Maps and Mapmaking in Africa

Thomas J. Bassett

With the exception of medieval Islamic mapmaking, the corpus of precolonial African maps is too small for us to generalize about distinctive cartographic traditions. B. F. Adler (1910) provides the only summary of sub-Saharan mapping, and most of his examples are maps solicited from Africans by European explorers. The paucity of extant maps may be explained by a number of factors. First, among literate cultures like the Muslim Hausa and Jula of West Africa, there existed effective substitutes such as travel guides written in Arabic script. These commonly took the form of itineraries that listed the names of towns between a starting point and destination (e.g., the road from Bornu to Mecca). In 1824 Joseph Dupuis provided examples of these "native charts" kept by merchants and pilgrims which he used to construct his own maps of West Africa. Second, the scarcity of maps in nonliterate societies may be explained by a common recourse to drawing maps on the ground. European explorers witnessed this indigenous form of mapmaking and were frequently impressed by its accuracy. However, the ephemeral nature of ground maps has left us with few traces of this apparently widespread practice (see below). Third, the demand for maps was probably very limited because of the hazards of traveling beyond one's territory. Even merchants risked being captured by neighboring groups if they did not travel in caravans, carry letters of introduction, or have contacts in distant communities. Under these circumstances, there was little demand for maps as conveyors of geographical knowledge to outsiders. Finally, in searching for African maps, we should be wary of looking for Western forms of mapping in societies whose spatial concepts and relationships to land are fundamentally different. Western maps are constructed upon culturally specific notions of property, territory, and political authority over bounded areas. One should not assume a priori that African peoples hold these concepts. Moreover, as Paul Bohannan shows in his discussion of the "genealogical map" of the Tiv of central Nigeria and the "rain shrine neighborhoods" of the Tonga of Zambia, there is tremendous variety within Africa itself in the conceptualization of space. Rarely does one find the expression of socio-spatial relationships in two-dimensional maps. Despite this restricted development of mapmaking in precolonial Africa, there are a number of interesting maps to consider.

One of the earliest examples of African mapmaking is an Egyptian map dating from about 1150 BCE. Fragments of the picture map depicting the Wadi Hammamat area between Thebes and the Red Sea port of Quseir are preserved on papyrus in the Muzeo Egizio at Turin. Other ancient Egyptian examples include plans of gardens and maps of the afterlife painted on stone during the second millennium BCE.

One of the foremost cartographers of the Middle Ages was al-Sharīf al-Idrīsī. He was born in Ceuta, Morocco, in 493 AH/AD 1100 and is believed to have died there in 560/1165. He was the court geographer of the Norman king of Sicily, Roger II, for whom he wrote his celebrated *Nuzhat al-mushtāq fī' khtirāq al-āfāq* (The Book of Pleasant Journeys into Faraway Lands, also known as the Book of Roger). This work contains a world map and 70 sectional maps that build upon both the Balkhī and Ptolemaic cartographic traditions. Although written in the twelfth century, al-Idrīsī's work was still influential five centuries later among North African chartmakers. The portolan charts of the al-Sharafī al-Ṣifāqsī family that thrived in the Tunisian town of Sfax for over eight generations are compilations based on al-Idrīsī and Catalan sea charts.

A distinctive form of schematic mapping dating from the eighteenth century is represented in Ethiopian manuscript maps of Tigre (Fig. 1). These maps consist of three concentric circles in which Aksum, the center of Ethiopian Christiandom, is situated in a box in the innermost circle, as in the figure here; the outer circles are divided into segments that contain the cardinal directions and the names of outlying districts. At least five versions of this map are known to exist, two of which are found in the manuscript titled *Kebrä Nägäst* (The Glory of Kings). Below the circle map is a "wheel of wind" or "wind rose" in which the cardinal directions are again shown with east at the top. More research is needed to examine the relationships between these circle maps and the texts in which they are found.

Evidence of African maps and mapmaking in the nineteenth century is largely found in European accounts of exploration and travel. In many instances, African mapmaking was stimulated by European interest in the geography of unexplored areas. A well-known example is the map drawn by Sultan Bello for Hugh Clapperton during his visit to the Sokoto Caliphate in 1824. Clapperton was particularly interested in the course of the Niger River whose outlet was one of the great geographical mysteries of the day. Sultan Bello drew a map in the sand showing the Niger's course and later reproduced this map on paper which Clapperton published in the account of his journey. Although dismissed by some Europeans as a "rude representation," Bello's map and geographical writings were valued by later explorers like Heinrich Barth in 1859. His map is also of interest because it demonstrates the "rule of ethnocentricity" common to most mapmaking traditions, in which the territory of a cultural group – in this case the Sokoto Caliphate – is placed in the middle of the map.

There are many other examples of Africans drawing maps on the ground in response to European questions on the geography of a particular region. The explorer Charles Beke was shown the incorrect course of the Gojab River south of Abyssinia by a Muslim merchant named Hádji Mohammed Núr who drew its course on the ground with his stick. In 1881, the Bohemian doctor Emile Holub recounts a similar experience when traveling in the mid-1870s in the Marutse Empire of the upper Zambezi River. Before leaving to explore the headwaters of the Zambezi, Holub asked the Maurtse chief, Sepopo, to suggest a good travel route. To Holub's great interest, Sepopo drew a map in the sand whose accuracy was confirmed by two other persons familiar with the area. While on a frontier reconnaissance mission in the dense tropical forests of southeastern Liberia in 1899, the French explorer Capt. Henri d'Ollone asked a person named Tooulou to draw on the ground with a piece of charcoal the distribution of the different ethnic groups in the region. After a moment's reflection and to d'Ollone's great surprise, Toolou drew a detailed ground map showing the location of villages, rivers, and mountains, as well as ethnic groups. The information gained from solicited maps was occasionally incorporated into European maps. For example, sections of the map of the Sahara produced by the French geographer Henri Duveyrier in 1864 were based on maps drawn in the sand by "Cheikh-'Othmàn." The German geographer Karl Weule preserved the maps he solicited by requesting that they be drawn on paper that he provided. Three of these solicited maps are found in Adler's 1910 book.

Among the Luba of central Africa, ephemeral maps were a common feature of initiation ceremonies. During one stage, the initiate is taken into a meetinghouse where elders have chalked maps on the wall showing major lakes and rivers, the location of various chiefdoms, and the dwelling places of spirits. While facing the map, initiates are quizzed about the residence of certain chiefs and spirits within the Luba kingdom. In the final stage of initiation, elders teach initiates about the origins of Luba kingship and customary taboos. In recounting the origin myths, elders use memory boards (*lukasa*) as mnemonic devices to aid their storytelling. These small rectangular boards are covered with beads and shells that map the migration history of the founding royal family. Rivers and villages are represented by the patterning of beads and shells into configurations that are recognizable to initiates.

An example of cosmographical mapping is found among the Bakongo of Zaïre in their initiation and funerary art. The Kongo cosmos is pictured ideographically as the sun moving through four phases: dawn, noon, sunset, and midnight. The cosmogram is composed of a cross representing the cardinal directions with a small circle at each end point. The horizontal line (*kalunga*) divides the realms of the living and the dead through which all persons travel. Only the most courageous and generous in life return as immortal spirits in natural forms and forces in the landscape.

A more secular and ambitious mapmaking took place in the Kingdom of Bamum in contemporary western Cameroun under the leadership of King Njoya. Njoya stands out as a highly creative and politically astute individual who collaborated with a succession of German, British, and French authorities to consolidate his rule. He was responsible for developing an alphabet which enabled him to write the history of his kingdom in his own language. He also appears to have been a self-taught mapmaker whose earliest preserved work (1906) is composed of a plan of his farm and a route map between Fumban, the capital of Bamum, and his fields. Njoya further honed his mapmaking skills when the German cartographer Moisel visited Bamum in 1908. One of Njoya's most impressive mapping projects was a topographic survey of his kingdom that employed up to 60 individuals. When the British took control of western Cameroun from the Germans in 1916, Njoya displayed his political skills by presenting a map of his kingdom to the British political officer stationed in Foumban. This map with its southerly orientation shows a well-defined territory in which all roads lead to the royal capital and historic center of political authority (Fig. 2). In his letter to the King of England that accompanies the map, Njoya seeks British protection against the Germans. In this context, Njoya's map becomes an instrument of power that legitimates his (contested) claim to be the ruler of Bamum and symbolizes his willingness to collaborate with colonial authorities.

In conclusion, the dearth of African maps seems to imply that mapmaking was not a common means of expressing spatial information. One could even argue that the maps solicited by explorers reflected European mapping traditions rather than African custom. However, the ability of individuals from across the continent to produce consistently accurate ground maps suggests that this was an indigenous practice. Ironically, these ephemeral maps led to the drawing of new and improved maps of Africa by Europeans who ultimately employed them in their partition of the continent into colonies.

Maps and Mapmaking in Ancient Egypt

Hans Barnard

Maps, plans and models present a reduced version of the real world, either existing or anticipated, by incorporating selected properties of reality, while intentionally disregarding others. The selection process is governed by the purpose of the final result. Maps and plans are two-dimensional representations of a three-dimensional reality, usually drawn at a smaller scale. This scale need not be uniform for a map to be useful, as clearly shown by the map of the London Underground, and can in special cases be 1 : 1 or even larger than reality. Selected details are replaced by symbols (such as the circles representing cities on a modern map of the world) or ignored (like individual buildings on the same map of the world). Other features are given a distinctive appearance (such as the color of the highways on a modern roadmap) or size (like the exaggerated width of the roads on the same roadmap). Many maps, plans and models are not in fact based on the real world, but rather predate reality which is then changed to fit such designs, blueprints, mock-ups or prototypes. These must have been as perplexing to members of an ancient culture as the Ancient Egyptian maps of the Netherworld, depicting the geography encountered in the afterlife, are to us. Maps and plans from different periods or cultures may not only have an unexpected subject matter, but the scale, symbols and orientation are often very different from what we are used to. Likewise, our convention of having North at the top of a map would not have been understood in Ancient Egypt as this would have the water of the Nile flowing up.

Maps were most likely used in Ancient Egypt since the beginning of the Old Kingdom (2575–2150 BCE according to the chronology of Baines and Malek 2000: 36–37). There are no unambiguous examples of maps from this early period, but there is ample evidence that at least certain members of Ancient Egyptian society were able to create and understand reduced representations of reality (Harrell 2001; Shore 1987). On the well-known Predynastic Narmer palette (dated about 3000 BCE, found in Hierakonpolis, now in the Egyptian Museum in Cairo) one of the images seems to represent a walled city in bird's eye view (Fig. 1). This is obviously not a map in the modern sense, nor is it meant to be, but nevertheless a representation of a geographical reality (a walled city) in a way in which it would not have presented itself to the artist (but rather in bird's eye view). Other early examples of maps include the "topographic design" on a Predynastic ceramic vessel (3700–3100 BCE, provenance unknown, now in the Petrie Museum in London), clearly showing rivers and mountains, and the very schematic "Map of the Netherworld" in the wooden coffin of General Sepi of the 12th Dynasty (1938–1755 BCE, found in al-Bersha, now in the Egyptian Museum in Cairo), showing the landscape awaiting the deceased according to the "Book of the Two Ways." (Fig. 2). Such "mythological" maps do not seem to have a complement in reality, but they must be placed in Ancient Egyptian perspective in which the Netherworld must have been deemed a physical reality and objects could magically obtain a measure of reality just by having been drawn.

A remarkable find from the third Dynasty (2650–2757 BCE) is a sketch of a vaulted roof (on a piece of pottery found in Sakkara, now in the Egyptian Museum in Cairo) on which the lengths of the (temporary) supports or (permanent) beams necessary

to build such a vault are clearly indicated in numbers (Arnold 1991; Edwards 1993). Several more elaborate plans of buildings survive from the Middle Kingdom (1975–1640 BCE). Some were apparently meant as architectural plan, such as the drawing of a garden or a temple on a paving slab from the temple of Pharaoh Mentuhotep of the 11th Dynasty (1975–1940 BCE, found in Luxor, now in the Metropolitan Museum of Art in New York), others seem to depict an existing structure, such as the drawing of his granaries inside the coffin of General Sepi (Arnold 1991; Peck 1978). Many models, mostly of workshops and boats, are known from the Middle Kingdom, for example the exquisite series of models from the tomb of chancellor and chief steward Meketre of the 11th Dynasty (1960–1948 BCE, found in Luxor, now partly in the Metropolitan Museum of Art in New York and partly in the Egyptian Museum in Cairo). Plans and models may not only have been used during the building of a structure, but alternatively to demonstrate its appearance to the client or as a votive item to offer to the gods (Arnold 1991).

As with many other aspects of Ancient Egyptian society, most of our information on ancient maps and plans dates to the New Kingdom (1539–1075 BCE). Examples of mythological maps from this period include those of the Netherworld, for instance in the tomb of Sennedjem in Deir al-Medina dating to the 19th Dynasty (1292–1190 BCE) and as an illustration with Spell 110 of the Papyrus of Any (19th Dynasty, found in Luxor, now in the British Museum in London). These maps are based on texts from the "Book of the Dead" (or the "Book of Going Forth Day by Day"). Astronomical (or astrological?) maps can be found painted on the ceiling of the tombs of the royal architect Senmut in Deir al-Bahri (near Luxor), dated around 1450 BCE, and of Pharaoh Seti I of the 19th Dynasty (1290–1279 BCE) in the Valley of the Kings. These display individual stars and the signs that were associated with them, which are markedly different from the Mesopotamian signs that are used today (Wells 1999). A cosmographical map was carved in the lid of the stone sarcophagus of Uresh-nefer of the 30th Dynasty (380–343 BCE, found in Sakkara, now in the Metropolitan Museum of Art in New York). This complicated image shows the goddess Nut, representing the sky, bending herself over an image of the world, depicted as two concentric disks. The god Shu, representing light and air, is also shown, directing the sun in its course (Hernandez Marin 1992–1994).

There are several plans of buildings and gardens preserved from this period. Some seem likely to depict actual structures, such as the plan of a house in the tomb of Djehuty-nefer and the plan of a garden in the tomb of Sennefer (both in Luxor and dating to the 18th Dynasty, 1539–1992 BCE), others appear to have served as architectural plans. Examples of the latter include part of a plan of a tomb, possibly that of Ramesses IV, on a length of papyrus (1156–1150 BCE, found in Luxor, now in the Museo Egizio in Turin) and another plan of a tomb, possibly that of Ramesses IX, on a flake of limestone (1126–1108 BCE, found in Luxor, now in the Egyptian Museum in Cairo). These plans are not drawn to scale, but have the measurements that were evidently deemed important, written out. Another remarkable feature is that the elevations, rather than ground plans, are shown of the passages between the rooms. The fact that such features occur on both plans indicate that these were most likely drawn to certain rules, much like modern architectural plans, but with different conventions.

The first unequivocal maps also date back to the New Kingdom. One depicts the events during the battle between the most famous Pharaoh of the 19th Dynasty Ramesses II (1279–1213 BCE) and the Hittite king Muwatallis at Qadesh (near modern Homs in Syria) in May 1274 BCE (Baines and Malek 2000: 202–203). Examples of this map can be found, among other places, on the first pylon of Luxor Temple and on the northern wall of the great pillared hall of the Great Temple in Abu Simbel. Shown are the Orontes, the city of Qadesh and the placement of the troops.

A second map from this period, drawn on a length of papyrus found in Deir al-Medina (near Luxor), is most reminiscent of a modern map (Harrell 2001; Shore 1987). It shows the gold mines, stone quarries and settlements in the Wadi Hammamat area, about halfway between Luxor and Quseir (on the Red Sea coast), and can be considered the oldest known geological map (Harrell and Brown 1992). The map, now kept by the Museo Egizio in Turin, was probably prepared by Amennakhte, son of Ipuy, for Pharaoh Ramesses IV (1156–1150 BCE) of the 20th Dynasty (Fig. 3).

Another ancient map with a modern appearance is from the Zenon Archive, dating to the Greco-Roman period (332 BCE–395 CE). This map was found on a length of papyrus recovered from the cartonnage of a mummy unearthed at the necropolis of Ghoran and is now kept in the Institut de Papyrologie de la Sorbonne in Paris (Harrell 2001; Shore 1987). It shows a schematic plan of the dikes and canals on a plot of land in the Fayum, an oasis southwest of Cairo, belonging to Apollonius, head of civil administration under Ptolemy II Philadelphus (285–246 BCE). Astronomical ceilings from this period have been preserved in, for instance, the temples of Edfu and Esna as well as in the Hathor Temple in Denderah (now in the Musée du Louvre in Paris). These show both Egyptian stars, similar to those in the tombs of Semnut and Seti I, and the Hellenistic version of the Mesopotamian zodiac, a fusion that had started during the 27th Dynasty (525–404 BCE), the "Persian Period." The belief that the position of the stars can influence human destiny was probably introduced at a later date.

Alexandria was the capital of Egypt during the Greco-Roman period and by far the most powerful and influential city in the region. Thanks to the patronage of the Ptolemaic rulers and the renowned library of Alexandria (with about 500,000 "books") scholarly and scientific knowledge advanced greatly. This was partly fueled by a renewed onomastic tradition, compiling existing knowledge in long lists. One of the librarians of Alexandria was Eratosthenes, born in Cyrene (Libya) and brought to Egypt by Ptolemy III Euergetes

M

Maps and Mapmaking in Ancient Egypt. Fig. 3 The Eastern part of a topographical and geological map of Wadi Hammamat, in the desert between the Nile and the Red Sea, drawn on papyrus around 1150 BCE (kept in the Museo Egizio in Turin, photograph used with the kind permission of J. A. Harrell).

