (Bastian 1963: 24).

The native people of central North America fashioned myriad forms of elemental copper artifacts, using simple techniques of repeated cold-hammering and annealing. Despite a search that has already lasted for more than 150 years, there is no unequivocal evidence for intentional melting, smelting or casting of metal artifacts in the Lake Superior region or elsewhere in the eastern United States. All known artifacts were produced in much the same way: careful repeated hammering and heating to recrystallization temperatures. The finished copper objects ranged from weighty woodworking tools to finely crafted ornaments and decorative objects. It is probable that the basic knowledge of elemental metal-working was more or less common across North America, because many elemental metal deposits were known and exploited: at multiple localities in the eastern United States, in Mexico, in the southwestern US, and along the western rivers of Canada. The region around the Lake Superior basin with its large numbers of copper artifacts from local sites allows the researcher a fairly comprehensive look at how specific artifacts were designed and manufactured. Modern researchers established, via experimental replication as well as microscopic studies, the basic outline of prehistoric metalworking techniques (Clark and Purdy 1982; Leader 1988; Vernon 1990). Using the methods of cold or hot-hammering and annealing, the artifacts were carefully fashioned by repeated cycles of heating, hammering, and cooling, with carefully directed blows from a stone hammer creating the final form. Annealing, or reheating to recrystallization temperatures (in excess of ca. 250–300°C), restores malleability and was an essential part of the process; otherwise the hammered copper quickly became brittle and cracked under additional stress. Metallographic inspection of hammered copper revealed “the hammering technique, although primitive in itself, was carried out with assurance and skill; the sheet metal is often of fairly uniform thickness even though laminations are sometimes present” (Wayman et al. 1992: 133–34). Larger artifacts, such as wood-working tools, were hammered and annealed to render a nodule of copper to a desired form. Or, copper sheets were hammered to an even thickness, rolled and then rehammered to consolidate the copper into a thicker artifact form. Final annealing was frequently done, and annealing temperatures may have exceeded 600°C for some artifacts. Ornaments (such as beads) and sheets of copper were sometimes hammered around wooden forms, or mandrels, to produce a final artifact shape. Other artifacts, such as Hopewellian earrings and decorative ornaments of some Mississippian cultures, were composite artifacts of wooden cores clad with a thin cover of fine sheet copper (Fig. 2 and 3).

Finishing touches sometimes included additional limited cold-hammering to harden work edges of tools such as knives and projectile points. Grinding or beveling of work edges was also fairly common, and some artifacts such as harpoons or projectiles were perforated

to enable the securing of a wooden shaft or handle via a copper rivet. Hopewellian and Mississippian cultures used elaborate finishing techniques on their ornaments. Decorative items were embossed, cut out, and perforated in a wide variety of forms depending upon the particular cultural traditions of the artisans producing the artifacts. Some were finished with a high gloss or polish produced by systematic rubbing with ashes and abrasives such as sand. There is some experimental evidence that prehistoric metal workers were able to draw thin strands of copper wire (Cushing 1894).

There is ample evidence derived from the study of the physical distribution of worked and unworked copper to claim that prehistoric people surrounding the Great Lakes communicated with one another, in part, through the exchange of raw and finished copper materials. In addition, overall close similarities in finished copper artifact forms that occur among and within regions close to bedded sources suggest active contact between people of different areas, and at least the copying of each other’s artifact forms, if not direct/indirect exchange of finished materials. This pattern is well documented for areas east and south of the Lake Superior basin (Brose 1994; Goad 1979; Walthall et al. 1982). It is also apparent from research conducted in the northern Plains, where Lake Superior copper may have been exchanged for locally derived lithics such as obsidian and catlinite (Vehik and Baugh 1994). Other raw materials reported from the western Great Lakes region that may have been involved in regional and interregional trade *vis a vis* copper include hornstone (Pleger 1996), Hixton orthoquartzite (Clark 1991), galena (Ritzenthaler 1957), Burlington chert (Pleger 1996), Knife River flint (Salzer 1986), and marine shell (Hruska 1967). Many authors agree that copper was likely widely distributed via trade over vast distances (Brose 1994; Goad 1979; Winters 1968). Other authors add that trade in perishable items, invisible for the most part in the archaeological record, was certainly part of the picture; meat, skins, shells, reed mats and tobacco are suggested as important commodities, especially in the seventeenth century (Smith 1996). Other less tangible commodities and/or motivators to trading activities may have been related to social status, ethnic differentiation, information exchange, and ritual knowledge (Martin 1999). There is, at least by the seventeenth century AD, a solid body of first-hand reporting that documents the connection between native ideologies and copper materials, which were sought after because they were believed to hold the ritual power to bring good fortune, health, wealth and hunting success (Kellogg 1917: 105).

The use of copper was widespread in prehistory and was an important part of the cultural adaptations of the native peoples of eastern North America, beginning by the seventh millennium BP and extending until the advent of European-influenced cultures. The earliest and strongest evidence for the importance of copper mining in native American technologies and lifeways comes from the region adjacent to the bedded copper deposits of the Keweenaw Peninsula, the southwestern shore of Lake Superior, and Isle Royale, Michigan. Here there is material evidence of systematic collecting for copper within surface glacial deposits as well as extensive evidence of the activities of hard rock mining and quarrying by native Americans. The technologies of mining and cold-hammering elemental copper have become well understood through the efforts of experimental (replicative) research and metallurgical studies. Copper was an integral part of the technological, social and ideological experiences of the region's first people, and was equally significant as a material from which to fashion a tool, a social interaction or a ritual transaction. Copper's significance included social reckoning as expressed in burial and in decorative contexts among peoples of many regions and cultures, as well as social interactions as expressed through trade contexts, and finally within religious representation as expressed in elaborate beliefs about its ritual power.

Cosmetic Surgery in Ancient India

Richard L. Nelson

Cosmetic operations form a special corner in medicine – much in demand and yet often much maligned for being unnecessary or frivolous. This assumes a clear-cut division between a narcissistic desire for an improved appearance, the correction of a disfigurement or injury that altars appearance in an alarming way without altering physiologic function, and the real disability and danger caused by a disease. Whatever the clarity of the division, the demand persists and also reaches back into antiquity. The undisputed father of the field of cosmetic surgery is Suśruta, a surgeon, educator and compiler who lived probably around the sixth to eighth century BCE, though his possible dates vary greatly from 1200 AD. to well before 1000 BCE. No original texts of his great work, the *Saṃhitā*, exist today. It has been edited and revised throughout its history, the most significant contributions made by Nāgārjuna, who lived most probably in the second century BCE.

The *Suśrutasaṃhitā* is a remarkable work in its originality and scope. Though Suśruta is remembered as a surgeon, and division of medical specialists was practised at his time (into surgeons, physicians, poison curers and demon-doctors), the Saṃhitā covers a very broad range of medicine as well as surgery, from discussions of the origins of disease, to the treatment of post-partum depression, to the causes of obesity. Remarkable detail is presented on the pre-operative preparation of patients and the post-operative care of their wounds. Methods of intra-operative anaesthesia and post-operative pain relief are discussed. Over 760 medications are described, 1,120 medical conditions including 76 of the eye alone, more than 125 surgical instruments and 300 surgical procedures in over 1,000 pages of text and 186 chapters. A broad scope of surgery is also presented, including intestinal repair (with black ants) and Cesarean section. Methods of medical education are discussed including cadaveric and animal dissection for the purpose of learning surgical anatomy; only the bodies of children less than two years old could be dissected. Physiology, medical botany, hygiene and public health are discussed, and Suśruta embraced the Ayurvedic (the science of life) approach to medical care.

Yet it is as a cosmetic surgeon that Suśruta is remembered, at least outside of India. And largely for a single operation and even more specifically for a single aspect of the technique for that operation: that of flap formation for the reconstruction of a severed nose. Here is a selection from the 1907 complete (first) English translation of the *Suśrutasaṃhitā* by K. K. Bhishagratna:

> Rhinoplastic Operations: Now I shall deal with the process of affixing an artificial nose. First the leaf of a creeper, long and broad enough to fully cover the whole of the severed or clipped off part, should be gathered; and a patch of living flesh, equal in dimension to the preceding leaf, should be sliced off (from down upward) from the region of the cheek and, after scarifying it with a knife, swiftly adhered (sutured) to the severed (base of the) nose. The cool headed physician should steadily tie it up with a bandage decent to look at and perfectly suited to the end for which it has been employed (Sadhu Bandha). The physician should make sure that the adhesion of the severed parts has been fully effected and to insert two small pipes into the nostrils to facilitate respiration, and to prevent the adhesioned flesh from hanging down. After that, the adhesioned part should be dusted with the powders of Pattanga, Yastimadhuka and Rasanjana pulverised together; and the nose should be enveloped in Karpasa cotton and several times sprinkled over with the refined oil of pure sesamum. Clarified butter should be given to the patient for drink, and he should be anointed with oil and treated with purgatives after the complete digestion of the meals he has taken, as advised. Adhesion should be deemed complete after the incidental ulcer had been perfectly healed up, while the nose should be again scarified and bandaged in the case of semi- or partial adhesion. The

Cosmetic Surgery in Ancient India. Fig. 1 Suśruta pictured performing a rhinoplasty.

adhesioned nose should be tried to be elongated (or trimmed) where it would fall short of its natural and previous length, or it should be surgically restored to its natural size in the case of the abnormal growth or its newly formed flesh. The mode of bringing about the adhesion of severed lips is identical with what has been described in connection with a severed nose with the exception of the insertion of the pipes. The physician, who is conversant with these matters, can be alone entrusted with the medical treatment of a King.

The innovation that made Suśruta's reputation is the skin flap to make a nose. It involved cutting three sides of a rectangle on the cheek, elevating the skin, while maintaining a blood and nerve supply from the fourth side of the rectangle, thus assuring the viability of the skin flap, which could then be slid over and formed into a new nose. Once healing was complete (and a new blood supply formed through the suture line), the fourth side of the rectangle may have been (Suśruta does not actually say he did it) divided and the donor site freed from the new nose. This is a technique used all over the body to replace skin defects today. Later editors changed the donor site to the forehead, but otherwise the technique remained largely unchanged for the next 2,000 years. Nasal reconstruction was an important part of medical practise in ancient India because nasal injury was common, sometimes through disease, but more often due to amputation, a form of punishment for many offences, including adultery.

Yet in one manner of speaking, this is not a frivolous cosmetic operation, but a reconstructive one, replacing a severed or damaged part. The Oxford English Dictionary defines 'Cosmetic' as 'Of surgery: improving or modifying the appearance. Of prosthetic devices (like grafted noses): recreating or imitating the normal appearance.' In that regard the nasal, ear lobe, lip and eyelid reconstructions described by Suśruta are certainly cosmetic.

Cosmetic Surgery in Ancient India. Fig. 2 Drawings of surgical instruments described by Suśruta.

The technique of rhinoplasty is quite briefly described with much less detail than a surgical trainee would want today before tackling this operation for the first time. Much is made today about length/width ratios of the flap or flap thickness to assure viability of the mobilised skin. Too narrow or too thin a flap would not have enough blood flow to the mobilized tip to remain viable. The graft would then die and sluff off leaving the unrepaired defect. The width and depth of stitches, the distance from the flap to the recipient site, the degree of rotation and the time before safe detachment are all left for one to guess in the *Saṃhitā*. Much more space is devoted to the problem of severed (or bivalved) ear lobes, caused by downward pressure and erosion of earrings worn in pierced ears. Suśruta describes skin flaps again (mobilised from the nearby neck), or debridement and primary closure of the lobe if the amount of tissue was sufficient. Reconstructive procedures are also described for repair of defects, sometimes caused by surgical excision of tumors or ulcers of the eyelid and, as stated above, the lip.

Cosmologies of India

John Mcucim Malville

From the viewpoint of modern astrophysics, cosmology is the study of the history, structure, and dynamics of the universe. Many of the traditional cosmological concepts of Indian culture have general counterparts in astrophysical cosmology. For example, the parallelism of the macrocosm and microcosm is an important concept for both approaches; our terrestrial physics is mirrored in the stars, galaxies, and distant quasars. Gravity and other long range forces thread the entire universe. The geometry of Indian temples, cities, and pilgrimage landscapes often replicates the larger cosmos.

Modern physical science relies heavily on quantitative measurement, and according to the architectural traditions of India, the structure of home, temple, and city are based upon a shared religious symbolism, which involves the bringing of cosmic order out of primordial chaos partly through the act of measurement (Zimmer 1946; Malville 1992). Measurement as *cosmogenesis* is asserted in many texts of Indian philosophy and mythology. Puruṣa, the architect of the universe, "bears the measuring rod, knows division, and thinks himself composed of parts" (Vāyu Purāṇa 4: 30–1: Kramrisch 1946: 131). The universe was created as Puruṣa was divided into parts, many of which are the measured and ordered features of our current world such as verses, chants, social orders, time, and temples, and cities.

The universe is understood to have spread outward from a primordial center into the four cardinal directions forming a square (Kramrisch 1946, Vatsyayan, 1983; Malville 1991). The geometric structure of the universe, as described in the sixth century AD *Bṛhat Samhitā,* was represented by the *vāstu-maṇḍala*, usually consisting of 64 or 81squares or *padas,* which was also the fundamental plan for houses, palaces, and cities. The *Bṛhat Samhitā* was primarily a treatise on astrology and astronomy, which provided instructions for determining auspicious dates for laying out the foundation *maṇḍala* of a building or city as well as instructions for its precise orientation to the cardinal directions using shadow casting by gnomons. Major features of the *vāstu-maṇḍala* are (1) true cardinality, i.e., parallelism to the fundamental directions in the celestial realm, (2) a center, out of which creation has emerged, (3) mathematical division of interior space into squares or *padas*, (4) the organization of space according to socioreligious rules, assigning specific *padas* to gods, kings, and social classes, and (5) a boundary that represents the barrier between internal order and external chaos.

As organized by the *vāstu-maṇḍala*, the religiously planned city was meant to be a geometrically exact copy of the macrocosm with its pantheon of gods. The symbolism of the city and temple included the point source of creation, the *garbha gṛha* (womb chamber) of the temple, the cosmic tree separating heaven and earth, the *axis mundi*, and the surrounding squares were assigned to 44 Vedic gods, of whom eight were the all-important protector guardians of the cardinal points. The royal palace was to be constructed on one-ninth the total town area to the north of the center. A few of India's ancient cities have achieved the ideal of the *vāstu-maṇḍala* in their design, such as the excavated sites of Sisupalgarh near Bhubaneswar and Vaisali in North Bihar (Chakrabarti 1997; Krishna Deva 2000; Joshi 2000). Often the ideal *vāstu-maṇḍala* was compromised by local topography, as, for instance, the construction of the city on the irregular banks of a river such as Pataliputra (modern Patna) on the Gaṅgā and Ujjain on the Sipra (Krishna Deva 2000). Furthermore, prominent geographic features often created symbolic forces that drew the orientation of structures toward them and away from cardinality. In the case of the great city of Vijayanagara natural features of its dramatic landscape such as hills, caves, and river played major roles in its organization (Fritz 1985; Fritz and Michell 1991). The most powerful organizing feature of the city was the precise north–south axis that cuts through the center of the Royal Center and passes over the local manifestation of the cosmic mountain, Matanga Hill (Malville and Fritz, 1993a, b; Malville 1994a, b, 2000).

Cosmology as Illustrated in the Hindu Temple

The Hindu temple can be used as a mnemonic for a wide range of cosmological concepts of India. Manifesting the parallelism between microcosm and macrocosm, it contains in its center the chaos out of which the universe emerged. Spreading outward along cardinal and inter-cardinal directions, the stones of the temple are the cosmos into which the universe has transformed itself. The temple is set upon the *vāstu-puruṣa-maṇḍala*, the geometric yantra symbolizing the sacrifice and dismemberment of Cosmic Man, Puruṣa, and the re-establishment of cosmic order. The idea of primordial chaos, which is structured into the center of the temple, is found in many of the cosmological mythologies of the subcontinent and is a well-established feature of the early universe. Creation through disruption of equilibrium, expansion of space-time, and separation of parts are shared concepts of myth and modern cosmology.

The living Indian temple is both a model of cosmos carved in stone and a participatory cosmology. The devotee who enters the temple can travel backward in time by moving from the world of the present, which lies beyond the temple compound, to its center where space and time are collapsed. At the center of the temple, enshrouded by a darkness pierced by only a few lamps, lies the *garbha-gṛha*, the womb chamber symbolic of the chaos, potentiality, and undifferentiated wholeness out of which the universe emerged (Karmrisch 1946). Spiraling inward in space and backward in time, one proceeds from brightly lighted exterior space of the ordinary world to darkness. The large open spaces of the entrance are replaced by the confined small center; the extravagant richness of carving and decoration turn into the simplicity of the unadorned center. Space is focused like a converging beam of light upon the center, becoming ever more constricted and confined as the garbha-gṛha is approached. It is the center, which provides personal renewal and rebirth, paralleling the renewal and rebirth of the universe itself.

Chaos and Equilibrium

"In the beginning was darkness swathed in darkness; all this was but unmanifest water" *Ṛgveda* 10.129.3

The birth of the universe from primordial chaos is one of the most fundamental creation mythologies of our planet (O'Flaherty 1975). In Hindu cosmology, the metaphors for chaos are water, darkness, disorder, lawlessness, and potentiality. Chaos in the center of the temple is protected by massive stones, priests, and doorway guardians. The garbha-gṛha is the cave in the side of the cosmic mountain, Mount Meru, which is the axis mundi, connecting heaven and earth. The cave is the womb out of which the world and life have emerged. The small cubical space of the garbha-gṛha is symbolic of the primordial seed of creation. Chaos, as a source of creation, is thus contained, protected, preserved, and intensified in this dark space. The energy of the cosmic cycle is contained in the temple, and is available each day of the year for the purposes of cleansing, symbolic death and rebirth, and rejuvenation.

Indra and Vṛtra

The conversion of chaos into cosmos is described in two well-known Hindu myths, the battle of Indra and Vṛtra and the churning of the cosmic ocean. Vṛtra, the Restrainer, held the dark waters of creation tight within his coils and had to be destroyed by Indra in order for the waters of time and creation to flow. The battle between the Aryan war god Indra and his archenemy Vṛtra is rich in thermodynamic meaning. The universe was initially imprisoned as dark and unmoving waters held tightly within the coils of Vṛtra. Actualization of potential inherent in the universe was thus prevented; time could not flow and space could not expand. This metaphor addresses one of the great mysteries of existence: what initiated expansion of space-time? As the god of lightning and thunder, Indra slew Vṛtra with his thunderbolt, the *vajra*. The death of Vṛtra symbolizes the victory of change over stasis, time over eternity, light over darkness, as well as summer over winter. One interpretation of the slaying of Vṛtra is that it is a depiction of the transformation of winter ice into summer waters as the light and heat of the sun destroy the darkness and frozen immobility of winter; the mountain streams, which are held fast in winter's coils, are released to flow to the ocean when winter is conquered by the springtime sun.

The initial symmetry, quietude, and perfect balance of the cosmos was broken when the circular coils of Vṛtra were forced open, and, like the escaping contents of a broken pot, the imprisoned waters of time and change were allowed to flow. The sun and moon, locked as embryos in the dark waters, were born with the death of Vṛtra. The transformation from the state of stasis to that of change involved violent activity, disruption of tranquility, and death of the old.

Churning of the Cosmic Ocean

Thermodynamic elements abound in the story of the churning of the primordial ocean for the purpose of obtaining *amṛta*, the elixir of immortality (O'Flaherty 1975). Primordial equilibrium, symbolized by the undifferentiated cosmic ocean, was disturbed by the outside agent of the inverted Mt. Mandara, used as a churning stick. In a manner similar to that of the patterns of convection in a heated pot of water, structures hidden in the water were evoked. The cooperation of all aspects of creation was needed for such transformation of chaos: *asuras, devas*, Viṣṇnu who as the cosmic tortoise provided support for Mt. Mandara, Śiva who drank the poison which emerged before the *amṛta*, the cosmic mountain, and the cosmic serpent, Vasuki. The transformation of equilibrium required extraordinary actions, and the inversion of the cosmic mountain seems to symbolize that ordinary, traditional action was inadequate for such an endeavor. Ordinary action can not bring about major transformation when powerful self-maintaining cycles, i.e. negative feedback, suppress perturbations. The old standards and ordinary behavior were inverted: Mt. Mandara was converted into a stirring stick, the *asuras* and *devas* cooperated, and the serpent as the churning rope became the agent for change rather than the traditional agent for eternity and stasis. The consequences of the churning were violent: fire, loud noises, upsetting of nature, death of many creatures. Polar opposites emerged from the waters such as poison and the elixir of eternal life, *amṛta*. All beings and gods were protected from the poison by Śiva who acquired a blue throat while drinking it. Out of the disrupted equilibrium of the ocean emerged the embryonic sun and moon.

Rescue of Earth from the Waters

The story of the rescue of Mother Earth from the waters involves one of the ten incarnations of Viṣṇu as the boar and is a member of the worldwide class of earth diver creation myths (Long 1963; *Taittirīya Saṃhita*, *Viṣṇu Purāṇa*: O'Flaherty 1975). In each of these stories, a creature dives to the bottom of the ocean to retrieve mud which, when brought to the surface, grows to become the planet on which we live. In one version of the Hindu story, there is a violent battle between the cosmic boar and the demon of the waters who, like Vṛtra, has held the earth prisoner, preventing thereby the flow of time. The recurrent symbols of creation in these Hindu myths are again present: formless, rich, and fertile primeval material locked in the eternal, changeless dark waters is released only after a violent struggle. Another important aspect of this myth involves Viṣṇu in his role as expander and extender. After bringing Earth to the surface of the waters, he spreads her out into a flat disk so that, like a lotus leaf, Earth can float on the waters and not sink back to the oblivion of the dark waters and the death of equilibrium. In the astronomical universe, it is the continuing expansion of space-time which causes departures from equilibrium and prevents structures from sinking back into equilibrium.

Primordial Incest

The stories associated with Prajāpati and his daughter, Rohiṇī, form a highly complex collection of symbols involving both sexual and astronomical allusions (Kramrisch 1981). Back in the timelessness which existed before the creation of our world, the "first created," Prajāpati, desired a second. Instead of a wife he acquired a daughter with whom he sexually united. The on-looking gods were so outraged by such an unthinkable violation of a fundamental law of nature that they created Rudra, the archer, to prevent and punish the incest of Prajāpati. The arrow shot by Rudra struck Prajāpati, too late, causing him to withdraw from his daughter and spill his seed on the ground. From such an unlikely sequence of actions human life sprang from the impregnated soil.

> Meant to prevent the act, the flowing of the seed, the shot failed to prevent its consequences. The failure in timing at the dawn of the world was due to time itself, for the latter had not set in as yet; it was just about to begin. The transition from an integer without dimension of space and time into existence is a danger zone between eternity and the passing moment… Had the timing been perfect, the flying arrow of Rudra would have prevented the coming into existence of man and the flowing down on the earth of the substance of the Uncreate." (Kramrisch 1981: 26)

The sequence of events can be described in thermodynamic terms as follows. Primordial equilibrium contains within itself processes which may become unstable and grow out of control; the result can be a destruction of the old system and the production of something entirely new. As already mated, an equilibrium system has self-maintaining processes built into it designed to prevent such destruction of equilibrium and stability. Incest as a violation of equilibrium was present in the original plenum of creation. In order to prevent change, a negative feedback loop was created in the form of Rudra to suppress the perturbation. Ironically, the consequence of Rudra's action was the opposite of the original intent. The incestuous act was not punished in a manner such that the original equilibrium could continue, but, quite the contrary, the initial instability grew, life on the earth appeared, and the unchanging primordial state was replaced by time and change.

The Prajāpati myth may have astronomical implications concerning a very early discovery of the precession of the equinoxes. Between 4500 BCE and 3500 BCE at the time of vernal equinox the constellation which we know as Orion rose heliacally just ahead of the sun. Prajāpati was identified with that constellation (Tilak 1972; Kramrisch 1981). Prajāpati was also the year (*Śatapatha Brāhmaṇa 3.2.2.4*) which, exhausted from his labors, needs to start afresh at the time of the vernal equinox. The rejuvenation and rebuilding of Prajāpati, the year, was accomplished symbolically by the construction of the Vedic altar, the bricks of which symbolized the days and seasons of the year. The death of Prajāpati, the old year, was necessary for the continuation of the annual cycle of vegetative life. The symbolism of Orion-Prajāpati rising heliacally on the morning of the vernal equinox may have had great ritualistic significance, announcing by its presence in the equinoctial dawn the time for the rebuilding of the sacrificial altar and the rejuvenation of the exhausted year.

For over a millennium, following 4500 BCE, the constellation of Orion-Prajāpati had provided that announcement. But around 3000 BCE Prajāpati no longer appeared briefly in the ruddy dawn of vernal equinox, having been replaced due to precession by his daughter, Rohiṇī, the red star Aldebaran, the eye of the modern constellation of Taurus the Bull. The shock of this change in the makeup of the heavens may have been considerable. No longer was the start of the year announced by the heliacal rising of the grouping of stars which had symbolized the year, no longer was there a synchronization of the heavens with terrestrial phenomena and human affairs, no longer could the heavens be viewed as eternal and unchanging. The astronomical language which is used to describe this event is extraordinary in its allusion to the forbidden act of incest. Prajāpati as the beginning of the year had moved into Rohiṇī due to the process of precession.

A complex variation on the Rudra-Prajāpati-Rohiṇī myth is the story of Dakṣa, the antagonistic and jealous father-in-law of Śiva. The wife of Śiva, Satī, was the first born daughter of Dakṣa. He had 27 other daughters who had been given to the moon in marriage; these are the Nakṣatras, the asterisms through which the moon passes each month in his journey along the sky. Dakṣa performed a great sacrifice but did not invite Śiva nor did he reserve a portion of the sacrifice for Śiva. Dakṣa's jealousy toward Śiva at one level of the myth may symbolize the desire to preserve primordial equilibrium. Satī reproached her father for not having invited her husband. In anger and shame she committed suicide by throwing herself into the sacrificial fire ignited by her father. Śiva, outraged at the consequence of Dakṣa's insult, came in the form of Vīrabhadra, a fierce manifestation of Śiva. He cut off Dakṣa's head with a sacrificial knife, and replaced it with the head of a ram. Vīrabhadra picked up the corpse of his wife and performed a wild and agonized dance with it over the face of the earth. In his dance, his arms flailing to the far reaches of the universe, the stars were scattered by the sweep of his hair. Fearing that the wild dance, the Tāṇḍava, would destroy the earth, Viṣṇu cut the body of Satī into pieces, and where each piece of flesh dropped to earth a shrine was built (*Devībhīgavata Purāṇa*: O'Flaherty 1975). Here again, we encounter the use of horrible and unthinkable mythic deeds to dramatize the consequence of the disruption of cosmic equilibrium and consequent creation in the form of the establishment of shrines and temples across the land.

The Waters and Fires of Chaos

Though structureless themselves, water and fire are infinitely creative (Eliade 1967). Everything which possesses form has separated itself from water. The gods of chaos must be sacrificed in order for life to appear. When form emerges beyond water there is a dying of potentiality, and form becomes subject to limitation by the laws of time, change, and decay.

In the temple tank, fed by deep underground springs, lie the dark and murky waters of chaos, reinforcing the meaning contained in the dark sanctum of the temple. Water is a transformational symbol, both life-giving and life-threatening, the source of vitality and creation as well as the agent for destruction. The waters of the *pralaya,* the cosmic flood at the end of time, provide the source for new creation and new birth. Life is born out of these dark, destroying waters which periodically sweep the earth.

In the city of Vārāṇasī, also known as Kāśī, one finds the intensified symbols of water and fire (Eck 1983). In the center of Kāśī in the Viśvanātha Temple is the Jyothir liṅga, the great pillar of fire connecting heaven and earth. Near the center is the Maṇikarṇikā *kuṇḍ,* the place of the very first dawn of the world at the beginning of time. In an interesting twist, the *kuṇḍ* associates water in the form of sweat with the act of creation. The *kuṇḍ* was excavated by Viṣṇu using his discus and filled by his sweat before he created the world. Viṣṇu symbolizes the activity, expanding power, and movement of the sun as it traverses the sky with great strides. The discus, which is carried in one of his hands, is a sun symbol (Begley 1973). Glowing brilliantly, yet terribly dangerous, it is called *sudarśana,* "beauteous sight". The chaos of the earth has thus been disturbed by the sun disc. The water so necessary for creation has come from god himself. Maṇikarṇikā is also identified by local tradition with the jeweled earring of Satī, fallen to the ground while Śiva was performing his dance after her death by fire.

A central theme of Hindu cosmology is the homology of universe and human body, i.e., the body is a microcosm, a model both of the universe but also for the universe. The universe is the dismembered body of Prajāpati and Puruṣa, the Cosmic Man. It is a complex cosmological homology as, in this view, the human body is both a description of how the universe behaves and a model *for* the universe, i.e., how it should behave. The significance of these "of" and "for" models in cultural symbols has been explored extensively by Geertz (1973). The equality between the sun and the *ātman* which lives in everyone's heart is one such homology. Another homology, suggested by Parry (1981), relates the process of creation and destruction of the universe to the constant stream of sacrificial cremations staged at the Maṇikarṇikā *ghāt*. Parry argues that the human body has been so "cosmicized" in India that the cyclic movement of the entire universe relies upon the unceasing human acts of cremation at Maṇikarṇikā.

The Hindu temple with chaos in its center is surrounded on all sides by the chaos of the profane world; the walls of the temple serve as ramparts against the threatening flood of chaos. Such a flood of chaos can be creative as well as destructive. The devastating flood may be followed by a creative flood as described in the myth of the temple town of Kumbakoṇam:

> When the time of the universal deluge drew near, Brahmā came to Śiva and said, 'Once the world has been destroyed how will I be able to create it anew?' Śiva instructed him to mix earth with *amṛta*, fashion a golden pot, and put the Vedas and other scriptures into the pot along with the Seed of Creation. Brahmā made the pot and decorated it with leaves, and, when the flood began to rise, he put the pot in a net bag and sent if off on the waters. Pushed by the wind and waves, the pot floated southwards; the leaves fell off and became holy shrines, and the pot came to rest at a spot proclaimed sacred by a heavenly voice… Śiva took the form of a hunter and shot an arrow, which hit the pot and let loose a flood of *amṛta*. When the waters of the deluge receded, Brahmā fashioned a *liṅga* from earth mixed with *amṛta*, and Siva merged into the lingam in the presence of the gods (Shulman 1980).

Creation thus follows the flood of *amṛta.* The creative flood flows because Śiva has broken the restraining pot. Creation thus results from the violent disruption of equilibrium. He repeated the archetypal act of Indra when he slew Vṛtra with his thunderbolt, the *vajra*, and allowed the waters of time and creation to flow. The arrow of Śiva was a shaft of light and time entering the darkness of the watery chaos that existed before creation; the pot was the womb, which releases life.

Other Tamil temple myths echo this theme in which a moving shaft such as a spear plays a crucial role of creation following a flood (Shulman 1980:73). In over seventy Śaiva temples of Tamil Nadu, the sun penetrates the centre of the shrine at sunrise or sunset on a few days of the year near the equinoxes. There are numerous interpretations of the event celebrated as a Sūrya *pūjā*. A popular myth is that Sūrya has become afflicted with leprosy and is requesting that Śiva relieve him of the disease. The reference to leprosy may have been associated with an unusually high level of sun spot activity that we know occurred in the thirteenth century. Another interpretation of the event is that the horizontal shaft of sunlight lighting the Śiva *liṅga* in the otherwise dark *garbha gṛha* is symbolic of the first shaft of light that destroyed the darkness of chaos (Malville 1985, 2006; Malville and Swaminathan 1998, 2006).

The temple doorway, through which pass shafts of light, arrows of time, priests, and devotees, contains symbols of chaos and water: the marvelous water creature the *makaram* with wings of a bird, body of a crocodile, and snout of an elephant, yawns widely on either side. Out of the opened mouth of the *makaram* flow the forms of creation to be reabsorbed at the end of the world age by the opposite *makaram.* Intertwined about the doorway are stalks and leaves of water plants and river goddesses. To pass through the doorway from the profane to the sacred world requires transformation which water provides. The priest when he enters the *garbha-gṛha* experiences a transmutation "promoted by the (water) divinities on the door jambs" (Kramrisch 1946: 313–314). Coormaraswamy (1980) has written extensively and creatively on the symbolism of this "water cosmology" of India. Upon murky waters floats the white lotus, unpolluted by the mud, a symbol of separation of creation from the waters of chaos. Out of the waters it climbs on a stalk which is the *axis mundi,* connecting primeval mud with the light of the sun. The earth, the sun, or Brahma is carried by the lotus, suspended above chaos, protected from sinking back into oblivion by the lotus raft. The lotus is also the characteristic symbol of Sūrya, always carried in his hands, expressive of the separation of creation from chaos provided by the light of the sun.

Expansion, Separation, and Differentiation

Nonequilibrium in the universe is the consequence of the expansion of outer space. Portions of the universe were thrown out of equilibrium following the Big Bang as the initially homogeneous matter clumped and hot stars separated from cold space. Expansion is the fundamental dynamic of our universe, constantly forcing matter and energy out of equilibrium and allowing structures to form and complexity to grow.

Viṣṇu as the expanding dwarf who tricked the demon Bali into giving him all the space he could cover in three steps is an oft-repeated allusion to cosmic expansion (*Viṣṇu Purāṇa* 2.36.74–86). As an expanding fish, Viṣṇu saved Manu from a return to chaos through the flood (*Śatapatha Brāhmaṇa* 1.8.1.1–6). When Viṣṇu as the Boar rescued Earth from the bottom of the waters of chaos, he expanded Earth and spread her out, to prevent her from sinking back again into chaos. The infinitely expanding *liṅga* of fire which confounded Brahmā and Viṣṇu during the darkness before creation as it rose from the cosmic ocean, reproduces these resonating symbols of dark waters and expanding form (Zimmer 1946).

The central tower of the temple, the *śikhara*, the "mountain peak," is another *axis mundi*, which pillars apart heaven and earth and lets creation proceed. In Vedic terms, to separate is to create, and to merge and reabsorb is to dissolve and destroy (O'Flaherty 1975: 125). The myth of the triumphant destruction of the triple cities of the demons by Śiva, as Tripurāntaka, again resonates with the insight that to separate is to create, and, conversely, that which causes polar opposites to unite and lose their separate identities is to reverse the course of creation and return to chaos (O'Flaherty 1975). The triple cities symbolize heaven, earth, and sky and their reabsorption returns the universe to formless equilibrium and chaos.

The symbolism of chariots and wheels is found both in the temple architecture itself and in *ratha* festivals. The temple of Konārak has been fashioned into huge chariot of the sun with 24 wheels pulled forward into the east by seven horses (Malville 1989). The wheel is a pre-eminent symbol of time with stillness at its center, which allows movement and change. It is also a symbol of sustained separation of the earth and the heavens. The wheels of the sun's chariot are supported and separated by the axle tree, which performs the same function as the *axis mundi*, holding apart the turning wheels of earth and sky. Creation is possible only because of the separation provided by the axle. The wheels are those of Kāla, time, bringing life out of darkness and returning life to darkness and death.

A frequent icon in many temples is that of Kirttimukha, the "face of glory," another image expressive of creation emerging from separation. Kirttimukha represents both the awesome destructive power of Shiva and the creative powers of the cosmos. Creation flows from his open mouth only so long as it is open; once his jaws close, creation ceases. Fortunately, since Kirttimukha lacks a lower jaw, the mouth of creation can never be closed (Kramrisch 1946).

The sacrifice of Puruṣa, Primal Man, contains the three primary cosmological symbols of chaos, separation, and differentiation (*Ṛgveda* 10.90.1–16). Primal man represents chaos and infinite potentiality. He must be sacrificed before in order for creation to occur. Like water and fire, chaos and creation, equilibrium and ordered structures are mutually exclusive; once water becomes structured it is no longer water, but it is plants, fish, and people. The strongest image of the sacrifice of Puruṣa is that of differentiation of the original parts of primordial chaos. Various parts of the body became the infinite variety of the cosmos: the atmosphere, the heavens, and the earth, the creatures of the earth, and the social classes, waters. Prajāpati, also the primal man, "fell apart", separated and dispersed to become our cosmos: his semen became sun and heaven, his breath became wind and atmosphere, his body became food and earth (*Śatapatha Brāhmaṇa* 7.1.2.1–6).

Symbols of Expansion, Separation and Differentiation

1. Lotus: separation from mud and water; suspended above chaos
2. Śikhara: separation of earth and sky; expansion upward
3. Tree: expansion downward and upward
4. Gopuras: expand outward and upward from centre
5. Wheels: separated by axle tree
6. Vishnu as dwarf: expanded to step across three worlds
7. Viṣṇu as fish: expanded to save Manu
8. Viṣṇu as boar: expanded earth to prevent it from sinking into chaos
9. Kirttimukha: open mouth allows continuing creation
10. Indra: separates earth and sky by expanding
11. Puruṣa: separation and differentiation
12. Tripura: separation of the three worlds

Return to Chaos

At the end of a thousand world ages, a day of Brahmā, a Kalpa the world becomes barren of life. Siva scorches the earth with his eye, drying up the oceans and rivers. The earth catches fire and burns until it is as bare as the back of a turtle. Then the rains come and pour water on the earth for a 100 years, converting the earth into a shoreless ocean. At that time, when only the ocean exists, all creation is absorbed and united into Vishnu who sleeps on his bed of coils of Ananta, meaning infinite, in the darkness of cosmic night (*Viṣṇu Puraṇa*: Dimmitt and van Buitenen 1978). Over and over, this sequence is repeated without end. Life appears and vanishes as passing days and nights. As in the story of the cities of Tripura which were destroyed when they are brought together by the arrow of Siva, union and absorption mean equilibrium and death.

Our astrophysical understanding of the end of the universe involves death by fire in the collapse of space

Cosmologies of India. Hindu Cosmochronology (Dimmitt and van Buitenen 1978; O'Flaherty 1975)

Yuga	Duration (years)
Kṛta	1,728,000
Tretā	1,296,000
Devāpara	864,000
Kali	432,000
1 Mahāyuga: breath of Brahma	4,320,000
1 Kalpa: day of Brahma	4,320,000,000

into a cosmic black hole or death by cold of unlimited expansion. In death by expansion, gravitational collapse may well dominate as stars eventually fall into black holes in the centers of galaxies and the universe becomes a dark and cold system of galactic black holes, silently, and darkly revolving one around the other. Even black holes are subject to change, and matter and energy will eventually evaporate from them to produce a return to chaos in the form of a vast photon ocean of thin, cold light. Lurking somewhere in the immensity of future time there must be other universes waiting to be born.

Cosmology of the African San People

Sven Ouzman

Using words to capture and convey our beliefs and experiences may seem precise and comprehensive, but such omniscience is illusory (Mitchell 1994). It may, however, be possible to fragment the totalising influence of words and concepts like 'cosmology' – knowledge of the world – by using historically specific texts, images, sounds and sensoria to promote epistemological diversity. This approach works well within a culture. I can, for example, distinguish between Southern Baptist and Greek Orthodox as two heterodox forms of Christianity. But what about other people, in other places, at other times? The people on whose behalf we interlocute – in this case the San or Bushmen of southern Africa (Endnote 1) – have histories marked by imperialism, colonialism, missionisation and Apartheid (Fig. 1). How then do we know when our information about these people draws on their remembrances of original traditions or when it embodies recent histories of violence? Despite ethnography's ethical problems (Clifford and Marcus 1986), we can use multiple strands of evidence to produce working knowledge that tacks between absolutism and hyper-relativism (Benhabib and Fraser 2004).

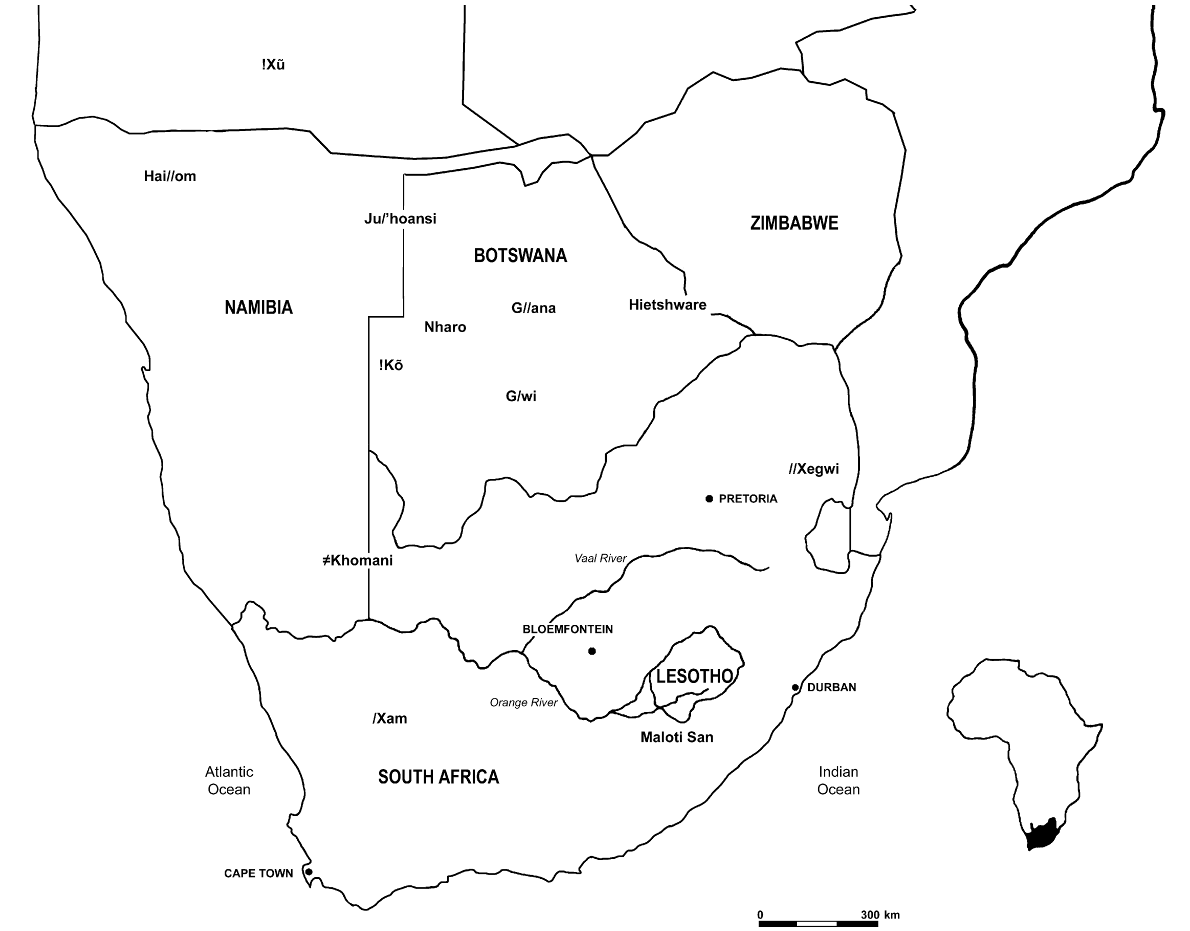
Cosmology of the African San People. Fig. 1 Bushman group, colonial South Africa, 1884. From Bleek and Lloyd (1911: 99).

A First People

The San of southern Africa (Fig. 2; Hyperlink 1) are the most studied people on earth because of their perceived uniqueness as models of original humanity. Such study has not always been accurate. In 1719 the German astronomer Peter Kolb published the statement that Hottentots worshipped the praying mantis (*Mantis religiosa*), generating the Mantis God myth (Marshall 1999: 242–245). In fact, this insect worship was San genuflecting to the powerful trickster, Kaggen, in one of his many corporeal forms (Barnard 1992: 84–85). Even today myths endure. San contextual egalitarianism, shamanic healing and environmental stewardship are often represented as timeless and apolitical, ossifying the dynamic and idiosyncratic flow of San life in which individual action and cosmological constants combine to create a flexible matrix for being in the world (Endnote 2). San groups present and past do, however, show remarkable congruence in "territorial organisation, gender relations, kinship, ritual, and cosmology" (Barnard 1992: 3). For example, colonial ethnographies suggest a common origin realm inhabited by "People of the Early Race" (Bleek and Lloyd 1911: 55–57, 175–199), who both created the cosmological order and delight in transgressing its boundaries. This primal time relies less on personnel, location or temporality than on the relationships between these components (Katz et al. 1997: 47–62). What we comprehend as separate Spirit and Ordinary worlds constantly intersect.

A Connective Cosmos

The Ordinary World has nodal topography studded with campsites, hunting grounds and what Ju/'hoansi call *n!oresi* – bundles of relationships and obligations between animals, beings, people, places, plants and things (Katz et al. 1997: 16, 50). Material traces of these relationships date back millennia, appearing as artefacts archaeologists classify on a continuum between functional and symbolic. Thus, artisanal artefacts such as stone tools and bone points grade into non-utilitarian items like ostrich eggshell beads and decorations, which intensify into symbolic crystals and rock art (Figs. 3 and 4). Some say functionality is easier to prove than symbolism. Yet our best evidence of San life is symbolic rock art present at over 30,000 sites (Ouzman 1998; Endnote 3). What



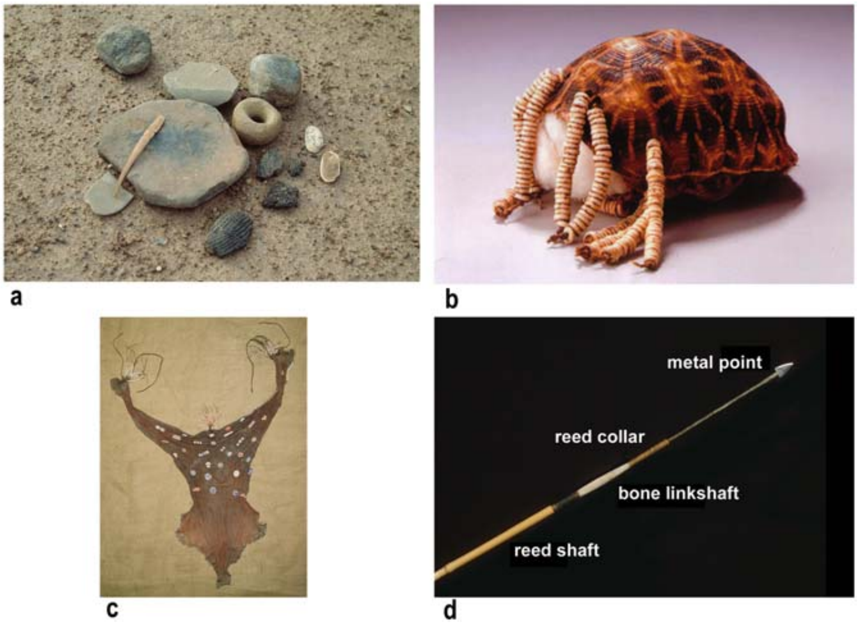
Cosmology of the African San People. Fig. 2 Distribution of San language groups.

we call images were for San actual apocalypse dogs, Beings, cynosuric animals, rain-animals, supernatural potency and part-human therianthropes emergent from an inner Spirit World behind the rock face.

Other connexions to the Spirit World, which exists in multiple locations above and below the Ordinary World, are via water, striking landscape features, and events like death and dancing. These do not permit universal access because the Spirit World is dangerous and inversive. It requires great skill to negotiate its pathways, cul-de-sacs, and denizens like the Spirits of the Dead. Two great but capricious gods – whom the G/wi call *N!eri* (creator) and *//Gauwa* (trickster) – have a fearsome entourage of wives, carnivores and spirits (Guenther 1999: 61–64). Consequently, the task of traversing worlds is left to shamans – skilled negotiators of boundaries who make sense of the seemingly impossible such as being neither and both male and female (Atkinson 1992: 319). This skill is superhuman and requires what Ju/'hoansi call *n/om* – a supernatural potency vested by God in certain interconnected receptacles such as comets, honey, lightning, large animals, plants, rain, shamans or sun (Marshall 1999: 20, 49–62, 218).

> The spirit is in the air. When you dance it comes down to you. When it gets into you, you can see it as a string of light. The light carries you in the dance. It can take you to another person who needs healing or it can carry you to another village in the sky. The light is *num* [*n/om*]. It doesn't have another name than *num*. Xixae Dxao (Keeney 2003: 41).

But potency, like the gods, is complementary – a foundational feature of San cosmologies. Small amounts of potency aid apotropaism astral travel, healing, and rainmaking, but high concentrations can kill. Controlling potency and passage to the Spirit World requires everyone's labour (Katz 1982: 34–57). Nowhere is this complementarity better exemplified than in the Medicine Dance – perhaps humanity's



Cosmology of the African San People. Fig. 3 San material culture. (a) Bored stone, bone scraper, freshwater mussel shells, grindstone, lithics, pottery. (b) Medicine container. Hearst Museum, University of California Berkeley, California. (c) Decorated leather woman's apron. (d) Arrow.

oldest surviving ritual (Hyperlink 2). The atmosphere of the Dance is social and electric. People clap, dance, sing and talk to create a spiritually charged and socially cohesive atmosphere that launches shamans to the Spirit World.

It is endlessly varied by disciplined improvisation, within the bounds of repeated musical phrases. When the awesome sound of the men's rattles is added to the singing and sharply clapped cadences, a music of truly unearthly beauty is

> produced. This music is one of the basic vehicles of transcendence, enabling curers to achieve the altered state of consciousness called trance (Biesele 1984: 165–166).

> In trance, with the support of the women in the community, who sing and clap, a master of trance works himself into a state where he transcends himself and enters the realm of the supernatural where the ghosts of dead ancestors live. Here he struggles with the ghosts. The struggle is intense both emotionally and physically. He is overcome with pain and fear, afraid that he will lose himself in the realm of the supernatural and not return (Wiessner and Larson 1979: 25).

The physical and spiritual labour of females, males, children, movement, sound, spirits and potency is thus not equal but harmonises. Shamans are pre-eminent but they serve a community. The Medicine Dance is an enduring *genius loci* still performed in Angola, Botswana and Namibia where it attracts non-San like Damara, Herero and Tswana for healing and community. The Dance incorporates elements of ecstatic Christianity and political resistance, whereby shiny European goods are eschewed and shamans act as agents of social change by voicing concerns about alcoholism, marginalisation and so forth (Guenther 1999: 195–6).

San Science: Past, Present and Future

San cosmology is thus not narrowly spiritual but entails "an all-encompassing world-view, the influences of which extend into every sphere of their existence" (Yates and Manhire 1991: 3). An especially complete synthesis of gender, science, religion and technology is !Kõ and //Gana arrow poison (Heinz 1978: 151; Neuwinger 2004; Hyperlink 3). The paralysing toxin comes from the haemolymph of *Diamphidia simplex* beetle larvae and cocoons, but not the adult beetle (Fig. 5; Hyperlink 4). These larvae live up to 1 m below the ground near a host tree, the sandy corkwood (*Commiphora angolensis*). Six to ten larvae are sufficient for one arrow's toxin, which is applied by man-the-hunter (Hyperlink 5). San arrows are tripartite constructions designed so that the impetus of the linkshaft breaks the reed collar, causing the shaft which the animal could otherwise dislodge from its body to fall away, leaving just the arrow point behind to deliver the toxin (Fig. 3d). But men are ignorant of the toxic larvae's location until women, more attuned to subterranean signs (Hyperlink 6), tell them where to look. This female–male, nature–science relationship is spiritually triangulated through the great God ≠Gao N!a who "taught them how to find it and how to put it on their arrows so that they would have meat" (Marshall 1999: 32).

Lest San be characterised as waning guardians of an ancient spirituality, it is useful to examine complementarities between San and Western worlds. Sometimes this juxtaposition is conflictual. Pfizer Pharmaceuticals were sued for bio-pirating ≠Khomani intellectual property of the appetite suppressing properties of the *Hoodia gordonia* plant, now marketed as a slimming product (Wynberg 2004). In more fulsome spirit, the Cybertracker project pairs renowned San tracking skills with Global Positioning System (GPS) technology to aid game management and counter poaching (Hawthorne 1999; ►www.cybertracker.co.za). San trackers, often text-illiterate but masters at reading sign, note spoor by selecting species-specific keypad icons. The GPS registers this input, capturing data like the location, movement, number and health of animals, which is transmitted to a central database. This hybrid approach is more effective than either San or Western science. Indeed, Western science may originate out of the art of tracking:

> To interpret tracks and signs trackers must project themselves into the position of the animal in order to create a hypothetical explanation of what the animal was doing. Tracking is not strictly speaking empirical, since it also involves the tracker's imagination. Generally speaking, one may argue that science is not only a product of objective observation of the world through sense perception. It is also a product of the human imagination (Liebenberg 1990: v).

More than science, San tracking is a deeply spiritual activity necessary for the renewal of life. "Tracking is like dancing. This is the Great Dance. You are talking to God when you are doing these things" (Hyperlink 7). However, while San cosmological complementarity works well in Habermasian ideal speech situations,[1] these examples of accord should not mask the devastation of acculturation, cultural property theft, forced removals and genocide experienced by many San. Celebrating only the positive can veer dangerously close to liberal social contracts and commons that are open to unpunishable abuse (Hardin 1968). Mindful of this, San have reformulated their egalitarian ethos to uplift

[1] Habermas (1929-) sets out five conditions for his ideal speech situation (a) Every subject with the competence to speak and act is allowed to take part in a discourse; (b) Everyone is allowed to question any assertion whatever; (c) Everyone is allowed to introduce any assertion whatever into the discourse; (d) Everyone is allowed to express his attitudes, desires and needs (e) No speaker may be prevented, by internal or external coercion, from exercising his rights as laid down in (a) and (b). (*Diskursethik*: 86). These conditions make possible free discourse and pure communicative action.

themselves and to educate well-intentioned and wilful outsiders (WIMSA 2003; ►http://www.san.org.za). The long and ongoing tradition of San cosmology is not something conservative and ancient, it is a fund of beliefs, places, objects, skills and stories that allow people to innovate and to impact the modern world.

Endnote 1: The Name Game – San or Bushman?

Ethnonomy – the process by which people name themselves, are named by others, and the politics that determine which names stick – is critically important to people's sense of self. Both San – a Nama word meaning "vagabond" – and Bushman – an anglicisation of the Dutch *bosjemans* – are exonyms. Today's approximately 100,000 San who live in Angola, Botswana, South Africa and Zambia have group-specific autonyms like /Gwi, Ju/'hoansi, and !Kõ, which translate as people, real people or red people, but that do not apply beyond the group – even to other San (Traill 1995; ►http://en.wikipedia.org/wiki/Khoisan_languages). The corporate term Khoisan was coined by Leonhard Schultze in 1928 (Barnard 1992: 7) and conflates the overlapping but distinct histories of Khoekhoe herders like the Nama, with San. During Apartheid, Bushman and *Boesman* were deeply offensive, but today these words are being reclaimed as a form of resistance (Gordon 1992: 6–7). Where possible, group specific names should be used. Elsewise either San or Bushman are acceptable, if used respectfully.

Endnote 2: San and New Ageism

Thanks to films like Jamie Uys' *The Gods Must be Crazy*, books like Laurens van der Post's *The Lost World of the Kalahari*, and high profile academic research, San are viewed as a distillate of pure humanity – noble savages. Such stereotyping, while well intentioned and having some basis, leads to social and political marginalistion. Nowhere is this more apparent than in the New Age movement's appropriation of San shamanism and rock art (Sullivan 1995) and archaeology in general (Morris 2005). Modern primitives' urge to leave offerings at archaeological sites, to mimic ceremonies and dress, and continued idealistic portrayal of San cosmology causes communities great distress (Katz et al. 1997). New Ageism is a very partial practice that selectively ignores modern circumstances like the syncretic adoption of Christianity and very real social problems such as alcoholism, domestic violence and persecution and how San succeed and fail to deal with these.

Endnote 3: The Meaning of San Rock Art

In 1945 the French prehistorian Abbé Henri Breuil sent word to South African Prime Minister Jan Smuts of “a portrait of a charming girl who has been waiting for us on a rock in the Brandberg range for perhaps three thousand years.” Breuil was describing what he thought to be a Phoenician White Lady painted on the rocks of Namibia’s Brandberg (Breuil 1955; ►http://www.namibia-1on1.com/Namibia-Northern/White-Lady-Of-Brandberg.html). Breuil’s inability to acknowledge indigenous authorship of southern African rock art was influenced by the Eurocentric Great Chain of Being (Lovejoy 1936). Hierarchically ordering the world between God atop and rocks below; white humans were placed nearer God while San, Bantu speakers and Khoekhoen were placed near and even under rocks. Art produced by these lower races was believed either simply to record daily life or to spring from an innate native ability to make art. Appreciation of San rock art’s symbolic and spiritual meanings lay dormant until half-forgotten nineteenth and twentieth century ethnographies (►www.lloydbleekcollection.uct.ac.za) revolutionised southern African rock art research (Lewis-Williams and Pearce 2004; ►http://rockart.wits.ac.za). Today we know that most southern Africans made some form of rock art. Whether shamanistic San statements, group-specific Khoekhoen engravings and paintings, initiation and political resistance arts of Bantu speakers, or Depression-era marks of white work gangs, the landscape bears a multitude of marks – some of which have yet to be understood.

Cosmology in Mesoamerica

Keith Jordan

The Native American peoples who occupied Central and Southern Mexico, the Yucatan Peninsula, Guatemala, Belize, El Salvador, and Western Honduras prior to the Spanish Conquest of the sixteenth century shared many aspects of both material culture and ideology. This cultural unity, underlying varying expressions of the basic pattern across linguistic, ethnic, and political divisions, is the basis for the modern anthropological construct of Mesoamerica as a distinct culture area. Among the achievements of the pre-Columbian Mesoamerican civilizations of the Aztecs, Maya, Mixtecs, Zapotecs, and others are complex myths and mental maps of the universe as they understood it. These elaborate conceptualizations encompass multiple realms of existence and sequences of creation and destruction across vast epochs of time. While each distinct culture generated its own cosmology, all such models of the nature of the cosmos are united by common features marking them as distinctively Mesoamerican. This entry will employ as representative examples the world views of two Mesoamerican cultures for which much information has come down to us across centuries, the Aztec and the Maya. The reader unfamiliar with the sources and chronology for Mesoamerica should view Notes 1 and 2 before reading further.

Shared Features of Traditional Mesoamerican Cosmologies

Although details vary across time and political/linguistic boundaries, pre-Columbian Mesoamerican cosmologies share a number of general characteristics. The universe is conceived as arranged in multiple levels, broadly divided into an upper world (the sky), a middle world (the earth), and an underworld beneath the earth. The upper world, home of the gods, may have 13 levels, while the underworld, land of the dead, usually has nine. The earth is pictured as a disc, square, or aquatic reptile floating on the sea. Its surface is divided into four quarters corresponding to the cardinal directions. At its center is a vertical axis symbolized by a tree or primordial mountain, bridging the multiple tiers of the cosmos above and below. This center may be identified with a capital city or sacred site, or with the body of a ruler. Deities, rulers, and ritual specialists use the central axis as a conduit to travel between levels of the universe. Other portals to the ancestral realm of the underworld are depicted as the mouths of mythical reptiles, and equated with caves. Mountains are envisioned as hollow sources of plenty, repositories of water and maize.

Similarities in maps of space are matched by shared, cyclical conceptions of time. The present universe is the last of a series of creations. Each prior cosmos fell victim to catastrophic destruction. A ritual calendar year of 260 days is paired with an approximate solar year of 360 days, a hallmark of Mesoamerican culture (see Calendars in Mesoamerica in this volume). Unlike contemporary Western thought, in the Mesoamerican vision, cosmology is distinguished neither from religion nor from politics. The social order and its activities – like warfare and human sacrifice – are part of the natural order and crucial to the viability of the entire cosmos. The forces that animate and manifest as the phenomena of nature are supernatural beings.

Mesoamerican thought is characterized by dynamic pairings of binary oppositions: male/female; upper world/underworld; rain/dryness; and death/life. Although sometimes labeled as dualism, these conceptions are not dualistic in the Platonic or Manichaean senses, i.e., separating mind and matter. Rather, the opposite qualities interact dynamically and are themselves manifestations of an underlying unity (Fig. 1).

Origins

The beginnings of Mesoamerican cosmology are lost in the distant past. Mesoamerican world views share features with Asian, Native North American, and South

Cosmology in Mesoamerica. Fig. 1 Ehecatl/Quetzalcoatl (*right*), a deity associated with life and fertility, and Mictlantecuhtli, god of death and ruler of the underworld, showing duality of opposing forces in the cosmos. Reproduced by permission of Alan Rodgers.

American shamanic traditions – e.g., a multilevel universe bridged by a vertical axis conceived as a world tree. Because of these similarities, some scholars trace the roots of Mesoamerican cosmologies back to the presumed shamanistic beliefs of the first settlers of the New World who crossed the Bering Strait or arrived by boat along the Pacific coast during the last Ice Age. Other parallels suggest connections with Asia: the occurrence in both areas of directional symbolism associated with colors, or the identification of the markings on the surface of the moon as a rabbit. However, the archaeological record does not yield clear evidence for cosmological beliefs in Mesoamerica from the arrival of the first hunter–gathers (pre-10,000 BCE) through the transition to a sedentary agricultural lifestyle (ca. 2000 BCE). The relevance of shamanism to understanding Mesoamerican civilizations has been questioned (Note 6).

The earliest clear signs of a developed mythic cosmology occur in the monumental art of the Olmec culture of the Mexican Gulf Coast. This civilization, which flourished between 1200 and 400 BCE, has been touted as the "mother culture" of Mesoamerica, although more recent views hold it to be the most developed regional manifestation of a pan-Mesoamerican art style and ceremonial complex. In the absence of readable glyphic inscriptions, reconstruction of Olmec cosmology is a speculative exercise, drawing on inferences from Maya beliefs (see shamanism in Mesoamerica in this volume).

Maya Cosmology

On the basis of artistic, inscriptional and ethnographic data, we know that the Maya of the Classic through Postclassic periods envisioned the earth as a disk or square surrounded by water, or as an aquatic animal, a turtle or a caiman. The earth's surface could be represented as a quadrilateral, based on the traditional Maya maize field or milpa. In the *Popol Vuh* (Note 5), this shape was mapped out by the gods using a cord during the last creation. This surface was divided into eight by the four cardinal and four intercardinal directions, and transfixed vertically in the center by the world tree, the central axis and path between upper, middle, and lower worlds. This cosmic tree was identified with the ceiba tree, whose sanctity may be related to the resemblance of its sap to blood. In Classic reliefs from Palenque, the world tree is depicted as a cross, with the Celestial Bird, Mut-Itzamna, perched at the top, and the entrance to the underworld, personified as the skeletal jaws of the White-Boned Serpent or Centipede, gaping at its base. In the sky, the world tree seems to have been equated with the Milky Way, called "the White Road" in Classic texts. Its uppermost terminus was located at the north celestial pole. Deceased souls, along with shamans, move up and down this conduit between cosmic tiers, hence the euphemism for royal death, "he entered the road," in Classic texts. As shamans, Classic kings were supposed to navigate between worlds along the world tree via trance states induced by bloodletting. The king's body itself is symbolically equated in art with this *axis mundi*.

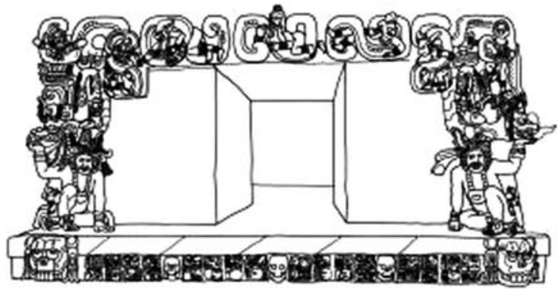
Each of the four cardinal directions was equated with a symbolic color. Red, color of the sunrise, represented the East, a positive direction because of its solar associations. By contrast, West was associated with black and had negative connotations because of its connection with sunset, and by analogy, death. North (white) was the direction of the sun's zenith, followed by dead kings in their apotheosis to the celestial world (Note 7). It was the domed house of the sky, raised by the Maize God during the last creation of the world. South (yellow) pointed to the depths of the underworld. The earth was supported by four beings referred to as Bakabs or Pauhatuns. According to the *Chilam Balam of Chumayel* (Note 5), they were survivors of the destruction of the third creation. In other sources, they are the winds. The Maya rain god, Chaak, is also depicted with four manifestations corresponding to the cardinal directions.

Below the earth lay the nine-tiered underworld, Xibalba, "place of fright." This underwater realm was pictured as dark, foul, cold, associated with disease, death and rot, home of monsters and malevolent gods like the Lords of Death named in the *Popol Vuh* by such epithets as "Pus Master" and "Stab Master." Xibalba rotates over the earth at night to become the night sky. Caves, the jaws of the earth, were entrances to Xibalba, paths taken by the setting sun as it entered the underworld. At the same time, caves carried connections with fertility, being the source of rain, clouds, and maize. Another type of cosmic portal, perhaps a manifestation of the *axis mundi*, is represented in Classic art by supernatural snakes, Vision Serpents. These entities, brought into transient existence by the bloodletting rites of Maya kings, serve as bridges between the rulers and the realm of their ancestors, who are seen emerging from the serpent's jaws to bestow their blessings (Fig. 3).

The upper world, with its 13 levels, was represented in art by the Skyband, a two-headed serpent or crocodile symbolizing the ecliptic. The serpent image may be a visual pun: in the Cholan Maya language, *kan* (snake) resembles *can* (sky). Skybands were used as borders demarcating the upper world in art. The ecliptic can also be represented as a cord which guides the celestial bodies across the sky. The daytime sun was represented by the male deity, Ah Kin or Kinich Ahau. At night, the sun passed through Xibalba, where it took the form of the Jaguar God of the underworld (although an alternate interpretation connects him with the moon). The moon could be represented by a goddess, often depicted as a youthful seductress, accompanied by the rabbit that was seen in its features. Lunar eclipses, recorded and predicted with accuracy, may have been the preserve of a separate divinity (Figs. 4–6).

The Maya also charted the movements of Venus. As in other parts of Mesoamerica, this planet was associated with warfare. It is possible that military engagements were timed in the Classic period according to the planet's 584-day cycle, though recent epigraphic work suggests that more pragmatic factors no doubt also influenced such decisions. In the *Popol Vuh*, Venus is depicted as carrying the sun. The Maya kept track of the behavior of other planets visible to the naked eye, but our understanding of their planetary symbolism remains uncertain. For example, Mercury may have been identified with the deity Kawil, whose reclining posture may reflect the planet's observed position just above the horizon, but another interpretation links the same deity to Jupiter.

The stars were set in motion by the raising of the world tree at the last creation. Maya conceptions of the zodiac and constellations remain poorly understood. It appears that the Pleiades were envisioned as a rattlesnake (*Sab*), while the belt of Orion was equated with a turtle (*Ak*), through whose shell the Maize God



Cosmology in Mesoamerica. Fig. 2 Doorway of Temple 22, Copan, Honduras, Late Classic Period. The decoration of this temple structure symbolizes the Maya cosmos. At the top, the serpentine Cosmic Monster represents the sky. The crouching figures on either side of the entrance are bacabs or pauhtuns, the deities who support the world. The skulls at the base represent the underworld. The doorway itself represents a symbolic cave, entrance into the underworld. When the Copan ruler Waxaklahun Ubah Kawil (18 Rabbit), who commissioned the structure, entered the temple he was symbolically entering a portal to the supernatural world of his ancestors. Cosmology in Mesoamerica. Fig. 5 Skybands from Palenque, Late Classic Maya. Reconstruction of stucco relief sculptures from "bicephalic Room," House E, Palace. The top drawing shows the Celestial Bird and skyband, from the north wall. The bottom drawing represents a second two-headed deity, a composite of skyband segments from the west and east walls. The skyband on the Western wall has a saurian or reptilian head with Venus markings. Drawing/text by Linda Schele, copyright David Schele, reproduced courtesy of FAMSI.

Cosmology in Mesoamerica. Fig. 6 Paddler Sun, Early Classic Maya. Drawing of lidded four-legged vessel. Each of four legs represents a downward facing peccary. Atop the lid, the Sun God, wearing a cap marked with k'in ("sun") paddles his canoe through a watery environment containing fish. This vessel has been interpreted as representing the Sun God paddling his canoe across the ecliptic and the constellation of Gemini. Drawing/text by Linda Schele, copyright David Schele, reproduced courtesy of FAMSI.

resurrected at the last creation (Note 7). Alternatively, *Ak* may correspond to Gemini, and the Pleiades were also identified with 400 boys killed by the monster Zipacna, an event placed by the *Popol Vuh* shortly before the last structuring of the world. A scorpion constellation may be identical to Scorpio, or correspond to Gemini. Mut-Itzamna, avian shamanic alter ego of the sky deity Itzamna, seems to have been identified with the Big Dipper.

For the Maya, the present universe is the most recent of cyclic creations destroyed by past catastrophes. The last reordering of the cosmos occurred in 3114 BCE, the mythic starting point of the Long Count dating system (Note 6). According to an inscription in the Temple of the Cross at Palenque, the creator deities First Mother and First Father (the Maya Maize God) set three hearth stones at the center of the universe, identified with the stars Alnitak, Saiph, and Rigel. As the sky lay flat upon the earth, the Maize God lifted it up to its present position, supported by the world tree. This ordering of the cosmos set in motion time and the movements of the stars.

In the *Popol Vuh* creation myth, the gods of creation reside in watery chaos, silent and dark. They create the first version of the universe, populated by animals, but are unsatisfied because the beasts are incapable of worshipping their makers. To rectify this deficiency, the gods create the second world and make the first humans out of mud. However, these creatures were incapable of thought, and the gods destroyed them and their world by water. On the advice of an elderly couple skilled in divination, the gods created the humans of the third creation out of wood. These people were able to speak, but had no emotions, and did not recognize the gods as their creators. This failed experiment was brought to an end by a flood and rain of pitch. The few surviving wooden men were transformed into monkeys.

Order was brought out of the chaos left by the flood by the erection of the vault of the sky and separation of the earth from water. The gods created the current race of humans from maize, but they proved to be too smart for their creators' liking. As a countermeasure, the gods limited their understanding. From the interior of the terrestrial cornucopia, First True Mountain, came seeds, maize and water for the sustenance of humanity.

Aztec/Nahua Cosmology

The Mexica, or Aztecs, and related peoples of Postclassic Central Mexico, envisioned the universe as a fluxing reality permeated with spiritual forces in endless transformation. Like the Maya, they seem to have believed in an upper world of 13 levels and an underworld of nine, though this conclusion, based on colonial sources, has been questioned. The earth was pictured as a disk or a floating crocodilian or toad-like monster, Tlaltecuhtli, bounded by a square or circle of water joined to the vault of the sky. For the Aztecs, the central axis connecting the three realms of the universe transfixed the earth at their capital city, Tenochtitlan, on the site of the Templo Mayor (great temple). As in Maya cosmology, the world was divided by the four cardinal directions. East, associated with solar hues of red and yellow, was viewed as positive. North was referred to as the Land of the Dead, as it was believed that the journey of souls to Mictlan, the underworld, began here. It was cold and its color was black. West, the Region of Women, was associated with the positive colors, blue and green, while South, called the Region of Thorns, was symbolized by white. Each direction had its own version of the rain god, Tlaloc, in a similar fashion to the Maya Chaaks. A slightly different Nahua conception of directional symbolism, probably produced in Puebla or Tlaxcala, is illustrated in Note 8 (Figs. 7 and 8).

On the earth's surface, mountains were hollow repositories of water and clouds, entrances to Tlalocan, the paradise of the rain god. The mythical Mountain of Sustenance was the source of maize, from where it was stolen by the god Quetzalcoatl at the last creation for the benefit of humans. Rivers and caves were the hungry orifices of the Earth Monster, who bore crops for human survival but devoured humans when they returned to the earth at death (Fig. 9).

The upper realms included the paradise of the sun, to where the souls of warriors slain in battle or captured and sacrificed, and of women who died in childbirth, ascended after death. They were privileged to accompany the sun on its daily journey across the sky. Tlalocan was another celestial paradise where the spirits of humans who died by drowning, lightning, or diseases associated with water went to spend the afterlife in joy. The uppermost heaven belonged to the primordial couple, the creator deities Ometecuhtli and Omecihuatl. The sun

Cosmology in Mesoamerica. Fig. 7 Detail of ceremonial mosaic shield interpreted as representing the central axis of Aztec cosmology. A world tree sprouts on the upper level, the sun symbol with the four directions and the center laid out in a quincunx pattern decorates the middle level. A serpent spirals through the four layers of the cosmos. Drawing/text by Linda Schele, copyright David Schele, reproduced courtesy of FAMSI.

was represented by the god Tonatiuh, and also equated with the Aztec tribal patron, the war god Huitzilipochtli. As among the Maya, Venus had a malevolent role among the heavenly bodies. The god of Venus as the Morning Star, Tlahuizcalpantecuhtli, is represented in the Borgia group of manuscripts with a skeletal mask, hurling darts at his victims. This deity was a manifestation of Quetzalcoatl. It is commonly repeated in the literature that another form of Quetzalcoatl, the dog god Xolotl, represented Venus as the Evening Star. Meteorites were equated with caterpillars and worms and were referred to as the excrement of the stars. Some stars were *tzitzimime* – demons who will devour humans at the end of the present creation. The Milky Way was represented as a divine couple, Citlaltonac and Citlalicue (Fig. 10).

At the nadir of the underworld was Mictlan, land of the dead, destination of those souls who did not die in battle or by sacrifice. This was a shadowy half-world much like the Greek Hades, where the dead were not tormented but faded into nonexistence. It was reached by the soul after an arduous journey through bitter cold and obstacles like wind-blown knives. A dog was sacrificed and included in burials to help the departed navigate this difficult passage.

The Aztecs saw the present world as the fifth in a series of successive creations, or Suns, brought to an end by a series of destructions. According to one

Cosmology in Mesoamerica. Fig. 8 The five directions of the Nahua cosmos: the four cardinal directions and center, with deities. Clockwise from top right: sun god, patron of the East; Tlaloc, god of rain, patron of the South; Xipe Totec, Our Lord the Flayed One, god of agricultural fertility and patron of the West; Mixcoatl, god of hunting, patron of the North. commonly repeated variant of the creation myth, the first world, Four Jaguar, was created out of primordial chaos, and ruled over by Tezcatlipoca, the protean god of kingship, fate, the night, and sorcery. The first created humans were giants – the Aztecs identified the bones of mastodons as their remains. At the end of this era, jaguars devoured these primal men. This catastrophe coincided with the defeat of Tezcatlipoca by his rival, Quetzalcoatl, god of the wind, fertility, and a culture bearer for later humans. The second creation, Four Wind, was effected and ruled by Quetzalcoatl in his manifestation as the wind, Ehecatl. In turn, he was defeated by Tezcatlipoca, and his world and its humans wiped out by hurricanes. The few survivors became monkeys. Tlaloc governed the third world, Four Rain. This creation was brought to a violent end by fire and water, and the survivors became dogs, turkeys, and butterflies. Four Water, the fourth world, appropriately had Chalchiutlicue, goddess of ground water, as its patron. Fittingly, Four Water was destroyed by a flood; its human survivors were changed into fish (Fig. 11).

After the destruction of four Water, Quetzalcoatl and Tezcatlipoca collaborated to raise the sky from the earth, supported on the trees of the four directions. The Milky Way marks their path where they walked across the new sky. A crocodilian monster, variously identified as Tlaltecuhtli or Cipactli, was vanquished by the two gods and split in half to become the earth. The gods altered her body to yield crops for humans, but in her pain, she required blood sacrifice in return for her bounty. Quetzalcoatl retrieved by trickery the bones of past humans from Mictlan to create new humans. He animated them by letting his own blood, another reason for offering blood sacrifices to the gods in gratitude. The gods assembled at the ancient city of Teotihuacan, to sacrifice themselves to create the Fifth Sun and start its motion across the sky. A disfigured god, Nanahuatzin, ("the purulent one"), sacrificed himself by immolation and became the sun. The future moon, who had hesitated to volunteer his life, followed Nanahuatzin's example and emerged from the flames as brilliant as the sun. The other gods, remembering his

cowardice, dimmed his brilliance by striking him in the face with a rabbit, leaving the pattern visible still on the moon's surface.

This present Sun, Four Movement, will be destroyed by earthquake. In the hopes of delaying this catastrophe, the Aztecs found further justification for human sacrifice on a grand scale to strengthen and nourish the cosmos.

Note 1: Historical Time and Space in Mesoamerica

The indigenous peoples of Mesoamerica, like all other Native Americans, are the descendants of migratory hunter–gatherers who arrived in the New World from northern Asia by 12000 BCE, and perhaps considerably earlier. By 2000 BCE, the first Mesoamericans had developed a system of agriculture based on the staples of beans, squash, and most important, maize. This shift in economy led to the rise of permanent village communities and increasing levels of social stratification and cultural complexity.

By 1500 BCE, hierarchical societies with sophisticated cosmologies, monumental architecture, urban settlements, and specialized artists had emerged along the Mexican Gulf Coast in the modern Mexican states of Veracruz and Tabasco, and in the highlands of Chiapas and southern Guatemala.

Mesoamerican scholars traditionally used the term "Preclassic" or "Formative" to refer to the period from these first manifestations of civilization down to the third century of the Christian era. This terminology is an artifact of the historical development and biases of Mesoamerican studies over the last 200 years. Because Maya art is relatively naturalistic and reminded nineteenth and twentieth century archaeologists of the Classical styles of the ancient Mediterranean, it was given a privileged status relative to the rest of Mesoamerican art. This, and Maya achievements in mathematics, astronomy and the calendar, led early scholars to equate the apogee of Mesoamerican civilization with the period when the Maya erected cities and monuments dated by hieroglyphic inscriptions using the Long Count system. This time interval, ca. 250–900 CE, thus became the Classic Period, and rather predictably, the periods before and after it became the Preclassic (1200 BCE–250 CE) and Postclassic (ca. 950 CE–1521). During the Classic, it was alleged, the Maya and other Mesoamerican civilizations were governed by theocracies of astronomer priests and lived in utopian peace, free from conflict. During the Postclassic, the political and social order found among the societies encountered by the sixteenth century Spanish, based on war, human sacrifice, and monarchy, supposedly eclipsed this priestly paradise.

Discoveries in archaeology and epigraphy during the second half of the twentieth century have shattered the illusion of a Classic period governed by pacifist stargazers. It is now clear that the Classic civilizations, especially the Maya and the city of Teotihuacan in the Basin of Mexico, were engaged in warfare and human sacrifice on a large-scale, and that the Classic Maya were ruled by kings who were as much politicians and warriors as they were priests. It is also apparent that Mesoamerican civilization did not "degenerate" after the Classic period. It merely changed in directions that did not suit the prejudices of early pundits. But the chronological system has remained in use, despite proposed alternatives. The Preclassic, however, is now generally referred to as the Formative, in an attempt to characterize it based on its own characteristics – the formation of the general Mesoamerican cultural pattern – rather than by comparison with the Classic.

The Formative Period is in turn divided into three stages. During the Early Formative (ca. 1500–900 BCE), Olmec civilization flourished on the Gulf Coast around the site of San Lorenzo, while chiefdoms in Oaxaca, Chiapas, and southern Guatemala participated with the Olmec in a system of trade and shared ideologies among elites. During the Middle Formative (ca. 900–300 BCE), San Lorenzo collapsed, and Olmec civilization became focused on other sites like La Venta. Elite centers as far away as the Mexican states of Guerrero and Morelos shared symbolism and perhaps even artists with the Gulf Coast. In Oaxaca, the Zapotec people founded the great city of Monte Alban, where the first evidence of the distinctive Mesoamerican calendar system appears. In the Maya region, urban centers with monumental architecture appear in both the highlands and lowlands of Guatemala.