(246–221 BCE) as a tutor for his son. He is said to have collected a comprehensive geography of the then known world, which is lost but was cited extensively by the Greek geographer Strabo (63 BCE–24 CE). Eratosthenes was also the first to attempt to calculate the circumference of the earth, by comparing the difference in the height of the sun in Alexandria and in Aswan, and came surprisingly close to the actual figure (Berthon and Robinson 1991). A compilation of geographical and astronomical knowledge that did survive is that of Claudius Ptolemy, an Egyptian who lived and worked in Alexandria around 150–200 CE (Dilke 1987: 177–200). His works form the basis of many early Arabic and European maps, especially after some of his works were rediscovered at the end of the thirteenth century CE in Istanbul (Constantinople) by the monk Maximus Planudes (Berthon and Robinson 1991).

The first maps of Egypt by outsiders were drawn in the early Christian period and have been preserved in, for instance, the fifth century CE "Nile mosaic," in Zippori (Sepphoris) in Israel, and the "Mosaic Map" in Madaba (Jordan). The early Christian view of the world that was developed by Cosmas Indicopleustes ("India traveler") also has its roots in Egypt. Born in Alexandria in the sixth century CE, Cosmas was a merchant who, according to his moniker, traveled extensively. Later in life he converted to Christianity and settled in Saint Catherine's Monastery in the Sinai. There he wrote *Christian Topography*, in which he describes the world as a chest, owned by God, of which the lid is the sky and the bottom holds the lands and the seas. The sun orbits a large mountain rising from the bottom of the chest and casting a shadow that is responsible for the night (Dilke 1987: 261–263; Berthon and Robinson 1991). This seems a rather unsatisfactory conclusion of a development that started over 3,000 years earlier and had already resulted in the brilliant works of Amennakhte and Eratosthenes.

Maps and Mapmaking of the Australian Aboriginal People

David Turnbull

One of the most common forms of representation in Australian Aboriginal culture is the map. Bark paintings are often maps, as are sand sculptures, body painting, and rock art. Spear throwers and log coffins may be decorated with maps. Message sticks and Toas (waymarkers) may incorporate geographical information. In 1957 the anthropologist Donald Thomson visited the central Australian desert country belonging to the Pintupi people and described his experience:

> I was able to…live and hunt with a group of desert-dwelling aborigines who still followed the life of their ancestors… On the eve of our going (return) Tjappanongo produced spear throwers, on the backs of which were designs deeply incised, more or less geometric in form. Sometimes with a stick or with his finger, he would point to each well or rock hole in turn and recite its name, waiting for me to repeat it after him… I realized that here was the most important discovery of the expedition that what Tjappanongo and the old men had shown me was really a map, highly conventionalized, like the marks on a "message" or "letter" stick of the aborigines, of the waters of the vast terrain over which the Bindubu hunted.

Tjappanongo was clearly endeavouring to convey topographic information and hence was non-problematically drawing a map. Peter Sutton argues such maps should be distinguished from iconic representations which, while spatial, are largely symbolic and performative (Sutton 1998a: 362). However, it seems plausible to accept an inclusive definition of a map as a device for organizing knowledge spatially, Courts of law are now accepting paintings of the Dreaming tracks of the ancestral beings as evidence of ownership and hence the distinction between maps and icons is becoming blurred (Turnbull 1998). Why then are maps so ubiquitous in a culture that has no written language and, purportedly, has little of the social complexity held to characterize contemporary Western culture? The answer is that Aboriginal culture is far from simple, having as it does one of the richest religious systems in the world, and that its central values are embodied as knowledge; knowledge that is spatially organized because the land and relationships to it underpin everything. Aboriginal culture is spatialized linguistically, socially, religiously, artistically, and epistemologically. Aboriginal ontology is one of spatialized activities, of events and processes, people, and places. To talk of things is to speak of the relationships of processes at named sites, it is to consider the connections between actions of the ancestral beings and humans. Every moment of daily life is replete with spatial references; asking someone to move over may be phrased as "move northwards please". Dreams and narratives are cast in a framework of spatial coordinates. Visiting groups at ceremonial gatherings distribute themselves in a spatial replication of the location of their homelands. Ceremonial and initiation grounds are spatially constructed and oriented either to other sacred sites or to the sun. The pervasiveness of spatiality in Aboriginal daily life jointly derives from the semantic structure of the language in which the subjects of sentences are not things but relations and from the centrality of the land in Aboriginal cosmology. It is the land that is the source of value and meaning, of rights and obligations. Everywhere is sacred since all the land was created in the Dreaming by the activities of ancestral beings as they moved across the landscape. These journeys left Dreaming tracks, knowledge of which is recreated in song, story, and ceremony. Everyone has a spiritual linkage to the land by virtue of birth such that they are the land. Knowledge of the Dreaming tracks, of the activities that created the land of one's birth, is therefore evidence of possession of the land and by the land. Continued prosperity of the land depends on the fulfilment of the ceremonials and rituals which are in effect both a celebration of ownership and a continuation of the act of creation. The landscape is the source of meaning and value and the repository of history and events and can be read as a map of itself and its own creation (Watson, Helen and the Yolngu community at Yirrkala 1993: 36).

However, it is knowledge that is the primary marker of status and the primary item of exchange (Palmer 1991). Surface knowledge is the outside knowledge that anyone can speak of; inside knowledge is that which only the initiated can speak of and which is gradually revealed through life as maturity is attained. The way the Yolgnu of Eastern Arnhemland structure their system is typical of the ways in which it is possible for Aboriginal groups to have a detailed understanding of their environment. Their knowledge system is dependent on the joint articulation of two modes of patterning. One is genealogical – *gurrutu* the kinship system; the other is spatial – *djalkiri* the footsteps of the ancestors or the Dreaming tracks (Watson, Helen, the Yolngu community at Yirrkala, and David Wade Chambers 1989: 37). The kinship system provides an unlimited process of recursion that enables all things to be named and related and thus imposes an order on the social and natural world that gives it coherence and value. It provides the framework within which social obligations with regard to life, death, marriage, and land can be negotiated. The other mode of patterning is provided by the stories, myths, or Dreamings that relate the travels and activities of the ancestors in creating the landscape in the form of tracks or songlines that traverse the whole country. The kinship system and the songlines together form a knowledge network that allows for everything to be connected. The concept of connectedness is an extremely powerful one in Aboriginal culture and is exemplified by the Yolgnu term *likan*, which in the mundane sphere means elbow – the connection of the upper and lower arm – and in the spiritual sphere connotes the connections among ancestors, persons, places, and ceremonies. A wide variety of Australian Aboriginal paintings have been interpreted as being simultaneously geographic and social; they represent both the tracks of the ancestors and detailed maps of places. Hence bark paintings are encoded knowledge of connections.

The Kunwinjku people of Western Arnhemland paint both bark and bodies at the Mardayin ceremony in the "X-ray" style that shows internal body parts. In the Mardayin ceremony the bodies of the initiates are painted so that in effect their own body parts are mapped with a design that represents the body parts of the ancestral beings and features of the landscape. These paintings can be read on one level as maps of the way Kunwinjku "conceive of the spatial organization of sites in their land in terms of an abstract model of the divided yet organically related body parts of the ancestral beings that created those lands. Such sites are described as transformations of the actual body parts of the ancestral being, and all the sites thus created are considered to be intrinsically connected" (Taylor 1989).

The connective function of bark paintings like this helps children to learn the shape of the *wanga* (territory, land, country) and to have respect for it and the animals in it by integrating the activities of the ancestors,

M

people, and places. Ownership of the land thus means having the right speak of the land, the right to have the knowledge of it, and also to have responsibility for both the land, and the knowledge and for its sustenance and transmission.

While the land may have boundaries that can be known with precision, it is not good custom to display them, because they are permeable rather than fixed entities with rites of access being required and most frequently granted. "Boundaries are to cross" (Williams 1983), and "the content of ownership is the right to be asked" (Myers 1986: 99). Areas can be owned by more than one group, and routes can be common property. Boundaries are more properly the subject of negotiation and exchange in ceremony, ritual, and protocol. Protocols are exemplified in the formal role of the go-between, the diplomat or *djarrma* the messenger. Moreover Yolgnu conceptions of place do not correspond to Western legal notions of enclosure but are more typically open and extendable "strings" of connectedness (Keen 1995). Consequently, while Australian Aboriginal groups constantly map their land, this is a very different process from that of the dominant white society. Being mapped in the white manner may have advantages, for example, in making native title claims. In fact it has become standard procedure for anthropologists to record Dreaming tracks on Western topographical maps as evidence that this knowledge is the property of the claimants. Aboriginal relationships with country do not equate with the notions of boundary precision, exclusion, and individual property rights and the linkages to the state implicit in Western maps. Aboriginal maps keep those relationships alive by celebrating and performing connections between people and land in stories, ceremony, and painting.

Maps and Mapmaking: Celestial East Asian Maps

F. Richard Stephenson

For the purpose of this article, East Asia will be understood to comprise the three countries of China, Korea and Japan. In common with many other aspects of culture, mapping of the night sky in both Korea and Japan began much later than in China and closely followed the Chinese tradition.

The origins of celestial mapping in East Asia are lost in the mists of time. Very ancient rock carvings clearly depicting the Big Dipper have been found in North Korea, and these are considered to be date from several thousand years BCE. Occasional stellar names – such as *Dou* (the Ladle: presumably the Big Dipper) and *Huo* (the Fire Star: probably identified with the bright red star Antares) – are recorded on Chinese bone inscriptions from the Shang Dynasty (ca. 1500–1050 BCE). Several of the folk songs in the *Shijing* (Book of Odes) – some of which may date from around 1000 BCE – mention star groups. One of these odes cites the names of four asterisms: the Celestial Han River (i.e. the Milky Way), the Draught Ox, the

Winnowing Basket and the Ladle. The description of the Ladle is fairly specific: “In the north there is the Ladle; it raises its western handle”. The apparent motion of the Big Dipper around the north celestial pole has provided a convenient seasonal and hourly marker to a variety of civilisations since remote antiquity.

The first known systematic list of constellation names from East Asia dates from around 433 BCE. This was uncovered in 1978 from a tomb in Hubei province and lists the names of all 28 *xiu* (lunar lodges): asterisms which were of key importance in astrology and positional astronomy. There is a persistent tradition that detailed mapping of the stars began in China during the fourth century BCE with the work of astronomers such as Shi Shen and Gan De. However, the evidence to support this notion is relatively late: no earlier than the seventh century AD. Modern investigations of the measurements in a portion of a star catalogue supposedly compiled by Shi Shen and preserved in the eighth century *Kaiyuan Zhanjing* (Kaiyuan Treatise on Astrology) have indicated a date around 70 BCE.

The earliest catalogue of constellations covering the whole of the sky visible from China is preserved in the *Shiji* (Records of the Historian). This was compiled by Sima Qian around the middle of the Former Han Dynasty (202 BCE to AD 9) and gives brief qualitative descriptions of about 100 star groups. Later catalogues list as many as 280 separate asterisms.

The oldest surviving astral map from China dates from the first century BCE, towards the end of the Former Han Dynasty. Beginning with this dynasty, the development of celestial mapping in China can be traced with increasing confidence, although it is known that many important star charts and celestial globes have failed to survive. Since the stars appear to us as scattered points of light, any attempts to divide them into groups must necessarily be artificial. This is illustrated by the great diversity between the constellation patterns as depicted on Eastern and Western charts of the night sky. Chinese and other East Asian stellar maps further differ from their Western counterparts in the following ways:

- There is virtually no symbolic representation of the constellations by human or animal figures, etc;
- Star groups tend to be much smaller, typically containing only about five stars;
- Individual stars are represented by circles or dots of almost equal size – regardless of brightness; and
- An equatorial (rather than ecliptic) co-ordinate system is standard, with division of the sky into 28 unequal zones of RA, the *xiu*.

Chinese celestial mapping reveals negligible traces of Western influence (whether of European, Arab or Indian origin) until as late as the seventeenth century when the Jesuits introduced improved knowledge and techniques.

Whereas many Western constellation names are derived from Babylonian and Greek mythology, Chinese names tend to be much more mundane. From an early period, the celestial vault came to be regarded as a direct counterpart of the Chinese empire. Star groups, together with certain individual stars, were regarded as representing members of the imperial family, courtiers and other officials – as well as domestic animals, crops and important buildings (from palaces to prisons). Any event occurring in a particular constellation – such as the appearance of a planet or comet, or “new star” – was regarded as an omen of change affecting the terrestrial equivalent.

Until about 30 years ago, very few Chinese celestial maps were known to be extant from before AD 1000. In his *Shiji*, Sima Qian asserted that an “astronomical chart” was depicted on the ceiling of the tomb of Qin Shihuang, the first Emperor of China, who died in 213 BCE. This has yet to be excavated. However, recent excavations at a variety of sites have brought to light a number of important star charts, mostly decorating the ceilings of tombs. The earliest surviving such artefact depicts only 28 star groups – the lunar lodges. This rather crude but colourful painting adorns the ceiling of the tomb of an official of the Former Han Dynasty. It was discovered accidentally in 1987 during building work in Xi’an, near the site of the Former Han capital. Coins found on the floor of the tomb date from around 25 BCE. Individual constellations are depicted in a ring of approximate diameter 2.5 m; stars – represented by small circles – are joined into groups by straight lines, as in most later astral maps.

No further chart of the night sky is preserved until the sixth century AD, but there is documentary evidence that a number of accurate stellar charts and celestial globes were produced by leading astronomers in the intervening time. Around AD 250, Chen Zuo is said to have produced a map of the stars based on the schools of the ancient astronomers. This was said to represent 1,464 stars in 283 groups – numbers which were to become almost canonical. The purpose of such artefacts was to predict the risings and settings of the constellations as well as to follow the movements of wandering celestial bodies such as planets and comets. Unfortunately, none of these works survived for more than a century or two.

A star map dating from AD 526 was discovered during excavations at Luoyang – another ancient capital of China – in 1973. This chart is painted on a tomb ceiling of the late Wei Dynasty (AD 386–557), and is some 3 m in diameter. The Milky Way features very prominently, but the constellations are very sketchily depicted. Clearly, there is no particular reason why stellar maps painted on tomb ceilings should compare in quality with those produced by contemporary astronomers.

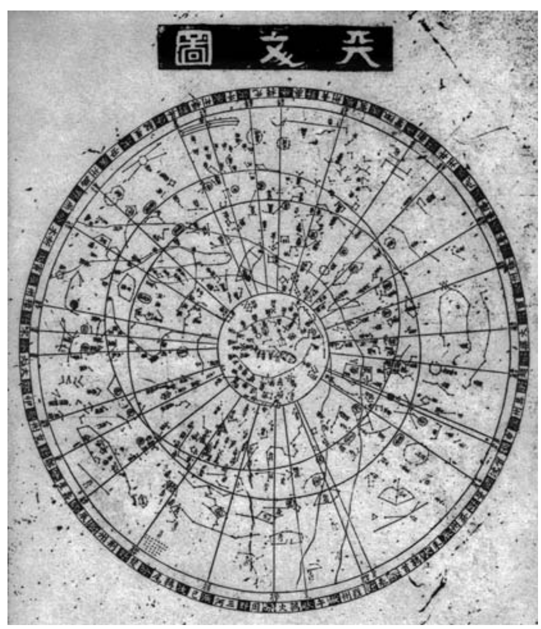
After AD 526 until well into the tenth century AD, only a single important celestial map survives. This paper chart, measuring approximately 110 × 25 cm, was amongst the vast number of manuscripts uncovered by Sir Aurel Stein in a Buddhist grotto at Dunhuang (Xinjiang province) in 1907. The crude but attractive chart, which is now in the British Library, portrays – in 13 sections – the whole of the night sky visible from China. Stars are depicted in three colours (red, black and yellow), possibly reflecting a tradition which had its roots in the Warring States Period. A suggested date for this interesting artefact is around AD 700.

A few decades ago, two huge star maps, dating from AD 941 and 952, were uncovered from the tombs of Prince Qian Yuanguan and his wife Wu Hanyue. Qian Yuanguan was ruler of the small state of Wuyue in eastern China, the capital of which was close to present-day Hangzhou. The two star charts, each some 2 m in diameter, were engraved on thick stone slabs which formed the ceilings of the tombs. Regrettably, the map from the tomb of Wu Hanyue was destroyed during the cultural revolution, although an accurate scale drawing is preserved. Fortunately, the chart from the tomb of Qian Yuanguan still survives, although it is badly damaged. This latter chart depicts with fair accuracy the 28 lunar lodge constellations, together with a few polar star groups. The celestial equator and north circumpolar circle (circle of constant visibility) are also carefully positioned.

Many astral maps and celestial globes are known to have been produced during the highly advanced Song Dynasty (AD 960 – 1279) in China, but most have long since disappeared. Only one of the *original* artefacts of any consequence, dating from AD 1247, is known to exist today. This remarkable chart was produced by a scholar and was intended for the instruction of a future emperor. It is exhibited at the Suzhou (=Soochow) Museum in Jiangsu province. The circular chart, 1.05 m in diameter, is engraved on a stele measuring 2.2 × 1.1 m. The surface is still in very good condition and rubbings are occasionally taken. Entitled *Tianwen-tu* (Astronomical Chart), the map portrays the whole of the sky visible from central China on a polar projection. A recent count asserts that it depicts 1,436 stars in 277 constellations. Celestial equator, ecliptic and polar circles are shown, together with radial lines representing the boundaries of the lunar lodges; the Milky Way is also clearly depicted. Modern measurements demonstrate that most star positions are accurate to within about 2°, which represents tolerably good precision (Figs. 1 and 2).

The great Song Dynasty astronomer Su Song is known to have produced a celestial globe 1.7 m in

Maps and Mapmaking: Celestial East Asian Maps. Fig. 1 "Star observing tower" at Kyongju, Korea, dating from AD 647 (photograph courtesy of Prof Nha Il-Seong, Seoul).