By the Late Formative (300 BCE–250 CE), the Olmec culture declined and vanished from the archaeological record. In the central highlands of Mexico, the huge metropolis of Teotihuacan emerged as a major power with influence felt throughout Mesoamerica. In Veracruz and Chiapas, the oldest known inscribed dates in the Long Count come from this period. In the Maya region, huge cities rivaling their "Classic" descendants were raised at sites like El Mirador in Guatemala, and the ideology of Maya kingship began to take shape.

The Classic Period is usually divided into Early and Late phases. During the Early Classic (ca. 250–600 CE), Teotihuacan reached its peak of political, religious, and artistic influence on the rest of Mesoamerica, even apparently interfering in the political affairs of distant Maya city–states like Tikal, Guatemala. In the Maya area, fully developed hieroglyphic inscriptions appear. Centers like Tikal and Copan rose to political prominence and artistic glory. In Oaxaca, the Zapotec capital of Monte Alban reached its florescence. The Late Classic saw the full cultural and political development of Maya cities such as Tikal, Copan, Palenque, Yaxchilan, and Piedras Negras. In Central Mexico, Teotihuacan's sacred center was burned and abandoned, ending the city's dominant position, while other centers like Xochicalco and Cacaxtla flourished in its wake. Long-distance trade contacts are revealed by the eclectic art of these sites, showing influences from as far away as the Maya.

By 900 CE, most of the southern Maya cities were abandoned after overpopulation, soil exhaustion, drought and warfare led to the breakdown of the Classic Maya institution of kingship. No more Long Count dates were recorded. In Yucatan, however, Maya centers like Uxmal and Chichen Itza continued to thrive, the latter perhaps for several centuries. In Central Mexico, a multiethnic people, the Toltecs, established their capital at Tula in the modern state of Hidalgo, marking the transition to the Early Postclassic (950–1150 CE). In Oaxaca, the warring Mixtec dynasties described in their screenfold books began their rise to power. An art style or group of related styles, usually called "Mixteca-Puebla" after the two regions believed to be its place of origin, became an international visual language among Mesoamerican elites.

In 1168 CE, Tula was sacked and burned by invaders from the north, an event sometimes used to mark the inception of the Late Postclassic. In Yucatan and Guatemala, the Maya split into small warring polities. In Central Mexico, a certain degree of political unity was brought about by the Mexica or Aztecs. Originally from the north, the Aztecs migrated into the Basin of Mexico and founded their capital city of Tenochtitlan on the site of modern Mexico City, in the early fourteenth century. Within less than two centuries, they had established a system of tribute states, often erroneously labeled an empire, west into Guerrero, south into Oaxaca and Chiapas, and east to the Gulf Coast. The arrival of the conquistadors in 1519 brought Aztec hegemony – and native rule of any kind in central Mexico – to an abrupt end. By 1521, Tenochtitlan had been destroyed and Mexico became the Viceroyalty of New Spain. The Maya, less centralized, and with less gold to attract the attention of the invaders, held out longer. Yucatan was not firmly under Spanish control until the 1540s, and the last autonomous Maya kingdom, Tayasal in Guatemala, was able to maintain its independence until it finally fell to Spanish forces in 1697.

Note 2: Sources and Their Problems

Our knowledge of prehispanic Mesoamerican world views derives from several sources via which evidence of cosmological beliefs has survived both the ravages of time and the impact of the Spanish Conquest of the sixteenth century. Yet, each line of evidence is marked by ambiguities and gaps in information, simultaneously preserving and obscuring pre-Columbian conceptions of the universe. From the period of initial Spanish contact with Native Mesoamericans, we have written documents, chronicles, and letters by conquistadores and missionaries. In particular, the writings of Duran and Sahagun on the Aztecs, and Landa on the Yucatec Maya, have preserved much information about Mesoamerican cosmology in the sixteenth century. However, Colonial accounts of indigenous beliefs are frequently incomplete, propagandistic in their efforts to justify conversion of the "idolatrous" natives, and distorted by the conceptual frameworks of their authors. Western assumptions are forced onto very different views of the cosmos, leading to debate and uncertainty for centuries to come (Note 3: Did Mesoamericans Have Gods?). In addition, the validity of using these late traditions to interpret the beliefs of earlier Mesoamerican civilizations is limited, since systems of thought rarely remain static for centuries. Many attempts to "read backwards" from colonial sources to interpret earlier belief systems founder on the uncertainty created by such large gaps in time.

At the same time as they were preserving aspects of Mesoamerican cosmology in their writings, the friars of the sixteenth century were busy destroying another type of evidence – indigenous screenfold books. Many of these documents, painted on bark paper or deer skin, were burned by the colonists in their zeal to destroy Native Mesoamerican religions. Few have survived as a result (Note 4). These painted books contain scenes illustrating episodes from cosmogonic myths, symbolic maps of the universe, and astronomical observations. Unfortunately, they are frequently fragmentary or poorly preserved. Without surviving oral tradition, their imagery is often difficult to interpret, and owing to their fragility, only examples from the centuries immediately preceding European contact have endured.

Over the last half century, epigraphers have made tremendous progress in deciphering Maya hieroglyphs. These advances have led to increased understanding of Maya cosmology during the Classic Period (ca. 250–900 CE) on the basis of inscribed texts. However, work in this field is still in an early, rapidly developing stage, with the result that newly published translations are often provisional and sometimes quickly superseded – hallmarks of a discipline in flux.

Art historians have contributed to our comprehension of pre-Columbian conceptions of the cosmos through interpretations of iconography. While their work has led to the recognition of cosmograms, astronomical symbols, and creation myths in Mesoamerican art, it is frequently speculative and controversial. In particular, attempts to interpret the religious art of earlier cultures by using Conquest-era sources are fraught with uncertainty, as noted above. In a similar fashion, archaeology has played its role in the recovery of ancient Mesoamerican world views via careful excavation of monuments and art as well as traces of ritual behavior. But again, interpretation of the data in the absence of written texts or clear-cut continuities with historic observations remains limited by the incomplete nature of the archaeological record. The looting of archaeological sites, leading to the appearance on the art market of artifacts orphaned of their context, has further contributed to the loss of information.

A hybrid discipline, called archaeoastronomy in the US and astroarchaeology in Britain, arose in the 1970s out of collaboration between archaeologists and astronomers. It focuses on ancient knowledge and practice of astronomy as revealed by site orientations, building alignments, and visual images. In Mesoamerica, it has elucidated the understanding and observation of celestial phenomena in pre-Conquest times, frequently working in close conjunction with epigraphy and archaeology.

Traditional Mesoamerican cosmologies are by no means dead systems confined to the past. Indigenous conceptions of space, time, and creation persist among some of the present-day descendents of the pre-Columbian peoples, notably Maya groups in rural Guatemala and Chiapas, and the Mixtec of Oaxaca. Historic and contemporary ethnographic data have been used to clarify prehispanic beliefs, although again caution is needed when extrapolating meanings from the present to the past across centuries marked by the disruption of colonization and the influence of Christianity (Note 5).

Note 3: Did the Ancient Mesoamericans Believe in Gods?

The sixteenth century missionary friars who recorded accounts of Mesoamerican religions for the ultimate aim of destroying them, imposed preconceived frameworks derived from the classical Mediterranean and Judeo-Christian traditions onto the alien belief systems they sought to understand. Faced with images and stories of a myriad of supernatural forces, the colonial writers classified these mythic entities along the lines of the Greco-Roman pantheon of deities, each a discrete being with clearly distinguished personality, function, and symbols. The limits of this approach led to strange contradictions from the start. For example, the mercurial Aztec deity Tezcatlipoca, associated with both kingship and sorcery, was equated by the Spanish chroniclers with both Jupiter and Lucifer. However, the Eurocentric assumptions behind such taxonomies remained unquestioned until well into the twentieth century (Fig. 12).

In the 1970s, a number of scholars began to argue from closer reading of colonial sources as well as the results of archaeological, ethnographic and art historical research, that the Aztec, Maya, and Zapotec peoples had no conception of separate and distinct gods. Rather, what the Spaniards erroneously interpreted as a well-defined pantheon was in fact a series of overlapping symbolic complexes, representing natural phenomena conceived as protean and fluxing manifestations of a generalized notion of holiness or sacred force. The words employed for this dynamic concept – *teotl* in Nahuatl, *ku* in Maya, and *pee* in Zapotec – had been translated as "gods" by the Spanish.

Some modern writers – most notably the American anthropologist Joyce Marcus – have argued the extreme conclusion that ancient Mesoamericans had no gods at all, just symbols of natural phenomena and venerated ancestors. This interpretation in its strictest sense certainly applies to some alleged "deities." The Maya icon designated "God C" by the nineteenth century scholar Schellhas in his attempt to classify the supernatural images in Maya codices is now generally accepted by epigraphers and art historians to denote a general quality of holiness rather than a specific divine personality. On the other hand, it seems clear from recent hieroglyphic decipherments that the Classic Maya did believe in a series of relatively separate gods whose

Cosmology in Mesoamerica. Fig. 12 Tezcatlipoca, reconstruction of MS painting from the *Codex Borgia*, p 17, Mixteca-Puebla Style, Puebla/Tlaxcala region, Late Postclassic. acts are recorded in texts and whose distinctive emblems appear in art. While more fluid and dynamic in their identities than the denizens of Olympus, these entities can be usefully conceptualized as gods, a view argued by the American anthropologist and iconographer Karl Taube, among others.

Note 4: Mesoamerican Screenfold Books

At the same time as they were creating one source of evidence for prehispanic Mesoamerican cosmologies via their writings, the Catholic missionaries of the Spanish Conquest were busy destroying another – the screenfold books of the indigenous peoples. These fragile testimonies to Native American thought were burnt as symbols of the "heathenism" or "diabolism" that the friars sought to replace with forced conversion to Christianity. As a result of this holocaust of texts, very few of these manuscripts have survived to receive the attention of modern anthropological, epigraphic, and art historical study.

Mesoamerican folded manuscripts, often referred to in the literature by the Eurocentric term "codices," consisted of long sheets of beaten bark paper or (in the Mixtec area) deer skin. Narrative scenes, deity images, and glyphs were painted, usually in polychrome, on a thin outer surface of plaster. The paper was folded like an accordion, dividing it into "pages" or "folios." The resultant manuscript was "opened" by unfolding it.

No prehispanic Aztec painted books survived the depredations of the colonial clergy. A manuscript illustrating Aztec deities and calendrical practices, the Codex Borbonicus, was once thought to represent such a miraculous survival, but art historical data now suggest a date early in the colonial period. From this transitional epoch, we have several manuscripts, in both screenfold and European bound formats, commissioned and annotated by Spanish officials and missionaries but painted by Aztec artists. Frequently, the style is a fusion of pre-Conquest traditions with varying admixtures of the visual language of European Renaissance art. Some of these books preserve Aztec myths and calendric information, albeit incompletely.

A group of screenfold manuscripts of late prehispanic (Late Postclassic) date have been labeled the Borgia Group because of their stylistic affinities with the best-known example, the Codex Borgia. These manuscripts appear to have been collected at the time of the Conquest and to have found their ways by often untraceable routes into famous European collections, hence their names. In the opinion of the majority of art historians and anthropologists, this group was painted in the present-day Mexican states of Puebla and Tlaxcala, though a small scholarly contingent still suggests a Mixtec origin. They are frequently labeled as "Aztec" in the popular literature. If the dominant theory is correct, the artists who created these works spoke the same language as the Aztecs (Nahuatl) but were politically and ethnically distinct. The Tlaxcalans, in particular, were the traditional enemies of the Aztecs and assisted Cortes in his destruction of Aztec power. The manuscripts of the Borgia Group seem to have been guides for a divination system based on the 260-day ritual calendar, also containing prescriptive representations of other rituals, astronomical information, and narrative scenes of mythic events in a distinct style characterized by bright, flat colors, bold outlines, and cartoon-like exaggerations of distinguishing features and costume elements. Their symbolic maps of the universe – like the frontispiece of the *Codex Fejervary-Meyer* reproduced here – constitute excellent graphic evidence for ancient Nahuatl cosmology.

Another group of screenfold manuscripts collected during the Spanish invasion and scattered through European collections was produced by the Mixtec in what is now the Mexican state of Oaxaca. Although the style has similarities to that of the Borgia group, the content consists mostly of historical and genealogical narratives documenting the deeds and land claims of elite families. The most famous of these manuscripts is the *Codex Zouche-Nuttall*, which chronicles in pictorial form the exploits of the eleventh century Mixtec king Eight Deer. All date from the last centuries before the arrival of Europeans. Although their emphasis is not on ritual or calendrics, images of origin myths and deities contribute to our knowledge of Mixtec cosmology.

All of these Central Mexican manuscripts include glyphs of names and dates in the 260-day calendar, rebus writing and symbols for geographic locales, but only the Maya painted books contain phonetic texts. Three examples escaped the friars' fires in the sixteenth century to appear in Europe: the *Dresden Codex*, the *Madrid Codex*, and the *Paris Codex*, named after their present-day locations. These books appear to have been painted shortly before the Conquest in Yucatan. A fourth book appeared in 1973, with claims that it had been discovered by looters in a dry cave in the Mexican state of Tabasco. Although it was rejected in some circles as a fraud at the time, subsequent radiocarbon tests indicate an age in the twelfth to thirteenth century CE, and the Venus tables it contains reflect Maya concepts that were not rediscovered until several years after the book's appearance. Contemporary consensus therefore holds it to be genuine. All of these Maya books contain tables of observations for predicting eclipses and the movements of celestial objects like Venus, almanacs for agriculture, and guides to ritual performance. Like the Borgia Group, they were once the property of indigenous priests.

Note 5: Maya Myths in Historic Manuscripts

In the centuries following the Spanish Conquest, some indigenous myths, including much information on cosmology, were preserved by being recorded in Latin script by Native writers. In Yucatan, several versions survive of the *Book of Chilam Balam*, or Jaguar Priest. These variations of the text are titled after the town that was each one's origin. The most famous example of these was composed in the town of Chumayel. These contain oral historical traditions, astrology, ritual practices, and prophecies tied to the cycles of time in the Maya calendar. Some of this material appears to be of prehispanic origin and is a valuable source for understanding the world view of pre-Columbian Yucatan. However, it is also clear that events from colonial history and the Judeo-Christian tradition also figure in the *Books of Chilam Balam*, suggesting the need for caution in using their contents uncritically as a basis for understanding pre-Christian beliefs.

In the southern highlands of Guatemala, an epic poem of the Quiche Maya, the *Popol Vuh* or "book of the mat" (mats were a symbol of rulership in ancient Mesoamerica), was apparently written down in Latin script by a Spanish-schooled Maya shortly after the Spanish Conquest. No original of this early version has been preserved, but copies were transcribed into the mid-nineteenth century when they came to the attention of European scholars. Like the *Books of Chilam Balam*, the *Popol Vuh* seems to contain a considerable amount of prehispanic material, drawn both from oral tradition and screenfold manuscripts, though here, too, Catholicism and colonialism have made their mark upon the contents. The *Popol Vuh* is a history of the Quiche people incorporating a version of the Maya myth of the previous creations and destructions of the universe. Perhaps the most well-known section is the saga of the Hero Twins, Hunahpu, and Xbalanque, whose adventures intertwine with and set the stage for the last creation of the cosmos and man.

Recent studies in Maya epigraphy and iconography have demonstrated that aspects of the *Popol Vuh* – especially the Hero Twins epic – represent survivals of Maya myths dating back to the Classic period and probably earlier. The Hero Twins' legendary battles with the gods of the underworld recur in Classic Maya vase painting, and contribute to the trappings and ideology of Classic Maya kingship. The art historical and hieroglyphic material has in turn begun to permit the reconstruction of sections of the Classic version of the myth that did not survive to be incorporated in the colonial text. The identification of the father of the Hero Twins with the Maya maize god, his role in the creation of the world, and further details of the twins' defeat of the lords of death have emerged from Classic scenes and texts. The case of the *Popol Vuh* is one instance where post-Conquest materials have been fruitfully used to increase our understanding of pre-Columbian beliefs and symbols.

Note 6: Olmec Cosmology

According to the theories of Joralemon (1996), based on his readings of Olmec iconography, the Olmec lived in a shamanic, multilevel mental universe akin to that of their Maya successors. In his view, the earth was pictured as a crocodilian Earth Dragon floating in a primordial sea. Mountains were its scutes, and vegetation sprouted from its back. Mountains may have been viewed as containing water as in later myths – certainly archaeology shows that the Olmec venerated mountains and springs. The sky was represented by a Bird Monster, and the ocean under the earth by the shark-like Fish Monster. As in Maya belief, this watery underworld was the home of ancestral spirits. According to Joralemon and other scholars like Reilly (1996), carvings of rulers seated in jaguar or serpent mouths are shaman-kings accessing portals to the underworld (Reilly) or the upper world (according to Karl Taube) through trance and ritual. The site of La Venta is now interpreted, along Maya lines, as a cosmogonic center, recreating the creation and structure of the cosmos through its architecture, buried offerings, and associated rituals. A stone mosaic intentionally buried there has been read as an image of a jaguar, associated with the underworld via later Aztec and Maya myths; or as the saurian earth monster on the surface of the sea. Serpentine (greenstone) pavements from the same center have been interpreted as representations of the blue–green watery underworld itself. A massive pyramid, forerunner of later temple platforms throughout Mesoamerica, is equated with the primeval "Snake Mountain" which emerged from watery chaos at the creation of the world in later cosmogonies. Schele (1996) has interpreted Olmec art as reflecting belief in a world tree, the bridge between levels of the cosmos, equated as among the Maya with the person of the ruler. These interpretations, which seek to demonstrate continuity between Olmec and later cosmologies, are widely accepted, but not without critics who call assumptions of such continuity in beliefs over several millennia into question (Fig. 13).

Cosmology in Mesoamerica. Fig. 13 This inscribed greenstone celt from Rio Pesquero, Mexico, depicts an Olmec ruler symbolically equated with the *axis mundi*. His legs form the head of a serpent, and he holds another in his arms. The four-stylized corn plants represent the four directions. The ruler occupies the center, representing the mediating vertical axis of the universe which, like the king himself in his role as shaman, provides humans access to the supernatural worlds above and below the earth. This interpretation is by Linda Schele and F. Kent Reilly and is based in part on later Maya iconography (Middle Formative, ca. 900–400 BCE). Drawing by Linda Schele, copyright David Schele, reproduced courtesy of FAMSI (text by Keith Jordan).

Note 7: The Maya Hero Twins

The myth of the Hero Twins Hunahpu and Xbalanque from the *Popol Vuh* is intertwined with the Maya creation myth. Its action is set during the transition between the end of the third creation and the inception of the fourth. Recent discoveries from epigraphy and art history reveal that the Classic version of this myth was even more explicitly tied to the story of the making of the fourth world.

The saga begins with a first set of brothers, Hun Hunahpu and Seven Hunahpu. During the Classic period, Hun Hunahpu was identified as the Maize God, and his death and rebirth in the narrative were associated with the cyclical growth of corn. This first pair were avid players of the traditional Mesoamerican rubber ball game, known in the archaeological record from Olmec times, played by the Aztec and Maya at the time of European contact, and still practiced today in parts of rural Western Mexico. Unfortunately, the noise created by the brothers' favorite pastime irritated the ruling gods of Xibalba, who summoned them to the underworld and challenged them to a ball game where the stakes were life or death. Because of the supernatural powers and trickery of the lords of Xibalba, Hun Hunahpu and his brother were rapidly defeated and executed. Their bodies were buried but Hun Hunahpu's head was hung up on a tree for display. As befitting a maize god, its presence made the formerly barren tree sprout an abundance of fruit, identified with the calabash in the *Popol Vuh*, but apparently with cacao (chocolate) in some Classic Maya vase paintings.

One of the daughters of a lord of the underworld, Blood Moon, visited the tree out of curiosity at its sudden fertility. The skull of Hun Hunahpu hanging there spit into her palm, magically impregnating her. When her father learned of her pregnancy, he attempted to have her murdered, but she fled Xibalba to the middle world where she gave birth to Hunahpu and Xbalanque.

As youths, these twin boys distinguished themselves by a number of exploits. They defeated the bird monster Seven Macaw, who falsely proclaimed himself to be the sun. This usurper seems to have been equated in the Classic period with Mut-Itzamna, the Celestial Bird shown perched atop the world tree. The vanquishing of this false sun seems to coincide with the destruction of the last creation. The twins also conquered Seven Macaw's son, the crocodilian Zipacna.

Eventually Hunahpu and Xbalanque discovered the ball game equipment of their father and took up the sport with great energy. Their noise eventually also reached the Lords of Xibalba, who summoned them to a challenge like that which their father and uncle had failed to master. Unlike the first brothers, the Hero Twins rose to the occasion, outwitting the ordeals and tricks of the gods of the underworld with clever strategies and magical powers of their own. In the last and most spectacular of these supernatural feats, the Hero Twins followed the advice of a diviner and submitted to execution. Their bodies were burned and their ashes cast into the waters of Xibalba. The rulers of the underworld believed they had defeated these troublemakers as decidedly as they had beaten their father.

But Hunahpu and Xbalanque were reborn, appearing first as catfish and then disguised as itinerant magicians. They performed a magic trick in which they killed each other and then magically restored the other to life. Hearing of this spectacle, the lords of Xibalba were intrigued and summon the performers to demonstrate this wonder. Having seen this miraculous resurrection, the underworld gods are so enthusiastic that they demand to be used as volunteers for the trick. Predictably, the twins kill the lords of death as requested, but do not bring them back to life.

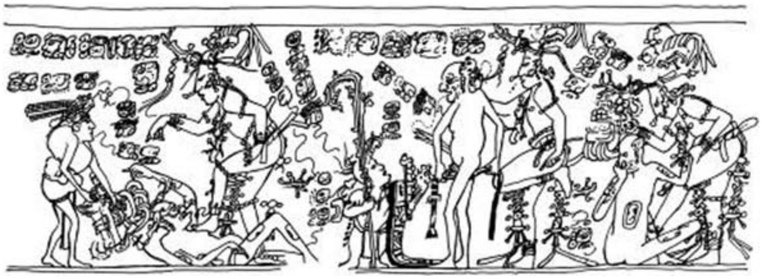
In the *Popol Vuh*, the twins attempt to raise their father and uncle from death, but are only partially successful, and cannot bring them back to the land of the living. The iconographic and inscriptional evidence from the Classic period provides an alternative ending. After defeating the lords of death, apparently with the connivance of the moon goddess and her rabbit, they succeed in resurrecting the Maize God, who is shown in several painted scenes as emerging from the body of a turtle representing the earth. The Maize God then acts as the demiurge of the most recent creation, separating earth from sky, raising the world tree, setting up three hearthstones (the traditional number in Maya houses) at the center of the universe, and erecting the vault of the heavens. In the Classic scenes and texts, the chief of the underworld gods is God L, an elderly deity associated with wealth and the profession of merchant. He appears not to have been sacrificed but humiliated and forced to pay tribute to the gods of the sky (Figs. 14 and 15).

Cosmology in Mesoamerica. Fig. 14 Resurrection of the Maize God. This scene from a Classic Maya (600–900 CE) painted ceramic vessel shows the resurrection of the Maize God, pictured emerging from a cleft in the carapace of a turtle representing the earth. He is attended by his sons, the Hero Twins. The skull at the base of the cleft represents the head of the Maize God, decapitated following his defeat by the rulers of Xibalba. As corn sprouts from seeds, so human bones were viewed by the Maya as the seeds of eventual rebirth in the afterlife, following the pattern set by the Maize God's story. Drawing by Linda Schele, copyright David Schele, reproduced courtesy of FAMSI (text by Keith Jordan).

The Hero Twins have been equated with the sun and moon, and the first brothers with Venus in its twin guises as Morning Star and Evening Star. In both versions of the myth, the victory of the Hero Twins limits the power of death in the world and points the way toward the hope of rebirth. Like the first brothers, the Maya elite were believed to descend to the underworld after death, but they hoped to be reborn as were both the Hero Twins and the Maize God, and to ascend triumphantly to the celestial world like the latter following his resurrection. Like the Christian myth in Europe, the story of the Hero Twins was the template for tomb art and funeral practices among the kings of the Maya, a model for their anticipated conquest of death.

Note 8: A Nahua Cosmogram

The Codex Fejevary-Mayer is a painted manuscript belonging to the Borgia Group, manufactured probably



Cosmology in Mesoamerica. Fig. 15 This scene, painted in black line on a white background on a ceramic vessel of the Late Classic period, illustrates a section of the Classic version of the myth of the Hero Twins not found in the later *Popol Vuh*. Following his resurrection by the Twins, their father, the Maize God, is depicted triumphant over God L, chief of the Lords of the underworld. On the left, the Maize God is trampling his former persecutor, while in the scenes at center and right, the Lord of Death is stripped of his regalia by the victorious Maize God. The dwarf accompanying the Maize God represents the undeveloped or stunted ears of corn frequently found attached to complete examples. Drawing by Linda Schele, copyright David Schele, reproduced courtesy of FAMSI (text by Keith Jordan).

in the Mexican states of Puebla and Tlaxcala in the century preceding the Spanish Conquest of 1521. The first image in this amazing pictorial document is a symbolic map of the cosmos organized around the four cardinal directions, complete with their associated divinities. This diagram, frequently reproduced in surveys of Mesoamerican art and religion, is a remarkable window onto the world view of the Nahuatl-speaking peoples of Central Mexico in the Late Postclassic period.

At the center of the diagram is the black world axis connecting the vertical layers of universe, represented by the fire god Xiuhtecuhtli. This deity spanned the three realms, and was thus equated with the *axis mundi*, as was his implement, the fire-drill. Streams of blood flow toward him from the four cardinal directions, representing the human sacrifices to sustain the gods. Each direction has its own associated tree, the pillars of the sky. As in most Mesoamerican maps and cosmograms, East is on top, with its patron deities Itzli (a personified sacrificial knife) and Tonatiuh, the sun god, its colors appropriately red and yellow. To the left is the North, ruled by Tepeyollotl, an aspect of the royal god Tezcatlipoca, and Tlaloc, the rain deity. North for the Nahuatl-speaking peoples was the direction where the difficult journey of souls to the afterlife began. Fittingly, its color is black. At the bottom is West, where the earth monster Tlaltecuhtli swallows the sun at sunset. The patron gods shown here are Chalchiutlicue, goddess of ground water, and Tlazelteotl, "eater of filth," a goddess of sin and confession. Its color is white. To the right is South, associated with blue and green. Here a cocoa tree accompanies the ruling deities of this direction, Mictlantecuhtli, the skeletal god of death and the underworld, and Centeotl, the goddess of mature corn. Between the arms of this cosmic cross are the four intercardinal directions: summer solstice sunrise, upper left; winter solstice sunrise, upper right; summer solstice sunset, lower left; and winter solstice sunset, lower right. The eight-lobed band around the world trees represents the 260-day ritual calendar. Like the other books of the Borgia Group, Fejevary-Meyer contains information for divining the future of individuals based on their birth date in the 260-day cycle. It probably belonged to a priest or oracle.

Cotton Weaving in Ethiopia and Nubia

Michael Gervers

Archaeological material finds provide invaluable information about the nature and source of textiles and textile fibres in Nubia in the early Christian era. In the half century since Griffith and Crowfoot first identified cotton among the textile fragments excavated at Karanog and Meroe, much more cotton fabric has been retrieved from the rescue excavations of early habitation sites along the Nile subsequently inundated by Lake Nasser; i.e., between Aswan in Upper Egypt and Wadi Halfa in northern Sudan. The oldest fragments identified as cotton have been dated to the Roman period and may be as early as the first century AD. The great majority are attributable to the late Meroitic period, ca. 200–ca. 330 AD, at which time cotton appears to have been the most commonly available fabric. The following period, from ca. 330 to ca. 550 AD, sees a swift and remarkable change in the predominant textile fibre in the region. The use of cotton plummets and is replaced by animal fibre, largely camel's wool.

The quantity of cotton found in excavations of the Roman and late Meroitic periods has led many to conclude that the fibre reached Lower Nubia from the south, where it is thought to have been grown, since this area lies in the rain belt and could have provided the environment necessary for growth. However, no specific sites for cotton cultivation in Nubia and the Sudan at this period have been identified and in view of the chronology of the archaeological evidence, and of what is known of the political and economic situation and agricultural production of the period, there is good reason to suppose that vegetable fibres for textiles were not then grown in Nubia or even in the Sudan. Rather, the Nubians, lacking any such indigenous source of raw material, were obliged to import whatever they required either as cloth or raw fibre. These goods included linen, which, throughout much of the Middle Ages under the provisions of the *baqt* agreement, was one of the principal items received by the Nubians in exchange for slaves. The *baqt* was first formulated in the seventh century, by which time, in the absence of adequate supplies of cotton, the Nubians seem to have sought imported linen as an alternative. The cotton would have been *gossypium arboreum*, and its ultimate source would have been the west coast of India. How it reached Nubia is uncertain. It could have come via the eastern desert trade routes from such ports as Suakin on the Red Sea, or via the kingdom of Axum, which by 300 AD. enjoyed a thriving trade with India. The costs and difficulties of overland transport, however, make it more likely that cotton reached Nubia through the Roman world to the north via the Nile. Since the archaeological cotton remains from Nubia were not made from locally grown fibres, there can be little question of cotton reaching Ethiopia from the Sudan. One early reference which is universally accepted speaks of the direct importation to the Red Sea Axumite port of Adulis of cotton from India in the first century AD. The first indication we have of the production of fine cotton cloth in Abyssinia occurs at the end of the thirteenth century in the commentary of Polo: "Good cotton and buckram cloths are woven here". If his source for the supply is accurate, one can reasonably conclude that by that time cotton cultivation and weaving was well established in the highlands.

Textiles, especially imported, have always been an expensive commodity. Their distribution through the ranks of a society depends directly on the geographical diffusion of the raw material, the quantities produced and the availability of mechanisms to spin and weave it into cloth. An Egyptian source for cotton grown in India would explain why a blue and white cotton tapestry decorated with Egyptian symbols was among the Meroitic finds from Qasr Ibrim. It would also explain why the cotton, if imported raw from India and locally spun, would appear different in texture from contemporaneous cotton cloth of Indian origin discovered at Palmyra. Cotton cloth woven in the humid atmosphere of India could be much finer than that produced in the arid climate of Egypt or Upper Nubia. The latter, if woven on the warp-weighted loom, as is supposed, would have to be much thicker and coarser to prevent it from breaking under the stress of the weights. Consequently, it would have appeared softer than the material from Palmyra and more like wool. When cotton became less available from the fourth century and was replaced by wool, the warp-weighted loom would have been all the more appropriate for weaving it. Weaving in Ethiopia today is carried out almost entirely on a pit-treadle loom, whose treadles are suspended in a hole in the ground. The weaver sits at the edge of the pit with his legs inside so that his feet can operate the treadles. The origin of this loom in Ethiopia is uncertain, although numerous writers have noted how closely it parallels the Hindu loom, and some suggest that the technology is the result of direct importation from the Indian subcontinent. Endrei believes this loom originated in India for the purpose of cotton weaving. The specific characteristics of the Abyssinian loom, according to Boser, are its sturdy frame, the width of the comb and consequently of the cloth produced, and the depth of the pit. Boser goes on to say that regardless of how this loom got to Abyssinia, it did not spread thence to other parts of Africa. It did not spread, until recent times at least, even to southern and western Ethiopia. A close relative is the warp-weighted pit loom which is found frequently in Persia, Syria and Egypt where it was, and is, used particularly for weaving woollen, and in Egypt at any rate for weaving linen thread. It does not seem to be appropriate for weaving with a cotton warp as the strain placed by the weights on the thread would cause it to break. This restriction would explain the absence of the warp-weighted loom in Ethiopia, where cotton is by far the principal fibre used for weaving today. The technical association of the Ethiopian loom with cotton would also argue in favour of a common development, if not introduction, of cotton growing and weaving to the Abyssinian highlands.

Crops in Pre-Columbian America

MURDO J. MACLEOD

Before the European invasion of the Americas, the native peoples harvested a large variety of crops under many types of agricultural and gathering regimes.

Dense concentrations of people had existed for centuries in Mesoamerica and Andean America, and had evolved complex societies of agricultural peasantry and stratified urban elites. These peoples, in fact most Native Americans, had selected and adopted a miracle grass, maize (*Zea mays*), which reached yields of over one hundred to one in regions of good soils, intensive irrigation, and monoculture such as the *chinampas* or "floating gardens" of the central valley of Mexico. These high yields led to maize dominance in many diets, and the societies which evolved around this cereal may have resembled those of paddy rice China, which had highly intensified, quasigardening systems, rather than those of Europe or Africa, which had lower yielding but more diversified systems associated with wheat, barley, millet, and sorghum.

Maize was often associated, especially in Mesoamerica, with various varieties of American beans, especially *frijoles* of the genus *Phaseolus*, which climbed the maize stalks; with squashes (*Cucurbitae*) and their relatives; and with chili peppers (*Capsicum*), often planted between the maize stalks. The insufficiencies of this basic diet led to heavy foraging and to the harvesting of unoccupied areas and forests. In fact, even in settled societies there appears to have been a harvesting continuum from irrigated maize gardens to collecting, often in forests which were themselves results of centuries of human selection and propagation. Thus, the modern student finds, paradoxically, intensive monoculture, plus slash and burn, plus areas of great biodiversity, all used by the same population.

Tubers of many kinds were widely cultivated but were somewhat more geographically restricted than the maize, beans, squash, and chili complex. Yams (genus *Dioscorea*), cassavas, or maniocs (*Euphorbiacae*), some of highland origin, were intensely planted, and eaten after conversion to flours and breads, in tropical zones such as the Caribbean and the Amazon Basin. In many such regions, cassava was the staple diet. Musae (bananas and plantains) also appear to have been or become a staple in parts of the tropical lowlands, but scholars dispute their origin, some claiming that they are not native to the Americas.

In the Andes, tubers were also of great importance. Varieties of potatoes (*Solanum*) have been cultivated there for about 8,000 years, selected by humans for the many microenvironments of the mountain tropics. Andean farmers sometimes plant as many as 200 varieties in a single field, although most are being phased out in favor of the modern selected potatoes. Several other tubers were cultivated in highland America, such as *achira* (*Canna edulis*); *arracacha* (*Arracacia xanthorrhiza*); *jicama* (*Pachyrhizus erosus*); *machua* (*Tropaeolum tuberosum*); *ova* (*Oxalis tuberosa*); and *ulloco* (*Ullucus tuberosus*), still a staple in parts of the Andes. This area also produced tubers and grains which could be grown at great altitudes in poor climatic and soil conditions. Maca (*Lepidium meyenii*), a tuber, can be grown just below the snowline, as can *kaniwa* (*Chenopodium pallidicanle*), and the better known quinoa (*Chenopodium quinoa*), both cereal grains rich in proteins and other nutrients.

Several other crops in America were traded widely before the European arrival. Cacao (*Theobroma cacao*), probably of Amazon origin, was known in the regions today called coastal Ecuador and Venezuela, but it was in Mesoamerica that cacao reached its greatest prominence. Planted along the Pacific coast from Colima to El Salvador, and in parts of Honduras, Tabasco, and Veracruz, cacao was important in trade, tribute, and ritual. In some parts of the region it was used as coinage, and there are also reports that in some states its consumption was limited to the aristocracy. Tobacco (*Nicotiana tabacum*) was somewhat different. Although traded in many regions of America, its use may have been limited to ceremonial occasions.

Mesoamerica also produced vegetable and insect dyes, especially blues from indigo (*Indigofera tinctoria*) and reds from cochineal (*Opuntia cochinellifera*). Both items were traded, paid over as tribute, and used for ceremonial purposes. American cotton and thread from cactus were parts of textile trades and tribute.

European invasion and its consequences had widespread effects on American crops and their diffusion. The catastrophic fall of the native population and the introduction of large- and medium-sized domesticated animals, such as horses, cattle, sheep, goats, and pigs, caused abandonment of fields, destruction of crops, and the disappearance of many forms of ground cover. European need for wood for construction, shipbuilding, and fuel led to the cutting down of forests and the crops harvested in them. Colonial demands for uniformity in taxation caused peasants to give up the growing of marginal cultigens, or ones unfamiliar, distasteful, or useless to the dominant culture. The introduction of animals, and of plants such as wheat, citrus trees, and sugarcane, all cultural preferences of Europe, took up agricultural lands, and drove out native species.

Many scholars have stressed the more positive side of these intrusions and exchanges. Introduced crops such as wheat and animals such as cattle transformed the American diet, and the vast quantities of wheat grown on the prairies of the United States and Canada, and on the Pampas of Argentina, have fed large numbers of people in many parts of the world.

The more positive view also emphasizes the diffusion of American plants throughout the world, while admitting that the impact of some of these exports has been noxious (tobacco) or ambivalent. The potato, for example, the introduction of which to northwestern Europe met some resistance at first, was blamed by some for the Irish famine. Its high yields and ease of cultivation led to a monoculture, rapid population growth, then famine and mass emigration – ironically to the Americas – when the potato crop failed. The advantages brought, nevertheless, by this productive, nutritious, human selection to the everyday diet of peoples living in the temperate zones are, of course, immense.

Some American crops, while having a generally beneficial impact when exported, had their "booms" modified or cut short by new technologies or crops. The two great American dyes, indigo and cochineal, after enjoying a century or two of flourishing trade, were destroyed by the invention of aniline dyes in the mid-nineteenth century. Sugarcane, not originally an American plant, nevertheless achieved great importance only when exported to the Americas. Plantation sugar, always prized by Europe but historically in short supply because of poor access to tropical areas and labor, boomed when northeast Brazil and the colonial islands of the Caribbean combined tropical climates, African slavery, intensified production, and reasonably close markets, and began to export huge shipments. Sugarcane transformed much of the world's diet, and was an important fuel for the industrial and commercial revolutions of the nineteenth century. Although it continued to be of importance its monopoly was destroyed by the rise of beet sugar.

There can be little doubt, however, about the continuing beneficial impact of the diffusion beyond the Americas of many of the native crops. Maize, with rice one of the world's two "miracle" cereals as far as yields are concerned, has spread, now largely as a hybrid, throughout the world, and its productivity has increased since the "Green Revolution." It has become a staple in parts of the Mediterranean, the Balkans, Africa, and South Asia, and continues to be the largest food item for the masses in many parts of Latin America.

Some American crops required modification or additions before their use expanded. Cacao did not suit European tastes when first encountered; indeed it was repugnant to many, until people learned to add sugar and vanilla. After Swiss and Dutch houses learned the process of making milk chocolate, cacao became an item of world diet, and West Africa is the main producer today.

Indeed, so pervasive today are some of the high-yielding American crops that their pre-Columbian American origins have been forgotten by the general public. Indian curry and Hungarian paprika, both based on American chili peppers, Italian tomato sauce, Irish potatoes, West Africa *ogi* and *kenkey* (maize doughs), and Swahili *posho* (maize meal), Turkish tobacco, and Swiss chocolate, are now thought of as age-old, integrated parts of regional and national cultures far from the Americas.

Cuneiform

Carol F. Justus

Cuneiform was the script used throughout the Ancient Near East from the fourth to the first millennium BCE. Although a hieroglyphic script came to predominate very early in Egypt, the international second millennium correspondence of the Egyptian Sun King, Iknaton, used the cuneiform script. In the last millennium BCE Mesopotamian art depicts a set of scribes, one writing with a stylus on clay tablets, another on parchment. This later overlap between the use of parchment and clay as writing material foreshadowed the demise of cuneiform, the script by means of which literacy as a technological advance spread throughout the ancient world from early Mesopotamian sites such as Uruk in the lower Euphrates River Valley and Susa in what is now Iran.

The Script Form

Cuneiform (from Latin *cuneus* "wedge"; cf. German *Keilschrift* "wedge-script") is so named because of the wedge-shaped signs which make up the characters of the script. A reed stylus created these signs that resemble the head of a nail. Pressing one corner of the stylus into the damp clay of the tablet made a *Winkelhaken* or corner wedge (𒌋). This corner wedge could be elaborated by adding a vertical (𒁹) or horizontal tail (𒀸), or by tilting the tail at an angle. These basic shapes combine to produce the more than 700 signs of the cuneiform writing system. Cuneiform signs are read left to right, as are western European alphabetic symbols.

Alphabets used to write modern Western languages reduce those languages to writing on the principle of one sound to one written symbol. The principle underlying the cuneiform system was by no means so simple. A single sign might have phonetic or logographic values. A corner wedge alone could, as a syllabic unit, represent the syllable sound of "u" as in "U-gan-da" or, as a logogram, refer to the word for the numeral "ten". Two raised corner wedges combined with a vertical wedge (𒌓) form the phonetic syllable "ud" which also had the logographic meaning "day". While vowel sounds had a one-to-one correspondence with a sign as in "a, i, u": "a" (𒀀), "i" (𒄿), and "u" (𒌋), there were no signs for consonants such as "p", "t", "k", or "m". Cuneiform signs had phonetic values as syllables, so there were signs instead for "pa, ta, ka, ma, pi, ti, ki, mi" and so on. But a sign also had a logographic value as in the case of *ud* "day". This logographic–syllabic principle underlying the cuneiform script, unlike that underlying an alphabet, used signs to refer either to entire words (logograms) or to phonetic (syllabic) units.

The syllable sign "ud" is typical of signs that refer to vowel plus consonant sequences. Cuneiform also had syllabic signs for consonant–vowel sequences, e.g. (𒁲) "di", (𒄀) "gi", or (𒉌) "ni", and, less frequently, for consonant–vowel–consonant sequences: (𒋻) "tar" or (𒆳) "kur" (Table 1).

This system of writing thus easily recorded a language with consonant–vowel sound patterns and consonant clusters in the middle of a word, but not words which begin or end with consonant clusters like "st", or "sk" as in English "stop, skate, nest" or "desk".

Cuneiform. Table 1 Cuneiform signs and their sign list keys (cf. Borger or Labat)

Numerical key	Usual value	Sign shape
411	u	𒌋
480	dish	𒁹
1	ash	𒀸
381	ud	𒌓
579	a	𒀀
142	i	𒄿
457	di	𒁲
85	gi	𒄀
231	ni	𒉌
12	tar	𒋻
366	kur	𒆳
597	NINDA	𒃻
13	an	𒀭
533	mesh	𒈨𒌍, 𒈨

While cuneiform syllabic signs often represented speech sounds, the same sign might also have non-phonetic uses as well. In addition to syllabic (phonetic) uses, signs might function as determinatives as well as logograms. As a determinative, a cuneiform sign preceded (or followed) one or more sets of signs without any phonetic value. The non-phonetic determinative merely signaled to the reader that a word in question was of a particular semantic type. Typically, the determinative for "female" preceded a woman's name, the determinative for "male" a man's, or the determinative for "deity" the name of a god or goddess. Used as a logogram, as noted, a cuneiform sign stood for an entire word. Thus, either the single sign (𒃻) or the syllabic sequence *ni-in-da* might stand for Sumerian "bread". Likewise, "deity" might be written logographically in a Sumerian text using the "an" sign (nr. 13) or syllabically with the sequence *di-in-gi-ir*. Such dual mechanisms illustrate not only the relation between logographic and phonetic representation of words but also something of the syllabic structure of the Sumerian language which had word-medial (*-nd-* and *-ng-* in *ninda* and *dingir*) but not word-initial or word-final consonant clusters.

Scribes often used signs logographically for the lexical content of common words and syllabically for grammatical markings such as the possessive of a noun. Thus, "of god" in Sumerian might be written phonetically as *di-in-gi-ir-ra* (*dingir* plus the possessive suffix *a*) or logographically with the "god" sign plus the syllabic sign, *-ra*. Transliteration conventions using the Roman alphabet distinguish among determinative, logographic, or syllabic uses of cuneiform signs on a tablet by using lower case, upper case, and raised letters. Signs used phonetically are transliterated with lower case letters; signs used logographically but interpretable on the basis of a Sumerian word are transliterated using capital letters for the Sumerian word form. The Sumerian scribe's writing of the logogram for "god" plus syllabic *-ra* would thus be transliterated DINGIR-*ra* to distinguish it from a scribe's entirely syllabic rendition, *di-in-gi-ir-ra*.

Determinatives are transliterated as raised sequences, either before or after the "determined" word. Characteristically the plural determinative follows, while others often precede. Thus, "gods", written with the logogram for "god" (𒀭) plus a plural determinative whose Sumerian phonetic value was "mesh" (𒈨𒌍), might be transliterated in Roman letters DINGIR$^{\text{MESH}}$ and translated "gods". Similarly, the Sumerian sun god, Utu, would begin with the determinative for "deity" (𒀭) and continue with the name, Utu, written syllabically $^{\text{DINGIR}}$U-tu. However, the sun god's name was usually written logographically using the logogram for "day", $^{\text{DINGIR}}$UD (𒀭.𒌓), transliterated $^{\text{DINGIR}}$UTU (Sungod). To bring the use of cuneiform signs full circle, one might recall that the "god" sign (𒀭), besides its logographic reference to the Sumerian word, *dingir* "god", also had a syllabic reading, *an*. For a scribe, the same sign thus had multiple values. The sign (𒀭) had a phonetic (syllabic) value *an*, a logographic value "god" (Sumerian DINGIR), and a non-phonetic use as the determinative for "deity" to which modern scholars assign the phonetic value, *dingir*, for purposes of transcription.

Like determinatives, which had no phonetic counterpart in the speech represented by cuneiform signs, horizontal lines were often drawn across the tablet as a kind of punctuation aid. Because the structure of the languages written in the cuneiform script was very different from English, punctuation principles might also be expected to vary. In fact the scribes' horizontal lines across the tablet probably marked something corresponding in part to our sentences and partly to our paragraphs. These scribal lines occur from earliest Sumerian tablets down through adaptations of cuneiform to write Semitic and Indo-European languages.

Languages Written in Cuneiform

Questions about the range of sounds that written symbols might need to distinguish, and indeed which units of language should be represented by individual signs, have concerned linguists seeking to reduce languages to writing. Western European languages often solved these problems by borrowing the Roman alphabet. Cultures of the Ancient Near East borrowed the cuneiform script, as the alphabet did not yet exist in the third millennium BCE. Cuneiform scribes thus dealt with issues of defining the linguistic units to be represented by altering a system of cuneiform signs already in use to write Sumerian. Scribes in fact used the cuneiform script to write languages that differed from Sumerian. They then had to adapt the script to fit the needs of the languages they spoke. The words of some of the languages had long series of suffixes, for example, while others used word-internal vowel changes much as English does in "sing, sang, sung" or "stand, stood", and Indo-European languages had word-initial and word-final consonant clusters.

A major adaptation of cuneiform was for the East Semitic Akkadian that served as the basis for the spread of cuneiform throughout much of the Near East. Besides Old Akkadian, which had its own conventions for phonetic representations using the cuneiform script, major East Semitic languages include the Old Babylonian in which the southern Mesopotamian Code of Hammurapi was written and Old Assyrian, which records the northern merchant trade between Assur and Anatolian Kanesh (near modern Kayseri, Turkey) even before the time of Hammurapi. Babylonian and Assyrian continue in ever-changing regional forms for nearly 2000 years as Middle Babylonian, Middle Assyrian, Neo-Babylonian, and Neo-Assyrian. To the east of Mesopotamia the ancient language of Susa, Elamite, also used cuneiform, while Hurrians in Northern Mesopotamia, Syria, and Anatolia adapted cuneiform at different times to write their language. In second millennium Anatolia, the scribes of Hattusa used cuneiform to write Hittite, Luwian, and Palaic, Indo-European languages related to Greek, Latin, and the Germanic language family from which English is descended.

When scribes adapted cuneiform for use in writing other languages, some things changed more than others. While the signs often came to have peculiarly local values in different scribal schools, the most constant aspect of the cuneiform script was its core repertoire of determinatives and logograms. Where cuneiform was used, determinatives such as those for male, female, deity, land, and plural remained the same. Logograms for basic vocabulary, for god, ox, sheep, child, king, mountain, and river, also remained constant. The Akkadian scribe, for example, now had all the options available that the Sumerian scribe had, plus those that involved the phonetic representation of Akkadian. Akkadian nouns had three different forms depending on whether they were used as subject or object in the sentence, or as a possessive. The Akkadian word for "god" was thus *ilum* (nominative), *ilam* (accusative), or *ilim* (genitive), written as phonetic *i-lu-um, i-la-am, i-li-im* or logographic DINGIR-*lum*, DINGIR-*lam*, DINGIR-*lim* where syllabic signs differentiate case, or simply DINGIR, if the context was clear without the case ending.

When cuneiform spread via an Akkadian-based scribal school, scribal practices also spread. Thus, sign sequences were now often interpretable, not only on the basis of recognizing Sumerian, but also Akkadian, words. This created a further complication for scholars transliterating the tablets into a Roman alphabet. Instead of signs interpretable as Sumerian logograms (Sumerograms in capital letters), there are now signs interpretable as Akkadian logograms (Akkadograms) which scholars transliterate using italic capitals. Since the Hittites borrowed the script as a form of Akkadian cuneiform, Hittite scribes had still more options for writing "of god". While the Sumerian scribes wrote "of god" as phonetic *di-in-gi-ir-ra* or logographic DINGIR-*ra* and the Akkadian scribe used phonetic *i-li-im*, logographic DINGIR-*lim* or DINGIR-RA-*lim*, the Hittite scribe could write phonetic *si-u-ni-ya-as* (Hittite "god": nominative *sius*, genitive *siunias*), Sumerographic DINGIR-(RA), Akkadographic *I-LIM*, or some combination, DINGIR-(RA-)*LIM* or DINGIR-(RA-)*LIM-as*.

The Origin of the Cuneiform Script

The earliest attested use of cuneiform as a developed system of symbols to write a language was its use to write Sumerian ca. 3100. Modern Japanese, which has borrowed Chinese (logographic) kanji characters as a basis for reducing Japanese to writing, likewise uses syllabic symbols to augment logographic symbols. Because the Japanese syllabic symbols (*hiragana*) are an independent Japanese invention to adapt the Chinese script to a language structure for which the kanji characters were inadequate, scholars have hypothesized that Sumerian, with its logographic–syllabic script, represented an adaptation of an earlier "Proto-Tigridian" script of which we have no record, one used for a pre-Sumerian language of the Tigris river valley. Studies in the origin of writing, however, suggest that writing emerged as a new technology in what became the Sumerian city of Uruk.

The forerunners of the earliest cuneiform tablets were "impressed" tablets, tablets impressed first, not by the stylus which came to be used to write cuneiform, but by small clay artifacts known as tokens. The token-impressed tablets were economic documents recording amounts of various commodities that the society stored or transferred. Discrete symbols for commodities such as sheep, barley, or jugs of wine and oil were impressed on to the tablet. At first repetitions of the sheep symbol, for example, referred to the quantity of sheep in question and repetitions of the "oil jug" impression designated the quantity of oil. As the technology for writing and enumeration matured, forms became stylized to reflect changes in the thinking about the content. Concepts of quantity evolved separately from those for commodity, and both became increasingly abstract. What began as impressions of commodity signs and repetitions of the same sign to indicate quantities evolved as two sign types, "numerical signs" and pictographic signs, that developed independent logographic and syllabic values. "Numerical signs" were so-called before it was clear that their earliest forms did not stand for the abstract numeral values of today but only came to have numerical values as the "systems of numeration" evolved. Originally the 60 shapes of the "numerical signs" stood for values in a measure unit system that was specialized for a particular commodity or class of commodity. Sign values varied depending on the commodity quantified much as traditional measure units such as "foot", "inch", "bushel", "cup", and "quart" still do. While there are 12 in. in a foot and four cups to a quart, a "foot" does not have the abstract numerical value 12 nor quart the value four. Quantity values were also relational within the system for measuring commodities; they did not yet refer to abstract numerals.

Over time, the early accounting systems of the Sumerian city states that had used older systems of weights and measures with local values became standardized on the sexagesimal basis of factors six and ten. With further standardization on the base ten of the decimal system, the way was paved for the abstraction of number and the association of abstract numerical values with numeral words and signs. Calculation of amounts of commodities in terms of measure units and "numerical signs" replaced the older one-to-one calculation reflected in the early repetitions of impressed commodity symbols, and both are now mostly replaced by systems of abstract numerals. The specialization of script signs as "numerical signs" separate from commodity signs reflected an early stage in this evolution. In this respect, the evolution of cuneiform writing is inseparable from the evolution of early calculation and counting as the evolution of shapes took place as part of the evolution of the new meanings that motivated that evolution.

Commodity unit shapes developed independently of shapes for "numerical signs" when, instead of impressing the token into the clay, the scribe used a stylus to draw the shape of some tokens but continued to impress other shapes, some composite or with added lines. Drawn and impressed shapes that developed logographic and syllabic values became more and more abstract when the corner of a reed stylus came to create wedge-shaped cuneiform signs (http://www.utexas.edu/cola/centers/lc/numerals/numerals.html).

Over the millennia in which cuneiform was used, the shapes of the signs evolved from more pictographic forms to highly stylized symbols. Later Ugaritic use of wedge-shaped signs as an alphabet broke with the cuneiform tradition in assigning new values to sign forms.

Early Non-Cuneiform Scripts

The existence of other early scripts in the Ancient Near East attests to the rapid spread of literacy and numeracy. While Egyptian hieroglyphs are clearly independent script forms, the basis for reducing the early Egyptian language to writing is probably not independent of the new technology which arose in Mesopotamia as a response to economic and lifestyle changes involving the storage and transfer of surpluses of essential commodities. In the second millennium too a hieroglyphic script, Hieroglyphic Luwian (at first known as Hieroglyphic Hittite) developed independently in Anatolia and North Syria. This Luwian Hieroglyphic and the cuneiform script coexisted in different functions. The local hieroglyphic script recorded royal inscriptions in the Luwian language on stone monuments but cuneiform was the script of clay tablets. The fact that Hittite cuneiform tablets of Anatolia refer to "old wooden tablets" has led to speculation that hieroglyphic may have been inscribed into a wax coating on wooden tablets. Since none of these waxed wooden tablets has survived, such inferences, of course, remain speculative. The forms of the hieroglyphs are unrelated to the forms of cuneiform signs, but again the two scripts share a common conceptual basis for reducing language to writing. Hieroglyphic Luwian, like cuneiform and Egyptian hieroglyphics, is based on logographic–syllabic principles.

Decipherment

The cuneiform script was deciphered in the nineteenth century as a result of a trilingual inscription found at Behistun in Iran. The languages of the inscription were Elamite, Old Babylonian, and Old Persian, all written in a form of cuneiform. Both Elamite and Old Babylonian were unknown languages at the time, but Old Persian was known from Zoroastrian religious texts. The Old Persian inscription was first deciphered on the basis of hypotheses about the recurring symbols in Old Persian royal names. From there, hypotheses related the signs used to write the Old Persian with signs in the unknown scripts. Little by little, Old Babylonian and Elamite began to be deciphered. With the decipherment of the script came the decipherment and study of the different languages and cultures that used cuneiform to record their history and socio-economic structure. A not insignificant aid in the subsequent decipherment of Sumerian turned out to be the discovery of grammatical texts that Akkadian scribes had developed as pedagogical devices for teaching the learned language of the second millennium BCE, Sumerian, thereby training scribes to support the ever-growing bureaucracy of the ancient world.

Ongoing work on early cuneiform texts and their predecessors is now being catalogued as the Cuneiform Digital Library Initiative (CDLI: ►http://cdli.ucla.edu/).

Dams and Irrigation in Ancient Arabia

Michael Harrower

Among the many scientific and technological accomplishments of ancient Arabia, dams and irrigation systems stand out as a remarkable testament to advanced skills in hydrological engineering. Arabia's ancient inhabitants developed sophisticated means of capturing and diverting water that not only involved detailed knowledge of water flows, but also required coordination of considerable labor for construction, operation, and maintenance. Although sometimes overshadowed by better-known Egyptian, Mesopotamian, and South Asian irrigation systems that supported some of the world's earliest and most influential civilizations, the remains of advanced water control systems have also been found throughout Arabia. Some of the ancient world's largest dams and most advanced flash-floodwater systems were constructed in Southwest Arabia (Yemen) during the late first millennium BCE. Southwest Arabian floodwater (spate) systems irrigated thousands of hectares and supported ancient states that gained wide recognition for trading aromatic tree resins including frankincense and myrrh to as far away as the Mediterranean. The tenth century AD geographer and historian al-Hamdānī was one of the earliest scholars to report on irrigation works of Southwest Arabia. In the eighth book of his treatise *al-Iklīl*, al-Hamdānī describes ancient monuments and briefly mentions a number of large dams, including the famous dam near Maʾrib, Yemen (Faris 1938 [945]: 34–35, 67–69). Ancient Southwest Arabian irrigation systems subsequently captured the attention of early western explorers, including Arnaud (1874) and Glaser (1913), and they remain a topic of considerable scholarly interest today (e.g., Brunner 1997a, b, 2000; Brunner and Haefner 1986; Darles 2000; Francaviglia 2000, 2002; Gentelle 1991; Ghaleb 1990; Hehmeyer 1989; Vogt 2004; Vogt et al. 2002).

The dam near Ma'rib (Yemen), capital of the ancient state of Saba, is one of the largest and most impressive examples of ancient floodwater irrigation (Fig. 1). Small-scale irrigation began in the region as early as the late fourth to early third millennium BCE (e.g., Ghaleb 1990) and by the first few centuries AD a dam 680 m long and 16 m high diverted water (via two massive sluices at it northern and southern extremities) to irrigate as much as 9,600 ha (Brunner 2000; Brunner and Haefner 1986). Interestingly, ancient Southwest Arabian state capitals such as Maʾrib developed not in relatively humid highlands where rainfall agriculture was possible, but along the margins of the Ramlat as-Sab'atayn Desert where irrigation farming required far more labor but could also dramatically boost agricultural production. Ancient Southwest Arabian kingdoms of Ma'īn, Awsān, Qatabān, and Hadramawt were part of an intricate network of trade and political relations and utilized analogous flash-floodwater irrigation technologies (Brunner 1997a, b; Francaviglia 2002; Gentelle 1991; Gentelle and Coque-Delhuille 1998). By the sixth century AD the power and influence of the Saba had dramatically waned. Damaged by powerful floodwaters the inhabitants of Maʾrib were unable to mobilize the labor necessary to repair the dam and agriculture continued at only a fraction of its former grandeur (Vogt 2004).

Many important questions surrounding the origins of irrigation in Arabia (including the degree to which local technologies developed independently or were inspired by developments elsewhere) remain largely unanswered. Unlike systems of Egypt, Mesopotamia, and South Asia that frequently diverted water from perennial flow rivers such as the Nile, Tigris, Euphrates, and Indus, irrigation systems of the Arabian Peninsula involved diversion of flash-floodwaters that typically occur only a few times a year, quickly appearing and disappearing in a matter of hours. Egypt and Mesopotamia are known to have some of the earliest and most extensive systems, and some scholars have thus speculated that diffusion from one or both of these regions was likely responsible for systems in Arabia (e.g., Bowen 1958). But if irrigation systems of Southwest Arabia did indeed diffuse from distant regions, dramatic modifications would have been required before they could operate amidst very different topographic, hydrological, and social circumstances. In Egypt and Mesopotamia, where a tremendous wealth of archaeological research has been conducted, a long history of alluvial deposition and land-use make

Dams and Irrigation in Ancient Arabia. Fig. 1 The massive south sluice of the ancient dam near Maʾrib, Yemen (photo by the author).

identifying the earliest irrigation and the precise techniques first involved a significant challenge (e.g., Wilkinson 2003). Although some of the world's first farmers experimented with water management in the Levant during the Neolithic, possibly as early as the seventh millennium BCE (Bar-Yosef 1986; Betts and Helms 1989; Miller 1980: 331–332) most relied on direct rainfall and/or naturally water-rich areas. By the sixth millennium BCE the prevalence of irrigation had begun to increase substantially. Farming settlements were established in areas of middle and lower Mesopotamia where rainfall was insufficient for cultivation (Maisels 1999: 125, 147–150), canal fragments are dated to before 5000 BCE at Choga Mami (Oates and Oates 1976), and linear arrangements of sites in Mesopotamia and Iran suggest they were located along canals (Adams 1965:119; Sumner 1994: 57). It was not until substantially later during the fourth millennium BCE that large-scale irrigation became a widely predominant means of plant food production. In both Egypt and Mesopotamia centrally coordinated irrigation was well underway by this time (Butzer 1976; Postgate and Powell 1988). While the first appearance of irrigation in Southwest Arabia may have been stimulated by aforementioned developments in the Levant, Mesopotamia, or Egypt, investigations in Yemen have traditionally focused on prominent large-scale systems, rather than their small-scale predecessors from which farmers first accumulated knowledge of water flow patterns and developed organizational means to control them. Recent investigations have made important strides toward identifying Southwest Arabia's earliest systems. Small-scale hillslope runoff systems have now been identified and dated to the late fourth millennium BCE in a number of widely dispersed locales throughout Yemen's rugged highlands (Ghaleb 1990; Harrower 2006; McCorriston and Oches 2001; Wilkinson 1999).

While peoples of ancient Southwest Arabia developed increasingly sophisticated flash-floodwater irrigation, other regions were simultaneously designing water control systems tailored to their own local circumstances. By the first millennium BCE underground infiltration galleries that captured water from upland aquifers (known in Iran as *qanats*) spread to Southeast Arabia (Oman) where they rapidly became a primary means of agricultural production (J. C. Wilkinson 1977, 1983; Lightfoot 2000). The inhabitants of Nabataean cities such as Petra (Jordan) and Meda'in Saleh (Saudi Arabia) constructed extensive hydraulic systems of dams, canals, conduits, pipes, and cisterns to provide water for domestic consumption, gardens, and fields (Akasheh 2002; Ortloff 2005). Increasingly complex perennial flow systems supported long and highly productive agricultural histories in Egypt and Mesopotamia. South Asian cities including Mohenjo-Daro and Harappa operated some of the world's first household water supply systems for drinking, bathing, and to remove domestic sewage (Scarborough 2003: 144–145).

In addition to irrigation's importance as an example of ancient technological expertise, water control has held an enduring place in explanations of ancient sociopolitical change. During the 1950s Wittfogel (1957) and Steward (1949, 1955) became key proponents of the hypothesis that the need for bureaucracies to coordinate large-scale irrigation was a primary factor responsible for the rise of centralized political leadership and the emergence of the world's earliest civilizations. Although scholars now recognize that irrigation was certainly not the only factor responsible for the rise of the world's first state societies, Wittfogel and Steward played an important role in emphasizing the near ubiquity of water control among early civilizations. Their assertions prompted a wealth of research on coordination and management of irrigation (e.g., Downing and Gibson 1974; Hunt and Hunt 1976; Kelly 1983; Millon 1962), and irrigation continues to be a focus of cross-cultural archaeological and anthropological research (Mabry 1996, 2000; Scarborough 2003). In some cases large-scale systems developed by accretion as individual farmers or groups of farmers constructed independently devised systems, while in others large-scale systems were designed, constructed, and operated by irrigation administrators with state sanctioned authority (Mabry 1996, 2000). While the so-called "hydraulic hypothesis" in its most simplistic formulation is clearly flawed and long outdated, water control undoubtedly did play a significant role in shaping the history of many ancient societies including those of Arabia and other arid environments.

Decimal Notation

K. V. Sarma

Decimal notation is a system which imparts to nine figures (digits) an absolute numerical value and also a positional value which latter increases their value ten times by being shifted by one place to the left. Thus, the digits: 1, 2, 3, 4, 5, 6, 7, 8, and 9, coupled with the figure '0' which stands for zero or *śūnya* (nothing, empty), while expressing just their individual values when standing alone, can express also any quantity of any magnitude by their repeated use in the same number, and shifting of places, as needed. The importance of this contrivance is apparent from the words of the great French mathematician Laplace, when he says, "The idea of expressing all quantities by nine figures whereby both an absolute value and one by position is imparted to them is so simple that this very simplicity is the reason for our not being sufficiently aware how much admiration it deserves" (Srinivasaingar 1967). Halstead observes, "The importance of the creation of the zero mark can never be exaggerated. This giving to airy nothing, not merely a local habitation and a name, a picture, a symbol, but helpful power, is the characteristic of the Hindu race from whence it sprang. It is like coining the *Nirvāṇa* into dynamos. No single mathematical creation has been more potent for the general on-go of intelligence and power".

In Indian tradition, the need for enumeration and decimal notation stemmed from the adoration of gods and for ritualistic purposes. From Vedic times, the Hindus used the decimal notation for numeration. The *Ṛgveda* (ca. 2000 BCE) groups gods into three (1.105.5); there are three dawns (8.41.3); there were seven rays of the Sun-god (1.105.9); there were seven sages (4.42.8), and seven seas (8.40.5). There were 180 Marut-gods, or three times 60 (8.96.8); the God śyāvā gave as gifts cows numbering 210 or three times 70 (8.19.37). There were 21 followers of Indra, or three times seven (1.133.6), and the number of horses prayed for was thrice seven times 70 or 3 × 7 × 70 (8.46.26). In Vedic literature, besides the primary numbers, one to nine, expressed by the terms, *eka, dvi, tri, catur, pañca, ṣaṭ, sapta, aṣṭa*, and *nava*, the decuple terms from ten to 90, expressed by *daśa, viṃśati, triṃśat, catvāriṃśat, pañcāśat, ṣaṣṭi, saptati, aśīti* and *navati* are found. These are then sequentially multiplied by ten, taking terms from 100 to 10 to the power of 12, the terms being *śata, sahasra, ayuta, niyuta, prayuta, koṭi, arbuda, nyarbuda, samudra, madhya, anta*, and *parārdha*. In the matter of the arrangement of decuples in compound number–names, the practice generally followed in Vedic literature was to put the term of higher denomination first, except in the case of the two lowest denominations, where the reverse method was followed. See, for example, *sapta śātāni viṃśatiḥ* (seven hundreds and twenty, *Ṛgveda* 1.164.11), *sahasrāṇi śata daśa* (thousands hundred, and ten, *Ṛgveda* 2.1.8) and *ṣasṭ, sahasra navatim nava* (sixty thousands, ninety and nine, 60,099 *Ṛgveda* 1.53.9).

With respect to written symbols for numbers, since no palaeographic records of the Vedic age have been preserved, little can be said. However, a few Vedic passages occur where written numerical symbols are mentioned. In the *Ṛgveda* (10.62.7) certain cows with the mark of '8' (*aṣṭa-karṇī*) are referred to, and *Yajurveda-Kāṭhaka Saṃhitā* makes mention of pieces of gold with the mark '8' imprinted on them (*aṣṭa-pruddhiraṇyam, aṣṭāmṛdam hiraṇyam,* 13.10). Inscriptions and manuscripts, of later ages, all over India, use numerical symbols profusely. The tendency had been, from early ages, to spell out the numbers or make use of things permanently associated with a number to represent that number. For instance, eyes, hands, etc. were used for 2; moon, sky, etc. were used for 1, seasons for 6, and week for 7. Another method was to attribute specific numerical values for the letters of the alphabet and use those letters to indicate the specified numbers, a method which was mentioned by the Sanskrit grammarian Pāṇini of the fourth century BCE. These methods were very popular in the classical age in India, especially with mathematicians and astronomers.

Decimal System and Measurement in East Asia

Shigeo Iwata

Decimal System

There exists at least one root word that seems to be common to all languages, namely, *tik*, which means a finger, an arm, or the numeral "one." The word *te* in Japanese language that belongs to Sino-Tibetan languages refers to a "hand" and *iti* means "one" (Table 1).

When modern humans branched out from Africa some 150,000 years ago, they may have been aware of the number "one." The Caucasoids branched off 100,000 years ago, and Australians 100–70 years ago. The Australians knew numbers as large as three before the eighteenth century. Mongoloids reached East Asia 70,000–50,000 years ago. The Japanese islands constituted an integral part of continental Asia about 12,000 years ago.

Sorai Ogyu (1666–1728) discovered that the cardinal numerals of one type in Japanese include a reduplication system of the vowel-exchanging type. In other words, the replacement of one vowel with another has the effect of doubling the value of the number as can be seen in *hito* (1): *huta* (2), *mi* (3): *mu* (6), *yo* (4): *ya* (8), and *itu* (5): *towo* (10). Apart from Japanese, examples of similar multiplication systems can also be found most typically in Korean (dialect: 1), Taiwanese (8), Micronesian (5), Melanesian (3), and Amerindian (15). The numbers that cannot be obtained in this method are 7 and 9, which can be readily given by combining the approach of one-to-one correspondence.

Peoples using these languages belong to the Mongoloid race. It has been estimated that the cardinal numerals between 1 and 10 emerged no earlier than 50,000 years ago, before these Mongoloids migrated outward from an area of East Asia and made their way to the North, East, and South.

Each of the several bone pieces of 28,000 years ago that were discovered in Shiyu site in China bears a number of lines. Each of these lines denoting a number suggests that the people used to record 20 or more numbers. The 22,430-year-old bone tubes excavated at the Zhoukoudian site in the southwest of Beijing bear symbols that have been deciphered as representing 3, 5, 10, and 13. The shape of the symbol for 10 leads us to believe that its creators employed the decimal system. Presumably, the Mongoloid completed the decimal system 50,000 years ago when they branched into East Asia, both North and South America, and the Pacific islands. The Chinese people recorded numbers as large as 30,000 in the period 3,300 years ago.

Decimal System and Measurement in East Asia. Table 1 Root word and meaning

Family or language	Form	Meaning
Nilo-Saharan	tok-tek-dik	One
Indo-European	dik-deik	To indicate/point
Caucasian (south)	titi, tito	Finger, single
Uralic	ik-odik-itik	One
Austroasiatic	ti	Hand, arm
Sino-Tibetan	tik	One
Indo-Pacific	tong-tang-ten	Finger, hand, arm
Eskimo	tik	Index finger
Amerind	tik	Finger
Na-Dene	tek-tiki-tak	One

Measurement

The greatest numbers of discoveries in East Asia consist of pit dwellings. In most of these cases, the wooden pillars no longer remain; the only evidence left is the postholes. The center of each posthole bottom presumably constitutes the center of gravity. Statistic calculations of the intervals between the centers derive a unit.

Table 2 indicates the age and unit length of typical dwellings. The plan views of some of the dwellings are given in Fig. 1. The mean value of the length of one unit is 17.3 cm. The magnifications of the unit of lengths most frequently used are multiples of 5. In the rare case where irregular numbers only are detected, it is presumed that no ruler was used for the construction.

These dwellings were designed according to a triangular standard, with the particular use of isosceles triangles and occasional employment of an equilateral triangle. Later in 8000 BCE or thereabouts, rectangular dwellings emerged.

The era when the practice of measurement began is considered to be the period in the middle of the range with the upper limit of 50,000 years ago when the decimal system was presumably completed and the lower limit of 25,000 years ago, which is the oldest

Decimal System and Measurement in East Asia. Table 2 Era and unit of length

No.	Site	Region	Year (BCE)	Unit of length (cm)	Standard deviation (cm)
1	Hasamiyama	Japan	26,000	17.3	0.67
2	Nishi-gagara	Japan	22,000	17.2	0.82
3	Shimonjo	Japan	18,000	17.3	1.01
4	Kogure-higashi-arayama	Japan	16,000	17.6	0.94
5	Tana-mukaihara	Japan	15,690	17.4	0.54
6	Taejon	Korea	13,000	18.1	0.60
7	Ushki	East Siberia	12,000	16.8	0.55
8	Kuzuharazawa	Japan	9,000	17.3	1.01
9	Momijiyama	Japan	7,120	17.2	0.68
10	Guhu	China	6,230	17.0	0.37
11	Egou	China	5,950	17.2	0.73
12	Gungsan	Korea	4,750	16.5	0.40
13	Uriba	Japan	4,620	17.4	0.31
14	Banpo	China	4,476	17.5	0.26
15	Giangzhai	China	4,182	17.3	0.18
16	Ichinosaka	Japan	3,875	17.4	0.34
17	Dadiwan	China	3,190	17.4	0.61
18	Ogakuchi	Japan	3,050	17.0	0.33
19	Wangwan	China	2,842	17.6	0.29
20	Ukonjiro	Japan	2,060	17.3	0.74

era indicated in Table 1. The region where measurement began in East Asia has yet to be determined.

The origin of the length 17.3 cm is not evident. At present, it is considered to match the hand length of an average female adult of a matriarchal society or the span of thumb and middle finger. Seven rulers that were used in the Chinese Shang dynasty in 1300 BCE or thereabout were found, of which four were made of bone, two of ivory, and one of jade. The shortest length of 1 *chi* is 15.773 cm and the longest 18.672 cm. The mean value and standard deviation of the length of 1 *chi* is 17.1 ± 1.47 cm. A ruler of 1 *chi* bear the graduations of 1/10, namely *cun* and 1/100, *fen*. Then, the length of 1 *chi* significantly increased because of the turbulence of social order. In the period from thirteenth century BCE to third century BCE, it took about 48 years for a measure to propagate from China to the Korean Peninsula, and 150 years or thereabouts to the Japanese Islands that were isolated from the Continent.

The construction ruler (a ruler used for building structures) is the first standard scale of each race and differs from others in the unit of length. The cubit in Egypt measured 52.5 cm, while the cubit in Mesopotamia was 50.0 cm long, the fathom in Indus was 168 cm, and the hand length in East Asia averaged 17.1 cm.

On the Dadiwan site in China, four measures used in the period of 3,190 ± 170 BCE were discovered. The mean value of unit volumes was 264 cm^3, which was close to the volume of *a gowpen* (*double handful*). Then, 2,800 years later in China, the standard of volume was set to 209 cm^3 with the unit name of *sheng*, which was four times as large as the volume of *a single hand-cupped gowpen*.

In Japan, it is highly probable that some of the potteries excavated from ancient sites of a period ranging from 2,800 to 2,300 BCE were made in accordance with standards of length and volume.

Assuming that such a positional notation as the decimal system was established before 50,000 years ago when modern humans arrived at East Asia and branched into various directions, the first measuring of length was used for building dwellings in a period between the above-mentioned era and 28,000 years ago. In the upper and lower ranges than the subject unit, one or more superior or inferior units were then created. With the gradual implementation of measuring systems of volume and other physical quantities, regional or racial cultures developed, and these different cultures integrated and evolved into the entire Chinese civilization. Thus, "Measurement was the mother of civilization," and "civilization began with measurement."

Deśāntara

K. V. Sarma

In Indian astronomy, the *Deśāntara* of a place is its terrestrial longitude, i.e. the 'distance of the place' from a universally accepted zero meridian. In modern times, the meridian at Greenwich in England is accepted as the zero meridian, and the longitude is expressed in terms of the angle subtended, at the pole, by the Greenwich meridian and the meridian of the place in question. Indian astronomy had, from early times, taken as the zero meridian the meridian passing through the ancient city of Ujjain in Central India, cutting the equator at an imaginary city called Laṅkā and passing through the south and north poles. Again, in order to facilitate the conversion of the local time to that of the zero meridian and vice versa, the *Deśāntara* was expressed in terms of time-measures like *nāḍī* (or *ghatī*), equal to 24 min, as converted from the corresponding degrees. Since the earth completes one eastward rotation of 360° in 24 h, it is 15° an hour or 1° in 4 min. In terms of Indian measures, since 60 *nāḍīs* are equal to 24 h or two and half *nāḍīs* make 1 h, the rotation of 15° corresponds to a period of two and a half *nāḍīs*. Since 1 *nāḍī* = 60 *vināḍīs*, and 1 *vināḍi* = 6 *prāṇas*, the rotation will be 1° in 10 *vināḍīs,* or 1 min in 10 *prāṇas*. The *deśāntara* which is expressed in terms of time measure is done through either *nāḍīs*, *vināḍīs* or *prāṇas.*

Since the planetary positions derived by Indian astronomical computation are all related to the mean sunrise at the zero meridian, viz., the Ujjain meridian, to arrive at the positions at local places, a longitude correction or *deśāntarasaṃskāra* is called for. It is calculated in time-measures, as above, and is subtracted if the place in question is east of Ujjain and added if it is west of Ujjain.

The *deśāntara-saṃskāra* is expressed also in terms of the distance, i.e. in *yojanas*, of the desired place from the Ujjain meridian in the same latitude, at the rate of 55 *yojanas* for 10 *vināḍīs* or 1 min.

Devācārya

K. V. Sarma

Devācārya, son of Gojanma and author of the astronomical manual *Karaṇaratna* (lit. Gem of a Manual), hailed from Kerala in South India. The epoch of *Karaṇaratna*, i.e. the date from which planetary computations were instructed to be commenced in that work, is the first day of the year 611 in the Śaka era, which corresponds to February 26 of AD 689. This places Devācārya in the latter half of the seventh century. We know he came from Kerala because he used the *Kaṭapayādi* system of letter numerals and the *Śakābdasaṃskāra*, which is a correction applied to the mean longitudes of the planets from the Śaka year 444 or AD 521, and a unique method of computing the solar eclipse, all of which are peculiar to Kerala, and because his work is popular in that part of the land.

Devācārya uses the elements of the Āryabhaṭan school of astronomy as the basis of his work, as he himself states towards the commencement of *Karaaratna*. His work is based both on the *Āryabhaṭīya* and on the second work of Āryabhaṭa, the *Āryabhaṭa-siddhānta*, as abridged in the *Khaṇḍakhādyaka* of Brahmagupta. The influence of the *Sūryasiddhānta* and of Varāhamihira are also apparent. It is also noteworthy that Devācārya himself innovated several thitherto unknown methodologies and techniques.

In eight chapters, the *Karaṇaratna* encompasses almost all the generally accepted aspects of Hindu astronomical manuals. Chapter I of the work is concerned with the computation of the longitudes of the sun and moon, and also the five basic elements of the Hindu calendar (*pañcāṅga*). Computation and graphical representation of the lunar and solar eclipses are the subjects of chapters II and III. Chapter IV deals with problems related to the gnomonic shadow, and chapter V with the calculation of the time of the moon-rise and allied matters. In chapter VI, heliacal rising of the moon and elevation of the moon's horns are dealt with. The last two chapters are concerned with the derivation of the longitudes of the planets, planetary motion, and planetary conjunctions.

Several peculiarities characterize Devācārya's work. Among these are the computation of the sun, moon, moon's apogee, and moon's ascending node using the 'omitted' lunar days, the *Śakābda* correction, and the application of a third visibility correction for the moon. However, what is most significant in the work is the recognition of the precession of the equinoxes and the rule that he gives for its determination on any date. Devācārya's measure of the rate of precession is 47 s per annum, its modern value being 50 s. Devācārya's importance lies in the fact that his work formed a record of the astronomical practices and methodologies for the quick derivation of astronomical data that prevailed in India during the seventh century AD.

Divination: Science, Technology, and the Mantic Arts in Traditional China

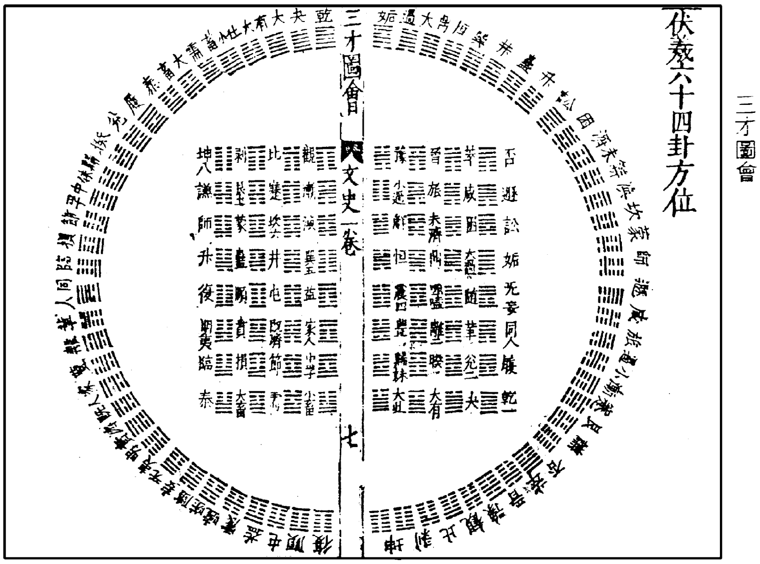
Richard J. Smith

From Neolithic times into the twentieth century, divination occupied an extremely prominent place in Chinese culture. By the third millennium, BCE at the latest – and some recent research suggests considerably earlier – specialists in reading stress cracks in the bones of various animals had already emerged as a distinct occupational group in north China. During the Shang dynasty (ca. 1500–ca. 1100 BCE), the interpretation of so-called oracle bones (the dried plastrons of turtles and the scapulae of cattle) reached a high degree of sophistication. Royal diviners sought spiritual advice on behalf of the Shang kings concerning a wide range of important topics, from the weather, agriculture, hunting and travel, to civil and military administration, the construction of buildings, the location of cities, religious sacrifices, and personal problems.

The inscriptions on Shang oracle bones do more than indicate the preoccupations of rulers, however; they also reveal patterns of thought and behavior that have lasted for several millennia in China. For instance, they document the early use of sexegenary cyclical characters ("stems" and "branches;" *ganzhi*) for marking time – a practice that continued in all subsequent dynasties and can still be seen today in traditional Chinese almanacs. They also suggest a deep interest in dream interpretation that has persisted throughout Chinese history. Furthermore, oracle bone inscriptions testify to an early preoccupation with astronomical observation, astrological prediction and numerology. Indeed, some Chinese scholars have argued that Shang dynasty numerological concerns led to the invention of the extraordinarily important divinatory symbols known as hexagrams in English (see below).

Paradigmatic Chinese sources such as the *Shijing* (Classic of Poetry), the *Shujing* (Classic of History), the *Yijing* (*I Ching*; Classic of Changes), the *Chunqiu* (Spring and Autumn Annals), the *Zuozhuan* (Commentary of Zuo), the *Liji* (Record of Ritual), and the *Zhouli* (Rituals of Zhou) – together with recently excavated inscribed bronzes and writings on both silk and bamboo, attest to the social and geographical spread of divination in the Zhou dynasty (ca. 1100–256 BCE). During the early Zhou, divination remained primarily a royal prerogative, but by the Spring and Autumn era (722–481 BCE) it had become far more diversified and widespread.

A particularly important development during this time was the "invention" of the legendary *Zhouyi* (Zhou Changes) – a divination manual based on sequences of 64 six-line symbols known as hexagrams (*gua*). Each hexagram had a name that referred to a physical object, an activity, a state, a situation, a quality, an emotion or a relationship – for example, *Ding* (The Cauldron), *Shi* (The Army, *Dun* (Withdrawal), *Meng* (Juvenile Ignorance), *Yu* (Contentment), *Song* (Contention), and *Tongren* (Fellowship). Each hexagram also possessed a short description of several characters called a *tuan* or *guaci* (usually rendered "judgment") and a brief, one-sentence "line statement" (*yaoci*) elucidating each line. Over time, the hexagrams and their two constituent

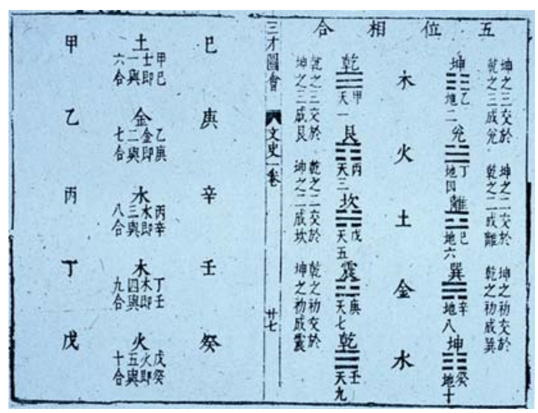


Divination: Science, Technology, and the Mantic Arts in Traditional China. Fig. 1 The Sixty-four hexagrams, organised in square and circular configurations based on the so-called Former Heaven (Xian Tian) sequence.

"trigrams" (also *gua*) came to be used in a wide variety of divinatory systems and also as scientific symbols (Fig. 1).

By the late Zhou period, a great number of mantic systems had developed in China, including various "schools" of astrology (*zhanxing*, *xingming*, etc.), geomancy (*dixing*, *xingfa*, *kanyu*, and later *fengshui*), physiognomy (*xiangren*, *kanxiang*, etc.), and various computational arts (known generically as *shushu*). This growing interest in divination was part of a general burst of remarkable philosophical creativity in the so-called Warring States period (453–221 BCE) – an era marked by social and geographical mobility, the exchange of new ideas, increased professional specialization, and the introduction of new technologies, including advanced methods of astronomical and calendrical calculation. Also, from the late Zhou dynasty into the twenty-first century, almanacs or "day books" (*rishu*, *tongshu*, *huangli*, etc.) – based on elaborate astrological calculations and correlations – specified propitious and unpropitious times for all kinds of activities, from mundane matters such as bathing, traveling, and beginning various kinds of work to extraordinarily important rituals.

During the Han dynasty (206 BCE–220 CE), the correlative cosmology of Dong Zhongshu (ca. 179–ca. 104 BCE) – based on concepts such as *yin* and *yang* and the five "agents" or "activities" (*wuxing*; identified with the "qualities" of wood, fire, earth, metal, and water), as well as the eight trigrams (*bagua*), the ten "stems," the 12 "branches," and the 64 hexagrams – influenced virtually all forms of Chinese divination, not to mention the related realms of medicine and natural science (Fig. 2). A significant feature of early Chinese divinatory, medical and scientific thought is that *yinyang*, *wuxing*, and other correlations often seem to have been more compelling than empirical observation – even when the correspondences and analogies were internally inconsistent or mutually incompatible.



Divination: Science, Technology, and the Mantic Arts in Traditional China. Fig. 2 Cosmic correlations involving the eight trigrams, the five phases and the ten heavenly branches.

During the early Han period, in 136 BCE, a series of pre-existing commentaries known as the "Ten Wings" (*Shiyi*), attributed erroneously but convincingly to Confucius, became permanently attached to the *Zhou Changes*, and the work became one of the court's officially recognized "Confucian" classics – hence the new name of the document, *Yijing*. These "wings," especially the so-called "Great Commentary" (*Dazhuan*; aka, the Appended Phrases or *Xici*), invested the *Changes* with a powerful, colorful, and inticing philosophical flavor. Moreover, they helped to explain the cryptic "judgments" and "line statements" of the basic text, attaching to both the hexagrams and trigrams a great many new meanings and associations. These ranged from family relationships, social roles, animals, and parts of the body to directions, seasons, times of the day, and colors.

Scholarly approaches to the *Yijing* varied substantially during the Han – in part, perhaps, because different versions of the work existed. We know, for example, that the Mawangdui silk manuscript of the *Changes*, produced in the early Han period, differs in several significant respects from later "standard" editions of the classic – not only in some of its judgments and line statements, but also in its ordering of the hexagrams (and even some of the names attached to them). But scholarly differences in the Han were also a function of the many ways in which the received text of the *Changes* could be interpreted. Indeed, for the next 2,000 years, literally hundreds of different approaches to the *Yijing* developed. Although only two main interpretive lineages are usually identified with the "Learning of the *Changes*" – the "Images and Numbers (*xiangshu*) School" and the "Meanings (or Morality) and Principles (*yili*) School" – in practice scholars drew freely from both traditions, developing complex schemes that related lines, trigrams and hexagrams to various calendrical, numerological, and philosophical interests and orientations.

At the same time, the *Yijing* inspired a host of derivative works, from simple prognostication texts (*chanwei* or *tuchan*) to more elaborate "apocryphal" treatises such as the *Qian zao du* (Opening Up the Regularities of the [Hexagram] Qian; also transliterated *Qian zuo du*). The *Changes* also provoked an extremely interesting divinatory book known as the *Taixuan jing* (Classic of Supreme Mystery) by a brilliant scholar named Yang Xiong (53 BCE–18 CE). This eclectic work reflects standard Han dynasty cosmological assumptions and intellectual fashions, but instead of using 64 hexagrams and 384 lines it employs 81 tetragrams (*shou*) and a total of 729 lines – each with an "appraisal" (*can*) loosely patterned on the line texts of the *Yijing*.

The wide circulation of Han divination texts suggests the ever-growing appeal of fortune-telling at all levels of Chinese society. Occult specialists known generically as *fangshi* dominated the mantic landscape in the Han and immediate post-Han periods, and as a result, every subsequent dynastic history, not to mention many local gazetteers and other such sources, contained special sections devoted to biographies of *fangshi*, usually called "technicians" (*fangji*).

Among the many divination techniques employed by *fangshi* were increasingly varied forms of astrology, "fate calculation" and numerology. Specialists also emerged in a myriad of related techniques: consultation of two diagrams closely associated with the *Yijing* and known as the *Hetu* (Yellow [River] Chart) and the *Luoshu* (Luo [River] Writing), the use of divining boards, oracle bones, milfoil stalks, and prognostication texts; the geomantic analysis of landforms; the selection of lucky days, the analysis of heavenly stems and earthly branches; communication with spirits; crack-making with bamboo; the interpretation of winds and vapors, birdcalls, and dreams; physiognomy, and eventually the divinatory evaluation of written characters. Most of these techniques had existed in the late Zhou period or earlier in some form, and virtually all of them continued to be used throughout the Imperial Era (up to 1912). The principal innovations of later years were the incorporation of certain zodiacal elements of Indian astrology into Chinese astrology, the use in front of temples and shrines of "spiritual sticks" (*lingqian*) and "divining blocks" (*jiao*), and a particularly dramatic form of oracular spirit possession known as "spirit-writing" (*fuji* or *fuluan*).

From the Six Dynasties period (222–589 CE) onward, Chinese Buddhists and Religious Daoists appropriated the symbolism of the *Yijing* and used a variety of other mantic texts in order to "know fate" – even though one's future was, in a certain sense, ordained by behavior in both systems of belief. In any case, we find a number of monks, priests and lay adherents from various periods of Chinese history who were experts in one or another divinatory technique. Some clerics even compiled mantic texts (*bujing*), such as the mid-fifth century work titled *Guanding jing* (The Sutra of Consecration). One of the most famous clerics in medieval China was Yixing (d. ca. 740), a Buddhist monk and official court astronomer during the reign of emperor Xuanzong, who excelled in fate calculation, physiognomy and geomancy as well as mathematics, calendrical science and classical studies. He is well known for his studies of Han scholarship on the *Yijing* and as the author or editor of several books on astrology and other forms of divination. He also served as a trusted adviser and interpreter of portents for his imperial patron.

From the Song dynasty (960–1278) onward, diviners increasingly relied upon a new device, the geomantic "compass" (*luopan*, *luojing*, etc.), to ascertain the relationship between "heavenly patterns" (*tianwen*) and "earthly forms" (*dixing*). This invention, derived in part from Han dynasty divining boards (*shi*), delineated celestial and terrestrial relationships by means of a series of concentric circles marked with standard Chinese symbols of time and space. Among the *Yijing*-related symbols regularly employed in these devices were the eight trigrams, the stems and branches of the sexegenary cycle, the 28 lunar "lodges" (*xiu*) and other such cosmic variables (Fig. 3).

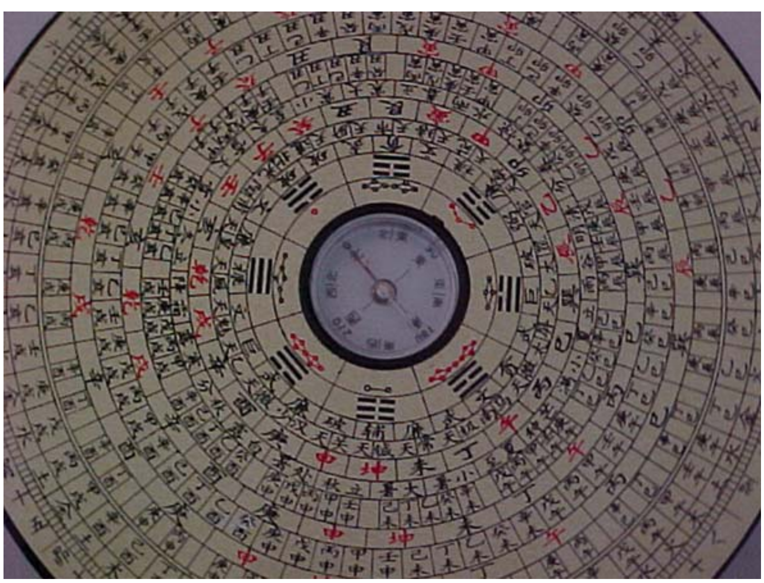
A Song dynasty poem reproduced in a famous Chinese encyclopedia testifies to the importance of the compass to the geomancer's craft. It contains the following lines:

> Between the lodges Xu and Wei points clearly the needle's path,
>
> But to the south the lodge Zhang "rides upon all three".
>
> The trigrams Kan and Li stand due north and south, though people cannot recognize [their subtleties],
>
> And if there is the slightest mistake there will be no correct predictions.

Over time, compasses became increasingly sophisticated, with up to 24 concentric rings and a host of symbolic variables that applied to several different divination systems. Similarly, fate calculation based on the time of one's birth grew more complex. Whereas pre-Song techniques involved at most a consideration of the year, month and day of birth, later diviners took into account the hour as well. These "four pillars" (*sizhu*) of destiny, each designated by two characters, came to be known as one's "eight characters" (*bazi*), an extremely common term in Chinese divination up to this very day.

The many hundreds of life stories contained in Yuan Shushan's massive and fascinating *Zhongguo lidai buren zhuan* (Biographies of Diviners in China by Dynastic Periods; 1948) abundantly testify to the central role divination has played in nearly all aspects of Chinese life for thousands of years. Many of the mantic specialists discussed by Yuan were employed by Chinese officials as formal or informal advisers, and many served in some sort of military capacity. A number made calendrical calculations and/or predicted weather, droughts and famines. Physiognomers in the employ of bureaucrats often evaluated personnel and sometimes also interrogated witnesses and prisoners. A few even served as negotiators with dissident groups. Diviners also assumed active roles in law enforcement, assisting with difficult legal cases, solving crimes, and helping to apprehend suspects or escaped prisoners. A great many fortune-tellers gave useful advice to officials concerning water management, public works, and the construction or repair of city walls, temples, schools and yamens (the office or residence of an official).

What made diviners effective enough in these roles to warrant biographies in local gazetteers and other such sources? Putting aside claims to supernatural power, the answer seems to be their technical expertise and social value – the product of both experience within their communities and psychological insight. Although experts in analyzing wind, rain, and clouds (*fengjiao*, *xiangyu*, *zhanqi*, etc.) – like all Chinese



Divination: Science, Technology, and the Mantic Arts in Traditional China. Fig. 3 A geomantic compass, with concentric rings reflecting various cosmic variables, including trigrams.

fortune-tellers (and most of the rest of the Chinese population as well) – they believed in the influence of supernatural forces, including “star-spirits.” They were also careful observers of natural phenomena. Geomancers used compasses to identify auspicious sites and times for building and making repairs, but they also knew a great deal about landforms and hydraulic systems – information of value in public works as well as military affairs.

Exponents of numerological techniques such as *liuren* (“the six *yang* waters”), *dunjia* (“evasive techniques”) and *Taiyi* (“method of the Great Unity [Spirit]”) – although concerned primarily with calculations to determine proper times and locations, often studied the arts of war as part of their training. And all diviners – fate calculators and physiognomers in particular – were quite naturally careful observers of human behavior. In short, well-cultivated talents of empirical observation and psychological insight gave fortune-tellers a substantial role to play in Qing administrative affairs.

In local communities, quite apart from their service to Chinese officials, diviners played important roles in helping to resist rebel invaders and bandits. Fortune-tellers provided technical assistance to their local communities in other ways as well. Some undertook famine relief, managed schools, or supervised public works projects. Others used their special talents in *liuren*, *dunjia*, and *Taiyi* predictions to help neighbors find lost or stolen property.

In a number of significant ways, fortune-tellers were like physicians in traditional China – an affinity too seldom acknowledged by historians of medicine. At least 170 of Yuan Shushan’s 1,115 biographical entries refer to individuals who knew both medicine and divination (*yibu*). One common denominator between the two diagnostic and prescriptive approaches was a shared cosmology, centered on theories of “responsive correspondence” (*ying* or *xiangying*). These correspondences involved considerations of time, place and spirituality (or demonology) as well as notions of physiology and psychology. Discourses in divination and medicine almost invariably revolved around the same basic cosmological concepts, including *yinyang* and *wuxing*, the eight trigrams and 64 hexagrams, the sexegenary stems and branches, positive and negative spirits (*shen* and *gui*, respectively) and so forth.

The four standard categories of Chinese medical examination – visual inspection, listening and smelling, questioning the patient, and touching the body – correspond closely to the approach of many diviners, physiognomers in particular. From the standpoint of treatment, practitioners of traditional Chinese medicine and divination often considered a patient’s moral behavior to be a significant factor in that person’s well being. Clients of both doctors and diviners were therefore advised to cultivate good thoughts and to banish selfish desires.

As “technicians,” physicians and fortune-tellers occupied the same status in Chinese society. Scholars conventionally described both professions as “minor employments” (*xiaodao*), to be investigated, perhaps, but not to be earnestly pursued. They also suffered many of the same criticisms. These had to do primarily with inconsistent theories, inaccurate predictions, and fraudulent therapies.

Scholars were particularly critical of fortune-tellers for their exploitation of the “ignorant” masses, and for their obviously mercenary motivations. They could not, of course, assail the idea of divination itself, for the practice had far too long and illustrious a pedigree in China’s classical tradition to ignore. But elites made a sharp (albeit rather artificial) distinction between their own “enlightened” beliefs and the “crude” customs of the populace at large. In short, the bias against certain “popular” forms of divination was fundamentally a class prejudice, masked by the rhetoric of Confucian morality. This elitist view of divination is reflected in a well-known adage attributed to the famous Song dynasty scholar Zhang Zai: “The (*Classic of*) *Changes* is for the planning of the superior person, not the planning of the petty person.”

Yet Chinese intellectuals made no significant headway in their effort to eradicate popular mantic practices during imperial times. Why? In the first place, most divination systems, like the cosmology on which they were based, had a high degree of complexity. This provided conceptual flexibility, and made “scientific” falsification all but impossible. In the minds of many, wrong predictions simply indicated that someone had misinterpreted the huge number of cosmic variables involved, or that either the diviner or his client was insufficiently “sincere” (*cheng*).

In the second place, as indicated above, fortune-tellers played important social roles in premodern China, serving as the equivalents of modern-day scientists, technicians, doctors, psychologists, and social workers. Moreover, divination drew strength from the fact that so many of its features resonated powerfully with other aspects of traditional Chinese culture, including philosophy, religion, art, literature and social customs. It reflected, for example, the eclectic, synthetic features of Chinese thought, the importance of writing (evident in mantic messages of all kinds, as well as charms, and the analysis of written characters), aesthetics (particularly evident in the case of geomancy), mythology, medicine, cosmology and popular symbolism (notably the popular *yinyang* illustration known as the “Diagram of the Supreme Ultimate” (*Taiji tu*) and the ubiquitous eight trigrams.

Finally, we should remember that the Chinese government reinforced the inherited cosmology and sanctified orthodox practices of divination in every way possible, at all levels. Officials and emperors sought mantic assistance in a wide variety of circumstances, determined to find the right time and the right place for all ritual events, large and small, the conduct of war, the construction of buildings, and so forth. Perhaps the single most significant manifestation of this administrative attitude was production of the state calendar, which dictated auspicious and inauspicious activities for each day of every year, based on the calculations of official diviners at the capital, who were located in the Imperial Bureau of Astronomy (Qintian jian) (Fig. 4).

During the late nineteenth century, Western imperialism brought new challenges to China, as well as new political, social and cultural options to Chinese intellectuals. Under these unprecedented circumstances, a new kind of cosmological critique arose – a political attack on the cosmological foundations of Chinese kingship itself. It was successful, and when the Qing dynasty finally fell in 1912, state-sponsored cosmology suffered a mortal blow. During the so-called New Culture Movement (ca. 1915–1925), which followed in its wake, modern-minded intellectuals such as Chen Duxiu (1879–1942) railed against Confucian values and ridiculed old-fashioned "superstitions" (*mixin*). He wrote in 1918, for example, that only by first casting away practices such as geomancy, fortune-telling, spirit writing and the use of charms, spells and alchemy, could the Chinese people begin to "put their minds right." He was not attacking a straw man, for old-style mantic techniques and cosmological assumptions remained in force, judging from the remarks of a well-informed foreign observer in the midst of the New Culture Movement: "At the present day," he wrote, "soothsayers, diviners and fortune-tellers abound throughout the land, and the people place implicit faith in their vain forecasts."

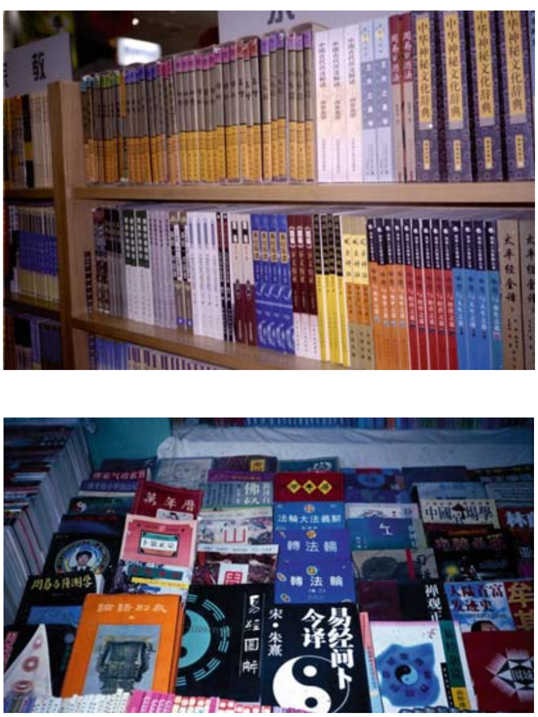
Periodic efforts were made by the Republic of China (from 1912 to 1949 on the Mainland and from 1949 – present on Taiwan) and the People's Republic of China (1949 – present) to discourage or eradicate "superstitious" mantic practices, but with only limited success.

Divination: Science, Technology, and the Mantic Arts in Traditional China. Fig. 4 A map of Heaven (round) and Earth (square), showing the influence of the eight trigrams and various heavenly bodies, including the sun, the moon, and the twenty-eight lunar lodges (xu).

Virtually all forms of traditional Chinese divination have flourished in both Hong Kong and Taiwan, and even in the People's Republic, despite sometimes fierce "antisuperstition" campaigns, particularly during the fanatical and destructive Cultural Revolution (1966–1976). Popular divination is alive and well, especially geomancy (*fengshui*).

Moreover, the so-called "Open Policy," inaugurated on the Mainland in 1978, has encouraged a dramatic revival of interest in, and publications on, divinatory works such as the *Classic of Changes*. During the 1980s this enthusiasm was known widely in the Chinese press as *Yijing re* ("*Yijing* Fever"). Part of the reason for this fever, which touched virtually every sector of Chinese society on the Mainland, is a profound spiritual crisis (*jingshen weiji*), which has induced many people to reexamine the contemporary relevance of their ancient past (Fig. 5).

The result has been a burst of new and creative *Yijing* scholarship, fueled by dramatic recent archaeological discoveries. On both sides of the Taiwan Straits, encyclopedias, dictionaries and other comprehensive compilations – as well as compendia produced by literally dozens of scholarly organizations devoted to *Changes* studies – have chronicled at great length the *Yijing*'s wide-ranging cultural contributions. So have



Divination: Science, Technology, and the Mantic Arts in Traditional China. Fig. 5 Examples of books on divination in Mainland Chinese bookstores and bookstalls.

the authors of general studies such Wang Shusen's *Zhouyi yu Zhonghua wenhua* (The *Zhou Changes* and Chinese Culture), Zhai Tingpu's *Zhouyi yu Huaxia wenming* (The *Zhou Changes* and Chinese Civilization), and Ying Dingcheng's *Zhongguo wenhua zhi benyuan* (The Origins of Chinese Culture).

Meanwhile, a number of more narrowly focused works have also appeared in a spate of recent scholarly series – notably the *Yixue wenhua congshu* (Collectanea on the Culture of *Changes* Studies) and the *Yixue zhihui congshu* (Collectanea on the Wisdom of *Changes* Studies). The individual volumes in these two series alone cover topics such as the relationship between the *Yijing* and Confucianism, Daoism, Buddhism, mathematics, medicine, astronomy, the humanities, historiography, aesthetics, geomancy, architecture, business management, the environment, *qigong*, and other forms of traditional physical and mental cultivation (*yangsheng*), and so forth.

In addition, there are a great many individual monographs with titles such as Xu Daoyi's *Zhouyi kexue guan* (The Scientific Outlook of the *Zhou Changes*) and his *Zhouyi yu dangdai ziran kexue* (The *Zhou Changes* and Contemporary Natural Science) – two of many similarly titled books and articles – He Shiqiang's *Yixue yu shuxue* (*Changes* Studies and Mathematics); Jiang Chengqing's *Yijing yu Zhongguo yishu jingsheng* (The *Classic of Changes* and the Spirit of Chinese Art); Chen Liangyun's *Zhouyi yu Zhongguo wenxue* (The *Classic of Changes* and Chinese Literature); Wang Zhenfu's *Zhouyi di meixue zhihui* (The Aesthetic Wisdom of the *Zhou Changes*); Shao Xuexi's *Yixue yu bingfa* (*Changes* Studies and the Art of War); and Tang Mingbang's *Dangdai Yixue yu shidai jingshen* (Contemporary *Changes* Studies and the Spirit of the Times).

One of the most powerful and persistent tendencies in recent *Yijing* scholarship has been the tendency to look at the *Changes* as a "scientific" document. During imperial times, a great many Chinese thinkers tried to approach the *Yijing* by way of mathematics, or at least a highly sophisticated numerology – notably Jing Fang in the Han, Shao Yong in the Song, and Jiao Xun in the Qing. And, as indicated briefly above, the symbolism of the *Changes* also came to be used as an explanation for various phenomena in the natural world. But efforts to link the *Yijing* to math and science in the twentieth century are now predicated on modern "Western" understandings of these two related realms of knowledge. Thus, impelled in part by national pride, Chinese scholars today – especially those educated in the West – have begun to use "data" from the *Yijing* to show connections to a number of different realms in modern mathematics and science, from linear algebra and quantum mechanics to molecular biology and computer coding. A readily available example in English is Johnson Yan's *DNA and the I Ching*.

Dwellings and Settlements

NEZAR ALSAYYAD, ROMOLA SANYAL

Traditional dwellings and settlements are the built expressions of a heritage that continues to be transmitted from one generation to another. Usually the product of common people without professional intervention they provide the habitat for much of the world's population. In fact, it is argued that professionally designed dwellings account for less than 1% of the total housing stock in the world. According to one estimate, traditional dwellings and settlements house between eight and nine million households in a variety of urban and rural settings (Oliver 1987).

In the twentieth century, interest in the social and cultural values, images and perceptions underlying traditional dwellings and settlements has become widespread among scholars in various disciplines. Specific labels, such as "vernacular," "indigenous," "primitive," "tribal," "folkloric," "popular," and "anonymous" have been introduced to describe the subjects of a variety of inquiries. Nevertheless, the inability to come up with a single appropriate label should not prevent a categorization of these dwellings and settlements as one analytical group. One thing common to all the above qualifiers regarding buildings and spaces is that they describe a process that becomes a norm when enough people in a given society adopt it. In this regard, traditional settlements exist in every part of the world and cannot be regarded as being simply primitive or exclusively a product of the developing world.

Since adoption of a practice into a norm is one of the fundamental qualities of tradition in built form, it is legitimate to use "tradition" as an all-encompassing umbrella term. Used this way, the term may also be useful in an age when scholars are beginning to recognize that the study of those dwellings and settlements, whose form originated as part of everyday processes rather than specialized professional aesthetic judgments, is an interdisciplinary arena. Unlike professional traditions like those of science or medicine, or professional architectural practice, the traditions of dwellings and settlements will remain an open field subject to great changes in position.

One may argue that a thing is traditional if it satisfies two criteria. First it should be the result of a process of transmission from one generation to the next; second it should have cultural origins mainly involving common people. As such, traditional dwellings and settlements are those buildings and spaces which provide for the ordinary activities of common folks and which are produced by both utilitarian logic as well as local aesthetics.

The vast numbers of traditional dwellings and settlements also allow for such built forms to be legitimately classified under the different names and qualifiers mentioned above. Many of these qualifiers originated from particular disciplinary bases and may not be interchangeable. For example, vernacular architecture in many parts of today's world often cannot be regarded as indigenous because it relies on imported materials to achieve local styles. "Indigenous" means of place, and has to do with origin. "Vernacular" means of the masses and hence does not have to be indigenous. It is also a category that has an underlying basis in class and social grouping. "Traditional" as a description is appropriate to use when discussing a system of core values that are transmitted from one generation to another. It is about process; as opposed to vernacular and indigenous, which are descriptions of how things are put to use (AlSayyad and Bourdier 1989).

The study of traditional dwellings and settlements as a field is not new – it was started in the early nineteenth century by Morgan and Morris. Bernard Rudofsky's famous exhibition at the New York Museum of Modern Art entitled *Architecture without Architects* and an accompanying book further popularized the study of vernacular architecture in the 1960s. The latter part of the decade saw further developments in the field with the publication of such ground breaking books as *House Form and Culture* by Amos Rapoport culminating in the *Encyclopedia of Vernacular Architecture of the World* by Paul Oliver. Some more recent publications include Paul Oliver's *Dwellings: The House Across the World* and Enrico Guidoni's *Primitive Architecture*.

The study of traditional dwellings and settlements can be defined less by subject than by method. Different means of analyzing traditional dwellings and settlements such as anthropological, architectural, archaeological, behavioral, structural, and so forth use different lenses to understand the ways and means by which people build dwellings and the symbolism and utilitarianism involved in building and conceptualizing these structures. Such varying approaches to studying traditional dwellings and settlements points to the fact that elaborate methods and meanings dictate the form and process by which dwellings are constructed. Factors such as culture, religion, gender relations, privacy matters, climate, security, economic conditions, and so forth intersect to produce dwellings that become part of the popular culture of a place.

Using such varying methods points to the various forms of settlements that are viewed as being "traditional." For example, in China, cave and pit dwellings found in the Hunan region are viewed as traditional forms of settlements (Fig. 1). Many of the people who live in these dwellings are peasant farmers who come from relatively low-income backgrounds. Cave and pit dwellings therefore allow them to not only save precious farmland, but also to save substantially on the cost of building a house as digging is the cheapest form of labor in the region. The Tunisian troglodyte dwellings, some 10,000 miles away, are primarily habitats of the ethnic Berbers. Largely found in the Matmata plateau area, in the south of the country which is part of the Sahara desert, these dwellings were claimed to have been built for purposes of defense against the invading Romans and later the Arabs (Fig. 2). As the threat increased or decreased, so

did the height at which these dwellings were carved or constructed. Thus these dwellings are a product of not only a traditional way of life but also climatic and topographic constraints under conditions of war and peace.

Such climatic and cultural conditions have also been used to explain the forms of Tharu homes in the Terai region of Nepal (Fig. 3). These homes are closely built together not only because the Tharu people live predominantly in forested regions where they are prone to animal attacks, but also because of their traditional beliefs in ghosts and the notion that anyone who sleeps alone is prone to attacks by evil spirits.

Additionally, climate has often been cited as the primary condition for the development of courtyard houses through much of the Middle East. While this type of building is associated primarily with Arab culture, its distribution extends from North Africa to South Asia where the *haveli* or atrium house is common to cities such as Jaipur and was developed under Mogul influence. The basic courtyard plan of the Ancient Egyptian peasants which partially survives today includes long single-storeyed rooms on three sides of a yard, the fourth being closed off by a wall as high as the buildings. Constructed of mud, the walls are the thickest where they are exposed to the sun. The courtyard plays a climatically important role regardless of the height of the building. At midday, the sun may reach the courtyard floor but the thickness of the walls and the adjacent buildings prevent excessive solar heating. Cool air in the rooms is drawn into the courtyard and warm air begins to rise, causing convection currents. The deep shadows created by the low angle of the sun offset the circulation of the air currents. When the sun sets, the temperature drops rapidly and the air circulates through the various rooms surrounding the courtyard keeping them cool till the next afternoon (Oliver 1987: 119–120).

Similar to climatic constraints are constraints presented by the environment as well. This includes the constraint of finding appropriate building materials. In the Altiplano and high Punda regions in Northern Chile, the only source of wooden building material is a cactus commonly known as *cardon* or *pasacana*. The plant once cut and dried produces a wood that is not only very strong, but resistant to rotting. It is cut into boards and bound together to construct doors, ceilings and floors. The bark, which is denser material, is used for window frames, rafters, and furniture-making (Sainsbury 1997: 223).

Questions of privacy are important factors in determining the form of space in traditional dwellings and settlements. How societies regard their relationship to external or public space is often a measure of the importance that they place on privacy. The delineations of public and private spaces vary from one culture to another. In some cultures such as that of the Ashanti, one finds most of the domestic tasks along with economic ones taking place outside the house itself, not inside as it is in most other cultures (Oliver 1987: 142).

As noted earlier, values and symbols play an important role in the development of traditional dwellings and settlements. One example of such practices is that of the Navajo Indians and the symbolic meanings of spaces in their hogans (Fig. 4). Here, the floor slightly dished represents the female (earth) and the roof slightly concave represents male (sky). Pollen smeared on the house posts supporting the roof symbolizes poles that support the sky. In the middle is the hearth which symbolizes the center of the world. Movement through this space is sun-wise (Oliver 1987: 142).

Aesthetics play an important symbolic role within vernacular architecture practices. In Sumatra, the Toba Batak *huta* (village) comprises of two rows of buildings

facing the *halaman* or village plaza which in turn is always oriented east–west (Fig. 5). The massively constructed Toba Batak house has saddle-back pointed roofs and curving eaves which convey an impression of lightness and gable fronts that give shade. Planked panels are fixed over the external gable which comprise of three levels including a stair and balcony. These panels take on decorations which include finely carved spiral and foliated volute patterns and painted in black, red, and white. Female breasts and the *boraspati*, a local lizard, are also carved on to the façade, possibly as fertility signs. Batak houses are meant to be seen and admired from the *halaman*, the hierarchies of the village evident in the size of the dwelling and the quality of workmanship exhibited, which can be restricted by the village heads (Oliver 1987: 173–174).

Parallel to the Batak traditions of using aesthetics as a marker of social hierarchy is the Hausa practice of using external decorations to show wealth and prosperity (Fig. 6). The characteristic external house decorations of the Hausa appear to have developed in this century when attitudes to *azziki* or the gaining of prosperity and respect, which had thus far been restrained, were relaxed. Displays of success by homes of merchants and traders appear to have been condoned until 1930s by which time many houses had been elaborately decorated in *zanen gida* fashion and were seen in such cities such as Kano and Zaria. Over the mud walls, the finishing mud plaster was molded into the desired shapes by hand and coated with water-resistant layer of local cement made from mud, dung, and *laso*-mixed animal hair, and dye-pit residues. The pattern scribed with fingers with the unwanted parts scooped away left figures that stood in relief against the background. This was finished with local cement and whitewashed or painted in earth colors or in commercial paints (Oliver 1987: 180–181).

Methods of defining vernacular architecture have been categorized by others into four avenues of enquiry namely: object-oriented studies, socially oriented studies, culturally oriented studies and symbolically oriented studies (Upton 1993). While the first type tries to interpret the intention of a dwelling's creator and the second is concerned with overall social history, the third and fourth suggest a shift toward a typologized study of dwellings within certain socio-cultural and historic contexts, with the purpose of uncovering the enduring values of their builders and the symbols that signify deeper structures of society. A possibly fifth avenue of inquiry is that possibly qualified as "design-oriented studies" which include the work of those people who seek better ways of understanding the past without accepting a simplistic return to earlier traditions. While the above methods have been largely utilized to examine the American vernacular scene, one can easily apply such approaches to the larger field of traditional dwellings and settlements (Upton 1993).

The various methods of analyzing traditional dwellings and settlements also require a parallel study of the meaning of tradition itself. Some have argued that tradition is something that we value and pass on. The value attached is the element of "traditionality" sanctioned by history or nature itself. Intrinsic to tradition is the constraint of choice. The inability to choose the possibility of waiting is what provides value to an object or a practice. Unique to this concept is the introduction of time and of waiting to the concept of tradition. At some level, traditions emerge simply as a result of the absence of choice. It is the practice evolving out of constraint and that which we are able to reproduce that ultimately becomes tradition and is passed down from generation to generation. In modern societies, consumerism has eliminated many of the constraints folk societies faced and overcame by building on and creating traditions (Tuan 1989).

It can also be argued that there is no such thing as a "traditional building" but that there are only buildings that embody traditions. The idea that a building embodies tradition rather than it being the means by which the building came to be allows us to see the continuities between form, content, and process.

The application of the term traditional is vast and all encompassing. For this reason, defining a dwelling as being "traditional" requires an understanding of the attributes that lead to its being qualified in this manner. These attributes may include scale, temporality, continuity, economy, and technology. They may also be expanded to include the process and the product characteristics of built environments ranging from the identity of the designers and their interest on one hand to the degree of cultural specificity and morphological integration on the other hand (Rapoport 1989). The term traditional has almost always been seen as the opposite to the modern. Hence, in the view of some, it is not uncommon to view the traditional as being precontact and preliterate. This view, however, does not take into account how traditions emerge.

An important concern that lies at the heart of studying traditional dwellings and settlements is the common mistaken assumption that such built environments mainly exist in the Third World. It is interesting to note that those who study such places almost invariably do so by going elsewhere rather than looking at home. The Eurocentric view that modernity is fundamentally a Western project created an unjustified duality between the developed and the developing worlds when it came to viewing built environments. Begun earlier under British and French colonial rule, the "respect for the native" and the discussion around "traditional" forms was the outcome of the romanticism attached to the exercise of imperialism. Hence, modern was equated with Western, which has lead to an ongoing nostalgia particularly in the West for "authenticity" and "tradition" (Abu-Lughod 1995: 7–10). Similarly, this romantic view of traditional dwellings and settlements has led those who study and admire them to call for their preservation. But in many Third World societies, the rejection of the so-called traditional way of life should be seen as a natural evolutionary or reactionary process as opposed to a destructive one.

It has also been argued that the categorization of buildings and settlements into a "traditional" category has been a deliberate exercise on behalf of the community of architectural researchers. The idea of the architect as an aesthetic expert depended on distinguishing between professionally designed, aesthetically pleasing architecture, and the mundane structures produced by the masses for purely functional uses. Today, the search for the "traditional" must be seen through the need for differentiated products in a postfordist era. New movements in architectural practice such as New Urbanism attempt to use vernacular and traditional forms as a means of creating a sense of community by creating highly coded and zoned communities that reflect a continuity with the past. Designs borrowed from the traditional homes of the American South, for example, are used to invoke a sense of history. Here, the idea of invented tradition becomes intricately linked to the sense of identity and heritage that a community wants to project to outsiders. Poundbury, an experiment in town planning and architecture undertaken by the Prince of Wales, is a good example of this trend, produced under the belief that the best of architectural progress can be achieved by simply remaking new buildings in a traditional garb. Among the criticisms leveled at Poundbury has been the accusation of it being un-modern and nostalgically harking back to a past. Its praises have included the sentiments of its residents decrying contemporary architecture as being alienating and out of touch with the needs and aesthetics of the common people.

Today, and in many parts of the Third World following independence, many of the former colonies engaged in the exercises of modern nation-building. Their attempt to articulate a unique national identity became an important requirement for maintaining sovereignty. Traditions, whether new or invented, became part of a nation's identity and of the character of its physical spaces allowing these nations to create markers of uniqueness in an increasingly diversifying and competitive world.

One important cause of debates around using tradition as a means for designing and maintaining buildings and settlements has been the rise of global tourism. Some have argued that modernity depends in its very essence on instability and inauthenticity. For moderns, authenticity is thought to be elsewhere – in other historical periods and other cultures, in purer, simpler life-styles. The need for people to overcome the discontinuity of modernity materializes in their desire to see the authentic, the primitive, and the historical. In many instances, this desire materializes in the form of visiting the spaces of the "authentic" or "primitive" people and to view their ways of life (MacCannell 1976).

The search of tourists for authenticity and traditional lifestyles has become an important means by which countries and localities are able to generate substantial incomes. The preservation of traditional dwellings and settlements hence is not only a means of constructing local and national identity, but has emerged as an important mechanism to survive within the global economy. In this sense, "tradition" fulfills the multiple roles of identity creation, economic stimulus, and in some cases a tool for physical development.

Finally, the discussions about the consumption of tradition and the manufacture of heritage in a global era have led to calls for the end of tradition (AlSayyad 2001, 2004). Tradition, however, does not end. What may have ended, however, was our conception of it as a reservoir for revered authentic values. Today tradition may be found not only in real places but equally in the simulated and virtual world we inhabit. Tradition in built form will always be what we make and sustain everyday and everywhere through the occasionally contemptuous and ever-changing act of living.

Dyeing: Indigo Dyeing in Sierra Leone

Cyrus Macfoy

Although many crops have played colorful roles throughout history, indigo appears to be the most colorful. Dyeing with indigo can be traced as far back as 7000 BCE, and is still widespread even today. This form of dyeing using various plant species is practiced in many countries and continents throughout the world, for example, in Mexico, Europe, Egypt, West Africa, Sumatra, Central Asia, Japan, the Americas and China (Adrosko 1968; Fox and Pierce 1990; Pettit 1974). Ancient Britons and other Europeans obtained the dye from *Isatis tinctoria* (woad) but later *Indigofera* from India and other Eastern countries. *Indigofera tinctoria* is native to India and Africa, while *Indigofera anil* of Central and South America, and *I. suffructicosa* is a native tropical American species adopted in Africa (Pettit 1974). Indigo is a vat dye (Vat Blue1), produced without mordants by a process consisting of a complex series of chemical reactions for the dye to be successful. A lot of care and patience is required. It shows fastness to light and water, it is insoluble and will dye all types of fibers (Adrosko 1968).

Now synthetic indigo used to dye blue jeans has almost totally replaced the natural one in most societies. This is because it is thought that synthetic indigo is cheaper to produce and more uniform in concentration than natural indigo. Natural indigo tends to be used today primarily by artists and craftsmen producing specialty products and by those dyers involved in textile conservation or historical recreation, or on ceremonial occasions notably weddings and funerals, and in traditional medicine (Abbiw 1990; Balfour-Paul 2001). These days some add a few crystals of synthetic indigo to the final dye in order to darken the hue.

Indigo dyeing using the plant species *Lonchocarpus cyanescens* or *Indigoferrra suffructicosa,* or other *Lonchocarpus* and *Indigoferra species,* such as *I. tinctoria* and *I. arrecta* all of which grow wild, were the most common and popular sources of color throughout West Africa (Polakoff 1982). Both Anglophone and Francophone countries were quite active in this indigenous technology, e.g. Mali, Nigeria, Senegal, Guinea, Gambia, Liberia, and Ivory Coast. Research on excavations from caves in Mali has shown that the indigo dyed cotton garments dated between the eleventh and the sixteenth centuries, indicating that by the eleventh century, weaving and indigo dyeing had already reached a high standard in West Africa. Many of the tie-dye designs found are similar to those still in use today (Balfour-Paul 2001).

Though the process is quite arduous, it provided a rich color usually missing in synthetically dyed fabric. The basic method of dye production is quite similar throughout the West Coast of Africa with some variation (Polakoff 1982).

In Sierra Leone, the word *gara* was once reserved only for indigo dyeing, but now it is used more widely for any form of dyeing, natural or synthetic. Since the 1960s, when commercial dyes started to be imported into the country from Germany, U.K. and Nigeria, various colors (violet, green, blue, red, brown, mauve, yellow etc.) became available in the market, apart from the blue "gara" color. The preparation of the commercial dyes and their application are far less complex and less time-consuming, but they are more expensive. Thus an improvement of the local natural dyes industry, taking due cognizance of the environment, will be invaluable in reducing the price. This latter unfortunately is now rarely used except by a few traditional dyers.

The gara industry, a local craft industry, has expanded over the years, giving an additional sense of economic satisfaction and self worth to these mainly female entrepreneurs who are self-employed. On occasion, men and children are also involved in the industry. Some gara dyers are full-time employees in other establishments but do the gara dyeing on a part-time basis. Some have even been trained at the Crystals Youth Club, a vocational center in Freetown. Other centers in different parts of the country include those sponsored by World Vision programs funded by the Canadian International Development Administration (CIDA) (CIDA Update 2001); CADS i.e. Center for Alternative Development Strategies for training and production of dyed goods; United Nations Mission in Sierra Leone (UNAMSIL) Trust Fund for training; Commonwealth Human Ecology Council who funded a gara project; and the Christian Reformed Church of North America. These regard the art of gara dyeing as more than a craft; it signifies hope. Displaced women as a result of the civil war, combatant girls and women have all benefited from such income generating tie-dye and batik training *inter alia.* Some non-governmental organizations (NGOs) have initiated microcredit schemes of which gara dyeing is one of the most commonly supported, but availability does not satisfy demand (Walker 1997). Since 80% of the dye producers are women and 95% of their raw materials imported, improvements of this dyeing technology will inevitably help improve the status of women and the environment.

Whatever the source of the dye, the beauty of the finished products obtained gives a great sense of pride and satisfaction to the dyers. This is more so with natural dyes since it gives some kind of connection to nature. Although attempts have been made to develop other colors such as green, brown and pink from local plants, these have not been followed up, mainly because of time and labor constraints.

Gara dyers also frequently investigate by trial and error. Innovative dyers sometimes investigate different types of fabrics, e.g. cotton, wool, polyester, viscose and rayon, rugs; different combinations of plants, and color fastness. Some even investigate adding the dye at various stages in the production of a garment (to fiber before it is spun, to yarn before it is woven or knitted into a fabric, or to the finished fabric or garment).

Even though there is tremendous usage and potential for development, especially for a country just coming out from a ten-year war, very few research investigations have been conducted in Sierra Leone on dyes, apart from reporting the methods used for indigo dyeing (Cole and Hamilton 1978; Crystal Youth Club 1985) and preliminary laboratory work on "gara" leaves (Wright and Cole 1988). In view of this paucity, further work on various plant species has however been conducted by MacFoy, Pratt, McEwen and Johnson at Fourah Bay College, University of Sierra Leone; and by MacFoy in the U.K. and USA.

Some of the results obtained from this work are reported in detail elsewhere (MacFoy 2003, 2005) on the ethnobotanical survey of the natural dyes used in Sierra Leone and on the history of indigo dyeing. In this West African country there is a wide gap between the rich and the poor and this latter group could benefit immensely from the development of natural dyes as a source of income generation. This research involved interviewing dyers, surveying the literature, cataloguing and collecting the plants used for preparing the dyes, obtaining knowledge of how the dyes are produced and the fabric dyed, and botanical identification of the plants.

Process for Indigo Dye Production and Dyeing of Fabric

This indigo dye is the most common natural dye in Sierra Leone, and several methods (seven identified in this study) are used with varying degrees of similarities for its production and subsequent use in fabric dyeing. In general, they involve production either from fresh leaves in the dyepot, leaf fermented into leaf balls but dye not extracted, indigo dye extracted into an insoluble lump, or use of the synthetic dye. In some cases up to four other plant species are added to the dye bath, for example, *Morinda germinata* (wanda) roots, and *Cola nitida* fruits (cola), *Mangifera indica*, *Rhizophora recemosa, Jatropha curcas* (fignut), *Capsicum frutescens* (pepper); and caustic soda (sodium hydroxide), which creates an alkaline pH environment for the fermentation to proceed from 3–7 days; local alum or ash from the 'Kobe' tree (*Sterculia tragacantha*); a black powder called colmet. Rusty nails or metal cups, or *Alchornia cordifolia* (Christmas bush) are also sometimes added to darken the shade. Another method involves mixing the indigo dye with sodium hydroxide (caustic soda) and sodium hydrosulphite in a ratio of 1:1:1 in water.

Dyeing is achieved by first washing the fabric with soap and water and then immersing the cloth (a special white fabric called bryleon of varying quality, or poplin (cotton/polyester) in the dye for different periods of time (sometimes varies from hours to 3–4 days) drying, dipping again, drying and so on, until the desired shade is obtained. After this, the dyed fabric is washed, dried in the sun and ironed by traditionally pounding with a stick on a wooden slab to produce a glossy shine on the cloth or by using other modern forms of ironing.

Pattern Production

Apart from dyeing the whole material uniformly, various patterns can be produced by dyeing only parts of the fabric, leaving the remainder undyed. These methods are known as sewing, tie-dyeing, knotting, folding, and resist dyeing or the use of candle wax/batik.

The full details of these are reported in MacFoy 2005.

It is clear from the above that natural dyes have a tremendous potential in Sierra Leone and other developing countries. There is a high demand for natural dyes in textile dyeing and in the food, beverage and cosmetics, paper and pulp industries in the US, Europe and Japan. Natural dyes can also serve as useful materials for teaching and experimenting in Adult Education Programs, and in schools and colleges.

Apart from dyeing fabrics, the colors obtained from the natural dyes could also be used as watercolors on paintings by making them thicker as well as experimenting on them for their use as food colorings, biological stains, inks, hair dyes, indicators in titration, in addition to their use in soaps, photography, paper, leather, medicine, eggs, plastics, rubber, automobile finishes, cosmetic industries, rugs, and table mats. Natural dyes can also be used to redye old clothing.

Dyes

MURDO J. MACLEOD

The human urge to paint the body with symbolic, warlike, or identifying colors may have been among the earliest impulses which led to the discovery of color-yielding clays and plants. The dyeing of human clothing followed. Encounters, both warlike and peaceful, between groups then led to the identification of certain colors with specific regions or groups of producers, and exchanges began. This specialization and trade eliminated many of the poorer dyes of prehistoric times, which may have numbered many hundreds, and by the time recorded history took note of dyes only a relative few still saw widespread use.

Dye exchanges at first were very local. The major ones in ancient times were usually confined to the great areas of early culture and urbanization such as China, northern India, and the eastern Mediterranean. Later, trade in dyestuffs became more long distance, and, with European intrusions into Asia and invasion of the Americas, transoceanic and worldwide. This huge trade in natural dyes was destroyed and again reduced to a local level by the invention of coal tar or aniline dyes and other chemical dyes, in the mid-nineteenth century.

The production and exchange of colorants were always associated with certain other industries. Cloth manufacture and weaving were certainly the main ones. Others arose out of the limitations of some natural dyes. Many were not "fast"; i.e., they tended to fade or discolor when exposed to light, frequent washing, or wear and tear. Accordingly, much effort was historically expended in the search for mordants (dye fixers). Many of these were readily available, such as blood, dung, or urine. Various acids, alkalis, and wetting agents were widely used. Alum, an astringent, was probably the most common, and large cargoes were mined and shipped to dye factories and market towns. Minerals such as copper, tin, and iron also came to be used for mordanting, and thus added to the importance of mining for these minerals. Tree-borne dyes led to forest cultivation and above all, to extensive and destructive logging industries. The dye-yielding attributes of plants such as indigo stimulated the creation of plantation complexes.

The production of natural dyes and their use in dyeing textiles were often complicated skills requiring apprenticeships and years of training. Certain towns became known as dye centers or markets, such as ancient Tyre or medieval Venice in the Mediterranean, or Oaxaca in colonial Mexico. Guilds of dyers and castes devoted to weaving and dyeing were of considerable importance in European and Indian societies from medieval times.

Before European intrusion reached sub-Saharan Africa, Asia, Australia, and the Americas, there were several dyes which were produced and distributed over large areas. Perhaps the best known of the early root dyes was madder (from the Rubiaceae, of which there are over 30 species). *Rubia tinctorum* roots were used to obtain red dye in India, and were also known to the ancient Persians, Egyptians, Greeks, and Romans. For centuries Baghdad was the center of the madder trade, and it was cultivated extensively – rather than gathered as elsewhere – in Mesopotamia. After its use spread to Western Europe, the Dutch became the most systematic and scientific madder growers, combining it with their leading role in cloth making (wool) and cloth importing (silks and linens). The French began to compete in the eighteenth century, but the French revolution damaged the industry and it never revived.

Before the European expansion, the most widely used dye made from plant leaves was woad (*Isatis tinctoria* of the Cruciferae family). It yielded various blues and grays. Although easy to produce in the temperate areas of Europe and Asia, it was not a very brilliant or fast dye. Woad in medieval and early modern Europe was manufactured and marketed by powerful guilds which – by monopolies, boycotts, and powerful legislation – managed to prevent large-scale intrusions of other blues, especially indigos, from America and Southeast Asia, until the seventeenth century.

The leading dye made from woad has always come from brazilwood (*Caesalpinia echinata*), although many other trees such as lima, sapan, and peachwood, all soluble redwoods, are often lumped together as brazilwoods. These medium-sized trees have been widely used for dyestuffs in many parts of the world. They are cut into small logs, ground to powder, then soaked and fermented, often with an aluminum or other metal ore mordant. They yield reds and browns, except on silks. Before the sixteenth century, India, Sumatra, and Ceylon (Sri Lanka) were the main producers. Other woods, such as camwood from India, which imparted a rough feeling to cloth because of its resins, were also traded. Cutch or kutch, a brown dye, has been manufactured in India for over 2,000 years and comes from the leaves and twigs of various acacia and mimosa trees.

Humans have elaborated dyes from the bodies of insects and animals for millennia. The most expensive, prestigious dye of ancient times was Tyrian purple. It was manufactured in Crete by 1600 BCE, but is usually associated with the Phoenicians. Tyre became the great market center for this dye until captured by the Arabs in AD 638. Phoenician traders had spread its use all over the Mediterranean. It was so rare and costly that in many areas this fast, blue to purple dye was restricted to the clothing of high ecclesiastics, the aristocracy, or simply the ruling family. This colorant is extracted from a gland found in several shellfish, most notably *Murex trunculus*. A few similar dyes were used in the Americas before and after the European invasions, especially in Nicoya (Costa Rica) and on the Peruvian coast, but the American sources never produced enough dye to be of importance beyond local markets.

Insects have also been significant to the natural dye industry. Kermes is the oldest and most widespread of these dyestuffs. The insects harvested, *Coccus arborum* and *Coccus ilicis*, live on the holm oak (*Quercus ilex*), the shrub oak (*Quercus coccifera*), and a few other trees. Kermes is Armenian for “little worm” and is a scarlet dye. It is mentioned in the Old Testament and in the writings of ancient Greece, but its origins are probably Asiatic and it was much used in India.

The European invasions of South and Southeast Asia and of the Americas greatly changed dye usage by bringing new and better colorants into the international markets. Indigo, which produces a range of blues, became for about two centuries the most important of all dyestuffs. It is a vegetable dye of considerable fastness, and has been known in parts of Asia for over 4,000 years. *Indigofera tinctoria*, of which only the leaves bear dye, is of the order *leguminosae*, and belongs to the pea family. It was found in India, Southeast Asia, Africa, and America. It has been discovered in both Egyptian and Inca tombs, and its continent of origin is obscure.

Dutch ships carried indigo throughout the Indian Ocean, and then, in the seventeenth century, to Europe, where, despite a struggle, it eventually displaced woad. Bengal supplied large quantities in the late eighteenth century to the British textile industry. When American indigo, mostly produced in Central America, the Carolinas, and Georgia, began to flood the market in the eighteenth century, the woad industry collapsed in the face of this cheaper and better dyestuff.

Cochineal, a scarcer and more expensive dye, had a similar history. It is made from an American insect, *Coccus cacti*, which feeds on a cactus (*Nopalia* or *Opuntia cochinellifera*), and was used in Mesoamerica, especially in the Oaxaca region, long before the Europeans arrived. While its production is elaborate and costly, the result is a superior scarlet or crimson dye, and it soon replaced kermes in Asian and European markets and dyeworks. After bullion it was the most expensive item carried by the Spanish treasure fleets.

The brazilwood industry grew after the products of the American continents began to enter world commerce. Vast new stands were found in Brazil – hence the name – and to this was added logwood or campeachy wood, a large, tropical American tree (*Haematoxylon campeacheanum*) found especially in Campeche, Tabasco, and Belize. It yields black or blue dyes, plus edible seeds called *allspice*. By the seventeenth century it was in use in Africa and Europe.

One crop from America moved to Asia. Annato (*Bixa orellana*) was used by Mesoamerican peoples largely as a food additive and colorant, but when taken to Southeast Asia and India this dye, which is a poor, fugitive yellow to red, was used for cloth, especially monks' robes. It is so culturally accepted in these regions today that many writers describe it as indigenous.

The new dominance achieved by Asian and above all American dyes such as indigo and cochineal, both of which were spread by European expansion, lasted less than two centuries. They, in their turn, were overwhelmed by the new coal tar or aniline dyes invented in the mid-nineteenth century. Many of the natural dyes, however, remain in use in local and peasant economies.

East and West

Edwin J. Van Kley

As traditionally used in the West, the terms East and West imply that the two are somehow of equal importance. While that might be arguable in the nineteenth and twentieth centuries it was certainly not true during the long reaches of human history prior to the nineteenth century. By 500 BCE the globe supported four major centers of civilization: the Chinese, the Indian, the Near Eastern, and the Western, considering Greek culture antecedent to what eventually became the West. Of the four the West was probably the least impressive in terms of territory, military power, wealth, and perhaps even traditional culture. Certainly this was the case after the fall of the Roman Empire in the fifth century AD. From that time until about AD 1500 the West probably should be regarded as a frontier region compared to the other centers of civilization.

From roughly 500 BCE to AD 1500 a cultural balance was obtained between the four major centers of civilization. During these millennia each center continued to develop its peculiar style of civilized life, and each continued to spread its culture and often its control to peoples and lands on the periphery. While the inhabitants of each center of civilization were aware of the other centers, sometimes traded with them, and occasionally borrowed from them, the contacts were sufficiently thin so that no one center threatened – commercially, militarily, politically, or culturally – the existence of the others. During this long period, that is through much of civilized human history, there was no question of Western superiority or hegemony. No visitor from Mars would likely have predicted that the West would eventually dominate the globe.

Obviously the Greeks and Romans knew quite a bit about the Near-Eastern world, especially about the Persian empire, that of Alexander the Great, and the successor states formed after its collapse. About India and China they knew much less, and what they knew was much less accurate. Although Herodotus (ca. 484–425 BCE) reported some things about India, most of the information available to the Greeks came from the writers who described Alexander's campaigns in the Indus Valley (326–234 BCE) and from Megasthenes. They described India as fabulously rich, the source of much gold and precious stones. It was hot; the sun stood directly over-head at midday and cast shadows toward the south in summer and toward the north in winter. They described huge rivers, monsoons, tame peacocks and pheasants, polygamy, and the practice of *suttee* (widow burning). However, they also reported fantastic things such as gold-digging ants, cannibals, dog-headed people, and people with feet so large that they served as sun shades when sitting. The Romans knew that India was the source of spices and that China, which they called Serica and well as Sinae, was the source of silk. There are even possible traces of Asian influence in some Roman silver and ivory work and perhaps even some influence of Buddhism on Neo-Platonism and Manichaeanism.

From about the fourth century, even before the fall of the Roman empire, until the return of Marco Polo from China in the late thirteenth century, Europe or the West added little factual information to its understanding of India and China. After the fall of the Roman empire there was no direct trade between Europe and Asia, and thus there were no opportunities to test the stories by observation. The rise of Islam in the seventh and eighth centuries completed Europe's isolation. During these centuries the old stories inherited from the Greeks were retold and embellished with little effort to distinguish fact from myth. To these were added three legends of more recent origin: the stories celebrating the heroic exploits of the mythical Alexander; those rehearsing Saint Thomas the Apostle's missionary journey to India and his subsequent martyrdom; and those describing the rich, powerful, Christian kingdom of Prester John somewhere to the east of the Islamic world with which European rulers dreamed of allying against the Muslims. Even the trickle of precious Asian products brought to Europe by intermediaries seemed only to confirm the image of Asia as an exotic and mysterious world, exceedingly rich and exceedingly distant.

The rise of the Mongol empire in Asia during the thirteenth century resulted in direct overland travel between Europe or the West, and China. The Mongols' success also revived hopes among European rulers of finding a powerful ally to the east of the Muslims. Even the devastating Mongol incursions into Poland and Hungary in 1240 and 1241 scarcely dampened their enthusiasm. Already in 1245 the pope sent an embassy led by John of Plano Carpini to the Mongol headquarters near Karakorum. He was followed during the ensuing century by a fairly large number of envoys, missionaries, and merchants, several of whom wrote reports of what they saw and did in Eastern Asia. Marco Polo's was the most comprehensive and reliable, and the most widely distributed of the medieval reports. By the time the Polos first arrived at Kublai Khan's court in 1264 it was newly established at Cambaluc (Beijing), from which the khan ruled the newly conquered Cathay (China). Like many other foreigners during the Mongol period (the Yuan Dynasty in China, 1260–1368) the Polos were taken into the khan's service. They were employed in the Mongol administration for 17 years during which time Marco traveled extensively throughout China. On his return to Europe he produced the first detailed description of China in the West based primarily on first-hand observation and experience. No better account of China appeared in Europe before the middle of the sixteenth century. Marco Polo described China as the wealthiest, largest, and most populous land in the thirteenth-century world. While his understanding of Chinese culture was minimal he accurately and admiringly described cities, canals, ships, crafts, industries, and products. He noted the routes, topography, and people encountered in his travels, including his voyage home through Southeast Asia to Sumatra, Ceylon and along the west coast of India.

The decline of the Mongol empire and the establishment of the Ming Dynasty in China in 1368 severed the direct connection between Europe and China. The fall of Constantinople in 1454 and establishment of the Turkish empire in the Near East disrupted the older connections between Europe and the near East and India. Europe's isolation from the outside world was complete, not to be restored until the opening of the sea route around the tip of Africa in the waning years of the fifteenth century. During this period no European appears to have traveled to China. Some few travel reports refer to India and Southeast Asia. Of them only that written by the humanist Poggio Bracciolini in 1441 and based on Nicolò de Conti's travels added to the West's store of knowledge about India and confirmed some of the more accurate of the ancient Greek reports. In fact amid the Renaissance humanists' enthusiasm for the rediscovery of ancient Greek literature, the Greek reports of India received new respect and attention.

During the long era of cultural balance before AD 1500 many important technological and scientific inventions and innovations appear to have migrated to the West from the other centers of civilization, more often from China than from the others. The migration of technology was usually gradual, involving one or more intermediaries, the inventions usually being established in the West without any clear ideas about their origins. Much of the basic technology that enabled the Europeans to sail directly to Asia in 1500 and later to begin their march towards global domination, was known earlier in the Asian centers and only later adopted or separately invented in Europe.

Among the more important technological borrowings were gunpowder, the magnetic compass, printing, and paper, all apparently originating in China. For none of them is the path of migration entirely clear, and thus for none of them can the possibility of independent invention be entirely ruled out. Gunpowder, for example, was known in China by 1040 and did not appear in Europe until the middle of the thirteenth century. The magnetic compass was fully described in an eleventh-century Chinese book, *Meng Qi Bi Tan* (Dream Pool Essays), written by Shen Gua in 1088. It began to be used in Europe during the late twelfth or early thirteenth century. Most likely Europeans learned about it from the Arabs. The case for moveable-type printing having been borrowed from the Chinese is more hotly debated than that for gunpowder or the compass. Wood-block printing was used in China by the seventh century, and paper was invented much earlier; the first printed books appeared there during the ninth century, six centuries before the invention of printing in the West by Johannes Gutenberg in 1445. Block printing probably became known in Europe through the introduction of printed playing cards and paper money during the Mongol period; medieval travelers frequently mentioned these. Because of the large number of Chinese characters the Chinese continued to prefer printing from page-sized blocks of wood carved as a single unit; European printing almost immediately employed moveable type, thus convincing some scholars that it was a separate invention. However, while they may have preferred block printing the Chinese also developed moveable type as early as the eleventh century. For none of these basic inventions taken separately – gunpowder, the compass, and printing – is the case for its diffusion from China to Europe indisputably demonstrated. Taken together, however, along with a rather large number of other technological and scientific innovations such as paper, the stern-post rudder, the segmented-arch bridge, canal lock-gates, and the wheelbarrow, which all appear to have migrated from China to the West, it becomes apparent that the general flow of technology and science in premodern times was from East to West. This would seem to increase the likelihood that these basic innovations also migrated to Europe from Asia. Those who used the technological innovations probably cared little about their ultimate origin and apparently did not seek it out. Nevertheless European mariners after 1500, confronted first hand with evidence that printing, gunpowder, the mariner's compass, and the like had been in use much longer in Asia than in Europe, frequently suggested that they had been borrowed from the Asians.

Even before gunpowder a group of military innovations found their way to Europe from China and India, again through intermediaries and apparently without Europeans' being aware of their origins. The Chinese form of the Indic stirrup was the most important of these and may have been as important to military development in the eighth century as gunpowder was later. The Javan fiddle bow and the Indian Buddhist pointed arch and vault were acclimated in Europe before 1100. The traction trebuchet along with the compass and paper appeared in the twelfth century. Still more important for subsequent Western scientific achievements was the adoption of Hindu–Arabic mathematics in the twelfth and thirteenth centuries: the Indian system of arithmetical notation, trigonometry, and the system of calculating with nine Arabic numbers and a zero were all practiced in India as early as AD 270. Some components of Indian mathematics may have come from Babylonia or China. They came to Europe, however, through the translation of Arabic writings, and the European borrowers usually credited India rather than China, Babylonia, or the Arabic intermediaries as the source of the new mathematics. Along with Indian mathematics, Europeans learned some elements of Indian astronomy and also became fascinated with the Indian idea of perpetual motion.

Also before 1500, Europeans sometimes attempted to imitate desirable Asian products, not always successfully. Already in the sixth century the Byzantine emperor Justinian monopolized the silk trade in his realm and expressed his determination to learn the secret of its manufacture. In 553 a monk supposedly smuggled some silkworm eggs into Constantinople carrying them in a hollow stick, perhaps of bamboo. Nothing is said in the story about the importation of silk technology, but less than a century later sericulture had obviously taken root in Syria. From there it spread to Greece, Sicily, Spain, Italy, and France. In Italy during the fourteenth century, water power was used in silk spinning, as it had been used in China much earlier. Attempts to imitate Chinese porcelain, however, were unsuccessful. The best attempts to do so were made in northern Italian cities during the fifteenth century. None, however, approached Chinese porcelain in composition, color, or texture. Nor did the Dutch Delftware of the seventeenth century, another attempt to imitate the Chinese product. Not until the eighteenth century were European craftsmen able to produce a hard-paste porcelain to rival that of China. Also appearing in Europe before 1500 were less important devices or techniques such as the Malay blowgun, playing cards, the Chinese helicopter top, the Chinese water-powered trip-hammer, the ball and chain governor, and maybe Chinese techniques of anatomical dissection.

While impressive, the West's importation of Asian science and technology before 1500 in no way deflected Western culture from its traditional paths. Seldom was the provenance of the new inventions or techniques known, and they could all rather easily be incorporated into the traditional Christian European world-view. They did not provoke any serious questions about the European way of life, its religious basis, its artistic and cultural traditions, or even its traditional scientific views. This is also true for the artistic and cultural borrowings from Asia prior to 1500. They too were often unconscious, and even when they were not they were regarded as embellishments or decoration, rather than in any way a challenge to traditional themes. For example. the incorporation into the Christian calendar of Saints Baarlam and Josephat, derived as they were from stories of the life of Buddha, resulted not in a Buddhist challenge to the Christian faith but simply in the addition of two new saints to the growing Christian pantheon.

Nevertheless, the borrowing and adaptation of Asian science and technology by the West before 1500 was indispensable in making the long overseas voyages to Asia and the protection of the ships and shore installations possible. Without gunpowder, cannons, the compass, the stern-post rudder, etc. there would have been no European expansion. While they had lagged well behind the other centers of civilization through most of civilized history, by 1500, European marine and military technology were beginning to equal that of the Near East. India, and China, and were obviously superior to that of the peripheral areas of Africa, Southeast Asia, and the Americas. The Portuguese voyages down the coast of Africa and Columbus' voyage across the Atlantic attest to Europe's rapidly improving technology.

A small Portuguese fleet under Vasco da Gama reached Calicut on the Malabar Coast of India in 1498, thus establishing direct contact between Europe and Asia by sea and also inaugurating a new era in the relationships between the four major centers of civilization on the globe. Soon after 1500 the Europeans began to dominate the seas of Asia, the Portuguese in the Indian Ocean being the first. The Portuguese, and later the Dutch and the English, moved along sealanes, visited seaports, and fitted into a trading world which had been developed earlier by Muslim traders and which stretched from eastern Africa to the Philippines. As the Europeans at first tried to compete in that world and later tried to dominate and even to monopolize it, they found Muslim merchants and merchant-princes to be their most formidable opposition. That they were able to move so rapidly and effectively into that international trading system was due not so much to their superior technology and fire-power as to the fact that the great Muslim empires of the sixteenth century – the Ottoman Turkish, the Safavid Persian, and the Mughul in northern India – seem to have been too busy consolidating their newly won empires to contest the European intrusion. These Muslim empires, as well as the Southeast and East Asian empires of Siam, Vietnam, China, and Japan had all as a matter of governmental policy turned away from the sea and looked inward to control of their land empires and to land taxes as the source of their wealth and power. Had any or all of these major Asian and Near-Eastern states seriously resisted the western incursion the story might have had a different conclusion. Apart from Muslim traders in the Indian Ocean those who formidably opposed European power in the sixteenth and seventeenth centuries were small Muslim commercial port-city states like Makassar on Celebes and Aceh on Sumatra. The Mughul emperors in northern India usually allowed the Europeans to trade freely in their ports, often exempting them from customs duties. Apart from the illegal but locally tolerated Portuguese settlement in Macao the Europeans were not permitted to trade in China at all. China briefly contested Dutch maritime power only in 1624 after the Dutch had spent 2 years raiding the coast of Fukien Province, burning villages, seizing junks, enslaving their crews, and constructing a fort on one of the Pescadores Islands; all in an effort to force the Chinese to allow them to trade freely at some port along the Chinese coast. Confronted with a full scale Chinese war fleet the Dutch commander hastily sued for peace and gratefully accepted the Chinese admiral's offer to let the Dutch trade on Formosa, which was not yet considered Chinese territory. From 1500 until about the middle of the eighteenth century the Europeans were able to carve out empires in the Americas, insular Southeast Asia, and the Pacific Islands, but they did not threaten the major centers of civilization in Asia.

During the first three centuries of direct maritime contact between Europe and Asia (1500–1800) the Westerners showed little sense of cultural superiority toward the high cultures of Asia. If anything they tended to exaggerate the wealth, power, and sophistication of the other centers of civilization. Most Europeans were confident that Christianity was indeed the true religion, and they quickly began to send missionaries to convert Asian peoples. By 1600, if not earlier, they were also justifiably confident that European mathematics, science, and technology were superior to that of the Asians. Those areas aside, however, Europeans were endlessly fascinated with what they discovered beyond the line and realized that they still had much to learn from the high cultures of Asia. Between 1500 and 1800 the currents of cultural influence continued to flow mainly from east to west, but during this era the impact of Asia on the West was usually more conscious and deliberate than previously, and it was primarily in areas other than science and technology.

The new seaborne commerce with Asia almost immediately brought greatly increased quantities and varieties of Asian products into Europe. Pepper and fine spices were the first to appear on the docks in European ports, but they were soon followed by such goods as Chinese porcelain and lacquerware, tea, silks, Indian cotton cloth, and cinnamon. Following these staples of the trade came also more exotic products: Japanese swords, Sumatran or Javanese krisses, jewelry, camphor, rhubarb, and the like, the list is very long. Some of these products, such as tea, provoked striking social changes in Europe. Attempts to imitate others resulted in new industries and in new manufacturing techniques, Delft pottery in imitation of Ming porcelain, for example. Attempts to compete with cheap Indian cotton cloth seem to have touched off a technical revolution in the British textile industry which we customarily regard as the beginning of the industrial revolution.

Along with the Asian products came descriptions of the places and peoples who had produced the products. The earliest sixteenth-century descriptions usually seem designed to inform other Asia-bound fleets about the conditions of trade. After Christian missions were established they were often intended to elicit support for the missionaries. However, before long the travel tales and descriptions became popular in their own right and profitable to publish. During the seventeenth century what had been a sizeable stream of literature about Asia became a veritable torrent. Hundreds of books about the various parts of Asia, written by missionaries, merchants, mariners, physicians, soldiers, and independent travelers were published during the period. For example, during the seventeenth century alone there appeared at least 25 major descriptions of South Asia, another fifteen devoted to mainland Southeast Asia, about twenty to the Southeast Asian archipelagoes, and 60 or more to East Asia. Alongside these major independent contributions stood scores of Jesuit letterbooks, derivative accounts, travel accounts with brief descriptions of many Asian places, pamphlets, newssheets, and the like. Many of the accounts were collected into the several large multivolume compilations of travel literature published during the period. In addition to the missionaries accounts, travel tales, and composite encyclopedic descriptions, several important scholarly studies pertaining to Asia were published during the seventeenth century: studies of Asian medicine, botany, religion, and history; and translations of important Chinese and Sanskrit literature.

The published accounts range in size from small pamphlets to lavishly illustrated folio volumes. They were published in Latin and in almost all of the vernaculars, and what was published in one language was soon translated into several others, so that a determined enthusiast could probably have read most of them in his own language. They were frequently reprinted in press runs which ranged from 250 to 1,000 copies. Five to ten editions were not at all uncommon, and some of the more popular accounts would rival modern "best sellers." In short the Early Modern image of Asia was channeled to Europe in a huge corpus of publications which was widely distributed in all European lands and languages. Few literate Europeans could have been completely untouched by it, and it would be surprising if its effects could not have been seen in contemporary European literature, art learning, and culture.

From this literature European readers could have learned a great deal about Asia and its various parts. Perhaps most obviously their geographic horizons would have been continually expanded. Gradually Europeans gained accurate knowledge about the size and shape of India, China, and Southeast Asia. During the seventeenth century, for example, several puzzles which had plagued earlier geographers were solved: for example, the identification of China with Marco Polo's Cathay, the discovery that Korea was a peninsula and Hokkaido an island. By the end of the century Europeans had charted most of the coasts of a real Australia to replace the imagined antipodes as well as those of New Guinea, the Papuas, numerous Pacific islands, and parts of New Zealand. Interior Ceylon and Java, as well as Tibet were visited and accurately described by Europeans before the end of the century. By 1700 only areas of continental Asia north of India and China, the interior of Australia, New Zealand, and New Guinea and parts of their coastlines remained unknown to the Europeans. Most of these lacunae were filled during the eighteenth century. Even more impressive than the greatly expanded geographic knowledge available to European readers in early modern times was the rapidly increasing and increasingly detailed information about the interiors, societies, cultures, and even histories of Asia's high cultures. Already during the seventeenth century European readers could have read detailed descriptions and even viewed printed cityscapes and street scenes of scores of Asian cities, interior provincial cities as well as capitals and seaports, and they could have learned countless details about Asia's various peoples, their occupations, appearance, social customs, class structures, education, ways of rearing children, religious beliefs, and the like. Details regarding Asia's abundant natural resources, crafts, and arts were described as well as its commercial practices and patterns of trade. Asian governments were described in exceedingly close detail, especially for major powerful states such as China, the Mughul Empire, Siam, and Japan. Jesuit missionaries in China, for example, described the awesome power of the emperor, his elaborate court, the complex imperial bureaucracy and its selection through competitive written examinations, and the Confucian moral philosophy on which it was all based. They also described the frequently less orderly and less savory practice of Chinese government, complete with detailed examples of officials' abuse of power and competing factions within the administration. Similar details were reported for the governments of all the major states as well as for countless smaller states. By the end of the seventeenth century European observers had published many sophisticated accounts of Asian religions and philosophies; not only the frequently deplored Hindu "idolatry" and widow burning, but also the Hindu world view which lay beneath the panoply of deities and temples, the various schools and sects of Hinduism, and the ancient texts of Hindu religion. Similarly sophisticated and detailed accounts of Confucianism and Buddhism were available, as well as descriptions of the beliefs of peoples like the Formosan aborigines, the Ainu of Hokkaido, and the inner Asian and Manchurian tribes. Seventeenth and eighteenth-century readers could also have learned much about Asian history; especially, but not exclusively, that of Asia's high cultures. By the mid-seventeenth century, for example, a very detailed sketch of China's long dynastic history culled from official Confucian histories by Jesuit missionaries had been published. Martino Martini wrote the *Sinicae historiae decas prima*, which was published in Munich in 1658. During the eighteenth century an important Chinese history, the *Tongjian Gangmu* (Outline and Details of the Comprehensive Mirror [for aid in government]) by Zhu Xi, was translated into French in its entirety by Joseph-Anne-Marie de Mailla and published in Paris (*Histoire générale de la Chine*, 1777). Not only history, however, but also news was reported to Early Modern readers. Their image of Asia was surely not that of a static world far away. Among the more important events reported in almost newspaper-like detail during the seventeenth century alone were the Mughul emperor's successful campaigns in the south of India, the Maratha challenge to Mughul supremacy, the fall of the Indian states of Golconda and Vijayanagar, the Manchu Conquest of China in 1644, the feudal wars and the establishment of the Tokugawa shogunate in Japan (1600), and the internal rivalries and wars in Siam and Vietnam. Natural disasters such as earthquakes, fires, volcanic eruptions, and the appearance of comets were also regularly reported. Readers of this richly detailed, voluminous, and widely distributed literature may well have known relatively more about Asia and its various parts than do most educated westerners today.

The post-1500 literature on Asia also contains a great many descriptions of Asian science, technology, and crafts: such things as weaving, printing, papermaking, binding, measuring devices, porcelain manufacture, pumps, water-mills, hammocks, palanquins, speaking tubes, sailing chariots, timekeepers, astronomical instruments, agriculture techniques and tools, bamboo and other reeds for carrying water, as well as products such as musical instruments, wax, resin, caulking, tung-oil varnish, elephant hooks and bells, folding screens, and parasols. Some, such as Chinese-style ship's caulking, leeboards, and strake layers on hulls, lug sails, mat and batten sails, chain pumps for emptying bilges, paddle-wheel boats, wheelchairs, and sulfur matches were quickly employed or imitated by Europeans. Some provoked documented experimentation and invention: Della Porta's kite in 1589, and Simon Stevin's sailing chariot in 1600. The effects of the new information on the sciences of cartography and geography are obvious and profound. Simon Stevin, whose sailing chariot was inspired by descriptions of similar Chinese devices, also introduced decimal fractions and a method of calculating an equally tempered musical scale: both of which might also have been inspired by Chinese examples. The sixteenth-century mariners' cross staff may have been inspired by the Arab navigators' *kamals*. The Western science of botany was profoundly influenced by the descriptions of Asian flora and by the specimens taken back to Europe and successfully grown in European experimental gardens; rice, oranges, lemons, limes, ginger, pepper, and rhubarb were among the most useful. More important for botany, however, the Asian plants provoked comparisons with familiar plants, the development of comprehensive classification schemes, and thus the beginnings of modern plant taxonomy. Some Asian cures (herbs and drugs) were borrowed, especially for tropical medicine. Chinese acupuncture, moxibustion, and methods of diagnosis by taking the pulse were minutely described and much admired by European scholars, but it is not yet clear to what extent they were actually used in Europe.