Maps and Mapmaking: Celestial East Asian Maps. Fig. 2 Computerised reversal (i.e. black on white) from rubbing of the Suzhou star chart (the star chart is in the Suzhou Museum, Jiangsu Province, China).

diameter in AD 1092. This was said to represent 1,464 stars in 283 constellations – standardised figures since ancient times. Although the globe was destroyed a few decades afterwards, star charts in extant copies of Su Song's *Xinyi xiang fayao* (New Design for an Armillary and Globe) are believed to reproduce closely the star patterns on the celestial globe. Copies of an these charts, which were first printed in AD 1094, are still available, although the earliest extant version dates from AD 1781; this is now in the National Library at Beijing. The entire night sky as seen from Central China is portrayed in five sections. One of these sections, depicting the southern hemisphere, has a central void; this corresponds to the region of the sky near the south pole which was permanently below the horizon at the Chinese capital (Kaifeng) of the time. Apart from isolated constellations such as *Denglonggu* (Frame of the Lantern, identical with the Southern Cross), no far southern stars appear to have been mapped in any detail until the Jesuit era. Careful modern measurements show that typical positional errors on the Su Song maps – or at least the extant copies – are fairly large, some as much as 4°.

In recent decades, several well-preserved celestial charts have been uncovered during excavations of Buddhist mausoleums of the Liao Dynasty (which flourished in Northern China between AD 916 and 1125). Two of these colorful artefacts, painted on the ceilings of tombs, are particularly interesting. As well as depicting stylised versions of the 28 lunar lodge patterns, they also show symbols – rather sinified – representing the 12 signs of the Western zodiac. A large bell, cast in AD 1174, is also adorned with the zodiacal signs. The signs of the zodiac were first introduced into China around AD 600, with the translations of Buddhist *sūtras*. Not long afterwards, during the Tang Dynasty (AD 618–907), horoscope astrology – based on Western methods – became popular in China. However, this had negligible effect on official practice – e.g. at Court. No significant pictorial relics survive until long after the end of the Tang.

A number of substantial star maps are preserved from the Ming Dynasty (AD 1368–1644), but apart from those revealing Jesuit influence (after about AD 1630), none is of the caliber of the Suzhou chart of AD 1247. Commencing in the late Ming, members of the Society of Jesus made important contributions to astronomy in China, and for nearly two centuries (from AD 1644 to 1826) Western missionaries held the position of Astronomer Royal in China. Today, many fine Jesuit celestial globes and maps produced in China still survive. These include works by Adam Schall von Bell (AD 1634), Ferdinand Verbiest (1673) and August von Hallerstein (1757). The Jesuit astronomers did not try to supplant the Chinese constellations with those of Western origin. However, they measured stellar positions in existing asterisms with hitherto unrivalled precision and in some cases added further stars to individual groups – as well as bringing knowledge of the far southern stars which are invisible from China. All significant representations of the night sky throughout the Qing Dynasty (AD 1644–1911) either directly or indirectly reveal Western influence in these ways and are thus outside the scope of this article.

Korea

The earliest surviving astral map produced in Korea dates from AD 1395. Entitled *Ch'onsang yolch'a punyajido* (chart of the regular division of the celestial bodies), this left a lasting impression on celestial mapping in Korea. Indeed, until the end of the last dynasty (the Yi) in AD 1910, virtually all surviving star charts produced in Korea which do not show Western influence appear to be based on it. History records that the original celestial map, which is 90 cm in diameter and engraved on a marble slab measuring 2.1 × 1.2 m, is an accurate reproduction of a much older map which had been presented to Koguryo, one of the three early kingdoms of Korea, by a Chinese emperor. Although this stele was abandoned in a river during a battle in the Korean peninsula in AD 670, a rubbing still survived in 1395, and this was used to make a new engraving. On the reverse of the stele is a virtually identical copy which may possibly date from AD 1425. Both the AD 1395 chart and a careful stone replica produced in 1687 are still preserved in Seoul museums. They are in good condition, although the earlier artefact has suffered damage down the centuries – notably during a Japanese invasion in AD 1592 (Fig. 3).

Each of the stone engravings depicts the usual circles and lunar lodge boundaries, as well as the Milky Way. However, several constellation patterns differ considerably from medieval Chinese representations, while modern measurements of the star positions suggest an early date – possibly around 30 BCE. Hence the two steles may well preserve traditions of celestial mapping which are far older than the detailed Chinese charts which are still accessible today.

Japan

In 1973, a crude chart showing the 28 lunar lodges in a square measuring 80 × 80 cm was discovered on the ceiling of a Japanese tomb dating from around AD 700. This work, the earliest Japanese celestial chart so far discovered, clearly shows Chinese influence. Detailed maps and globes of the night sky based on Chinese originals are known to have been produced at various stages in later Japanese history. However, none has survived before the sixteenth century. A chart compiled by Ase Yasuyo around AD 1315 was the oldest extant

Maps and Mapmaking: Celestial Islamic Maps. Fig. 3 Computer scan of Korean star chart engraved in AD 1687. This chart, engraved on stone, is an accurate copy of a damaged stone chart dating from AD 1395 (illustration courtesy of Prof Nha Il-Seong, Seoul).

Japanese celestial map until it was destroyed near the end of the Second World War. Fortunately, some replicas still exist. The chart – in two sections – showed the Chinese constellations, ecliptic, celestial equator, Milky Way and the lunar lodge boundaries. It was designed to assist the observation of lunar conjunctions with stars.

The two oldest extant star maps of Japanese origin both date from around AD 1540. Each is circular, extending from the north celestial pole to the region of perpetual invisibility (the area of sky always below the observer's horizon), and shows the traditional Chinese constellations and co-ordinates. Both the Suzhou celestial map of AD 1247 and the Korean chart of AD 1395 have had an important effect on Japanese celestial cartography and many copies of each from the seventeenth century onwards can be found in Japan.

In recent decades, the study of East Asian celestial cartography has been enhanced by the growing worldwide interest in records of comets and supernovae recorded in China, Korea and Japan. The positions of these celestial bodies were often carefully described in relation to specific star groups. In order to trace the movements of comets (notably Halley's Comet) or deduce the locations of past supernovae, it is necessary to make a detailed investigation of the individual constituents of asterisms with reference to modern star catalogues. This work continues.

Maps and Mapmaking: Celestial Islamic Maps

Emilie Savage-Smith

The earliest evidence of Islamic interest in celestial mapping is a vaulted ceiling in a small eighth-century provincial palace, known as Quṣayr ʿAmrah, in the desert of present day Jordan. One of the bathrooms in this palace has a domed ceiling painted to resemble the vault of the heavens. It is the oldest astronomical dome of heaven preserved today. Though the ceiling has badly deteriorated, enough remains to ascertain that the artist was influenced by late Antique and Byzantine two-dimensional flat maps of the skies. The iconography of the constellation figures, the lack of stars, and the method of projection are in keeping with classical and early Western medieval maps of the heavens. The sequence of the constellations on the domed ceiling, however, is not as one would see it when looking up into the sky, but rather as it would appear when looking down onto a celestial globe (see Savage-Smith, Celestial mapping).

The celestial globe is the oldest form of celestial mapping, for its origins can be traced to Greece in the sixth century BCE, though the earliest preserved example is an eleventh-century Islamic globe made in Valencia. This three-dimensional model of the skies presented the stars as seen by an observer *outside* the sphere of stars, so that the relative positions of the stars are the reverse, east to west (or right to left) of their appearance when viewed from the surface of the earth. Islamic celestial globes were made from the ninth through the nineteenth centuries, steadfastly maintaining the basic classical design and encouraging the concept of a spherical universe rotating around the earth.

No flat two-dimensional star maps on paper or parchment from Islamic lands have survived, if indeed any were made, although planispheric maps of the skies drawn on parchment exist today from the Roman and Byzantine worlds. Displaying the entire surface of a sphere on a flat surface – such as parchment or paper or a metal plate – requires a system of mathematical projection. In addition to the method called stereographic projection known in late antiquity, other methods for flat mapping were described in the early eleventh century by the versatile scholar Abū al-Rayḥān Muḥammad ibn Aḥmad al-Bīrūnī (b. 973) working in Iran. Three of his proposed methods correspond in modern terms to orthographic projection, azimuthal equidistant polar projection, and globular projection. His ideas, however, appear to have had no direct effect upon subsequent celestial mapmaking in the Islamic world, and no maps employing these novel methods are known today (see Savage-Smith, 'Celestial mapping').

The evidence for Islamic interest in flat mapping of the entire sky is found only in instrument design and production. The flat, planispheric astrolabe was, in fact, the most commonly used form of celestial map in the Islamic world, for it consisted of a pierced star map placed over a projection of the celestial coordinate system as it related to the observer's position on earth. The resulting representation of the positions of the stars with respect to the local horizon forms a two-dimensional model of the heavens. The method of stereographic projection required for the astrolabe's construction was certainly described by the Greek astronomer Ptolemy in the first century AD, though not the instrument itself. It was also Ptolemy who compiled a star catalog giving coordinates for 1,022 stars, with descriptions of 48 constellation outlines based mostly on Greek mythological characters which served as mnemonic devices for mapping the skies. This star catalog was the basis for all the medieval Islamic star catalogs as well as instruments employing stars (See Kunitzsch and Knappert). It seems certain that the astrolabe was a Greek invention, but its design and production were perfected in the Islamic world, where it was manufactured in many variations from Spain to India from the early ninth through the nineteenth century.

The influence of early modern European celestial mapping is evident in an astrolabe plate engraved in Iran in 1654–1655 by the instrument maker Muḥammad Mahdī of Yazd. His metal plate reproduces the northern and southern hemispheric maps from a planispheric celestial map printed about 1650 by the Parisian engraver Melchior Tavernier, whose brother Jean-Baptist Tavernier had made six trips to the Near East before his death in 1689 and probably served as the conduít by which the map reached Iran. Tavernier's star map included the new chartings of the southern skies at the end of the sixteenth century, and these were carefully rendered by Muhammad Mahdī, who changed the labels of the Ptolemaic constellations into Arabic, but did not attempt to give Arabic names to the newer non-Ptolemaic constellations. Muḥammad Mahdī made at least two additional copies of these plates, but they appear to have had no subsequent influence on Islamic celestial cartography (See Savage-Smith, Celestial mapping; and also Savage-Smith Wake field).

Celestial space was also often represented by schematic diagrams that did not involve the mathematical determination of coordínates (necessary for globes) or methods of projection (required for planispheric maps or astrolabes). In such diagrams, concentric circles were often used to indicate in general terms the orbits of the planets and the sphere of the stars about the earth, which was viewed as being at the center of the universe. More complex and abstract diagrams illustrating the orbit of an individual planet employed concentric and eccentric circles to explain the peculiarities of the planet's path (see Van Brummelen).

Mapping the entire sky or heavens was not the only form of celestial mapping to occupy Islamic thinkers. Maps of individual constellations rather than the entire sky had the advantage of not employing a coordinate system or requiring knowledge of projection methods. The most important guide to constellation diagrams in the Islamic world was undoubtedly an Arabic treatise written in the tenth century by ʿAbd al-Raḥmān ibn ʿUmar al-Ṣūfī, a court astronomer in Isfahan. He provided two drawings of each of the 48 classical constellations, one as it would be seen in the sky by an observer on earth and one as it appears on a celestial globe (see Wellesz). According to one account, al-Ṣūfī obtained his images by laying very thin paper over a celestial globe and tracing the constellation outlines and individual stars. While taking pains to make clear to the reader the mirror–image relationship between constellations as imagined in the sky and those on a celestial globe, by treating each one individually al-Ṣūfī ignored the spatial interrelationships of the constellations to each other. Al-Ṣūfī also preceded the discussion of each constellation with a survey of traditional Bedouin constellations visualized in the same area of the sky, such as the constellation of a lion much larger than Leo with gazelles running before the large lion.

Numerous copies of this popular treatise exist today, with dress and general presentation of the figures changed to reflect local artistic fashions and conventions, and many later writers incorporated the constellation images into their treatises. Sometimes in later works the constellations were illustrated without stars, with only the animal or human mythological form that gave rise to the constellation outline, and occasionally even the understanding of the mythological figure was lost or confused. The diagrams of individual constellations of stars yielded an easily understood nonmathematical guide to portions of the skies, while giving wide scope to the artist in interpreting the animal and human outlines.

Another form of Islamic celestial mapping was the emblematic or symbolic representation of celestial bodies (planets as well as constellations of stars) and their spatial relationships. The 12 zodiacal signs were often represented as emblematic motifs rather than as constellation diagrams. No attempt was made to represent the stars forming the asterism or even the basic outline of the constellation. Rather, each constellation was represented by a commonly accepted convention, such as a two-headed man sitting cross-legged for Gemini, or for Libra a squatting man with scales over his shoulders or held overhead. The seven classical planets (Moon, Mercury, Venus, Sun, Mars, Jupiter, and Saturn) were designated by human personifications. Venus, for example, was portrayed as a woman playing a lute-like instrument or Jupiter as a man reading a book. In astrological writings, zodiacal signs were related to the planets by a series of “domiciles.” Thus the moon was most frequently associated with, or domiciled in, Cancer, and the sun in Leo. The remaining five planets were each assigned two zodiacal signs as their domiciles; Venus, for example, was assigned to both Libra and Taurus. Artisans working in metal or with manuscript painting would represent these spatial relationships by depicting Taurus as a bull ridden by a lute player (Venus), or Cancer with a lunar disk, or Leo as a lion surmounted by the radiant disk of the sun. In a second system, the zodiacal signs were combined with the “exaltation” or “dejection” of a planet, which could also be represented symbolically. The lunar nodes (the northern and southern intersections of the moon’s orbit with the ecliptic) were referred to as the head and tail of a dragon, which came to be regarded as a pseudo-planet associated with Sagittarius and Gemini and often represented graphically. Such symbolic representations of celestial bodies and their spatial relations formed an important part of medieval Islamic understanding and graphic interpretation of the heavens. They did not require the difficult technical knowledge necessary for geometrically projected mappings and they were an attractive subject matter for artists to interpret flexibly (see Savage-Smith, ‘The Islamic Tradition’).

Each type of Islamic celestial mapping was directed at a different audience. The fairly educated audience who could interpret the symbolic and allegorical representations of celestial bodies was probably more select than those who could appreciate a constellation diagram. Different still would be those who could appreciate as a scientific instrument the celestial globe with its stars positioned by coordinates or the astrolabe with the stellar coordinates projected geometrically onto a flat plate. The Islamic world’s apparent lack of flat stellar maps of the entire visible sky drawn on paper or parchment has yet to be fully explained (see Sabra).

Maps and Mapmaking in China

Cordell D. K. Yee

The Chinese have one of the world’s longest histories of mapmaking – more than 2,000 years. An adequate account of this history, however, has yet to be written. For some time spans, the first to the tenth centuries, for example, losses from warfare and neglect have probably been great. Almost no examples of maps remain, so that one must make inferences on the basis of textual sources and other evidence. For other periods, especially from about the seventeenth century on, so many maps, as well as supplementary textual sources, survive that no one has adequately surveyed them.

Despite these difficulties, it is still possible to make some broad generalizations. Before the twentieth century, mapmaking in China was an activity of the educated elite, those who formed the pool from which posts in the government bureaucracy were filled. In the course of their duties, these scholar-officials developed mathematical techniques and instruments needed to produce measured maps of high accuracy. Such maps have features familiar to users of modern maps – scalar indications, directional markers, conventional signs to represent topographic features, and a lack of perspective. Their look is planimetric, all features being represented as if lying on the same plane and as if viewed from above. Maps like these form only a portion of the body of surviving works, and partly for this reason it would be misleading to characterize Chinese mapmaking before the twentieth century as what we in the West now call science. As will be discussed later, it was a broader activity than the word "science" usually connotes, one that often involved measurement.

The foundations for quantitative mapping were established early in China's cartographic history. The magnetic properties of lodestones, or south-pointers, were known from about the third century BCE. There is textual evidence that during the second century BCE the idea of map scale was understood. Around this time Chinese surveyors and mapmakers already had considerable technical resources available to them for producing maps drawn to scale: graduated rods, carpenter's squares, plumb lines, and compasses for drawing circles, and even sighting tubes that could be used for measuring inclination. In addition, a reference frame suggestive of a coordinate system for identifying locations had been hinted at by astronomers who divided the heavens into sectors, or lunar lodges (*xiu*).

A few hundred years after these beginnings, Pei Xiu (223–271), a mapmaker known for large-area maps drawn to scale, formulated a set of principles necessary to produce accurate maps. These principles stressed the importance of consistent scale, directional measurements, and adjustments in land measurements to correct for irregularities in the terrain being mapped. The principles had some influence on later mapmakers. Jia Dan (730–805) drew a large-area scale map following Pei Xiu's principles, as did Shen Kuo (or Gua, 1031–1095). But none of the works by these mapmakers survives, so that it is impossible to judge how well they followed Pei's principles. Moreover, none of Pei's own work survives, so it is not known how well Pei followed his own ideas.

Some researchers have claimed that maps dating from the fourth to the second century BCE are evidence that mensurational techniques were being applied to mapmaking (Cao, Vol. 1, plates 1–2). One of these, discovered in Hebei Province, is a bronze architectural plan of a mausoleum. Perhaps better-known examples are two silk maps discovered at Mawangdui, near Changsha, Hunan (Cao, Vol. 1, plates 20–21, 25–26). Other early maps are a set of maps drawn on wood discovered at Fangmatan in Gansu (Cao, Vol. 1, plates 4–17). There is some disagreement over what areas the maps found at Mawangdui and Fangmatan represent and how they should be reconstructed. Such questions need to be resolved before it can be determined whether the maps were drawn to scale. Pei Xiu, in articulating his principles of mapmaking, had complained about the lack of accuracy in maps before his time. It is not yet clear whether his assessment of his predecessors was justified.