The flow of cultural influence was not exclusively from East to West between 1500 and 1800. Many Asians became Christian. Able Jesuit missionaries translated scriptures and wrote theological works in Chinese and other Asian languages; they also translated European mathematical and scientific treatises into Chinese. The Kangxi emperor himself studied Euclidian geometry, Western astronomy, geography, the harpsichord, and painting under Jesuit guidance. Like many Chinese he was fascinated by European clocks. Many Asians, including the Chinese, learned how to use western firearms and cast western-style cannon. However, the cultural consequences of these efforts were disappointingly small and of short duration. Before the end of the eighteenth century they seem largely to have disappeared along with the Christian mission. The Japanese, however, even during the closed-country period after 1640, were far more curious about Western science. Samurai scholars, for example, studied Dutch medicine and science and in the eighteenth century repeated Benjamin Franklin's kite-flying experiment. Nevertheless through most of the early modern period the Europeans were far more curious about and more open to influence from Asia than were any of the high cultures of Asia to influence from the West.

During the seventeenth and eighteenth centuries the new information about Asia influenced Western culture primarily in areas other than science and technology. The extent of this impact remains to be comprehensively studied, and even of that which is known only a few examples can be mentioned here. Asian events and themes entered European literature in scores of instances from Lope de Vega, Ariosto, Rabelais, and More in the sixteenth century to the several Dutch, German, and English plays and novels depicting the fall of the Ming Dynasty and the triumph of the Manchus in the seventeenth century, to Voltaire's literary and philosophical works in the eighteenth. Even popular literature, seventeenth-century Dutch plays and pious tracts, for examples, shows surprising familiarity with the new information about Asia. Asian influences in European art, architecture, garden architecture, and the decorative arts also began in the sixteenth century and culminated in the *chinoiserie* of the eighteenth century. Confrontation with China's ancient history challenged the traditional European Four-Monarchies framework of universal history and touched off a controversy among European scholars which by the mid-eighteenth century resulted in an entirely new conception of ancient world history. Some scholars, beginning with Pierre Bayle in the late seventeenth century, have detected a Neo-Confucian influence in the thought of Spinoza and in some aspects of Leibniz's philosophy. Chinese government and especially the examination system were frequently held up for emulation by European states during the seventeenth and eighteenth centuries. It might well be that the institution of written civil-service exams in Western states, beginning with eighteenth-century Prussia, was inspired by the Chinese example. Of more general importance that any single instance of influence, however, was the challenge presented by long-enduring, sophisticated, and successful Asian cultures to traditional European assumptions about the universality of their own. Perhaps here can be found the beginnings of cultural relativism in the West.

By 1600 European science and technology generally and especially marine and military technology outstripped that of any Asian society, whatever had been borrowed earlier from them. Also, while the fascination with and appreciation of the high cultures of Asia continued through most of the eighteenth century, the West between 1600 and 1800 experienced the radical transmutation of its traditional culture which resulted in the development of a rational, scientific approach to the use of nature, and society – to agriculture, business industry, politics, and above all warfare – which we have traditionally associated with the Scientific Revolution, Enlightenment, and Industrial Revolution. This transmutation has enabled Western nation-states during the past two centuries to establish the worldwide competitive empires which came to dominate all the other centers of civilization and has resulted in the global dominance of Western culture. The triumph of this transmuted Western culture has reversed the centuries-long East-to-West flow of cultural influence and threatens all of the world's traditional cultures. It should be remembered, however, that this rational, scientific, industrialized Western culture was not an obviously natural outgrowth of traditional Western culture, that in its early development it received important basic components from Asia, and that its triumph threatens traditional Christian Western culture almost as seriously as it threatens those of Asia.

East and West: Africa in the Transmission of Knowledge from East to West

M. A. Tolmacheva

Africa's role in the transmission of knowledge from the East to the West has been strongly conditioned and circumscribed by its geographical location and relative isolation from European and Asian centers of civilization. Africa is to the south of Europe, home of the "West"; it is also positioned to the west and south of Asia, the historical and cultural "East" of Europe, from which it is separated by distance, the Sahara desert, and the Indian Ocean. The contiguity of the Eurasian landmass makes it easy for East–West communications to bypass Africa. Nevertheless, at various periods of premodern history Africa transmitted systems or elements of knowledge and culture to Europe, some generated in Africa, others developed in Asia in the Near, Middle, or Far East. The parts of Africa most actively involved in such exchanges are delimited by the waters of the Mediterranean and Red Seas, the latter guiding to Arabia and the Indian Ocean. The precise role played in these exchanges by Egypt, Ethiopia, and North Africa across time was subject to fluctuations in the environment, growth of early civilizations, long-distance trade, and the development of cities and elites. Nevertheless, Africa had a role to play in alleviating Europe's relative geographical isolation and, especially after the opening of the Cape route from the Atlantic to the Indian ocean, in supporting the global trading system connecting the Old World with the New.

Historically, the intellectual contribution of African societies to world civilization has been overshadowed by the magnitude of African economic and cultural inputs. In addition, numerous direct contacts between Africa and Asia (especially in the northern part of the continent and across the Indian Ocean) bypassed Europe for simple geographical reasons, or failed to have an impact on Western civilization because of circumstances of political, cultural, or religious nature (for example, the rise of Islam). This lack, inconsistency, and sporadic nature of intellectual interaction between Africa and the West are overlooked in some enthusiastic attempts to assert African primacy in world civilization based on incorrect interpretations of evidence. Reconstruction of the African cultures of the past faces serious problems because of the lack of writing systems among the majority of premodern African societies. In the absence of a written record, the historical existence of knowledge is often inferred from contemporary anthropological evidence or archeological data. To complicate things further, the secret of some African scripts that had existed in the past has been lost, as is the case with Libyan, Meroitic, and Tuareg. Thus the internal written evidence for the ancient period is currently limited to texts recorded in Egyptian hieroglyphics and the Ethiopic script. However, few of the surviving texts deal with scientific knowledge or formal disciplines of learning.

African elements in the culture of Ancient Egypt came primarily from the South (the Nile Valley above Aswan, where ancient Nubia and Kush were located) and the West (Libyan desert, Saharan oases and possibly Lake Chad region, and the rim of the Mediterranean). The prosperity and cultural splendor of Egypt during the Old and Middle Kingdoms (ca. 2600–1780 BCE) were second to none. Both depended on a flourishing agriculture which in turn reflected and supported the high development of astronomy, mathematics, hydrology, and technology. The texts and practices of ancient Egyptians provide evidence of elaborate knowledge of medicine, human anatomy, and chemistry. About the time of the transition from the Middle to New Kingdom (ca. 1500 BCE) Egyptian influence reached the Greek periphery. The early cultures of Crete and Archaic Greece show traces of Egyptian and North African influence. Later, Phoenician colonies in North Africa (most prominently Carthage) became a bridge between Africa and the northern Mediterranean. Although there is no record of formal transmission of knowledge from the Punic roots to Rome, some elements of Punic culture spread through the expanse of the Roman Empire as far north as the British Isles. Beginning with Herodotus (fifth century BCE), early Greek descriptions of Egypt and Africa make clear the Greek admiration for Egypt and vaguely acknowledge a certain cultural continuity with Egyptian learning and philosophy. Greek mythology hints at North African (Libyan) religious influence, and Greek folklore (e.g., Aesop's fables) reflects a cultural–philosophical connection with sub-Saharan Africa ("Ethiopia" of the Ancients). Egypt was recognized by the Greeks as both an integral part of Africa and a crossroads on the way east. After the conquest by Alexander the Great, Egypt (especially Alexandria) became a major center of cosmopolitan Hellenistic culture and long-distance trade connecting the Mediterranean with Arabia, Ethiopia, India, and East Africa. Late Greek and Greco-Roman astronomy, mathematics, geography, medicine, and philosophy drew upon the knowledge and thinking of Hellenized Egyptians. The geographical and astronomical works of the Librarian of Alexandria, Claudius Ptolemy (second century AD), continued to influence Western and Islamic scholarship until the sixteenth century.

With the rise of Christianity, Egypt, Ethiopia, and North Africa became a major stage for religious rather than scientific developments. Some of them involved religious controversies with Constantinople, Rome, and Near Eastern neighbors, and resulted in cultural and spiritual separation of the Asian and African Christian communities from mainstream Christian societies even where geographical isolation and remoteness (as in Ethiopia) were not a factor. A further transformation of cultural networks occurred after the Arab conquest of Egypt and North Africa in the seventh to early eighth century AD. Arabic became the language of learning and Islam the dominant ideology. A fragile cultural connection between Ethiopia, Egypt, and Byzantium survived for a few more centuries in the religious sphere; it channeled limited influences in theology, art, and hagiographic literature. One unrecognized consequence of this link is the use of Coptic (originally Egyptian hieroglyphic) elements in the Glagolitic (later Cyrillic) script invented in the ninth century for the Slavic vernaculars by the Byzantine monks, Cyril and Methodios.

The early Islamic science was a synthesis of Hellenistic, Middle Eastern, and Indian sciences, to which was added a considerable body of original knowledge, especially in mathematics, optics, geography, and medicine. Egypt and North Africa became a bridge by which these sciences were then transmitted from the Middle Eastern centers, especially Baghdad, to the rest of the Islamic world and to Europe. Islamicized societies of tropical Africa were most influenced by the legal, theological, and philosophical thought. This Islamic contact stimulated the adoption in the Middle Ages of the Arabic alphabet for writing in some African languages, such as Swahili in East Africa and Hausa in West Africa. Europe, on the other hand, primarily borrowed Islamic knowledge in the fields of natural and applied sciences and philosophy. The Iberian peninsula was involved in this process in a number of ways: first, through the spread of Asian food and technical crops and cultivation techniques as a result of Arabo-Berber occupation in the eighth century; second, in the eleventh to thirteenth centuries under the Almoravid and Almohad empires when Spain was united with northwest Africa as far south as the Senegal River; third, through the Christian translation activities of the late eleventh to sixteenth centuries; and finally as a transit point for transmission to the New World.

From the period of the later Crusades and under the Mamluk dynasties Egypt became the dominant Islamic partner of European traders on the Mediterranean and gained exclusive control of the Red Sea and thus access to the trade of the Indian Ocean. By the thirteenth century the transmission to the Mediterranean of the magnetic compass and the lateen sail (both of them products of the Indian Ocean societies) had been accomplished. After the Mongol conquest of Baghdad in 1258 Cairo became the foremost center of culture and learning for the Near East and Africa. In addition, it was a major transit point on the pilgrimage route to Mecca, visited by many Africans for purposes of both ritual and learning. Cairo kept this role despite the ravages of the Black Death in the mid-fourteenth century and the Ottoman Turkish conquest in 1516, and has retained it to a certain extent to this day. However, even before the fall of Byzantium in 1453 the balance of secular learning in the eastern Mediterranean had shifted, and Muslims became eager students of the early modern West. In the western Mediterranean, the European and Islamic powers interacted in the hostile atmosphere of the Christian Reconquista and piracy; by the sixteenth century the technological balance of power had tilted in Europe's favor, and the geographical arena of progress moved to the Atlantic.

In modern times, the European discovery of the New World and the expansion of the West to overseas colonial empires led to new patterns of communication which could connect Africa with Asia and the West Indies or the Americas without involving Europe. The new global networks served very different purposes and produced dramatically different results. One such early modern network was the Portuguese seaborne empire spread over three continents; its shipping lanes led from Goa in India east to Macao or west to Mozambique and Angola to Brazil, the vessels often completely bypassing Portugal itself. Another was the Dutch empire that connected the West Indies with the West African coast, South Africa's Cape settlement, the Persian Gulf, India, Malacca, and Indonesia. The new societies developing overseas were molded by the West but no longer European. A special, modern example of crosscultural interaction in the "Old World" is the South African colonial society where European farmers benefited from observing the herding practices and environmental adaptation of the indigenous groups (the Khoi-, San-, and Bantu-speakers). The Dutch-based Afrikaans language of white South Africans contains African loan words illustrative of such informal, unrecorded, and often unrecognized transmission of African knowledge to Western societies.

The Americas experienced heavy influxes of Africans capable of preserving in their midst some of the living African culture even under the conditions of slave plantation economy. These influences originated mostly in the tropical and equatorial areas of western Africa. Another channel of unstructured cultural transmission to early Latin America was the importation, within Iberian culture, of "Moorish" (i.e., Islamic or North African) elements, for example in architecture. Traditional knowledge of the African environment, technology, medicine, philosophy, and folklore, including occasional Islamic elements, colored the social, economic, cultural, and spiritual life of African immigrants in the New World and fed into the culture of the larger society despite cultural, religious, and social barriers. African food crops as well as methods of plant cultivation and food preparation spread first in the Caribbean and then on the American mainland. The introduction of rice as a North American plantation staple was accompanied by targeted purchases of slaves from African ethnic groups familiar with rice cultivation, including women whose role in African rice cultivation included seed selection, sowing, hoeing, weeding, and transplanting, as well as milling and cooking. Slaves imported from West Africa brought with them skill complexes that helped make the Carolinas and Georgia into rice exporters on a global scale. Africans contributed their experience of rice cultivation in rain-fed areas, river floodplains, and tidal lagoons; plant breeding skills, the use and adaptation of African agricultural tools, and rotational land use combining cattle grazing and agriculture in tropical and equatorial areas.

East and West: China in the Transmission of Knowledge from East to West

Christoph Koerbs

Despite the distances between them and their totally different cultures, there has been more or less continuous communication between the West and China since classical Greek times. Although the connection was indirect and limited to trade in luxury goods, there were even in ancient times marvelous resemblances between Western and Chinese inventions in technology and engineering. Therefore it is natural to believe that a transmission of ideas and knowledge must have occurred, even if it is impossible to describe the exact exchange of any particular scientific achievement.

In the thirteenth century there was some considerable personal contact between the West and China, of which that of William of Ruisbroek (1210–1270), Marco Polo (1254–1324), and Odoric of Pordenone (1286–1331) are but the most famous examples. By the end of the sixteenth century in China an era of isolation ended and a new stage of intercultural exchange began. In this period the first Jesuit missionary fathers entered China, bringing with them knowledge of the sciences of Renaissance Europe. The Jesuits' scientific instruction was intended to aid their religious teaching by adding to the prestige of the culture they represented. Although in many respects Chinese technology was more advanced than European technology until the Renaissance, it lost ground in subsequent centuries. Francis Bacon (1561–1626) saw Chinese inventions, namely the magnetic compass, gunpowder, and the printing press, as crucial for the transformation of European society. However, after the generation of Leibniz (1646–1716), Wolff (1679–1754), and Voltaire (1694–1778) with the end of the Enlightenment movement, European philosophers and historians began to speak in a disparaging way of Chinese culture. From the late eighteenth century on, the myth of a closed China was born, and Europeans saw the scientific exchange between China and the outside world solely in terms of what the Chinese borrowed from the West. Though Chinese technological advances were old and undeniable, many authors of textbooks on the history of science, technology, and medicine still assured their readers that China never created science as a persisting institution and never consciously developed technology on the sound basis of a theory for applied science.

The British historian of science Joseph Needham (1900–1995) with his work *Science and Civilisation in China* began to restore the reputation of China as a cradle of scientific inventions (Needham 1954). He showed the patterns of transmission of these inventions and enriched the knowledge of Chinese science and technology. Sivin (1977, 1988), an American historian, introduced a different angle. He presented the argument that it is impossible to equate divisions of modern science and engineering with premodern Chinese divisions. Chinese science was not integrated under the authority of philosophy, as schools and universities merged them in European and Islamic cultures. The Chinese had sciences but not "science," not a single conception or word for the sum of all scientific divisions. Traditional Chinese terms for science might exclude empirical methods but include ethical or religious principles discovered through reflection on authoritative texts.

Since there is neither sound evidence for early adoption of Chinese science in the West, nor agreement as to whether Chinese science is distinct from sciences in the West, we have to answer each complex of questions separately. First of all, when immediate contact between China and the West was too limited to be noteworthy, we have to determine whether the Western world owed much to foreign influences which in turn made use of knowledge from China. Second, we must ask whether the conception of Chinese sciences inevitably leads to disparaging treatment by those scholars who are measuring two radically different things by the same standard. To draw a more balanced picture of Chinese scientific thought, we have to look for autochthonous features of ancient Chinese sciences and explain their characteristics.

To solve the first part of the puzzle, we have to consult Chinese historical records which contained much information on foreign relationships. Although there is clear evidence for Arabic, Babylonian, and Indian relations with China, recent archeological finds demonstrate the originality of Chinese culture in many ways. We still do not know enough about the routes and intermediaries by which neighboring states imported cultural artifacts from China. Many transmissions which finally reached the West transformed Chinese, Indian, Iranian, and Greek contributions simultaneously.

Under the Han rule (221 BCE–AD 220), as a result of military campaigns and diplomatic activities, China's immediate contacts with other cultures grew to a degree so far unrivaled in Chinese history. In this period China spread her concepts and skills around all of Asia. As early as 130 BCE, Chinese government officials set out to explore the routes into Central Asia and North China. The success of these missions is very difficult to reexamine, and yet it is probable, because in the official documents of these times we find many references to China's intercultural exchange. The first record of official visitors arriving at the Han court from Japan is for the year AD 57, and we can furnish proof of a mission from Rome which had reached China by ship in AD 166.

With the downfall of the Han Dynasty in AD 220 China entered a period of decline and disunity with respect to the transmission of ideas. After a period of domestication and growth under the later Han, Buddhism came from India into China. The spread of Indian thought was attended by a dispersion of Chinese thought westward. For the next 300 years the Silk Road which linked China with the West was the most important connection between the different culture groups. On this trade route goods and ideas were carried between the three great civilizations of Rome, India, and China.

Under the Sui reign (589–618), when China was consolidated again, grandiose plans aiming to unify the empire culminated in projects for new canal systems. As a result a great canal linking central and southern China was constructed, and long campaigns in Manchuria and on the Korean frontier were prepared. There was a direct relationship between waterway construction works and active foreign policy. Using the new canals for logistical support, the Sui realm was able to establish sovereignty over old Chinese settlements in the south, and extend its influence to other territories, especially in central Vietnam. In addition to these military operations expeditions were sent to Taiwan, and relations with Japan were opened. Sui colonies were established along the great western trade routes, and rulers of several minor local states of Central Asia became tributaries. This was the time when China was in contact with the eastern Turks, who occupied most of the Chinese northern frontier, and the even more powerful western Turks, whose dominions stretched westward to the north of the Tarim Basin as far as Sassanid Persia and Afghanistan. We can learn from the writings of the Arabian scientist and philosopher Al-Bīrūnī (973–1048) that the Turkish sphere of influence was a fertile soil for intercultural exchange. As a consequence of the history of Turkish engagement in Inner Asia remarkable transmissions of technological know-how took place and helped to spread, among other things, Chinese defense engineering and mechanical skills.

Various imports and influences into Arabic empires originated essentially from China, or were at least transmitted through the intermediary of the Turks. As we can prove by discoveries of imported pottery and textiles the links between Iran in the Sassanid period (AD 226–651) and China were extremely close. With the decay of Turkish power the new Tang dynasty (618–906) extended its power all over East Asia. Chinese western dominions extended even farther than in the great days of the Han, and trade developed with the West, with Central Asia, and with India. The Chinese capital was thronged with foreign merchants and monks. Every great city contained a variety of non-Chinese communities and had Zoroastrian, Mazdean, and Nestorian temples, along with Buddhist monasteries. This set the stage for even more transfers of knowledge and inventions.

Perhaps it is not exaggerated to call China under the Song rule (960–1279) the most advanced civilization at that time. During the Song dynasty an agricultural revolution produced plentiful supplies for a population of more than 100 million. Acreage under cultivation multiplied in all directions, and a variety of early ripening rice, imported during the eleventh century from regions in modern Vietnam and Cambodia, shortened farming time to below 100 days and made two crops a year the norm and three crops possible in the warm South. Among other new crops the most important was cotton, which provided clothing for rich and poor alike; silk and hemp were also important. Improved tools, new implements, and mechanical devices that raised manpower efficiency were widely used. Although advanced skills were guarded as trade secrets, many technical inventions of these times found their way into printed manuals used at home and abroad. Productivity of such minerals as lead, tin, silver, and gold increased tremendously. In manufacturing the Chinese improved processing in skill-intensive patterns; they began with mass production, and a division of labor as well, while skills and products entered into diversified specialization. High-quality earthenware progressed to genuine porcelain, which attained international fame.

Despite the fact that until the early eleventh century Chinese maritime trade had been dominated by foreigners, Chinese artisans developed a new type of ship at the end of the century, helping the Song empire to take control over the transport of merchandise and passengers across the waters of East Asia. The Chinese ocean-going junks with large proportions and tonnage were bigger, more solid, but also more comfortable than the Arabian and Indian ships. From the twelfth to the fourteenth centuries the Chinese fleet was at the peak of its power, at least on the routes linking China with the ports of South India. Chinese trade with Southeast Asia increased for the very last time at the end of the fourteenth century when China flooded Sumatra and Borneo with ceramics, and also coins, in exchange for spices, aromatics, medicinal drugs, and precious woods. Chinese ceramics of this period have been found in quite large quantities not only along the silk road, but also on the sites of ancient ports or depots along the navigation routes toward Indonesia, and in the great commercial cities of the Middle East.

In the thirteenth century after the Mongol conquest of China and the founding of the Yuan dynasty (1280–1367) Europeans developed a lively interest in Chinese affairs. The Roman Catholic Church also looked for potential converts among the non-Muslim people of Asia. After Franciscan envoys brought back information on what was known as China in the mid-thirteenth century, Pope Nicholas IV dispatched a mission to the court of the Grand Khan. The Mongol capital Khanbaliq (Beijing) became the seat of an archbishopric, and in 1323 a bishopric was established. From then on missionaries traveled to China and brought back first-hand information to medieval Europe. These reports inaugurated an era of discoveries and created a new vision of the world, with China as a part. Furthermore, shortly after direct contact with China was established, European philosophers and clerics speculated upon Chinese modes of thinking. Chinese medical treatises were translated into Persian, and Persian pottery techniques show some influences of Chinese handicraft. In addition, Chinese-type administration and chancellery practices were adopted by various Mongol dominions in Central Asia and the Near East. Some scholars suggested that the invention of gunpowder and printing in Europe was due to a sort of stimulus diffusion from China, although there is no sound evidence for a direct influence from China via the Near East.

During the Ming reign (1368–1644) Europe was unable to maintain its contacts with the Far East, partially because the Black Death broke off many overseas trade relations. Toward the end of the fourteenth century China was almost forgotten. Meanwhile Ming dynasty bureaucracy reoriented foreign policy, which made foreign contacts much more difficult. Ming China's influence in Southern Asia reached its climax during the early fifteenth century when official exploratory voyages brought most important South Asian states into the Ming political sphere. Besides protecting China's southern borders, these voyages were undertaken to monopolize the overseas trade by preventing private individuals from taking control of seafaring activities. Foreign states responded to these overtures not only because they feared military reprisals if they refused, but also because they saw great commercial benefits in relations with China. In these years Chinese missions established contacts with most of the important countries from the Philippines to the Indian Ocean, the Persian Gulf, and the east coast of Africa.

The Ming rulers also maintained China's traditional relationships with foreign peoples; they took for granted that the Chinese emperor was everyone's overlord and that other rulers of non-Chinese states were in a strict sense nothing but feudatories. Foreign rulers were expected to acknowledge the supremacy of the Ming emperor and to send periodic missions to the Ming capital to demonstrate their fealty and present tribute of local commodities. Tributary envoys from continental neighbors were received in selected frontier zones while those from overseas states were only accepted at three key ports on the southeast and south coasts. All envoys received valuable gifts in acknowledgment of the tribute they presented and also were permitted to buy and sell private trade goods at officially supervised markets. Luxury goods flowed out of China and some rarities flowed in. In order to preserve the government's monopolistic control of foreign contacts and trade, and to keep the Chinese people from being tainted by so-called *barbarian customs*, the Ming rulers prohibited private dealings between Chinese and foreigners and forbade any private voyaging abroad.

In the sixteenth century China came into contact with Jesuit missionaries who impressed the Chinese with the superiority of Western astronomy. The most famous of them, Adam Schall von Bell (1591–1666), was trained in Rome in the astronomical system of Galileo. After curing the Empress Dowager of a strange illness, Schall became an important adviser to the first emperor of the Qing dynasty (1644–1911/1912). He was soon given an official post and he also translated Western astronomical books and reformed the old Chinese calendar. Matteo Ricci (1552–1610), another Jesuit, produced the first edition of his remarkable map of the world, the Great Map of 10,000 Countries, which showed China's geographical relation to the rest of the world. Moreover Ricci taught the rudiments of mathematics and translated many mathematical treatises on Western science and engineering into Chinese, notably the first six books of Euclid. At the same time, many books and correspondences of Catholics like Ricci were published in Europe and caused an interest in Chinese culture. This period of intensive cultural exchange came to an end with the imperial decree of 1717 which prohibited the preaching of Christianity and ordered the deportation of all missionaries from the empire with the exception of those working at the court.

From this time on, for more than 100 years China reduced her contact with the West to a minimum. Trade was rigidly limited to a few ports where officials regulated it strictly and taxed all merchandise excessively. Chinese attitudes toward foreign relations clashed with those of the rising Western powers, especially after the newly expanding states of Britain, France, and Holland all began to develop major overseas empires. In these times, during the last decades of the eighteenth century, China's image changed, and

Chinese affairs were viewed in a rather negative way. After the turn of the century China no longer received favorable attention in the West, but metamorphosed into the very archetype of a backward country. By teaching the Chinese the science and technology of the West, Europeans believed they had to stimulate the scientific development of a culture without any noteworthy tradition of its own. For a very long time it was quite inconceivable to Europeans that China had anything to offer in return.

As mentioned above, to draw a more balanced picture of Chinese scientific thought, we have to look for special features of ancient Chinese sciences and explain their singularities. It is easy to understand why traditional Chinese sciences are hard to describe in the modern terms of Western science or engineering. For example, the Chinese science of geomancy (*fengshui*, or wind and water) cannot be assigned to any department of modern science. Since the concepts of geomancy differ significantly from premodern European natural philosophy, even recourse to ancient traditions of the West does not help. The geomancer aimed to adapt the dwelling places of the living and the dead in a suitable way to arrange them in harmony with the energy balances existing in a region. In Chinese thought every place has its peculiar topographical characteristics which can alter the local energies of nature. Directions of watercourses, shapes of wooded areas, or forms of hills are treated as important aspects for everything living in this region, and the forms and structure of objects built by humans are believed to be significant factors too. As the art of geomancy was dedicated to exploring the relations between the landscape and the living conditions of its inhabitants, it was an official state science, directed by the Board of Rites in the capital and patronized by the emperor himself.

Western scientists who have written about geomancy agree that this science recognizes certain types of energy which permeate the earth and atmosphere and animate the forms of nature. Further understanding has been obstructed by the impossibility of equating these energies with phenomena recognized by modern physics. In one aspect they evidently correspond to the emanations from the earth which are detected by water-diviners, or to the earth's magnetic currents. In another aspect they correlate to traditional Chinese medicine and acupuncture. Just as Chinese doctors commanded a great diversity of therapies and techniques, which they generally used in combination, geomancers did the same, and so traditionally both techniques are described as departments of the same science. Acupuncture is based on the same principles as geomancy, being concerned with the flow of subtle energies in the human body which correspond to those perceived by geomancy in the body of the earth. These remarkably abstract and comprehensive systems of acupuncture and geomancy are based on concepts describing the relations of the body, the mind, the immediate physical surroundings of the body, the earth, and the cosmos which are very different concepts from those in the West. What makes geomancy even more complicated are the differences between special schools of this science. One school believed that natural shapes in the landscape tended to affect the characters and destinies of those living within sight of them, while another school paid more attention to astronomical factors, horoscopes, and reading of the geomancer's compass. In Western terms geomancy seems like a mixture of obscure medicine, applied protophysics, esoteric speculations, superstition, or even swindling.

Another example of the interrelationship of different branches of traditional Chinese learning is the alchemical sciences (*fulian*). We can distinguish two major divisions of alchemy, internal (*neidan*) and external (*waidan*). Internal alchemy was concerned with longevity practices and interpreted immortality as the highest kind of health. A special branch also existed for the alchemical process of internal transformations. Adepts of this school considered the interior of the human body as a laboratory in which elixirs could grow by meditation, breath control, or sexual gymnastics.

In theories of external alchemy, the transmutation of metals into gold and the production of universal remedies for diseases were the focus of interest. Chinese adepts of external alchemy by and large were not interested in exploring chemical reactions, but in simulating cosmic series of transformation and creation. In the laboratories alchemists intended to produce new substances or to convert given materials into new substances by means of allegorical imitations of natural phenomena rather than by controlled chemical experiments.

It is important to outline some Chinese cosmological ideas briefly. This will help us to relate theories of creation and change to patterns of Chinese mathematical astronomy (*lifa*) and astrology (*tianwen*). In traditional Chinese thought, ideas about the origin of the world do not involve any concept of creation by an almighty creator but only by impersonal processes of spontaneous self-creation. The first fully developed cosmological idea is the *gaitian* (heaven as cover, or umbrella heaven) theory, whose origins are around the first century AD, although its first traces are to be found as early as 239 BCE. According to this theory, heaven and earth are flat and parallel planes. A variation of this theory depicts heaven and earth as bodies having a mild curvature very similar to the curvature of an umbrella. In both theories heaven is thought to rotate once daily about an imaginary axis, normally held to be vertical, and carry with it all the stars and heavenly bodies. Since the observer is some distance from the vertical

E

axis, it is no contradiction that the polestar is not overhead. Rising and setting of the sun, moon, and stars are optical illusions caused by their entering and leaving the observer's pretended narrowed range of vision. Advanced variations of this theory initiated the idea of a spherical or complete heaven (*huntian*) which was thought to surround the earth and rotate daily about an axis inclined to the horizontal. In this theory heaven and earth are compared with the shell and yolk of an egg, e.g., the earth is said to be completely enclosed by heaven, rather than merely covered from above. Chinese astronomers continued to think in flat-earth terms until the seventeenth century, when Jesuit missionaries introduced Western theories.

Traditional Chinese astronomy does not use a zodiac of 12 signs laid out along the sun's annual path through the constellations. The celestial sphere is sliced into 28 unequal segments, which are said to radiate from the north celestial pole in the same way in which lines of longitude radiate from the poles of a terrestrial globe. These slices are called lunar mansions or lodges (*xiu*). Each mansion bears the name of the constellation found in it. By means of this system, astronomers were able to follow the progress of the stars in the sky, but the mansions also have an astrological function. Each mansion has a corresponding terrestrial territory to which the predictions based on phenomena observed in the sky are applied. The appearance of comets, haloes, or clouds guided the actions of the governors of the states associated with the mansions where those phenomena were observed. Along with the mansion system, 24 guiding stars were chosen by which the position of the other stars in the sky could be determined. In this, Chinese astronomy differs greatly from Greek helical astronomy, which is based on the observation of the rising and setting of stars just before dawn and just after dusk. In China, where the celestial Pole symbolized the Emperor, astronomers studied the circumpolar movements of the constellations around the Pole.

Another science very closely related to mathematical astronomy and in the same way entirely different from its Western correspondent is Chinese astrology. To distinguish mathematical astronomy from astrology we have to remember that from the very beginning astronomy was designed to make celestial phenomena predictable, whereas astrology served as an aid for interpretations of those phenomena which were unpredictable. In the West astrology is in a way the same as horoscopy, but in the Chinese context astrology and horoscopy differ widely. In traditional China the appearance of celestial phenomena guided the actions of the governors of the states. The Chinese astrologer observed and interpreted anomalous celestial or meteorological phenomena to reveal faults and shortcomings in the political order. There was a close correspondence between the cosmic and the political domains. For instance, from the second century BCE there has been the theory of *fenye* (field allocation). The sky was mapped upon political segments, so that strange phenomena discovered in a particular segment could be related directly to the corresponding political realm existing on earth. Throughout Chinese history the mediator between celestial circumstances and mundane affairs was the Emperor, who was responsible for the undisturbed course of all regularities on heaven and earth. Therefore, astrologers interpreted celestial omens as indications of imperial negligence or correctness. This attitude toward celestial phenomena also influenced calendrical and planetary astronomy. As a result of this attitude toward omens, almost every government aimed to control and sponsor mathematical astronomy and astrology.

Since changes in the heavens predicted important changes on the Earth, Chinese astronomy and astrology were incorporated into the system of government from the dawn of the Chinese state in the second millennium BCE. The result was a system of astronomical observations and records, thanks to which star catalogs and observations of eclipses and novae that go back for millennia survived. Chinese records, therefore, are still of value to every student of the history of astronomy. In our times Western astronomers have identified ancient Chinese observations of the sudden appearance of bright stars with the supernova explosions whose remainders have been detected by radio astronomy. Moreover, observations of sunspots made from the first century BCE onward helped to solve some problems of the variation of solar activity over the centuries.

Astronomy and astrology had no real effect on Chinese mathematics (*suanxue*). On the whole Chinese mathematics was algebraic and numerical in its approach rather than geometric. Since ancient Chinese mathematics was primarily oriented toward practical application, any search for the hypothetical meaning of numbers was rather a system of occultism built around numbers than an exploration into the realm of abstract mathematics. Some historians of mathematics have claimed that only the Greeks produced an abstract, logical mathematics that could function as the language of science. Chinese mathematics, however, consisted of reckoning rules, and, in spite of their great sophistication, these were only intended for practical use.

Perhaps mathematics serves best to demonstrate the whole problem of contingent affection of China by the West. In the first phase this Chinese science was disregarded, because it was inconceivable that a non-European culture was endowed with an efficient mathematical system. In the second phase, a few Western scholars made an attempt to understand such things as an abacus or counting-rods, but still theoretical primary sources were not used. In the next phase mathematical treatises were carefully studied and summarized in a reliable form. Today we can find several first-hand characterizations of the subject by experts in this field, but it is very difficult to obtain a balanced picture. It is clear that ignorance of Chinese sciences was mainly caused by misunderstanding.

East and West: India in the Transmission of Knowledge from East to West

Susantha Goonatilake

The exchange of ideas was more balanced in the time before the European Scientific Revolution, after which the lipid growth of knowledge in the West dwarfed the interregional traffic that had taken place earlier. The Western tradition of the last few centuries has become the only system studied in universities and practiced in centers of science and technology worldwide. Quite often there is no interaction between this new tradition and the earlier knowledge from regions such as South Asia, even though there are many areas of learning that could enrich the Western tradition.

A study of the growth of the European and the South Asian scientific traditions shows considerable areas of overlap and mutual influence from very early times. When Europeans in the Renaissance looked back to Greek sources for new inspiration, they were in fact looking to Greek sources partly influenced by the South Asians.

Generally speaking, India was outside the world of shared ideas and values of preclassical Greece. After the wars with the Persian empire the myth of a division into East and West was born, as was the concept of Europe. The conditions for a large scale traffic of culture and ideas between Greece and Asia were created when the Persian Empire became a bridge from the Mediterranean to the Indus. One sees South Asian concepts that arose between 700 BCE and 500 BCE in the later Vedic hymns, the *Upaniṣads*, and among the Buddhists and the Jains, being echoed in Greek thought.

There are striking parallels between the two traditions. The *Upaniṣads* seek one reality; this has its echoes in Xenophanes, Parmenides, and Zeno. Pythagoras is thought to have been influenced by the Egyptians, Assyrians, and Indians. He believed in the possibility of recalling previous lives, which is also typical of South Asian philosophy. Pythagoreans abstained from destroying life and eating meat, as do Jains and Buddhists. They expounded many theories in the religious, philosophical, and mathematical sphere that were known in sixth century BCE India.

In Plato's philosophy, the "cycle of necessity," a concept similar to Karma, was central. Humans were reborn as animals or other humans. The Indian elements *pṛthvī* (earth), *ap* (water), *tejas* (fire or heat), *vāyu* (air), and *ākāśa* (ether, or a nonmaterial substance) have their counterpart in Empedocles, who believed that matter had four elements: earth, water, air, and fire.

After Alexander's encounter there was explicit dialogue with India. Several who traveled with Alexander are said to have met with Indian sages. In late antiquity India was seen in some debates as the origin of philosophy and religion. In the second century AD Lucianus stated that before philosophy came to the Greeks, Indians had developed it. It has also been suggested that Gnostic thought was influenced by Buddhist literature. Gnostic Carpocratians strongly supported the idea of transmigration. At least one Gnostic philosopher, Bardesanes of Edessa (ca. AD 200) had traveled extensively in India. Mani, the Persian Gnostic of the third century AD, incorporated several Buddhist ideas into Manichaeism. By the second century AD India had almost replaced Egypt as the presumed origin of Greek thought and learning.

At a later period, Plotinus, the father of the Neoplatonic school, took part in the military campaign against the King of Persia. Neoplatonism recommended abstention from sacrifice and meat eating. Neoplatonism, *vedānta*, yoga systems, and Buddhism all have strong similarities. In the second century AD, Clement of Alexandria spoke often about the existence in Alexandria of Buddhists, being the first Greek to refer to the Buddha by name. He was aware of the belief in transmigration and the worshipping of *stupas*.

During the Roman Empire, contacts between the two places continued. There was heavy trade in luxuries with South India and Sri Lanka by the Romans, and ambassadors were sent to Rome. An Indian delegation visited Europe in Emperor Antoninus Pius' reign. In the reverse direction, Apollonius of Tyana traveled to India. These repeated interactions between the two regions probably resulted in the exchange of ideas from South Asia to Greece. The Buddhists had sophisticated discussions prior to Heraclitus around the concept of being in a state of flux. Buddhists and Ājīvakas added joy and sorrow to the five elements, which precedes Empedocles's views that love and hate acted mechanically on the elements. The Buddhists and others taught a doctrine of the mean several centuries earlier than Aristotle (340 BCE). In medicine, the Hippocratic treatise *On Breath* deals in much the same way with the pneumatic system as we find in the Indian concept of *vāyu* or *prāṇa*. In his *Timaeus*, Plato discussed pathology in a similar way to the doctrine of *tridoṣa*.

The above examples should not suggest that there were no transmissions in the opposite direction. The ancient world had much cross flow of intellectual traffic. A well known example from Greece to South Asia concerns ideas on geometry and astronomy.

When the Classical age collapsed, European and South Asian contacts continued in the Middle Ages through Arab intermediaries. The Arabs performed the functions earlier performed by the Persian, Alexandrian, and Greek empires which brought together the ideas of East and West. It is useful to trace the transmission of Indian sciences to Europe as well as trace those that were not transmitted but remained in the region only to be rediscovered much later. This is done to some extent in the article on Indian mathematics in this Encyclopaedia.

The European Renaissance and Scientific Revolution brought about many changes that have been considered unique. However, the evidence indicates that many of the results were known, some albeit in an incipient form, in South Asia.

Alchemy was an important precursor to the development of chemistry. Greek alchemical texts do not show an interest in pharmaceutical chemistry, a marked contrast with China and India. In the *Atharva Veda* (eighth century BCE) there are references to the use of gold for preserving life. The transmutation to gold of base metals is discussed in the Buddhist texts of the second to fifth centuries AD by concoctions using vegetables and minerals.

In the West, iatrochemists, especially Paracelsus, were of the view that the human body consisted of a chemical system of mercury, sulfur, and salt. Sulfur and mercury were already known to the alchemists; salt was introduced by Paracelsus. This theory differed from the four humors theory of the Greeks advocated by Galen (AD 129–200). An Indian alchemist by the name of Ramadevar taught a salt-based alchemy in Saudi Arabia in the twelfth century.

In medicine, the work of Suśruta laid the foundations for the art of surgery. Suśruta emphasized observation and dissection, and described many instruments like those used in modern surgery, listed several kinds of sutures and needles, and classified operations into types. The operations described included those for hydrocele, dropsy, fistula, abscess, tooth extraction, and the removal of stones and foreign matter. The ancient Indian surgeons practiced laparotomy and lithotomy, plastic surgery, and perineal extraction of stones from the bladder. The region had considerable knowledge in dentistry including artificial teeth making. In AD 1194 the king Jai Chandra when beaten in battle was recognized by his false teeth. Suśruta describes details of operations for the conditions of obstructions in the rectum and for removal of a dead fetus without killing the mother, considered a very difficult procedure. He describes plastic surgery of the nose and cataract operations on the eye.

At the end of the eighteenth century the British studied Indian surgical procedures for skin grafting to correct for deformities of the face, which became the starting point for the modern specialty of plastic surgery. Dharmapal collected several illuminating accounts by Britons on Indian medical practices in the eighteenth century. This included one by Holwell, who gave a detailed report on the practice of inoculation against the smallpox. The smallpox epidemics in the nineteenth and early twentieth centuries have been attributed to the cessation of this practice before the vaccination system could become widespread.

In the West after Democritus, atomic theories were further expanded by Lucretius in the first century BCE but then virtually vanished from intellectual view for 1600 years. In the seventeenth century Gassendi, Boyle, Newton, and Huygens revived the atomic perspective. Atomic views of several schools such as the Buddhists, the Jains, and the Vaiśeṣika persisted. The Vaiśeṣika's theory of atomism considered atoms as eternal and spherical in form. The disintegration of a body results in its breaking down to constituent atoms. A solid block like ice or butter melts, and this is explained as a loosening of the atoms, giving rise to fluidity.

Evolution is one other element in the modern phalanx of scientific ideas. Evolutionary ideas had existed among pre-Socratic Greek and Indian thinkers. However, evolutionary thinking in Greek tradition was brought to a sudden end by the ideas of Plato and Aristotle. Plato viewed the real world as consisting of unchanging forms or archetypes; Aristotle viewed the physical world as a hierarchy consisting of kinds of things. For Aristotle the universe was unchanging and eternal. The idea of evolution is found in the *Upaniṣads*, the writings of the Buddhists, and others.

The *Encyclopaedia Britannica* lists three major innovative transformations in British agriculture in the Era of Improvement in the eighteenth century. They were the invention by Jethro Tull in 1731 of the drill plough, "whereby the turnips could be sown in rows and kept free from weeds by hoeing thus much increasing their yields," the introduction of rotation of crops in 1730–1738 by Lord Townshend, and the selective breeding of cattle introduced by Robert Bakewell (1725–95). There is evidence that all three were in existence in India, as reported by British scientists working there.

Roxburgh, generally recognized to be the "father of Indian botany" in the contemporary tradition, put this as follows: "the Western World is to be indebted to India for this system of sowing," meaning the implicit rotation of crops in the Vedic period where rice was sown in summer and pulses in winter in the same field. Other British works have attested to the use of "careful breeding of cattle," various kinds of drill ploughs, and rotation of crops and mixed cropping.

The Scientific Revolution had a deep impact on the philosophical underpinnings of Europe. There was for example the dethroning of human exclusivity as the special creation of God, as exemplified by the trials of Copernicus or the criticisms of Darwin's evolutionary theory. The discovery of the unconscious by Freud and others is also in this class. None of these events would have had the same impact on South Asia, whose cosmology allowed for a large number of worlds, for evolution and change, for humans as part of a larger living world, and for a subconscious.

Aside from these historical examples, are there innovations occurring even now which are drawing sustenance from the earlier South Asian tradition?

Helmut von Glasenapp observed that ancient South Asian ideas on fundamental issues had several parallels with those in modern science. Some of these concepts were (1) an infinite number of worlds exists apart from our own; (2) worlds exist even in an atom; (3) the universe is enormously old; (4) there are infinitely small living beings parallel to bacteria; (5) the subconscious is important in psychology; (6) doctrines of matter in both Sāṃkhya and Buddhism are similar to modern systems; (7) the world that presents itself to the senses is not the most real; and (8) truth manifests itself differently in different minds giving the possibility of a multiplicity of valid truths.

Following are examples of innovations based on the past taken from a few disciplines. The first is medicine. A recent study has documented the use of honey and sugar as treatment for wounds and ulcers in both Āyurvedic and contemporary biomedicine. The tranquilizer Reserpine was based on an ancient āyurvedic medicine. Hoechst, the West German pharmaceutical company, used Āyurvedic literature to help identify useful medicinal plants. By the early 1980s, over 200 Indian medicinal plants were being tested every year in this program.

A recent study has evaluated the effect of *Rasayana* therapy which aims at promoting strength and vitality. The study covered six drugs from classical Āyurvedic literature. The clinical studies indicated that the drugs toned up the cardiovascular and respiratory systems and improved physical stamina. On the biochemical side, a significant drop in lipids was noticed.

References to curative plants in the Indian tradition go back to the Ṛgvedic period (3500–1800 BCE). The *Suśrutasaṃhitā* and *Carakasaṃhitā*, two compendia which are summaries of earlier works, dealt with about 700 drugs, some of them outside the subcontinental region. Clearly, a vast reservoir of explorable scientific knowledge exists.

One of the areas of study with a very long tradition in South Asia is psychology. There is also a very long tradition of sophisticated discussions on epistemology. There is potential for a fruitful interaction between these and the contemporary study of the mind, including the philosophy of language, methodology, ontology, and metaphysics.

Memory, motivation, and the unconscious are shown to have parallels in the theories of Freud and Jung, as well as in Patañjali. Similar parallels have been noted between the psychoanalytical theorists Heinz Hartmann and Erik Erikson, and the Hindu theory on the stages of life, as well as between Buddhism and early twentieth century analytical thought. Strong parallels between the concept of self-realization used in subcontinental traditions such as Vedantic Hinduism, Theravāda, and Mahāyāna Buddhism and the concept of self-actualization as developed in humanistic psychology by Arthur Maslow and Carl Rogers have been demonstrated.

Francisco Varela, a theoretical biologist and student of cognitive science and artificial intelligence, and coworkers have used Buddhist insights in extending the limitations of both the neo-Darwinian adaptation in biological evolution and of the current paradigm in cognitive sciences. Having noted that in Buddhist discourse, classical Western dichotomies like subject and object, mind and body, organism and environment vanish, Varela applies these discourses to several areas where these dichotomies had traditionally appeared. These include cognitive psychology, evolutionary theory, linguistics, neuroscience, artificial intelligence, and immunology.

Their position is that if cognitive science is to incorporate human experience, then it must have a means of exploring the dimension which is provided by Buddhist practice. Buddhist experiences of observing the mind are in the tradition of scientific observation. They can lead to discoveries about the behavior and nature of the mind, a bridge between human experience and cognitive science.

Another area of interest is that of adaptation in evolutionary biology. In the conventional view it is assumed that the environment exists prior to the organism, into which the latter fits. This is not so. Living beings and the environment are linked together in a process of codetermination or mutual specification. In this light, environmental features are not simply external features that have to be internalized by the organism; they are themselves results of a long history of codetermination. The organism is both the subject and object of evolution. The processes of coevolution result in the environment's being brought to life through a process of coupling. Taking the world as pregiven and the organism as adapting can be categorized as dualism. Buddhism transcends this duality in its codeterminative perspective.

The standard arithmetic that we use today, based on the decimal place system and the use of zero, was transmitted through the Arabs from South Asia. It entails certain standard procedures, algorithms, to perform various operations. But are these the only such operations that exist and are these the ones that are computationally the most efficient? Could there be algorithms that did not get transmitted from India through the Arabs, or those that were developed after the transmission?

Indeed there are many such, as Ashok Jhunjhunwala, a professor of electrical engineering in the Institute of Technology, Madras, has discovered recently. He has examined everyday practices in arithmetic in areas not yet influenced by European techniques such as those used by artisans and businessmen in the non-Europeanized sector. He came across simple but fast methods of calculation. He described eight of these methods which are faster than conventional methods. These included means of finding area, multiplication, squaring, division, evaluation of powers, square roots of numbers, divisibility of numbers, and factorization. They also included methods to catch errors. Jhunjhunwala has compared the speed of some of these old approaches with contemporary ones and found that some are faster. He is now applying these general methods to speed up calculations in computers.

Jhunjhunwala's collection of mathematics at the local level shows the proliferation of methods possible once the decimal system is understood. Local groups discovered new tricks, a process of grass roots creativity very much like the different responses to changing agroclimatic conditions across the world and the resultant variations in agricultural practices.

Time is yet another area to explore. There are many different philosophical discussions on *Saṁsāra* concerning what could be termed the nature of long duration processes. According to some Jain views, time was one of the causal factors in the evolution of nature; and Buddhism alone has a very large tapestry of conceptions of time.

One of these approaches developed an elaborate theory not only of atoms but also of moments, with some schools recognizing four types of moments and others three. Other theories were also proposed by different schools to relate the theory of moments to the fact of continuity of temporal events.

Virtual Reality brings into question the constructor and the constructed. These types of questions are regularly dealt with in Buddhist and other South Asian philosophies. In the virtual realities that use visual representations, parallels also exist with visualization techniques in certain branches of Buddhism. The author of a text on the topic, Howard Rheinhold, says that the Virtual Reality "experience is destined to transform us because it's an external mirror of something that Buddhists have always said, which is that the world we think we see 'out there' is an illusion."

The ethical and conceptual questions of the future brought about by modern science and technology could have many uses for South Asian perspectives.

There are many stores of valid information still to draw from. One authoritative estimate of manuscripts, roughly covering the areas of mathematics and astronomy, is about 100,000. Yet the recently published book *Source Book of Indian Astronomy* lists only 285. Of these only very few have been studied. They are mines of mathematical ideas and applications that have hardly been touched.

A passage from Suśruta stimulated the growth of modern plastic surgery in the nineteenth century in Europe. However, as Krishnamurty points out, that was only a stray reference in the many procedures described. It had the fortune of catching the imagination of a western expert. There could very well be many other descriptions that could be rediscovered for modern medicine. Under treatment for mental diseases Suśruta gives a very large list of plants. It is possible that screening of these plants could give rise to a much larger set of useful remedies.

Varela stated that the infusion of Eastern ideas into the sciences of the West would have as much an impact as did the Renaissance rediscovery of Greek thought. How far this may be true is for the future to decide. However, this would help make the present Western knowledge system more universal while still maintaining the rigor developed in the last few centuries. It would help both to enlarge the knowledge terrain covered by the present system as well as retrieve what is relevant from other traditions.

East and West: Islam in the Transmission of Knowledge East to West

Richard C. Taylor

Prior to its explosive expansion from the Arabian Peninsula, Islam itself had no substantive body of scientific learning. The Arabic term for knowledge or science, ^{c}*ilm*, had a developing history steeped in religious reflection and writing as a consequence of the extensive use of its Semitic root ^{c}-*l-m* in the Qur'ân. In contrast to the pre-Islamic "Time of Ignorance" (*jâhilîyah*), the advent of Muhammad as Prophet conveying the words of God in the Qur'ân marked the presence of a new, and frequently detailed and legalistic, understanding of how human beings are to submit (*islâm*) to the will of God in all aspects of their lives. Knowledge on the part of humans was viewed as having its source without exception in the Divine, though signs of the presence of Creator were understood to be evident in the created world. For Muslims, as a result, the place of primacy goes to religious sciences directly (the Qur'ân, the Hadîth, etc.) or indirectly (grammatical studies, law, etc.) which deal with what has been divinely revealed, without at the same time excluding natural knowledge. Later forms of knowledge were sometimes divided into the religious and the foreign sciences (al-Khwârizmî, ca. 976), the religious and nonreligious or rational (al-Ghazâlî 1058–1111) or the traditional religious and the philosophical (Ibn Khaldûn 1332–1406), although the philosopher al-Fârâbî (870–950) gave a different account classifying the sciences into those of language, logic, mathematics, natural philosophy, metaphysics, politics, law, and theology. While such distinctions in some cases reflected believers' deep distrust of foreign learning as superfluous to the guidance and injunctions of the Qur'ân and the natural perception of human beings, the readily apparent value of medicine, mathematics, astronomy, and even astrology led ultimately both to the full incorporation of Greek scientific and philosophical learning into Muslim intellectual and cultural life and to its enhancement and development at the hands of scientists and scholars in the Islamic milieu.

In the course of its expansion, Islam came to have dominance over populations of Christians, Jews, Zoroastrians, and others in Egypt and the greater Middle East who were already possessed of Greek medicine, technology, and scientific learning and who were active participants in the construction of long traditions of intellectual reflection on God, nature, and human

E

learning. In addition to interest in medicine universal to all peoples, Arabian Muslims and converted native populations had practical religious interests in astronomy and geography because of Islamic precepts calling for prayer by the faithful in the direction of Mecca at five separate times daily and because of the need for exact calculations for holy days and for the proper arrangement and placement of mosques and their interiors. For those in positions of political leadership, there was also the practical need to discern matters related to quality and character of life present and to come as read in the stars by astrologists. Another sort of practical need which contributed to the demand for Greek scientific texts of a logical sort was that posed by theological debate both intramural and extramural to Islam. Christians as well as Jews and their Muslim students marshaled powerful arguments with enviable sophistication thanks to Syrian and Greek intellectual roots in a Hellenistic cultural tradition which had a long theological interest in Aristotelian logic due to controversies among Nestorians, Monophysites and others. In these contexts there arose demand for deeper understanding of the conceptual foundations of Greek knowledge incompletely conveyed in medicine and other vital areas. Thus, there was a need for translations of works which set out the theoretical and philosophical structures for medical, astronomical, astrological, and other studies. The comprehensive multigenerational translation movement arose in part in response to these needs in a way that would eventually have profound influence on Latin Europe.

Yet it was also driven by the ascendancy of the Abbasid dynasty (758–1258) and its ideology of inclusion of non-Arabian peoples in Islam and in its political, economic, and religious institutions to the benefit of its Persian supporters and to the detriment of traditional Arabian tribes. The unequivocal opening of Islam and its developing culture to all peoples seeking to become Muslim on the part of the Abbasids enhanced the dynasty's power and independence from past sources of political control. That independence was most evident in the founding of the new city of Baghdad with its deliberately designed planning for the location of institutions in the city which was quickly to become the center of a vast empire and the most important locus for the study of science and the development of knowledge in the world in the ninth to twelfth centuries. Recently Dimitri Gutas (1998) has offered the intriguing thesis that operating underneath all these obvious reasons for the translation movement was the continuation of a "Zorastrian imperial ideology" on the part of Sassanian leaders committed to the recovery of all knowledge conceived of as having been scattered throughout the world following the conquest of the Persians by Alexander. On this account, al-Mansur (r. 754–775), Abbasid founder of Baghdad under whom the translation movement was initiated in earnest, should be regarded as continuing the Sassanian project as part of a Zorastrian inspired agenda to amass all knowledge in the dominant language of the era, Arabic.

Transmission of Knowledge to Islam

The transmission of works of medicine, astrology, science, philosophy, and other materials was modest before the ninth century. An Arabic rendering from Sanskrit of the *Zij al-Arkand* derivative upon the *Khandakhadyaka* of Brahmagupta which was available around 738 provided important astronomical tables employed by Abû Ja`far M. b. Mûsâ al-Khwârizmî (d. 850) whose work was so important to the Latin West. He also made use of Ptolemy's *Geographia* and *Megale Syntaxis*, the latter available in Arabic as the *Majisti* by about 796 and known in the Latin West as the *Almagest*. As early as the late seventh century the Jewish physician Mâsarjawayh had rendered the medical *Panducts* of Ahrûn of Alexandria from Syriac into Arabic perhaps for use at Jundîshâpûr, the famous medical center. Organized and sponsored translations from Indian, Iranian, and Greek sources into Syriac and Arabic began to be produced in abundance under the `Abbasids, particularly during the reigns of al-Mansûr (754–775) and Hârûn al-Rashîd (786–809) at Baghdad, and under the influence of the Barmakid family of physicians and administrators. `Abdullâh b. al-Muqaffa` rendered from Old Persian or Pahlavi into an exemplary Arabic version an Indian work under the title *Kalîlah wa-Dimnah*, while he or his son Muhammad translated Aristotle's *Categories*, *On Interpretation* and *Posterior Analytics* and the *Isagoge* of Porphyry during the reign of al-Mansûr (754–775). The era of al-Ma'mûn (r. 813–833) who set himself as Islamic caliph over an Islamic empire was a time of religious turmoil (with the mihna or "inquisition") and also a time of a continuously increasing expansion of translations and scientific studies which continued under his successors to the Caliphate.

In the ninth century two major groups of translators can be discerned by style, vocabulary, and, to some degree, by interest. The name of the philosopher al-Kindî (801–866) is associated with a group with strong metaphysical interests. Ustâth/Eustathios was responsible for the translation of Aristotle's *Metaphysics* while ᶜAbd al-Masih al-Naᶜîma al-Himsî, a Syrian Christian from Emessa, provided a deeply influential paraphrase and commentary on *Enneads* IV–V of the Neoplatonist Plotinus, part of which was known as "The Theology of Aristotle" in an edition by the Baghdad philosopher al-Kindî. There were also translations from the *Elements of Theology* by Proclus

(412–485), head of the Academy at Athens, including modified versions in the treatise, *Kalâm fi mahd al-khair* (*Discourse on the Pure Good*), which was attributed to Aristotle or Proclus in the Arabic manuscripts and was later famously known in the Latin West as the *Liber de causis (Book of Causes).* These works indicate a powerful interest in late Greek Neoplatonic theology and its accounts of the One, the hierarchy of principles constituting the universe, the structure and functioning of the cosmos, and the ability of the human soul or intellect to apprehend principles and cosmological realities and to transcend the body for its own fulfillment and happiness. Also included in this group is Ibn al-Bitriq who translated Aristotle's *On the Soul, Meteorology*, *On the Heavens*, *Generation of Animals*, *Parts of Animals*, and perhaps a version of the *Parva Naturalia*, as well as Plato's *Timaeus*. As a group, their translations may contain transliterations, neologisms, and a tendency to simplify or eliminate complicated Neoplatonic hierarchies. Not himself a translator, al-Kindî championed the value of philosophical texts with the argument that foreign philosophical materials lead to the establishment of the sovereignty of God as the True One and as such should be welcomed by faithful Muslims. What is of special interest here is the implicit view that philosophical wisdom is a source at least coequal with Islamic revelation in the ascertaining of the nature of creation and the Creator. The importance of this moment becomes all the more evident in later philosophers for whom philosophy with its demonstrative argumentation is viewed as having primary access to truth, while religion and revelation are understood to be secondary manifestations of truth through image and representation. Of the same era of early translators was Theodore abû Qurrah, bishop of Harrân, who knew Greek, Syriac and Arabic and followed John Damascene in polemic against Islam and translated Damascene into Arabic.

The second group of the ninth century was that associated with the Nestorian Christian Hunayn b. Ishâq al-`Ibâdî (808/9–873) and his assistants whose achievement and influence in the transmission of knowledge was without equal in the entire Middle Ages. The account of Hunayn's role in the transmission of knowledge is a story of personal achievement and high scientific and scholarly standards. Removed from medical studies by his teacher at Baghdad, the physician, translator, and scholar Yuhannâ b. Mâsawayh, Hunayn disappeared into Byzantium (*bilâd al-Rûm*) to reappear 2 years later with a mastery of Greek and a penchant for quoting Homer in the original. The now trilingual (Syriac, Arabic, and Greek) Hunayn established his expertise with a translation of a Galenic work and attained a funded place among his colleagues. Sometimes translating into Arabic directly from Greek or Syriac, other times translating from Greek into Syriac and then from Syriac into Arabic, Hunayn and his assembled team of translators, `Îsâ b. Yahyâ, Mûsâ b. Khâlid, Yahyâ b. Hârûn, his son Ishâq, his nephew Hubaysh b. al-Hasan and others, set a high standard of quality for their work: they sought out Greek manuscripts to collate into a single version, worked to standardize Arabic technical vocabulary, and rendered phrases and sentences, not translating word-for-word, in a sophisticated effort to capture the sense of the texts. Hunayn was particularly interested in the work of the physician and epitomizer Galen (129–200?) and translated over 100 of his works and studied the corpus throughout his lifetime. Thanks in great measure to the *Fihrist* or *Catalogue* of the Baghdad bookseller Ibn al-Nadîm (ca. 935–990), our knowledge of works translated and of works available in his day is substantial. Details concerning the translation of Galen by his group are spelled out in a preserved the *Epistle* which Hunayn wrote giving an account of methodology and of which works by Galen had been translated to the extent of his knowledge. Other medical works translated included works of Hippocrates and the *Materia Medica* of Diosorides which constituted the Arabic pharmacopoeia. This latter was possible only because of extensive Greek pharmacological and botanical vocabulary on the part of the physician Hunayn. They went on during or shortly after his lifetime to translate into Arabic or Syriac, and to comment upon or abridge Plato's *Laws*, *Sophist*, *Timaeus*, and *Politics*, Aristotle's *Categories*, *On Interpretation*, *Prior* and *Posterior Analytics*, *Sophistics*, *Rhetoric*, *On the Soul*, *Magna Moralia*, *Metaphysics*, *Nicomachean Ethics*, *On Generation and Corruption* and *Physics*. This second phase of the translations also includes the work of the mathematician Thâbit b. Qurrah, a Sabian from Harrân and contemporary and collaborator with Ishâq b. Hunayn. Thâbit worked with a group of astrologers and mathematicians in the Harrânian tradition and translated Nicomachus of Gerasa's *Introduction to Arithmetic*, improved existing translations by Ishâq of Euclid's *Elements* and Ptolemy's *Almagest*, commented on Aristotle's *Physics*, and worked to carry on the Greek Neopythagorean metaphysics of numbers and astrology. Also active in the same era were the Muslim Abû [c]Uthmân al-Dimashqî who translated Aristotle's *Topics* and Porphyry's *Isagoge* as well as texts of Alexander and medical and mathematical works and the Christian Qustâ b. Lûqâ who rendered works of Galen and Hippocrates as well as the *Metaphysics* of Theophrastus, the *Mechanica* of Hero, the *Arithmetica* of Diaphantus and the *Placita Philosophorum* (*Opinions of the Philosophers*) wrongly attributed to Plutarch. Among other translations were commentaries and related philosophical materials by Alexander of Aphrodisias, Porphyry, Proclus, Themistius, and Nemesius as well as works by Ptolemy, Archimedes, Euclid and others. Many of the works mentioned here were translated more than once.

The final phase of translation began with the work of the Syrian Greek Christian Abû Bishr Mattâ b. Yûnus (d. 940) who had Muslim, Christian, and Jewish teachers, was an accomplished trilingual writer, and had as his student the renowned philosopher al-Fârâbî (870–950). He translated Aristotle's *Meteorology*, *De sensu*, *Poetics*, and *On the Heavens*. He also rendered into Arabic the *Posterior Analytics* from the Syriac of Hunayn and Ishâq as well as Aristotle's important philosophical account of the divine, book *Lambda* of the *Metaphysics* with the commentary of Alexander of Aphrodisias and other works by Alexander. Al-Fârâbî's student Yahyâ b. ^{c}Âdî (893/4–974) was a philosopher, theologian and logician as well as a translator and apparently rendered some Syriac translations by Hunayn, Ishâq and others into Arabic. He was involved with the preparation of translations of Plato's *Laws* and *Timaeus*, Aristotle's *Categories*, *Topics*, *Sophistic Elenchi*, *Physics*, *On the Soul*, *Metaphysics*, and *Poetics*, the *Metaphysics* of Theophrastus, and commentaries on Aristotle's' work by Alexander of Aphrodisias, Themistius and Olympiodorus. He also wrote commentaries on most of Aristotle's logical works while writing works of his own on logic, mathematics, natural philosophy, metaphysics, ethics, theology, scripture, and medicine. Of the same era were Ibn Zurcah (942–1008) and Ibn al-Khammâr (942–1017) who were also involved in translations of Aristotelian works, among them *On Generation of Animals*, *History of Animals*, *Meteorology* and works from the *Organon*. Their work brought to a close for the most part the great translation movement which had some beginnings during the reign of the Ummayads but was for the most part a phenomenon of the era of the Abbasids. A massive portion of Greek scientific, philosophical and other literature had been translated and was now in the process of being assimilated. As mentioned earlier, al-Kindî had argued for philosophy as a source coequal with revealed religion for the understanding of creation and the Creator. In the tenth century, the assimilation of philosophical learning in the work of al-Fârâbî takes a further more controversial step in asserting the primacy of scientific and philosophical argumentation over religion which is characterized as opinions set forth by the ruler for the end which that ruler determines. With profound implications for later Arabic philosophy up to the thirteenth century and for its impact on the Latin West, al-Fârâbî boldly asserts the primacy of independent natural reason characterizing religious revelation as at best a diminished, image-filled, and emotive form of the truth obtained properly by philosophers and scientists in the apprehension of primary principles and the attainment of philosophical and scientific demonstration. The universe was conceived by al-Fârâbî not as created ex nihilo but as emanated from the One as First Being in a hierarchy of intellects and cosmological spheres descending to the earth where human beings exist in a realm of natural generation. In his classical rationalism in Arabic philosophy al-Fârâbî is followed by Ibn Sînâ/Avicenna in the eleventh century and Averroes in the twelfth. What is more, in his construction of a framework of the sciences in his *Enumeration of the Sciences* al-Fârâbî set out clearly an Aristotelian inspired division of the sciences which would be central for the conception of knowledge both in Arabic thought and in the Latin West. Further, in his *Aims of the Metaphysics of Aristotle*, he set aside al-Kindî's view of philosophical metaphysics as a pursuit of God or theology as its object and argued instead that the object of metaphysics is being qua being in all its forms, with God studied as cause of being. This reinforced the view that religion and its revelation are regarded as secondary sources for truth and knowledge provided primarily for the guidance of those unable to take full advantage of the intellect's natural powers of reasoning and intellectual understanding. In this and in many other ways al-Fârâbî was influenced by the late Neoplatonic philosophers of Athens and Alexandria.

As indicated in the work of al-Fârâbî in particular, the story of the transmission of knowledge is not merely one of texts moving from one language to another. It is, in an equally important way, a story of the movement of ideas and their reception and development in a new language and cultural framework. This is all the more so in the case of knowledge and its movement from East to West via the Islamic route, for what was transmitted was oftentimes not only texts but methodological thought and intellectual advances and achievements made on the basis of wisdom garnered from foreign sources. Nearly all of the translators mentioned above were also physicians, scientists, or philosophers in their own right. It was primarily out of their desire for knowledge that they studied foreign works. Translation was in part a consequence of a natural thirst for knowledge on the part of the translators, their patrons and Muslim, Christian, and Jewish intellectuals. Thinkers such as al-Kindî and al-Fârâbî worked closely with those who were studying foreign texts and preparing translations. By the time of the Persian Ibn Sînâ/Avicenna (980–1037), the most influential of the philosophers, the cultivation of foreign knowledge within the context of Islam was yielding more new fruits on native Islamic soil. Ibn Sînâ himself developed a philosophical system with a new conceptual approach to metaphysics and other philosophical matters which had an overwhelming influence in Arabic and a powerful and longlasting impact on the Latin West. Conceiving God as the Necessary Being with arguments which would become standard fare in Arabic and Western Latin philosophical texts, Avicenna argued for a distinction of essence and existence in created entities inspired by issues in the Islamic theological tradition of Kalâm. Drawing on thinking from the Greek Neoplatonic Alexandrian school tradition, Avicenna set forth a view of the human soul as per se rational, immaterial and imperishable, a view much welcomed in translation in the Latin West.

Al-Bîrûnî (973–1043), an encyclopaedic contemporary and correspondent of Ibn Sînâ, wrote extensively on mathematics, astronomy, astrology, the astrolabe, pharmacology, gems, metals, and other matters in addition to his work on Indian thought. Working with translated Greek texts on mathematics and optics as well as more physical accounts of visual perception, Ibn Haytham (d. 1039), a physician as well as astronomer and mathematician, developed a theory of optics (*perspectiva* in Latin) and intromissive visual perception which became dominant in Islam and later in the Latin West where Roger Bacon championed his work. In the area of alchemy, the name of Jâbir b. Hayyân (d. ca. 815) and that of the great physician and scholar, Abû Bakr M. b. Zakariyyâ' al-Râzî (d. ca. 925), stand out in both Islam and the Latin West, although contemporary scholars raise questions about Jâbir's contributions to the corpus of works traditionally attributed to him. The great Islamic theologian, al-Ghazâlî, while severely critical of the philosophers on metaphysical matters, encouraged acceptance of and elaboration upon logic, mathematics, medicine, and the physical sciences. He vigorously combated many insufficiently well founded views of the classical rationalists al-Fârâbî and Avicenna in his *Incoherence of the Philosophers* and argued that the primacy of certainty regarding the human apprehension of the Divine can only be found in the Sûfî experience of gnostic *dhawq* ("taste"). Ironically, however, his *Intentions of the Philosophers*, apparently written in preparation for refuting the philosophers, was viewed as a work by a loyal follower of Avicenna in the Latin West where its explanatory opening section was lost in early transmission of the translation. In spite of the attack of al-Ghazâlî, classical rationalism continued its development in the East (where it moved closer to religious thought) and in Andalusia which was destined to become the primary locus of the transmission of science, philosophy, and the tradition of philosophical commentary to the Latin West. There the works of al-Fârâbî, including commentaries on Aristotle's writings, were studied by Ibn Bâjjah (d. 1139) who wrote his own commentaries and Averroes (Ibn Rushd d. 1198) whose commentaries of various sorts came to play a central role in the development of philosophy in Hebrew and Latin translations. Both these thinkers continued al-Fârâbî's rationalist approach giving primacy to philosophy and intellect, but Averroes distinguished himself by seeking to make a full return to the philosophical principles and texts of Aristotle and to set aside the accretions from Neoplatonism and from unsuitable religious sources. His *Long Commentaries* – containing complete texts of Aristotle with detailed commentary – had a profound impact on the Latin West and some important influence on Jewish thought. His arguments, *secundum Aristotelem*, for the unoriginated and eternal nature of the world, for the perishable nature of the individual human soul, and for the primacy of the philosophical over the religious, shocked the Latin West when properly understood and contributed in a central way to the Condemnations of 1277 which profoundly affected philosophical studies in Paris and other Latin centers of scientific, philosophical, and theological study. Nevertheless, his *Long Commentaries* on the *De Anima*, *Physics*, *On the Heavens*, and *Metaphysics* were constantly studied guides to the thought of Aristotle and also to the Greek Commentators Theophrastus, Alexander and Themistius whom Averroes cited and engaged in argument. In Hebrew translation the *Middle Commentaries* and *Short Commentaries* or *Epitomes* of Averroes came eventually to supplant the works of Aristotle and became the basis of new Commentaries in the Jewish philosophical tradition. In the Arabic tradition, however, the effort of Averroes to return to the pure arguments of Aristotle was not continued, in part due to the banning of philosophy in Andalusia as result of religious and political conflicts, in part due to a lack of interest to return to an Aristotelianism devoid of the mystical at a time when interest in Sufism and forms of illuminationism were on the rise, and in part due to the overwhelming influence of Avicenna throughout the lands of Islam. Another contributing factor was the strife in Andalusia itself as Christian and Muslim kingdoms contested for the Iberian peninsula.

Transmission of Knowledge to the Latin West

In the Latin West science and advanced learning had to be actively sought out from Greek and Arabic sources and then translated into Latin and carried North or West for an economically and politically expanding and intellectually developing Europe. In contrast to Islam, the West did possess some remnants of earlier Greek learning including translations of portions of Aristotle's *Organon* by Boethius (d. 524) and some other works such as Calcidius' incomplete *Timaeus* translation and commentary, as well as an understanding of the importance of philosophy and philosophical argumentation from Greek Fathers and in particular Augustine of Hippo whose influence in the West was pervasive and dominant in theology and philosophy for much of the Middle Ages. Moreover, Greek science and philosophy, while recognized as arising from a pagan culture, were not feared as foreign in the way that they were sometimes in Islam; rather, they were recognized as intellectual treasures to be recovered and put to use in the service of Latin Christianity. Individual scholars began to seek out Greek texts and learning and came to the frontiers of Islam in search of knowledge and more sophisticated intellectual understanding from a culture which had benefited from and added to the Hellenistic learning which it had received. Spain was by far the most productive geographic area for translations from Arabic, although some important work was done in Sicily with a few other works of significance being rendered into Latin in the Near East. Not unlike the Arabic translation movement, the Latin movement can be distinguished into periods during each of which translations were being made from Arabic as well as Greek sources.

While an important Barcelona manuscript containing Latin translations and other materials from the late tenth century provides valuable evidence of early interest in Arabic scientific knowledge about the astrolabe, the first translations of significance from Arabic began to appear in the eleventh century. Constantine the African (d. ca.1087), apparently a widely traveled and well-educated North African Muslim, converted to Christianity and became a Benedictine monk at Monte Cassino. According to one source, he brought with him many texts and undertook the task of translating and composing works on medicine when he had learned of the poverty of Latin Medieval medicine. His contribution to the Latin corpus was substantial and included works by Galen (*Ars medica* and a summary of the *Metategni*) and Hippocrates (*Aphorisms* and *Prognostics*, with commentaries by Galen) as well as work by `Alî b. al-`Abbâs al-Majûsî/Haly Abbas (*Pantegni*), Hunayn b. Ishâq/Johannitius (*Isagoge* or *Introduction to Galen's Tegni*) and others. These translations and other work by Constantine played a substantial role in forming the foundations of medicine and its study by Europeans. But it was the Twelfth and Thirteenth centuries which saw floodgates open and a wealth of learning pour forth into Latin Europe.

In the twelfth century, scholars engaged in translation and transmission of Arabic texts were, like their counterparts working in the Islamic milieu centuries earlier, eager and inquisitive scientists and scholars first and translators second. The great majority of them found Spain to provide the needed environment for their work. Some of them were natives to the area but a large number came from afar in search of scientific learning. An exception to this was Adelard of Bath (d. ca. 1142) who studied in France and then traveled widely in Italy and the Near East before returning to his native England. Among his translations were two of monumental importance to the Latin West: in astronomy al-Khwârizmî's astronomical tables in the usable version of Maslamah b. Ahmad al-Majrîjî of Cordoba and in mathematics Euclid's *Elements*. In 1126 he translated Abû Ma`shar's astrological *Introductorium in astronomiam*.

Toledo was a natural center for translation work after its conquest since its libraries contained books of science, philosophy, and religion and because it remained a place where Arabic was spoken and used by an educated class. It also became a place of refuge for trilingual Jews fleeing persecution in the South by the Almohad regime. There John of Seville (fl. c. 1130–1142) translated Qustâ b. Lûqâ's *De differentia spiritus et anime* for Raymond, the archbishop of Toledo (1125–1152) and famous patron of the translators, and a large number of astrological texts by Mâshâ'allâh, Abû Ma`shar and al-Farghânî in addition to the abbreviated version of the pseudo-Aristotelian *Secretum secretorum*. Robert of Chester apparently worked with Herman of Carinthia in that era to produce a translation of the Qur'ân. In mathematics Robert translated al-Khwârizmî's *Algebra*. Herman produced a second translation of Abû Ma`shar's *Introductorium* and perhaps also a second translation of Euclid's *Elements* in addition to Ptolemy's *Planisphere*. Plato of Tivoli was also interested in astrology and translated Ptolemy's *Quadripartitium* and a work by al-Bâttanî, an astronomer and disciple of Thâbit b. Qurrah the Harranian astrologer and mathematician.

At Toledo Dominicus Gundisalvi (d. 1190) devoted himself to the study of Arabic and Jewish thought, translating a number of important philosophical works, among them the *Fons vitae* of Ibn Gabirol/Avicebrol or Avicebron, the *Maqâsid al-falâsifah* (*The Intentions of the Philosophers*) of al-Ghazâlî/Algazel, and a large number of works from the comprehensive *Shifâ'* (*Healing*, rendered into Latin as *Sufficientia*) of the philosopher Ibn Sînâ/Avicenna, among them the *On the Soul* with Avendauth (Ibn Da'ud) and the *Metaphysics* with an anonymous assistant. Gundissalinus apparently worked frequently with an assistant. The nature of their collaboration is far from clear even though an account of it is given in the dedication of his translation of Avicenna's *On the Soul*. It apparently involved an intermediate step of translation into the local vernacular or a reading of the text out loud. He is also thought to have translated Isaac Israeli's *Book of Definitions* and al-Kindî's *On the intellect* as well as al-Fârâbî's *On the intellect*, *Enumeration of the Sciences*, and *Liber excitativus ad viam felicitatis (Indicating the way to happiness)*. Regardless of the precise nature of his collaborations, it is clear that his study and translations had substantial influence on the thought of Gundissalinus himself as evidenced in his own philosophical works, such as *On the Procession of the World* and *On the Division of Philosophy*, which in turn together with the translations played an important role in the formation of the thought of the great philosophers of the thirteen century and later such as William of Auvergne, Albertus Magnus, Thomas Aquinas, Duns Scotus, and others who made extensive use of these works as well as the translations of another scholar at Toledo, Gerard of Cremona.

At Toledo at the same time was the great scholar, lecturer and translator par excellence of the age, Gerard of Cremona (ca. 1114–1187), who had come from Italy to Spain in search of Ptolemy's *Almagest* which he then proceeded to translate from Arabic into Latin. He was a canon at the cathedral and, so, like Dominicus, under the patronage of Archbishop Raymond. The list of Gerard's translations is long and detailed and includes works on mathematics by Euclid (*Elements*) Thâbit b. Qurrah, al-Khwârizmî, al-Kindî and others; works on astronomy by Thâbit and al-Farghânî; a medical work by Avicenna, the great *Qânûn fî tibb* (*Canons of Medicine*), which was in use into and beyond the Renaissance; philosophical works of Aristotle: *Meteorology*, *On Generation and Corruption*, *Physics*, *On the Heavens* and the *Posterior Analytics*; works by the philosophers al-Kindî and al-Fârâbî; the influential pseudo-Aristotelian *Liber de causis*; and a vast array of other works of Islamic philosophical and scientific learning. Like Gundissalinus, Gerard seems to have sometimes worked with an assistant, although this does not seem to have always been the case. As for style, much scholarly work remains to be done in the definitive identification of genuine translations by Gerard before any comprehensive remarks can be made. Still, in his translations Gerard sometimes used a common method following the work of Boethius in translating from Greek into Latin in the early sixth century: *verbum ex verbo*. The attempt was made to give translations which reflected as precisely as possible the original text in the grammatical structure of the original language's sentences and in word-for-word translation. In the case of Indo-European Greek texts, this was a somewhat reasonable way of proceeding. But in the case of Latin translations of Semitic Arabic works, some of which had already gone through translation from Greek into Syriac and then into Arabic, the medieval Latin reader was left with an intellectually challenging exercise with the result that later translations from Greek were oftentimes preferred. Nevertheless, the translations from Arabic by Gerard (and Gundissalinus) frequently conveyed well and clearly the sense and letter of the Arabic.

Translators of the later twelfth and early thirteenth centuries include the Englishman Alfred of Sareshal who translated the pseudo-Aristotelian *De plantis*, on which he wrote a commentary, and Avicenna's *De mineralibus*. Marc, a canon at Toledo, translated medical works, the Qur'ân and some theological tracts of Ibn Tûmart. Most accomplished of Latin translators from Arabic of this era was Michael Scot who was in Toledo in 1215, Bologna in 1220, and Sicily in 1227 as court astrologer to Frederick II where he died in about 1236. Michael completed his translation of al-Bitrûjî's *De spheris* in 1217 at Toledo where he also translated Aristotle's *On Animals* in part. His greatest achievement, however, was responsibility for making works of Averroes available to the Latin West where they continued to be read through the time of the Renaissance. While it is certain that Michael was the translator of *the Long Commentary on Aristotle's On the Heavens*, on the basis of current scholarship it can only be said that it is likely that Michael was also the translator of Averroes's *Long Commentaries* on Aristotle's, *On the Soul*, *Physics* and *Metaphysics.* All of these Long Commentaries contained the complete text of Aristotle with detailed commentary by Averroes drawing on materials from the Greek and Arabic tradition. Michael also seems to have translated the *Middle Commentaries* on *On Generation and Corruption* and part of the *Meteorology,* as well as Averroes's *Short Commentaries* or *Epitomes* of *On the Heavens*, *Parva naturalia* and *On Animals*. Hermannus Alemannus, William of Luna, Petrus Gallegus, and Philp of Tripoli working in the mid-thirteenth century complete the list of well-known translators from Arabic. Herman is responsible for the Latin of Averroes' *Middle Commentaries* on the *Ethics* and *Poetics* as well as for the widely circulated ethical epitome, *Summa Alexandrinorum*. William also translated some of Averroes' texts: epitomes of logical works of Aristotle and middle commentaries on the *Posterior Analytics* and *Categories*. Petrus rendered Averroes' epitome on Aristotle's *On the Parts of Animals*. To Philip is ascribed the complete Latin of the *Secretum secretorum*.

While this enormous wealth of Greek and Islamic learning was being rendered into Latin from Arabic sources in Spain, Sicily, and the Near East, twelfth century Europe was also the recipient of a vast array of translations directly from the Greek by James of Venice, Henricus Aristippus, a certain Ioannes and others. In the thirteenth century there were substantial efforts of translation from Greek by Robert Grosseteste, William of Moerbeke and others. The transmission of knowledge into the Latin West came along two different roads, each of which had its origins in Greek learning. Via the Islamic route, however, the Latin West also received the sophisticated reflections and intellectual advancements of Islamic thinkers whose religiously oriented philosophical and theological reflections on the world and its Creator were oftentimes much closer to the mentality of Christian Europe than were the texts of Ancient pagan authors. The philosophical texts of the Islamic philosophers Avicenna and Averroes, sophisticated interpretations and complex new intellectual syntheses, early on "explained" Aristotelian works to Medieval Latins and thereby had a profound influence on the methodologies and analyses worked and developed by Christian theological and philosophical thinkers from the twelfth and thirteenth centuries and beyond.

For Jewish communities the thought of Moses Maimonides was dominant and, though he was much influenced by al-Fârâbî, it was Averroes who was most important in that tradition. In southern Europe few works of Aristotle were available in Hebrew, though Samuel ibn Tibbon translated the *Meteorology* in the early twelfth century. Instead the *Short Commentaries* (or *Epitomes*) and *Middle Commentaries* of Averroes on Aristotle's *On the Soul*, *Metaphysics*, *On the Heavens* and others proved most important. Some of the translators were Moses ibn Tibbon, son of Samuel, Shem Tov ben Isaac, Zerahyah ben Isaac Hen and Kalonymous ben Kalonymus who undertook translations of Averroes's *Long Commentaries* on the *Posterior Analytics*, *Physics* and *Metaphysics*. In the Jewish tradition the various commentaries of Averroes came themselves to be the subject of commentaries, most notably by Gersonides and his followers who wrote the so-called "super-commentaries" in the fourteenth century. One Kalonymos translated the *Incoherence of the Incoherence* – the commentary of Averroes on the *Incoherence of the Philosophers* by al-Ghazâlî – into Latin for the King of Naples, Robert of Anjou, in 1328, though sources are insufficient to determine whether this is the same or a different Kalonymos who translated from Arabic into Hebrew.

In the thirteenth and fourteenth Centuries translations in Andalusia and elsewhere continued to be made from Arabic into Latin and Hebrew and also into the local vernacular. Alfonso X (el Sabio), King of León and Castile (1252–1277), sponsored translations from Arabic into Castilian including codes of law, astrology, magic, and astronomy. In these centuries the translated texts of Arabic science and medicine became central to Western development and texts of philosophy came to play a central role in Christian theological and philosophical argumentation up to and beyond the Renaissance. In the fifteenth and sixteenth centuries more translations of works of Averroes appeared, this time mostly from Hebrew into Latin. What was most significant in this was their inclusion in Renaissance printings of the works of Aristotle. The Giunta edition printed in Venice in 1550–1552 (and reprinted many times thereafter) in eleven volumes also contained revised texts and new translations by Jacob Mantino (d. 1549) and allowed for the easy use of the translated works of Averroes and the earlier versions of the works of Aristotle to be consulted and studied together.

The centrality of the notion of ^{c}*ilm* or knowledge in Islam encouraged the pursuit of learning in all its various forms and the sharing of knowledge among all the people of society, Muslims, Christians, and Jews. Scientific study and philosophical discourse in the Islamic milieu was much influenced by the late ancient schools of Neoplatonism at Athens and Alexandria. That influence is evident in recognition of the independence of philosophy as an intellectual discipline distinct from religious tradition and its development of theological argumentation. Natural reason and intellectual insight as found in philosophy in the classical rationalist tradition constituted an independent way to the understanding of human beings, the cosmos and the First Cause. The philosophical and scientific works translated into Latin were from the most part from this classical rationalist tradition and conveyed methodologies of investigation bearing an understanding of the attainment of knowledge quite different from that found in the Latin West where the Augustinan notion of faith as the foundation for understanding and knowledge was widely dominant. In the Latin later Middle Ages rationalism of the sort found in the Arabic translations danced a careful and sometimes dangerous dialectic with thinkers committed to that Augustinian notion. Thomas Aquinas developed the notion of theology conceived along the lines of Aristotelian science. Siger of Brabant was attacked in argument and charged by Church authorities for his assertions about independent rationality. And the Condemnations of 1277 caused many thinkers to move away from the more explicit rationalism of Averroes and to find philosophical inspiration in the more compatible conception of God and creation and the rational found in Avicenna's works of metaphysics and psychology. The rationalist movement in the West continued to develop into the Renaissance and Early Modern periods where the Reformation and nationalism undermined Catholic dominance and philosophy and science generally developed into something which viewed itself and its methods as separate from traditional theology, revelation and its issues. The conceptions of knowledge by thinkers of the Islamic milieu founded on translated Greek texts and developed and reconceptualized by scientists and philosophers of the Islamic tradition came to play a central role in that development thanks to the Latin translators of Spain, Sicily, and other border lands. To that extent, the role of Islam, its culture and its people, played a central part in the modern conception of science as a discipline distinct from religion, a distinction at the foundation of today's world.

Eclipse Observations

F. Richard Stephenson

The theme of this article is eclipse *observations*; for information on calculating and predicting eclipses, see the article on *Eclipse Theories*. Eclipses of the Moon and Sun are by no means rare events. In a typical century, as many as 95 lunar eclipses and 40 solar obscurations are visible at any given location (weather permitting). Observations of both types of event are frequently recorded in the history of several non-Western cultures. In ancient times, reports originate almost entirely from Babylon and China; these mainly commence after about 700 BCE. Although extant Babylonian eclipse records cease around 10 BCE, Chinese accounts continue (almost uninterrupted) down to the modern era. After the middle of the first millennium AD, further observations become available from Korea and Japan and also the Islamic world.

As yet, virtually no eclipse records have been uncovered from other major non-Western civilizations–such as ancient Egypt, India or Central America. Possible explanations for these deficiencies include loss or inaccessibility of original records, or less concern in these cultures with observation rather than prediction.

Surviving reports of eclipses are found in two quite distinct types of text: (1) chronicles and other literary works; and (2) astronomical treatises. Texts in the first category mainly note eclipses on account of their spectacular nature. Such reports, although often quite descriptive (especially in the case of total eclipses of the Sun) are usually devoid of technical details. However, astronomers often made careful timings of the various stages of an eclipse, as well as estimating the degree of obscuration of the Moon or Sun when the eclipse was at its height.

Most early non-Western cultures adopted a lunar (or luni-solar) calendar. For instance, in Babylon–and later in the Muslim world–each month commenced with the first sighting of the young crescent Moon. However, throughout East Asia months began at the conjunction of the Moon and Sun. On these systems, solar eclipses occurred either at the end or the beginning of a lunar month, while lunar eclipses took place close to the middle of a month.

Modern computations enable the date, time of day or night and other local circumstances of past eclipses to be determined with high precision. Early references to eclipses sometimes prove of value in dating historical events, while the more careful observations enable long-term variations in the rate of rotation of the Earth to be investigated with remarkable accuracy. Eclipses are thus among the most interesting of all celestial phenomena mentioned in history.

Before about 700 BCE, very few records of eclipses are extant and for most of these the dates are in doubt. It has been suggested that astrological tablets from the city of Ur contain allusions to eclipses occurring around 2000 BCE, but this is disputed. Clear references to eclipses, mainly of the Moon, are recorded on Chinese "oracle bones" from the latter part of the Shang Dynasty (ca. 1350 to 1050 BCE). These bone fragments, inscribed with a primitive script, are mainly concerned with divination. Unfortunately, few bone inscriptions are intact. In the case of the eclipse observations, the year is invariably missing, while the lunar month is only rarely preserved. As a result, determination of the exact dates with the aid of astronomical computations presents considerable difficulties.

An example for which the month is extant may be translated as follows:

> The divination on day *guiwei* was performed by Zheng: "Will there be no disaster in the next ten days?" On the third day *yiyu* an eclipse of the Moon was reported. (These events occurred) in the eighth month.

In common with numerous other Shang inscriptions, dates are expressed in terms of a 60-day cycle. This cycle has probably continued uninterrupted down to modern times. *Guiwei* and *yiyu* were the 20th and 22nd days of the cycle. The term *shi*, used to identify an eclipse, has remained in use in China down to the present day.

Probably the earliest surviving eclipse report for which a date can be confidently derived is from Assyria. This is recorded in the *Assyrian Chronicle* and may be translated as follows: "(Eponym of) Bur-Saggile of Guzana. Revolt in the citadel; in (the month) Siwan, the Sun had an eclipse (*šamaš attalu*)."

The *Assyrian Chronicle* is mainly a list of annual *limmu*–senior officials after whom the year was named. A complete list of *limmu* is preserved from 910 to 646 BCE, as well as the names of several Assyrian kings. Hence the year of the eclipse can be deduced as approximately 763 BCE. Computation shows that during the entire eighth century BCE only a single solar eclipse was large in Assyria: BCE 763 June 15. This date conveniently fits the lunar month Siwan, which was equivalent to May-June.

A few scattered reports of other eclipses (of both Sun and Moon) are preserved in Assyrian sources. However, much more extensive accounts of these phenomena are to be found in the records of ancient Babylon. Probably commencing about 750 BCE, Babylonian astronomers maintained a systematic watch for eclipses (as well as many other celestial phenomena) for around eight centuries. As well as noting the exact date of such events, estimates were given of the time of occurrence and magnitude (the maximum degree of obscuration of the Sun or Moon). The aim was to use these observations to enable better prediction of future eclipses to be made, although the ultimate goal was astrological. Both genuine observations and failed predictions are recorded on the Late Babylonian astronomical texts which were recovered from the site of Babylon in the late nineteenth century. Most of these clay tablets–many of which are badly damaged–are now in the British Museum. The operational rules of the Babylonian calendar are well understood. Although earlier years were counted from the accession of each king, they began to be continuously numbered from the Seleucid Era (311 BCE) onwards.

Among Babylonian records of eclipses, the best known is the total solar obscuration of 136 BCE. This is reported on two separate British Museum tablets, which give overlapping details. A composite translation–based on the work of Prof. H. Hunger of the University of Vienna–is as follows:

> Year 175 (Seleucid), intercalary twelfth month, day 29. At 24° after sunrise, solar eclipse (*šamáš* AN-KU). When it began on the south-west side, in 18° of daytime in the morning it became entirely total. Venus, Mercury and the Normal Stars were visible, Jupiter and Mars, which were in their period of invisibility, were visible in its eclipse [...]It threw off the shadow from south-west to north-east. [Time interval of] 35° for onset, maximal phase and clearing. In its eclipse, north wind...

When reduced to the Julian calendar, the Babylonian date is identical to that of a computed solar eclipse visible in Babylon: BCE 136 April 15. Computation shows that at that time, both Jupiter and Mars were too close to the Sun to be seen under normal circumstances, whereas Venus and Mercury were better placed for regular visibility. The unit of time here translated as "degree" (i.e. *uš*) was precisely equivalent to 4 min. Measurements were presumably made with the aid of a water clock, although reference to the device used is lacking. The "Normal Stars" were certain reference stars in the zodiac belt. Many similarly detailed descriptions of both solar and lunar eclipses are preserved on the Late Babylonian astronomical texts. Extant observations range in date from 713 to 10 BCE.

On many Late Babylonian astronomical texts, the date is damaged. However, unambiguous restoration is often possible. In the following account of a lunar eclipse, the name of the king is missing, but this omission presents few problems.

> [...] year 42, twelfth lunar month, day 15. At 1,30 (= 90) ° after sunset [lunar eclipse...] 25° duration of maximal phase. In 18° it became bright. West (wind) went. It was eclipsed 2 cubits below γ Vir.

The small tablet on which the above observation is preserved also mentions another lunar eclipse–in the 6th month of the same year. Among Late Babylonian kings, only Nebuchadrezzar II (42nd year = 563/2 BCE) and Artaxerxes II (42nd year = 363/2 BCE) are known to have reigned for such a long time. However, computation reveals that whereas during the appropriate year of Nebuchadrezzar there were indeed lunar eclipses in the sixth and twelfth lunar months, in the 42nd year of Artaxerxes II eclipses only took place in the third and ninth months. The date of the eclipse in the above text can thus be reduced to BCE 562 March 3. Furthermore, on this night the Moon would be about 3° to the south of γ Vir, in close accord with the record.

Occasional indirect allusions to eclipses are found in the Old Testament, notably in the books of the Prophets Amos (VIII, 9) and Joel (II, 31). However, the most direct reference to an eclipse in the history of ancient Israel is recorded by Flavius Josephus, a Jewish historian of the first century AD. In his *Bellum Judaicum*, Josephus described this event as occurring only a few days before the death of Herod the Great, and it is thus of importance in dating the birth of Jesus Christ. Josephus gives the following account:

As for the other Matthias who had stirred up the sedition, he (Herod) had him burnt alive along with some of his companions. And on the same night there was an eclipse of the Moon. But Herod's illness became more and more severe.

Josephus uses the standard Greek term *ekleipsis* for an eclipse. The events described occurred around the time of Passover, a spring full-Moon festival. Computation shows that between 17 BCE and AD 3, the only springtime lunar eclipses visible in Judea occurred on March 25 in 5 BCE (a total obscuration) and March 13 in the following year (a partial obscuration). The latter date fits better the chronology of the period, although the two dates are conveniently close together.

For several centuries after the birth of Christ, scarcely any eclipses (whether of Sun or Moon) are recorded in the non-Western world outside East Asia. However, during the ninth century AD, both Muslim astronomers and chroniclers began independently to note the occurrence of these events. Between about AD 830 and 1020, astronomers–largely based at Baghdad or Cairo–frequently made careful observations of eclipses, measuring the times of the various phases and estimating the magnitudes. The main motive for these activities was to test the reliability of contemporary eclipse tables, but lunar eclipses were sometimes effectively used to determine the difference in longitude between two selected cities. Astronomers would first make a prediction of when an eclipse would occur and then assemble one or more groups to observe it.

Our principal source of such observations is the *Zīj* (handbook) compiled by the Cairo observer Ibn Yūnus, who died in AD 1009. This work, dedicated to Caliph al-Ḥākim, is entitled *Ḥākimī Z'īj*.

Medieval Muslim astronomers were in the habit of determining eclipse times indirectly by measuring the altitude of the Sun, Moon or a bright star (probably with a sextant or astrolabe) and then converting the measurement to local time with the aid of an astrolabe or tables.

Among the many preserved lunar and solar eclipse reports, the following provide useful illustrations: a lunar eclipse observed at Baghdad on a date equivalent to AD 856 June 22 and a solar eclipse seen in Cairo on AD 993 August 20. The usual Arabic term for an eclipse was *kusūf*, meaning a 'cut' in the solar or lunar limb.

> (1) There was a an eclipse of the Moon on the night of the second day of the week (Monday), the middle of the month of Ṣafar in the year 242 of *al-Hijrah*… It was found by observation that the beginning of the eclipse occurred when the altitude of *al-dabarān* (Aldebaran: α Tau) was 9;30° in the east. The amount of revolution of the (celestial) sphere from midnight to this time, as we determined (from this measurement) with the astrolabe, was 50°. We did not determine its times except for the beginning. It was found (by observation) that the uneclipsed fraction of its body was more than one-quarter and less than one-third.

> (2) This solar eclipse occurred in the forenoon of the first day of the week (Sunday), the 29th day of (the month) of Jumāda al-Ukhra in the year 383 of *al-Hijrah*… The eclipse began when the altitude of the Sun was 27° in the east and was complete (i.e. reached its maximum) when the altitude was 45° in the east. The Sun cleared when its altitude was 60° in the east. About two-thirds of it was eclipsed.

In both of the above examples, the equivalent Julian date corresponds precisely to that of a computed eclipse.

It would appear that virtually no eclipse observations made by Muslim astronomers have survived for several centuries after AD 1020. However, many later reports of eclipses by chroniclers are preserved; these writers often emphasised the spectacular nature of these phenomena. A careful description of a total eclipse of the Sun occurring on a date equivalent to AD 1061 June 20 is recorded by the Baghdad chronicler Ibn al-Jawzī. Although he wrote a century after the event, his account is clearly based on an eyewitness description.

> (453 A.H.) On the fourth day of the week, when two nights remained to the completion of (the month of) Jumāda al-Aula, two hours after daybreak, the Sun was eclipsed totally. There was darkness and the birds fell whilst flying. The astrologers claimed that one-sixth of the Sun should have remained but nothing of it did so. The Sun reappeared after four hours and a fraction. The eclipse was not in the whole of the Sun in places other than Baghdad and its provinces.

Reference has already been made to eclipses recorded on ancient Chinese oracle bones. However, the earliest accurately datable reports of eclipses from China are found in a chronicle, the *Chunqiu* (Spring and Autumn Annals), covering the period from 722 to 481 BCE. Although no lunar eclipses are recorded in the *Chunqiu*, this work cites as many as 36 reports of solar eclipses. By this period solar obscurations were regarded as major portents, whereas lunar eclipses were considered to be of little astrological significance. Lunar eclipses only began to be recorded regularly in China from the fifth century AD.

For each of the solar eclipses which it records, the *Chunqiu* gives the full date–year of the ruler, lunar

至之日日在斗二十一度少檢十一年七月十
六日望月蝕加時在卯到十五日四更二唱丑
初始蝕到四唱蝕既在營室十五度末景初其
日日在軫三度以月蝕所衝考之其日日應在

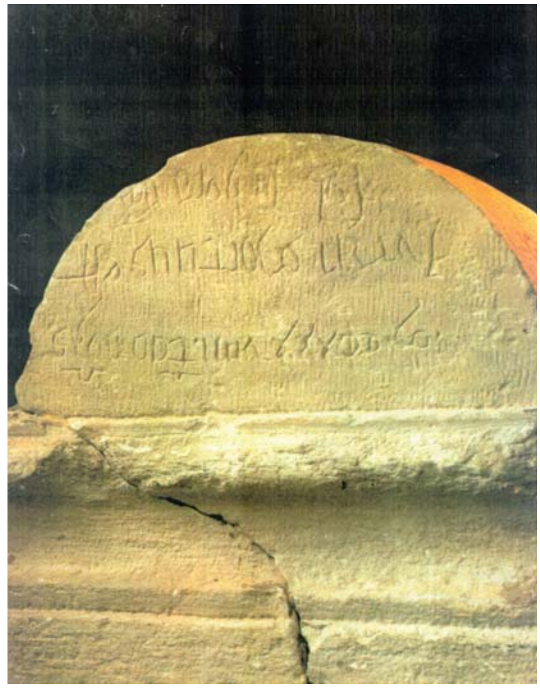
Eclipse Observations. Fig. 1 Chinese text in the calendar treatise of the *Songchu* containing timings of the lunar eclipse of AD 434.

month, day of the month and day of the 60-day cycle. Use of the sexagenary cycle (as in later Chinese history) greatly expedites the accurate conversion of dates to the Julian calendar. In almost every case the reduced date corresponds exactly to that of a computed eclipse visible in China.

Three total eclipses–occurring on dates equivalent to BCE 709 July 17, 601 September 20 and 549 June 19–are noted in the *Chunqiu*, but there are no allusions to such effects as darkness or the appearance of stars by day. Three further accounts (from 669, 664, and 612 BCE) describe eclipse ceremonies in which drums were beaten and oxen were sacrificed.

Records of the Han dynasty (202 BCE to AD 220) contain several reports of large partial eclipses of the Sun. For instance, the account of the eclipse of BCE 89 September 29 may be rendered as follows:

> Zhenghe reign period, fourth year, eighth month, day *xinyu*, the last day of the month. The Sun was eclipsed; it was not complete but like a hook… At the hour of *fu* (= 3–5 p.m.) the eclipse began from the north-west. Towards the time of sunset it recovered.

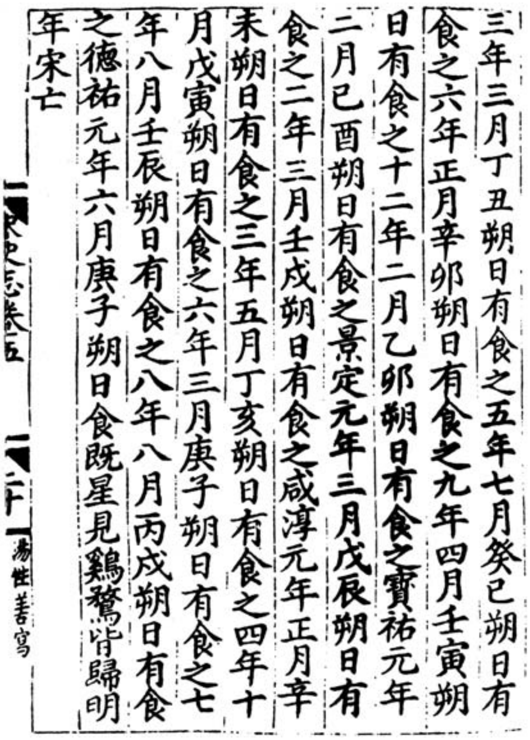


Eclipse Observations. Fig. 2 Latin inscription recording the "death of the Sun" as a result of the total solar eclipse of AD 1239. This is carved on a pillar at Marola, Italy. Photograph used with the kind permission of Dr G.R. Levi-Donati, Perugia, Italy.

The above record only notes the time to the nearest double hour. However, commencing in the fifth century AD eclipses of both Moon and Sun were often carefully timed using water clocks. The main purpose was to verify the accuracy of astronomical tables. Solar eclipses were usually timed to the nearest *ke* ('mark')–1/100 of a day and night–roughly equal to 15 min. For lunar eclipses, times were often expressed to the nearest fifth of a night watch instead–especially in earlier centuries. The period from dawn to dusk was divided into five equal *geng* (night watches), each of which was in turn divided into five equal intervals. Hence the watches and their subdivisions varied in length with the seasons.

The following account from the *Songshi* (History of the Song dynasty: AD 960–1279) uses both types of time units; the date is equivalent to AD 1186 March 25:

> Jiandao reign period, fourth year, second month, fourteenth day, *dingwei*, full Moon. The Moon was eclipsed… (various predictions)… On this evening when the Moon rose there was light cloud. Until the fall of darkness it could not be



三年三月丁丑朔日有食之五年七月癸巳朔日有

年宋亡

Eclipse Observations. Fig. 3 Chinese text in the astronomical treatise of the *Songchi* describing several 13th century solar eclipses, including the total solar eclipse of AD 1275.

> seen that the Moon was totally eclipsed. When the third mark of the initial half of the (double) hour *xu* was reached, as expected it was (partially) shining and so it could be known that the eclipse had been total on rising. It was restored to fullness at the third mark in the central half of the hour *xu*. This was the second division of the second watch.

The very earliest Korean records of eclipses appear to be copied from Chinese history and probably do not become independent until around AD 700. However, the many accounts of both lunar and solar eclipses which are preserved in later Korean history tend to be very brief, seldom giving more than the date of occurrence and noting if the eclipse was total. Eclipse records are mainly found in two major works. These are the *Koryo-sa* (the official history of Korea from AD 936 to 1392) and the *Choson Wangjo Sillok* (an extensive chronicle extending from AD 1392 to modern times). The Chinese luni-solar calendar was closely followed in Korea, although years were numbered from the accession of Korean monarchs. Around AD 1200, there are occasional references to lunar eclipse ceremonies in which the king, arrayed in white robes and accompanied by his closest ministers, attempted to rescue the Moon. However, these may have been no more than empty rites.

Commencing around AD 600, Japanese observations of eclipses are also numerous. Japanese historical sources are much more diverse that those of China and Korea, and it is fortunate that in the 1930s Kanda Shigeru made a detailed search of Japanese history down to AD 1600 for references to eclipses and other celestial phenomena. The earliest Japanese account of a total solar eclipse dates from AD 628 April 10, but this is extremely brief. Several detailed reports of later similar events are preserved, notably in AD 975 and 1460. The following account of the eclipse of AD 975 August 9 is taken from the *Nihon Kiryaku*, a privately compiled history:

> Ten-en reign period, third year, seventh month, first day. The Sun was eclipsed… Some people say that it was entirely total. During the (double) hours *bo* and *shin* (between 5 and 9 a.m.) it was all gone. It was the color of ink and without light. All the birds flew about in confusion and the various stars were all visible. There was a general amnesty (on account of the eclipse).

In this brief article it has only been possible to cite a minute proportion of the available eclipse records from the non-Western world. However, it should be clear from the selection offered here that many detailed and important descriptions are preserved. Early eclipse observations often reveal a remarkable level of sophistication, particularly in the measurement of times.

Eclipses: Calculating and Predicting Eclipses

J. M. Steele

Many reports of attempts to predict the occurrence of eclipses of the sun and moon are preserved in the histories of non-Western cultures. The majority of these records come from ancient Mesopotamia, ancient and medieval China, and medieval Japan, with a few scattered examples from Demotic and Greco-Roman Egypt, India, and the Islamic world. In addition, descriptions of the methods by which the circumstances of eclipses can be calculated are known from China, India, the Islamic World, and Mesoamerica (for the latter, see the entry Eclipses in the Americas).

The earliest reports of attempts to predict eclipses are recorded in the correspondence between the Neo-Assyrian kings of Mesopotamia and their scholars during the seventh century BCE (Hunger 1992; Parpola 1993; Steele 2000b; Brown 2000: 200–206). For example, a letter sent by one Mar-Issar to the king reads (Parpola 1993: 347):

> To the king, my lord: your servant Mar-Issar. Good health to the king, my lord! May Nabû and Marduk bless the king, my lord! May the great gods bestow long days, well being and joy upon the king, my lord! Concerning the lunar eclipse about which the king, my lord, wrote to me, it was observed in the cities of Akkad, Borsippa, and Nippur. What we saw in Akkad corresponded to the other (observation)s. A bronze ket[tledrum] was set up; the darkness [… (break) …] I have extracted the [relevant] interpretation written on the tablet and s[ent] it, together with this letter, to the king, my lord. Moreover, I shall keep watch for the solar eclipse, as the king, my lord, wrote to me. Whether it occurs or not, I shall write to the king, my lord, whatever it may be. This lunar eclipse which took place, afflicted all countries, but all its evil is heaped upon the Westland. "Westland" means the Hittite country (Syria) or, according to another interpretation, Chaldea. With the king, my lord, all is well. However, the guard should not be neglected, and the relevant apotropaic ritual should be performed for the king, my lord.

This letter reveals much about the practice of astronomical observation during the Neo-Assyrian period. The author not only reports his sighting of a lunar eclipse in Akkad, but also notes that the eclipse was seen in two other cities, Borsippa and Nippur, and that all three observations were in agreement. The letter also illustrates the serious nature of eclipses in Mesopotamian divination: even though the evil associated with this particular eclipse is directed toward the "Westland," the king is nevertheless advised to have apotropaic rituals (involving the playing of a kettledrum) performed. Mar-Issar also says that he will keep watching for an upcoming solar eclipse. This reflects an awareness by the Neo-Assyrian scholars that eclipses of the sun and moon often take place half a month from one another: a lunar eclipse in the middle of a month may be preceded by a solar eclipse at the end of the previous month, or followed by one at the end of the current month (lunar months beginning with the first visibility of the lunar crescent were used in the Mesopotamian calendar).

Several other letters attest to this awareness of a half-month interval between eclipses of the sun and moon. For example, the report Hunger (1992: 502) states:

> An eclipse of the moon and sun in Sivan (Month III) will take place. These signs are bad fortune for the kings of Westland and Akkad; and now, in this month of Kislev (Month IX), an eclipse will take place.

The author of this report appears to be saying that during the current month, the ninth of a year, an eclipse will take place, and this will be followed 6 months later, in the third month of the following year, by both an eclipse of sun and moon. The scholar is referring to the observable fact that the shortest period between visible eclipses of the same kind is 6 months. This circumstance is due to the inclination of the moon's orbit to the ecliptic; for an eclipse to occur the moon must not only be in opposition (for a lunar eclipse) or conjunction (for a solar eclipse) with the sun, which recurs after one synodic month of about 29.5 days, but also be sufficiently close to the points where its orbit crosses the ecliptic (the ascending and descending nodes), which recurs after half a draconitic month (or a whole draconitic month to return to the same node). Because the draconitic month is a little over two days shorter than a synodic month eclipses do not take place every syzygy. After 6 synodic months, however, the accumulated discrepancy between the synodic and draconitic months will be roughly half a draconitic month, and so at this sixth opposition or conjunction the moon will now be close to the opposite node, and an eclipse may occur. In fact, however, the average interval for the moon's elongation at opposition or conjunction to increase by 180° is about 5.86 synodic months. This means that occasionally eclipse possibilities are separated by only 5 months. The existence of eclipse possibilities at 5-month intervals is alluded to in the letter Parpola (1993: 45):

> Concerning the watch of the sun about which the king, my lord, wrote to me, it is (indeed) the month for a watch of the sun. We will keep the watch twice, on the 28th of Marchesvan (Month VIII) and the 28th of Kislev (Month IX). Thus we will keep the watch of the sun for 2 months.

Understanding the nature of eclipse possibilities marks a crucial step in the development of eclipse theory.

Combined with an awareness of long-term eclipse cycles, it provides a means of identifying all eclipse possibilities (months in which a eclipse might occur as opposed to those where an eclipse will definitely not). The most well-known, and indeed most practical, eclipse cycle is the so-called "Saros" of 223 synodic months (which is very close to 242 draconitic months), after which eclipses recur with almost the same magnitude, and roughly 8 h later in the day. The Saros may very well have been identified and used by the Neo-Assyrian scholars (e.g., Parpola 1983: 51; Brown 2000: 205) although we lack the evidence to be certain (Steele 2000b). However, we have ample evidence that Late Babylonian astronomers knew and understood the Saros by at least 600 BCE (Steele 2002).

The knowledge that eclipse possibilities generally occur at 6-month intervals, with occasional 5-month intervals, allows the immediate determination of the number of eclipse possibilities within one Saros period of 223 months as follows: If there are a eclipses at 6-month intervals and b at 5-month intervals with Saros, then the relationship $6a + 5b = 223$ must hold, and so a must equal 33 and b equal 5. It is then a simple step to distribute these 5-month intervals as evenly as possible within the 223 months of the Saros to result in five groups of eclipses each beginning with a 5-month interval and subsequently containing eclipses at 6-month intervals, comprising eight, seven, eight, seven, and eight eclipses. This whole distribution repeats after one Saros, resulting in a large matrix of eclipse possibilities which can then be aligned with observed eclipses to produce a scheme for predicting all future eclipse possibilities (Britton 1989; Beaulieu and Britton 1994; Steele 2000b). Several Babylonian texts are set out in just such a matrix. These include a group of theoretical texts known as "Saros Canon" tablets which contain the months of eclipse possibilities (Aaboe et al. 1991) and a remarkable group of tablets that contain a compilation of more than 400 years worth of lunar eclipse observations and predictions put into a Saros matrix (Hunger 2001: 2–4; see also Walker 1997; Steele 2001; Huber and De Meis 2004). This collection is all the more impressive because over the 400-year period it covers, no eclipses were visible in Babylon that had not been predicted in advance by this matrix scheme.

The Late Babylonian Astronomical Diaries and related texts (Sachs and Hunger 1988, 1989, 1996) provide evidence that the Saros scheme described above was used until the end of the cuneiform record, with only occasionally minor realignments to account for the very rare unpredicted eclipses. However, beginning in at least the fifth century BCE, and therefore contemporary with many of the records in the Astronomical Diaries, the Babylonians developed theoretical mathematical methods to calculate eclipses. These developments culminated into two distinct lunar theories, known today as System A and System B (Neugebauer 1955). Both Systems A and B have as their goal the calculation of the moment of successive lunar syzygies, whether an eclipse will occur at that syzygy, and the date of first visibility of the lunar crescent which determines the beginning of the month by highly ingenious mathematical schemes which involve separating out the effects of lunar and solar anomaly. However, the two theories differ in how they calculate the various phenomena. For example, in System A, the increase in the moon's longitude from one syzygy to the next syzygy of the same kind is functionally dependent upon the moon's position in the zodiac at the previous syzygy (a so-called "step function"), whereas in System B it is dependent upon the previous increase (a "zigzag function"). In both systems, an eclipse is predicted whenever the moon at syzygy is closest to the node. The node itself is assumed to regress at a uniform rate through the ecliptic (Aaboe and Henderson 1975), and the moon's nodal elongation can then be used to gauge the magnitude of an eclipse (Britton 1989). It remains an open question why these mathematical methods, which admittedly result in predictions that are not significantly better than the Saros methods described above, were apparently not used to make the predictions found in the Astronomical Diaries.

Many aspects of Mesopotamian astronomy were transmitted to India, either through Persia or Greek intermediaries. However, most Indian eclipse theories are founded upon the basic principles of Greek geometrical astronomy. For example, in the *Pañcasiddhāntikā* of Varāhamihira (Neugebauer and Pingree 1970), a description of five astronomical theories written in the sixth century AD, we find several methods of calculating eclipses, all of which rely on determining the longitude of the moon and the lunar node at syzygy. If the distance of the moon from the node falls below a certain amount (known as the "eclipse limit") then an eclipse will take place. The circumstances of the eclipse are then calculated taking into account the effects of parallax.

Remarkably, eclipse theories of the kind reported in the *Pañcasiddhāntikā* were still being used during the eighteenth century in parts of Asia. A report written by Lt Col. John Warren in 1825 describes his meeting with a Tamil villager who computed a forthcoming lunar eclipse using shells on the ground as counters. He had memorized the tables resulting from Indian eclipse theories in oral fashion, and he was able to predict the eclipse with a remarkable level of accuracy (North 1994: 165–166).

Many hundreds of predictions of solar and lunar eclipses are reported in the dynastic histories of China

(Steele 2000a). These records, generally found in the *Dianwen* treatises, are often indistinguishable from reports of observed eclipses, simply giving the date of an eclipse. However, study of these dates has revealed that many do not correspond to eclipses that could have been observed in China and so they must have been calculated. Eclipse prediction was one of the most important tasks of the officially promulgated astronomical systems known as *Li* (customarily translated as "calendar"). The *Li* were reformed frequently throughout Chinese history, more often than not for political, rather than astronomical, purposes (Cullen 1993). Descriptions of these *Li* are found in the calendar treatises of many of the dynastic histories.

The oldest calendars to contain rules for calculating eclipses, the *Santong li*, the *Sifen li*, and the *Qianxiang li*, date to the Han period (ca. second century BCE to second century AD). All three make use of an eclipse cycle of 135 months. As in Mesopotamia, the eclipse cycle was used to identify all eclipse possibilities, not just eclipses which come 135 months after an observed eclipse. Assuming that the 23 eclipse possibilities within the 135-month cycle are evenly spaced, the mean interval between eclipse possibilities is 5 20/23 months. Adding on 5 20/23 months from the epoch date of the calendar (when it was assumed an eclipse had occurred), keeping the fractions in the running total, but rounding down to find the month of an eclipse, allowed the dates of all future eclipses to be calculated (Sivin 1969).

The first mathematical treatment of eclipses in China is found in the *Qingchu li* of the third century AD (Yabuuti 1963). Beginning with this calendar, eclipses were calculated by determining whether the moon at syzygy was sufficiently close to a node to produce an eclipse. However, unlike in India, the eclipse limits which were used to determine whether or not an eclipse would occur were not expressed in degrees of longitude, but used instead the number of days it would take the moon to reach the node, given by the ratio distance from node/daily lunar motion = x days. For example, in the *Dayan li* a lunar eclipse would occur if x was less than 3523.9/3040, and if x was less than 779/3050 the eclipse would be total (Yabuuti 1963). A simple arithmetical formula could then be used to determine the magnitude and duration of the eclipse from the quantity x.

A detailed theory of parallax was never developed in traditional Chinese astronomy; instead a number of semiempirical corrections were added into their calculations to try to account for its effect (Nakayama 1969: 144–145). However, these corrections were not generally sufficient. For example, in the *Dayan li* corrections were applied to take into account the moon's declination, but not its hour angle at the time of the eclipse. Similarly, the effect of geographical location was not fully taken into account in Chinese eclipse theory. In the *Dayan li* crude adjustments to the eclipse calculations were introduced to take into account the observer's latitude, but no corrections were applied for his geographical longitude.

Other countries in East Asia, most notably in Korea and Japan, adopted Chinese eclipse theory, along with many other parts of Chinese astronomy. Often, however, this adoption would lag significantly behind the reforms of the calendar which took place in China. For example, the *Xuanming li* was replaced in China in AD 892 but was still being used in Japan until AD 1685. Several hundred reports of predicted eclipses are preserved from Japan. Interestingly, these often include the calculated time and magnitude of the eclipse. Because the calendar did not take into account the difference in geographical longitude between China and Japan, the times are systematically off by about an hour and the magnitudes of solar eclipses are frequently very inaccurate (Steele 1998). A rare report which contains both the calculated and observed circumstances of an eclipse illustrates these discrepancies (Steele 2000a: 221):

> 2nd month, new moon, *dinghai* day [21 February 1319 AD]. The previous night heavy rain fell and a great wind blew. At dawn the wind and rain stopped and the sky cleared. That day the sun was fourteen fifteenths eclipsed. The loss [should have] begun at 4 marks and 17 *fen* in the hour of *mao*, as the calculated time [of the middle of the eclipse] was at 4 marks and 22 *fen* in the hour of *chen*, and [the sun should have] returned to fullness at 4 marks and 27 *fen* in the hour of *si*… Investigating at that time (it was seen that) the loss began during the hour of *chen* and it returned to fullness during the hour of *wu*. The calendar gave the eclipse as fourteen fifteenths, but it was only seven fifteenths eclipsed.

Despite these large discrepancies, we have no evidence of any attempts to correct or improve the *Xuanming li* eclipse theory in Japan.

Eclipses in the Americas

Hugh Thurston

We have no information about eclipses observed in America before the arrival of the Spaniards. There are two descriptions by Bernard Sahagún in his *General History of Things of New Spain* (Book 7: 8–10). Here is a précis.

> When the moon was eclipsed darkness spread. Pregnant women were afraid that their unborn children might be turned into mice. To protect themselves they put obsidian in their mouths and on their breasts.
> When the sun was eclipsed it turned red, became troubled, and turned yellow. There was tumult and everyone was frightened. People of light complexion were sacrificed and captives were killed. Suitable chants were sung in the temples. People said that if the eclipse is total it will be dark for ever.

This applies to the Aztecs. The Incas in South America, according to Garsilaso de la Vega (1609), thought that when the moon eclipsed it was ill. When an eclipse began they became afraid and sounded everything that would make a noise, even beating their dogs to make them yelp, so that the noise would awaken the moon from the sleep caused by the sickness.

Eclipses of the sun in 1496 and 1531 were pictured in the Aztec Codex *Tellerianus Remensis*.

Perhaps the most interesting eclipse observed in Mesoamerica is an eclipse of the moon on February 29th, 1506. Columbus was stranded in Jamaica, whose natives refused him provisions. He knew that there would be an eclipse of the moon that evening and threatened to destroy the moon if the natives did not agree to provide provisions. When the eclipse started, they agreed.

We have no records of eclipses observed by the Mayas. But we do have calculations concerned with eclipses. There are displayed on pages 51–58 of the Dresden Codex.

Each half-page of each page is a unit. The upper halves come first, so the lower half of page 51 follows the upper half of page 58. The first half-pages are an introduction; the table itself starts on page 53. It has 69 columns, which I have numbered, separated by broad

Eclipses in the Americas. Table 1 Transcription of the numbers from pages 51 to 58 of the Dresden codex

columns ending in pictures which are not part of the table. In each column the top two glyphs are not astronomical; for example, in column 14 they are "death" and "owl" (Davoust 1997). Then comes a number, presumably a count of days, then three successive days in the sacred round, then another number.

In Table 1 I have translated the Mayan numerals into decimals and replaced the Mayan glyphs for each day in the sacred round by its position in the round (e.g. 1 Imix by 1, 13 Ahaw by 260 and so on). The diagram shows just the middle one of the three days. The top row is a cumulative total of the numbers in the bottom row.

There are a few mistakes in the Mayan table. For example, a dot is missing from the first number, which reads 157 instead of 177. But so many totals are right that it is easy to correct the few wrong ones. The interval between the days of the sacred round agrees with the intervals in the cumulative total. There are six places where 178, not 177, is added to the cumulative total (and to the sacred round).

To the nearest whole day, 177 is the number of days in six months and 148 is the number of days in five months. This suggests that the table is concerned with eclipses; an interval between eclipses of the moon is nearly always the sum of a number of six-month intervals with or without one five-month interval. (Because an eclipse of the moon occurs only at full moon, a whole number of months – lunar months, not calendar months – must elapse between eclipses.) The intervals between successive eclipses of the moon visible in northern Yucatán between AD 400 and AD 500 are 6, 11, 12, 17, 18, 23, 29, 35, 41, 53, 59, and 65 months. Each of these is made up as described: for example 17 is 6 + 6 + 5. This could easily give rise to the idea that a table for eclipses should use six-month intervals and a few five-month intervals.

Very few eclipses of the sun were visible in the Maya region and only a very nearly total eclipse would be seen. If the sun is even as much as 90% eclipsed the light will not be noticeably dimmed and looking at the sun would be painful.

How would the table be used? There are far too many columns for each to mark an eclipse, and far too few pictures for the entry before each to mark an eclipse, even though the gap between pictures consists of six-month intervals plus one five-month interval. Probably the Mayas had discovered how to pick out dates on which eclipses could not occur and the 69 columns represent 69 full moons that could not be ruled out (out of the 405 covered by the table), so the table eliminates 336 false alarms. (The Babylonians had a table which did this.)

Most early cultures had a relation of the form so many months equal so many days. The Mayas seem to have had 405 months equal to 11,958 days. (i.e. 135 months equal 3,986 days).

If we have a starting date for the table we can add the cumulative totals to it to find a date for each column. The introduction contains four dates in the Mayan long count (a) 9.16.4.10.8; (b) 9.16.4.11.3; (c) 9.16.4.11.18; (d) 9.19.8.7.8. Date (a) is 755 AD November 12th Gregorian, and is close to the date of a new moon. Date (b), 15 days later, is close to a full moon, and date (c) is close to the next new moon. Date (d), some 60 years later, is neither. With (b) as starting date we find from Liu and Fiala's *Canon of Lunar Eclipses from 1500 BCE to AD 3000*, that there were 49 eclipses of the moon in the period covered by the table, and every one is within 2 days of the date of a column. The ones near the beginning are mostly correct; several later ones are 2 days early. This may be because the table covers 11,958 days, whereas 405 months average 11,960 days.

Extra: Eclipses in the Americas

Authorities are not agreed on whether the Mayan table refers to eclipses of the sun or eclipses of the moon (or perhaps both). In favor of eclipses of the moon is the fact that there are enough of them for the Mayas to be able to deduce something about their distribution. In favor of eclipses of the sun is the fact that two of the dates in the introduction are dates of the new moon.

Although many writers of programs on television and authors of popular books believe that the Mayas could predict eclipses, few astronomers and Mayanists do. Exceptions are Victoria and Harvey Bricker, in Current Anthropology (1983) 24: 1–18.

Elements: Reception of Euclid's *Elements* in the Islamic World

Sonja Brentjes

Euclid (ca. 3rd century BCE) was a Greek mathematician. His name and his major work, the *Elements*, are famous not only among mathematicians, but also to students of other disciplines.

The *Elements* were sent by the Byzantine emperor from Constantinople to the Abbasid caliph al-Manṣūr (r. 754–775) in Baghdad. We do not know if any of the scholars of his time prepared a translation or at least a summary for him or the scholarly community.

The earliest translation, according to medieval historical sources, was carried out by al-Ḥajjāj Ibn Yūsuf Ibn Maṭar (fl. between 786 and 833) for the famous Barmekide Yaḥyā Ibn Khālid (d. 805), wazir of caliph al-Hārūn al-Rashīd (r. 786–809) or, perhaps, the caliph himself. This translation seems to be lost in Arabic.

Some 20 years later, al-Ḥajjāj composed a second Arabic version of the *Elements*, which he dedicated to caliph al-Maʾmūn (r. 813–833). One of those sources reports he did this to gain the caliph's support, because al-Maʾmūn's love for knowledge and his generous attitude toward scholars were well known (Codex Leidensis 399, 1, 1897). To achieve this goal al-Ḥajjāj is said to have rewritten the *Elements* extensively with respect to their language, methods, and didactical features for people with knowledge in and love for this discipline, without changing the contents itself.

Some fragments of his version 2 seem to have been preserved in different forms:

1. As part of a collection of mathematical texts put together in about the sixteenth or seventeenth century in Persia
2. As additions to Arabic translation manuscripts in those parts which transmit by and large the edition of Isḥāq Ibn Ḥunayn's (d. 910/911) translation by Thābit Ibn Qurra
3. In parts of Book III and the complete Book IV of the preserved Arabic translation manuscripts
4. Perhaps as a variant of books XI–XIII in two of the translation manuscripts; and in a barely recognizable form
5. As parts of a commentary written by al-Nayrīzī probably at the beginning of the tenth century
6. As a paraphrase composed around a hundred years later by Ibn Sīnā (d. 1036)

Those fragments, although they differ in some essential aspects, are characterized by a technical language using expressions from algebra, arithmetic, early logical or theological writings, as well as some words borrowed from Syriac, characteristic of the early translations into Arabic.

Furthermore, two of the Latin translations of the twelfth century, one by Adelard of Bath (so-called version 1), the other ascribed by the editor to Hermann of Carinthia (Busard 1968, 1977), contain at least extracts, possibly also more, of one of the Ḥajjāj versions. It is still an unsettled question as to how close these translations are to an original Ḥajjāj text and to which Ḥajjāj version they are related. A third possible, but also still disputed, source for the Ḥajjāj tradition is the only surviving Syriac fragment of Book I. Finally, some of the Hebrew translations of the *Elements* contain notes which are related to some of the additions ascribed to al-Ḥajjāj in the above-mentioned Arabic manuscripts.

Al-Ḥajjāj's work, evidently, was crowned by success. In 828/829 he was ordered to translate the *Almagest*. The scholarly community eagerly accepted his translation and edition. They organized meetings discussing the *Elements*, the *Almagest*, and, probably other subjects. They composed editions and commentaries. Among the earliest works of this type are the editions made by al-Jawharī and al-Kindī (d. ca. 873). Except for short fragments, their texts are lost.

A fresh start was made in the second half of the ninth century. Perhaps because of the shortcomings ascribed to the earlier translation or for some other reasons unknown to us so far, Isḥāq Ibn Ḥunayn prepared a completely new translation of the *Elements*, probably before 872. Together with his translations of other important mathematical and astronomical texts, it was revised by Thābit Ibn Qurra at about the same time. Yet, we neither know the reasons for nor the extent of those revisions.

The version contained in nearly all preserved Arabic translation manuscripts seems to be this edition – at least in the Books I, II, V, and VII–IX. Other books, however, seem to be based on al-Ḥajjāj's work (see above). Most of the Hebrew translation manuscripts as well as the Latin translation by Gerard of Cremona are also derived to a great extent from Thābit's edition. This so-called Isḥāq/Thābit tradition exercised the greatest influence upon mathematical research and teaching in the medieval Muslim world until the late thirteenth century. It is characterized by a very literal translation of a text connected with the Greek edition made by Theon of Alexandria (fourth century). It differs in several aspects from the Greek critical edition made by Heiberg (1883). In some cases, Thābit is ascribed variant readings or even whole proofs taken from newly available Greek sources or other Arabic manuscripts, probably derived from the Ḥajjāj tradition. In other cases, the differences in text, diagrams, and proofs might well have been already present in the

Greek manuscript translated by Isḥāq Ibn Ḥunayn. This leads to two questions that we are unable to answer at the moment:

1. Did Isḥāq follow the methodological rules devised by his father Ḥunayn Ibn Isḥāq and collate manuscripts to establish a reliable Greek text or not?
2. Which criteria motivated him in his choice between different variants of the same theorem?

Until the end of the thirteenth century several new Arabic editions based on the two ninth-century traditions were produced. The most successful in terms of later influence were the two ascribed to Naṣīr al-Dīn al-Ṭūsī. Only one, however, consisting of 15 books, was composed by him. The other one, which contains only the genuine 13 books of Euclid, was finished in 1298, after al-Ṭūsī's death. Both versions replaced the earlier traditions, judging by the number of preserved copies, marginal notes in manuscripts, and references to the *Elements* in mathematical and nonmathematical works.

While the two ninth-century traditions follow the Greek text relatively closely, the two so-called al-Ṭūsī revisions are a free rewriting of the *Elements* with respect to language, didactics, proofs, and variations. Proofs are generally abbreviated and condensed, further definitions or lemmata have been added, and for some difficult points new proofs have been provided. Such a free attitude toward a received text by an accepted authority deviated from values characteristic of or defended by the scholarly communities in medieval Islamic societies. It can be observed, nevertheless, since the beginning of the ninth century in nearly all Arabic editions and commentaries on the *Elements*. This is one of the reasons that contemporary research about textual history is so difficult and the study of the mathematical results of the transmission so fruitful.

Although all 15 books of the *Elements* attracted the attention of Muslim scholars, the central points of interest were the parallel postulate (Book I), the definitions of ratio and proportion (Book V), and the geometrical theory of quadratic irrationalities (Book X).

Efforts to prove the parallel postulate started with Greek mathematicians and philosophers, since the form given by Euclid did not fit into their ideas about what an axiom or a postulate should be. Parts of this discussion were translated into Arabic as Simplikios' (sixth century) commentary on the definitions of Book I and, perhaps, Heron's (second century?) commentary on the *Elements*. Both commentaries are lost in Greek and Arabic. Extracts from both are preserved in a revised form in al-Nayrīzī's commentary on the *Elements*. Extracts from Heron's commentary can also be found in Ibn al-Haytham's great commentary. The Arabic analysis of the parallel postulate started at the beginning of the ninth century with al-Jawharī and other scholars.

The geometers working on this postulate followed two different approaches. One approach, represented by ᶜUmar al-Khayyām (d. 1131), sought to establish a theory of parallels independent of the Euclidean postulate which would allow them to prove theorem I,29, the first which Euclid proves on the basis of the parallel postulate, without using this postulate. In modern terms one could call this an effort to establish an absolute geometry. The second approach, represented by al-Jawharī, Ibn al-Haytham, Naṣīr al-Dīn al-Ṭūsī, and other scholars, was concentrated solely on proving the parallel postulate.

With respect to Book V the main result of the debate was, however, cautious and reluctantly formulated, the introduction of a new number concept, which enlarged – speaking in modern notions – the Greek concept of numbers as natural numbers (without one) to the positive real numbers (without zero) by ᶜUmar al-Khayyām and Naṣīr al-Dīn al-Ṭūsī. It was developed discussing compound ratios, i.e., the multiplication of ratios, already dealt with by Greek mathematicians. One of the reasons stimulating this research was its use in astronomy. Closely connected was the debate about the proportion theory for geometrical magnitudes. Although Arabic commentators did not reject this theory as wrong, they were dissatisfied with the fundamental definitions V,5 and V,7 about identity of ratios and inequality of ratios. They argued that the equimultiple concept used in those definitions, for instance definition, did not express the essence of a ratio clearly, which in their opinion was the measuring of one quantity by another one. They replaced it by a definition built upon the so-called Euclidean algorithm or, speaking in modern terms, on the comparison of the expansion of each ratio into a continued fraction. Among the medieval scholars who wrote treatises on it were al-Jawharī, al-Māhānī (ninth century), Thābit Ibn Qurra, and ᶜUmar al-Khayyām. The latter thought he had proven the equivalence between both theories of proportion, which allowed the use of all Euclidean theorems in Books V and VI in the second theory. Since proportions were of primordial importance for deriving and proving new results in geometry and astronomy, this was an essential project. His proof was based on a theorem that to three proportional magnitudes a fourth proportional always exists. The fundament of his proof for that theorem was a principle attributed to Aristotle about the infinite divisibility of (geometrical) magnitudes. Lacking the notion, not to mention a strict definition, of continuity, this principle, however, was insufficient for his purpose.

The main issue discussed with respect to Book X – which was perceived as the most difficult book of the *Elements* – was the question of how the geometrical magnitudes treated in it were related to the roots of non-quadratic numbers used by algebraists and arithmeticians. To answer this question in a meaningful way meant developing a new conceptual understanding of the objects involved and creating a technical language which made it possible to speak about geometrical and algebraic-arithmetical irrationals on the same mathematical level. After several incomplete trials during the ninth and tenth centuries, the equivalence of the different kinds of geometrical irrationals of Book X and simple as well as compound algebraic-arithmetical irrationals was established in the sense that one type could be translated into the other one. This debate not only brought the heirs of theoretical Greek mathematics together with practitioners trained in Eastern traditions, but it also attracted laymen from other fields, who ordered – at least until the fourteenth century – copies of such commentaries on Book X, asked for explanations of their contents, and were proud to possess them.

Embalming in Egypt

Aidan Dodson

Embalming is the artificial preservation of the body. In Egypt, the first examples date to Late Predynastic times (late fourth millennium BCE), when the tight wrapping of the corpse is first found at the site of Heirakonpolis. Prior to this, bodies were simply laid in graves in the desert, where in some cases the hot and dry conditions promoted the natural desiccation of the body, producing a wholly natural 'mummy' (Fig. 1).

It has been generally assumed that it was the observation of such corpses that led to the Egyptians developing artificial methods once the introduction of proper tombs divorced the body from the natural preservative environment. It has been further surmised that the motivation so to do was derived from a belief that physical preservation of the body was required for the successful existence of the spirit in the next world. However, there are no explicit statements of this in the ancient texts.

During the Early Dynastic Period and Old Kingdom (ca. 3000–2500 BCE), the emphasis was on the exterior appearance of the completed mummy. Each limb was separately wrapped, and a layer of plaster applied to the outer layer, enabling the modelling of the facial features, genitalia and other elements. On

Embalming in Egypt. Fig. 1 Naturally preserved mummy, now in the Egyptian Museum, Turin (photo by author).

occasion, the finished body was dressed in real clothing. The body was invariably placed on its left side, initially with the legs drawn up tightly against the body, later in a more relaxed, mildly flexed, pose (Figs. 2 and 3).

At the same time the first moves towards the preservation of the actual corpse itself were made. The internal organs, a key source of putrefaction, were sometimes removed and placed in four 'canopic' jars and/or a chest (Figs. 4 and 5). The viscera were ultimately under the protection of four particular deities: Imseti (liver), Hapy (lungs), Duamutef (stomach) and Qebehsenuef (intestines). The heart was always left in the body: according to Egyptian belief it was the seat of intelligence and thus needed to remain in place.

Embalming in Egypt. Fig. 5 Canopic jars of King Taharqa (Twenty-fifth Dynasty) from Nuri, and now in the Museum of Fine Arts, Boston, Massachusetts (photo by author).

The organs were desiccated using natron – a mixture of sodium bicarbonate, sodium carbonate, sodium sulphate and sodium chloride. It is found naturally in

Egypt, most commonly in the Wadi Natrun some 64 km northwest of Cairo. This material came to be fundamental to the embalming process, and by the end of the Old Kingdom, the key activity in the mummification process was the placement of the body on a stone slab, upon which it was covered with powdered natron for approximately 40 days. By tradition, the entire mummification process was supposed to take 70 days, although there are known examples of its taking longer.

By the beginning of the Middle Kingdom (2100–1700 BCE), there had been major changes in the external presentation of mummies. Rather than having their limbs separately wrapped and left visible, the plaster was omitted and extra layers of padding and wrappings added to make the mummy essentially cylindrical, with a mask placed over its head and shoulders. These changes coincided with the rise to prominence of Osiris as god of the dead, and made the corpse into a simulacrum of the god (Fig. 6) which now lay fully stretched out, albeit still lying on its left side, facing east (Fig. 7).

As far as the physical body was concerned, a fair degree of experimentation is seen during the Middle Kingdom. Many were eviscerated in what was to become the traditional fashion, via an incision made in the left flank. There were, however, several mummies that seem to have been treated with an enema of tree-oil, most probably juniper or turpentine. This partially dissolved the viscera, the remains of which seem to have been extracted anally. The skin, desiccated with natron, was sometimes coated with resin. Brains were generally left in place, but in some cases were removed via the nose. To do so, the ethmoid bone at the back of the nose was broken through and a probe used to break up the decaying brain tissue, which was then allowed to drain out of the nostrils. The cavity would often be filled with linen and/or resin.

It was during the New Kingdom (ca. 1550–1070 BCE) that mummification reached its ‘standard’ form. Brain removal and organ extraction through the flank became usual in high-status interments, although some bodies retained their brains. Natron treatment often produced excellent results, particularly demonstrated by the considerable number of royal mummies that have survived. Resin was lavishly employed and, as well as being poured, via the nose, into the emptied cranium, was frequently applied to the face and body and moulded into little balls and used to plug ears, and, occasionally, the anus. It should be noted, however, that simple wrapping with linen was still practiced in the middle and lower ranks of society, as had always been the case, and always would do.

Various ritually protective items were increasingly placed on the body during the New Kingdom and later. For example, a stone beetle (the ‘heart scarab’) was placed above the heart, and an ornamented plate over the embalming cut in the flank. Various other amulets might also be placed within the wrappings, to surround the body with ritual protection (Fig. 8).

By the Twentieth Dynasty (ca. 1190–1070 BCE) a number of innovations began to appear. Lichen and sawdust began to be used to pack out the abdomen,

Embalming in Egypt. Fig. 8 Protective plate from the embalming wound of Queen Henttawi (Twenty-first Dynasty), now in the Cairo Museum (photo by author).

Embalming in Egypt. Fig. 9 Face of the Twentieth Dynasty mummy of King Ramesses IV (Cairo Museum), which has small onions acting as false eyes (photo by Martin Davies).

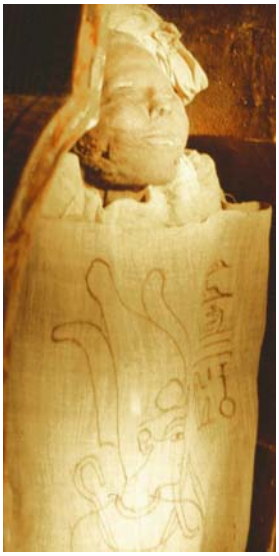
while small onions were sometimes placed in the eye sockets, all to impart a more lifelike appearance to the emaciated corpse (Fig. 9). This was taken further during the next dynasty, when elaborate packing began to be placed under the skin (Fig. 10). When successful, it produced a very lifelike effect; however, there were many examples of over-packing, and at least one body suffered the splitting open of its face as the skin continued to dry and contract.

Typically, the body cavity was filled via the evisceration cut, through which the back was also dealt with. Often, through this same cut the neck area was filled with semi-liquid mud or sawdust. The thighs were also accessible from this incision with the aid of sticks to push the filling down, although sometimes they were filled from a cut made in the back of the knees, an incision that was generally used to fill the calf. Some mummies show vertical incisions for stuffing in each buttock, with incisions at the ankles used to stuff the feet. Arms were packed through horizontal incisions made in the ventral and dorsal sides of the shoulders and sometimes in the elbows. To complete the effect, make-up was applied to the face, false eyes fitted and hair enhanced with hair extensions.

A further change, which started to appear during the Twentieth Dynasty, was the return of the viscera to the body after their separate desiccation, often accompanied by wax images of the four protective genii (Fig. 11). Interestingly, although now without a physical function, canopic jars were often retained as purely ritual objects, ultimately becoming solid.

The stuffing of the body was fairly short-lived, and had largely disappeared by the end of the Twenty-second Dynasty, although the body cavity was still generally filled with earth and sawdust. There was a revival in the placement of the viscera in canopic jars during the Twenty-fifth Dynasty (ca. 720–663 BCE), but during the Saite and Late Periods (663–332 BCE) the visceral packages were placed between the thighs or lower down, between the legs.

During the Graeco-Roman Period (from 332 BCE), there was a gradual decline in the quality of embalming. A typical feature of mummies of first century BCE and first century AD is the heavy use of liquid resin both inside the body cavity as well as on the surface of the body. The third and fourth centuries AD show that the bodies were neither eviscerated nor de-brained, but thickly covered with resin. One innovation of the Early Roman Period, however, was the gilding of the mummy. Fingers, toes, eyelids, lips, hands, feet, genitals, and on occasion the entire body were covered with a fine layer of gold. Another interesting feature of the Roman Period is the arm position found on many mummies. For the vast majority of Egyptian history, arms had been placed at the sides. However, the crossed pose is found on occasion during the Middle Kingdom



Embalming in Egypt. Fig. 10 The mummy of the High Priest of Amun, Masaharta, showing the packing typical of the Twenty-first Dynasty. It is now in the Museum of Mummification, Luxor (photo by author).

and, in particular, on the mummies of the kings of the New Kingdom. The pose – associated in particular with the god Osiris – was then revived in Roman times and is found in a large number of burials.

Mummification effectively came to an end with paganism, although there are a few examples of mummies that clearly belong to Christians. The creeds of Christianity and Islam took a very different view of the role of the corpse, bringing to an end three and a half millennia of development.

Embalming in Egypt. Fig. 12 Mummy of a ram, sacred to the god Khnum, and buried in his temple at Aswan, now in the Louvre Museum, Paris (photo by author).

Mummification was not restricted to human beings. At all periods of Egyptian history many gods had an animal form, and a representative of that creature would be kept in a temple as an incarnation of the god. These were often embalmed after death using similar methods to those employed for humans (Fig. 12); pets of high-status individuals were also mummified. In Late and Graeco-Roman times the production of animal mummies was greatly expanded to provide votive offerings for sale to pilgrims. In these cases the external appearance of the mummy was most important, and the actual embalming could be poor. Indeed, some such 'mummies' could contain minimal animal remains, or be wholly fake.

Engineering

Arnold Pacey

Engineering has become the paradigm or model for almost all technology in the West, hence terms such as “genetic engineering”, or “systems engineering”. Applied to the non-Western world, this use of language can be grossly distorting, preventing recognition of other paradigms. Thus the word “engineering” is best limited to construction works and related mechanical devices. Moreover, the smallest of such works, as carried out by individual house builders or farmers practicing irrigation, may often be better considered in other contexts, such as “building” or “agriculture”.

Three kinds of construction works need to be considered, namely those related to fortifications, monuments, and water management. Methods of construction were nearly always labor-intensive, so various ways of organizing a labor force are important for understanding what was involved. In Southeast Asia, for example, irrigation systems for rice culture were often built by groups of farmers working cooperatively. Thus on the island of Bali, there was a social unit known as a *subak* comprising all the farmers whose fields were watered from the same source, who had to come to a mutual arrangement about regulation of water flow, repairs and new construction.

By contrast, very large construction works were usually carried out by order of a king or emperor, supervised by state officials, and using conscript or corvée labor. An example is the New Bian Canal in China, completed in AD 635, on which five million people were said to have worked at different times.

The organization of labor, supervision of construction, and payment for materials might take other forms if the work was being done for a rich villager or other notable, or if it had been initiated by a religious community based at a temple. The latter were often very important, and in China, Buddhists helped pioneer the use of iron in bridge building as well as in the architecture of temples between AD 500 and 1200. Buildings for religious or funerary purposes were also built at the instigation of rulers, often on a very ambitious scale. One thinks of the pyramids of Egypt, Maya temples in Central America, and numerous temples in India and Southeast Asia.

Such buildings could be linked to apparently utilitarian engineering works. The temples of Angkor in Cambodia, founded about AD 880, were built on mounds created by the excavation of large reservoirs or tanks that were part of a system for supplying water for rice culture, and were also linked to a system of transport canals. Stone for building the temples was brought to the site along these canals. The irrigation works reached their fullest extent by about 1150, after which environmental damage – the formation of a ferrous hard pan – seems to have contributed to their decline.

Other remarkable works of hydraulic engineering include large reservoirs with elaborate systems of feeder canals in Sri Lanka, where some canals pass through tunnels from one catchment to another. These systems evolved slowly from about 200 BCE to AD 1300, and like the works at Angkor, may have had monumental as well as utilitarian significance. There were also early canal irrigation systems in India, and in Iran there was a specialized technique for tapping groundwater known as the *qanat*.

In the Americas, there were the impressive Chicoma canals in Peru and the dikes in the former Lake Texcoco built by the Aztecs to separate artificial cultivated islands (*chinampas*) from the salty water of the main body of the lake. The Aztec capital of Tenochtitlan adjoined this system of islands and dikes.

Reviewing early engineering along these lines leaves one with a strong impression of its connections with agriculture, especially where irrigation or other water control was necessary, and indicates the frequent role of state or government authorities with their interest in using engineering also for religious or monumental constructions. The latter were important in demonstrating and legitimizing the authority of the state and its ruler.

This view of engineering can be interpreted in terms of the theory of “hydraulic civilization” associated particularly with the work of Karl Wittfogel. According to him, the food requirements of growing populations made it essential to develop centralized states capable of organizing large-scale irrigation works. Thus hydraulic engineering is seen as primary, with many other forms of large-scale engineering developing from it. The importance of irrigation in much of Asia, in Egypt, and in parts of Central America seems obvious, and it is at least plausible to think that the necessity for such irrigation works was a driving force for innovation in engineering techniques and for growth of government organizations capable of managing them.

An alternative interpretation of world history arises from the argument that military power emerged for the first time as a distinct force in human affairs – as opposed to an occasional and ad hoc assembly of fighting men – toward the end of the Neolithic, not long before 3000 BCE. Proponents of this view point out that it was in states that expanded as a result of the growth of organized military power that engineering developed most rapidly. The earliest examples were in Mesopotamia and Egypt, but there were parallel developments in many other parts of Asia, notably with the rise of the first Chinese dynasties. Later on, the emergence of empires in Central America and Peru can be seen as having a roughly similar technological outcome. By contrast, kingdoms that remained small, tribal societies, and isolated communities of cultivators and pastoralists had different kinds of technology that hardly involved engineering at all. What may have made the difference was that the experience of creating and commanding armies provided a model for recruiting, organizing, and disciplining the labor force needed to construct fortifications and other large-scale works. In this view, then, military engineering was primary, and monument building and hydraulic engineering were extensions of the same basic techniques into other areas that interested rulers and their officials.

Military technology, of greater or lesser significance depending on which of these interpretations is adopted, is the subject of a separate article in this volume. Looking in more detail at the civil branches of engineering, we may note that state officials often played a part in surveying and supervising works, and typically had a good knowledge of the mathematics needed for laying out sites or estimating quantities. The first pyramids in Egypt were accurately square and were built on carefully leveled foundations. Centuries later, Chinese bureaucrats studied books on arithmetic that told them how to calculate quantities and estimate volumes of earth-moving needed on construction sites – but books on machines were rare.

Much early engineering involved the excavation of canals or the building of earthworks in the form of fortifications, dikes, irrigation terraces, or dams, with few striking innovations beyond increases in scale, surveying methods, or the use of gabions (wickerwork containers of stones) in China. Where irrigation canals needed gauging weirs or distribution boxes to divide the flow equally between several farmers, some intriguing designs were developed in Iran, many of them made of stone.

The earliest engineers used stone in construction long before iron tools were available, so that quarrying and dressing the material presented considerable problems. In Egypt, the pyramid builders used wedges and dolerite hammers to work limestone, and the architect and minister of state Imhotep, who was active around 2660–2650 BCE, was credited with the invention of building in stone. Transport was by barge where possible and then on sledges hauled along lubricated wooden tracks. In the absence of pulleys or any other lifting gear, stones were raised by hauling up ramps.

In the Americas, the most remarkable engineering in stone was the terracing and building accomplished by the Incas in Peru. As in Egypt, there were no iron tools, but stones of quite hard rock, including granite, were shaped by grinding until they fitted together very precisely. In the Americas, as in ancient Egypt and many other parts of the world, sun-dried mud brick provided a further option for the construction of buildings and fortifications. A notable example is the fortress of adobe brick at Paramonga, in the lowlands of Peru. In West Africa, mud or clay was sometimes used rather as modern architects use concrete, to form domes and shell-vaults (for example, at Zaria in northern Nigeria). City walls of mud brick (adobe) date back to the twelfth century AD at Kano (also Nigeria). They were extended twice in later centuries to encircle a 17-km perimeter, and in 1903 successfully withstood cannon fire from the British army.

While much hydraulic engineering depended on earthworks, spillways needed to be faced in stone to prevent erosion, and a dam designed so that overflow water could pass over its crest would usually need to be stone-faced throughout. A fine example was the long, low Cauvery River dam, built to serve an irrigation system in the Chola Kingdom of South India. It was built of masonry laid in clay around AD 200. At about the same date, Persian engineers were using iron dowels set in lead to fix together the massive stones they used in facing some of their dams, and also poured molten lead into the space between stones.

Looking back to an earlier age to consider mechanical aids for construction, one should note that the movement of large blocks of stone along the ground on rollers was not a simple procedure, and was rarely practiced in Egypt. However, the consensus remains that the invention of the wheel derived from experience with rollers, perhaps in Mesopotamia. There, at any rate, wheeled vehicles were in use by 2500 BCE. Moreover, in conformity with the view that military technology was the leading sector in engineering, the first known examples were on chariots and army supply vehicles.

The development of mechanical engineering from that time on is hard to document in detail. Some commentators stress the emergence of mechanisms involving wheels or rotary motion, such as the pulley (by 800 BCE) or the first toothed gears, probably made in the eastern Mediterranean regions soon after 500 BCE. Another approach is to notice the importance of three main kinds of mechanical development – firstly, a slow evolution of levers, pulleys, and hoists for lifting stone on construction sites; secondly, the development of siege engines, catapults, and other military hardware; and thirdly, the evolution of water-raising devices, sometimes for drawing water from wells, but sometimes also to supplement irrigation from canals or rivers.

One kind of mechanical water-raising device was the chain-of-pots. The simplest form of this may have originated before 100 BCE as a "necklace" of pots hanging over a roller or pulley which was hauled around manually. The bottom of the necklace dipped in water, and as it was pulled round, pots filled at the bottom, and then were tipped over the roller at the top to empty into a trough. An animal-power version, driven through wooden gears, and with a large wheel replacing the roller or pulley, developed five or six centuries later. Known as the *saqiya* or "Persian wheel", it came to be widely used in North Africa, the Islamic countries, India, and China. For example, as recently as 1904 some 4,000 were recorded in the Dongola province of Sudan, each irrigating about 15 acres (6 ha).

Other mechanical water-raising devices include the pedal-driven "dragon spine" pump used in Chinese rice culture, and the *noria*, a water wheel with containers attached to its rim, powered by the flow of a river. The latter was known in western Asia by 100 BCE and also has a long history in India and China extending into the twentieth century. Other water-raising mechanisms used in modern peasant cultures have included a form of Archimedean screw in Vietnamese rice paddies and lever-based devices in Indonesia.

The first water-powered mills for grinding corn were adapted to mountainous areas with streams rushing down steep gullies, and their design was perhaps suggested as much by experience of the potter's wheel as also undoubtedly by the *saqiya* and *noria*. Thus we might expect the first water mills to have been made in a mountainous district where there were people with experience of all these devices and also where there were quarries producing millstones for rotary hand-mills. These considerations support evidence indicating that Iran or Iraq is the place of origin of the water mill some time prior to 350 BCE. There were quarries known for their millstones both in Iran, and on the upper Tigris, in a region now in Turkey.

The mills invented at this date had horizontal, propeller-like water wheels that drove the millstones directly, and it appears that they were so effective that they were soon adopted in southern Europe and also China. Later, this type of corn mill was used in northern European countries (where it became known as the "Norse mill"), and most notably in the foothills of the Himalayas, especially in Nepal.

The alternative type of water mill which has a vertical water wheel driving the millstones through the wooden gears developed later, and had a more restricted distribution. However, it is noteworthy that it used the same kind of gears as the more widespread animal-powered *saqiya* or Persian wheel, namely "peg and lantern" gears, i.e., a wooden crown wheel with projecting peg teeth on the same horizontal axle as the water wheel meshed with a lantern pinion on the vertical axle.

Almost the only non-Western countries in which this type of gearing was developed beyond the basic corn mill or Persian wheel format were Iran, Iraq, and Syria in western Asia and China in the East. It is striking how little mechanical devices of this kind were used elsewhere. However, in western Asia and China, a considerable variety of water-powered (and animal-powered) machinery was developed, including machinery associated with papermaking and sugar refining, and windmills were also used, all before AD 950. In preparing pulp for papermaking, for example, water wheels turned cam shafts which operated trip hammers. On a smaller scale, experiments were also made with geared astrolabes and clock mechanisms, and in China, an astronomical clock powered by a slow-running water wheel was made by Su Song in the 1080s. At about the same time in Chinese industry, water-powered bellows provided the draught for a few of the many iron furnaces, and water-powered spinning mills were evolving in districts that produced the coarser kinds of textiles.

One distinctive feature of Chinese machinery (as compared with practice in the Islamic world) in the period up to AD 1300 was a preference for using an endless rope running over pulleys for transmission of power from water wheels, instead of gears and shafts. A comparable contrast in style and practice in the West occurred in the nineteenth century when American designers of New England textile mills favored rope drives from water wheels or turbines to different parts of a mill, whereas European millwrights still preferred gears and shafting.

In conclusion, it is worth observing that although a steady development of engineering can be discerned in several parts of Asia up to about AD 1200, it is hard to identify major innovations dating from after that time. Engineering was never the most important branch of technology over much of that continent, but even where it had developed strongly there was little further progress. One factor was undoubtedly the devastating Mongol conquests of Iran, Iraq, and China, completed by 1260, and then the European conquests that were beginning in 1500. The Mongols destroyed irrigation systems in parts of northern Iran, and allowed others to decay, thus undermining the basis of much engineering in that region. However, it is difficult to believe that conquest and political disruption are the whole story, and one must also look to institutional and economic factors that are beyond the scope of this article.

Another general point is that by concentrating on the civilian uses of technology and leaving the military aspects for separate treatment, this article inevitably demonstrates the great importance of hydraulic engineering. This may seem to justify the idea that many non-Western societies were "hydraulic civilizations." However, we probably need to be more aware of the many mechanical and structural ideas originating from the experience of building siege engines, chariots, city defenses, moats, and forts. Maybe, too, we ought to appreciate that military engineers traveled more than their purely civilian counterparts and probably contributed more to the spread of ideas. In the third century AD Persian rulers employed a captured Roman army on a dam-building project, presumably learning a little of Roman engineering in the process. In AD 751 a battle between Chinese and Islamic forces in Central Asia led to the employment of Chinese experts on papermaking in Samarqand, and resulted in the transfer of papermaking technology into the Islamic world.

However, the most important point we tend to neglect is that the organization and discipline of armies seem likely to have been a model, at many points in Western, as well as non-Western history, for the organization and management of civilian technology, especially large-scale construction projects.

Environment and Nature in Africa

Marina Tolmacheva

Africa's location astride the equator subjects the continent's environment to tropical and subtropical conditions. Mean temperatures range above 15°C in the winter and above 25°C in the summer. During the northern summer the weather is hot and wet over Central Africa and the Guinea coast, arid conditions prevail over northern and most of southern Africa, and the east coast is affected by the southwest monsoon. During the northern winter the Sahara and the Mediterranean are affected by the westward flows of warm dry air, and the northeast monsoon regulates the weather over the east coast; warm rainy conditions prevail elsewhere except along the southwest coast. The surrounding waters have mean sea-surface temperatures above 20°C but regional peculiarities distinguish the coastal zones: the Guinea coast with its abnormal subhumid conditions; the hyperarid southwest coast with the cool and foggy Namib desert; the temperate Cape zone; the east coast affected by the monsoon winds and rains, the tropical easterlies, and the semidiurnal tides up to 6 m; and the Red Sea region with its extremely hot and arid climate and the highest seawater salinity in the world.

Only 9% of Africa's total land surface is well suited to agriculture. Most of the continent's ecological systems occupy latitudinal belts with the climate varying from subhumid to semiarid. The dense tropical forest extends several hundred miles on either side of the equator and along the Guinea coast where precipitation may reach 3,000 mm a year. To the north and south it thins out to woodland savanna and drier forest or bush. The southern edge of the Sahara, called "Sahel" (Arabic for "coast, edge"), forms a transitional zone between savanna and desert. The Horn of Africa is persistently dry, but the Kalahari desert is mostly grassland and scrub, with waterholes and even some marshes. The Ethiopian highlands form the largest single area on the continent where fertile soils, numerous rivers, and abundant rainfall allow for productive agriculture. The width of the coastal zone varies from less than 1 km to over 300 km (200 mile). Most African countries have mixed farming, and most land by area serves as pasture. The rainfall has had a profound influence on the distribution of population. Three rainfall thresholds mark the risk margin in traditional economies (1) where average annual precipitation is below 500 mm, agriculture cannot be sustained and total dependence on cattle is necessary; (2) where rainfall varies between 500 and 750 mm per year, it is impossible to subsist on agriculture alone, and supplementary stock-rearing is the customary solution; and (3) rainfall in excess of 750 mm per year is generally more predictable and more evenly distributed. Even then, the actual potential for agriculture and livestock raising depends on soil fertility, water evaporation, and ground water retention. African soils are generally poor, and agriculture requires large labor investment for subsistence maintenance. Only where soil fertility is combined with adequate water resources is surplus production possible.

Precarious existence in marginal environments makes for particularly strong connections between ecology and society. The harsh lands where water is scarce and grazing restricted historically produced fierce competition within a society and between neighboring societies. Cultivators and herdsmen displaced hunters and gatherers; possession of iron for weapons and implements played a key role in this process. For insurance against famine, in addition to stock-keeping, farmers cultivate different plots, if possible in more than one ecological zone to take advantage of variations in the seasonal rainfall patterns and temperatures either using the same crop (e.g., maize or bananas) or different crops. Usually, two harvests are possible. Cultivation became linked with the idea of civilization, and the conceptual opposition between culture and nature found expression in the dichotomies of farm/bush, coast/hinterland, and civilization/barbarism noted in various settled societies. This polarity was also reflected by the classification of animals into wild or carnivorous, therefore “evil” and unfit for human consumption, and domesticated or herbivorous, suitable for food.

Subsistence patterns affect residential mobility, division of labor, dominant forms of property and ownership patterns, land tenure, social networks, typical marriage age, and marriage transactions. The transhuman cycle depends on the particular botanical and hydrological environment and may vary from regular moves between wet-season villages and dry-season camps to a continual migration of over 1,000 km throughout the year. In mixed-economy societies, women often provide the bulk of the wet-season horticultural labor and men the bulk of the pastoral activities. Traditional forms of wealth associated with production and sustenance, such as iron hoes or cattle, are still included in bridewealth payments. In sub-Saharan Africa, land was traditionally held in tenure by the producers rather than owned. Towns grew in ecological oases or on trade routes. Markets developed between two ecological zones whose growing and harvest seasons differed, to trade for seed, food (in case of famine), and local specialties. There were seasonal markets, like those on the east coast regulated by the monsoon calendar, and “weekly” markets (e.g., held every fifth day as in the Shambaa country).