In any case, a map produced within a half century of Shen Kuo's death suggests that mapmakers were capable of following Pei's principles quite rigorously: this is the much celebrated *Yu ji tu* (Map of the Tracks of Yu [the Great, legendary emperor]) (Cao, Vol. 1, plates 57–59; ►http://www.henry-davis.com/MAPS/EMwebpages/218.1.html). It was carved in stone in 1136 and measures 80 × 79 cm. It represents all of China, and is impressive for the accuracy of its depiction of China's coastline and the courses of the Yellow and Yangtze Rivers. The map is also notable for the square grid imposed on its surface. According to a note on the map, each grid increment represents 100 Chinese miles. The grid is thus a scaling device, not a coordinate system like latitude and longitude. After the *Yu ji tu* the best known examples of grid maps are printed in the *Guang yutu* (Enlarged Terrestrial Atlas, ca. 1555) by Luo Hongxian (1504–1564) (Cao, Vol. 2, plates 147–156). This atlas is a revision of a map no longer extant, the *Yutu* (Terrestrial map, 1320) by Zhu Siben (1273–1337). It contains a general map of China and individual maps of provinces, all with grids. According to Luo, the grid, in addition to serving as a scaling device, served as an aid in aligning sections of maps drawn or printed on different sheets.

The origins of the Chinese cartographic grid are unknown. Its use is certainly consistent with Pei Xiu's call for scale and attention to directions, and it has some similarities with the lunar lodges long used in Chinese astronomy. The polymath Zhang Heng (78–139), credited with an armillary sphere, a seismograph, and a topographic map, has been suspected of using a grid. But there is no direct evidence that any mapmaker before the *Yu ji tu* employed the device.

On other Chinese maps made at roughly the same time as the *Yu ji tu*, the grid is conspicuous by its absence, perhaps an indication that their makers were not particularly concerned with measurement and scale. A number of these maps are, like the *Yu ji tu*, engraved in stone, but are not considered as accurate as the *Yu ji tu*: for example, the *Hua yi tu* (Map of Chinese and

Foreign Lands, 1136) (Cao, Vol. 1, plates 60–62; ►http://www.henry-davis.com/MAPS/EMwebpages/218.html), engraved on the other side of the stone on which the *Yu ji tu* appears, and the *Jiu yu shouling tu* (Map of the Prefectures and Counties of the Nine Districts [the empire], 1121) (Cao, Vol. 1, plates 63–65). As their titles suggest, these maps, like the *Yu ji tu*, represent all of China. An example of a stone map depicting a smaller area is the *Pingjiang tu* (Map of Pingjiang Prefecture, 1229) (Cao, Vol. 1, plates 79–81). It, too, lacks a grid, and its scale has been found to vary from about 1:1,300 to 1:2,800 in the central portion and from about 1:10,000 to 1:77,000 at the periphery.

The evidence thus suggests that by the twelfth century Chinese mapmakers had the resources to produce measured maps of high quality, but in many cases did not make full use of those resources. This is not necessarily a defect. In general Chinese mapmakers seem to have regarded their task as encompassing more than representation according to a consistent scale. The Chinese word *tu*, commonly translated as map, also means picture, diagram, or chart. As the range of meaning suggests, the forms of Chinese mapmaking extend beyond what are easily recognizable as forerunners of modern measured maps.

Maps served a variety of functions for which uniform scale might be necessary or desirable: navigation, water conservancy, public works, defense and military planning, government administration, and record keeping for land tax accounting. But they also served purposes for which attention to scale might not be so important: they might be used to symbolize political power, to represent unseen other worlds, or to illustrate configurations of energy (or *qi*), knowledge of which was useful in "siting" (*dili* = land patterns or geonomy, or more popularly, *fengshui* = wind and water or geomancy) (Fig. 1).

Maps and Mapmaking in China. Fig. 1 Pictorial map of Hainan island dating from the nineteenth century. Notes on the map describe marriage and other ceremonies of the Li people. The mapmaker has distorted the shape of the island so that it resembles a rectangle, an auspicious form. North is at the bottom. Ink and color manuscript, 184 × 93 cm. Courtesy of the Library of Congress (G7822.H3E62 18–.H3 Vault).

The media used for mapmaking also show considerable diversity. Already mentioned have been flat maps engraved on bronze and stone, drawn on silk, wood, and paper, and printed with woodblocks on paper. Maps were also painted on walls of caves and tombs. Three-dimensional relief models were also made. One of the largest of these, described in the *Shi ji* (Records of the Grand Historian, ca. 91 BCE, by Sima Qian), is contained in the tomb of Qin Shihuang (d. 210 BCE), founding emperor of the Qin Dynasty (221–207 BCE). It supposedly consists of representations of the heavens above and the empire below, with mercury-filled streams representing rivers and the sea.

Mapmaking in pre-twentieth-century China did not develop into a distinct specialty of learning as it did in Europe. As the variety of map functions suggests, mapmaking was located at the intersection of a number of activities and traditions of learning. This is consistent with the educational background of the intellectual elite who made maps. Their educations generally emphasized broad learning, frequently encompassed humanistic and scientific disciplines, and often centered around texts. Not surprisingly the activity of mapmaking often involved textual study. This was the case with Pei Xiu, Jia Dan, Shen Kuo, and Luo Hongxian, those who are credited with advancing quantitative mapmaking techniques.

Among the major sources of geographic information a mapmaker might consult were the dynastic histories, which conventionally included geographic records, and local gazetteers, compendia of historical and geographical information focusing on China or one of its various subdivisions. Gazetteers often included maps, usually at the head of the geographic section. These maps often lack scalar indications and are frequently pictorial. In such instances, they do not seem to have been intended to be used or studied in isolation, but were meant to be complemented by the accompanying text. The maps give an idea of the spatial relationships between geographic features, while the texts provide detailed information on distances and directions. This relationship between image and text does not seem to have been restricted to maps in gazetteers. Jia Dan and Shen Kuo, for example, say that their maps were accompanied by extensive notes, and Luo Hongxian's *Guangyu tu* consists mostly of text.

The relationship between map and text seems to reflect the close ties among painting, calligraphy, and poetry. From about the tenth century on, many Chinese artists, themselves often members of the bureaucratic elite, conceived the highest work of visual art as a combination of all three arts, each contributing in different ways to the aesthetic effect of the entire artifact. *Tu* (maps or pictures) of geographic subjects often had poems inscribed on them, suggesting that maps were valued like other forms of visual art for their emotional and expressive effects (Figs. 2 and 3). In addition to employing quantitative techniques and devising means to present the information gleaned from those techniques, Chinese mapmakers drew upon the resources of the visual arts to express their responses to the land. The "language" of Chinese maps thus seems to have been more than one of denotation, of correspondence to material realities. This seems to be true even with maps of utilitarian function. Scholars have long noted, for example, that some of the representations on the nautical chart in the *Wubei zhi* (Treatise on Military Preparations, ca. 1621, comp. Mao Yuanyi) resemble elements often seen in Chinese landscape paintings (Cao, Vol. 2, plates 168–171).

Maps and Mapmaking in China. Fig. 2 Poetry on scroll bearing map, stamped in red ink (at *lower left*). The couplet, by the poet Du Fu (712–770), reads: "Most certainly this is Jiangnan's lovely landscape;/In the season when the leaves fall I meet with you again." The couplet was stamped in response to a long map, a detail of which appears in Fig. 3. (*Minsheng yanchang quantu* (Complete Map of the Salt Fields in Fujian, 1746). Courtesy of the Library of Congress (G7823.F8H5 1746.M4 Vault Shelf).

One result of the interactions between mapmaking and other areas of learning seems to be that grid maps in particular and measured maps in general constitute a small proportion of the surviving corpus of Chinese maps made before the twentieth century. The disparity in the numbers of measured maps and more pictorial maps seems especially pronounced during the seventeenth through the nineteenth centuries, long after the development of woodblock printing, which made possible the relatively quick production of multiple copies of maps (see Fig. 3). This disparity has fostered the conclusion that after the sixteenth century Chinese mapmaking declined, as mapmakers seemed to pay less attention to quantitative techniques and accuracy.

It is just as reasonable to view Chinese cartographic history after the *Yu ji tu* not simply as a decline in mapmaking, but as an implicit, if not conscious, rejection of the measured map as the representing mapmaking at its best. A mathematical map is reductive in at least two ways: a quantitative approach regularizes the earth's surface, and is less challenging and demanding than a qualitative approach. A mathematical map can be drawn by almost anyone; pictorial maps with their greater detail require more advanced drawing skills. The compilation of a map like the *Yu ji tu* is an impressive achievement. But once it is drawn, it is simple to draw it again. Pictorial maps are visually more complicated.

Chinese mapmakers seem to have noticed the same difference and preferred maps that allowed them to demonstrate artistic skill. An index of this preference is the large number of manuscript maps intended as final products, even after the development of printing. In Western Europe manuscript maps intended as final products are rare after the advent of printing. Mathematical techniques and printing technology made possible the production of large numbers of exact copies of originals. Yet in China, scholar-officials often copied maps by hand, introducing variations, or drew their own maps. The production of manuscript maps was an opportunity to display skill with the brush both in painting and in the art of writing – possibly one reason for the close ties between mapmaking and landscape painting.

Thus it is no surprise that in China there was little innovation in measured mapping, little interest in developing quantitative technique further, after the twelfth century. Improvements in the mariner's compass

Maps and Mapmaking in China. Fig. 3 Mingsheng yanchang quantu (Complete Map of the Salt Fields in Fujian, 1746; detail). The look of this map belies its use in law enforcement – as an aid to prevent salt smuggling. Ink and color in silk, 33 × 571 cm. and measurements of celestial latitude, for example, do not seem to have influenced Chinese mapmakers, as such developments affected European mapmaking. In addition, Chinese mapmakers did not develop projection techniques for transferring points from a spherical to a plane surface. Mapmakers seem to have believed the earth's surface was generally flat, so that, in their minds, drawing maps on plane surfaces would not result in appreciable distortion.

In 1267 a Persian astronomer presented the Chinese imperial court with a "geographic record" that represented the earth as round, but the representation seems to have had no effect on Chinese mapmaking. The Chinese did not begin to adopt techniques of spherical projection until the late sixteenth century when Jesuit missionaries, notably Matteo Ricci (1552–1610), introduced Ptolemaic cartography with its coordinate system into China. Some Chinese copied Ricci's maps, and in the eighteenth century, Jesuits were commissioned by Chinese emperors to survey and map the entire empire. In carrying out this work, the Jesuits employed Chinese assistants. But even so, Chinese adoption of European techniques was slow, since the Jesuits were limited in their access to China, and many Chinese intellectuals resisted a view of the earth as round. The bulk of maps made in China continued to be made in the traditional manner up to the late nineteenth century. There was little uniformity in mapmaking, even within the government. Maps might be planimetric; they might be pictorial; they might be drawn to scale; they might not be; they might have grids (Fig. 4); they might lack them; even if they had grids, they might not be drawn to scale (Fig. 5); and late in the nineteenth century they might have square grids as well as lines of latitude and longitude. They also varied in physical format and could be made on sheets, scrolls, fan-folded strips, and bound volumes (see Extra).

Circumstances in the nineteenth century, however, fostered change in this situation. As China weakened as a result of domestic problems and encroachments by European powers, many Chinese intellectuals began to believe that China needed reform. Some pointed out that European maps were superior to those of the Chinese. In response, the government tried to standardize mapmaking practices, stipulating that standard projections and scales be used. Progress in instituting these changes was difficult since there was a shortage of personnel capable of employing the necessary techniques. Not until after the collapse of the empire in the twentieth century did the European conception of cartography as primarily quantitative fully supplant the traditional Chinese idea of a map as an intersection of various lines of learning including the literary and visual arts.

In the first half of the twentieth century the quality of measured maps improved as more Chinese were trained in the earth sciences. During the Second World War, however, accurate measured maps were still not in good supply – a situation that hampered the Chinese military. To remedy that situation, the Chinese government took steps to promote cartography. In 1956 it established a State Bureau of Surveying and Mapping which undertook to produce a series of topographic maps for the whole country. Since then more institutions have

Maps and Mapmaking in China. Fig. 4 *Huangchao zhi sheng fu ting zhou xian quantu* (Complete Map of Provinces, Prefectures, Subprefectures, Departments, and Counties under the Qing, 1864). This map has a grid in which each grid increment equals 200 Chinese miles. A legend explaining the various signs on the map appears on the right. Woodblock print, hand-colored to show provincial boundaries, 57 × 58 cm. Courtesy of the Library of Congress (G7820 1864.H8 Vault).

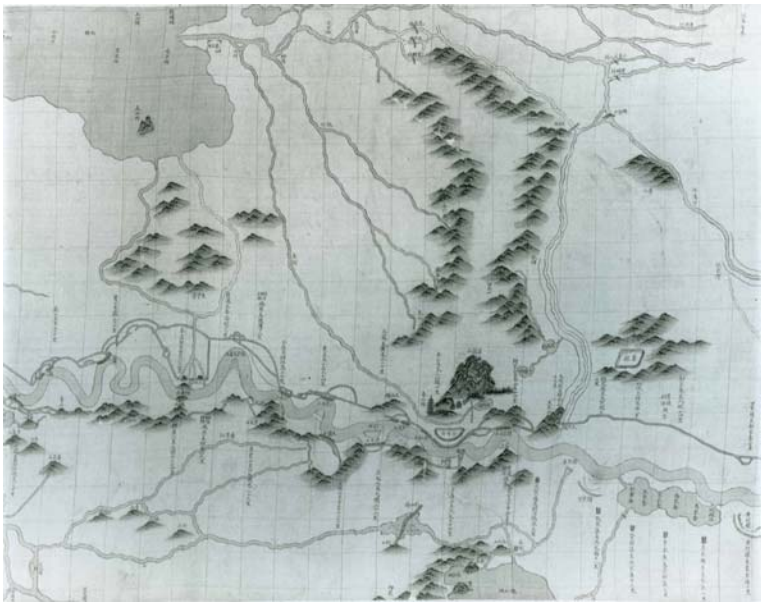
been established to make maps, and others, such as the Wuhan Technical University of Surveying and Mapping, have been set up to teach cartography. As part of China's effort to modernize, Chinese cartography has employed the latest technological advances: remote sensing, satellite photography, and geographic information systems.

Extra: Maps and Mapmaking in China: A Controversy

Some scholars would question whether the Jesuit surveys deserve the brief account they are given here. The surveys have been taken as evidence that China entered the early modern world as early as the eighteenth century (see, for example, Needham and Hostetler).

I have no objection to describing the Jesuit surveys as early modern. Describing the Jesuit atlas as early modern emphasizes its departure from traditional Chinese practices. Most maps made under the Qing were not early modern. Maps drawn to scale were part of the Chinese mapmaking tradition, but according to the available evidence, pictorial maps were made in far greater numbers. Traditional Chinese mathematical cartography was not the same as modern mathematical cartography in that it did not employ spherical coordinates or map transformations. Thus the Jesuit surveys were not representative of what Chinese mapmakers were doing or were even capable of carrying out; the influence of the Jesuit surveys was limited primarily to the central government.

The claim that the use of early modern maps justifies calling Qing-dynasty China an early modern map culture comparable to early modern European map cultures rests on a superficial resemblance. An equation of Qing China and early modern Europe is possible only if the use of mathematical maps for the exercise of political control is the sole criterion of early modernity. But to use this single criterion is to overlook the many ways in which Qing-dynasty China differed from early modern Europe intellectually, socially, and economically. The predominance of the mathematical map in Europe did not come about simply because of its usefulness for political control and inventory. Modern cartography is not simply a matter of mapmaking technique and map use. There is a philosophy of nature associated with it. That philosophy implies that certain methods, based on mathematical reasoning, should be used to understand nature. That philosophy of nature and the emphasis on mathematical reasoning were largely absent from the Qing scholarly world until late in the



Maps and Mapmaking in China. Fig. 5 *Huanghe tu* (Map of the Yellow River, nineteenth century, before 1854; detail). This map is oriented with south at the top and shows flood-control works along the lower course of the Yellow River before 1854. Distances between places are given in notes on the map, and from these it does not seem that the mapmaker attempted to maintain a consistent scale. The grid appears to have been drawn after the image was completed, perhaps as an aid to copying. A manuscript map could not be reproduced by woodblock printing without destroying it, so hand copying skills were important for mapmakers. Ink and color on silk, 38 × 183 cm. Courtesy of the Library of Congress (G7822.Y4A5 18 – H9 Vault Shelf).

nineteenth century. Chinese evidentiary scholarship, for example, does not yield anything resembling Newtonian mechanics. The inadequacy of the mathematical map as a measure of the modern becomes clear when one recalls that mathematical maps of the entire empire were available in China as early as the twelfth century. On that basis one could locate, as some have on other grounds, early modern China in the Song dynasty. The problem is that after the twelfth century Chinese mapmakers generally turned away from the mathematical.

Furthermore, a number of political, social, and intellectual developments occurring in early modern Western Europe did not occur in Qing-dynasty China – for example, those fostering the formation of modern democratic institutions. One could argue that those conditions still have not fully arisen in China. A case in point is the dissemination of information. Modern mathematical maps were widely circulated among the middle class in Europe; it was simply not the case that modern maps were understood and used only by a few in early modern Europe. Such widespread familiarity with modern mathematical maps was slow to come in Qing-dynasty China, if it ever did come. It does not seem likely that left to themselves, Chinese mapmakers would have developed the map transformations of modern cartography. In fact they tended to resist them and what they implied about the world's size and shape. Map transformations are predicated on an understanding that the earth is spherical; Chinese mapmakers before the late nineteenth century generally dealt with the earth's surface as if it were flat. Modern cartographic techniques may be available to anyone in principle, but historically they have not been acceptable to everyone. There was something that stopped Chinese mapmakers from adopting the map transformations brought by the Jesuits. Qing rulers used early modern cartography, but Chinese mapmakers did not produce early modern maps until late in the nineteenth century. If one wants to understand what Chinese mapmakers were doing under the Qing, one does not study the maps produced as a result of the Jesuit surveys. They had little effect on Chinese mapmakers. They did not participate in the modern cartographic revolution until well after the Jesuit surveys. This statement may perpetuate an image of a China resistant to change, but in making their own maps, they were. The image in some cases is justified.