There is no formalized or universal world view in African systems of thought. Man is the center of the universe but he is not master of it. If harmony between man and nature is lost, the ensuing chaos harms man the most. In most cosmologies, the earth exists for man’s sake but he must show it respect. Nature is seen as animated by spirits, and people depend on it for survival. Nature rituals, especially agricultural rites, punctuate the annual religious cycle: planting, first-fruits, and harvest ceremonies, etc. Special rituals relate to stock-keeping. Rain-making rituals are the most important. They are performed by specialists–priests, witch-doctors, or royalty (such as the Lovedu rain-queen in southern Africa fictionalized by Ryder Haggard as “She Who Must be Obeyed”). Shaka, the founder of the Zulu warrior state, declared himself the greatest of all rain-makers. Such specialists are not “mere” witch-doctors but well trained in weather lore: people are aware that there is order in the laws of nature which normally do not change. They do not ask for rain in the middle of the dry season; the rituals are performed before the rains to ensure their proper and timely coming, if the rains fail to arrive, or to stop the rain when too much water may damage the crops and fields. In Zambia, when the rains start, people wait for a few days before working in the fields. An Ashanti farmer addresses his ancestors and the earth at the beginning of cultivation, saying:

> The yearly cycle has come round and I am going to cultivate. When I work, let a fruitful year come upon me, do not let a knife cut me, do not let a tree break and fall upon me, do not let a snake bite me.

At planting, the Venda of South Africa distribute grain symbolically cooked in the field over a grass fire. At first-fruits ceremonies, grains of the new crop may be sprinkled in the field for the spirits or the remains of last-year’s crop cooked and eaten. Among the Basuto the first gourds are taboo until the chief tastes them and offers a cooked dish of the new food to the ancestors.

Traditional African views of nature are thoroughly socialized and transmitted through folklore and rituals. West African cultivators hold that while gold is rare and expensive, iron was given to man by God for universal use as tools. The Zulu believe that the sun, moon, and stars were given by God so men could see, and that cattle were created by God to be man’s food. The Masai think that cattle were given by God exclusively to them, and so consider raiding the herds of their neighbors legitimate. A chief's fields must be cultivated first because their fertility, as his virility, guarantees the whole community's well-being. At the Yoruba harvest festivals, gifts of yam tubers due the chief from each household serve as a tool of unwritten population census. When women pound meal, their long-stemmed pestles are thought to knock against the sky. The stars of the Pleiades are thought to follow one another "like cattle returning home from pasture." Water is sacred, and boiling it "kills" the water spirit. Many plants and seeds are used for medicinal purposes. Sacrifices at religious festivals, rain-making ceremonies, and seances of divination and spirit-possession involve agricultural produce (e.g., yam, various cereals) and cooked foods, and domestic animals and fowl (especially chickens; sheep among Muslims, and on very special occasions cattle).

The universe is unending in space and time. The past and present matter greatly, the future matters only within the next growing cycle. The major rhythms of time are the seasons of rain and dry weather, migrations of birds and animals, flowering of certain plants, lunar months, and day-and-night sequences. The minor rhythms are in the lives of humans, animals, and plants as they move from birth to growth, then procreation and death. The calendars of African peoples are punctuated by references to natural phenomena and production activities. Since there is little temperature variation, the difference is not between the hot and cold seasons, but wet and dry. Usually, the two major seasons are the Greater Rains and the Lesser Rains. The Bantu word for "year," *mwaka*, literally means the rains at the beginning of the Greater Rains. On the East African coast they come in March; the Lesser Rains beginning in July or August are not a good planting season, but about October come the Latter Rains, the second cultivating season. Despite long-term Islamic influence and many Arabic loan-words, the Swahili language has preserved Bantu names for the cardinal points, dominant winds, days of the week, and times of day which reflect the sailing, agricultural, and stock-rearing aspects of Swahili culture. Some coastal cities created an office of "Master of the Sea" or "Master of the Beach." The word "Swahili" itself is derived from the Arabic for "coasts, coastal settlements." The name "Benadir" for the coast of southern Somalia means "harbors."

The pre-Islamic Bantu calendar calculated the annual cycle in 12 months of three 10-day "weeks" (decades, as in ancient Egypt) but within the year it distinguished lunar months in two phases. Different African peoples have "weeks" of 4, 5, 7, 8, 9, and 10 days. Traditional African time-reckoning is not mathematical but event-based. For example, the historical chronology of the Shambaa people of Tanzania is based on the memory of famines. The daytime computation of the Ankole of Uganda begins with the morning milking (about 6 a.m.) and follows the sun with references to times of rest, drawing water for people, driving cattle to drink, returning them to grazing, etc. The lunar months may be called "hot month," "month of rains," "weeding month," "bean harvest month," "hunting month," and so on.

The dwelling and settlement patterns too are affected by reference to the universe and nature, as well as gender. The Dogon of West Africa orientate their village north to south and visualize its plan as a human body prostrated on the ground. The smithy is the head, the family houses are in the center, and separate women's and men's houses, like hands, are on the east and west. Millstones and a foundation altar are lower down like sexual organs, and other altars are at the feet. The shape and orientation of the house mimics the Dogon vision of the earth and the sky as a couple in union. The rooms, the roofs, and the supporting posts indicate the male and female parts; the placement of the hearth, door, and stones supporting cooking pots, even the sleeping arrangements are regulated by traditional spatial orientation. Gender relations in Africa may control the division of both labor and space, and even the use of space for burial. Women play an important role in cultivation, especially of garden crops, and food processing, including disposition of vegetable refuse. Often in charge of food crop seed selection, they also specialize in the knowledge and use of medicinal plants. Men dominate tasks and space involved in herding and animal care, from breeding to the disposition of animal dung, important as organic fertilizer. Among the Bemba of Zambia, who practiced slashing and burning trees for ashbed millet cultivation, the axe became the symbol of masculinity.

Environmental factors have conditioned some major processes in African history, such as population movements and settlement, agricultural production, state formation, and long-distance trade. For example, the arid expanses of the Sahara desert both protected and isolated West Africa from more extensive contacts with North Africa, the Mediterranean, and the Nile Valley, and the remoteness and paucity of resources of the equatorial forest led to historically low population density and lack of contacts with the outside world; the highlands of Ethiopia kept the country independent and self-sufficient but also isolated for much of its history. By contrast, the Swahili culture of the East African coast was totally predicated on coastal location with easy and regular contacts with the Indian Ocean world, its prosperity fed by fishing, agriculture, and trade. In the West Sudan, the rise of medieval empires of Ghana, Mali, and Songhay was supported by efficient agriculture, access to gold and control of the rivers. However, most African rivers, including the Nile, are not navigable throughout their complete course or through the year; they are thus unable to serve as major communication arterials. Material culture of different localities still demonstrates its dependence on availability and qualities of timber, fiber, clay, and pigments. Traditional architectural forms developed in West Africa reflect the needs of mud construction in the rainy climate, while in East Africa stone architecture was limited to the coast because of reliance on coral rock.

The numerous migration legends of African peoples are misleading in that they highlight the movement of small segments of population while masking a general cultural stability reflective of ecological zones rather than specific ethnic groups. In areas suited to agriculture, shifting cultivation was a usual response to soil exhaustion or population growth until the twentieth century. Although access to water and pasture normally was a key to stability of settlement, some societies developed a tradition of moving large cities to prevent exhaustion of natural resources. Archeologists have suggested that the decline of Great Zimbabwe in the fifteenth century followed overexploitation of subsistence agriculture, in addition to droughts and other factors. Inland East African irrigation and terracing systems were able to support dense populations of people and cattle, but were abandoned before the nineteenth century. On the Atlantic coast, intricate knowledge of food crops and local conditions allowed for wetland rice cultivation in the alluvial and tidal lands; salt-water-tolerant varieties of rice were later exported to the Americas along with enslaved skilled practitioners of cultivation and food processing. In drier areas with sparse vegetation and meager topsoil, ecological changes could lead to long-distance migration, especially by herding populations. The West African *jihads* of the eighteenth and nineteenth centuries were spearheaded by mobile, pastoralist communities such as the Fulani, and affected mostly the Sahel and savanna zones of the Sudanic belt where both cattle and horses (for cavalry) could live. In the sixteenth century, agricultural Ethiopia suffered major invasions first by the nomadic Somalis and then by the cattle-herding Galla (Oromo). In a later expansion of the Amhara Ethiopian empire, the Amhara armies invading Oromo territories could not feed themselves because the Oromo pastoralists did not grow crops and could evacuate their herds from the path of an advancing army. Once some Oromo settled and became cultivators, they avoided stock-rearing for fear of cattle-raiding Somalis or Masai. In the nineteenth century, southern Africa became the theater of two major late migrations based on cattle-herding and a search for pasture: the southbound Mfecane led by the Zulu and the northbound Great Trek of the Dutch Boer farmer immigrants.

The wagons used by the Boers were the first wheeled transport in sub-Saharan Africa, where trade was moved by head porterage in consequence of the tsetse fly infestation and lack of salt in animal diet, which caused the absence of draft and pack animals. Growing contacts with the Western world led to the development of new trade patterns and regional economies: new trade routes connected the forest societies with the Atlantic coast, and some mobile groups (e.g., with access to rivers in the west or sea in the east) became the major agents of change. In the interior, populations seeking safety from slave-raiding moved their villages into inaccessible hills while those seeking trade moved their towns from mountain slopes into plains. By mid-nineteenth century a transcontinental system of routes was in place.

To this day, Africa's food production and raw material bases are still traditional, small-scale and rural; food productivity is the lowest in the world. Sixty-five percent of the continent's population derives its livelihood from agriculture. However, the picture of a static self-subsistence economy is false. African societies have shown both adaptability to change and readiness to experiment. The early spread of three Asian crops – yam, taro, and banana – revolutionized the economy of the humid regions. American food crops (especially cassava, sweet potato, maize, and groundnuts), introduced early by the Portuguese, spread quickly across the continent and still continue to displace indigenous crops; they were followed by tomatoes, various beans, chili, potato, tobacco, cocoa, agave, and avocado. Innovation improved food supply stability and contributed to agricultural intensification and population growth. Former hunters and fishermen, like the Bakuba of the Congo (Zaire) basin, once they were able to produce agricultural surplus, underwent an economic revolution which allowed them to develop the handicrafts and create a kingdom in the seventeenth century. The risk and responsibility for trying the new crops dwelled with the chiefs or kings, who were deemed responsible for environmental management. In the first half of the nineteenth century the sultan of Zanzibar became a major innovator and plantation owner when he transformed the island into a clove-producing garden; coconut plantations were developed, some numbering hundreds of thousands of trees. While for almost 2,000 years the main articles of African trade with the outside world had been gold, slaves, and ivory, agricultural diversification in the nineteenth and twentieth centuries has led to increasingly varied international trade.

European settlement succeeded only in temperate zones free of tropical fevers. The emphasis on cash crops and the spread of perennial crops (oil palm, cocoa, coconuts, coffee, cotton, etc.) have reduced shifting cultivation and sometimes undermined indigenous strategies for coping with the threat of famine. Application of Western methods of agriculture has been successful in cultivating sisal, tea, and pyrethrum but has shown no advantage in the production rubber, groundnuts (peanuts), oil palms, cocoa, coffee, or sugarcane. Indigenous cattle, although considered poor by Western standards, have shown greater resistance to epidemics of rinderpest, lung sickness, etc., several of which devastated regions of eastern Africa in the nineteenth century, facilitating European colonization. Although, in general, adoption of new crops gave people additional means to shape their environment, many rural anticolonial movements were linked to environmental issues. Sometimes European settlers tried to limit indigenous hunting to protect game for colonial elite or misinterpreted African agricultural methods as destructive, thus justifying land expropriation. Numerous attempts to introduce western agricultural machinery, both pre- and postindependence, have failed because of their unsuitability to weak soils, traditional multicrop multistory cultivation, and the socially determined patterns of labor and land tenure. Today, the hoe remains the major farm implement and women still grow 80% of the food consumed by their families and 50% of the cash crops. The lack of protein, especially in the children's diet, persists as a major obstacle to the development of a productive and healthy African society.

Africa is a continent rich in resources which faces enormous environmental challenges, including deforestation, desertification, loss of biodiversity, and degradation of water resources. In 1960 Africa was a net food exporter but since the 1970s it has developed a dependence on food imports and aid. The droughts and famines of the 1970s, 1980s, and 1990s have been exacerbated by civil wars and government policies, in addition to poor communications and transportation. Deforestation, inefficient cultivation, and destruction of the wildlife are tolerated to feed people quickly. Draining marshes helps reduce the incidence of malaria, typhoid, river blindness, and cholera, but creation of new reservoirs increases bilharzia (schistosomiasis). Hydroelectric power dams built in recent decades have eased Africa's energy dependence, but during droughts the water supply is sometimes insufficient for electricity. Despite government steps for natural preservation and sustained development, some colonial practices such as big game hunting have been replaced by poaching; in Angola and Mozambique, warring factions engaged in predatory elephant hunting for ivory – during the conflicts of the 1970s to 1990s. Nevertheless, Africa suffered from colonial intrusion relatively less than other, formerly more isolated, continents, and Africa's potential for preserving and successfully exploiting the environment is higher than in any other developing areas of the world. Under the prevailing low-technology conditions, indigenous ecological knowledge is an important developmental resource. Planning, changes in mentalities of both rural and urban populations, and wide dissemination of appropriate information are keys to the solution of the many current problems.

Environment and Nature in the Amazon

Leslie E. Sponsel

The Amazon is bordered by the Andes Mountains, Guyana Highlands, Brazilian Highlands, and the Atlantic Ocean. The Amazon is about the size of the continental United States of America. Portions of the Amazon are included within the territories of nine South American countries: French Guiana, Surinam, Guyana, Venezuela, Colombia, Ecuador, Peru, Bolivia, and Brazil. However, about 80% of the Amazon is in Brazil.

The Amazon remains a mystery to most outsiders, but their impressions are often more fiction than fact. Demystifying the Amazon requires an understanding of its diversity and human residents. Here biological, indigenous, and colonial ecologies are briefly considered.

Biological Ecology

About half of the world's tropical rain forest is in the Amazon region, the largest reservoir of biological diversity in the world. Typically within just a few square miles of forest live more than a thousand species of plants and hundreds of species each of birds, mammals, amphibians, and reptiles. Most of the Amazon is a variant of tropical rain forest. Among the variants are moriche palm, cloud, mangrove, and anthropogenic forests. However, there are also pockets of various kinds of savanna or grasslands within many forest areas.

The climate in tropical rain forest is characterized by high temperature, rainfall, and humidity rendering it the norm for plant growth on this planet. Every other kind of plant community is some deviation in response to stresses such as lower rainfall and/or temperatures. The Amazon is frost free. There is usually no synchronous dormant period in plant growth, unlike in drier and colder regions. The average yearly temperature is around 75°F (24°C) and the average yearly rainfall is 2,000 mm or more. The greatest temperature fluctuations are diurnal instead of seasonal.

The dynamics of the ecosystems of the Amazon are mostly related to variations in the amount and distribution of water through time and space. Variations in rainfall more than temperature usually mark the seasons. In the wet season it rains almost daily while in the dry season it rains at least a few days each week although not necessarily for the entire day. Changes in the distribution of water trigger changes in the local distribution and abundance of fish and other wildlife.

Throughout the Amazon water is common in one form or another such as rivers, streams, lakes, ponds, pools, and swamps. The Amazon River is the longest in the world (6,700 km), has more than 1,000 tributaries, drains about 40% of the continent of South America, and carries 20% of all of the river water in the world. The flood plain (fluvial zone) and the interior (interfluvial zone or terra firme) are two general types of environments in the Amazon. During the wet season the level of the water in various aquatic ecosystems may rise as much as 20 m. However, actual flood plains compose less than 10% of the region. Thus, most of the Amazon is interior forest that is not regularly flooded.

There are at least three major types of water in the Amazon (clear, white, and black) with very different physical and biological characteristics. For example, black waters are associated with white sands; they are tea colored, high in acidity, and low in nutrients, productivity, and diversity.

It has been estimated that there are at least 30,000 species of vascular plants in the Amazon, although the number may be much higher. The plant community of the tropical rain forest is characterized by its height, luxuriance, and diversity. Giant trees with few, if any branches in their lower levels stand like tall columns. Often there are several layers in the structure of the forest which reflect a vertical zonation in the microclimate and associated plants and animals.

Animals are relatively scarce in most ecosystems of the Amazon. While species diversity is high, their population density is low and individuals within a population are patchy in spatial distribution. Moreover, most species are arboreal, small in body size, solitary, camouflaged, and nocturnal. Also animals only comprise a fraction of the mass of the forest, and most of those are invertebrates. Accordingly, animals are not readily available for the hunter, zoologist, or tourist. The major exception to these generalizations about animals is the peccary (wild pig) which is terrestrial, large in body size, large in group size, diurnal, noisy, and leaves obvious trails. Wild pigs are usually the most important prey by weight for most indigenous hunters. However, in riverine areas fish are the primary protein source for millions of people. The Amazon as a whole has the richest freshwater fish fauna in the world with some 3,000 species.

Until a couple of decades ago it was thought that these forests were primeval, pristine, and static. But more recent research reveals that forest distribution has alternately contracted and expanded with oscillations in rainfall abundance and distribution over the last million years correlated with Pleistocene glaciations. The Amazon is also influenced by the climatic oscillations called El Niño and La Niña.

Indigenous Ecology

The extent of human antiquity, farming, population settlement, and density in the Amazon implies significant human influence on the environment over time. Estimates of human antiquity in the Amazon range to more than 11,000 years ago. Pottery dated from as early as 7,500 years ago has been recovered at various sites. Pottery is associated with relatively permanent settlements and farming. By about 1,000 years ago chiefdoms were flourishing along the larger flood plains with some population centers estimated up to 100,000 people.

It might appear that the environmental impact of traditional indigenous societies is negligible because of their usually low population and lack of Western technology such as chainsaws. However, collectively through space and cumulatively over time their environmental impact can be substantial. Yet most of this impact is within the levels and processes of natural disturbances. This is the case for traditional swidden or shifting horticulture. Annually during the dry season members of a household or community cut small plots of forest. After they have dried out the debris, it is burned, and then crops are planted just before the rains of the wet season begin. The garden is harvested for a few years after which it is gradually phased out over a decade or more as the forest encroaches. Through time the swiddens in various phases in an area collectively create a mosaic of plant and associated animal communities at different stages of ecological succession (development), thereby enhancing local biodiversity. Estimates are that 10–40% of the terra firme forest is anthropogenic.

The descendants of the original colonizers of the Amazon created societies that were usually to some degree ecologically and socially sustainable. In the interior forests away from major rivers these societies were most often characterized by a population with low density and high mobility combined with a rotational system of land and resource use and management for foraging (hunting, fishing, and gathering) as well as for farming. Most traditional indigenous populations enjoyed relatively good nutrition, health, and quality of life prior to major disruptions from Western contact, such as the Yanomami in the mountainous border area between Brazil and Venezuela. The viability of precontact cultures was usually facilitated by a worldview integrating attitudes, values, customs, and rituals emphasizing harmony between humans and nature, such as in the case of the Desana of Colombia.

Through intimate daily experience and observation in interacting with their habitat, local people have acquired extensive, detailed, and reliable knowledge about the animals, plants, soils, waters, and other aspects of the ecosystems in their territory. This is reflected in native languages with extensive vocabularies of words for plants, animals, environments, and other natural phenomena of the ecosystems in their local and regional habitats. As an example, the Ka'apor of Brazil recognize at least 768 species of plants, 112 of which have medicinal uses. In Peru, the Matsigenka distinguish 69 different environments based on vegetation, 7 based on fauna, and an additional 29 based on various abiotic factors. They recognize ten different types of soils as well. Also in Peru, the Matses identify as many as 178 different environments.

All of this ecology is further complicated by the reality that many cultures do not segregate the natural and supernatural. For instance, many Amazonians believe that shape-shifters exist as animals that might assume human form and vice versa. Usually shape-shifters are species that are mysterious and powerful from a human perspective, such as jaguars, anacondas, otters, and dolphins.

The indigenous cultures of the Amazon have contributed much to the rest of the world. For example, the root crop manioc or cassava was probably domesticated in the Amazon some time between 7,000 and 9,000 years ago. It grows well even in the poorest of tropical soils and it is resistant to pests and drought. The starchy roots are naturally stored in the ground until needed for food. The distinct advantages of manioc account for its spread throughout the tropics of the world since European contact. Today it ranks as the fourth most important source of food energy in the world. The cashew nut, guava, papaya, peanut, and pineapple are among the foods now consumed in many parts of the world that were originally domesticated by ancient Amazonians.

Among the numerous technological innovations discovered and developed from nature by Amazonians are the drug curare which is used to tip arrows and blowpipe darts for hunting monkeys; the poison rotenone from vines and other plants used to stun fish in quieter sections of waterways; and the rubber latex used for waterproofing containers and footwear. Now the world uses curare for anesthesia, rotenone as an insecticide, and rubber for tires and a multitude of other purposes.

Colonial Ecology

Today some 800,000 people live in 379 distinct indigenous cultures in the Amazon. In addition, millions of other people have migrated into the region in the last few centuries since its "discovery" by Europeans. Now the total human population of the Amazon is more than 25 million. Most of these people are peasants living in rural areas with a mixture of subsistence and market economies. Also they are in various ways and degrees a biological, cultural, religious, linguistic, and ecological mixture of Europeans, Africans, and Amerindians.

Many peasants, like indigenes, believe that areas of the forests and waters are enchanted. These places may be associated with drowning, ghosts, mysterious lights, and other extraordinary phenomena. They are thought to be frequented by potentially dangerous spirits. These beliefs influence the way resources and places are used, and this probably helps to preserve the biotic productivity of species of game, fish, and plants.

In the last few decades Western experiments in economic development have repeatedly failed with grave economic, social, and ecological consequences. The accumulated historical record of the many blatant failures clearly demonstrates that to this day Westerners do not yet know how to develop the Amazon without degrading and even destroying it. A different combination of causal factors is responsible for environmental destruction in different places and times in the Amazon, but among the principal ones are cattle ranching, logging, monocrop plantations, mineral and oil extraction, hydroelectric dams, and transmigration (government colonization programs).

There has been considerable investigation and documentation on Amazonian systems of natural resource use, management, and conservation. Yet most Westerners have yet to recognize that, prior to European "discovery," the Amazon had already been discovered, colonized, and even developed by indigenes for millennia. If outsiders would recognize and appreciate the intelligence, creativity, philosophy, science, technology, medicine, cultures, and religions of indigenous and peasant societies in the Amazon, then they might learn sustainable uses of the forest and aquatic ecosystems. Fortunately, in recent decades Amazonians themselves are becoming increasingly organized, vocal, and assertive in defense of their land, resource, and other rights.

The keys for outsiders to unlock the mysteries of the Amazon include attention to diversity in all its manifestations; to the worlds, perspectives, and concerns of the residents; and to scrutiny of history and colonization.

Considering the accelerating gravity and urgency of the environmental and social degradation and destruction in Amazonia, it is questionable whether this basic science approach is sufficient and ethical. A new approach is required that seeks to integrate basic and applied research with advocacy and action. It would be concerned primarily with promoting the self-determination and other basic human rights of the residents of the Amazon through collaborative research that empowers them with strategic information.

The Amazon environment is no longer an undiscovered frontier awaiting Western colonization under the pretense of progress through civilization and economic development. Coming decades will reveal whether or not outsiders have the knowledge, understanding, and wisdom to treat the Amazon and its people in a more reasonable and just manner than previously. If there is any hope for the future of the Amazon, it lies primarily with the people who actually live there.

Environment and Nature in the Andes

David L. Browman

The Central Andes were the home of the Incas, an ancient civilization who created an enormous empire, larger in area than the Roman empire. Only indigenous peoples of the Himalayas have adapted as well as the native Andeans to high mountain environments. The ancestors of the Incas arrived in the Central Andes as nomadic hunters and gatherers perhaps 15,000 years ago. They began agropastoral lifeways (camelid herding and plant cultivation) around 8,000 years ago. Many of the contemporary human–nature relationships can first be identified as developing during that period.

An essentially treeless grassland – the Ecuadorian *paramo*, the Peruvian *puna*, the Bolivian *altiplano*, and the Argentine salt *puna* – which is the home of the native herders and sierra farmers – occurs along the upper slopes, plateaus, and tablelands of the Andean mountain chain. Because similar elevations support trees elsewhere in the world, the question is raised: why is the zone essentially treeless today? Is it because of the elevation and low temperature regimes currently extant? Is it because of a past climate shift? Is it because of human agency?

A popular theory is that somehow the native people destroyed the trees through mismanagement. However, pollen samples prove that these areas were significant grasslands long before any substantial human settlements existed. They supported large herds of wild camelids – guanaco and vicuña – whose subsequent domestic relatives – llama and alpaca – were the basis of support the first Andean civilizations and continue to be economically important today.

On the other hand, one cannot deny significant and extensive impact on the landscape by the humans and their domestic animals. Overgrazing has resulted in decrease in palatable species; an increase in thorny and woody bushes, cacti, and less palatable grass species like *ichu* (*Stipa Ichu*); and an increase in plants toxic to grazing animals. Annual or semiannual burning of pastures to provide new growth for herds has also resulted in changes in plant assemblages, as it removes trees and other woody plants. Cutting trees and woody plants for fuel has further increased deforestation of the small refuge zones where trees persisted. In the presence of grazing pressure from domestic camelids, the tree species usually cannot regenerate. Grazing pressure and human agropastoral activities have significantly depressed the tree line on the eastern slopes of the Andes.

Human activities thus have markedly impacted the local environment since the first major presence of human groups in the high Andes, but the presence of extensive treeless areas predates the colonization of this area by humans. Thus, while human activities are clearly very important in the present configuration, the contributions from the wild herds of deer guanaco and vicuña which preceded the humans must also be an important factor in the occurrence of these grasslands, as well as that of elevation and meteorological conditions.

The domestic llama and alpaca herds were critical for survival of several highland groups. They provided meat, fat, blood for food; wool for clothing, bags, and rope; leather for footgear and equipment; bones for tools and religious items; dung for fertilizer and fuel; and labor power as caravan animals carrying trade goods. They also served as "banks on the hoof," resources which could be mobilized for emergencies during the irregularly occurring but not infrequent environmental catastrophes such as sustained droughts, unseasonal frosts, and the like.

Risk and uncertainty also contributed to reliance on extrasomatic sources of help as well. The gods responsible for protecting the flocks and for insuring their increase were believed to dwell among the surrounding peaks. Annual ceremonies, called *pagos*, from the Spanish verb "to pay," were held to "pay" the gods for current success and to petition for the future increase of flocks. A male and female animal were selected from the herds, fed *chicha*, the local corn beer (*making chicha*), and "married" to begin the next season's offspring. These llamas and alpacas were treated and thought of as kinfolk of the herders. Today these ancient fertility ceremonies have been conflated with Catholic rituals, and are held during Carnival. Often small *illa* or animal figures of the desired type of animal are blessed and buried with offerings. In Inca times these were sometimes gold and silver, while today they are ceramic, stone, or tin (*Hammered gold objects*).

Plant agriculture was an exceedingly risky undertaking at this elevation; folklore suggests that crop failure occurred as often as 25–35% of the years. Andean people thus sought to reduce agricultural risk through a variety of strategies. Because rains could fall on one field but not on another a kilometer away, or because early frosts or late freezes could hit a valley bottom one time, but a high slope another time, the farmer might own two dozen or more small plots, scattered over several elevations, in several microenvironmental areas. Every farmer maintained a dozen or so varieties each of potatoes and other seed plants, because in one year a tuber which thrived in dry soils would be the only one to produce, in another year a variant which thrived in moist soils excelled, and in a third year a variety which did well in saltier soils yielded best.

In addition to the procedures to manage risk in maintaining biodiversity among their crops, the local residents developed other strategies as well to cope with risk. Elaborate freeze-drying techniques were employed to produce dehydrated potatoes, *chuño* (*potato's poisonous roots*) and other tubers. These technological procedures served two purposes: enhancing palatability and providing storable surplus. Most of the high elevation plants grown for consumption had significant quantities of phytotoxins, making them poor choices for foodstuffs until various dehydration processes removed the phytochemicals. As a serendipitous by-product, the resulting detoxified tubers could be stored up to 20 years, providing a critical component of sustainability.

Herders often provided a necessary component of this detoxification process, as in following their herds, they located "salt" or mineral licks with various comestible earths. They collected these geophageous clays and traded them with agriculturalists. These clays were fabricated into sauces to consume with meals. Residual phytotoxins in the tubers which had not been removed by dehydration processes, freeze-drying, or by cooking became bound with the clays. In addition, bioavailable minerals were exchanged, thus doubly enhancing the quality of the food.

Propitiation of the resident gods for plants was as important as it was for the herd animals. The deity known as *Pachamama* (earth mother) was responsible for providing plant foods for the humans. Proper behavior involved offering a few coca leaves or other items before planting the field, much more substantial rituals at the harvest, and practices in daily life such as always decanting a few drops "for Pachamama" each time one took a drink, thus attempting ritually to insure adequate moisture for the crops.

Andean farmers developed a series of strategies to modify the landscape to control nature, particularly moisture and temperature parameters. Andean peoples did not simply adapt to the ambient conditions – they were active agents who shaped and created Andean environments, and who transformed and built the landscape in which they lived.

The Lake Titicaca basin is an excellent example of the variety and range of practices employed. The local farmers, who practice small-scale intensive agriculture, make capital improvements to their lands, which are inherited by their descendants. The current elaborate landscape patterns are thus the result of multiple small increments accumulated for millennia. The flat plains usually were poorly drained; they suffered from too much water in the rainy season and too little in the dry season.

The local agropastoralists constructed raised fields systems or *waru–waru* (*Waru waru*) and sunken smaller garden patches or *qochas* (*Qochas*) to address these problems. Construction of raised, ridged fields, with swales or canals between the ridges, resulted in ridge top areas above the waterlogged soils in the rainy season, eliminating rot among the tubers. Both the *qocha* system and the intervening canals among the raised fields trapped rainwater, which was curated through the dry season to provide a continuing water supply.

In addition to managing moisture, these systems also ameliorated temperature extremes. Thus the raised field patterns, and furrows in the *qochas*, were constructed either parallel to, or perpendicular to, the path of the sun, an orientation which permitted maximum solar energy capture by the water. This water kept the fields slightly warmer at night, and often radiated enough heat to prevent frost damage while the surrounding unmodified grasslands suffered heavy freezes.

While this technology was employed through the Inca period, European invaders brought the oxen and plow (and in this century, the tractor). Raised fields could not be plowed efficiently by European technology, and hence they were leveled. Although Western technology permits much less labor per unit area, and thus is more efficient in that sense, the productivity per unit area has fallen off.

Anthropologists have recently reconstructed experimental raised fields in the Titicaca basin. These fields provide both increased yields and decreased environmental risk: local seed growing without any high-tech inputs have produced two to four times more per unit than crops growing on the European-style fields. On more than one occasion, unusually severe, out-of-season frosts have destroyed all the crops in the plowed flat fields, but have at worse only inflicted a little freeze damage on plant tops in the raised fields. While more labor intensive, the original indigenous technology has proved superior to Western technology in these environmental circumstances.

In addition to the raised fields and *qochas*, other landscape modifications were constructed to provide the same kinds of soil improvement and nutrient capture, erosion control, microclimate control, and moisture control or water management. Most noted among these are the stone-faced terraces or *andenes* (*Andenes*) and irrigated pastures or *bofedales* (*Bofedales*). For example, among the local hills, as well as the mountain valleys elsewhere in the Central Andes, often only the valley bottoms or hill bases had adequate moisture for crops, but because cold air is heavier and settles to the lowest areas, these same locations had the greatest risk from frosts. Elaborate terrace systems were constructed, with water provided by extensive canal networks. Thus hillslopes initially too steep to be plowed were remade into a myriad of small, level, irrigated plots. Because they were along the lower and middle valley/hillslope flanks, they were too low for high elevation freezes but above the pools of supercooled air that collected on the valley bottoms. Thus agricultural terraces were often frost-free during most of the growing season.

Irrigated pastures (*bofedales*) were another means of managing water and temperature for the alpaca and llama herds. While llamas are more like camels in their ability to secure nutrition from high cellulose and other less palatable forage, alpacas thrive on moister, softer vegetation varieties. The neonates of both species are vulnerable to low temperatures in the first few days after birth. Herders thus developed elaborate canals and check dam systems, to bring water into suitable low-lying areas, where artificial rather swampy irrigated pastures (*bofedales*) were created. The lush environment created optimal fodder for the alpacas, and the ponds provided heat-sinks to ameliorate nearby temperatures on cold nights.

The modification of the environment is exhibited in multiple other ways as well. Rivers and streams have been channelized, artificial canals have been constructed, springs have been enlarged and improved, and various holding ponds and reservoirs have been constructed. Various causeways, roads, and paths lead to constructed villages, defensive retreats (*pucaras*), cemeteries, shrines, and monuments. Fields are marked off by stone walls; large rock piles are scattered among the landscape, some for agricultural reasons and others for religious purposes. Stone corrals are found at various elevations. The Andean peoples of the Titicaca basin thus extensively transformed the local environment; such transformation is typical throughout the Central Andes.

Various strategies were employed in agropastoral production zones to provide the structure and rules for the allotment of irrigation water, distribution of communal and individual land, regulation of land use, scheduling of agricultural activities, definition of crop types, and cycle of rotational fallow. Included in these was the development and maintenance of high biodiversity among crops suited for a wide range of environments.

The Andean peoples often anthropomorphized their environment. The indigenous concept known (in Aymara) as *taypi* structures part of the human relationship with nature. *Taypi* physically is the center between two opposing concepts, the point of necessary convergence where the cosmological centrifugal forces that permit differentiation exists simultaneously with the centripetal force that ensures their mediation. It is thus both an integrating and separating center. The human body is divided into three components, with the *taypi* integrating center the heart and stomach. The cosmos is divided into an upper world, this world, and a lower world, with the earth as the mediating point between the upper and lower world. Hence humans, as residents of this earth, arbitrate not only between forces of good and evil, but also serve to mediate between the natural environment and the gods. Just as the human body is animated and integrated as a whole by an exchange of fluid elements (blood circulating, water drunk and expelled, air inhaled and exhaled), so too is nature. Analogies are made between the circulation of fluids to animate humans and the circulation of fluids to animate nature.

The human imagery overlay upon nature is even extended to the organization of some of the Andean groups. One of the mechanisms employed to deal with the environmental risks is to spread humans over the landscape, in a pattern similar to the spreading of fields discussed above. Thus a village might send family members up to a new hamlet in the herding zones, or down to lower elevation corn growing areas, spreading production risk so that in case there was complete failure in one zone, the community would have direct access to resources in other environmental zones because they had residents living there. In the case of one group from the Qollawaya, the settlements in the lower, middle, and upper ecological zones were conceptualized and referred to by terms of the human body, with the middle elevation home village thus seen as the heart and vitalizing component of the group, and the landscape itself as replicating the human body. Andeans hence perceive their lifeways as essentially harmonious and replicating nature.

The environment thus is a dynamic, historically contingent component of the Central Andes. The Andean peoples did not simply adapt themselves passively to ambient ecological conditions. Rather they were active agents in the creation, shaping, and transformation of a highly patterned, artificial landscape.

Environment and Nature: Australian Aboriginal People

Dorothy Tunbridge

Australian Aboriginal people's traditional relationship to their land from a philosophical, economic, and spiritual viewpoint was quite different from that of the Europeans who arrived toward the end of the eighteenth century. Aboriginal environmental philosophy was related to their being observers, knowers, and users, rather than managers and interferers. This approach was the essence of their genius, enabling them to survive successfully for 40,000 years – perhaps much longer. Their philosophy could be described as nonmaterialistic ecocentrism, expressed through totemism, Dreaming, and the law, contrasting markedly with European materialistic anthropocentrism.

During the millennia before European occupation the continent had undergone big climatic changes followed by enormous environmental ones. Aboriginal people experienced the gradual extinction of the megafauna, commencing from the earlier part of their occupation, and, between 15,000 and 6,000 years ago, the decrease in the size of the continent as the sea level rose, mostly imperceptibly.

One of the significant technological innovations affecting Aboriginal use of the environment was the grinding stone or "grindstone". Dating from around 18,000 years ago, it gave impetus to settlement in the arid center where there was heavy dependence on seed foods. A lack of suitable stones in some areas, e.g., southwest Queensland's Channel Country, brought about trade in the course of which grindstones were carried very long distances. Aboriginal mythology underlines the importance of the grindstone right up to the time of European occupation.

As the sea level rose, mainland Australia became separated from Tasmania as well as from New Guinea. As the new conditions became stabilized, an extremely rich and diverse flora and fauna developed. Then, in the period from 1500 BCE to the beginning of the Christian era, colder and drier conditions emerged – perhaps the reason that around this time Aboriginal people made major changes in their methods of exploiting resources. Technological innovation included the emergence of the small tool tradition, and in Victoria, the introduction of water control systems. The building of brush and stone fence traps and pitfalls may also have been developed during this period to allow bigger catches of wallabies and kangaroos. There is some evidence of the reorganization of society at this time, perhaps to enable better exchange and sharing of resources in the face of new conditions.

Economic Use of the Environment

Although the archaeological record gives a general picture of Aboriginal life, the most detailed knowledge comes from the ethnographic record made since European occupation. Aboriginal cultures and life-styles varied considerably throughout the continent, according to specific needs, beliefs, knowledge, and availability of resources.

Aboriginal people were hunter–gatherers who mostly operated freely within a limited range – their own "country" – in small groups or bands who moved according to the season and the availability of resources. They were not acquisitive, often leaving behind all but the most needed tools as they moved around. With few (arid zone) exceptions, they did not store food. Included in the diet was a wide variety of flora and fauna – fish, land and sea mammals, some insects, birds, lizards, and snakes, depending on where people lived – providing a healthy, mostly nutritious diet, low in fat and sugar. Generally people did not take out more plants or animals than were needed for day to day survival.

Housing, implements, weapons, clothing, and other utilitarian, ritual, and decorative items were fashioned from materials taken from the environment, e.g., stone, plant material (wood, fibers, thorns, leaves, twigs, branches, gum), animal products (bone, hair, skin, feathers), and soil (mud, ochre).

Examples of cnafted wooden instruments and weapons include the spear, waddy or club, and boomerang (each used in fighting and hunting), the scoop-shaped dish (a carrying bowl, ash cooking bowl, or shovel), digging stick, shield, playstick, message stick, and spear-thrower. Wood was also the basic construction material for boats. Shelter in most areas was constructed of wood and branches, and of bark; they were quickly made and easily abandoned. Wood could be selected for its shape, requiring little or no working for some implements such as building poles, witchetty grub hooks, skewers, brooms, walking sticks, axehandles, spindles, firesticks, fire-making sticks, laddersticks, and implements of secret rituals such as droughtsticks for causing drought. Other plant materials were used in making the tools of daily life, e.g., plant fibers for making string to be woven into bags, nets, headbands, etc., and for making baskets, thorns for tattooing, leaves for bedding, branches for brush fences, and gum for glueing.

Animal skins were used against cold winters for clothing, and animal hair was woven for string from which such items as headbands, phallocrypts, belts, net traps, and bags were made. Bone items included awls and the bones used in "boning" rituals.

Stone items included hafted hatchets and adzes, unhafted cutting tools chipped from hard stone or quartz, clubs (handheld and thrown), and grindstones. These items were often traded by those communities who had the best supply of raw material. In places where stone abounded, e.g., the Flinders Ranges, stones were also utilized as meat-chopping blocks, throwing weapons for killing, gravestones and other sorts of site markers and stone arrangements.

Modification of the Environment?

Debate continues regarding the extent to which Aboriginal people modified the environment in times past. Many scholars believe that although they utilized materials from the environment, they did not *substantially* alter the environment itself. Others differ. Two issues often debated are the extinction of the megafauna and the use of fire.

It has only recently been confirmed that in antiquity Aboriginal people killed megafauna species at all. As to fire, the fact that they used it extensively is not disputed; what is debated is whether or not they used it deliberately to manipulate and alter the environment substantially. There is still no conclusive evidence that they did this to a degree that made the Australian environment vastly different from the way it would have been had they never inhabited the continent. From everything known about Aboriginal environmental philosophy and practice, large-scale intervention in the environment to change the way things were would seem unlikely. Aboriginal people's skill lay in their observation and utilization of nature as it was, including the natural potential fire regime.

The concept of Aboriginal "firestick farming" arose in the 1950s as a reaction to the somewhat idealistic view of Aboriginal people's "[having lived in] harmony with the environment". This notion is part of a general view that in recent millennia Aboriginal people modified their environment to the point of being the most significant agents of change within it. More likely, however, is the view presented here, that as change occurred – mostly imperceptible at any given time – Aboriginal people gradually adapted to the new conditions.

The "firestick farming" model has become popular because of its idealistic portrayal of "traditional" Aboriginal people in European terms, firstly as more like (superior) European farmers, and more recently as "resource managers". This is also often the case with new views of Native Americans and other indigenous people.

Traditional Ways of Looking After the Land

Aboriginal people, like all hunter–gatherers, were above all observers of their environment. Their traditional concept of "looking after the land" was diametrically opposed to a European view. First and foremost it was a question of knowing, and to some extent, of not doing rather than of doing. Every individual had both the need and the right to know his own country to which they were attached through totemic affiliation and the ties of kinship, and to be informed on its terrestrial and celestial natural phenomena.

Dreaming history (mythology) was largely the encyclopedia of knowledge. Here were "stored" maps, vital environmental information, and laws concerning people's relationship to the land. Knowing the land meant above all maintaining the Dreaming. The Dreaming had an ecological rationale, the actions and habitat of the totemic ancestral species mostly coinciding with those species' typical behavior and habitats. Place names reflected the Dreaming; they remain today as windows on Australia's environmental past, many incorporating names of species of flora and fauna once prevalent but now extinct.

Knowing the rituals and accompanying songs was also considered crucial in looking after the country. Recently Aboriginal people have even blamed their own failure to maintain the songs and rituals for the dramatic loss of species following European occupation: "We can't look after the country now; no one knows the songs any more."

Totemism, whereby an individual or a clan was in a special relationship with a species or phenomenon in the natural world, was a powerful link between the people and the environment. Maintaining a proper ritual attitude toward one's totemic species was an essential part of looking after the country. In some places this meant maintaining a taboo on killing one of one's own or a near neighbor's totem species – an act akin to fratricide. In some regions, individuals had only one personal totem; elsewhere, through clan membership individuals had a number of totems.

In parts of Australia the lands belonging to a totem clan were located in that totem species' quintessential habitat. This meant that in those places species were protected from human predation in their best refuges. Taboos on hunting and food gathering also applied around certain sacred sites, sometimes ensuring that the best waterholes were completely protected. There are examples also of taboos on killing female kangaroos, which would help to ensure the continuity of the species, and on interfering with certain plants because these were a specific animal's food. These examples, however, do not represent large-scale strategic planning in conservation, even though their evolution would, to some extent, have had that effect.

Over all, then, Aboriginal people's "looking after the land" (rather than "land management" – a very European concept) was based on using knowledge skillfully and performing the associated rituals. Indeed, it was the very fact of *not* having management schemes that interfered unduly with the ecosystem, which was the secret of Aboriginal survival. The "strategy" for success was knowing.

Environmental Dispossession

According to the philosophy which European colonizers took with them to Australia from 1788 onward, it was the duty of individuals to give value to the land – otherwise seen as valueless – by going beyond the laws of nature through work. As the Australian environment was not "worked" in their understanding, they regarded it as completely empty – *terra nullius* – when they arrived. They would give it value by working it and extracting profit from it. Aboriginal nonmaterialistic ecocentrism, valuing both the human and nonhuman world in a holistic way, had nothing in common with European anthropocentrism and materialism. The philosophy of the dominant group soon prevailed, and Aboriginal people were dispossessed of their land and their traditional lifestyle, if not of their lives. The change to the environment as Aboriginal people knew it was irrevocable. Indeed, the speed and scale of faunal loss may have been unprecedented in the history of the world. For many communities today, the only records of the species which sustained their forefathers are subfossil material, old songs, and Dreamings.

Aboriginal People and the Environment Today

Dispossession has not occurred to the same degree for all. In the process of adapting to their changed environment as Aboriginal people have always done, some desert communities have in recent times introduced new ways of looking after the land, while not abandoning old ways of maintaining the Dreaming and the rituals which reinforce knowledge. Also, there is increasing interest in traditional Aboriginal environmental knowledge, and here and there attempts are being made to apply it with Aboriginal help, to "bring back" the country.

Traditional ways of caring for the country, however, operated within a supporting philosophical, religious, and economic framework – on a very different landscape, generally for different goals, and above all, on a continent wide basis. It is therefore unlikely that the traditional package of environmental nurture will be reintroduced on a large scale.

Perhaps more significantly, Aboriginal people are seeking – and getting – more involvement in environmental management. Some see it as one way of getting back the country. While dispossession may have left many with limited traditional knowledge to apply, it has not removed their sense of belonging to the land. Moreover, 1993 native title legislation (*Mabo*) is motivating a new appreciation of Aboriginal people's long relationship to the unique Australian environment.

Environment and Nature in Buddhism

LESLIE E. SPONSEL,
PORANEE NATADECHA-SPONSEL

Buddhism is an enormous, diverse, and complex subject. There are many variations on Buddhism's basic themes manifested in the three major traditions (Theravada, Mahayana, and Vajrayana or Tantric) and also in variants of these in the form of at least 18 schools and their numerous sects. Much of the diversity in the expression of Buddhism results from the diversity of its numerous geographical, ecological, demographic, historical, cultural, linguistic, religious, national, and political contexts. Although estimates vary, there are at least 354 million Buddhists living in 86 countries of the world. Another complication is that many Buddhists adhere to more than one religion, or follow a mixture of elements from different religions, such as Animism and Hinduism in Thailand, Confucianism and Daoism in China, or Shintoism in Japan. An additional variable is that, as in any religion, in Buddhism too there are differences between ideals and practice, text and context, clergy and laity, scholar and laity, urban and rural, young and old, and so on. This tremendous diversity within Buddhism renders most generalizations difficult and tenuous, and they should always be recognized as potentially problematic, especially without adequate explanation and qualification that is usually not feasible in a limited space.

Underlying the enormity, diversity, and complexity of Buddhism, nevertheless, are some common denominators. The three refuges chant usually begins Buddhist ceremonies:

Buddham saranam gacchami.
Dhammam saranam gacchami.
Sangham saranam gacchami.
In the Buddha I take refuge.
In his teaching I take refuge.
In the monastic community I take refuge.

This chant reflects the three ultimate components of Buddhism: the Buddha, his teachings (*Dhamma*), and the community of followers, especially the monks and nuns (*Sangha*). One formally becomes a Buddhist simply by publicly vowing to pursue these three refuges. The individual's pursuit of enlightenment commences with accepting the Dhamma, starting with the Four Noble Truths, and then following the Noble Eightfold Path as discussed below.

This essay surveys nature and environment in Buddhism within the framework of the Buddha, Dhamma, Sangha, and laity, and in relation to the Four Noble Truths and the Noble Eightfold Path. Furthermore, Buddhist ecology and environmentalism will be considered from the past to the present and into the future, from East to West, and in terms of contemporary criticisms, problems, issues, and controversies. This brief survey of the main points under each of these themes is distilled from one of our previous publications (Sponsel and Natadecha-Sponsel 2003). This brief version ends with a list of the references for the quotations and then a short list of selected books for further reading on various aspects of Buddhism in general. Also see the bibliography of books on Buddhist ecology and environmentalism at the end of this article. In this essay all Buddhist terms are in Pali, unless another language is used in quotes or in personal or place names. Pali is the ancient literary language for Theravada Buddhism and remains its ecclesiastical language.

Buddha

The relevance of the Buddha's life and teachings to nature and the environment is clear in at least three respects. First, major events in his life were associated with trees, groves, forests, and other natural phenomena. Second, he often drew on parables about animals and other aspects of nature to illustrate moral and other principles. Third, during his lifetime it appears that population and economic pressures were leading to deforestation and resource depletion in some areas where he lived and traveled. Thus, if nature was so relevant to the Buddha, then surely nature is relevant to Buddhism and vice versa.

In the early accounts of the Buddha's life it is not easy to distinguish between fact, legend, and myth. Nevertheless, these basic facts are clear: his birth as a human being, his renunciation, studies with Hindu spiritual teachers (*gurus*), long period of asceticism and intense meditation, enlightenment, 45 years of teaching followers, establishing the Sangha, and his discourses or sermons (*suttas*). In addition, the core principles of the Buddha's teachings, such as the Four Noble Truths and the Noble Eightfold Path, can be taken as factual.

Buddha is an honorific title meaning an enlightened or awakened being. The historic Buddha's original name was Siddhattha Gotama. His conventional dates are 566–486 BCE. He was born under a Sal tree (*Shorea robusta*) in a grove called *Lumbini Park* near Kapilavastu (now Madeira), about 130 mile north of Benares in the border zone between present-day India and Nepal.

During his youth Siddhattha's father, King Suddhodana, sheltered his son from sights of the suffering beyond the royal palace. However, eventually Siddhattha witnessed sickness, old age, and a corpse. These impressed him with the suffering and impermanence of human existence. Then when he observed a holy man, he was inspired to search himself for a spiritual solution to the problems of the human condition. Thus, at 29 years of age, Siddhattha made the Great Renunciation. This was a radical decision to leave his family, wealth, and future as a king to become a wanderer in a religious vision quest.

Nature was the context and source of Siddhattha's search for and eventual achievement of enlightenment. For 6 years he pursued spiritual awakening with various *gurus* and through rigorous asceticism in the forest. In the process, among many other things, Siddhattha realized that moderation (The Middle Way) was the best path, instead of the extremes of either asceticism or hedonism. Eventually he pursued contemplation and meditation on his own during 7 days at the base of a bodhi fig tree (*Ficus religiosa*) near the town of Bodhgaya. There, at the age of 35 years, he finally attained enlightenment (Buddhahood).

After his enlightenment under the bodhi, the Buddha subsequently spent a week meditating under each of several other trees: Nigrodha or Indian fig (*Ficus indica*), Mucalinda (*Barringtonia acutangula*), and Rajayatana or kingstead (*Buchanania latifolia*). Then he went to the royal Deer Park of Isipatana in Sarnath (now Dhamek), just north of Benares along the Ganges River. He knew that the five monks (*bhikkhu*) he had previously associated with would be there. In his first discourse the Buddha introduced to these monks the Four Noble Truths and the Noble Eightfold Path.

For the next 45 years of his life the Buddha wandered over much of northern and eastern India as a religious teacher. He died at the age of 80 while reclining between two Sal trees in a grove outside the small town of Kusinara and in the company of many of his followers. When death was near the Buddha declined to appoint a successor, instead he said the Dhamma and monastic rules (*vinaya*) should guide followers. In addition, in his sermons he repeatedly advised that every individual should think on his own and test his teachings against their own reason and experience. Accordingly, Buddhism lacks any single centralized authority, although different schools and sects may have recognized leaders, the most well known being the Dalai Lama for Tibetan Buddhists.

Teachings

Bodhi (1987: vii) aptly summarizes the relevance of the teachings of the Buddha's (Dhamma) to nature:

> With its philosophical insight into the interconnectedness and thoroughgoing interdependence of all conditioned things, with its thesis that happiness is to be found through the restraint of desire in a life of contentment rather than through the proliferation of desire, with its goal of enlightenment through renunciation and contemplation and its ethic of non-injury and boundless loving-kindness for all beings, Buddhism provides all the essential elements for a relationship to the natural world characterized by respect, care, and compassion.

For Buddhists, the pursuit of knowledge, understanding, and wisdom begins with the Four Noble Truths: all existence is suffering (*dukkha*); ignorance and desire are the primary causes of suffering; yet suffering can end; and the way to end it is to understand and pursue the Noble Eightfold Path. Suffering covers a wide diversity of conditions, including dissatisfaction, discontent, disharmony, discomfort, irritation, friction, pain, illness, dying, and death. The ultimate aim of the Buddhist is to reach enlightenment in order to end suffering; first, in one's present life; and second, in one's successive lives in the endless cycle of rebirths. As Ryan (1998: 2) asserts: "The fundamental postulate of Buddhism is that all beings are united in distress, in dukkha." From this perspective, then, the moral universe of Buddhism transcends humanity to encompass all beings, and accordingly, Buddhism becomes relevant to nature and environment (to explore some Buddhist texts see: ►http://www.accesstoinsight.org). The Mahayana tradition goes even further. In Mahayana, Buddha-nature refers to the potential of all beings and things to become enlightened. In Chinese and Japanese Buddhism, for example, trees and even rocks are considered to have Buddha-nature; thus it is assumed that they strive for and are eventually destined to achieve enlightenment. Consequently, a *Bodhisattva* is a person who forgoes seeking the end of his or her own suffering (reaching enlightenment or *nibbana*) in order to strive to reduce the suffering of all other beings and things.

Most lay Buddhists do not study the formal texts (sermons, monastic code, and scholastic treatises), but learn about the more important principles in them through the Sangha and popular media. The most outstanding example of the latter is the *Jatakas*, a collection of 547 parables about the Buddha's previous lives. In these he is often represented as an animal that sacrifices its own life to save others. These stories illustrate how the Buddha cultivated the core virtues of wisdom, nonviolence, compassion, loving-kindness, generosity, and so on. They also exemplify the interconnectedness and interdependencies among beings. Furthermore, they imply that animals have a moral sense; i.e., they are capable of making ethical choices and behaving accordingly. The great popularity of these stories probably influenced many Buddhists to have positive attitudes toward animals through affording them intrinsic value. The *Jatakas*, as readily accessible moral allegories, provide, in effect, many of the essentials of an ecocentric environmental ethic for Buddhists.

The Noble Eightfold Path through thought and action progressively encompasses wisdom (right understanding and resolve), virtue (right speech, action, and livelihood), and concentration (right effort, mindfulness, and meditation). Arguably each of these eight components is relevant to nature to the degree that it is correlated with the pivotal principle of extending nonviolence (*ahimsa*), compassion (*karuna*), and loving-kindness (*metta*) to all beings and things. Right livelihood, for example, would include occupations or life ways that do not harm any beings and things. Of course, it is impossible to live without causing some harm; even vegetarians sacrifice plants for food. However, a Buddhist can strive to minimize harm as much as possible. Buddhism makes the elemental and pivotal distinction between need and greed. In pursuing the Middle Way, an individual would attempt to satisfy as modestly as feasible the four basic needs that the Buddha recognized (food, medicine, clothing, and shelter). As a consequence, in effect the individual minimizes his or her harm to other beings and reduces pressure on the environment, including the inevitable waste and pollution that accompany resource consumption. Ideally, Buddhists should be concerned with the contemplation of nature instead of its consumption. This is what is now termed *voluntary simplicity*, one indispensable ingredient for developing a sustainable, green, just, and peaceful society. As Timmerman (1992: 74) asks: "How can we survive on a planet of ten billion points of infinite greed?"

The key to Buddhist ethics and practice is the primacy of the individual's mind. Ultimately this has profound importance with numerous ramifications in terms of recognizing the causes and solutions of environmental problems. From a Buddhist perspective, although certainly important, the usual sources – science, technology, education, government, law, politics, business, and industry – are neither the cause nor the solution of the ongoing and worsening global environment crisis. Instead, the cause and the solution are found in *the collective, cumulative, and synergetic consequences of the behavior of the individuals who* *compose humanity*, albeit some individuals and groups may be more responsible (or irresponsible) than others. Environmental health is then not so much a matter of the scientific, technological, and bureaucratic management of resources, waste, and pollution, as it is the spiritual management of ourselves. People must be motivated as well as informed to limit their own reproduction, consumption, waste, and pollution in order to minimize harm to other beings and things.

If it is understood that the first negative precept (nonviolence) and the first positive precept (compassion and loving-kindness) apply to all beings and things, not just to humanity or some sector thereof, then the environmental implications are immediately obvious and undeniable. Indeed, there is an ecologic here; it is possible to detect elements reminiscent of ecology in Buddhism, and conversely, elements reminiscent of Buddhism in ecology, even if these are only a coincidence. Both Buddhism and ecology (1) pursue a monistic rather than dualistic world view, instead of dichotomizing either organism and environment or human and nature; (2) consider all life, including that of humans, to be subject to natural laws; (3) adopt holistic and systems approaches regarding the unity, interrelatedness, and interdependence of the components of nature; and (4) teach respect and even reverence for nature, including the intrinsic as well as extrinsic values of other beings. Although most of these similar elements may be merely parallels rather than identities, surely they are complementary and can even be mutually reinforcing in both theory and practice for contemporary Buddhists.

Clergy

Ideally, the Sangha, the monastic community of monks or nuns, exhibits attributes that are similar, and in some instances even identical, to many of the characteristics of a sustainable, green, just, and peaceful society. Among these are a small-scale and egalitarian community based on nonviolence, moderation, cooperation, and reciprocity in satisfying basic needs. Monks and nuns have extraordinary sociocultural status and power to transform nations like Thailand that are overwhelmingly Buddhist into a more ecologically sound society because of their unique social and moral roles. By contrast monks and nuns hold a mirror to society, as, for example, in their vow of poverty. Spiritual development is their goal, rather than Western style economic development through materialism and consumerism. By drawing on the ecological wisdom embedded in the Buddha's life and teachings, monks and nuns have significant potential to contribute to far sounder environmental world views, attitudes, values, and practices of lay Buddhists.

Many of the more than 200 rules for monks (*vinaya*) are relevant to nature. Several aim to prevent monks from knowingly harming any living being. They can only eat fruit without seeds or if someone else has already damaged them. *Bhutagama*, the Pali term for a living plant, means the home of a being. For a monk to intentionally cut, burn, or kill a living plant is an offense. It might endanger some animal's habitat, among other things. Harming even small animals like ants should also be avoided, although harming large animals is much more serious. Injuring or killing an organism like a worm by digging in the ground is forbidden and could lead even to expulsion from the Sangha. Also a monk cannot deliberately have someone else kill an animal for him. The rains' retreat (*pansa*) is the period during the wet season each year when monks refrain from traveling in order to avoid trampling on young crops and small animals that are more abundant then. Monks should check water, or strain it, before using it for drinking or other purposes to avoid knowingly harming any visible organisms in it, even mosquito larvae. They are prohibited from polluting water in any way as well. A monk is prohibited even from acting in self-defense if that would injure another being. In these ways and in many others monks are supposed to protect and respect all life.

In several places in the sacred texts of Buddhism when the issue of vegetarianism arose the Buddha explicitly refused to prohibit monks from eating meat, mainly because they subsist on alms food volunteered by local laity. Vegetarianism was only an option. Today, although widely admired, it is not common in Theravada countries and Japan. However, most monasteries in China and Korea as well as Zen monks in Japan are strictly vegetarian. Vegetarianism is one way that an individual can reduce harm and offer compassion and loving-kindness to other beings as well as provide a model or raise awareness for other people (on vegetarianism see: ►http://online.sfsu.edu/~rone/Buddhism). Collectively and cumulatively over time Buddhist temples and monasteries may help promote the conservation of biodiversity. Many temple complexes can be viewed as sacred ecosystems with groves of bodhi, banyan, and other trees and associated animals. People are prohibited from disturbing plants, animals, fish, and other natural phenomena in and near a temple complex.

Instead of living in a temple or monastery, since the time of the Buddha many monks and nuns have spent much of their time wandering in forests or on mountains, or living and meditating in caves. Such secluded and peaceful places are more conducive to meditation and enlightenment. However, in recent times, many forest monks have become environmental activists as well. They view deforestation as sacrilegious, a threat to the forest monk tradition since the forest is their sacred habitat. Also they understand the suffering that deforestation causes to local humans and other beings. Out of compassion for the suffering which diverse beings experience as a result of deforestation, numerous monks have initiated environmental education programs, sustainable economic development projects, and rituals to protect remaining forests in Buddhist countries such as Cambodia, Laos, and Thailand (for examples of the above see: ►http://www.earthsangha.org, ►http://www.keap-net.org/project_environment.htm, ►http://www.mro.org, and ►http://www.suanmokkh.org). [Editor's note: see also Susan Darlington's article on Thailand's activist monks.]

Laity

For Buddhists the ultimate pilgrimage is the spiritual journey through meditation to discover the Buddha-nature within oneself. This is a vision quest that reveals the oneness of the individual and nature, and thereby the emptiness of self through interconnectedness and interdependence. However, since ancient times, Buddhists have also undertaken pilgrimages to sacred sites associated with the Buddha and other Buddhist personages, as well as to temples, shrines, and other sacred places, many on mountains and/or in forests. In Tibet, Mount Kailas is sacred to Buddhists as well as to the Hindu and the Tibetan Bon religions. At its foot Lake Manasarovar is also considered sacred and a component of pilgrimages. Because many of the sacred places associated with Buddhism require certain prescriptions and proscriptions, such as not killing any beings, the result, even if inadvertent, is that these sites often function in effect as sanctuaries of nature as well as religion.

To the extent that the laity follows the Buddha's example and teachings as well as those of the clergy, they are also relevant to nature. The laity and the clergy are interdependent. The laity provides for the material needs of the clergy, while the clergy provides for the spiritual needs of the laity. However, whereas the clergy cannot harm other beings, the laity must do so in order to obtain food and income from farming, fishing, and so on. Still, the laity is supposed to minimize harm to other beings as much as is practical.

To this day lay individuals may gain merit by planting trees, especially in and around temple yards. In Thailand sometimes tree seedlings are given to people attending a funeral so that they may plant them to gain merit for the deceased and themselves. Planting trees reminds people of the Buddha's life and teachings, including the interdependent relationships between humans and nature.

Engaged Buddhism belies the stereotype or myth that Buddhism is necessarily a detached, escapist, or egocentric religion. A phrase coined by the Vietnamese monk, Thich Nhat Hanh, engaged Buddhism is simply the active application of Buddhism for the benefit of others; i.e., putting compassion, loving-kindness, and other principles into practice. It is a matter of emulating the Buddha's life and following his teachings. Among the various concerns of engaged Buddhists are nonviolence, peace, human rights, participatory democracy, social work and community development to alleviate poverty and other problems, appropriate technology such as organic farming and recycling, sustainable and just economic development, and environmentalism (for examples of socially engaged Buddhism, see: ►http://www.bpf.org and ►http://www.sulak-svaraksa.org).

The West

Buddhism originated in northern India more than 2,500 years ago and in subsequent centuries spread far beyond into other parts of Asia. By at least the mid-nineteenth century, if not much earlier, Buddhism started to have some influence in the West. Today there are about four million Buddhists in the USA, over a million each in Europe and Russia, 140,000 in Australia, and 5,000 in South Africa.

East and West, however, are not completely separate. For centuries they have influenced each other in numerous and sometimes profound ways. For instance, Henry David Thoreau (1817–1862), a student of Asian philosophy as well an icon for environmentalists, first translated into English from French a portion of the *Lotus Sutta* for the Transcendentalist journal *The Dial*. Also his period of relative seclusion and voluntary simplicity in nature at Walden Pond near Concord, Massachusetts, was somewhat reminiscent of a forest monk. In turn, Thoreau's political tactic of nonviolent civil disobedience deeply influenced Mahatma Gandhi and others in Asia and elsewhere.

Beyond Thoreau, Buddhism was among the influences on many other seminal Western pioneers and leaders in ecology and/or environmentalism: Ernst Haeckel (coined word ecology), John Muir (pioneer conservationist), Aldo Leopold (land ethic), Albert Schweitzer (reverence for life), E. F. Schumacher (Buddhist economics), Arne Naess (deep ecology), Gary Snyder (Zen poet and deep ecologist), Bill Devall (deep ecologist), John Diado Loori (Zen environmentalist), Joanna Macy (Nuclear Guardianship Project), John Seed (Council of All Beings), Philip Kapleau (vegetarianism), Peter Matthiessen (novelist), Fritjof Capra (physics), Petra Kelly (German Green Party), Michael Soule (conservation biologist), and Rick Klugston (Director of the Center for Respect for Life and the Environment).

Today there are more than a thousand Buddhist centers in the USA alone, often with a mailing list of thousands. Many practice conserving resources, recycling, and reducing waste and pollution. Voluntary simplicity may be considered to be an environmental as well as Buddhist virtue. Vegetarianism is often followed using organically grown foods. Such practices can be observed, for example, at Green Gulch Farm in Sausalito, California; Zen Mountain Center near Mountain Center, California; and Zen Mountain Monastery at Mt. Tremper, New York.

Contemporary Buddhism and environmentalism resonate with one another in numerous and diverse ways. In particular, for Westerners, Buddhists and some others, Buddhism provides new perspectives, rationales, insights, values, and methods for dealing with environmental questions, problems, issues, and controversies. For instance, Buddhist monks have symbolically ordained trees to protect them in Thailand, and this has inspired similar ceremonies by activists in California (see Buddhist contributions on the UN Earth Charter: ►http://www.brc21.org).

Problems

Ultimately the problems and limitations regarding the relevance of Buddhism to nature and the environment appear to revolve around two types of related but separate discrepancies – ideal vs. actual behavior and academic vs. practical interpretations. The ideals of Buddhism seem to be environmentally friendly, whereas the actual behavior of many Buddhists is far too often not so. This paradox is evidenced in the widespread natural resource depletion and environmental degradation in most countries that are predominantly Buddhist, although it appears that Bhutan and Ladakh are lingering exceptions to this pattern for the most part. Nevertheless, this discrepancy does not invalidate the idea that in principle Buddhism can be environmentally friendly. One must be careful to avoid confusing Buddhism and Buddhists. There are internal contradictions and discrepancies in every religion as well as in other social institutions like government, science, and education. The deficiency is not in Buddhism, but in Buddhists, who, after all, are merely human. An important part of the solution is to educate people about the negative consequences of their actions so that they are more willing to alter their behavior to eliminate or at least minimize such consequences. Also Buddhists need to adhere more closely to the Noble Path as it applies to ecology and environmentalism.

The second discrepancy is the difference between the purely academic understanding of Buddhism, especially the interpretation of the texts, and the actual understanding and daily practice of Buddhism by Buddhists, i.e., context. Ideally context should faithfully reflect text, but critics deny that this is the case in reality. Much of the criticism boils down to the accusation that Westerners are imposing their modern concerns for ecology and environmentalism on Buddhism, whereas a supposedly authentic scholarly interpretation of the texts by the critic indicates that Buddhism is irrelevant to such matters. However, there is considerable room for differences of opinion in the interpretations of the same texts among Buddhologists (scholars of Buddhism) (for an example of a critic, see articles by Ian Harris in the online *Journal of Buddhist Ethics*: ►http://www.jbe.gold.ac.uk).

Such puritanical, literalist, or fundamentalist criticisms of the application of Buddhism to contemporary concerns like the environmental crisis do not afford sufficient attention to the actual practice of Buddhism by Buddhists who do not always think that rigid adherence to text is so important. Indeed, the Buddha himself repeatedly emphasized that individuals should test his teaching against their own reason and experience, instead of blindly accepting authority, tradition, or dogma. Furthermore, the scholarly study of Buddhist texts alone may not have much relevance for the actual realities of the daily practice of Buddhism by its adherents. At the same time, there are individuals who have been both Buddhist scholars and monks for decades. The most notable personages in this regard, Buddhadasa Bhikkhu from Thailand, Thich Nhat Hanh from Vietnam, and the Dalai Lama from Tibet, think that Buddhism has significant ecological and environmental relevance. Note that each of these scholar monks represents one of the three main traditions of Buddhism (for example, see: ►http://www.suanmokkh.org, ►http://www.plumvillage.org, and ►http://www.tibet.com).

Another criticism is that Buddhism is basically escapist; it is concerned only with individual enlightenment through meditation and therefore oblivious to any practical problems of ordinary human existence. This last point ignores the example of the Buddha himself, who, among other things, opposed the caste system in India. It also ignores socially engaged Buddhism that is no modern invention, even if the particular term is so. Beyond skeptics, critics, and antagonists who question that Buddhism has any relevance to nature, environment, ecology, and environmentalism, there are other problems. For instance, Kraft (1997) identifies these dilemmas facing Buddhist environmental activists:

1. Gaps between the Buddha's teaching and contemporary sociopolitical realities.
2. Buddhism emphasizes individual morality and action yet many environmental problems demand collective responsibility and action.
3. Competition between meditation and engagement.
4. Whether to be identified as Buddhist or just blend in with other activists.

E

5. The environmental soundness of spiritual practice and rituals. However, in the opinion of the present authors, as long as Buddhists are faithful to the core principles of the Dhamma, then compassionate actions of loving-kindness on behalf of all beings and things are still Buddhist, this no matter how new the particular situation or how innovative the specific actions (for examples of Buddhism in contemporary society, see: ▶http://www.globalbuddhism.org and ▶http://www.urbandharma.org).

Future

It is unlikely that people millennia or even centuries ago ever conceived of possibilities like anthropogenic mass species extinction or global warming which have increasingly preoccupied many in recent decades. However, inevitably new problems and issues arise that require creative interpretations and approaches by Buddhists, and this must have happened throughout the 2,500 years of the history of Buddhism, considering the diversity of contexts and situations in which it has flourished. That Buddhism has endured for so long is a clear demonstration of its continuing relevance and adaptability for its adherents. Now the most important challenge for Buddhists is to cultivate social, political, and environmental actions that more closely approximate the ideals of Buddhism, especially the Noble Eightfold Path.

If more Buddhists and other people were aware of the negative environmental consequences that are the collective and cumulative results of their individual behavior, then many might change for the better and thereby significantly relieve environmental problems. When reason and morality follow adequate knowledge and understanding of the continuing and even worsening environmental crisis, then this may lead to wisdom and action in improving how humans interact with nature. The difference Buddhism makes is that, instead of grounding environmental conservation in self-interest of the individual (egocentrism), society (sociocentrism), or human species (anthropocentrism) as most Western schemes advocate, it is based on respect for other beings and things as having intrinsic value (ecocentrism).

It is noteworthy that in Bhutan, Ladakh, Thailand, and elsewhere, clear symptoms are surfacing of a growing disillusionment with the uncritical and wholesale pursuit of "modernization" and associated phenomena like materialism and consumerism. Revitalization movements arise in many societies in response to the problems, stresses, and dissatisfactions with rapid and profound sociocultural change. Buddhist-motivated community development and environmental conservation initiatives are becoming significant forces in this revitalization within Buddhist societies.

Undoubtedly, the primary concern of the Buddha was suffering, its causes and alleviation. The Buddha repeatedly stated that ultimately he taught only two things, about the cause and the end of suffering. Certainly the world is bound to suffer even more than ever before during the twenty-first century as a result of accelerating human population and economic growth. With the inevitability of the increased suffering of humans and other beings in coming decades, Buddhism may well prove even more relevant than ever before. Buddhists must apply critical and radical thought in examining contemporary problems and issues, something needed in our time as much as in that of the Buddha and probably far more so. Now this must include genuine interfaith dialog so that everyone may learn from each other's religions by comparison and contrast in order to cultivate a more sustainable, green, just, and peaceful world.

For the future, the main task for Buddhists, as well as for those non-Buddhists who simply have an intellectual interest in Buddhism, is to explore deeper and wider into the relevance of this religion for nature and environment, especially for each of the different schools and sects, and in both text and context (see Prebish 1999). Those who are practicing Buddhists also need to strive to apply the Dhamma as faithfully as possible in their interactions with their local environment and nature in general. Buddhists owe no less to the Buddha, the Sangha, and other beings as well as to themselves. It is a matter of survival for Buddhism as well as for nature and humanity.

Environment and Nature in Buddhist Thailand: Spirit(s) of Conservation

SUSAN M. DARLINGTON

Two contradictory images strike the traveler in northern Thailand: first is the lush, forested mountains rising beyond expanses of rice paddy land and small farming villages. Second is the spotty appearance of the mountains, denuded of primary growth in large areas and filled instead with economic crops such as cabbages or corn. Both images are set against the backdrop of congested cities, particularly Bangkok and Chiang Mai, through which all travelers pass before seeing rural areas. The contrasts inherent in these scenes point to a major tension in Thailand between the push to develop economically and efforts to conserve and protect the nation's natural resources.

The struggle to find a balance between development and conservation occurs in many arenas, including culture and religion. Various actors for both pro-development schemes and conservation projects use cultural and religious beliefs, practices and attitudes toward nature to promote their positions. Religious beliefs themselves are not intrinsically either ecologically or developmentally oriented, but they can be interpreted in ways to support either conservation or development. The Thai government, for example, has used Buddhism to promote rapid national economic development; on the other hand, a handful of Buddhist monks and nongovernment activists incorporate both indigenous spirit beliefs and Buddhist practices to foster an environmental ethic on a local level. Both approaches claim to be based on intrinsically "Thai" understandings of the world as well as basic Buddhist teachings. Yet, as will be shown below, both are reinterpretations of religious beliefs and practices and, particularly in the case of activist monks, examples of cultural creativity designed to promote specific political agendas.

In the search for "Thai" approaches to environmental conservation, a key cultural source is Buddhism. The Thai population is approximately 95% Buddhist. It is important to note, however, that for Thais, Buddhism incorporates spirit and Brahmanic beliefs and practices (Kirsch 1977; Tambiah 1970). Yet scholars and activists often downplay spirit and Brahmanic beliefs in their environmentalist efforts, opting primarily to look at the ecological knowledge of rural peoples and at how Buddhism can be used to promote an environmental ethic (see Chatsumarn 1990, 1998; Darlington 1997a, b, 1998; Davies 1987; Kaza and Kraft 2000; Pipop 1993; Sponsel and Natadecha 1988; Sponsel and Sponsel-Natadecha 1995, 1997; Swearer 1997, 2001, 2003; Tucke and Williams 1997).

Buddhism alone, however, does not encompass the full range of concepts and attitudes of rural Thais toward nature and the forest. A complementary set of cultural beliefs that influence attitudes of and behavior toward the natural environment in Thailand is spirit beliefs. In particular, the interplay between Buddhism and spirit beliefs affects rural people's concepts of the forest and the ways in which they approach or value it. Similar beliefs are found throughout the Tai cultural region (which includes northern Thailand, Laos, southern Yunnan Province, China, and parts of Burma and northern Vietnam; see Pei 1985).

This syncretic religious system can be clearly seen in northern Thailand where, as across the nation, it contributes to an elaborate cosmology that includes the natural, human and spiritual environments (see Kirsch 1977). This sacred geography provides the framework for efforts to use cultural and religious concepts for both developmental and environmental – both inherently political – ends.

Spiritual Geography

There is no traditional word in the various Thai language dialects for "nature" (Davis 1984: 85). The word used today, *thammachaat*, is a combination word borrowed from Sanskrit. Its root words are *thamma*, or "dhamma," meaning truth (or the teachings of the Buddha, in a more specific context), and *chaat*, meaning life or rebirth (from the concept of reincarnation). Davis (1984: 85) argues that Thais adopted the concept of "nature" underlying this term because of European influence. This concept did not correspond with any indigenous ideas. It is, according to Stott (1991: 144), "too refined and wide in its meaning, embracing as it does all natural phenomena, such as rain, wind and sun, and even natural human behaviour." Applying the concept of *thammachaat* to the forest sanitizes the barbaric qualities of the wild, bringing it closer within the control of people (Stott 1991: 150). The effects of this process, as we will see, can be either pro-conservation or pro-development. It can enable people to take advantage of the forest resources without fear or concern over maintaining a balance between the civilized and wild worlds, by emphasizing domination and control of the former over the latter. It also has the potential to influence people's attitudes in the direction of responsibility toward rather than domination over the natural environment.

Before the introduction of the concept of *thammachaat*, there was a distinction between the human-built civilized world (*muang*) and the wild, uncivilized forest (*paa thu'an*) (Stott 1991). The civilized world centered on human settlements, particularly the walled cities of northern Thailand in which the kings and princes lived. In a careful linking of religion and geography, civilization radiated outward through the ruler's religious merit from the *muang* (here meaning the city) to nearby towns and outlying farming villages (Stott 1991: 145). The forest, on the edge of the social and religious domain of the *muang* and the ruler's influence, was the world of wild, dangerous and unpredictable beings, including tigers, bears, gods, spirits and non-Tai hill peoples.

Even today, lowland Thais (in the north called *khon muang* or "people of the *muang*") often consider the hill peoples backward or uncivilized because their ways of life are different from those of Tai peoples. The hill peoples follow their own cultures, speak their own languages, eat different foods, and, especially, are not Buddhist. They are predominantly animist, each group having its own elaborate set of beliefs and practices that the lowland, Buddhist Thais tend to see as primitive. Buddhism for Thais is an element of their cultural identity, and a key component of the sacred geography that has defined their civilization for centuries.

At the same time, most Thai Buddhists also believe the universe is inhabited by spirits and gods. Buddhism as a religion has never denied their existence. The classic treatise on Thai cosmology, *The Three Worlds According to King Ruang* (from the 13th century, translated by Reynolds and Reynolds 1982), describes the interplay between the heavens (the realms of *theewadaa* or celestial beings), earth (where the humans live), and the hells (the place of *phii* [spirits] or lower level beings living out the consequences of negative behavior). All sentient beings, according to this Buddhist cosmology, can be reborn at any level of these three worlds depending on the merit of their actions in each life. Even the gods, who lead lives of pleasure and comfort, will eventually pass away and be reborn. Only humans can achieve enlightenment, release from the cycle of rebirth and suffering.

While Thais view the three worlds as distinct, they are not isolated from each other. Usually the *theewadaa* and *phii* of the upper and lower realms are benign and do not harm humans. If provoked, however, the *phii* in particular may harass or even possess some humans. Thais believe some *phii* are malevolent and go out of their way to avoid or appease all spirits. Other *phii* may simply appear to people as their paths cross. Guardian

E

spirits (considered both *theewadaa* and *phii*, illustrating the vague nature of these concepts) monitor and protect particular places. Some are considered "lords of the land," associated with the *muang* or principalities of the past (see Shalardchai 1984). People fear the spirits, *theewadaa* and *phii* alike, because of their supernatural qualities and powers.

Many different kinds of spirits inhabit the northern Thai cosmos. There are ghosts, or *preta*. This ambiguous term covers the spirits that all people become at death before they are reborn into another form of existence. It also denotes the hungry ghosts, *phii* that are constantly hungry and thirsty because their tiny mouths cannot open fully. People believe these *phii* were greedy in a former life and are now paying the consequences of their actions through insatiable hunger.

Other kinds of *phii* include tutelary spirits that help people who ritually respect them and follow the ethics that they enforce. Some of these are guardian spirits of particular places, such as a village or a household. Spirits live in forested areas, occupying trees, fields and streams. People make offerings to these spirits before they cut down a tree or clear a field for their crops. Every year villagers hold a series of agricultural rites, including offerings to the spirits of the fields, continually thanking them for allowing the forest to be cleared and the crops to grow. Spirits also look after the cremation grounds and sacred groves that surround some villages as well. In some areas these are the only patches of forest that have not been cut down. They have been left standing due to people's fear of and respect for the spirits believed to live there.

A number of deities or celestial beings share the northern Thai world as well. These *theewadaa* also receive ritual offerings and propitiations for their powers to influence the human world. There are four lords who rule over the four cardinal directions, overseen by Indra. (Indra is a god borrowed from Indian cosmology and was probably introduced into the region before Buddhism's arrival.) Two female spirits affect people's interactions with the natural world. These are Mae Phosop, the rice goddess, and Mae Thoranee, or Mother Earth. These *theewadaa* can either help farmers with their rice and other crops or punish those who offend them.

The annual rituals performed in honor of the various *theewadaa* are examples of how northern Thais interact with supernatural beings. Humans do not have control over these beings, but exist in a balanced and dynamic relationship with them. People can influence the *phii* and *theewadaa* for temporary periods but must continually renew their relationship through rituals.

An example of these rituals is an annual rite performed in April during the Thai New Year in honor of Lord Indra, the Four Lords and Mae Thoranee. A layman trained in Brahmanic practices, often a former monk, usually conducts the rite. Even though technically there are no Buddhist elements to the ritual, I have seen the rite done by a monk. Northern Thais do not make such distinctions within their religious system, and none of the villagers, including the monk himself, saw any contradictions in his performing the rite.

The ritual involves propitiating the six deities with offerings of food, rice, betel nut, cigarettes, and clay models of buffalo, elephants, and other useful and powerful animals. After the formal ritual, conducted in the center of the village, trays made of banana tree trunk and bamboo, loaded with the offerings, are carried to the four cardinal points of the village boundary for the Four Lords. Two trays are left in the center of the village, one on a pole for Lord Indra, the other sitting on the ground at the pole's base for Mae Thoranee. In addition to honoring the deities, the ritual exorcizes the village of evil or harmful forces. These negative forces are carried to the edge of the village with the trays for the Four Lords and are exiled to the wild space beyond the settlement. The Four Lords help guard the village boundaries, as well as looking after the region of each direction. Besides the annual performance for the entire village, ritual specialists will perform this rite when serious illnesses or calamities occur within the village or individual households.

Probably the most feared of the spirit world are the *phii* that inhabit the forests. As the *paa thu'an* represents the antithesis of the civilized world, people see the spirits that live there as especially dangerous. The divide between *muang* and *paa thu'an*, and between Buddhism and animism, however, is not absolute. Even the forest can be used by people if they take the proper precautions, including conducting rituals to propitiate and appease the gods and spirits that dwell there. The rites need to be done on a regular basis or every time someone wants to use forest resources such as trees for building houses or animals for food.

Buddhism and Spirit Beliefs

Buddhism does not teach that spirits do not exist. Instead, its teachings emphasize developing one's ability to control fear, such as the fear of spirits, through recognizing the impermanence of all things, including one's self. This is a learned skill, however, often developed through years of practice and confronting fear (see Kamala 1997).

When I first began to study Thai Buddhism, I did not expect to find many monks who believed in spirits. Living in northern Thailand and studying with monks, however, I soon realized the extent of the interplay between Buddhism and animism. One monk's story in particular highlights the dynamic relationship between the two.

As a novice in his teens, living in a small, rice-farming village in northern Thailand, this monk walked several kilometers daily to attend classes on Buddhism. His journey took him along a long stretch of road that ran through the rice fields and forest between his village and the next. Often he traveled this road at night when his lessons ran late. He walked with trepidation as the villagers told tales of a hungry ghost that haunted the fields and forest at night.

One dark, moonless night, he related to me years later, as he walked the road, he saw a light across the field. No houses sat in that area, and it was not the season for villagers to be hunting frogs at night. The novice froze in his steps as the light glided across the field toward him. "The hungry ghost," he thought, hardly able to breathe.

As the light came closer, the novice tried to still his panic. All the warnings people had given him about walking this stretch of road at night flooded his mind and he regretted not heeding them. Then he remembered why he walked this way – to study Buddhist scripture in the temple in the district town. "I'm a monk," he thought, "I'm not supposed to fear ghosts. This ghost can't harm me."

With that thought, the light stood still a few meters into the field. The novice smiled at his own silliness and continued on his way home. He never told anyone of his experience until years later, after the forest had been mostly cut down and the road was more traveled, even at night. No point in fostering these fears, he told me, as his story would have only confirmed people's belief in the hungry ghost.

The tale of the hungry ghost involves only one kind of the many *phii* and *theewadaa* in northern Thai cosmology. Nevertheless, it shows how belief in a spirit causes fear and can potentially keep people out of certain places. It also illustrates the belief in the superiority of Buddhism over spirits in the cosmological hierarchy, a belief that has been used to change the spiritual geography, civilize untamed areas and develop the forest.

Buddhism and Forest Development

Buddhism has contributed to civilizing the forest in the modern era through subduing the wild forest and its spirits, enabling human settlements to expand beyond city boundaries. In the late nineteenth and early twentieth centuries, forest-dwelling monks bridged the space between *muang* and *paa thu'an* (Stott 1991: 149; see also Kamala 1997; Tambiah 1984; Taylor 1993a). These Buddhist monks chose to follow thirteen ancient ascetic practices, including forest dwelling, called *thudong*, that aided meditation and purification. Their spirituality enabled them to face the fears of the wild that most lay people held and enter and even live within the forest for extended periods (Kamala 1997). Forest monks brought elements of the civilized world to the forest, blurring the distinctions between the two. Their presence helped quell villagers' fears of the forest spirits, leading them to move into the forest, settling previously wild, dangerous and unlivable areas. If the monks could live there, people believed, then, under the protection of their spiritual powers, so could devout lay people.

Kamala (1997) points to the presence of forest monks as one of the factors that enabled the Thai government to "invade" and then "close" the forest in the twentieth century. She refers to two relevant eras. First was the Forest-Invasion Period (1957–1988), in which the military-backed government manipulated the Buddhist Sangha (or monkhood) in order to promote economic development that led to significant deforestation across Thailand (Kamala 1997: 229–243). The second was the Forest-Closure Period (1980-present), in which the government, in an effort to retain control of dwindling forest resources, banned monks – and most lay people – from living in the forests (Kamala 1997: 243–249).

The governmental efforts to develop and control forest resources, and the use of the Sangha in this process, was epitomized by Field Marshall Sarit Thanarat, the autocratic ruler who, after coming to power through a coup in 1958, pushed Thailand into an intensive development policy. Aiming to bring Thailand into the global economy, Sarit promoted agricultural intensification and expansion based on export and industry. He emphasized a shift toward cash cropping and bringing more forest land under cultivation, continuing the concept of "civilizing" the wild forest and making it useful for humans. He also drew on traditional cultural values to promote his development agenda. Ishii comments:

> Sarit thought that national integration must be strengthened to realize national development. To attain this goal he planned to start with fostering the people's sentiment for national integration through the enhancement of traditional values as represented by the monarchy and Buddhism (Ishii 1968: 869).

Sarit incorporated Buddhism into his development campaign through community development and missionary programs involving monks (Keyes 1971; Tambiah 1976: 434–471). These programs included *thammathud*, which sent monks as missionaries to politically sensitive and economically poor border provinces; *thammacarik*, through which monks worked among minority hill peoples to convert them from animism and bring them into the national economy; and community development programs sponsored by the two national Buddhist universities.The involvement of monks in development programs provided legitimacy and encouraged Buddhist lay people to participate. At the same time as they contributed to national economic growth, however, these monks inadvertently were a factor in the accompanying environmental degradation. The balance of the spiritual geography shifted. The elements of fear of and respect for spirits that limited encroachment into forested land in the past were negated by monks' engagement in and support of national economic development (see Somboon 1977, 1982).The contribution of individual Buddhist monks to the destruction of the forest can be seen on the local level as well, through the act of subduing forest spirits. The following quote from an ethnography done in a northeastern Thai village in the 1960s illustrates villagers' beliefs in forest spirits and the potential role Buddhism plays in overcoming them so that people can use forest resources. It concerns a particular kind of tree, the *takien* tree, in which spirits live.

> *Takien* trees are most well-known for female malevolent spirits. Nevertheless, the villagers have to overlook their harm whenever they wish to cut them down. A certain person with an especially strong *mantra* will have to conduct a ritual to subjugate the spirits. After a rite is performed, the tree may be cut down.
>
> If a person is uncertain as to whether or not it would be right to cut down the tree, he would cut the trunk with an axe and leave the axe stuck in the tree overnight. If the axe is found fallen from the tree in the morning, the man would be able to cut the tree unharmed. Sometimes if the government wants a particular tree, the cutter would put an official emblem on it. This would supposedly bring no danger to the cutter.
>
> When the *takien* tree is cut, one would usually hear the cry or groan of a woman. Sanguan Srisuwarn [a villager] recounts that once he went to carry a *takien* tree which had already been cut. He could not even get close to the tree. Big flies were swarming the tree so thickly that it was impossible to do anything with the tree. This is supposed to have been the doing of the *phi*. So they had to ask a monk from Wat Nong Yang to chase the *phi* away. The monk made holy water and sprinkled it all around with a *takien* branch. After a while the flies were gone (Kingkeo Attagara 1967: 44–5; quoted in Stott 1978: 16).

A professor at Chiang Mai University told me of stories of villagers asking monks to exorcize spirits from forested areas so that they could cut down the trees and establish farms in the northeast. I never directly met anyone who had witnessed such actions, but the logic of such actions makes sense. The accounts of the government using forest monks – directly and indirectly – to facilitate economic development of forested areas (Kamala 1997: 229–249) and involving other monks in community development and Buddhist missionizing activities since the 1950s (Keyes 1971; Tambiah 1976: 434–471), together with descriptions such as the quote above, suggest that the use of Buddhism to civilize the *paa thu'an* was a common event.

Spirituality and Conservation

In more recent times, however, a small number of monks are working to use Buddhism to protect the forest and the natural environment. These self-proclaimed "environmentalist monks" (Thai: *phra nak anuraksa*) promote environmental conservation based on Buddhist principles such as compassion and the interdependence of all beings. They are concerned about the suffering resulting from unmonitored economic development and environmental damage. They cite the Buddha's close connection with the forest, including stories that his birth, enlightenment and *parinibbana* (physical passing) all occurred in the forest, to support their calls for people to protect forested areas. Monks have undertaken projects to create protected community forests, clean up polluted rivers, and challenge illegal logging in national parks.

While environmentalist monks emphasize Buddhist principles in their work, they are aware of the importance of the cultural contexts in which they work. Some incorporate local beliefs in their environmental work. For example, Phrakhru Pitak Nanthakhun of Nan Province in northern Thailand recognizes the potential of spirit beliefs to support conservation projects and gain villagers' commitment to them. In 1990, he sponsored a ritual that symbolically ordained a tree in his home village in order to establish and sanctify a protected community forest (Darlington 1998). Before the tree ordination, the villagers held a ceremony asking the village guardian spirit, one of the region's "lords of the land," for permission to create the community forest and his help in protecting it. They established a shrine at the base of the tree to be ordained and made offerings to the guardian spirit. Phrakhru Pitak did not attend the ceremony, but neither did he oppose it. He commented later on the combined effect of the two rituals:

> Holding a tree ordination, establishing a shrine for the guardian spirit and placing a Buddha image as the "president" of the forest to forbid cutting trees are all really clever schemes. It's not true Buddhism to conduct such rituals. But in the villagers' beliefs, they respect the Buddha and fear some of his power. Thus we can see that there is

> nothing so sacred or that the villagers respect as much as a Buddha image. Therefore we brought a Buddha image and installed it under the tree which we believe is the king of the forest and ordained the tree. In general, villagers also still believe in spirits. Therefore we set up a shrine for the guardian spirit together with the Buddha image. This led to the saying that "the good Buddha and the fierce spirits help each other take care of the forest." This means that the Buddha earns the villagers' respect. But they fear the spirits. If you have both, respect and fear, the villagers won't dare cut the trees. (Quoted in Arawan 1993: 11; my translation)

Most villagers would agree with the assessment that since the tree ordination there has been greater co-operation in protecting the community forest and less encroachment within it.

While many of the villagers developed an understanding of the principles of ecological conservation through the education sessions held by Phrakhru Pitak prior to the ceremony, the impact of both the Buddhist principles applied to forest conservation and the power of the spirit's charge to guard the forest cannot be denied. The local people's indigenous knowledge of forest ecology, which is fostered and encoded in their spirit beliefs, their awe for the sacred aspects of the project, their respect for Phrakhru Pitak and the newly introduced concepts of conservation all work together to heighten the villagers' cooperation and responsibility to preserve the remaining forest.

Nevertheless, the element of fear may have had more of an impact than Phrakhru Pitak intended. Over the two years following the ordination ceremony, four deaths and several illnesses occurred in the forest that villagers attributed to retribution from the spirits for violation of the terms protecting the community forest. The people who died or became ill were all believed to be cutting wood or hunting within the protected areas. Their misfortunes were determined by spirit ritual specialists to have been caused by forest spirits who were offended by these people's actions.

Although some other monks have criticized Phrakhru Pitak for using the fear of spirit beliefs to achieve the ends of environmental conservation (due to both the use of fear and because many monks deny spirit beliefs as being counter to the teachings of Buddhism), he sees it differently. The villagers believe in and respect the spirits of the forest. Their relationship with these spirits defines and reaffirms their understanding of how the world works – in its natural, supernatural and human aspects. The monk also recognizes that northern Thai belief systems are not static. They have evolved over time, adapting to incorporate various elements of Indian culture, including Buddhism, that have entered the region over several centuries. He recognizes and uses the traditional sacred geography rather than trying to alter it to achieve his aims.

Just as Buddhism was used throughout the twentieth century by the government to encourage a shift in villagers' attitudes toward the forest in the service of development, Phrakhru Pitak sees the potential for using religious and cultural beliefs to change people's attitudes again – only this time in the service of conservation. Recognizing the continual evolution of people's beliefs and practices, Phrakhru Pitak integrates traditional beliefs with Buddhist practices to promote an ecological ethic. While the government and pro-development forces emphasize what they see as "pure" Buddhism (thereby invalidating non-Buddhist beliefs), the monk seeks to incorporate all attitudes toward the natural world. Rather than civilizing the forest through imposing Buddhist concepts in order to conquer and use it, he hopes to instill values that recognize the importance of the forest as an integral component of the environment, which includes humans (Buddhist and non-Buddhist alike), animals and spirits. Through the Buddhist concept of interdependence (Pali, *paticca-samuppada*, or dependent origination), he teaches that humans need the forest for a well-balanced life.

Accompanying such rituals as tree ordinations, Phrakhru Pitak offers villagers concrete methods for achieving this balance. He acknowledges that he cannot merely forbid people from using forest resources as these provide their livelihood. He works with farmers to develop appropriate, sustainable and organic agricultural techniques, including integrated agriculture. This method is based on using complementary plants and animals that sustain and support each other, rather than growing a single cash crop that requires chemical fertilizers or pesticides. Phrakhru Pitak encourages villagers to farm for their own subsistence first, only selling any surpluses that may remain. In this way, he hopes they can avoid getting into debt through the high costs and risks of growing a single cash crop.

Phrakhru Pitak does not only work with Buddhists. He involves the non-Buddhist hill peoples in Nan Province in his environmental education programs, recognizing their relationship with the forest and the potential demise of their traditional lifestyles through rapid economic development and deforestation. As with the lowland Buddhist villagers, Phrakhru Pitak emphasizes the importance of integrated agriculture and sustainability among hill peoples and respects and uses their spirit beliefs in engendering their understanding of their relationship with the natural environment and their cooperation in conservation efforts.

Phrakhru Pitak's tree ordination program is only one example of the kind of work he and other environmentalist monks undertake. In conjunction with the tree ordinations, for example, he also incorporates modified *thaut phaa paa* ceremonies, which are traditionally performed by villagers to offer "forest robes" (*phaa paa*) to monks in merit-making rituals. Phrakhru Pitak expanded the rite to include people's giving tree seedlings along with the robes. The seedlings, after being accepted and sanctified by the monks, are then given back again to the villagers to plant in deforested areas. The trees selected are kinds such as fruit trees that are productive without having to be cut down (Darlington 1998).

In 1993, Phrakhru Pitak expanded his work to increase awareness of the importance of water for all life through a project designed to show the polluted state of the Nan River and garner support for cleaning up and maintaining the quality of its water and wildlife. Again incorporating local beliefs, Phrakhru Pitak performed a traditional "long-life" ceremony for the river in a two-day event in Nan City attended by villagers, government officials, military personnel, nongovernment organizations, and over 200 monks from across northern Thailand. At the same time, he established a fish sanctuary, marking the boundaries of a section of the river within which fishing was not permitted and where the fish would be fed. Here he followed the model of a village upriver from the city; in this village, within a year of creating a fish sanctuary, villagers claimed the numbers of fish increased rapidly, and they were better able to balance between protecting the fish and providing food for their families.

The "long-life" ceremony itself, called *syyp chaa taa* in the Northern Thai dialect, is an exorcism ritual usually performed to rid a person of negative forces and promote a long and healthy life. While Phrakhru Pitak performs several such rites a month for his followers, he says he does not actually believe in the physical effectiveness of the ritual. Rather, he views it as an opportunity to teach people about ways to live their lives following the teachings of the Buddha, thereby decreasing the problems and suffering they face in their lives and ultimately living in greater harmony with the natural world. Adapting the ceremony to the river afforded a similar opportunity to teach the importance of caring for the river and its resources, both water and fish.

Phrakhru Pitak skillfully included elements of Thai society that often oppose the work of the environmentalist monks – government officials, military leaders and businessmen. All of these groups often have stakes in promoting economic development along the lines laid out through government policy, as discussed in the previous section. Phrakhru Pitak believes, however, that these people are not inherently bad nor do they aim purposely to degrade the natural environment and the quality of life of the people who depend upon it. They have merely been led astray through the traditional Buddhist evils of greed, ignorance and anger, on which most environmentalist monks blame the problems of rapid economic development. Through involving the government, military and businessmen in their projects, activist monks such as Phrakhru Pitak hope to teach them as well as the villagers the value of living an ecologically balanced life.

Activists in southern Thailand used a similar approach in organizing several Dhamma Walks (*Dhammayatra*) around Songkhla Lake (Santikaro 2000). The purpose of these walks was to bring attention to the environmental degradation of Thailand's largest lake, a unique and complex ecosystem, to local people and local and regional government officials. Participants aimed to strengthen the voice of local, usually poor and marginalized, people. The issues identified by local people included a lack of fish to eat, bad water and reduced water levels, theft of water taken before it drains into the lake, loss of land through nearby urban population increases, and the breakdown of community and loss of traditional livelihoods (Santikaro 2000: 208–209). Buddhist monks, members of a national, small but growing network of activist monks called Phra Sekhiyadhamma, led the walks, and included local people, village leaders, nongovernmental organization workers, foreign environmental activists, and some local government officials. The participants drew on local culture, both Buddhist and Muslim, in order to foster sympathy and commitment to protecting the lake's ecosystem (including the people whose lives are integrally entwined with it). Unfortunately, few Muslims actually participated in the walks, pointing to perhaps too great an emphasis on Buddhism rather than truly integrating local cultures in the project. Nevertheless, the group succeeded in building confidence among the lake's people, involving local monks who previously did not engage in environmental conservation and gaining awareness nationwide for the problems unique ecosystems such as Songkhla Lake face due to unmonitored development. Anthropologist Ted Meyer, who chronicled the walks, observed the potentials of the activities for creating change:

> I believe the lake walks have created a unique kind of public space in which a very broad range of issues can be explored by participants and observers. These issues include not only the current state of human relationships with nature at the local and global level, but also the meaning and significance of Buddhist practice, the possibilities and problems of cultivating relations of trust between people of very diverse backgrounds, and the challenges of designing effective strategies for social change. The breadth and openness of this space makes it possible, I believe, for a unique kind of spiritual and social creativity to take place. That same breadth and openness, however, also increases the range of difficulties that may be encountered (quoted in Santikaro 2000: 213–214).

Demonstrating further cultural creativity and the willingness to face the potential difficulties, environmentalist monks undertake numerous other activities across the country. These programs include a monk who teaches environmentalism to young people through a bird watching club in northeastern Thailand. Another leads children on Dhamma Walks in the forest surrounding their village in northern Thailand while taking the opportunity to talk with them about both the Buddha's teachings and the ecology of the forest. This same monk (the hero of the hungry ghost story) also runs a model integrated agriculture farm designed to teach villagers sustainable methods and encourage a shift away from cash cropping.

Even monks identified as "forest monks" (a category that indicates ascetic monks' retreat from the social world to meditate in the wilderness rather than any inherent activist stance toward the forest) protect and maintain the forest within their temple compounds even while everything surrounding them is being cut down (see Taylor 1993a: 246–252). As Taylor noted in 1993,

> Presently the only remaining primeval forests in the northeast with a semblance to that described by elderly informants and pre- and post-war bibliographical texts are small pockets dotted here and there throughout the relatively less accessible parts of the countryside. The forest monastery, the ancestor/spirit forest (*paadorn puutaa*) and cremation grounds (*paa chaa*) are normally the only forested areas in close proximity to villages (Taylor 1993a: 250).

The presence of monks, ancestors, and spirits, whether those believed to inhabit the forest naturally or ghosts of the recently deceased, all contribute to protecting forested land. Thai villagers respect and even fear both monks and spirits; thus they avoid destroying forested areas connected with both. This level of protection is not enough, however. These areas tend to be small, often surrounded by denuded land. The quality of the environment within these patches of forest often deteriorates as well due to the loss of the larger ecosystem that used to enclose them. And ironically, as noted earlier, even the presence of forest monks can often empower people to overcome their fears and cut the forest.

The two approaches described here reflect a (self-) conscious shift in the application of religious beliefs and practices toward influencing people's attitudes toward the natural world. The case of Thailand illustrates the various ways religion, tradition and culture have been used to influence people's relationship with nature, in favor of both economic development and nature conservation. While neither is intrinsically superior to the other – arguments are made on each side of the need for either development or conservation for the good of the country – the potential for affecting the future is clear. Given the severity of environmental degradation and deforestation in Thailand, largely attributed to rapid economic development (see Hirsch 1993, 1996a, b; Hirsch and Warren 1998; Lohmann 1991, 1993, 1995; Pinkaew and Rajesh 1991; Rigg 1995a, b; Rigg and Stott 1998), I find it encouraging that some monks and activists, such as Phrakhru Pitak, are engaging in the creative use of all Thai traditions and beliefs – Buddhism and spirit beliefs – for the long-term benefit of both people and nature. The spiritual geography of Thailand has been altered for political ends, but hopefully not to the point of irreversible damage to either the natural environment or the people who live within it.

Environment and Nature: China

Kenneth J. E. Berger

China represents one of the four ancient civilizations of the world, the others being Egypt, Mesopotamia, and India. The one unifying feature of these civilizations is that they all developed along the floodplains of major rivers. The Chinese civilization started along the valleys of the Yellow and Wei Rivers and gradually expanded to the middle and lower parts of the Yellow River and eventually across the North China Plain. It was not by accident that this occurred. Flood plains are well suited to agriculture and China's greatest natural resource is her agricultural land. The river waters also served other purposes such as domestic (drinking, cooking, washing), aesthetic, recreational, irrigation, and fishing.

The early Chinese knew that their livelihood was dependent on nature and in turn believed that their fate and nature were intertwined. This belief caused them to hold the soil in reverential regard and, in some areas, even to consider the rain to be the life-giving seed of the Supreme Ruler in heaven. Humans were considered equals to all forms of life. Prosperity and happiness depended on an ability to adjust successfully to the various forces of nature. To go against nature or to tamper with it might disrupt its equilibrium and ultimately prove to be harmful.

This cooperation with nature, however, did not mean that the early Chinese submitted passively to life. Instead they felt that humanity was the means through which nature's full potential could be realized. In fact, according to some historians, the Chinese have had more of an effect on their environment that any other people (Keswick 1986). Nature, in turn, has endowed the Chinese with some of the world's most productive agricultural areas. The Chinese regarded the alteration of their environment as a type of adornment and not as a form of mastery and control. Through their diligence and devotion, they were able to develop a natural system to explain nature and the environment. Their understanding was further modified according to ancient traditions and customs, which preserved in the Chinese a spirit of sacred reverence for the divine powers of nature and a sense of community with it. They looked upon nature and the environment not as a dead or inanimate thing but rather as a living breathing organism, in a fashion somewhat similar to the present-day Gaia Hypothesis. The Chinese saw a chain of spiritual life running through every form of existence which bound together, as in one living body, all things existing in heaven above and earth below. They had an aesthetic, poetic, emotional, and reverential way of looking at natural objects.

The fourth and third centuries BCE marked a transition period during which ancient Chinese natural philosophy developed into a more sophisticated and systematized theory. Out of their observation, identification, and dependency on nature came Daoism, a philosophy based on nature. The Daoists championed the independence of each individual, and maintained that the only concern should be to fit into the great order of nature, i.e. the *Dao*. They believed that if left to itself, the universe proceeds smoothly according to its own harmonies. They emphasized the unity and spontaneity of nature. Mankind's efforts to change or improve nature only destroy these harmonies and produce chaos. Humanity's place in nature was to be in harmony with it since both humans and nature obey the same laws. Thus, they are in a constant dynamic relationship with one another, each able to affect the other's flow. As Laozi (ca. 561–467 BCE) stated in the *Dao De Jing*, "Man follows the way of earth, earth follows the way of heaven, heaven follows the rules. The rules are the *Dao*".

At the same time that Daoism was flourishing, another school of philosophic thought was also flourishing, known as the Naturalist School. This attempted to explain nature's workings on the basis of certain cosmic principles, one of which was the basic dualism of nature, the *Yin yang* Principle. *Yang* represents masculinity, light, hotness, dryness, hardness, roundness, activity, heaven, the sun, etc. *Yin* represents femininity, dark, coldness, wetness, softness, squareness, passivity, earth, the moon, etc. Rather than being in perpetual conflict, *yin* and *yang* are mutually complementary and balancing. The greater *yang* grows, the sooner it will yield to *yin*; likewise the greater *yin* grows, the sooner it will yield to *yang*. In addition, *yang* always contains some *yin* and *yin* always contains some *yang*. *Yin* and *yang* continually interact, creating cyclical change. For example, *Yin* and *yang* helped explain the seasons and the proper actions which should occur, in spring: plow, in summer: weed, in autumn: harvest, in winter: store. The interdependence of the two principles was well symbolized by an interlocking figure, which today is used as the central design element in the flag of South Korea. This *yinyang* concept was eventually incorporated into Daoism, with *Dao* being the natural process that unites the two.

When perfect balance and harmony exist between the *yin* and *yang* elements and qualities, growth of all living things flourishes and *qi*, the cosmic breath, enhances the environment. *Qi* is believed to exist in all living and nonliving things. This concept of *qi* is pervasive throughout Chinese customs and traditions, from acupuncture to kung fu. It is through *qi* that all things in the universe are related and attached to each other and integrated in the united whole.

The early understanding of the forces of nature which was accumulated over the years, together with the concepts of *yin yang, qi*, and later concepts, eventually developed into a complex science known as *feng shui*. Simply put, *feng shui* is an early form of ecology, conservation, and environmental science. It unites heaven, earth, and humans in such a way that a respect for nature is developed along with the ideas of renewability and sustainability of resources.

The most famous of the Chinese philosophers was Confucius (551–479 BCE). He was primarily concerned with society and interpersonal relationships. As such, the Confucian view of nature is only relevant with respect to how it affects human relationships and interactions. However, he did recognize the importance of the human–nature relationship. This can be seen in the Classics, a set of books associated with Confucianism.

In the *Yijing* (Book of Changes), it is stated that, "The great man is the one who unites his morals with heaven and earth." *Li Ji* (Book of Rites) in turn states, "Man is the heart of the heaven and the earth…, so a holy man must treat heaven and earth as the root of behavior." It also says that "to chop down a tree or kill an animal at the improper time is unfilial." The *Doctrine of the Mean* states, "Let the states of equilibrium and harmony exist in perfection, and a happy order will prevail throughout heaven and earth and all things will be nourished and flourish." Therefore, in order to unify with nature, we should obey the regularity of nature and take care of it. According to the *Yijing*, also known as the *I Ching*, the Chinese concepts are revere nature, unify with nature, adapt to nature, spare nature, learn from nature, and play in nature. The Confucian thus asks people to act in a proper manner and to take care of nature; so by leading a moral life, people can assist heaven and earth to maintain a harmonious balance.

Mencius (371–289 BCE), a disciple of Confucius, said, "If you do not interfere with the seasons of husbandry, the grain will be more than can be eaten. If you do not use a net in a fish pond, the fish and turtles will be more than can be consumed. When cutting wood only go into the forest and hills when it is the proper time, and the wood will be more than can be used. Not allowing the exhaustive consumption of fish and turtles, nor the exhaustive use of the woods, enables the people to live and die generation after generation without interruption." In other words, resources are for the perpetual use of mankind.

The last major influence on the Chinese concept of nature and the environment is that of Buddhism, which came to China from India in the first century AD. Buddhism gave to the Chinese a respect for the lives of all living things, because it is believed that all things have the potential to achieve Buddhahood and that animals are but a form in which something has returned in its new incarnation. Everything in the world has a relationship with everything else, be it animate or inanimate. The only difference is in the closeness of the relationship.

The concepts of nature and the environment in ancient China are basically a group of general principles, such as the cyclic nature of the natural world, the equality of the natural laws, the creativity of nature as expressed in its biodiversity and abundance, and the belief that everything contains both a positive and negative part. Through Confucianism, these concepts became part of morality; through Daoism, they became part of philosophy; through Naturalism, they became part of cosmology; through *feng shui*, they became a part of science; through Buddhism, they became part of religion. The concepts were easily understood and incorporated into an understanding as to how humans should live their lives, i.e., in harmony with nature.

Environment and Nature in Hebrew Thought

Jeanne Kay Guelke

It is perhaps inappropriate to include a section on Hebrew thought in an encyclopedia on non-Western cultures. When the Hebrew Bible was adopted in translation as the Christian Old Testament, it became one of the intellectual cornerstones of western civilization. The two principal divisions of Jewish culture and ethnicity, central and eastern European (*Ashkenazi*) and Mediterranean and Near Eastern (*Sephardi*), have extensive European roots. Nevertheless Christianity and Judaism diverged in critical ways over the interpretation of their shared scriptures.

The Hebrew Bible and Jewish Law

The essential core of Jewish belief is the first five books of the Bible, notably the set of 613 commandments (*mitzvoth*) handed down to Moses on Mount Sinai. The rabbinical interpretations of Mosaic law (*halakhah*) and explanations of biblical narratives codified principally in Babylon and Palestine during the first centuries of the Common Era as the Talmud (together with some subsequent commentaries on the Talmud) form the essence of traditional Jews' understanding of the cosmos and permissible activities within it. "Hebrew thought" as a body of literature in the Hebrew (or Aramaic) language is not identical with "Jewish thought" (which includes Yiddish prose and other writings from the Diaspora) but there is a strong correspondence based upon Jewish origins in the ancient Near East.

In the Hebrew Bible, one God created the heavens, the earth, and their creatures, and pronounced them "good." God placed the first humans in the beautiful Garden of Eden "to dress it and keep it." Humans were given control over soil and biota: "the fish of the sea, the fowl of the air," but the Bible explicitly reserves control over physical forces of the environment, notably climate, to God. The Bible links humans' ability to shape nature to their liking to their obedience to God's will. In the biblical narratives, few humans are righteous enough to accomplish dominion over nature.

God commanded the patriarch Abraham and his descendants, the Israelites, to worship God exclusively and to obey His commandments. The books of Numbers and Deuteronomy explain environmental change in the form of divine blessings and curses for human good deeds and misdeeds. The Israelites are to receive a homeland, abundant rainfall, and crop yields if they obey the *mitzvoth*, but drought, insect plagues, and the "scorched earth" resulting from warfare if they disobey. The environment is a principal means through which God expresses Himself and registers His authority.

The Hebrew Bible and Talmud have little explicitly to say about environmental conservation in the modern sense. There are proscriptions in Jewish law against cruelty to animals, destruction of fruit trees during warfare, tilling the soil during the sabbatical year, and working (and hence altering nature) on the Sabbath day. There is little evidence in the Bible that Middle Eastern, Iron Age farmers and pastoralists even understood that humans were capable of causing extensive environmental degradation (with the possible exception of overgrazing), and considerable evidence that they attributed environmental deterioration to God's wrath. These cast considerable doubt on some scholars' assertions that the Judeo–Christian tradition is the root of the West's callous treatment of nature, simply on the basis of a few verses in Genesis mandating human use and domestication of plants and animals. Needless to say, both Christian and Israeli settlers in recent centuries have subsequently cited the Genesis injunction for human dominion over nature and Isaiah's prophecy that the desert shall "bloom like the rose" as a license for resource exploitation.

The ancient Jewish dietary laws (*kasruth*) identify certain animals and slaughtering practices as "clean" or "unclean" as food for the Jewish people. Although the scriptural statement that some species are "abominations" on the Jewish table does not imply reverence for all of nature, the forbidden animals, by the same token, would not have been hunted or raised inhumanely. A modern environmentalist interpretation of kashruth is that God expressly limits Jews' exploitation of the Creation.

Today when many environmentalists seek to undo the dualism between humanity and nature, it is worth nothing that the Hebrew Bible indeed has no words for “environment” or “nature” that distinguish these concepts from culture: only the universal and integrative concepts of “everything” (*olam*) or Creation. In the Bible’s original Hebrew (though not in most English translations) animals have souls (*nefesh*, *ruach*) just as people do. Trees and stars praise God and shout for joy.

The Bible is full of evocative nature poetry, notably in the prophets, Job and the Psalms. Eagles, lions, the cedar forests of the mountains of Lebanon, the desert after a rain shower, and lush pastures seemed especially inspirational to the ancient Hebrew mind. The Israelites’ formative early experiences with the desert (as in the book of Exodus) and Mediterranean crop zone appear throughout their religious texts.

The Jewish scriptures also describe an annual cycle of holy days that were based on a lunar calendar and changing seasons as they would have affected ancient farmers and herders. The festival of *Shavuot* (Weeks), for example, celebrates the gathering of first fruits of the land. *Sukkot* (Tabernacles) in autumn culminates a series of days set aside for repentance and atonement with prayers for the winter rains so essential for agriculture in the Near East. While such environmental connotations were weakened among urban Jews of the Diaspora (who nevertheless continued to observe the holy days), they are quite obvious to visitors of rural Israel today.

Middle Ages and Early Modern Times

With the postbiblical Diaspora or exile from Palestine following Roman destruction of Judaism’s institutions and sacred sites, Jews literally scattered to the four corners of the earth. Often forbidden by host governments from attaining the most basic of human rights, owning land, living outside of urban ghettoes, or working at most occupations, many Jews were prevented by anti-Semitism from forming a close relationship with environments where they settled. Preserving their faith and studying Torah and Talmud were largely indoor activities.

Although development of Jewish environmental thought was thus limited, medieval Jewish philosophers and mystics who developed the Kabbalah teachings believed that all of nature was imbued with divine emanations, or even with divine substance. Some leaders of the eighteenth-century pietist Chassidic movement of Eastern Europe were noted for retreating alone to the fields and forests for prayer and mystical insight. The agrarian Zionist movement of the late nineteenth and early twentieth centuries advocated a return of Jews to Israel, in the belief that working the soil of their ancient homeland would redeem and ennoble oppressed European Jewry.

Recent Past and Present

The recent history of Hebrew thought on the environment and nature is best exemplified by the modern state of Israel. Since its inception in 1947, it has experienced many of the same environmental problems as other industrialized countries, with particular concerns about water scarcity and reforestation. Israel’s push for development of new settlements and industries despite a hostile international political scene, and its land use needs for military security often overrule environmental preservation priorities. Hostilities between Arabs and Jews clearly have had an environmental impact, notably in the recent expansion of Israel’s “security” landscape and in tensions between Arab range lands and Jewish reforestation projects.

Nevertheless Israel is one of the few nations in the Near East with a variety of environmental organizations, such as the Society for the Protection of Nature in Israel (founded in 1953), a Ministry of the Environment, and a system of nature preserves and national parks. Two noteworthy parks, Chai-Bar and Neot Kedumim, are maintained to preserve specimens of vanishing desert fauna and flora, respectively, mentioned in the Bible.

The Israeli response to nature has not lost its ancient religious roots. Some Orthodox Jews in Israel use traditional prayers for rain as a response to drought, and accept halakhic rulings about agricultural fields together with scientific agronomy practice.

Many Jewish environmentalists throughout North America today seek to integrate their faith and environmental concern. Some are reexamining the rabbinical concept of *Tikkun Olam* (healing everything) as the performance of *mitzvoth* necessary to restore planetary health. Vegetarianism for some fits in well both with Jewish dietary laws and environmentalist beliefs about the sanctity of life. Clearly the synthesis of ancient traditional texts, religious practice, and recent environmental awareness will lead to a rapid evolution of environment and nature in Jewish thought in the near future.

Environment and Nature: India

D. P. Chattopadhyaya

The philosophical and scientific ideas developed in India over the centuries are, on analysis, found to be deeply related to ecological issues, both generally and specifically. Like the ancient ideas of China and of the Hellenic world, the ancient Indian ideas of the comparable period are cosmological and comprehensive in character. The *Vedas* and *Upaniṣads*, Laozi's *Dao* or in Parmenides' *Nature of Being* were all engaged in search of the first principle, One. They were all obliged to relate it to Many–Many individual objects of knowledge. The One–Many relationship is pregnant with both cosmological and ecological implications.

Broadly speaking, the objects we know around us are biotic (living) or abiotic. However, to many thinkers, especially to the pluralists and evolutionists, this twofold classification is simplistic and inadequate. They try to draw our attention to different grades of being or reality – physical, chemical, paleontological, botanical, biological, psychological, and spiritual. The scientific philosophers of the Vedic insights, of the *Samkhya* persuasion, and also of later times could discern different subgrades within each of these grades. These graded characteristics of different living and nonliving beings have to be recognized if we are to understand the complex and the interactive character of our environment. This insightful approach to ecology as an integral part of cosmology is evident in the tradition of Indian thought. It is very clearly available, for example in *Caraka-Saṁhitā*.

In ancient India the good of human life was thought of in the context of life's environment. The right relation between the individual and his environment received serious attention even at the levels of primary and secondary education. The aim was to impart basic knowledge of personal hygiene and medicine. This education was meant for all. In a way medical education was universal. It is interesting to note the five compulsory subjects for all high school students: Grammar (*Śabdavidyā*), Art (*Śilpasthānavidyā*), Medicine (*Cikitsāvidyā*), Logic (*Hetuvidyā*), and Science of Spiritual philosophy (*Adhyātmavidyā*).

Both abstract and concrete areas of knowledge, understood in their interconnection, are all relevant to the exercise of adjusting to our environment. Linguistic communication, artistic articulation, logical ratiocination, and medication are in different ways intended to awaken the best in us and to strike a balance with the large world around us. From the strength of body to the span of life, from good health to peace of mind, all are a unified function of food, personal hygiene, right actions, and character.

Life has a rhythm of its own, which is not necessarily manifest. The *Dharmaśāstra* are full of injunctions on how to attain that rhythm in terms of purity, diet, regulation, ablutions, behavior, and physical and mental disciplines. These have to be followed as part of daily (*dinacaryā*) as well as seasonal routines (*ṛtucaryā*). Food and drink habits and fulfillment of natural urges, avoidance and indulgence in sexual acts, and eating some ordinary things like curds, buttermilk, and honey are all necessary to define our correct relation with the environment. However, this normative rhythm can hardly be generalized, for it is integrally related to the individual constitution (*prakṛti and svāsthya-vṛtti*).

The traditional Indian medical system (*Āyurveda*) takes a comprehensive view of a person. It neither encourages asceticism and mortification of the flesh nor promotes unregulated sensualism. It highlights the importance of a "sound mind in a sound body". It points out that *svāsthya-vṛtta* or philosophy of hygiene is to be supplemented by *sadvṛtta* or the right life. Rightly understood, the philosophy of hygiene is a way of life containing in it the principles of eugenics, ethics, and healing.

In ancient Indian thought the basic principles of ecology are ontologically oriented and cosmological in implication. The three main concepts of the Vedas which are evident in *Āyurveda* are *satya* (truth, right, reality, or being), *svadhā* (self-position, self-power, or spontaneity) and *ṛta* (proper, suitable, and settled order). The basic point which is being emphasized here is that the true nature of reality cannot be changed by human will which is not informed of that reality. No technological skill, no arbitrary will of this or that person, can go indefinitely against the true nature of reality without causing harm to those who try to follow this wrong path. Even the most sophistical biotechnology cannot tamper with the essential nature of reality, the true Nature or *Prakṛti*. This role of the concept of truth has both ontological and axiological implications. Humans are required both to know reality in its true nature and to live and shape their lives accordingly.

Humans are also aided by the principle of becoming or the dynamic nature of reality in shaping their best possible life. This possibility is contained in the concept of *svadhā*. Reality has within itself the impetus or power for self-unfolding or gradual disclosure. It is not static, fixed, or self-enclosed. The world as reality and as a whole is perpetually expanding. This macrocosmic truth of *svadhā* is at work also in human nature. Consequently, human freedom knows no bounds. Nature and its laws are not antagonistic to the human will to be free. When we can discover the laws governing the true nature of the relation between individuals and the world, our knowledge of the world helps us to live in harmony with it. That harmony creates a favorable environment which not only nourishes our bodies but also enables us to be free from social conflict and tension. When we are free from ill health, we are better placed in our relation to nature. When we fail to strike the balance with nature, we are not only likely to be poorer in health but also less capable of getting the best out of our environment.

Finally, besides the true nature of reality (*satya*) and the power of self-disclosure (*svadhā*) what helps us to have a right environment is suggested by the concept of *ṛta*. It is orderliness or the law-governed character of reality or nature. From the change of seasons to the changing periods of life, *ṛta* is clearly perceptible. Even human cultures are found to exhibit certain rhythms. Cultures are characterized simultaneously by fragile and stable features. The rhythm of nature is not antagonistic to the spirit of human freedom. Our lives, both individual and collective, are marked by a sort of dynamic equilibrium.

The above three concepts embodying certain abstract principles may appear irrelevant to our actual lives. However, to the thinkers of *Āyurveda* the principles of philosophy and ethics, or those of good living, are inseparable from the basic characteristics of reality.

The same principle is illustrated in defining the ideal principles of town planning and village planning. Aśoka, the Buddhist emperor of ancient India, said that trees, plants, and shrubs of medicinal value had to be planted around every village and along the roadsides. The people were allowed to use the leaves, fruits, and bark of the trees. This practice survives today. Like geography, history, science, and arithmetic, the general principles of hygiene and physiology and simple methods of curing cuts, wounds, and everyday ailments were prescribed for everyone's general education. The underlying belief was that individuals had to be able to take care of their elementary medical needs.

The Indians believed that every village should be so constructed that its population must have the professional service of a medical practitioner (*vaidya*). People were advised to reside in a place with plenty of water, herbs, sacrificial sticks, flowers, grass, and firewood, and which yielded abundant food. They were also advised to live where there was safety of property and person, where the outskirts were beautiful and pleasing, and where there was a strong presence of learned people.

Ancient Indian thinkers paid attention to the development and preservation of the right type of environment for human life. The state was assigned a very important role for the purpose. It was expected to lay down rules and regulations for rubbish disposal and drainage systems. The state also determined where and how the quality of food and drink should be preserved. Those who violated these rules and thereby polluted the environment were punished. Equally conscious were the decision-makers in charge of public health. The state had a very important role to perform for preservation and promotion of a healthy environment. Various types of punishment were prescribed for cutting for the tender sprouts of trees.

Kautilya mentioned elaborate laws for the promotion of agricultural activities. For example, he prohibited high agricultural taxes and bonded agricultural labor and attached much importance to animal husbandry and soil preservation.

Environment and Nature: Islam

Parvez Manzoor, Ziauddin Sardar

The sacred text of Islam, the *Qurʾān*, contains a theology of ecology, for nature and ethics are at the very core of its moral worldview. Indeed, so central is the theme of the affinity of nature and ethics that even outside observers, such as Marshall G. Hodgson, have epitomized the dictates of the Islamic commitment as "the demand for personal responsibility for the moral ordering of the natural world."

The creation of humanity is one of the grandest themes of the *Qurʾān*. It is alluded to either philosophically in a symbolic language or biologically, employing the medium of natural science. Philosophically, the first assertion is that of the purposefulness and meaningfulness of human life. The Quranic teleology is preeminently moral: humans are to execute the will of God, but it is an undertaking which they have imposed upon themselves. It is a pledge made by man and woman to God. Hence, God, for His part, has endowed them with all the faculties essential to undertaking this august moral mission. Nature is the testing ground of this moral responsibility. Men and women are thus enjoined to read its "signs." For this purpose, nature has been created both orderly and predictable. The creation of human beings and the creation of nature are thus two chapters of the single theme of moral responsibility and trust that is the *sine qua non* of Islamic commitment.

Nature, therefore, is a trust or *amāna* and a theatre for a Muslim's moral struggle. According to the *Qurʾān*, heavens, earth, and mountains refused to assume this responsibility which humans took upon themselves voluntarily. By doing this, no doubt, humans showed ignorance and hubris – but also their willingness to serve God's purpose. As trust is a mutual commitment, it may also be surmised that God, by entrusting people with this responsibility, expressed confidence in their ability. No wonder that in the Quranic worldview and Islamic tradition the individual is known as the trustee, or *khalīfa*, of God.

The Islamic rationale for an ecological ethics rests on the Quranic notions of *khalīfa* and *amāna*. Nature, being the gift of God to man, is accepted in Islam as an estate over which we have temporary control but no sovereign authority. Our relationship with nature thus can never be ethically neutral. Islam views nature essentially in a teleological perspective and therefore the claims of man's dominion over her have no resonance in Islam.

While Islam is a monotheistic faith belonging to the Arabrahamic tradition, its teachings on environment and nature contrast sharply with its sister religion of Christianity. To give an example, the Hebrew story of creation is transformed in Christianity into the doctrine of the fall. Creation thus appears to the Christian mind as "fallen," and nature is viewed as opposed to grace. St. Augustine, to take one example, believed that nature was "unredeemed," just as many Christian theologians maintain that nature cannot teach man anything about God and is therefore of no theological and spiritual interest. Salvation is the humbling of nature by the miraculous, the intrusion of the supernatural into history. The nearest thing in the physical universe that reflects the miraculous is man. Holiness exists only in a man-made environment. Thus, nature, so devoid of God's presence and grace, may be "tortured"; it may be justifiably subjected to scientific experimentation. The Islamic view is very different. Creation (nature) in the Quranic view always bears the "signs of God" and is necessary for man's salvation. It is in accordance with this that Islam holds that there is no such thing as a profane world. All the immensity of matter constitutes a scope for the self-realization of the spirit. All is holy ground, or as the Prophet Muḥammad said, "the whole of this earth is a mosque." Earth, creation and nature thus have a sacramental efficacy in Islam which can be ill-accommodated with the perverse applications of the "dominion ethics". The claim for nature's "salvational worth", however, may never be construed as a token of its autonomy. In fact, Muslim theologians have always claimed that nature has no meaning without reference to God; without Divine purpose it simply does not exist. (Hence, nature is simply known as the created order.)

The ethical link between faith in God and love for His creation is fully demonstrated in the life of the Prophet Muḥammad himself who declared that whoever is kind to the creatures of God is kind to himself. One authentic tradition narrates that a man once came to the Prophet with a bundle and said, "I passed through a wood and heard the voice of the young of birds, and I took them and put them in my carpet and their mother came fluttering around my head." And the Prophet said, "Put them down." And when he had put them down, the mother joined the young. And the Prophet said, "Do you wonder at the affection of the mother towards her young? I swear by Him who has sent me, verily, God is more loving to His servants than the mother of these birds. Return them to the place from where you took them, and let their mother be with them."

Such environmental teachings were actually translated into environmental policies and legislation in the classical Muslim civilization. For example, the Muslims developed the notion of *ḥaram* – inviolate zones – outsides towns, near water-courses, and other areas where development was forbidden. A second type of inviolate zone was *ḥima* which applied to forests, woods, and wild habitation and was designed to conserve wildlife. Ibn ʿabd as-Salam (fl. thirteenth century) formulated the first statements of animal rights. Muslims were also concerned about the protection of the urban environment; Islamic town planning and architecture provide ample demonstrations of this. Many classic cities, like Fez, were built with the full understanding of carrying capacity and were designed so that the city's population would not increase beyond a critical limit. The debate about conservation, protection of animals and their habitats, and the Islamic teachings on environment can be clearly seen in such classics as *Disputes Between Animals and Man*, which is a part of the *Rasāʾ-īl Ikhwān al-ṣafāʾ* (The Epistles of the Brethren of Purity) written in the tenth century. The deep respect for nature and environment is also evident in Sufism, the mystical strand of Islam, both in its thought and practice. The titles of some of the classic Sufi works reflect their concern with nature. *Gulistān* (The Rose Garden) and *Bustān* (The Fruit Garden) by Saʿdi of Shīrāz, and Farīd al-Dīn ʿAttār's *Manṭiq al-ṭayr* (The Conference of the Birds) provide good illustrations.

Contemporary Muslim societies have lost much of their traditional consciousness and concerns. Both colonialism and the mad rush for modernization have played their part in this oversight, but today we can detect a minor resurgence in Islamic environmental consciousness. This is evident both in the intellectual and academic efforts to shape a contemporary Islamic environment theory – for example in the works of Gulzar Haider, Seyyed Hossein Nasr, and Othman Llewellyn – and the frequent use of traditional Islamic concepts and technologies (such as *qanat*, the ingenious system of wells drained through a network of tunnels) in developing environmentally sound practices in the Middle East and Iran, Pakistan, and Malaysia.

Equipped with the ethical insights of *khalīfa* and *amāna*, and impelled by the Quranic dictates to assume personal moral responsibility in the world of nature, Muslims have a responsibility to meet the challenge of ecology to religious consciousness and provide mankind with a healing vision of the harmony of man and nature under God. Like everything else of value in Islam, its ecological insight can be summed up under the seminal concept of *tawḥīd* (unity). *Tawḥīd*, Islam's eternal quest for the unity of life and purpose, spirit and matter, human beings and nature, law and ethics, faith and morality, implies that man does not dominate the earth or commit violence in any form.

Environment and Nature: Japan

John A Tucker

In traditional Japan, the word *shizen*, also pronounced *jinen*, meant naturalness, or the mode of being which is natural. Its literal meaning is "from itself (*shi/ji*) thus it is (*zen/nen*)." In modern Japanese *shizen* by extension came to refer to nature, or the environment encompassing all between heaven and earth, especially the earth, oceans, mountains, rivers, flora, and fauna.

Premodern Japanese had no single word signifying nature as a unified entity. Nevertheless passages about nature abound in their ancient literature, philosophy, and religion. Words like *ten*, literally meaning heaven, and *tenka*, meaning heaven and earth, meant something like nature. An understanding of traditional conceptions of nature can be garnered by examining Japanese thoughts about aspects of nature such as heaven, earth, mountains, rivers, trees, flowers, and fields.

Ancient Japanese evinced an unabashed intimacy with the natural world in their earliest poetry as compiled in the eighth-century anthology, the *Man 'yōshū* (Collection of Myriad Leaves). Its poems spoke of the world of mountains, rivers, flora, and fauna in anthropomorphic, animistic terms, investing each entity with a living personality infused with *kami*, or mysterious spiritual energy. Mountains were deemed most divine. Indeed, in their verses the ancient poets immortalized Mt. Fuji as a peerless deity. Rivers were considered living forces, manifesting immense spirituality in their rushing flows of clean, life-giving water. The sea was viewed as a more awe-inspiring, fearful spiritual force, one supplying sustenance but also destruction. References to birds and beasts fill the poems, evoking a sense of the four seasons and the human feelings linked to them. The poems themselves were likened to the natural world: the *Man'yōshū* included myriad *yō*, or "leaves" of poetry.

The earliest histories of Japan, the *Kojiki* (Records of Antiquity, 712) and the *Nihon shoki* (Chronicles of Ancient Japan, 720), open with myths relating the Shintō cosmogony. They give the *Man'yōshū* vision of nature a strongly religious, spiritual grounding, leaving no doubt that the world of nature was the world of creative religious spirit. After heaven and earth congealed out of an undifferentiated, egg-like mass, successive generations of personified *kami* begot one another. Finally the *kami* pair, Izanagi and Izanami, created the first island, Onogorojima, by letting the brine drip off a spear they had plunged into the ocean's depths. On Onogorojima, Izanami gave birth to the elements of nature including the rivers, mountains, birds, beasts, and flowers and trees, and the forces of nature such as fire. Because of the divinity of the progenitors, Japanese traditionally considered their archipelago and all of nature within it as sacred.

According to one account, Izanagi and Izanami also gave birth to Amaterasu the Sun Goddess and her brother Susanoō the impetuous god of storms. Because both Amaterasu, a benevolent *kami*, and Susanoō, a mischievous if not malevolent one, are deemed divine beings, Japanese have not dismissed destructive forces of nature as evil. Nor have they branded acts against nature as necessarily wrong. Indeed, Shintō myths relate that Susanoō wreaked havoc in his sister's rice fields, implying that similar actions contrary to the general good of the world of nature might still have some divine sanction via Susanoō's example. Perhaps this partly explains why many Japanese, despite their close religious, poetic, and mythic ties to nature, have at times tolerated abuses of it.

Pollution, however, was considered anathema, and was dealt with via Shintō purification rites. Pollution did not necessarily mean physical dirtiness or noxious environmental conditions; however, those forms were recognized among the more spiritual nuances associated with the Shintō notion of pollution. Traditional abhorrence of physical and spiritual pollution perhaps explains the energetic opposition of many Japanese, though certainly not all, to environmental pollution.

Amaterasu and Susanoō parented the imperial line and the ancestral stock of all its human subjects. Belief in the divinity of their islands, their imperial family, and everything within their natural environment thus results from the supposed ancestry of Japanese in Izanagi and Izanami. This became a basic tenet of Shintō, one regularly repeated throughout Japanese history. In the *Engi shiki* (Religious Regulations of the Engi Period, 927) ritual prayers record a similar vision of nature as fully infused with divine spirituality. Kitabatake Chikafusa's (1293–1354) political tract, the *Jinnō shōtōki* (The Legitimate Succession of Divine Emperors, ca. 1340), opened with the declaration, "Japan is a sacred land (*shinkoku*)." Japanese Buddhists and Confucians almost unanimously have accepted the same, essentially Shintō doctrine.

Belief in the divinity of the archipelago encouraged some Japanese to xenophobia: foreigners, typically viewed as barbarians, were feared as potential agents of pollution. Japanese soil, they felt, would be violated if the barbarians were allowed on it. Since 1945, the Japanese have become more accustomed to the presence of foreigners in their country. Still their concern for nature often seems Japan-specific: some southeast Asian forests have been depleted to accommodate the Japanese preference for disposable, wooden chopsticks, even though forest conservation practices are followed within Japan.

Introduced to Japan in the mid-sixth century, Buddhism advanced various attitudes toward nature. The Four Noble Truths, the original teachings of the historical Buddha, Siddhārtha Gautama (563–483 BCE), characterize existence as suffering, implying that *samsara*, or the environment of reincarnation, was similar. Their religious solution, *nirvana*, which literally means "putting out the flame" (of existence in this world), seems to offer an escapist otherworldliness which might have permitted a relative disengagement from nature.

The Mahāyāna Buddhist ideas of the Indian thinker Nāgārjuna (ca. AD 150–250), which were accepted by most Japanese Buddhists, affirmed the natural order. Nāgārjuna equated *samsara* with *nirvana*, disallowing otherworldliness. Nāgārjuna's view was based on the doctrine that everything is empty (*sunya*). Empty here means empty of self-sustaining substance, i.e., a substance existing in and of itself. Nāgārjuna insisted that everything that exists does so through spatial, temporal, and causal relations with the remainder of the universe. Nothing exists independently of everything else. His ideas could be construed as anticipating the ecologist's belief that all life is interrelated, and that destruction of small niches endanger the entire ecosystem. Nāgārjuna's ideas surely facilitated a more positive appraisal of nature by Japanese Buddhists.

Traditional Buddhist cosmology, however, claims that the world is subject to creation and disintegration just as humans experience cycles of death and rebirth. Arguably this view could allow a cavalier attitude toward the natural environment since regardless of one's efforts the world will inevitably disintegrate and then begin anew. The Buddhist belief that attachment to things leads to suffering also might vitiate wholehearted involvement in an environmental ethic geared toward conservation of nature. The Buddhist two-level theory of truth, assigning ultimate status to *sunya*, and relegating common sense to secondary validity, allows for concern for nature but not in a primary way.

Otherworldly tendencies appeared in the popular Jōdo, or "Pure Land", School. Based on the Indian writing *Sukhāvatīvyūha-sūtra* (Discourse on Paradise), Jōdo posits both a heaven called the Pure Land presided over by Amida Buddha, and a multileveled hell where sinners suffer eternally. Yet some theorists claim that the Pure Land and hell are merely "expedients" meant to motivate non-believers to meditate on Amida Buddha as the way to salvation. If so, then the Pure Land becomes a symbol of *nirvana*, or existential extinction, while hell becomes a hyperbole of the Buddha's claim that life in this world, the world of nature, entails suffering.

Yet the ideas of many Japanese Buddhists evinced a religiously based concern for nature. The Kegon, or Flower Garland, school asserted that every particle of existence was infused with Buddha-nature, making the natural universe a spiritual one as well, one to be saved from suffering. The *Konkō kyō* (Sutra of the Golden Light), an important text in early Japanese Buddhism, claimed that rulers who promoted the Buddha's teachings would be protected, as would be their domains, by the Four Deva Kings, tutelary divinities who protected Buddhism throughout the universe. Compassion for all sentient beings, the core ethic inculcated by Māhāyana Buddhists, instilled in some a concern for the natural world.

Buddhist poets like Saigyō (1118–1190) even extolled the world of nature as the primary arena of Buddhist values. Others debated whether plants and trees, though nonsentient beings, could actually attain Buddhahood. Many Japanese Buddhists argued that they could. Some also claimed that nature possessed a healing and even soteriological capability. Probably influenced by Shintō beliefs, the Shugendō (Order of Mountain Ascetics) school had its practitioners make pilgrimages to sacred mountains to glimpse scenery foreshadowing the Pure Land. Buddhist temples aesthetically enhanced the environment. With their rock gardens, moss gardens, and vegetable gardens, temples were practically involved in local environmental improvement as a way of meditation. Zen Buddhists see enlightenment as an experience to be had in this world and in this body. Disregard of nature, therefore, cannot be allowed. Yet Buddhists are not known for authoring agricultural or environmental tracts. It was the Confucian and Neo-Confucian scholars who, in addition to admiring nature's beauty and revering it religiously, made the world of nature the focus of protoscientific research designed to conserve the environment for future generations.

Neo-Confucianism, the last major philosophical force to emerge in traditional Japan, encouraged scientific interest in and ethical concern for the natural world. Prompted by the sophisticated Buddhist metaphysics with its (to Neo-Confucians) repulsive doctrine of emptiness, Confucians reformulated their originally socio-political thought along novel metaphysical lines so as to refute the Buddhist challenge. Originally a Chinese movement of the Song dynasty (967–1279). Neo-Confucianism ultimately became a pan-Asian force decisively affecting China, Korea, Japan, Vietnam, and other East Asian areas up until the modern period. In Japan, it was a dominant force during the Tokugawa period (1600–1867).

Neo-Confucians endorsed common sense, declaring that the natural environment was both substantial and fully real. They believed that there was no other world. Rejecting emptiness, they asserted that everything consisted of a quasimaterial, psycho-physical energy called *ki*. Giving "matter" its rationale was another ontological element, *ri*, or "principle." The fusion of *ki* and *ri* accounted for the diversity within the natural world. The latter was created by heaven and earth, which engaged in constant production and reproduction as its Way. Most Neo-Confucians recognized the complementary forces of yin and yang as the cardinal modes of material being. They also admitted the five elements of earth, wood, fire, water, and metal, as essential processes defining all development within nature. Because nature and man were created by the same elements and by the same forces, Neo-Confucians reinterpreted their earlier sociopolitical ethic of humaneness in mystical terms of forming one body with the universe. This mysticism identified the human body with all that existed. Some even spoke of heaven and earth as their parents, and the myriad entities of nature, organic and inorganic, as their companions. Most Neo-Confucians declared human nature (*sei*), or the original psycho-physical disposition of human beings, to be good, not empty as the Buddhists claimed. Furthermore Neo-Confucians claimed that the nature (*sei*) of the universe, i.e., its moral character, was originally good. The human project, as defined by Neo-Confucians, was to preserve this original goodness by moral self-cultivation and by moral action in the world.

Confucius (551 BCE–479 BCE) too respected the natural world. The *Analects*, the most authentic record of his thought, states that the wise person loves water (Chinese: *shui*; Japanese: *sui*), while the humane person loves mountains (Chinese: *shan*; Japanese: *san*). This reveals that early Confucianism linked moral concerns to ecological ones. It is also artistically significant, for the Chinese word for landscape painting is *shansui* and the Japanese is *sansui*, denoting a combination of bodies of water with mountains or hills, which were the constituent elements in a landscape painting. The latter were not just idealized depictions of nature; they were equally reflections of the moral consciousness of the artist. Furthermore Confucians' and Neo-Confucians, following Confucius' views about mountains and bodies of water, believed that morality involved right behavior toward nature and humanity.

Evidence abounds revealing a practical interest in the world of nature by Confucians and Neo-Confucians in Japan. By the late-seventeenth century, forests throughout the archipelago had been depleted due to an overexploitation as a result of a boom in the construction of castles and urban residences. Confucian scholars diagnosed the environmental crisis and called for its cure. Yamaga Sokō (1622–1685), for example, argued that forests should be conserved to ensure future productivity. Sokō admonished loggers to harvest lumber only in the proper season, not to overcut, and to reforest areas they had cut. One of Sokō's disciples, Tsugaru Nobumasa, daimyo of Hirosaki domain in northeastern Honshū, claimed that the three fundamental concerns of a feudal lord were for (1) his family line, (2) his heir, and (3) his mountain forests.

In his *Daigaku wakumon* (Dialogues on the Great Learning), Kumazawa Banzan (1619–1691) argued that humane government involved afforestation, river dike repair, and other conservation practices that would maximize agricultural productivity. Noting the crisis at hand, his disciples declared that "mountains and rivers are the foundations of a country." Full of hope, despite the depleted forests that were all too evident to him, Kumazawa claimed even that bald mountains could be covered with trees again if oats and other cover crops were planted so as to retain a thin layer of soil long enough for a forest ecosystem to reappear. Ultimately, the *Dialogues on the Great Learning* advocated harnessing samurai energy for the sake of the agricultural ecosystem: Kumazawa argued that samurai should be allowed to return to the countryside to labor as farmers rather than required to live in castle towns where they fell prey to urban vices. Kumazawa's proposals were so radical, however, that they were not heeded. Generations after his death, however, his more environmentally-oriented ideas, as advocated by others, did find favor.

Kaibara Ekken (1630–1714), influenced by the Neo-Confucian call to investigate the principles of things, authored the first systematic botanical study in Japan, the *Yamato honzō* (Flora and Fauna of Japan, 1709), describing and classifying over 1550 trees, plants, flowers, birds, fish, seashells, etc., into some thirty-seven categories. Ekken's "Preface" declares that because heaven and earth produce and reproduce myriad lifeforms, scholars must study their principles. Many later studies in herbology, botany, pharmacology, and zoology were influenced by Ekken's *Flora and Fauna*. He also encouraged the research of Miyazaki Yasusada (1623–1697) which culminated in the conservation-minded *Nōgyō zensho* (Agricultural Encyclopedia, 1696). In his preface, Ekken observed that a sage government, which nourished and educated the people, was facilitated by studying the *Agricultural Encyclopedia* because through it people could understand how to assist heaven and earth by cultivating the productive forces of nature.

Some late-Tokugawa intellectuals were influenced by notions of Western science as introduced to Japan via Dutch traders permitted at Nagasaki. Satō Nobuhiro (1769–1850), exposed to Western science but also influenced by Shintō, advocated techniques of agricultural management, based on the scientific study of natural law, to improve agriculture. He argued that this would realize the divine aim inherent in creation. Rejecting such clever short cuts, Ninomiya Sontoku (1787–1856) insisted instead on following the natural, creative cycles of heaven in agriculture, and repaying the virtue of heaven with conservation techniques which would rejuvenate nature. Miura Baien (1723–89), influenced by Western science, slightly modified the Neo-Confucian project of investigating things by advocating the investigation of the rational order (*jōri*) of heaven and earth in a disinterested, objective way.

Given the dense population which appeared during the Tokugawa, and its heavy taxation of the fragile ecosystem of the archipelago, one extremely poor in natural resources, Japan could easily have become, as Conrad Totman has suggested, an eroded moonscape rather than a verdant archipelago. In the seventeenth century, Japan was well on its way to a state of deforestation. It was saved largely by Confucian and Neo-Confucian scholars who called for systematic, scientific action. Yet it would be far-fetched to deny credit to Shintō and Buddhism, although admittedly they were less conspicuous in enunciating a conservation program saving Japan's forests, and thus its mountains, rivers, and fields.

Following the Meiji Restoration of 1868, when Japan embarked upon a course of rapid Westernization, concern for the natural environment lessened as the new Meiji state presided over the beginnings of industrialization by fostering polluting industries such as railroads. Though anathema to many, the goal of the Meiji state was to match, if not surpass, the industrial prowess of the Western nations which had imposed unequal treaties on Japan during the nineteenth century. Voices of protest against the noxious side effects were either ignored or muffled until Japan had effectively modernized. Widespread water pollution caused by the Ashio Copper Mine in Tochigi Prefecture from the late 1870s resulted in a major ecological disaster and a political scandal which simmered for nearly a century, pitting farmers against private industry and the government. Though notions of "the supremacy of agriculture" (*nohon shugi*) circulated in the late-Meiji, these were frequently no more than ideological currents.

The leading twentieth century philosopher of nature was Watsuji Tetsurō (1889–1960). Watsuji's *Fūdo* (Environment, 1935) criticized Heidegger's *Being and Time*, arguing that space, i.e., natural setting, and not just time, was crucial to human culture. Watsuji correlated the latter with three environmental zones: monsoon, desert, and pastoral. Japanese culture, he claimed, emerged from a monsoon zone where climatic vagaries produced passive, forbearing, inconsistent, sentimental, intuitive, and temperamental traits.

Since 1945, a decreasing number of Japanese have chosen to remain in the countryside close to nature. Just as the Meiji state rushed to modernize, so did postwar Japan race to renew its industrial sector oblivious to air and water pollution during the 1950s and early 1960s. In Minamata, Kyūshū, a chemical factory was finally held responsible for mercury poisoning, fifteen years after the poisoning first occurred in 1953. By the 1960s, Tokyo became internationally notorious for its air pollution. Citizen's protest groups rallied in the 1970s and 1980s, forcing the government to regulate pollution. Since the 1970s, environmentalists have argued for "environmental rights" (*kankyōken*), basing their claims on the 1947 Constitution which guarantees Japanese a "wholesome and cultured life."

Environment and Nature: The Natural Environment in Native American Thought

Annie L. Booth

> We are the land… that is the fundamental idea embedded in Native American life… the Earth is the mind of the people as we are the mind of the earth. The land is not really the place (separate from ourselves) where we act out the drama of our isolate destinies. It is not a means of survival, a setting for our affairs… It is rather a part of our being, dynamic, significant, real. It is our self…
>
> It is not a matter of being "close to nature"… The Earth is, in a very real sense, the same as our self (or selves)… That knowledge, though perfect, does not have associated with it the exalted romance of the sentimental "nature lovers", nor does it have, at base, any self-conscious "appreciation" of the land… It is a matter of fact, one known equably from infancy, remembered and honoured at levels of awareness that go beyond consciousness, and that extend long roots into primary levels of mind, language, perception and all the basic aspects of being… Paula Gunn Allen, Laguna Pueblo (1979a: 191–192)

This is how one Native American presents her understanding of the indigenous understanding of nature. As will be explored in this article, many Native Americans present similar understandings. Their reciprocal relationships with nature permeated every aspect of life from spirituality to making a living and led to a different way of seeing the world, a more "environmental" way of seeing the world. But is this a true picture? Increasingly there has been debate over the nature of the Native American's relationship to the land, both past and present. This article will examine this debate as well as examine the way in which Native Americans view nature.

Caveats

Discussing any aspect of Native Americans requires caution, caution which has not always been employed when discussing Native American relationships with nature. Clear distinctions need to be drawn.

The first necessary distinction is that much is disguised in the concept of "Native American" or "Indian". The peoples who ranged, then and now, from the Arctic Ocean to Mexico and between two oceans encompassed a vast diversity of language, custom, practice and belief. They evolved to take advantage of different natural resources, to deal with dramatically different landscapes and climates and evolved again as they moved to different landscapes. To somehow lump this vast, rich diversity into a singular term is to fool ourselves into thinking we understand something we have no clear grasp of. It is to misunderstand the nature of people we are interested in understanding. Yet we do that lumping all the time. It leads to difficulty as when we misunderstand why two native tribes may choose different, conflicting courses of action: as for Scotland and England, proximity and the lumping in as "British" does not necessarily result in shared goals. Indeed the title of Native American is most equivalent to the idea of "European". There *is* something distinctly European when compared with North American, but there are limits to the understanding we can draw from the term.

Yet there may well be a "Native American" perspective when it comes to understanding the relationship with nature, and Native Americans as well as non-native writers frequently make this argument. This article itself will present the case for a sense shared across different native cultures, but I would urge the reader to use caution when thinking about "Native Americans".

The second necessary distinction is between the modern Native American and the historical Native American. When many writers discuss the Native perspective of nature there is a tendency to lump together

Native Americans from across the recorded historical period. The problems with this approach should be obvious: none of us live like our ancestors did 200 years ago. Modern Native Americans face different challenges than did their ancestors and many of those challenges affect how they can now relate to the land. Further, there is always a question of how well "traditional" philosophy and spirituality manage to translate into the modern world. Care must be taken not to conflate what is known about the beliefs and behaviours of the historical Native American and those of today's Native, although both might be instructive. While they inherit their past, they must live in the present.

Finally, I think it is worthwhile making the distinction between listening to what Native Americans say for themselves and what others write. Both bring different agendas to the table and it is useful to recognise that agenda when assessing the information presented. The Native speaks with the voice of cultural experience, an intimate understanding of native reality an outsider can never hope to achieve. Often they are privy to information or perspectives an outsider could not easily obtain. However, people from within cultures often have difficulty examining those cultures critically and are sometimes constrained about raising controversial issues. Non-natives do not have similar constraints and can be as critical as they wish. However, they will almost always lack that essential grasp, that innate understanding of a group of people and the way they think that a cultural resident will have. As such, it can be easy to misinterpret what is going on in a culture as modern critiques of anthropological findings are demonstrating. In terms of trying to grasp the nature of the Native American relation to nature, both past and present, it is most useful to explore both native and non-native writers, keeping in mind the perspectives of both.

The Native American Relationship with Nature

Although they varied significantly among different cultures, Native American relationships with the natural world tended to preserve ecological integrity, and appear to have done so over a significant period of time. These cultures engaged in relationships of mutual respect, reciprocity and caring with an Earth and fellow beings as alive and self-conscious as human beings. Such relationships were reflected and perpetuated by cultural elements including religious belief and ceremonial ritual.

In the songs and legends of Native American cultures it is apparent that the land and her creatures are perceived as truly beautiful things. There is a sense of great wonder and of something which sparks a deep sensation of joyful celebration. Above all else, Native Americans were, and are, life affirming; they respected and took pleasure in the life to be found around them, in all its diversity, inconsistency, or inconvenience. Hughes (1983) points out that only the newly arrived Europeans considered the land to be a "wilderness", barren and desolate. To Native Americans, it was a bountiful community of living beings, of whom the humans were only one part. It was a place of great sacredness, in which the workings of the Great Spirit, or Great Mystery, could always be felt.

Standing Bear (1933), a Lakota, wrote that Native Americans felt a special joy and wonder for all the elements and changes of season which characterized the land. They felt that they held the spirit of the land within themselves, and so they met and experienced the elements and seasons rather than retreating from them. For Standing Bear and the Lakota, the Earth was so full of life and beings that they never actually felt alone.

> There was no such thing as emptiness in the world. Even in the sky there were no vacant places. Everywhere there was life, visible and invisible… Even without human companionship one was never alone (Standing Bear 1933: 14).

This statement echoes a central belief consistent across many Native American cultures – that the Earth is a living, conscious being. The Koyukon of central Alaska, for example, see the Earth as something alive and powerful, and therefore, something which must be treated with respect:

> For traditional Koyukon people, the environment is both a natural and supernatural realm. All that exists in nature is imbued with awareness and power… all actions towards nature are mediated by consideration of its consciousness and sensitivity. The interchange between humans and environment is based on an elaborate code of respect and morality, without which survival would be jeopardized (Nelson 1983: 240).

The belief in a conscious, living nature is not simply an intellectual concept for Native American cultures. For most, perception of the landscape is important in determining perception of self. Native American cultures and histories are based in the land and their lives are inseparably intertwined with it. In a most real sense, it *is* their life. This interconnection between person and land is not merely a thing of historical significance. Present-day Native Americans continue to acknowledge their ties to the land. Utes in the Southwest, faced with the question of mining on their lands are deeply troubled, for the land is more than a mere resource, as several individuals have tried to explain:

> The land is a living body with spirit and power, which contains tribal genealogy. It is necessary for

E

> the people to remain in the place in which they have always been, as guardians, and as an inseparable part of that place and space.

The tribe does nt want to diminish the land, but not because of money issues. But because you diminish *us* when the land is eaten away (emphasis in original) (Romeo 1985: 160–61).

At the Tellico Dam congressional hearing in 1978, Jimmie Durham, a western Cherokee, tried to express what his people felt for a land they could no longer even live upon, but wished to preserve nonetheless:

> In the language of my people… there is a word for land: Eloheh. This same word also means history, culture and religion. We cannot separate our place on earth from our lives on the earth nor from our vision nor our meaning as a people… So when we speak of land, we are not speaking of property, territory or even a piece of ground upon which our houses sit and our crops are grown. We are speaking of something truly sacred (Matthiessen 1984: 119).

In Native American relationships with a living, conscious world, reciprocity and balance were required from both sides. Balance was vital: the world exists as an intricate balance of parts, and it was important that humans recognized this balance and strove to maintain and stay within this balance. All hunting and gathering had to be done in such a way as to preserve the balance. Human populations had to fit within the balance. For everything that was taken, something had to offered in return, and the permanent loss of something, such as in the destruction of a species, irreparably tore at the balance of the world. Thus, offerings were not so much sacrifices, as non-Natives were inclined to interpret them, but an appropriate acknowledgment of a great gift. In this way, the idea of reciprocity emerges. From the Native American perspective, as Hughes describes it, "mankind depends on the other beings for life, and they depend on mankind to maintain the proper balance" (Hughes 1983: 17).

The respect and approval is two-way: humans both give and receive value and self-worth from the natural world. Part of the idea of reciprocity is the necessity and importance of interaction. Participation in reciprocity is vital; a failure to interact, or a breakdown in interaction, leads to disease and calamity. Thus, everything that is used in everyday life is used for its part in that interaction; it becomes a symbol of sacred interaction and relationship between the people, the plants, the animals, and the land. Rituals such as those used for healing are not designed to ward off illness or directly cure the ill person. Rather, they are designed to remind the ill person of a frame of mind which is in proper relationship with the rest of the world, a frame of mind which is essential to the maintenance of good health.

An old Keres (Pueblo) song goes like this:

> I add my breath to your breath
> That our days may be long on earth
> That the days of our people may be long
> That we may be one person
> That we may finish our roads together
> May our mother bless you with life
> May our Life Paths be fulfilled (Allen 1986: 56).

The reciprocal relationship embodied in this song, the sharing of breath is the sharing of life, is one of the central insights into Native American worldviews. One does not act in isolation, but must act with respect towards the others one shares the universe with. Involved with a *living* universe, the Native American is engaged in a constant dialogue with a network of relations, human and non-human, and natural and supernatural. Sam Gill explains that Native Americans hold a "person to person" relationship with the environment as the power of life itself is personified and inextricably linked with, and identical to, the natural world (Gill 1989: 30). This sense of relationship is explicit in every aspect of life. Consider Ojibwa Winona LaDuke's (1990: 16) comments on the ordinary, mundane activity of hunting and gathering:

> Whether it is wild rice, whether it is fish, whether it is deer or turtles, when you go and take something from the land, you pray before you take it. You offer tobacco; you offer a prayer to that spirit and to the creation of a part of that. *You take those things because you have a relationship with all the other parts of the creation. That is why you are allowed to take those things*. You take that and you give something back as a reciprocal arrangement, because that is how you maintain your relationship (emphasis added).

As countless sacred rituals, ceremonies, songs and teaching stories make clear, maintaining the relationship between human life and non-human life is the heart of Native American spirituality. The Sun Dance of the Plains Indians, which has attracted considerable interest for its more gruesome aspects (including a long government ban on its performance), is not about the ability to endure pain. It is about humanity's willingness to offer blood and spirit towards the maintenance of the balance of life, as Brown's observations make clear:

> The Sun Dance… is not a celebration of man for man; it is an honoring of all life and the source of all life, that life may go on, that the circle be a

> cycle, that all the world and man may continue on the path of the cycle of giving, receiving, bearing, being born in suffering, growing, becoming, giving back to earth that which has been given, and so finally to be born again (Brown 1978: 12).

A sense of embeddedness in the rest of the world has profound implications for how one chooses to live and interact with others. It is also one reason why the displacement of Native Americans from their lands, and the subsequent damage to the land, was and is so socially and psychically devastating. As Allen points out, the despair that appears in many writings by Native Americans is the despair of having lost "that perfect peace of being together with all that surrounds one", a loss that is irreplaceable (Allen 1979a: 192). Peter Matthiessen agrees that this understanding is found consistently across a wide diversity of cultures:

> It is not a matter of 'worshiping nature,' as anthropologists suggest: to worship nature, one must stand apart from it and call it 'nature' or 'the human habitat' or 'the environment.' For the Indian, there is no separation. Man is an aspect of nature… (Matthiessen 1984: 9).

Or consider part of a sacred Navajo chant, designed to remind the person every day of their connections with life:

> The mountains, I become part of it…
> The herbs, the fir tree, I become part of it.
> The morning mists, the clouds, the gathering waters,
> I become part of it.
> The wilderness, the dew drops, the pollen…

I become part of it (Brown 1989: 20).

Momaday describes living apart from the land with horror: "such isolation is unimaginable" (Momaday 1979: 166). As Allen confirms, all poetry, ceremony, song and story remind Indians of their part in a living evolving whole by virtue of their willing participation (Allen 1979b: 226).

Part of Native relations with nature is encapsulated in traditional spirituality. Traditional Native American spirituality has been the target of attack and suppression by the European invaders since 1492 and it continues to be a significant political, legal and emotional minefield. After 500 years of suppression, some have legitimately questioned whether there is such a thing as "traditional" Indian spirituality. Much knowledge and practice was lost through genocide and through the devastating plagues that swept the New World after the arrival of the Europeans. Many Native Americans were forced, or chose, to convert to European religions, and their descendants remain faithful practitioners of Catholicism or some form of Protestantism. In both the United States and Canada what "traditional" practices remained were outlawed and remained illegal until recently. Yet in spite of everything, Native Americans themselves state that unique, viable spiritual practices continue to exist and flourish.

One key question is, what are spiritual practices intended to do? For many Native Americans, spiritual practices were part of an ongoing dialogue with the world. Lakota Deloria (1973: 102) describes it thus: "The task of the tribal religion, if such a religion can be said to have a task, is to determine the proper relationship that the people of the tribe must have with other living beings." Spiritual practices become a way of learning how to live well, and, in this case, to live well with the natural world. They are methodologies for reaching an appropriate level of consciousness, or mindfulness, of the world. Further, these practices, which interlink behaviours, feelings and ethics, are completely identified with the very survival of the people and the land.