In addition, to describe the Jesuit atlases as Chinese is to portray the Jesuits simply as Qing operatives – a disingenuous characterization at best. The Jesuits had their own purposes for carrying out the surveys. Their information was not intended solely for the Qing court. It was sent back to Europe where it had more influence on mapmakers than in China. There it changed the cartographic image of China, made it more accurate, and the importance of that geographic information for economic expansion is well known.

What is being said here is not to deny that European maps and Chinese maps have some similarities. Otherwise it would not make sense to speak of European and Chinese "maps." In both traditions pictorial and mathematical mapmaking were practiced. But the two traditions differed in the valuation placed on the two modes of mapmaking. In China pictorial mapmaking became dominant; in Europe mathematical mapmaking became dominant. In one history, text was more important than image as a bearer of information; in the other text was less important and was moved to the margins and eventually off the map. Among Chinese mapmakers there was little movement toward marginalizing text. Indeed, practices of evidentiary scholarship made the study of texts central.

As far as mapmaking is concerned, the evidence so far does not allow one to identify a specific dynastic period as equivalent to early modern Europe. The attempt to do so seems to privilege what happened in Western Europe as a norm when it is by no means clear that all societies have to go the way of Europe. It still makes sense to distinguish Western European culture from Chinese culture, as recent political events make abundantly clear.

Maps and Mapmaking: Chinese Geomantic Maps

Hong-Key Yoon

The Chinese geomantic map is a type of cartographic expression of a landform that portrays a place as geomantically auspicious or inauspicious. In search of an auspicious site for a grave, settlement, temple, or house, geomancers often make extensive field surveys using compasses. Determining an auspicious site, which is often found on a foothill, is a complex business achieved by considering landforms, watercourses, and the direction that the locality faces. The results of important surveys are often recorded in maps. Although the geomantic sketch map is a large-scale map, the scale is not accurate beyond the immediate area of the auspicious site, because the map is normally based on eye measurements and impressionistic descriptions of a locality.

Chinese geomantic maps have basically the same surveying and cartographic methods and identical or similar map symbols. A geomantic map may represent an auspicious site (the geomancy cave: normally designated as a grave or a house site) by the symbol of a small single circle or an even smaller circle inside a small circle. A geomantic map is a topographic map featuring mountain ranges most prominently, because the auspicious vital energy is said to flow through these ranges before accumulating in a geomancy cave. Mountain ranges are expressed in stylized but realistic shapes, using different symbols for different parts of a mountain: a single black line marks the end of foothills and the beginning of flat land; a serrated demarcation line shows slopes along the edge of mountain ridges; the mountain ridges and peaks are colored black. Broken lines symbolize a smaller watercourse. A broken line with a solid line on one side may represent a bigger river. A large lake, river or sea may adopt the symbol of scales, which are also used in other types of maps in East Asia.

The first main characteristic of a geomantic map is that it is a center-oriented map. The focus of the map is on the auspicious site of a given landscape which normally occupies the central position of the map. In the depiction of the topographic formations, only the mountains facing the auspicious site are presented in the map.

The second interesting point concerns the perspectives on the map. The point of perspective on the modern topographic map of contour lines is in the sky directly above the concerned landform. However, that for the relief formations of the mountain slopes on the geomantic map is on the ground at the auspicious site,

M

while that for watercourses on the map is in the sky directly above the waters concerned.

The third point is that there is a lack of map symbols indicating cardinal direction. Unlike modern maps, the top of the geomantic map is assumed to be southward, because an auspicious site is normally facing a southern direction. Although geomancy maps did not adopt a symbol of direction, the exact direction that an auspicious site faces is often noted with Chinese characters which enable a map reader to tell directions.

The fourth point is that the geomantic maps are generally large scale maps focusing on a small catchment area or a small basin. Other non-geomantic traditional Chinese maps are normally small-scale maps.

The fifth point concerns the emphasis on mountain ranges in the map. Especially emphasized are the relationships between the key mountain ranges encircling an auspicious site because mountain ranges are believed to be the route of the flow of *qi* (vital energy) which influences people auspiciously.

The origin of cartographic skills used in the geomantic map is not clearly understood yet by modern scholars. Fully developed geomantic maps had already appeared in a Ming Dynasty (1368–1644) geomantic manual, *Renze Shuji*. The technique of presenting relief formations in Chinese geomantic maps is perhaps more sophisticated than that on any other type of map in traditional China. However, their cartographic contribution is yet to be evaluated.

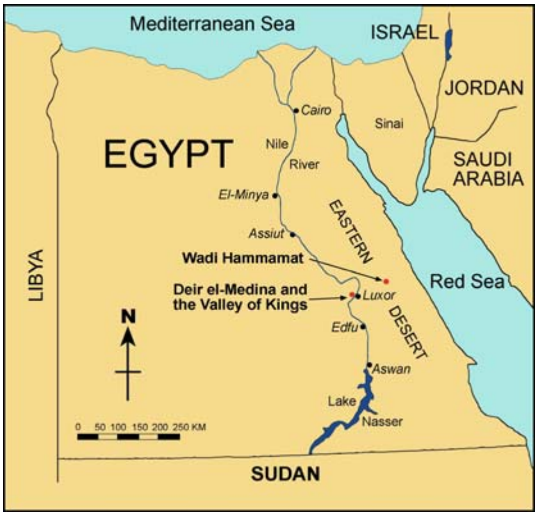
James A. Harrell

Discovery and Reconstruction of the Map

An ancient Egyptian map drawn on a scroll of papyrus paper was discovered between 1814 and 1821 by agents of Bernardino Drovetti, the French Consul General in Egypt. The map came from a private tomb in the ancient village of Deir el-Medina, near the modern-day city of Luxor (ancient Thebes) in Egypt (Fig. 1). This village housed the workers responsible for excavating and decorating the royal tombs of the Egyptian New Kingdom (1539–1075 BCE) in the nearby Valley of Kings and Valley of Queens (Černy 1973; Bierbrier 1982; Romer 1984). Soon after it was found, the map was sold to King Charles Felix, ruler of the northern Italian Kingdom of Sardenia and Piedmont. In 1824, this king established the Egyptian Museum in Turin, the kingdom's capital, and here the map has resided ever since. The many map fragments were originally considered parts of three separate papyri that were designated as "Papyrus or P. Turin" 1869, 1879, and 1899. Most of these fragments were eventually recombined to form a single map about 280 cm long by 41 cm wide (Fig. 2). This papyrus has long been recognized as one of the oldest geographical maps to survive from antiquity and much has been written about it (e.g., Gardiner 1914; Goyon 1949; Shore 1987; Harrell and Brown 1992).

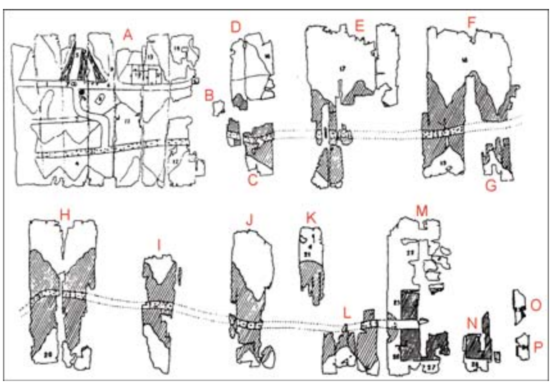
The current reconstruction of the map in the Egyptian Museum, which dates to the early 1900s, is incorrect in several of its details. A new arrangement of the map fragments has been proposed and this is shown in Figs. 3–6. The principal changes are the transposition of map fragments H-J and E, the placement of L at the bottom of E, and the narrowing of gaps between many of the fragments (which shortens the map to about 210 cm). This new reconstruction is consistent with the requirements that:



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 1 Map of Egypt showing the locations of Deir el-Medina, the Valley of Kings, and Wadi Hammamat.

1. the adjoining fragments should correlate closely in terms of the features drawn on the map side, the texts and drawings on the map's backside (Figs. 7–8), and the fiber patterns in the papyrus paper;
2. the width of the fragments and the spacing between the breaks within them should match for those fragments that are vertically juxtaposed; and
3. the topography and geology of the area shown on the map should be taken into account. Figs. 3 and 5–8 are computer-generated photo-mosaics derived from digital scans of photographs taken of the papyrus.

The map was rolled up when discovered and subsequently handled, and this explains the especially poor preservation of the rightmost portion in Fig. 3, which formed the outer abraded surface of the scroll. An unknown amount of the papyrus has been lost at its right edge and so fragments K and N-P cannot be correctly placed. The map is not truncated here, but drawings of an unknown number of stone blocks and the accompanying texts are missing. The Egyptian Museum has many small map fragments that it left out of its reconstruction (and are also missing from Figs. 3–8) and eventually these pieces of the puzzle will be added to create a more complete map.

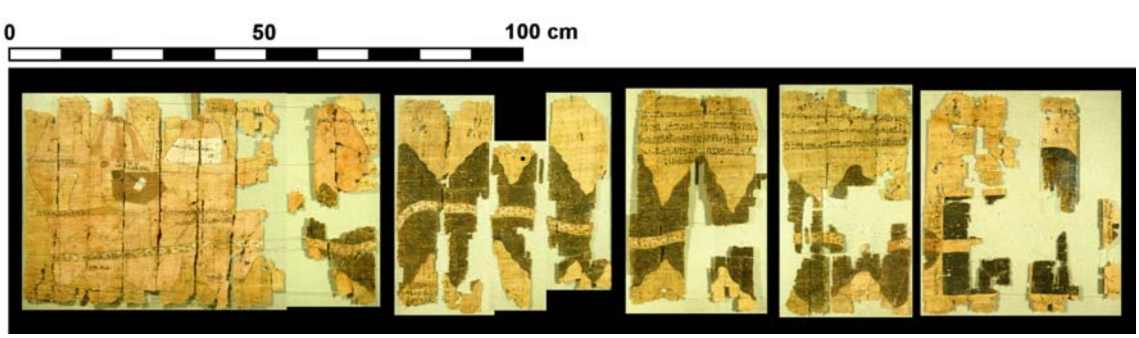


Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 2 The arrangement of the papyrus map fragments as currently displayed in the Egyptian Museum in Turin, Italy (adapted from Goyon 1949: Pl. 1 and 2; and reproduced in Harrell and Brown 1992: Fig. 2). The texts are identified by numbers (as in Fig. 4 and Table 1), and the fragments are identified by letters (as in Figs. 4–8 and Table 3).

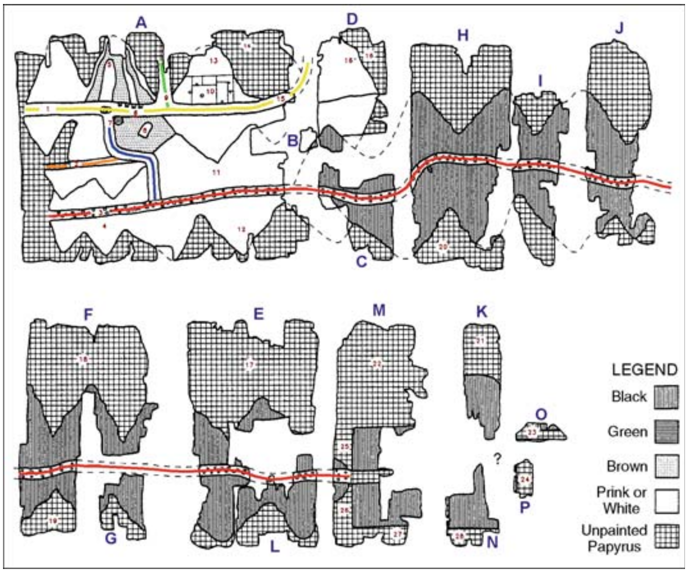
Topographic and Geologic Content of the Map

The Turin papyrus map is notable for being the only topographic map to survive from ancient Egypt and also for being one of the earliest maps in the world with real geographic content. Although there are a few older topographic maps from outside Egypt, they are all quite crude and rather abstract in comparison to the relatively modern-looking map drawn on the Turin papyrus. This map shows a 15 km stretch of Wadi Hammamat (Valley of Many Baths) in the central part of Egypt's Eastern Desert (Fig. 1). The top is oriented toward the south and the source of the Nile River with west on the right side and east to the left. There is no constant scale used on the map, but by comparison with the actual distances in Wadi Hamamat it is evident that the scale varies between 50 and 100 m for each 1 cm on the map.

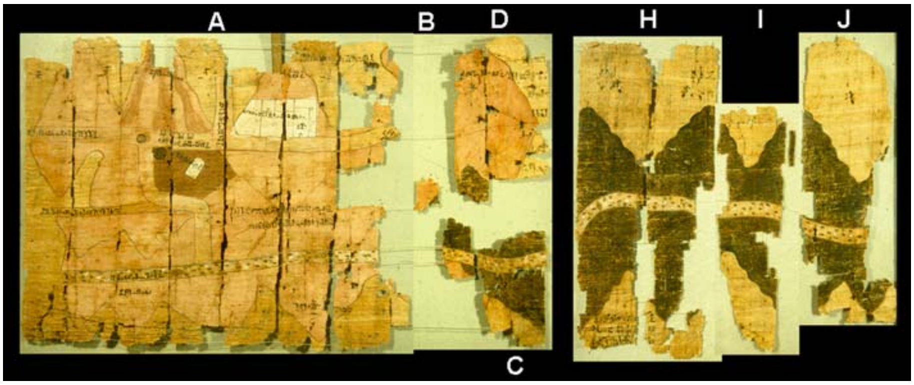
The topography and geology of the Wadi Hammamat area are shown in Fig. 9. The corresponding features on the ancient and modern maps are indicated by the colored lines in Figs. 4 and 9. From the good agreement between these maps, it can be seen that the papyrus clearly depicts Wadi Hammamat's long course and eventual confluence with wadis Atalla and el-Sid, the surrounding hills (shown as stylized conical forms with wavy flanks that are laid out flat on both sides of the valleys), the quarry for *bekhen*-stone, and the gold mine and settlement at Bir Umm Fawakhir (Well of the Mother of Pottery). *Bekhen*-stone (geologically, metagraywacke sandstone and siltstone) is a beautiful grayish–green ornamental stone that was highly prized by the ancient Egyptians. The only quarry was in Wadi Hammamat, and this was worked sporadically from the Early Dynastic period through Roman times (about



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 3 Papyrus map as reconstructed by Harrell and Brown (1992).



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 4 Schematic of the papyrus map showing the reconstruction by Harrell and Brown (1992: Fig. 3). The numbers refer to texts and the letters to map fragments as in Fig. 2. Corresponding features on this map and the modern one in Fig. 9 are indicated by the colored lines.

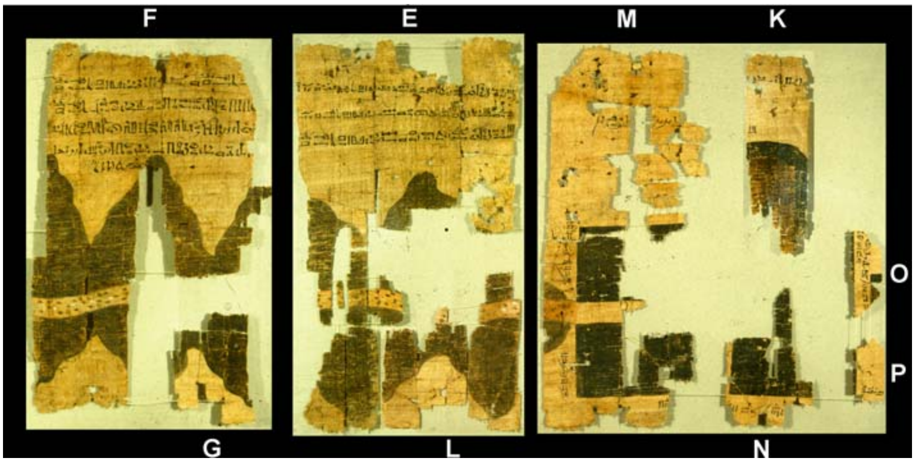


Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 5 The left (eastern) half of the papyrus map. See Table 1 for translations of the texts (as numbered in Figs. 2 and 4).

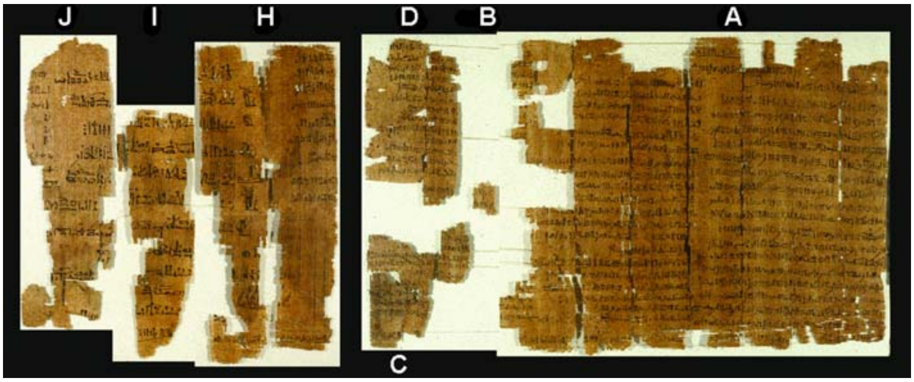
3000 BCE to 400 AD). The gold mine at Bir Umm Fawakhir was active during the New Kingdom and again in the Ptolemaic through Early Byzantine periods (about 1500 BCE to 600 AD).

Fragment A shows five cultural features associated with the gold-mining settlement, including: four houses, a temple dedicated to the God Amun (the large white area subdivided by walls), a monument stone honoring King Sety I (1290–1279 BCE of the New Kingdom's 19th Dynasty), a water reservoir, and, at the confluence of wadis Hammamat and el-Sid, a water well with an encircling wall that casts a shadow on its right side. The brown patch of ground opposite the settlement may represent an area where either mine tailings were dumped or farming was practiced.

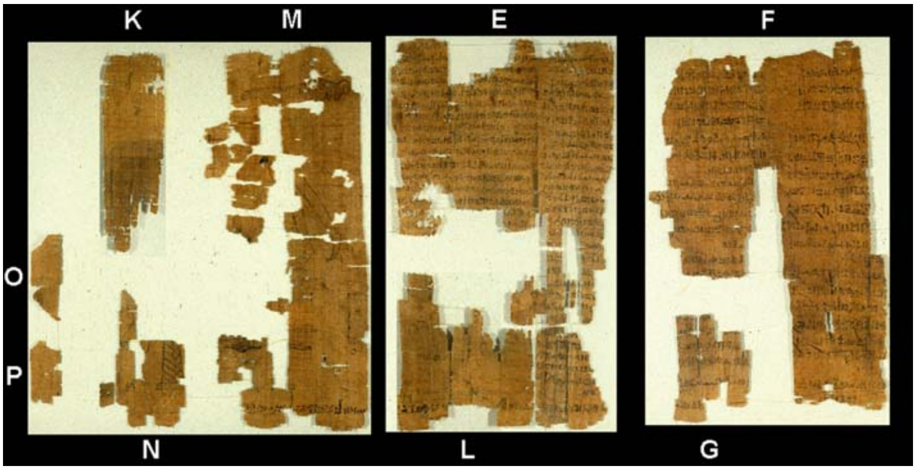
On map fragments A and H, within the main valley represented by multicolored dots, there are three small drawings of trees, which from their form can be identified as Tamarisks. The tree on fragment H (Fig. 10), which is drawn upside-down, is just opposite the *bekhen*-stone quarry (the green oval at the base of the brownish black hill) and at the center of the sharp bend in the valley. On the ancient map, this is the only major bend in Wadi Hammamat prior to its confluence with Wadi Atalla. As seen in Fig. 9, however, Wadi Hammamat actually has many sharp bends as well as wide meanderings. Because the ancient map was drawn on a papyrus scroll, which would have resembled a modern roll of paper towels, the author did not have the freedom to show the



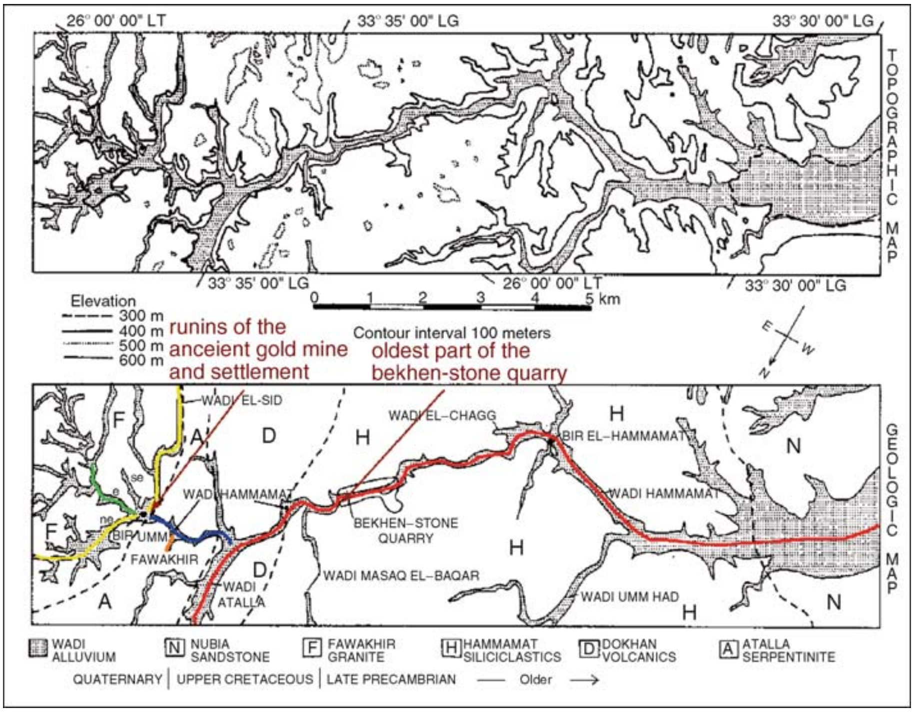
Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 6 The right (western) half of the papyrus map. See Table 1 for translations of the texts (as numbered in Figs. 2 and 4).



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 7 The backside of the left (eastern) half of the papyrus map. See Table 3 for comments on the texts.



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 8 The backside of the right (western) half of the papyrus map. See Table 3 for comments on the texts and drawings.



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 9 Topographic (above) and geologic (below) maps of Wadi Hammamat (adapted from Harrell and Brown 1992: Fig. 4). Corresponding features on this map and the ancient one in Fig. 4 are indicated by the colored lines.

Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 10 Detail of the papyrus map (fragment H) showing an upside down tree in the wadi directly opposite from the *bekhen*-stone quarry, which is shown as a greenish oval embedded within the brownish black hillside.

true wandering course of Wadi Hammamat and so included only the most important bend, the one near the *bekhen*-stone quarry.

The papyrus map also has numerous annotations written in hieratic script (the cursive form of hieroglyphic writing) that identify the features shown on the map (see Table 1 for translations), including: the destinations of the valley routes (texts 1–3, 9, and 16 on fragment A), the distance between the *bekhen*-stone quarry and gold mine (text 17 on fragment E), the location of gold deposits in the hills (texts 4–5, 11–12, and 16′ on fragments A and D), the gold-mining settlement (texts 6–8 and 10 on fragment A), the *bekhen*-stone quarry (text 20 on fragment H), and the sizes of the quarried *bekhen*-stone blocks (texts 23 and 25–28 on fragments M-P). Text 18 on fragment F is especially important for understanding the purpose of the map because it refers to a *bekhen*-stone quarrying expedition and the destination of the quarried blocks.

Besides being a topographic map of surprisingly modern aspect, the Turin papyrus is also a geologic map because it accurately shows the geographic distribution of different rock types (the black hills with Hammamat siliciclastics, and the pink hills with Dokhan volcanics, Atalla serpentinite and Fawakhir granite) and the lithologically diverse wadi gravel (the brown, green, and white dots within the main valley that represent different kinds of rocks), and it also contains information on quarrying and mining (see Table 2 for a description of the geologic units). Additionally notable are the representation of iron-stained, gold-bearing quartz veins with three radiating bands on the pink hill above the gold-mining settlement on fragment A (beneath text 5), and text 11 on fragment A, which reads very much like a legend on modern

Maps and Mapmaking in Egypt: Turin Papyrus Map. Table 1 Translations of the Hieratic Texts on the Map Side of the Turin Papyrus (Adapted from Harrell and Brown 1992: Table 1)

Text number[1]	Translation
1	the road that leads to the sea
2	another road that leads to the sea
3	the road of *Tent-p-mer* [the translation of the last word is uncertain – it may be the name of an unknown locality or it may mean "treasurer" or "harbor"]
4	mountains of gold
5	mountains of gold
6	the houses of the gold-working settlement
7	cistern [or "water reservoir"; the text is written on top of the water sign]
8	stela of *Menma'atre*, life, health, and prosperity! [King Sety I, 1290–1279 BCE, of the New Kingdom's 19th Dynasty][2]
9	the road of *Ta-menti* [the last word is apparently the name of an unknown locality]
10	the shrine of *Amun* of the pure mountain
11	the mountains in which gold is worked, they are colored pink
12	mountains of gold and silver [or perhaps "mountains of electrum", where electrum is a natural mixture of gold and silver]
13	…the hill of *Amun*
14	the hill where *Amun* rests
15	[not translatable; appears to be part of a name for some locality]
16	[too fragmentary to translate, but it appears to be comments on travel from one unnamed locality to another; a travel time of "one day" and "gold" are mentioned]
16′	mountains of gold [appears to be a continuation of 16 but is a separate text]
17	distance from the gold-working settlement to the mountain of *bekheny*,…*khet* [this text is repeated three times, apparently for emphasis; the distance in units of *khet* is missing][3,4]
18	…the *bekheny*-stone that is found in the mountain of *bekheny*, the King…[name lost] life, health, prosperity, having sent the great magistrates to bring the portrait statue of *bekheny*-stone…to Egypt. They deposited it in the Place of Truth beside the Temple of *Userma'atre setepenre*, the great God [i.e., near the Valley of Kings at the mortuary temple of Ramesses II, 1279–1213 BCE, of the New Kingdom's 19th Dynasty; also known as the Ramesseum]…left it at the enclosure of the Tomb and there it lay being half worked in year 6[3]
19	[not translatable]
20	the place in which they work in the great business of *bekhen*-stone which was established as a quarry
21	the measurement of this…
22	[not translatable]
23	…of stone that is pulled by men from the east…3 cubits wide [about 1.6 m][4]
24	…*bekheny*…
25	breadth of 2 cubits, 2 palms [about 1.2 m]; thickness of 2 cubits, 3 palms…fingers [about 1.3 m]
26	breadth of 2 cubits [about 1.0 m]; thickness of 2 cubits
27	…palms…fingers
28	…palms; thickness of 2 cubits…palms

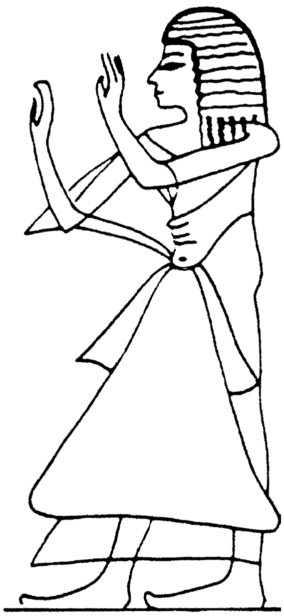
[1] See Figs. 2 or 4 for locations of texts. Note that "…" indicates missing text, untranslated ancient Egyptian words are italicized, and comments are given within brackets.
[2] All dates in this article are taken from p. 36–37 of Baines and Malek (2000).
[3] Texts 17 and 18 are written in a script that is bold, calligraphic and near-hieroglyphic in style. All other texts are written in a less elaborate hieratic script.
[4] The ancient Egyptian units of measure are as follows: 1 *khet* = 100 cubits; 1 cubit (the standardized distance from the elbow to the tip of the longest finger) = 7 palms (palm widths) = 28 fingers (finger widths); 1 cubit = 52.31 cm, 1 palm = 7.47 cm, 1 finger = 1.87 cm.

M

geologic maps by explaining what the pink coloring represents. The Turin papyrus is the oldest known geologic map in the world and it is all the more remarkable considering that it would be another 2900 years before the next geologic map was made and this was in France during the mid-1700s. There is no reason to think, however, that the ancient author intentionally set out to make a geologic map. From the colors used for the hills and wadi gravel, it is evident that he merely drew what he literally saw in the desert – the real hills and surface gravels have the same general colors as those on the map (Table 2).

Maps and Mapmaking in Egypt: Turin Papyrus Map. Table 2 Geologic Units in the Wadi Hammamat Area as Shown on the Map in Fig. 9 (Adapted from Harrell and Brown 1992: Table 4)

Geologic age	Name	Description
Quaternary	Wadi Alluvium	Sand with lithologically diverse pebbles and cobbles of many colors but especially white, pink, brown, dark gray, and green.
Upper Cretaceous	Nubia Sandstone	Sandstone. From a distance appears purplish-black due to a coating of "desert varnish".
Late Precambrian	Fawakhir Granite	Granite and granodiorite with abundant iron-stained, gold-bearing, hydrothermal quartz veins. From a distance appears pink to pale red due to natural coloring.
	Hammamat Siliciclastics	A variety of slightly metamorphosed sedimentary rocks, including (meta) greywacke sandstone to siltstone (the ancient Egyptian *bekhen*-stone), conglomerate and shale. From a distance appears dark brownish-gray due to a coating of "desert varnish".
	Dokhen Volcanics	A variety of slightly metamorphosed volcanic rocks, including (meta) rhyolite, andesite, and basalt. From a distance appears pinkish-brown due to weathering.
	Atalla Serpentinite	Serpentinite. From a distance appears pinkish-brown due to weathering.



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 11 Amennakhte, son of Ipuy (modified from Romer 1984: p. 115). Redrawn from a relief carving on a stela erected in Thebes by his family after his death (now in the New York Metropolitan Museum of Art).

Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 12 Ramesses IV's year-three stela (CM 12) in Wadi Hammamat's *bekhen*-stone quarry.

The Map's Author and Purpose

The map was made about 1150 BCE by the well-known "Scribe of the Tomb" Amennakhte, son of Ipuy (Romer 1984: 106–115) (Fig. 11). It was prepared for one of the quarrying expeditions sent to Wadi Hammamat by King Ramesses IV (1156–1150 BCE) of the New Kingdom's 20th Dynasty (Peden 1994). The purpose of these expeditions was to obtain blocks of *bekhen*-stone that would be carved into statues of the gods, king and other notables. A now famous rock-cut inscription or stela (officially designated CM 12) was left on the quarry wall by this king to commemorate his final and largest expedition during the third year of his six-year reign (Christophe 1948) (Fig. 12). According to the

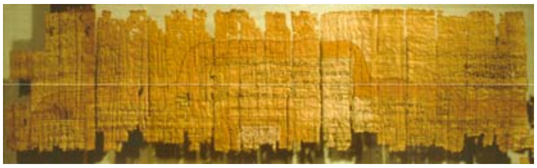
Maps and Mapmaking in Egypt: Turin Papyrus Map. Table 3 Comments on the Hieratic Texts and Drawings on the Backside of the Turin Papyrus Map (Adapted from Harrell and Brown 1992: Table 3)

Map fragment[1]	Comments
A (across top)	Synopsis: Amennakhte, in his house one morning, bears witness to a sworn oath and statement (not recorded in the text) by a "citizen" (name lost). Signed by Scribe of the Tomb Amennakhte (date lost). [this is almost certainly the earliest text written on the backside because Egyptian scribes filled in scrolls from top to bottom and right to left]
A (left half & top of right half)	Synopsis: A wooden statue of Ramesses VI is to be carved, and ornamented with a kilt of gold, and a crown of lapis lazuli (and another mineral?). It is to be placed in the mortuary temple of Ramesses II (the Ramesseum) in the Chapel of Hathor for the purpose of establishing a cult for the worship of Ramesses VI. The required offerings on festival days and the duties of the temple personnel attached to this cult are also described. [unsigned and undated, but Amennakhte's handwriting]
A (the rest of the right half)[2]	Synopsis, Part 1: Hori went to Karnak Temple in Thebes at the summons of Ramessenakhte, the High Priest of Amun. There he was told to gather a large quantity of copper [which would have been used for the tools wielded by the workers excavating the royal and private tombs] and bring them to the Temple. Hori returned to the necropolis in the company of two Guards of the Treasury, Paynodjom and Amenmose son of Tjewenany, and the servant Pnekhemope. Dated year 6, 3rd month of Akhet, day 20. Synopsis, Part 2: Hori returned to Karnak Temple in the company of Paynodjom and Amenmose plus the two Foremen of the Tomb, Nekhemmut (Hori's brother) and Anherkhe. They met with Ramessenkhte and turned over the requested copper to the Scribe Khonsmose, who received it for the Treasury of Amun. Dated year 6, 4th month of Akhet, day 7. Signed by Scribe of the Tomb Hori, son of Khons.
A (upper right edge), B & D	[untranslated, but possibly Hori's handwriting]
A (lower right corner) & C	[untranslated, but the handwriting is that of either Amennakhte or another, unknown scribe]
D (right edge & upper part of left edge)	[untranslated, but the handwriting is that of either Hori or another, unknown scribe]
H (right half), I & J	[untranslated, but appears to be a list, possibly of statues and their associated festival days; the large, bold, calligraphic and near-hieroglyphic script in this text is like that in texts 17 and 18 on the map side, and probably is Amennakhte's handwriting in his more formal script]
J (upper right edge), F (upper two-thirds of left half)	[untranslated, but appears to be a memorandum plus a hymn, possibly to Horus, that is in Amennakhte's handwriting]
F (lower one-third of left half)	[untranslated, but the handwriting may be that of Amennakhte or another, unknown scribe]
F (right half)	[untranslated, but Amennakhte's handwriting]
G	[untranslated, but Amennakhte's handwriting]
E	[untranslated, but possibly Hori's handwriting]
extending across the bottom edge of A, C, H, I, J, F, G, E, L & M	[untranslated, but one long line of text in possibly Hori's handwriting]
L & M (lower right edge)	drawing showing a scattering of squarish pebbles (?) plus two curved parallel lines, the latter similar to those used to indicate wadis on the map side
M	a grid-square in red ink with fragmentary drawings of the sky goddess Nut, and below, the god of air and light, Shu, or perhaps the god of Earth, Geb; a tiny stick-man is standing on Nut's back
M (top)	drawing of a crocodile
N	fragmentary drawings of a tree trunk (palm?) and a wing (either the vulture Goddess Nekbet or the falcon god Horus)

[1] See Figs 7 and 8 for locations of map fragments. Fragments K, O, and P have no texts or drawings.
[2] The gist of these two texts has been revised from Harrell and Brown (1992: Table 3) based on a new translation by Janssen (1994).

inscription, this included 8,362 men, which makes it the largest recorded quarrying expedition to Wadi Hammamat after one about 800 years earlier during the Middle Kingdom's 12th Dynasty. It is almost certainly for Ramesses IV's big expedition that the map was made, but what purpose it served is unclear. It could not have been a road map showing the way to the quarry because it only covers a small area with the 75 km between Wadi Hammamat and the Nile Valley excluded. Most likely, it was drawn as a visual record of the expedition to be viewed by either Ramesses IV or Ramessenakhte, the High Priest of Amun in Thebes, who organized the expedition for the king.