Native Americans saw that all that existed shared in sanctity as they were all fragments of God. While Native Americans did not worship nature, they recognized that all life around them was sacred, for "each form in the world around them bears such a host of precise values and meanings that taken all together they constitute what one would call their 'doctrine'" (Brown 1985: 37). When Native Americans saw themselves in terms of community, their definition of community included the natural community. Spirituality requires that humanity and "the rest of creation (be) cooperative and respectful of the task set for them by the Great Spirit" (Deloria 1973: 96). That task is dwelling with balance and with harmony.

> Respect in the American Indian context does not mean the worship of other forms of life but involves two attitudes. One attitude is the acceptance of self-discipline by humans and their communities to act responsibly towards other forms of life. The other attitude is to seek to establish communication and covenants with other forms of life on a mutually agreeable basis (Deloria et al. 1999: 51).

Deloria (1973) has given a particularly thorough consideration to the linkage between place and spirituality, contrasting it with Christian practice. Christianity, he notes, although originating in a particular land (the Holy Land), can and does exist almost anywhere on the face of the earth without extensive modification of the central creed; i.e. the Christian god is "portable". Traditional Native American spiritual practices, however, cannot without damage be moved from a given landscape. Rather, they have evolved to incorporate and reflect particular elements of the chosen land. Where would the Navajos be without the Four Mountains, or the Lakota without the Black Hills? When poet Paula Gunn Allen writes "We are the land…," her statement, to her, is literal truth. It is who she is as a Laguna (Allen 1979a). The same sense of identification is true for Kiowa N. Scott Momaday, who writes of giving himself to the "remembered earth" (Momaday 1979: 164–165). Or for Lakotas Black Elk and Standing Bear, who speak of the devastating loss of the Black Hills to gold miners (Standing Bear 1933; Neihardt 1932, 1975). The land is who a Native American is and it affects his/her responses to the world. Consider Ronald Goodman's interpretation of what, to the American government, was merely a question of land expropriation, but to the Lakota was an attack on their spiritual integrity:

> Traditional Lakota believed that ceremonies done by them on earth were also being performed simultaneously in the spirit world. When what is happening in the stellar world is also being done on earth in the same way at the corresponding place at the same time, a hierophany can occur; sacred power can be drawn down; attunement to the will of Waken Tanka can be achieved.
>
> Our study of Lakota constellations and related matters has helped us appreciate that the need which the Lakota felt to move freely on the plains was primarily religious. (Goodman 1990: 1)

Such an indelible bond with the land, however, is clearly a deliberate construction by the tribes. Indian groups have been migrating across the North American continent for the last 40,000 years. Some are very recent arrivals; the Navajo only migrated into the American Southwest from Alaska and the Yukon about 600 years ago (Dickason 1992). They are not then, "native" to the area. They have, however, reconstructed their religion to reflect the new land in which they dwell, in part by borrowing from earlier residents such as the Hopi. From this, Deloria draws a conclusion of interest: he believes it is possible for a cultural group to "consecrate" a particular landscape, if they are capable of seeing themselves in terms of that landscape (Deloria 1973: 295).

For the Native American, all living is spiritual practice. Thus, material possessions are symbolic of sacred relationships. Moccasins remind the wearer of their connection with the earth, with the plants and animals on it, and so of the nature of reality itself. A pipe becomes a teaching tool, a history of the people, and a reminder of how all in the world are related. When smoked in a sacred manner, it is offered to "all my relations" (Lame Deer and Erdoes 1972: 12; 150–253). Activity which maintains life is also part of the ongoing sacred process; for a Native American the acts of hunting or weaving or building a house are also religious activities. Toelken (1976) also points out that Native Americans rarely distinguish between their religious life and their secular life. Instead there is nothing in life that is *not* religious. Everything from hunting to healing is a recognition and affirmation of the sacredness of life. In the weaving of a basket is the creation of the whole world. In a proper life there is never a sense of disconnectedness from the Earth. As Peter Matthiessen suggests,

> …the whole universe is sacred, man is the whole universe, and the religious ceremony is life itself, the miraculous common acts of every day. Respect for nature is respect for oneself; to revere it is self-respecting, since man and nature, though not the same thing, are not different… (Mattheissen 1981: 12).

In all traditional Native American spiritual practice the sense of the earth as alive was part of a sacred understanding of life and human obligations to life, as Deloria discusses,

> Coming last (in creation) human beings were the "younger brothers" of the other life forms and therefore had to learn everything from these creatures. Thus human activities resembled bird and animal behaviors in many ways and brought the unity of conscious life to an objective consistency (Deloria 1999: 50).

This idea reoccurs in contemporary Native Americans as well. Allen sees the distinguishing characteristic between Western and Native American thinking as the "magicalness" in Indian perception. This is not a childish magicalness but a perception of everything in the world as alive, viable and subject to the need to grow and change. An Indian, she says, is one who

> assumes that the earth is alive in the same sense that he is alive. He sees this aliveness in nonphysical terms, in terms that are familiar to the mystic or the psychic, and this gives rise to a mystical sense of reality that is an ineradicable part of his being (Allen 1979b: 233).

The vital importance of maintaining essential relationships has serious implications for how Native Americans deal with their fur-clad relatives, the animals. The idea which appears over and over is "kinship" with other living beings, as Allen comments:

> All are seen to be brothers or relatives (and in tribal systems relationship is central), all are offspring of the Great Mystery, children of our mother, and necessary parts of an ordered, balanced and living whole (Allen 1979b: 225).

Brown (1985) comments that non-humans are the links between humans and the Great Mystery. To realize the self, kinship with all beings must be realized. To gain knowledge, humans must humble themselves before all creation, down to and including the lowliest ant. Nature is a mirror which reflects all things, including that which it is important to learn about, understand and value throughout life. Further, many tribes acknowledge that humans found a world to come in to and a way of making a living as the result of conscious, caring gifts from the animals. The creation myths of tribes such as the Arapaho or the Iroquois tell of how the Creator created the world with the help of animals, from mud brought up from beneath endless waters by a muskrat or rested on the back of a willing turtle. Sacred objects are donated, as when eagle grants the use of his feathers, and food is found because holy animals offer their flesh as a gift (Harrod 1987: 51).

However, some anthropologists such as Harrod (1987) or Hultkrantz (1981), see a tension inherent in the problem of having to kill animals with whom one had a deep, intimate relationship. Looking at the Plains Indians, Harrod observes that such tensions are apparent in creation myths. The Blackfoot, for example, tell of a time when humans were hunted by the buffalo. To change this, the god taught the Indians to make bows and arrows and then to hunt. In compensation for becoming food, the buffalo and other animals became spiritual helpers which the Blackfoot were to obey. In this fashion, and through other rituals, the tension inherent in eating social equivalents is partially resolved (Harrod 1987: 44–45, 53–54).

Most Native American legends speak of other species as beings who could shed their fur masks and look human. They once shared a common language with humans, and continued to understand humans after the humans had lost their ability to speak to the animals. The animals partook of the sacredness of life, and were often the descendants of the powerful beings who had lived on the earth before humans. An animal was something more than its furry, four-footed shape, more than what was seen by human eyes. It was, says Nelson (1983: 31), a personage and a personality with a lineage far older than humanity's. Laird describes animals this way:

> It is to be remembered that the pre-human Immortals (the gods, if you will) were Animals Who Were People. These Forerunners, these Ancient Ones whose bodies shimmered as it were between animal and human forms, these denizens of the elder dream-world, have long since taken their final departure; yet they remain as the visible animals of this everyday world… Mythic Coyote, supertrickster and pattern-setter for mankind, is not [coyote], raiding fields and howling on the hills before dawn – and yet in a certain mystical sense, he is (Laird 1976: 110).

Even into the present, the Native Americans respect their relationship with animals and believe that the respect and caring go both ways. Thus, communication is possible, as Yukon Indian Irene Isaacs explains:

> You can tell them and they do it, that wolf. You tell them, "Kill something for me!" And then the wolf will. Then you come, and they are going to kill a moose and you're going to find it and have moose meat. They do that, wolves. So they understand Indians. And other animals, that's what I tell my son about that too. You've got to treat animals good (McClellan 1987: 280).

Martin, discussing subarctic bands, also notes that a sympathy builds up between the hunter and the animal persons who are hunted, a sympathy which pervades human life. At all times, there is a mutual obligation felt, an obligation to be courteous. An animal is not killed unless the hunter obtains its consent in the spiritual world; the animal must be willing to surrender itself to the hunter. Hunting gives meaning to the hunters' lives; it gives a sense of identity. It is the animal who grants this sense of identity (Martin 1978).

According to Nelson, the Alaskan Koyukon believes that animals and humans are distinct beings, their souls being quite different, but that animals are powerful beings in their own right (Nelson 1982, 1978). Consequently a complex collection of rules, respectful activities and taboos surround everyday life and assist humans in remaining within the moral codes that bind all life. Hunting, therefore, is conducted with respect and with ritual from the moment the hunt is conceptualized until the animal's remains are properly disposed of. Animals are not offended at being killed for use, but killing must be done humanely, and there should be no suggestion of waste. Nor can the body be mistreated: irreverent, insulting or wasteful behaviour could result in the future loss of the species, which would no longer make itself available for killing. Even gathering must be done respectfully. Yukon women gathering roots are pleased by the find of caches of roots already collected by mice. However, they are careful to leave some for the mice. Otherwise the mice are likely to come raiding Indian supplies during the winter (McClellan 1987: 139–140).

The practical consequences of such relationships with animals are profound. Species were not endangered or exterminated, for exterminating a species would have meant the elimination not only an essential life, but a kindred being. Hughes (1983) believes that the "ecological consciousness" of the Native American was in part due to their sense of kinship with the rest of the world.

The need to both respect *and* use animals continues today, although it can engender controversy. Whaling, for example, continues to be a controversial subject. When a west coast tribe, the Makah, decided to return to their traditional practice of whaling in 1999 it provoked outrage on the part of environmentalists and even ordinary people; it prompted immense television coverage, the attempted intervention of the Sea Shepard Society and required the protection of the US Coast Guard for the hunters (Blow 1998). However as Tom Mexsis Happynook, chair of the World Council of Whalers, argued, whaling represents a modern practice of responsibilities which integrate the native culture into the environment, which "maintain the balance within the environment and ecosystems":

> For the Nuu-chah-nulth hunters the taking of any life was looked upon as the most sacred responsibility that we have had bestowed upon us, because of this my grandfather taught me the hunters had to pay dearly for the honour of taking a life. This especially applied to the whaling chiefs because they hunted the greatest and largest mammal on earth.

People have a very important role to play in the environment which is to help maintain the balance through our relationship with the ecosystem; that one of the most important tools we have at our disposal to meet this obligation is respectful, responsible and sustainable utilization of the resources (the gray whale population on our coast is a perfect example of that responsibility) (Happynook 1999: 3).

Non-natives see an intelligent, sympathetic endangered species. Whaling Natives see the same but also a creature with which they have had a profound relationship for millennia, the hunting of which underlies who they are as a culture.

This argument has a scientific basis as well. For example, the Inuit in northern Canada have long argued that they had a better sense of the whale population, through yearlong observation, than did the visiting government whale biologist and pushed for a larger harvest quota. Subsequent non-native research has begun to confirm the greater accuracy of traditional ecological knowledge in this instance (Wohlforth 2004). It is worth recognizing that the sense of relationship, of reciprocity and of participation in the world encapsulated in Native spirituality, and as reflected in how they interacted with animals, had a very practical ecological link for many Native Americans, as Deloria describes:

> The Indian principle of interpretation/observation is simplicity itself: "We are all relatives." Most Indians hear this phrase thousands of times a year as they attend or perform ceremonies… this phrase is very important as a practical methodological tool for investigating the natural world and drawing conclusions about it that can serve as guides for understanding nature and living comfortably within it. "We are all relatives" when taken as a methodological tool for obtaining knowledge means that we observe the natural world by looking for relationships between various things in it. That is to say, everything in the natural world has relationships with every other thing and the total set of relationships makes up the natural world as we experience it (Deloria 1999: 34).

Sounds remarkably like the modern science of ecology. But were Native Americans ecologists?

The Ecological Indian?

In the last two decades the academic discussion has moved slightly in focus from what view of nature Native Americans had in the past or present, to how this might translate into action. The key question appears to have become, where Native Americans truly the first environmentalists? Were they "ecological" Indians? Or were they, as Berkes terms it, "intruding wastrels" destructive of their ecosystems, surviving only because of they moved around and had fortuitously small populations (Berkes 1999: 145). Or are they "fallen angels", former noble savages whose ancestors lived in harmony with nature but whose descendants threaten fragile wildlife populations and at-risk wilderness? This is a challenging debate within ecological and anthropological circles, one to which entire conferences are devoted. A critical discussion of this issue is provided in a Extra to this article. As this Extra indicates, "using" Native Americans as ecological "models" is difficult and potentially misleading. That said I still wish to consider how they have adapted to the land and whether the adaptations could be considered ecologically successful. While most Native Americans, I think, would have considerable difficulty in fitting themselves into a category as shallow and narrow as "environmentalist", I believe that non-Natives have something to learn about living with the land.

It must be remembered that for most Native Americans, the land and its residents has many more shades of meaning than non-Native societies are willing to consider. The land is a source of sustenance, and was exploited for that purpose. However, the land also holds other meanings for past and present Indian cultures. Nelson remarks of the Alaskan Koyukon, principally hunters and gatherers, that their land

> is permeated with different levels of meaning – personal, historical and spiritual. It is known in its finest details, each place unique, each endowed with that rich further dimension that emerges from the Koyukon mind (Nelson 1983: 245).

To picture Native Americans as people who passed through the land leaving no trace, as some environmentalists are apt to do, is to deny an ecological reality, and, in passing, to damn the Native American with faint praise (with the implication that they were incapable of making such a mark). As Hughes remarks of the Northeastern Indians,

> Like all human cultures, the forest Indians were agents of change in nature. For at least 10,000 years, and perhaps much longer, they had lived within the forest ecosystems, hunting, fishing and gathering with skill and experience. Their land was not a wilderness, but a woodland park which had known expert hunters for millennia (Hughes 1977: 7).

That the lands remained productive was in part due to Native American lifestyles that were more or less mobile (even the farmers moved to new areas when the soil was exhausted), as Cronon (1983), Merchant (1989) and Krech (1999) document. It may have also been the result, in some cases, of a sense of stewardship. Many tribes deliberately took (and still take) steps to ensure that human induced changes did not damage their source of livelihood. Among the Yukon Indians, these steps took the form of a belief in ownership of certain areas.

> This kind of ownership meant that a headman and the people who traveled with him had the first right to use the products of the local land and water, but they also had the duty of taking care of these resources… It was part of their job to see that people did not overhunt, overtrap or overfish the area, as well as to see that as far as possible everybody got enough to eat… (McClellan 1987: 151–152).

Among the Cree, efforts to conserve resources took the form of dividing the land into regions, with a hunting camp in the centre. The camp was occupied until both animal populations and resources such as firewood and green bedding boughs were reduced. Old campsites were cleaned prior to leaving to avoid offending the spirits, who would send away the animals if the land was not cared for (Tanner 1979: 74–75). Such concerns did not mitigate the ecological impacts; the game population and the camp site recovered because the Indians moved elsewhere. However, the concern for the spirits' good will, in combination with a mobile population, may have limited irreparable damage, at least where overall human population numbers were low. Such land stewardship practices can still be found in modern native cultures across northern Canada and Alaska, as well as elsewhere.

Of great concern to Native Americans, for obvious reasons, was the conservation of game animals. Harrod notes the presence of several Trickster stories amongst the Plains Indians, in which the Trickster character exploits trusting animals to satisfy an insatiable appetite. In this pursuit he is foolish enough to eliminate almost all the animals, usually missing just one:

> That Trickster is foolish and even a dangerous hunter appears in the theme of the "last animal" which runs through the narratives. As a consequence of escape, often brought on by a momentary lapse in Trickster's character, an animal survives to continue the species. Clearly the hunting techniques of Trickster are not affirmed; rather, the foolishness and potentially disastrous consequences of such activities are underlined in these stories (Harrod 1987: 63).

There appears to have been a real concern, expressed through such stories, that the animal populations not be decimated. Recent anthropological work among the twentieth century Cree and Koyukon, among others, has uncovered what researchers feel are deliberate conservation practices. Tanner (1979) and Berkes (1999) observe that the Cree are constantly assessing plant and animal population levels. Long- and short-term changes in populations are understood both in spiritual terms (the activities of the Animal Masters) and in terms of environmental factors (food supplies, water, weather patterns, forest fires, and hunter activities). The Cree govern their hunting activity on the basis of these observations.

Among the Koyukon, conservation activities are also based on their keen observation of the ecological dynamics of their lands. The people regulate their harvests in a number of ways to ensure that plant and animal populations remain healthy. The Koyukon may consciously avoid taking more individuals than they believe can be naturally replaced, or they may take special measures that they hope will enhance the productivity of a species. They avoid killing female waterfowl, bears and moose in the spring when they are breeding. Hunting activities are usually spread over as wide an area as possible. Young plants and animals are usually not harvested, but are allowed to mature. Trappers are very cautious about where and how many animals are harvested (Nelson 1983: 221–223). For example, trappers are careful when trapping the sedentary beaver.

While such practices are noteworthy, Nelson is careful to point out that there is no objective data to prove that these intentional limitations actually achieve their conservation goals. He does, however, feel that the Koyukon could be considered to be practising a "conservation ethic". Tanner is also unable to document the impacts of the Cree's conservation practices on resource populations. Berkes, however, makes an extensive case for the conservation ethic of modern Cree, although he notes it was not without many mistakes and misapprehensions.

A final issue to consider is the modern need for Native cultures to make a living from the land upon which they live. This often involves necessary, and not always satisfactory, compromise between traditional beliefs regarding nature and resource extraction. Forestry is a common industry on many Native lands in both Canada and the United States. One well known, long term industrial forest operation has been undertaken by the Menominee of Wisconsin. The Menominee have been logging on their reservation for over a century and still have a robust and healthy forest ecosystem. Their forester, Marshall Pecore, argues it is a unique balancing act.

> It is said of the Menominee people that the sacredness of the land is their very body, the values of the culture are their very soul, and the water is their very blood. It is obvious, then, that the forest and its living creatures can be viewed as food for their existence... Their story is one of successful equilibrium between harvesting and using only what the land can provide, and maximising the jobs and other economic benefits that flow from a sustained-yield harvest (cited in Davis 2000: 55–56).

However it is also not always easily achieved. The band I work with, Tl'azt'en Nation, also runs a commercial forestry operation and have done so for 20 years. They feel they have been less successful in integrating traditional values and, correctly my analysis suggests, blame it on the restrictions surrounding forestry in British Columbia, as Grand Chief Ed John indicates:

> There's a conflict right there. That one is really a conflict that we're conscious of – trying to look at a bottom line and manage in a traditional way – and we haven't really been able to marry those two successfully and our teachings… they're still there but… you know there's a real major conflict in thinking and ideology right there along with our teachings, when you go into the bush to take a plant for medicine, you return something back. And then in logging you go in there and clearcut an area, you don't put anything back except new trees… I have a concern about that, and how we do that I'm not sure right now except to try to build those traditional teachings and principles into your management plans, push those, work those. Some of those don't necessarily, are not necessarily acceptable by the (British Columbia) Ministry of Forests, so it's an ongoing struggle there too because you have different thinking about how that forest should be managed (Booth 1999: 33).

However, Natives need to make their own compromises:

> Conservation and development-policy-making and -planning often seems to assume that we, the aboriginal peoples, have only two options for the future: to return to our ancient ways of life or abandon subsistence altogether and become assimilated into the dominant society. Neither option is reasonable. We should have a third option: to modify our subsistence way of life, combining the old and the new in ways that maintain and enhance our identity while allowing our society and economy to evolve (Erasmus 1989: 229).

Conclusions

Are Native Americans ecologists? Environmentalists? Or peoples with a unique understanding of the natural world that might or might not have translated into a better way of living with the earth. Readers will need to draw their own conclusions. However, I agree with Berkes (1999: 182) when he notes that, "A fundamental lesson of traditional ecological knowledge is that worldviews [and beliefs] do matter."

> The challenge is to cultivate a kind of ecology that rejects the materialist tradition and questions the Newtonian, machinelike view of ecosystems… The indigenous knowledge systems of diverse groups, from the Dene of the North American subarctic to the Fijians of the South Pacific, provide an alternative view of ecosystems. This is a view of an ecosystem pulsating with life and spirit, incorporating people who *belong* to that land and who have a relationship of peaceful coexistence with other beings.

Native American views of nature, as articulated in this article, attract a great deal of interest as well as controversy. There is a fascinating psychological question as to why, as a society we are attracted to them, even if they are not part of our cultural heritage. Perhaps we need to believe there are ways of seeing the world that might lead to the preservation of functioning ecosystems. Perhaps this is the same basis from which others are driven to criticise the concept of the ecological Indian: we do not have to feel as guilty for our behaviour if we are all equally, inherently, destructive of nature. The problem I see is not that we are able to be inspired by Native Americans, or that they drive us to justify our actions against ecosystems, but that in doing either we lose sight of the people themselves and the complex nature of the challenges they face. We need to allow ourselves that inspiration, the critical question as well, but we need to always remember the *people* who articulate a reality that perhaps all humans can understand.

> Once in his life a man ought to concentrate his mind upon the remembered earth, I believe. He ought to give himself up to a particular landscape in his experience, to look upon it from as many angles as he can, to wonder about it, to dwell upon it. He ought to imagine that he touches it with his hands at every season and listens to the sounds that are made upon it. He ought to imagine the creatures that are there and all the faintest motions in the wind. He ought to recollect the glare of noon and all the colours of the dawn and dusk.
>
> I am interested in the way that a man looks at a given landscape and takes possession of it in his blood and brain. For this happens, I am certain, in the ordinary motion of life. None of us lives apart from the land entirely; such isolation is unimaginable. We have sooner or later to come to terms with the world around us – and I mean especially the physical world; not only as it is revealed to us immediately through our senses, but also as it is perceived more truly in the long turn of seasons and of years (Momaday 1979: 164, 166).

Extra: The Ecological Indian?

In the last two decades the academic discussion has moved slightly in focus from what view of nature Native Americans had in the past or present, to how this might translate into action. The key question appears to have become: were Native Americans truly the first environmentalists? Were they "ecological" Indians? Or were they, as Berkes terms it, "intruding wastrels" destructive of their ecosystems, surviving only because they moved around and had fortuitously small populations (Berkes 1999: 145). Or are they "fallen angels", former noble savages whose ancestors lived in harmony with nature but whose descendants threaten fragile wildlife populations and at-risk wilderness?

This interest in Native American relationships with nature has an old history. Influential members of the early American conservation movement were deeply impressed by Native Americans and their relations with the natural world (Cornell 1985). This question however came under intense consideration with the 1960s environmental movement. Former Secretary of the Interior Stewart Udall (1973) articulated this best in his influential article entitled "Indians: First Americans, First Ecologists." Interest burgeoned and works such as *Black Elk Speaks* (Neihardt 1932, 1975), *Rolling Thunder* (Boyd 1974) and the now controversial speech of Chief Seattle became cultural icons. The story of Chief Seattle's speech is somewhat instructive in how eagerly and uncritically the public embraced the idea of the Native environmentalist. While Seattle, a Dwarmish chief, did indeed make a highly articulate speech to the US government on the appropriation of his tribe's land, what has become know as Seattle's speech was actually a highly liberal adaptation written by a non-native as narration for a 1970s film (Kaiser 1985).[1]

Native Americans were not unwilling to have this part of their culture articulated. Many writers of the 1970s and 1980s articulating the Native American and nature relationship were Native Americans such as Vine Deloria, Jr., Paula Gunn Allen, John Lame Deer, Winona LaDuke and N. Scott Momaday.

By the 1980s, however, the issue came under academic scrutiny and the picture was no longer clear cut. Anthropologists and historians marshalled on both sides. People like Hughes, Nelson, Cronon, Gill, Toelken, Brown and others presented plausible cases for cultures which, while not gentle nature lovers, nonetheless maintained functioning ecosystems through cultures which integrated nature into spiritual and living practices. Many were examining historical cultures, although Gill, Brown, Toelken and Nelson were working with modern cultures. Making the case that Native Americans were not model ecological citizens were scholars such as Callicott, Martin and Krech.

The debate has not as of this writing been resolved. Both sides have over time made some persuasive cases. The "good ecological" native arguments are, simplified, based on two threads. The first thread is the ecological knowledge and "philosophy" contained in Native culture past and present. This has been discussed in the section on Native views of nature. The second thread is the ecological state of North America when European explorers discovered it. While research has demonstrated that the landscape was not unmanipulated by human residents, nonetheless after an occupation of between 10,000 and perhaps 40,000 years (Dickason 1992) North America looked like an Eden to European arrivals. Forest cover was extensive. Wildlife, including large carnivores, appeared in astonishing numbers. It was a sharp contrast to the humanized, ecologically impoverished landscape that European explorers have left behind. This is the crux of the argument of those who argue that Native Americans offer models of human–nature relationships well worth admiration and study.

Those who argue against the concept of the "ecological Indian" also draw on evidence from the pre-European era. Shepard Krech III is now one of the leaders in the move to debunk the myth of the ecological Indian and he does so in his most recent book (Krech 1999) based largely on historical activities. He also does so by defining the truly ecological Indians clearly as ones who did *not* change, damage or irrevocably alter their ecosystem. By doing so, he clearly defines what we (or at least the scholars debating the ecological Indian myth) think of as ecological or environmental behaviour: the opposite. By this definition, as Krech successfully argues, the historical Native American was not ecological or an environmentalist. There is considerable archaeological evidence, for example, that indicates many cultures did indeed damage their ecosystem through overuse of resources. Krech cites the midwestern Cahokia culture which flourished between the twelfth and fourteenth centuries. They apparently denuded their landscape so severely they needed to import wood. The earlier southwestern civilization of the so-called Anasazi may have also collapsed as a consequence of overuse of resources (Krech 1999: 76–77). Other cultures constantly altered the landscape deliberately. Cultures in the eastern woodland and the prairies fired habitats, deliberately, to alter vegetation to attract different browsers or to force animals into more easily hunted areas (Krech 1999: 105) or to produce berries. While these fires were prompted by considerable ecological knowledge of fire succession stages, these fires often got out of control and were highly destructive. Along the east coast there are still areas burned down to rock (Patterson 1988). Krech also cites the hunting of bison through massive drives into pens or over cliffs, with subsequent waste of considerable meat. As Krech does point out, there is equal evidence of careful use of all resources as well. However, what is clear in all his careful scholarship is the Native Americans used, altered and in some cases damaged nature. By non-native definition they are unecological, non-environmental. Krech confirms earlier arguments put forward by scholars such as Callicott and Martin.

Both sides make careful sophisticated arguments that interested readers should approach in their entirety and draw their own conclusions. I remain uncertain as to utility of the debate itself (not

[1] A copy of the speech and more on the controversy can be found at: ►http://www.geocities.com/Athens/2344/chiefs4.htm.

that I disagree with debate). I have done a lot of work with a Native Canadian band (the politically correct Canadian term is First Nations) in north central British Columbia, who in turn have given me a nickname: the Blonde Woman. It is said with liking. I am grateful for the name, it means people are willing to talk to me when I show up at their door; the name came with trust. What I find fascinating however, is that it reflects the most visible feature by which I am defined as *non-Indian*. I have never met a blonde Carrier native; my blondeness defines me as completely the outsider. By its measurement I am most clearly not native. That definition of who is and is not is important, even crucial to people. But the Band I work with does not make the usual corollary mistake; they do not stereotype me as *the other*, and their focus on my blondeness reflects that too. It is the least important non-native characteristic they could focus on. Instead they let me prove myself as an individual, good or bad, trustworthy or not. They do not stereotype me. It is not a courtesy we tend to return.

To talk about the "ecological" or "non-ecological" Native American is to talk of stereotype. Part of the stereotype is to assume that all Natives are alike and can be characterised as part of that larger group. One bad (or non-ecological) Indian therefore manages to spoil the bunch. To be fair we do this to other groups as well, one bad poor black inner-city dweller casts a shadow on all, but this does not make it a good practice. If we wish to assess a native group's ecological goodness we should assess only that group within its ecosystem, history and circumstance. However, this glosses over a larger problem.

When we are assessing an "ecological Indian" status we are doing what my Band does *not* do to me, blonde hair not withstanding: we hold each Native group up against our concept of Indianness and, usually, judge them lacking. Even those disputing the ecological Indian concept are rebelling against an ingrained stereotype of the Native as nature child at home in the wilderness. Those images are as old as Christopher Columbus (Berkhofer 1979; Francis 1992; Berkes 1999). There are two key problems with this stereotype. The first is that there is something like an essential Indian or Indianness. The second is the imposition of a thoroughly non-Native concept of ecological or "good" nature–human relationships.

Take the first problem identified: it is part of the problem I identified early in this article, that we take for granted there is something that is a "Native American". I once sat in a university class taught by a Cherokee. After a discussion on blood quantum, a US government measurement of whether an individual could legally qualify as an American Indian, a student asked the professor "How much of an Indian are you?" It seems to me that we spend most of our time requiring Natives always to be answering that question. We continually measure Natives by whether they meet our definition of Indian, whether blood quantum or environmental mysticism, lifestyle or economic choices, rather than allowing Natives to be people, individuals, members of a community. Our ecological Indian is a stereotype of our expectations of an Indian; he is not a real human with real human, situationally unique problems, opportunities and choices.

The second problem is that when we allocate goodness as an assessment of ecological or environmentally correct behaviour it is based on a western definition of ecological or environmental goodness. As Allen and Deloria Jr, among others, point out this definition derives more from "the exalted romance of the sentimental 'nature lovers' [or] self-conscious 'appreciation' of the land" (Allen 1979: 192).

The non-native concept of nature, and consequently good environmental behaviour, is based upon a relationship that is largely separate from a day-to-day intimate interaction with that nature. It is something outside of our everyday lives, in the sense that when we think about nature it is not the bits of grass and single struggling trees along the sidewalks in our cities, or the squirrels and cockroaches that survive with us that we think about. We imagine *Sierra* magazine vistas, forests, steams and charismatic wildlife which we may manage actually to experience once or twice a year at best. As a result of separateness, and of the ability to make a living that is removed from the land, nature becomes a sacred, remote concept. Nature is something we are deprived of, often yearn for, do not understand or know as anything other than a desire. Worse, the undeniable ecological crisis of modern culture creates an image, a truthful image, of nature as fragile, threatened, in need of protection (although this does *not* mean most of us are willing to either change our lifestyle or voluntarily stay out of natural areas). So the day-to-day use of nature by many Natives is seen as unecological, particularly if such use includes making a living through exploiting resources through mining, trapping, logging, damming, or hunting whales. However, as Berkes (1999: 154) notes, wilderness is a questionable ecological concept; there are few landscapes on earth that were not manipulated by human cultures. Native American perceptions of nature include an intimate understanding of making a living from that nature. Part of living means making a living, and we all make a living from the land. Some of us can hide that fact from ourselves better than others. If nothing else, a native perception of nature and the human relation with nature is *honest*. But it does mean that it is often difficult to call Natives environmentalists or even ecological, if by that we mean they did not live with, change and use nature.

Using people to demonstrate a point often involves forgetting that the examples are flesh and blood. Beliefs do not translate perfectly into practice. And the definition of what *is* an ecologically sound practice has changed with the circumstances. Much depends on the natural context: population densities, existing ecological damage, and outside conditions. Today there is disagreement over whether "traditional, real" Indians drive pickup trucks, snowmobiles, powerboats and use assorted firearms to hunt. There are bitter disagreements over "traditional" harvests, for example the Inuit harvest of the seriously endangered bowhead whale using modern mechanical killing devices.

Time also plays a factor, particularly when looking at Native American practices. What was ecologically acceptable 600 years ago, such as stampeding herds of the incredibly numerous bison off cliffs, is not acceptable now when bison are endangered. A less dramatic example might be the hunting of eagles for ceremonial feathers, claws, etc. Native Americans are occasionally prosecuted under endangered species laws for these spiritually necessary practices. Yet while eagle populations are on the upswing, they are far from secure, as even Native Americans acknowledge. Who is the more "ecologically sound" citizen, the spiritually motivated Native American or the pragmatic US Fish and Wildlife Service officer who arrests them?

Finally, there is the question of which Indian you chose as a "model": the safely dead "traditional" Indian or the living descendant. The dead no longer have a voice to protest over how they are used. The living is facing very difficult questions on existence in the modern world. Environmentalists often seem to prefer the dead Indian; modern Indians too often make difficult partners. On some issues, Native Americans have welcomed the help of resource rich environmental organizations. On other issues, for example oil and mineral developments on the southwestern or Alaskan reservations, Native American tribes have been on opposite sides from environmentalists. Or consider the bitter divisions that resulted after Greenpeace successfully lobbied against the trade in harp seal skins. Many northern tribes lost much of their yearly income with the loss of the sealskin market, and they are angry in their condemnation of Greenpeace's cultural insensitivity. A similar issue has erupted as animal rights activists are increasingly successful in making the wearing of fur "politically incorrect". While some furbearers are ranch-raised, many are still trapped by northern Indian communities who stand to lose a significant source of income. White middle-class environmentalists are often slow to recognize the imperative of feeding children on reservations with 60% unemployment and chronic poverty. They also raise legitimate questions on the use of animals.

To conclude, there is no easy answer regarding this issue, academically. To the living, flesh and blood Indian, the debate is also academic, as they struggle to reconcile the invasiveness of western culture and their often fierce desire to hold on to older cultures, whether "ecological" or not, if only for their children and grandchildren's sakes.

Ethnobotany

RICHARD EVANS SCHULTES

There are numerous definitions of ethnobotany. The simplest is that it concerns the study of the uses of plants in societies. The term was first employed by John Harschberger in 1895. It was used narrowly in reference to the use of plants by aboriginal people. More recent authors believe that ethnobotany should consider not only the uses of plants but the entire range of relations between humans and plants.

Ethnobotany is a distinct field of research with a strongly interdisciplinary outlook. A number of subdivisions have developed, such as archaeoethnobotany (often called paleoethnobotany), ethnopharmacology, ethnoecology, and ethnomycology. There is even a possible subdivision which could be called "horticultural ethnobotany." With this rapid proliferation of interests, ethnobotanists have widened the definition to encompass the study of uses in aboriginal societies, native technological manipulation, classifications of the plants involved, indigenous nomenclature, agricultural systems, magicoreligious and mythological concepts connected with plant uses, and the general sociological importance of the flora in indigenous societies.

Ethnobotany itself is certainly not new. The earliest humans must have been incipient ethnobotanists. They must have classified plants in their surroundings – those of little or no utility, those which were useful in many practical ways, those which alleviated pain or otherwise ameliorated illness and those that caused illness or even killed outright. They must have wondered at the unwieldy effects of the few hallucinogenic or psychoactive species, and they could explain their extraordinary properties by assuming that they were endowed with spiritual power from supernatural forces.

It was not long before the knowledge and manipulation of the properties of plants became associated mainly with certain individuals, and the early medicine men or shamans ultimately acquired great powers over many aspects of the life and beliefs of the general population. Members of the general population, often especially women, were likewise conversant with the properties and uses of their food, medicinal, and other economic plants of daily use. Many peoples around the world are very knowledgeable about their ambient vegetation as a result of inherited knowledge, the result of hundreds of years of experimentation.

Modern ethnobotany can be of great value to many fields. Human health, new and better medicinally valuable phytochemicals, the domestication of new crop plants for food and industrial purposes, better understanding and use of plant biodiversity, and general environmental conservation – all might well reap significant advantages from proliferation of ethnobotanical investigations.

The world's flora, estimated to contain some half million species of flowering plants, have been analyzed with modern chemical techniques only on a limited scale. Tropical rain forests, which contain a greater part of the world's plant species, have been the least chemically studied even though they are extremely rich laboratories. The Amazon Valley, for example, has an estimated population of 80,000 species of angiosperms. When this wealth of species in other rain forest areas of the world is considered the opportunities for great advances in our knowledge of phytochemistry are obvious. If we consider only alkaloids, for example, the increase in our knowledge is significant. In 1950 we were aware of 2,000; in 1970 the number had increased to 4,000, and in 1990 it had reached 10,000.

If enough material of 80,000 species must be collected for chemists from such a difficult and extensive area for travel, transportation, and availability of resources, it is obvious that the task can never be completed, especially by random collecting. Ethnobotany can be a significant help.

More and more tribal peoples are succumbing to acculturation or westernization as a result of road and airport building, dam construction, increased missionary pressure, heightened tourism, or disruption from their centuries-old dwelling sites. In many areas of the great native Amazon Basin knowledge is disappearing even faster than the forests. When an Indian can get from a missionary, tourist, or commercial agent our effective and easily used drugs, this native knowledge disappears rapidly. Of the numerous subdivisions of the field of ethnobotany, none is more important than ethnopharmacology – the search for new medically valuable plants.

In the small area of the northwestern Amazonia (Colombia, Ecuador, and a small part of western Brazil), more than 1,600 species of biodynamic plants used by the Indians as medicines are considered to be an adjunct of routine cures by medicine men, or poisons (as in the manufacture of curare or arrow poisons). If chemists concentrate on those plants which Indian use has demonstrated to be in some way bioactive, understanding of the chemistry of the flora of the region can be accomplished more efficiently.

Another example of the value of ethnobotanical research lies in the Indians' familiarity with minor variations in plant species. This may be of great help in one phase of the study of biodiversity. One of the enigmas that botanists and other specialists have not had much success in understanding concerns the native's easy recognition of varieties of many of the plant species of their forests. These variants are so well established in the Indians' classifications that they usually have distinct names, in spite of the botanists' inability to see any distinguishing morphological characteristics. This skill is manifest not only in the few cultivated economic plants but also in their classification of many wild plants of no utilitarian, ceremonial, magical, or mythological importance. The Indians can usually tell at once and frequently on sight and often at a significant distance, without feeding, tasting, smelling, crushing, tearing, or other physical manipulation, to which category a plant belongs. While it is of interest to the anthropologist and psychologist, it is of extremely practical importance to chemists and botanists.

Yoco (*Paullinia yoco*, Sapindaceae) is a gigantic liana from the bark of which numerous tribes of the Colombian Amazonia prepare a very strong stimulating drink taken in the early morning before eating solids.

The drink has 3% caffeine. There are native names for at least 13 of these lianas. While several give a creamy white drink, others a slightly reddish brown product, there are no discernable morphological differences in them. Often several of the named "kinds" grow in relatively close proximity, so it cannot be due to ecological differences. Nor is it due to different parts of the liana.

Another example is ayahuasca or caapi (*Banisteriopsis caapi*, Malpighiaceae), a forest liana the bark of which is the source of an interesting vision-producing hallucinogenic drink employed widely by many tribes in the western Amazonia. Since the source plant was identified and botanically described as a species new to science in 1853 by the British plant explorer and ethnobotanist, Richard Spruce, many specialists and amateurs have written about it. We are certain now that one species of *Banisteriopsis* is used. There is now no doubt also that Indians can visually identify at a distance different "kinds" of the *caapi* liana. There is a long list of these variants, and the natives maintain that they are employed to prepare drinks of different strengths or in connection with various ceremonies or dances because of longer or shorter intoxications or because of special magicoreligious needs. There is one of the named variants from which a drink may be prepared according to the kind of animals the hunter wants to find and kill.

Could the ability of the Indian to recognize various types of *B. caapi*, often at a distance, be due to slight differences in the bark of the liana, presumed chemical diversity (which could not be seen), variation in leaf shape, ecological factors (growing in dense or open forests), or other dissimilarities? None of these can be considered logical explanations of the uncanny ability consistently to identify the named type of the liana. It remains an enigma which deserves further study.

Whatever the explanation of this perspicacity, specimens of 18 "kinds" of the ayahuasca vine were collected by Dr. E. Jean Langdon, an anthropologist who worked amongst the Siona in the Colombian Amazonia. They were submitted for botanical identification by a botanical specialist, Dr. Timothy Plowman, and almost all were referred to the single species, *B. caapi*. As Dr. Langdon states: "Further exploration between the conjunction of botany–chemistry–culture warrants further investigation."

This example of the unexplored horizon awaiting scientific investigation is typical of many other unexplained examples of the wealth of aboriginal concepts of natural phenomena awaiting technical solution around the world.

Ethnobotany, if intensified, can contribute extraordinarily to many fields of modern science, technology, and sociology, but time is of the essence in view of the worldwide uncontrolled acculturation of indigenous societies. As Prince Philip, former president of World Wildlife Fund, has pointed out: "The tropical forests and their traditional inhabitants are under very severe pressure from human encroachment, and it is sadly inevitable that many of these plant species and the tribes which understand their use are rapidly disappearing forever."

Ethnobotany of Alaska: A Southwestern Alaska Perspective

Dennis Griffin

Alaska is the home of many diverse native peoples who inhabit a wide variety of environments. To survive and flourish in these environments it was essential for people to be aware of the wide range of plant and animal species in their area on which their survival depended. Published texts on Alaskan Natives, particularly the Eskimo (Lee and DeVore 1968), have stressed the dependence of native people on hunting in order to survive. While this dependence is undoubtedly true, the awareness and intensity of use of vegetal resources has often been overlooked. While it is impossible to summarize, in a single article, the use of indigenous plants among all native peoples of Alaska, this article focuses on one area of Alaska, that of the Southwest, in order to illustrate the range of knowledge and use of indigenous flora by the Yup'ik Eskimo. This use includes the harvest of plants for food, medicine, and utilitarian purposes. Limited ethnobotanical references for native peoples in the remainder of the state are also included.

Alaska can be divided into two principal environmental regions based on general landform and vegetation: the Interior and Coastal regions. The Interior region is bounded by mountain ranges to the north and south (Brooks and Alaska Ranges, respectively) with a gradual transition in elevation west to the Bering Sea. American Indian peoples largely inhabit the interior. While not being addressed in this article, the ethnobiology of this region can be found in Carroll (1972), Fortuine (1988), Garibaldi (1999), and Kari (1987). The Coastal region extends along the border of the state to the north and west where it meets the Bering Sea, and along the southern coastal area where it borders the Sea of Alaska. The northern and western coastal areas are generally ice-bound in winter, and comprised of low-lying tundra vegetation. The southern coastal area is generally less affected by the ocean climate with its warmer sea temperatures with vegetation changing from a tundra regime on the Alaska Peninsula to a more forested environment to the east. The Coastal region is largely occupied by Eskimoan people,[1] that are divided into two linguistic subgroups, the Yup'ik and Inuit–Inupiaq (Woodbury 1984). Yup'ik was spoken aboriginally on the coasts of the Chukchi Peninsula in Siberia and Alaska from Norton Sound south to the Alaskan Peninsula, and then east along the Pacific to Prince William Sound (Fig. 1). Inuit–Inupiaq was spoken north from Norton Sound and east across Arctic Alaska and Canada to the coasts of Labrador and Greenland (see Anderson 1939; Nickerson et al. 1973; Jones 1983 for ethnobotanic information for the Inuit–Inupiaq portion of Alaska). This paper focuses on the ethnobotany of the Yup'ik Eskimo in southwestern Alaska, an area dominated by the Yukon–Kuskokwim Delta which includes both Nunivak and Nelson Islands.

[1] The Aleut occupy the southern tip of the Alaskan Peninsula and the Aleutian Islands. Their use of indigenous flora is not discussed in this paper (see Bank 1953).

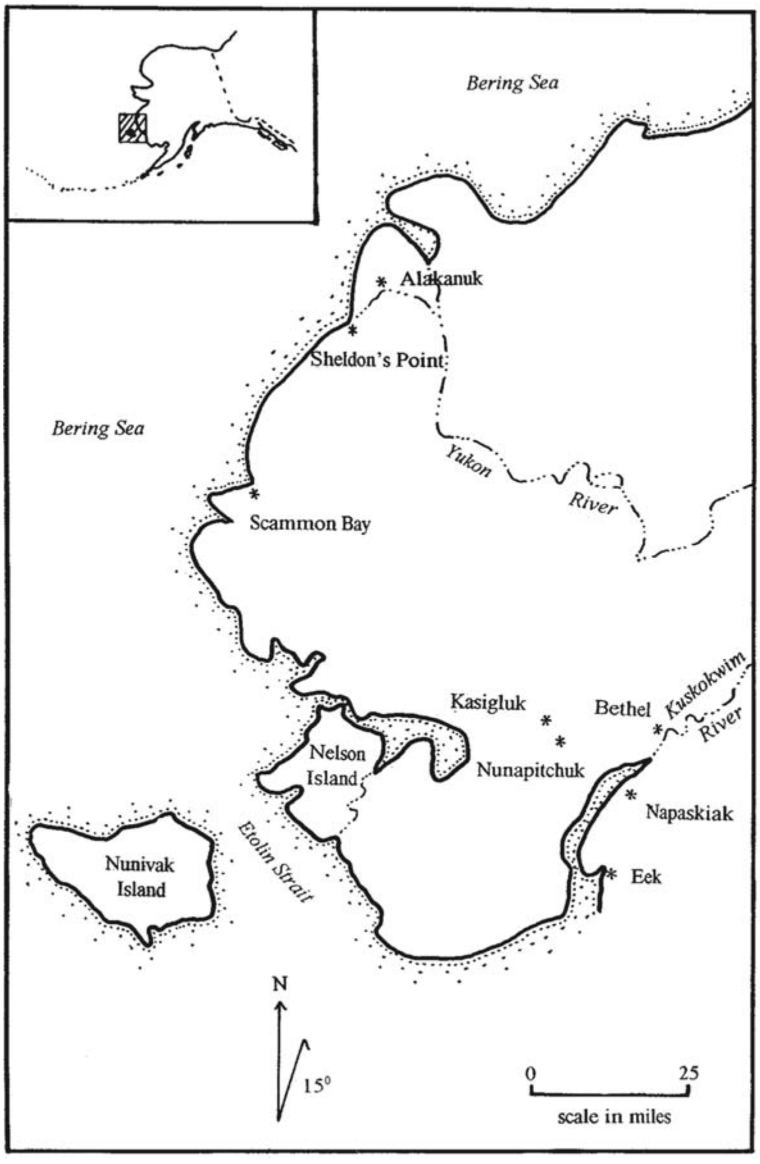
Ethnobotany of Alaska: A Southwestern Alaska Perspective. Fig. 3 Nunawarmiut elders examining plant specimens (from left to right: Nona Amos and Walter Amos).

Few early ethnographic studies in Alaska have highlighted the Eskimo's range of knowledge and use of local flora. In fact the opposite was often the case, in that many observers expressed a belief that Eskimos had little knowledge of local herbs and roots (Whittaker 1937: 115). Young and Hall (1969: 43) found that the Western Eskimo were more aware of and made use of more plant species than is generally acknowledged. While the present study summarizes the known traditional use of indigenous plants in Southwestern Alaska (Central Alaskan Yup'ik), comparative data are also included for plant use among the peoples of St Lawrence Island and Siberia (Siberian Yup'ik) and the Chugach of Prince William Sound (Pacific Yup'ik), when known. This information was primarily obtained from a 12-year (ca. 1995–2006) collaborative anthropological project with the Nuniawarmiut of Nunivak Island (see Figs. 2 and 3), and a compilation of published and unpublished sources of ethnobotanical use.

Regional Setting

The Yukon–Kuskokwim Delta (Fig. 4), a geographic and cultural area historically occupied by Central Alaskan Yup'ik-speaking Eskimos in southwestern Alaska, encompasses an area of almost 81 million kilometers (31,250 square miles) or 8.1 million hectares (20 million acres). This delta region consists of a vast and largely roadless expanse of low-lying tundra that has attracted limited attention from ethnographers in the past. Native villages are located along the area's major waterways with development largely limited to commercial fishing. The degree of early contact between subcultural groups within the Delta cannot accurately be determined due to conflicting early historical data and later movements of peoples throughout the region, but villages are known to have been linked by extensive trade networks, intermarriage among village residents, and village alliances during times of warfare (VanStone 1984: 224). Ponds, lakes, streams, and sloughs, which made travel throughout southwestern Alaska extremely difficult, cover half of the Yukon–Kuskokwim Delta. Not surprisingly, the immense wetlands provide suitable habitat for millions of waterfowl, small and large mammals, and abundant flora. The seasonal harvest of marine mammals (e.g., seals, sea lion, walrus) and many species of fish (particularly salmon, halibut, whitefish, and blackfish) remains vital for local survival.

E



Ethnobotany of Alaska: A Southwestern Alaska Perspective. Fig. 4 Map of Yukon–Kuskokwim Delta.

The Yukon–Kuskokwim Delta is subject to a subarctic maritime climate, influenced by the surrounding sea, which produces a relatively stable temperature. Summers are generally cool and windy, with some areas experiencing frequent fog; winters are cold with both wet and dry periods. The region's mean annual temperature is −2°C (30°F) with mean daily temperatures ranging from −25°C (9°F) in January and February to 10°C (50°F) in August (Selkregg 1976, Swanson et al. 1986). Rain and snowfall is heavier on the mainland than neighboring islands (e.g., Nunivak), with islands experiencing more frequent overcast days with dense fogs. This difference between the mainland and island delta regions is due to the greater effect of the Bering Sea on the island environment. Precipitation is moderate with a mean annual rainfall of 40.6 cm (16 in.) and snowfall of 127 cm (50 in.). Vegetation throughout the region remains similar.

The Yup'ik Eskimo of southwestern Alaska traditionally practiced a hunting, fishing, and gathering subsistence economy that revolved around the harvest of the above-mentioned species, in addition to the numerous plant species that were critically important to survival. Hulten (1966, 1968) has studied the vascular flora of the Yukon–Kuskokwim Delta, Bos (1967) and Palmer and Rouse (1945) that of Nunivak Island, and Young (1968) on St Lawrence Island. The region's vegetation is predominantly comprised of Arctic tundra containing a variety of lichens, grasses, sedges, flowers, and shrubs. It is similar to vegetation found throughout western and northwestern Alaska. The tallest tundra plants are shrubby willows that can reach up to 8 ft in height along some river courses. Major vegetation types include wet tundra, dry tundra, alpine tundra, and grass–browse (i.e., grass hummock and beach grass–forb). Wet tundra is most prevalent along the coast in poor drained areas, with the dominant cover species consisting of sedges (*Carex* spp.), cottongrass (*Eriophorum* spp.), willow (*Salix* spp.), crowberry (*Empetrum nigrum*), and various species of mosses and lichens (e.g., *Sphagnum*, *Pohlia*, and *Cladonia*). Dry tundra is found on areas of sloping terrain having good drainage and is dominated by species similar to those found in wet tundra areas, in addition to bearberry (*Arctostaphylos alpine*), Labrador tea (*Ledum palustre decumbens*), woodrush (*Luzula nivalis*), bog blueberry (*Vaccinium uliginosum*), and dwarf birch (*Betula nana exilis*). Alpine tundra, found at higher elevations on hills and mountains, is similar to that in dry tundra areas, and is dominated by crowberry, alpine bearberry, Labrador tea, White Mountain-avens (*Dryas octopetala*), and moss. Grass–browse is generally found interspersed with the dry tundra subtype and along edges of streams and rivers adapted to periodic flooding. This vegetation type is dominated by fescue (*Festuca* spp.), bluejoint (*Calamagrostis canadensis*), willow, lichens, sedge, wild celery, and seacoast angelica (*Angelica lucida*).

Use of Indigenous Flora

Indigenous plants were an integral part of the year-round diet of Eskimo people in addition to their incorporation in other facets of their lives. Contrary to the popular perception of Eskimo people surviving solely on fish and meat, they utilized a large number of local plants for food, medicinal, and utilitarian purposes. An earlier Alaskan study estimated that up to 15% of the diet of Western Eskimo people (Kotzebue to Alaska Peninsula) is made up of vegetable resources (Young and Hall 1969: 43). While plant resources remained sparse on some offshore islands such as St Lawrence Island (Young and Hall 1969), on Nunivak and Nelson Islands they provided a significant addition to the Native's year-round diet.

Knowledge of the Native use of indigenous flora in the Delta remains limited. Previous ethnobotanical studies are limited to research on Nunivak Island (Fries 1977; Griffin 2001, 2004; Lantis 1946, 1959; Nuniwarmiut Taqnelluit 2006), Nelson Island (Ager and Ager 1980), the Kuskokwim villages of Napaskiak (Oswalt 1957), Eek, Kasigluk, and Nunapitchuk (Andrews 1989; Lantis 1958, 1959), and several lower Yukon Delta and coastal villages (e.g., Alakanuk, Sheldon's Point, Scammon Bay) by Fienup-Riordan (1986). St Lawrence Island and the Chukchi coastal area of Siberia are similar in landform with Southwestern Alaska in that lands are covered by low-lying Arctic tundra, although the number and variety of plant species differ between areas. Knowledge of the indigenous use of plants in these areas remains limited to few published and unpublished accounts (Young and Hall 1969; Ainana and Zagrebin, unpublished data, respectively). Ethnobotanical knowledge among Pacific Yup'ik speakers is largely limited to studies among the Chugach (Birket-Smith 1953; Fortuine 1988; Wennekens 1985) in Prince William Sound, Kodiak Island (Graham 1985), and the Alaska Peninsula (Morseth 2003). Since the flora of the first two of these areas are very different from that of the Yukon–Kuskokwim Delta (i.e., forest vs. tundra), only information on the use of similar plant species is addressed here. Several recent, regionally based publications have attempted to summarize our knowledge of the indigenous use of plants throughout Alaska (e.g., Biggs 1999; Garibaldi 1999; Schofield 1989), however the Yup'ik-speaking areas remain poorly documented.

Table 1 provides a list of the seasonal use of indigenous food plants by the Yup'ik Eskimo. This index provides data on the Yup'ik use of 43 indigenous plant species in southwest Alaska. In Table 1, species

Ethnobotany of Alaska: A Southwestern Alaska Perspective. Table 1 Seasonal use of indigenous food plants among Yup'ik-speaking Eskimo

Scientific name	Common name	Season[a]	Plant part	Storage	Location[b]
Ammodenia peploides	Sea Purslane, Seabeach Sandwort	Su	Leaves	X	Nunivak
Angelica lucida	Wild Celery	Su	Leaves, stalk, root	X	Y–K Delta, Ak. Pen., Chugach
Arctostaphylos alpina	Alpine Bearberry	Su, F	Fruit		Y–K Delta, Inuit
Boltenia ovifera	Sea Potato, Sea Onion	S, Su	Bulb		Nunivak
Caltha palustris	Marsh Marigold	W, S	Entire plant	X	Y–K Delta
Carex spp.	Sedges	F	Root, stem		Nunivak
Cladonia spp.	Lichens	S	Entire plant		Nunivak
Claytonia tuberosa	Wild Potato, Tuberous Spring-Beauty	Su	Corm		Y–K Delta, Siberia
Conioselinum chinense	Western Hemlock-Parsley	S, Su	Root		Nunivak, Chugach
Dendroa aggregate		Floats to beach	Branches		Nunivak
Draba borealis or *Draba hyperborea*	Wild Lettuce	S, Su	Leaves	X	Nunivak
Dryopteris dilatata	Shield Fern	Su, F	Fronds, fiddleheads		Nunivak
Empetrum nigrum	Crowberry	Su, F	Fruit, plant	X	Y–K Delta, Ak. Pen., Chugach, Siberia, Inuit
Epilobium angustifolium	Tall Fireweed	S, Su S	Leaves, young shoots	X	Y–K Delta, Chugach, Inuit
Epilobium latifolium	Dwarf Fireweed	Su	Leaves, yg. shoots	X	Nunivak
Epilobium angustifolium	Tall Cottongrass	Su, F	Base of stem, greens		Y–K Delta, Inuit
Fucus spp. *F. Gardneri*	Bladderwrack Rockweed	Year-round S, Su, F	Plant, young plant		Y–K Delta, Chugach
Hippuris tetraphylla or *H. vulgaris*	Mare's Tail	S, F	Leaves, stems, roots	X	Y–K Delta
Honckenya peploides major	Beach Greens, Seabeach Sandwort	S, Su	Leaves, stems	X	Y–K Delta, Siberia, Inuit
Ledum palustre decumbens	Labrador Tea	S, Su year rd.	Leaves		Y–K Delta, Chugach
Ligusticum scoticum Hultenii	Beach Lovage, "Wild Parsnip/Parsley"	S, Su Su	Roots, leaves, stems		Y–K Delta, Ak. Pen., Chugach
Lycoperdon spp.	Puffball	S, Su	Yg. fruiting body		K-Delta?, Siberia
Mertensia maritima	Oysterleaf	?	Leaves		Y–K Delta
Oxycoccus microcarpus	Bog Cranberry	Year-round	Fruit	X	Y–K Delta, Chugach
Oxyria digyna	Mountain Sorrel	S, Su	Leaves	X	Y–K Delta, Siberia, Inuit
Palmaria palmata	Seaweed, Dulse	Su, W	Blade		Nunivak
Parrya nudicaulis (?)	Wild Cabbage/Celery	Su	Leaves	X	Nunivak
Pedicularis verticillata	Woolly Lousewort	S	Flowers, roots		Y–K Delta, Siberia, Inuit

E

Ethnobotany of Alaska: A Southwestern Alaska Perspective. Table 1 (Continued)

Scientific name	Common name	Season[a]	Plant part	Storage	Location[b]
Pohlia nutans/Webera nutans	Moss	S	Plant		Y–K Delta
Polygonum bistorta	Pink Plumes, Bistort	S, F	Leaves, root stalk	X	Nunivak, Siberia, Inuit, Ak. Pen.
Polygonum viviparum	Alpine Bistort, Wild Rhubarb	S, Su	Rhizome		Y–K Delta, Siberia
Ranunculus Pallasii	Pallas Buttercup	S	Leaves, stems		Y–K Delta
Rhodymenia palmata	Red Seaweed, Dulse	Year-round	Plant		Y–K Delta, Chugach
Rubus arcticus	Nagoonberry	Su	Fruit	X	Y–K Delta, Chugach, Inuit
Rubus chamaemorus	Cloudberry	Su	Fruit	X	Y–K Delta, Chugach
Rumex arcticus	Dock, Sour Dock	S, Su	Leaves, stems	X	Y–K Delta, Ak. Pen., Chugach
Salix alaxensis	Alaska Willow	S	Catkins, leaf top		Y–K Delta, Inuit
Salix pulchra	Diamondleaf Willow	Su	Catkins, leaves		Y–K Delta, Siberia
Saxifraga spp.	Saxifrages	S, Su, F	Leaves	X	Nunivak, Siberia, Inuit
Sedum rosea	Roseroot, Stonecrop	S	Flowers, plant		Y–K Delta, Inuit
Senecio pseudo-Arnica	Ragwort, Fleabane	Su	Leaves, stems, root, top of shoot	X	Y–K Delta
Streptopus amplexifolius	Twisted Stalk	S, Su	Fruit, young stalks		Nunivak, Chugach
Vaccinium uliginosum	Alpine Blueberry, Bog Blueberry	Su	Fruit	X	Y–K Delta, Ak. Pen., Chugach
Vaccinium vitis-idaea minus	Lingonberry, Low-bush Cranberry	Year-round	Fruit	X	Y–K Delta, Siberia, Chugach, Ak. Pen.

[a]Seasonality: S, spring; Su, summer; F, fall; W, winter.
[b]Location abbreviations include: Y–K Delta = Yukon–Kuskokwim Delta; K-Delta = Kuskokwim Delta; Inuit = Inupiaq-speaking area; Chugach = Prince William Sound; Ak. Pen. = Alaska Peninsula.

are arranged in alphabetical order by each species' botanical name. Details regarding season of harvest, plant part used, and if the species was stored for winter consumption/use is provided. In addition, the known range and extent of use of each species among Eskimo peoples is included.

While some researchers believed Eskimos had no knowledge of herbs or roots to combat or relieve sickness (Whittaker 1937), this has been found to be untrue. Medicinal knowledge of indigenous plants varies from area to area with over 28 plant species used in the Yukon–Kuskokwim Delta. Table 2 provides a list of medicinally used plants in the region, along with specific references to texts that provide greater detail on the collection, processing, and application of each species.

In addition to the use of plants for food and medicine, many plant species were used for a variety of utilitarian purposes. Table 3 provides details on 13 species used in southwestern Alaska. Data on plant name, season of harvest and specific use is included.

Native Plant Taxonomy

An examination of general Yup'ik terms (Jacobson 1984) provides comparative data useful in distinguishing some basic plant terminology distinctions. Yup'ik speakers (including Cup'ig speakers on Nunivak Island who speak the most divergent dialect within the Yup'ik branch) tend to divide plants into basic groups based on how plants were traditionally used, their similarity in appearance or physical characteristics. For example, on Nunivak Island, the Cup'ig plant name ***ciwassit***[2] translates to "wild greens that can be cooked" and is used to denote several distinct species that are prepared in a similar manner (i.e., *Rumex arcticus* [sour dock], *Polygonum bistorta* [bistort], and *Polygonum viviparum* [alpine bistort]. ***Kumarutet*** is used to denote all moss species (e.g., *Pohlia nutans*) based on the traditional use of moss as a wick in lamps (***kuman*** = lamp, light). Examples of plants grouped by similarity in appearance, characteristics or setting include: (1). ***elquat*** – term used to designate several varieties of seaweed (e.g., *Palmaria palmata* [dulse], *Fucus* spp. [bladderwrack]; (2) ***megtat neqiat*** – meaning bumble bee food for several local plant species (e.g., *Pedicularis verticillata* [wooly lousewort], *Sedum rosea* [roseroot]); and (3) ***agyam an'a(i)*** – used for all puffball species (*Lycoperdon* spp. and *Calvatia* spp.). In Yup'ik, ***agyam ana*** translates to meteor and meteors, which are traditionally said to turn into puffballs when they land (Jacobson 1984: 48). Still other plant names highlight distinctions within a genus such as ***qugyuguat***, which is used to refer to all *Salix* (willow) species except those exhibiting catkins, which are referred to as ***qimugkararat***. Further analysis is needed in order to fully understand the Yup'ik's concept and categorization of local flora.

A similarity of plant use and some Native plant names between Yup'ik, Cup'ig, and Inupiaq speakers (i.e., Seward Peninsula) to the north have been identified. Similarities between some Yup'ik, Cup'ig, and Inupiaq plant names (e.g., ***kavlak–kavlag–kavlaq*** [*Arctostaphylos alpine* (alpine bearberry)], ***paunraq–paunrat–paungaq*** [*Empetrum nigrum* (crowberry)], ***pekneq–pekner–pikneq*** [*Eriophorum angustifolium* (cottongrass)], ***tukaayug–tuk'ayut–tukaayuk*** [*Linguiticum scoticum* (lovage)]), and food preparations (e.g., ***akutaq–akutar–akutuq*** [Eskimo ice-cream comprised of berries, seal oil, reindeer tallow (Crisco), snow and sometimes salmon eggs]) highlight extended contact between western Alaskan peoples over time. Further research is needed to evaluate the degree of sharing between these language branches with regard to the recognition and use of indigenous plants.

Plant Harvest, Preparation, and Storage

In the Yukon–Kuskokwim Delta, women and children traditionally gathered most indigenous plants while the men were harvesting other available resources (e.g., caribou, waterfowl, seal) (Fienup-Riordan 1983; Lantis 1946). While fresh spring greens provided a welcome addition to the diet, which in winter was based largely on dried and stored foods, other greens were harvested throughout the year as they ripened, and used with some of those stored for winter use. With the melting of the winter's snow pack, local greens and berries not picked during the previous fall's harvest begin to appear and were added to the local diet. Depending on the time the ice pack began to break up, Yup'ik families began to move to their spring camps to harvest available resources. Along the coast, Yup'ik men would journey out along the ice to harvest arriving sea mammals (i.e., seals, walrus) while women would spend much of their time harvesting available plant resources (greens and seaweeds) and shellfish. Early harvestable spring food plants included: marsh marigold (*Caltha palustris*), sour dock (*Rumex arcticus*), wild celery, wild lettuce (*Draba hyperborea*), wild parsnip (*Ligusticum Hultenii*), wild rhubarb (*Polygonum viviparum*), mountain sorrel (*Oxyria digyna*), Pallas buttercup (*Ranunculus pallasii*), and Labrador tea.

After the completion of the spring hunting season, families would move to summer fish camps. Fish comprised the most prolific and essential subsistence resource for many Alaskan Natives living in the Delta

[2] Cup'ig spellings of all plant species are taken from the Cup'ig Dictionary by Amos and Amos (2003) and have been placed in bold italics. A glossary of Yup'ik and Cup'ig plant names are included in the Appendix.

E

Ethnobotany of Alaska: A Southwestern Alaska Perspective. Table 2 Medicinal plant use among the Yup'ik-speaking Eskimo

Scientific name	Common name	Plant part	Plant application	Symptom	Location[a]	Reference
Achillea spp.	Yarrow	Leaves, stem	Infusion, gargle, poultice, chew, switch	Congestion, sore throat, boils arthritis, uterine evacuation, increase milk after parturition	Nunivak, Chugach	Fortuine (1985), Morseth (2003), Schofield (1989)[b], and Wennekens (1985)
Alnus spp.	Alder	Leaves, bark, branch	Poultice, switch	Cut/scrapes, arthritis, sore muscles; stool softner	Y–K Delta, Chugach	Ager and Ager (1980), Garibaldi (1999), Morseth (2003), and Wennekens (1985)
Angelica spp.	Angelica	Root, stem	Chew, infusion, switch	General ill health, seasick remedy, sore joints	Y. Delta, SLI	Garibaldi (1999), Hulten (1968), Morseth (2003), and Young and Hall (1969)
Artemisia Tilessi	Stinkweed, Wormwood	Leaves, branch, seed head, plant	Poultice, switch, infusion/decoction, hair rinse, vapor, chew	Cuts, dandruff, sore muscles, arthritis, stomach trouble, constipation, bleeding	Nunivak, SLI; Y–K Delta, Chugach	Ager and Ager (1980), Fienup-Riordan (1986), Garibaldi (1999), Griffin (2001), Lantis (1959), Oswalt (1957), Overfield et al. (1980), Wennekens (1985), and Young and Hall (1969)
A. vulgaris	Stinkweed	Leaves	Poultice	Sore joints, gas pains	Nunivak, Norton Sound	Garibaldi (1999), Griffin (2001), and Lantis (1958)
Betula nana exilis	Dwarf birch	Leaves	Infusion/decoction	Boiled for stomach problems, intestinal	Nunivak, K. Delta	Griffin (2001) and Lantis (1958, 1959)
Caltha palustris	Marsh marigold	Leaves	Infusion/decoction, chew	Constipation, diarrhea	K. Delta	Garibaldi (1999) and Lantis (1959)
Dryopteris austriaca	Shield fern	Fronds	Infusion/decoction	Boiled for stomach problems, intestinal	Nunivak, K. Delta	Griffin (2001) and Lantis (1958, 1959)
D. dilatata americana	Wood fern	Plant	Infusion/decoction	Stomach trouble	K-Delta	Garibaldi (1999)
Epilobium angustifolium	Tall Fireweed	Leaves, root	Infusion/decoction, poultice	Boiled for stomach problems, intestinal, constipation, cuts	Nunivak, K. Delta, Chugach	Ager and Ager (1980), Garibaldi (1999), Griffin (2001), Lantis (1958, 1959), and Wennekens (1985)
Equisetum spp., *E. avense*	Horsetail	Upper stem, plant	Infusion/decoction, poultice	Internal bleeding, hemorrhages, pimples	Y–K Delta, Chugach	Ager and Ager (1980), Garibaldi (1999), and Wennekens (1985)
Eriophorum spp.	Cottongrass	Flower, cotton, stem, leaves	Chew, poultice	Cuts/scrapes, ill health, sores, inflamed eyes	Nunivak, K. Delta	Garibaldi (1999), Griffin (2001), Lantis (1959), and Oswalt (1957)
Fomes igniarius	Chew ash fungus	Fungus	Infusion/decoction	Constipation, stomach trouble	K. Delta	Garibaldi (1999) and Lantis (1959)
Ledum palustre decumbens	Labrador tea	Leaves, stems, flowers	Infusion, fumigant	Bleeding/hemorrhage, TB, constipation, stomach trouble	Y–K Delta	Ager and Ager (1980), Garibaldi (1999), Griffin (2001), and Lantis (1958, 1959)

Matricaria matricarioides	Pineapple weed	Seed heads, plant top, plant	Infusion/decoction; chew	Colds/flu, stomach trouble, TB, laxative, increase milk after parturition	Napaskiak; NI, Chugach	Ager and Ager (1980), Garibaldi (1999), Morseth (2003), Oswalt (1957), and Wennekens (1985)
Nephroma arcticum	Arctic kidney lichen	Plant	Infusion	Ill health	K. Delta	Garibaldi (1999) and Oswalt (1957)
Oxycoccus microcarpus	Bog Cranberry	Fruit	Chew	Pneumonia, stomach trouble	Y–K Delta	Garibaldi (1999)
Picea glauca	White spruce	Needles, gum	Infusion/decoction, chew, salve	Cit/scrapes, cough, chest congestion	Y–K Delta	Garibaldi (1999), Lantis (1959), and Oswalt (1957)
Rubus chamaemorus	Cloudberry	Fruit	Chew	Diarrhea, skin trouble	Nunivak, K. Delta	Garibaldi (1999), Griffin (2001), Lantis (1959), and Schofield (1989)
Rumex spp.	Dock	Leaves, root	Chew, snuff, poultice	Diarrhea, constipation, headache, chill fever	Chugach, Napaskiak	Birket-Smith (1953), Garibaldi (1999), Morseth (2003), Oswalt (1957), and Wennekens (1985)
Salix spp.	Willow	Leaves, bark, catkins, cambium	Infusion/decoction, chew, gargle, poultice	Lung hemorrhage, pain, sore throat or mouth, skin sores, cut/scrapes, eye trouble	Y–K Delta, Nunivak Chugach	Ager and Ager (1980), Garibaldi (1999), Griffin (2001), Lantis (1958, 1959), Oswalt (1957), and Wennekens (1985)
S. fuscescens	Willow	Leaves, catkins	Chew, swab	Sore mouth, watery eyes	Nunivak	Griffin (2001) and Lantis (1946, 1959)
S. pulchra	Diamondleaf Willow	Leaves	Chew	Sore mouth	Nunivak	Griffin (2001)
Sedum rosea	Roseroot, Stonecrop	Leaves, flower, root	Infusion/decoction, chew	Boiled for stomach problems, intestinal, sore mouth, TB	Nunivak, K. Delta, NI	Ager and Ager (1980), Garibaldi (1999), Griffin (2001), and Lantis (1958)
Sphagnum spp.	Sphagnum	Moss	Chew, poultice	Diarrhea, cuts/scrapes	K. Delta	Fortuine (1985), Garibaldi (1999), and Lantis (1959)
Vaccinium vitis-idaea	Low-bush Cranberry	Fruit	Chew, poultice	Diarrhea, eye trouble	K. Delta	Garibaldi (1999) and Lantis (1959)
Valeriana spp.	Valerian	Unknown	Unknown	Stomach trouble, good luck	Y. Delta; SLI	Garibaldi (1999) and Young and Hall (1969)
Nicotiana spp.	Tobacco (introduced)	Leaf	Poultice	Control bleeding	K. Delta	Lantis (1959)

[a]Location abbreviations include: SLI = St Lawrence Island; Y–K Delta = Yukon–Kuskokwim Delta; K-Delta = Kuskokwim Delta; NI = Nelson Island; Chugach = Prince William Sound.
[b]Schofield's reference Tuvas of Yarrow on Nunivak Island is believed to be in error based on a misintempretation of Smith's arctic pharmacognonon (1973: 325).

Ethnobotany of Alaska: A Southwestern Alaska Perspective. Table 3 Utilitarian use of indigenous plants by Yup'ik-speaking Eskimo

Scientific name	Common name	Season	Plant part	Purpose	Location
Aconitum delphinifolium	Monkshood	Year-round	Root	Hunting poison	Chugach, Nunivak?
Angelica lucida	Wild celery	?	Root	Hunting talisman	Siberia
Carex spp.	Sedges	F	Grass	Boot lining, socks	Y–K Delta
Cladonia rangiferina	Lichens, Reindeer moss	Year-round	Plant	Seal oil applicator	Y–K Delta
Elymus mollis	Wild rye grass	S, Su, F	Grass	Menstrual pad, basket roof thatching, mats	Y–K Delta Chugach
Empetrum nigrum	Crowberry	Su, F	Leaves	Storage pit liner	Y–K Delta
Equisetum arvense	Common horsetail	S, Su, F	Stems	Play matches for child	Y–K Delta
Eriophorum angustifolium	Tall Cottongrass	?	Reeds	Basket, mat	K. Delta
Petasites frigidus	Coltsfoot	Su, F	Leaves	Berry basket	Nunivak
Pohlia nutans/ *Webera nutans*	Moss	S, Su, F	Plant	Diaper, basket-lining, fire starter, pottery pad	Y–K Delta Chugach
Rumex arcticus	Sourdock	Su, F	Plant	Navigation aid, cache pit lining, landmark	K. Delta
Sphagnum spp.	Sphagnum moss	Year-round	Moss	Menstrual pad, diaper	Nunivak
Vaccinium vitis-idaea minus	Lingonberry	Su, F	Fruit	Dye	Y–K Delta Chugach

and its harvest would occupy the majority of the families' efforts for several months. Traditional indigenous plants would continue to be harvested as they ripened and were eaten fresh or placed in underground caches for temporary storage. By late summer/early fall, several berry species (e.g., cloudberry [*Rubus chamaemorus*], nagoonberry [*R. arcticus*], crowberry [*Empetrum nigrum*]) and local greens (e.g., sour dock [*Rumex arcticus*]) were ready to be harvested and women and children would spend most days on the tundra gathering plant resources.

Most plants were available in a variety of locales and their harvest did not dictate moving the family to specific camps. Plants that grew in abundance in specific terrain, such as several varieties of cliff greens, usually offered other resources that could be harvested at the same time (e.g., fish, Sandhill cranes). Greens such as *Rumex arcticus* could be found throughout the delta and old camp sites are said to contain buried cache pits once used for plant storage.

As an example, when harvesting "wild spinach" or sour dock, Nunivak elders state that they would stay in an area until they had harvested enough for their family's long-term needs (Amos 1991; Kiokan 1995). After picking, they would cook the spinach a little bit before placing it into a cache dug underground.

> Cook em half way, just for the leaves to just shrivel up and not take much space, and they would dig ditches and line it with a certain type of twigs and grass and put em' in there until the weather gets colder, before the ground get hard, knowing that when it freezes, that *Ciwassat* (*Rumex arcticus*) would freeze in with the earth. So before that time they would go over there again, pull the *Ciwassat* out and this time leave em' on top of the ground… They would cover them with grass, probably willows too to keep them together and they would leave them until it freezes (Amos 1991: 16).

Before placing the spinach in the caches, the cooked leaves would be drained of juice and the pit lined with woven grass mats (e.g., *Elymus mollis*). "Some people rolled them up like a ball and put them away. Each roll was made enough for one meal. They rolled the spinach ball big enough for their dinner or a snack. That's how they took them out of the ground" (Amos and Amos 1989: 25). Grass was placed on top before the cache was covered with rocks to insure it would not be disturbed until needed (Kiokan 1995). Berries were stored in much the same way, except that these pits would be lined with rocks (Kiokan 1995; Whitman 1995) and raw spinach (e.g., *Rumex arcticus*) was used

Ethnobotany of Alaska: A Southwestern Alaska Perspective. Fig. 5 Rock-lined cache pits at Nash Harbor village, Nunivak Island, Alaska.

as an inner lining (Kiokan 1995). The berries would have no juice when removed, since they would have dried out while being stored underground. In the fall, people would return to their seasonal caches and transport their stored berries and greens to their winter village. Curtis (1930: 36) describes berry caches as "a small box-like structure of flat stones lined with grass and covered with sod until air- and water-tight." Examples of such features were discovered during recent archaeological excavations on Nunivak Island (see Fig. 5).

Changes in Plant Use

While recent investigations on Nunivak Island (Griffin 2001, 2004; Nuniwarmiut Taqnelluit 2006) have added extensive details to previous knowledge of traditional subsistence procurement and storage techniques, one must keep in mind that the memories of earlier subsistence use may be affected by historic changes to native culture. The most obvious change in Yup'ik indigenous plant use, between that found in early ethnographies and at present, is the current lack of knowledge of many previously harvested plants. With the abandonment of many small Delta villages in favor of larger villages with established schools where native children were sent to be educated, and a subsequent increased reliance on western foods, fewer families rely on traditional subsistence resources. Studies (e.g., Nowak 1975) have documented a link between continued traditional subsistence activities and a family's economic position. With village centralization, the cost of purchasing and maintaining the equipment needed to continue traditional subsistence activities (e.g., boat, four-wheeler, gas) became dependent on having a steady source of income and time to pursue such activities. In time, information on earlier plant use is forgotten and influences resulting from increased contact with non-Yup'ik mainland peoples can add to or supplant earlier local knowledge. For example, in 1927 Curtis (1930: 35) recorded the use of willow leaves (*Salix* spp.) on Nunivak Island as a food and medicinal item. In 1939, Lantis (1959: 60) found only one elder on Nunivak who still recalled the earlier use of willow. Today elders routinely deny such traditional use. However, recent influence of northern Eskimos on the island population has resulted in a renewed use of the plant, although contemporary Cup'it elders believe that its use is only of recent innovation. A similar pattern of traditional versus recent use has been noted for stinkweed/wormwood (*Artemesia tilesii*).

It is easy to assume that observed Native lifeways in the early twentieth century reflect those practiced during the late prehistoric period or before. However, in spite of the evident continuity of tool use and general subsistence practices on Nunivak Island (Griffin 2001, 2004) and the Yukon–Kuskokwim Delta (Shaw 1983) throughout the past 500 years, traditional lifeways may have been different, possibly more complex, than those historically recorded. Following increased contact between mainland Native peoples (i.e., trade, intermarriage) and Euro-Americans during the nineteenth century, changes in the use of indigenous plants were probably an ongoing process, influenced by the degree and type of contact, as well as impacts from a serious loss in Native population resulting from the introduction of western diseases.

Previous research in Native communities within the Delta have focused on documenting changes to Native lifeways following the arrival of Euro-Americans to the region (e.g., Fienup-Riordan 1983; Lantis 1946). However, these studies have provided little detailed information on traditional use of indigenous plants. The collection of ethnobotanical information was rarely a focus of research efforts and a systematic analysis of Native plant use throughout the region has yet to be undertaken. Given the incorporation of western foods in Native diets and a corresponding decline in the harvest of many indigenous plants, efforts to collaborate with Native communities need to be undertaken before information on traditional use of area vegetation has been forgotten.

The degree of contact between mainland and island Eskimo people, prior to the arrival of Russian and Euro-Americans in the late eighteenth and nineteenth centuries, is unknown but would have largely been limited to trade between neighboring groups during the summer months. Having to rely primarily on locally available resources for their subsistence, the Yup'ik incorporated many indigenous plants into their year-round diet. Contrary to earlier stereotypes of Arctic peoples' sole reliance on a meat-based diet for survival,

Ethnobotany of Alaska: A Southwestern Alaska Perspective. Appendix: Glossary of Native Plant Names Yup'ik Native Plant Name Glossary

Scientific Name	Common Name	Yup'ik	Cup'ig	Siberian Yup'ik
Achillea spp.	Yarrow	punaiyulinu'kait		
Aconitum delphinifolium	Monkshood		cetegneg	
Alnus spp.	Alder	chufu'koak		
Angelica lucida	Wild celery	ikiituk	ik'itut, ik'iituq, ikkitug	
Arctostaphylos alpina	Alpine Bearberry	kavlak	kavlag