Although Amennakhte did not sign his name to the map, it is clear that he is its author. There are two pieces of evidence that support this identification. First, the text on the map side is in Amennakhte's distinctive handwriting, which is well known to Egyptologists who have studied his many other writings. And second, the first and earliest text on the backside of the papyrus (the first one listed in Table 3) was written and signed by Amennakhte. It is not at all surprising that Amennakhte would have made the map. As one of the two "Scribes of the Tomb" during Ramesses IV's reign (along with Hori, son of Khons, who also wrote some of the later texts on the back), Amennakhte was an important administrative official in the Theban region and this is where the map (text 18) says the blocks of *bekhen*-stone were taken. He is well known from his many other surviving works to be an individual with an unusual combination of scribal, cartographic and artistic skills as well as a "sense of geology". These attributes are especially well displayed on another of his papyri in Turin's Egyptian Museum. This is an architectural plan of Ramesses IV's tomb in the Valley of Kings (Carter and Gardiner 1917) (Fig. 13). It is by far the most elaborate and sophisticated tomb plan to survive from ancient Egypt. It has Amennakhte's distinctive handwriting labeling the parts of the tomb and giving their dimensions, and on the back is his last will and testament. The plan also includes elements of geology, such as a drawing of the king's sarcophagus in the central burial chamber painted to resemble the pink granite of Aswan from which it was carved, and the location of the tomb under a mountain of well-layered, inclined strata, which is an accurate depiction of the situation in the Valley of Kings.



Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 13 Ramesses IV's tomb plan drawn by Amennakhte, son of Ipuy (now in Turin's Egyptian Museum).

It is now known that Drovetti obtained both the quarry map and tomb plan, along with many other papyri, from Amennakhte's family tomb at Deir el-Medina. If the map was made for Ramesses IV's big quarrying expedition then why did Amennakhte keep it, and why did he and others reuse its backside for documents and drawings unrelated to the map? The answer to the first question is unknown, but that to the second is clear. Because papyrus paper was an expensive commodity in ancient Egypt, it was common practice among scribes to use the originally blank backsides once whatever was written or drawn on the front side was no longer needed. In other words, the papyrus map became scrap paper after the quarrying expedition it recorded lost its importance, perhaps following Ramesses IV's death a few years after the map was made.

Amennakhte's family tomb still exists as does, remarkably, his house in Deir el-Medina (Figs. 14 and 15). That it is his house is known from an inscribed door jamb, now removed for safe keeping that graced its entrance. It is interesting to contemplate that it may be in this very place where one of the world's oldest and most important maps was made over 3100 years ago.

Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 14 Ruins of the ancient village of Deir el-Medina, Egypt. Amennakhte's family tomb (no. 1338) is excavated into the hillside on the right, and his house (highlighted in red) is inside the rectangular, walled precinct at center.

Maps and Mapmaking in Egypt: Turin Papyrus Map. Fig. 15 House of Amennakhte, son of Ipuy in the ancient village of Deir El-Medina, Egypt. Only the ground floor (with four rooms) survives, but the remains of stairs (not visible) indicate that there was a roof terrace where people could work or sleep.

Maps and Mapmaking in India

Joseph E. Schwartzberg

In comparison to Europe, the Islamic world, and East Asia, the cartographic achievements of South Asia appear modest and until the 1980s were scarcely recognized by historians of science. In recent years, new archaeological evidence, surviving sacred and secular texts, and other evidence have led to a change in scholarly opinion. We now believe that some form of mapping was practiced in what is now India as early as the Mesolithic period, that surveying dates as far back as the Indus Civilization (ca. 2500–1900 BCE), and that the construction of large-scale plans, cosmographic maps, and other cartographic works has occurred continuously at least since the late Vedic age (first millennium BCE). Because of the ravages of climate and vermin, surviving maps from prior to the eighteenth century are rare and are largely in stone, metal, or ceramic. However, cosmographies painted on cloth date back at least to the fifteenth century, while palm leaf architectural plans from seventeenth-century Orissa are believed to be copies of manuscripts originally prepared as early as the twelfth century. Few surviving maps on paper predate the eighteenth century.

Though not numerous, a number of map-like graffiti appear among the thousands of Stone Age Indian cave paintings; and at least one complex Mesolithic diagram is believed to be a representation of the cosmos. Other map-like grafitti continued to be produced by tribal Indians over most of the historic period. The principal reason for supposing that surveying was a feature of the Indus civilization is that the regularity of its planned

M

grid-pattern urban settlements could not easily be achieved without it. Moreover, excavations have uncovered several objects that appear to have been simple surveying instruments and measuring rods. The uniformity and modular dimensions of the bricks for so much of the architecture over the vast extent of the Indus civilization are also noteworthy. During the ensuing period of the Vedic Aryans, the building of enormous sacrificial altars was an important religious activity. Texts known as *Śulbasūtras* set forth in great detail how these altars were to be constructed and called for drawing on the ground a plan prefiguring each altar. Again, a system of modular measures was employed. The ancient practice of building gigantic altars, once widespread, has died out over most of India, but survived into the latter half of the twentieth century in the Indian state of Kerala. Hindu temples were also built according to ancient detailed textual prescriptions, known as *Śilpaśāstras*, which also specified drawing on the ground, at full scale, the outline of the structure to be. That practice is still followed. Comparable, though simpler, rules applied, at least in theory, to the building of houses. The *Śilpaśāstras* also contained a variety of models for laying out towns and cities; however, the layout of present-day Indian settlements suggests that such models were seldom closely followed.

For the historic period, one of the earliest surviving artifacts that clearly embodies recognizable map symbolizations is an allegorical wall sculpture from Udayagiri in Madhya Pradesh, ca. AD 400, which shows the confluence of the Ganges and Yamuna Rivers in Madhyadesa (the sacred Central Region of India) over which the then Gupta Empire held sway. Other early datable works are sculpted bas relief cosmographies, some of which were quite elaborate. The earliest of these, depicting *Nandīśvaradvīpa*, the eighth continent of the Jain cosmos, was carved in Śaka 1256 (AD 1199–1200). It may safely be assumed that cosmographic paintings adorned the walls and portals of many ancient temples and monasteries of India's main religious groups – Hindus, Jains, and Buddhists – just as they still do in Jain religious edifices and in Buddhist establishments in other parts of the world. However, largely because of the ravages of time and partially because of the iconoclasm of Muslim invaders, virtually none of these survive from prior to the twelfth century, apart from fragmentary remains in the Buddhist caves at Ajanta.

Astronomy and its handmaiden astrology were well developed sciences in ancient India. The major texts provided detailed observations that enabled latter-day scholars to prepare elaborate celestial diagrams. Despite these, there is no unequivocal evidence that astronomical charts accompanied those early works or were otherwise drawn. Horoscopes were prepared to show the positions of major heavenly bodies at particular times (especially at times of birth), and iconic representations of those bodies as deities often appeared in sculpture and paintings, as did the signs of the zodiac. But none of these were formed into assemblages that one would readily designate as maps. During the Mughal period (1526–1857), however, planar astrolabes and celestial globes were manufactured in northwestern India. One Muslim family practiced the trade in Lahore over a period of several generations. Though some of these works used Sanskrit, rather than Persian, as was the norm, in naming various heavenly bodies, the tradition in which all were made has been dubbed "Islamicate." A variety of related objects in the form of giant masonry instruments appeared in the astronomical observatories constructed during the period ca. 1722–1739 by the Rajput king, Sawai Jai Singh, in his capital at Jaipur and in Delhi, Varanasi, Ujjain, and Mathura. Many of these are still usable.

At least five Hindu cosmographic globes are known, all based largely on *Purāṇic* texts from the mid-first millennium BCE to the mid-first millennium AD. The oldest of these is a brass globe, probably from Gujarat, dated Śaka 1493 (AD 1571). The largest (diameter ca. 45 cm) and most elaborate, and the only one to contain a substantial component of geographic information along with its mainly mythic elements, is a papier-maché globe, probably from eastern India, that appears to date from the mid-eighteenth century. One of the other globes is a painted wooden production, also thought to be from eastern India, probably from the mid-nineteenth century. Two are late nineteenth century bronze creations of unknown provenance. Unlike most Western globes, none of these was constructed with the use of gores, the triangular or moon-shaped pieces that form the surface of modern globes.

A number of planispheric world maps also survive. All but one of these, a crude Marathi map on paper, probably from the mid-eighteenth century, are essentially Islamicate productions, in which mythic elements (e.g., the Land of Gog and Magog) coexist with known geographic places. The largest and most ornate of the world maps is a richly illuminated eclectic painting on cloth, with text in Arabic, Hindustani, and Persian; it probably dates from the eighteenth century and may be of either Rajasthani or Deccani provenance. Additionally, a 32-sheet atlas of the "Inhabited Quarter" (i.e., the part of the world suitable for human life), forms part of a 1647 encyclopedic work by Sadiq Isfahani of Jaunpur in what is now Uttar Pradesh. The orientation on maps made by Muslims is typically toward the south.

Indigenous regional maps, mostly from the eighteenth and early nineteenth centuries, derive mainly form Rajasthan, Kashmir, Maharashtra, and Gujarat, probably in that order of frequency. These range in size from very large (several meters on a side) to page-size productions, the larger works being almost always painted on cloth. No clear schools of cartography emerge, though one can usually distinguish among regions of origin. Map symbols and orientation vary markedly, though some regional tendencies may be noted. No map has a consistent scale, though some contain textual notes on distances between places.

Route maps most commonly appear in strip form, occasionally as lengthy scrolls, and typically show the places and physical and man-made features encountered between two given points. Some route maps, largely relating to pilgrimages, which frequently take the form of circuits, are likely to be more complex. Surviving navigational charts are few in number, entirely from Gujarat, and in a tradition presumably derived from the Middle East. The oldest such known work is dated AD 1710.

The most common genre of maps are those that relate to relatively small localities, especially individual towns, as well as plans of specific forts, palaces, temples, gardens, and tombs. Such maps served many purposes: guides to pilgrims, aids for engineering projects, plans, or documents for military activities, commemorations of historical events, text illustrations, interior adornments, and so forth. Locality maps typically combine a largely pictorial rendition of specific structures, drawn in either an oblique perspective or in frontal elevation, with an essentially planimetric rendition of the encompassing space. Hill features on such maps (as well as on regional maps) are characteristically shown in frontal perspective. Colors for rendering hills, water features, and vegetation are naturalistic and not very different from what one would encounter on Western maps. The largest known Indian map, depicting the former Rajput capital at Amber in remarkable house-by-house detail, measures 661 × 645 cm. (260 × 254 in., or approximately 22 × 21 ft).

Although hundreds of Indian maps have now been studied and described, hundreds of additional recently discovered works await analysis; and it may be safely predicted in light of the interest aroused by recent research that many more maps will soon come to light.

Maps and Mapmaking: Islamic Terrestrial Maps

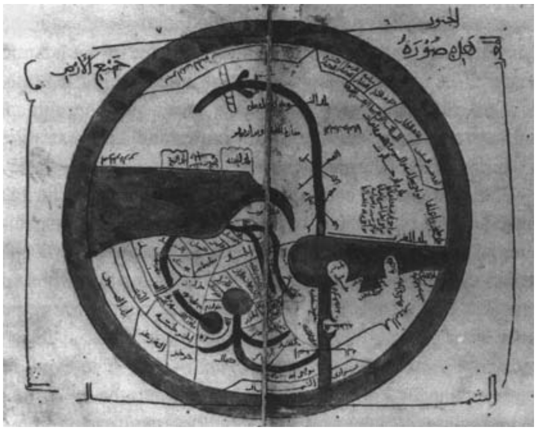
Ahmet T. Karamustafa

M

The cultural boundaries of premodern Islamic civilization (ca. 700–1850) extended from the Atlantic shores of Africa to the Pacific Ocean and from the steppes of Siberia to the islands of South Asia. Widely different traditions of empirical and theoretical cartography developed and coexisted within this cultural sphere. The academic study of these traditions is at its preliminary stages, and it is likely that further research will unveil hitherto unknown aspects of the cultural history of maps in the Islamic world (Figs. 1 and 2).

Practice

If one leaves aside purely literary references to maps and map use in historical sources for the first three centuries of Islamic history, the first significant corpus of Islamic terrestrial maps that survive are those that accompany texts written by the Balkhī school of geographers (al-Balkhī, al-Iṣṭakhrī, Ibn Ḥawqal, and al-Muqaddasī) during the tenth century. This set of maps normally comprised a world map, maps of the three seas (the Mediterranean, the Indian Ocean, and the Caspian Sea), and maps of seventeen regions of the Islamic world. Not based on any projection and lacking a scale, it is possible that these maps were based on geographical writings that described the postal routes and administrative divisions of the Islamic states.



Maps and Mapmaking: Islamic Terrestrial Maps.
Fig. 4 al- Bīrūnī's seven *kishvars*. From al- Bīrūnī, *Kitāb al-tafhīm li-avāʾil ṣināʿat al-tanjīm*, ed. Jalāl al-Din Humāʾī (Tehran, 1974), 196.

The other major cartographic school to develop in this period of Islamic history was the Ptolemaic. No early specimen of this school survived – the most spectacular of these seems to have been a world map produced for the ʿAbbāsid caliph al-Maʾmūn (r. 813–33) – and one has to turn to the celebrated geographical compendium of al-Sharīf al-Idrīsī, entitled *Nuzhat al-mushtāq fīʾkhtirāq al-āfāq* (The Book of Amusement for Those Yearning to Penetrate the Horizons) to appreciate fully the strength of the Ptolemaic cartographic tradition. Al-Idrīsī's work, completed in 1154 and accompanied by a large world map engraved on silver (no longer extant), contained a small world map and 70 sectional maps that collectively represented the whole of the known world. Latitudes and longitudes, not shown on the maps, were given in the text (Figs. 3–8).

Cartographic representation of the globe during the High Caliphal and Early Middle Periods (ca. 700–1250) was not confined to geographical mapping of the Balkhī and Ptolemaic schools. In their attempts to depict the world Muslims also resorted to geographical diagrams. At least three different traditions of

Maps and Mapmaking: Islamic Terrestrial Maps. Fig. 5 Seventy-two section scheme of sacred geography. By permission of the Topkapi Sarayi Müzesi Kütüphanesi, Istanbul (B. 179, fol. 52r).

diagrammatization were used: the seven-*climata* scheme, the seven-*kishvar* system, and the *qibla* charts. The seven-*climata* scheme, Ptolemaic in origin, divided the inhabited portion of the earth into seven zones (Arabic *iqlīm*) based on latitude calculations. In the seven-*kishvar* system, of Persian origin, the inhabited portion was represented in seven circular regions (Persian *kishvar*), arranged so that six of the regions totally engulfed the seventh central one. The *qibla* charts, occasioned by the religious prescription to perform various ritual acts in the direction of the Kaʿba in Mecca, divided the world into four, eight, 11, 12, or more sectors around the Kaʿba.

These cartographic traditions, originally developed during the tenth and eleventh centuries, formed the basis of further cartographic activity during the Later Middle Period and the Period of the Great Regional Empires (ca. 1250–1850). There took place a certain degree of interaction between the Balkhī and Ptolemaic schools, the most notable outcome of which was the attempt to place a graticule on the circular world map by Ḥamd Allāh Mustawfī (d. 1339) and Ḥāfiẓ-i Abrū (d. 1430). The formation of the Gunpowder Empires during the sixteenth century opened up new directions in Islamic mapmaking. We are particularly well informed about Ottoman maps and mapmaking. Graphic representation of space was used systematically for administrative purposes in the spheres of military operation and state-sponsored architectural construction. At least two new genres, visual itineraries and town views, were also introduced and heavily used in illustrated histories produced under imperial patronage. Perhaps the most significant and representative of such spectacular productions – of which over 30 are extant for the period 1537–1630 – is the *Mecmūʿ-i menāzil* of Maṭrakçı Naṣūḥ (d. 1564), an account of

Sultan Süleymān I's campaign into eastern Anatolia, Persia, and Iraq in 1533–1535. Not much is known on cartographic production in the Safavid and Mughal Empires.

Theory

Quite apart from cartographic practice and only tenuously related to it, a strong tradition of rigorous investigation of the earth was maintained in Islamic civilization from at least the ninth century onward. In addition to purely narrative geographical accounts, serious attention was paid to geodesy – the measurement of distances, or the determination of exact points, on the curved surface of the earth. As a result, a considerable number of geographical tables exist in Arabic and Persian, normally included in astronomical works. These either list places under climates, with no longitudes given and only the latitude of the climates specified, or assign longitude and latitude values for each place individually. The question of projection was also addressed in some detail. These theoretical aspects of Islamic cartography are perhaps best exemplified in the works of the scholar al-Bīrūnī (d. after 1050), whose output constitutes the culmination point of Islamic geodesy.

Map Use

The extant corpus of Islamic maps, when coupled with purely literary references to cartographic practice, suggest that the mapping instinct in Islamic civilization was by and large harnessed to the cause of scholarship and imperial artistic production. The majority of Islamic map artifacts were produced by the elite for the elite for the purposes of edification, illustration, and propagation of imperial glory. Practical application was the exception rather than the rule and remained confined to military maps and architectural drawings, which developed into distinct traditions only in the Ottoman Empire. The products of elite high culture, however, were infinitely more likely to be preserved, if only in literary form, than their popular or folk counterparts, so that the surviving cartographic record of premodern Islamic societies is only partially reflective of everyday mapping practices.

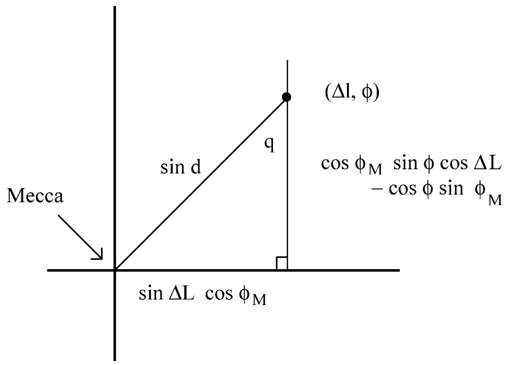
Maps and Mapmaking: Islamic World Maps Centered on Mecca

David A. King

Three remarkable world maps have come to light since 1989. The maps have Mecca at the center and are so devised that the direction of Mecca (*qibla*) and distance to Mecca can be read directly for any locality in the Islamic world between Andalusia and China (see the frontispiece for an illustration of the first world map). The maps are engraved on circular brass plates of diameter 22.5 cm and clearly hail from the same workshop. From considerations of the calligraphy and decoration they can be associated with Isfahan and dated ca. 1675. But they are all clearly copied from different originals, and so they are from a series of such world maps about which until recently we knew nothing.

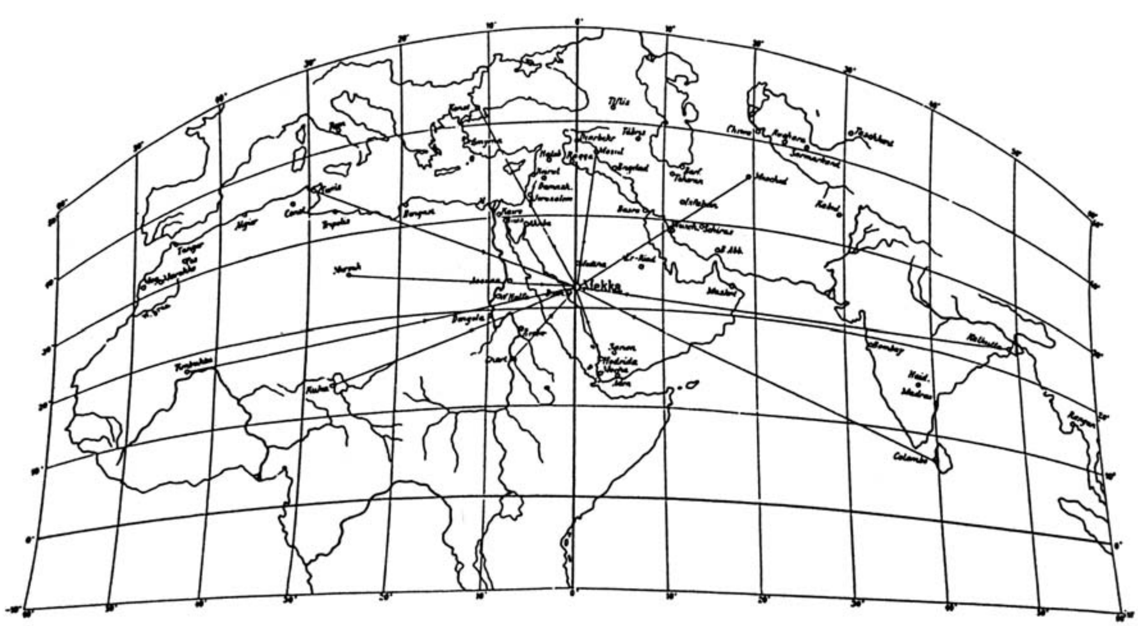
The highly sophisticated cartographical grid (see Fig. 1) is to be used in conjunction with the scale around the circumference, on which the *qibla* can be read, and with the nonuniform scale on the diametral rule, on which the distance to Mecca in *farsakhs* can be read. (A *farsakh* is equivalent to 3 mile.) There are some 150 localities marked on each of the maps, but the selection is not identical: their coordinates are at first sight based on those in the *Sulṭānī Zīj* of Ulugh Beg (Samarqand, ca. 1430), based in turn on those in the *Īlkhānī Zīj* of Naṣīr al-Dīn al-Ṭūsī (Maragha, ca. 1250), but there are several localities whose coordinates testify to the fact that they were taken from the common source of both the *Sulṭānī* and *Īlkhānī Zīj*es, namely, the mysterious anonymous *Kitāb al-Aṭwāl wa-l-ʿurūḍ li-l-Furs*, a source known to us only from citations by the astronomerprince Abu'l-Fidāʾ (Hama, ca. 1325). The *Kitāb al-Aṭwāl wa-l-ʿurūḍ* may be as early as the twelfth century. On the other hand several of the localities in India featured on the maps were not founded until the early fifteenth century. In fact, the earliest known geographical table featuring all of the localities on the two maps is found in a treatise on the astrolabe compiled in Najaf in 1702/03 by one



Maps and Mapmaking: Islamic World Maps Centered on Mecca. Fig. 1 The mathematics underlying the theory of the grid on the Isfahan world maps, enabling the user to read the *qibla* on the circumferential scale and the distance on the diametral scale. An approximation has been used on the world map so that the latitude curves are arcs of circles; this produces slight inaccuracies noticeable only on the edges of the map (that is, in Andalusia and China). Drawn by the author.

ʿAbd al-Raḥīm ibn Muḥammad, who wrote that he compiled his table from al-Ṭūsī, Ulugh Beg, "and others." But he also presented the *qiblas* and distances to Mecca for the 274 localities in his list, and at least some of these feature on various Persian astrolabes from the mid-seventeenth century, that is, some 50 year before he compiled his treatise. In fact ʿAbd al Raḥīm simply copied a table compiled in Kish near Samarqand in the first half of the fifteenth century. This was, in fact, the actual source of the geographical data on the three world maps. Since 1999, when the first two maps were published, Jan Hogendijk has found two sources, one from tenth-century Baghdad and the other from eleventh-century Isfahan, in which a solution to the qibla problem using conic sections is discussed. On the maps the circular arcs for the latitudes are excellent approximations to segments of ellipses. Now that we know what to look for, it is not too much to hope that a reference to a map grid based on this solution to the qibla problem might be found in some other early source.

Although the origin and development of these Mecca-centered world maps is still obscure, it is clear that they are entirely Islamic in their conception. Indeed they represent the culmination of Islamic mathematical cartography, and have no parallel in sophistication between Antiquity (the world map of Ptolemy, ca. 125) and European cartography of the seventeenth century. Prior to their rediscovery it was thought that the first



Maps and Mapmaking: Islamic World Maps Centered on Mecca. Fig. 2 The world map proposed by Carl Schoy ca. 1920 for preserving direction and distance to Mecca. There are major cartographic distortions for regions on the other side of the world. On the Isfahan world map, even though it was made ca. 1700, we are dealing essentially with the world as known to Ptolemy. (From Carl Schoy, *Gnomonik der Araber*. Berlin and Leipzig: Walter de Gruyter, 1923, between pp. 44 and 45.)

person to construct a world map centered on Mecca from which one could read off the *qibla* and distance to Mecca was the German historian of Islamic science Carl Schoy, who published such a map ca. 1920.

Maps and Mapmaking in Japan

Kazutaka Unno

The first record of Japanese mapmaking is an Imperial edict in AD 646 included in the *Nihon Shoki* (Chronicles of Japan), 720, ordering that each province reports its territorial range to the central government by means of a map. However, no fragment of such a map is extant now. The earliest extant maps relate to land ownership and date from the eighth century. These maps are almost all preserved in the Shōsōin, Nara, and consist of a map of Tōdai-ji temple precincts, 756, and over 20 maps of paddy fields. On these maps we can observe the traditional Chinese grid system. The majority of them are drawn on hemp.

The extant early general maps of Japan include: one dated the 12th month, the third year of the Imperial era known as Kagen (1305/06), now owned by the Ninna-ji temple, Kyoto; *Dai-Nihonkoku Zu* (Map of Great Japan) in the 1548 codex of an encyclopedia, *Shūgaishō* (Collection of Oddments); and *Nansembushū Dai-Nihonkoku Shōtō Zu* (Orthodox Map of Great Japan in Jambudvīpa) drawn in the mid-sixteenth century (Tōshōdai-ji temple, Nara). These maps show the coastline and the boundary lines between provinces by means of smooth curves, and have the common characteristic of showing the main routes from the province of Yamashiro, where the capital Kyoto had been located since 794, through almost all the provinces. Maps with such characteristics are called “Gyōki-type” maps, because they have an inscription indicating that the author was Gyōki (668–749), a revered Buddhist priest. But no one believes today that they were actually the work of Gyōki, for the capital in his time was not Kyoto but Nara, Yamato Province. Later, in the ritual of *Tsuina* (which had been instituted on Gyōki’s advice in 706 in order to offer prayers for national peace and the health of the people), a map of Japan came to be used to provide a concrete image of the country. It may be imagined that by association maps so used came to be called by his name.

The earliest extant map of the world is the *Go-Tenjiku Zu* (Map of the Five Indies), drawn by Jūkai, a Buddhist priest, in 1364, and now owned by the Hōryū-ji temple in Nara. The actually existing Buddhist continent called Jambudvīpa is drawn; India occupies a great part of the continent, and China, Persia, Japan, and many countries of Central Asia are shown. There are ten other extant maps which are copies made in later periods, and which belong to the same group. Incidentally, the above-mentioned *Shūgaishō* also contains a rough map of Jambudvīpa entitled *Tenjiku Zu* (Map of India).

European cartographical works were introduced to Japan in the late sixteenth century, and the coastlines of the Gyōki-type maps came to be drawn in detail, especially in the area of Kyūshū. This revision seems to have been done by the European pilots and by the Portuguese Ignacio Moreira, who resided in Japan between 1590 and 1592.

Exact maps of provinces were needed for state administration. But there are no known records about the compilation of national maps after the year 646 mentioned above (except for government orders of 738 and 796) until 1591, when the Toyotomi government embarked on such a project. The extant maps of two counties in Echigo Province are rare examples of the results of this project. The Tokugawa Shogunate, which succeeded the Toyotomi government and held its hegemony for two and a half centuries until 1867, gave orders for cartographical records of all provinces on five occasions during its reign.

These orders were issued in the tenth year of the Imperial era of Keichō (1605); about the tenth year of Kan’ei (ca. 1633); the 12th month of the first year of Shōhō (1645); the tenth year of Genroku (1697); and the sixth year of Tempō (1835). No detailed records remain as regards the first and second projects. After the third project, prescriptions aiming at some regularization of form were issued, for example, the scale was fixed at six *sun* to one *ri* (1:21,600). For the third project, the Shogunate also required the province to submit the plans of cities where the clan offices were located. These maps and plans are huge

M

and beautifully colored. All of the maps of the fifth project, and some earlier ones, are still extant in the National Archives in Tokyo.

General maps of Japan based on the provincial maps were compiled on each occasion except the fifth project. The earliest extant official map of Japan is the so-called Keichō map of Japan, compiled in the mid-seventeenth century and now in the National Diet Library, Tokyo. On this map the eastern half of Honshū is completely curved to the north, and depicted as smaller than it actually is. The island of Shikoku, which actually has projections in all four directions of the compass, is drawn in a rectangular form.

The best of the official maps of Japan compiled during the Edo era is the so-called Shōhō map of Japan, based on the results of the third cartographical project, and completed around 1670. Compiled by the famous surveyor Hōjō Ujinaga, this map shows the shape of the Japanese archipelago which is very close to actuality.

These maps strongly influenced private works of cartography. *Nihon Bunkei Zu* (Map of Japan Divided into Parts), published in 1666, and the series of works by the painter Ishikawa Ryūsen beginning in 1687, were based on the Keichō map of Japan; the former was the first printed atlas of Japan. Seki Sokō's *Nihon Bun'iki Shishō Zu* (Easily Understandable Atlas of the Regions of Japan), 1698, and Nagakubo Sekisui's works (first edition, 1779) were also based on this "Shōhō map of Japan".

In traditional cartography, little attention was paid to the existence of spherical coordinates, but latitudes are shown in the portolan charts of Japan (ca. 1670, Mitsui Bunko Library, Tokyo; National Museum, Tokyo). The first map of Japan made under the influence of these charts and having a network of parallels and meridians was Mori Kōan's *Nihon Bun'ya Zu* (Astronomical Map of Japan), 1754. In this map, however, parallels and meridians were simply added to the already existing official map. We also find such a network on Nagakubo's maps of Japan, but with only the degrees of latitude. It is evident that they imitated Mori's idea, and moreover had a greater social influence, because these latter maps were often printed, while Mori's remained only a manuscript.

The first map of Japan that was based on actual observation of degrees of longitude and latitude was completed by officials of the Shogunate astronomical observatory in 1821. The surveying began in 1800 and mainly concentrated on the coastlines, as the title *Dai-Nihon Enkai Yochi Zenzu* (Maps of the Coastlines of Great Japan) shows. The supervisor of the surveying throughout was the astronomer Inō Tadataka, and all the maps thus made in this project are called "Inō's maps". The 1821 maps consisted of 214 sheets on a scale of 1:36,000, eight sheets of 1:216,000, and three sheets of 1:432,000.

The making of topographical maps by triangulation began in 1781, and in 1944 the entire country was depicted on maps with a scale of 1:50,000. Western style charts began to be systematically executed by the navy in 1871.

Maps and Mapmaking in Korea

Gari Ledyard

Korea has a long history, but evidence of mapmaking comes only from about the fifth century AD, when a nobleman's survivors painted a map of Liaodong city (now in Liaoning Province, China, but then within the borders of the Korean Koguryŏ kingdom (37 BCE–668)) on a wall of his tomb. Since the tomb is in northern Korea, the map probably was meant to comfort him with an image of his far-off hometown. Koguryŏ's southern neighbors, the kingdoms of Paekche (18 BCE–663) and Silla (57 BCE–935) are known through written historical sources to have used maps in local administration, but no examples have survived. The same is true for the long Koryŏ dynasty (918–1392). The people of Koryŏ times had a sure sense of the peninsular outline of their country and are said to have commemorated it in the shape of the kingdom's standard silver bullion unit. Outlines of Korea also appear on a few Chinese maps of the twelfth century. Toward the end of the dynasty an enterprising scholar composed an elaborate map of the world – probably just the China–Korea region – and this work was probably connected in spirit to the *Kangnido* of 1402, which, in a copy of about 1470, is the oldest Korean-made map to survive.

The Artifactual Record

The succeeding Chosŏn dynasty built a much stronger and more durable state than had previously been known in the Korean peninsula. A vast amount of mapping was carried out in the fifteenth century, but aside from some prominent exceptions there is little remaining trace of this early production. Most surviving Korean maps are of the seventeenth century or later, and are most commonly found in albums, often hand-drawn but occasionally including wood-block prints. Larger maps are usually found preserved in silk or paper scrolls or on screens. A large sample of this material is now available in published color illustrations.

From the seventh century on, Korean kings presided over a strongly centralized, bureaucratic state. Provincial governors and district magistrates were responsible for producing maps of their areas in response to requests from central authorities for geographical, demographic, and fiscal information. Thus the central government maintained and frequently updated a broad range of data from which provincial and national maps could be compiled. The most complete such compilation to survive in its entirety is the *Sinjŭng Tongguk yŏji sŭngnam* (Complete Conspectus of Korean Territory, newly expanded; called the *Sŭngnam* for short) of 1531, descended from earlier editions going back to 1481.

Beginning in the late fifteenth century, the government generally limited publication and dissemination of maps for national security reasons, and the maps that were available, such as those in the *Sŭngnam*, were rather spare in detail. But security concerns also spawned the defense map (*kwanbangdo*) genre, which was rich in information relating to logistics and communciation.

Geomancy

In the late ninth century, Koreans began to articulate a national geomantic structure for their country. In its elementary form, geomancy (*p'ungsu*, Chinese *fengshui*) is an originally Chinese science employed in siting graves, human habitations, temples and shrines, and towns and cities. The landscape is the locus of forces which deliver energy and power through networks of montane "arteries" (*maek*) or riparian "veins" (*p'a*), which will be determined to be either favorable or unfavorable for the use envisaged for a particular site. Even today, specialists in this kind of knowledge can be found in most Korean communities, and indeed all over East Asia. But Korea is unique in developing this science into a nationwide framework for understanding and defining the physical aspects of the nation itself. From an early date the source of Korea's geomantic forces was seen to be located in Mount Paektu (2,744 m), which through Korea's mountain ranges and water sheds distributed vital forces to the entire country. It was thus of crucial importance to determine and map the mountain ranges of the land, so that the relationship of any particular spot to the overall network of "shapes and forces" (*hyŏngse*) could be clearly understood. Whether on the national or local level, a shapes-and-forces map (*hyŏngsedo*) would clearly configure the mountain ranges and water sheds, so that the physical lay of the land was easily perceived.

In the seventeenth century, following the Japanese (1592–1598) and Manchu invasions (1627, 1637), Korea went through a series of reforms which resulted in enhanced revenues and a more developed military. This was accompanied by economic growth and increased trade with China and Japan. In society at large these changes produced greater occupational diversity, a certain degree of social mobility, and a broader access to education. An intellectual movement in pursuit of "practical studies" (*sirhak*) extended scholarship into new areas of science and statecraft research. Thus it is not surprising that we see a development which might be called the privatization of cartography, leading to works by individual mapmakers that steadily grew in quality and diversity. Maps were no longer restricted to government offices but were much more broadly distributed throughout society. This resulted in a higher rate of preservation of maps into modern times.

In tracking this greater patronage we can notice two different kinds of map collections: administrative, and popular atlases. The administrative atlas typically would consist of a set of maps of Korea's eight provinces. Each provincial map would show the districts of the province, often with a shapes-and-forces accent that clarified the geographical character of the area. It would indicate principal roads and bridges, post stations and military bases, temples and schools, and other sites of official or civic importance. Distances between towns would be indicated either by notations on the map or in a table in the atlas. Accompanying essays would give a general historical and administrative overview of the province, and lists would be provided showing the rank of each magistracy, with statistics on its tax revenues, military reserves, and various other categories.

The popular atlas often had a similar organization, but it was distinguished by the addition of a general map of the world, or *ch'ŏnhado* (map of "all-under-heaven"), a general map of China, sketchier maps of Japan and the Ryukyu kingdom, and a map of Korea as a whole.

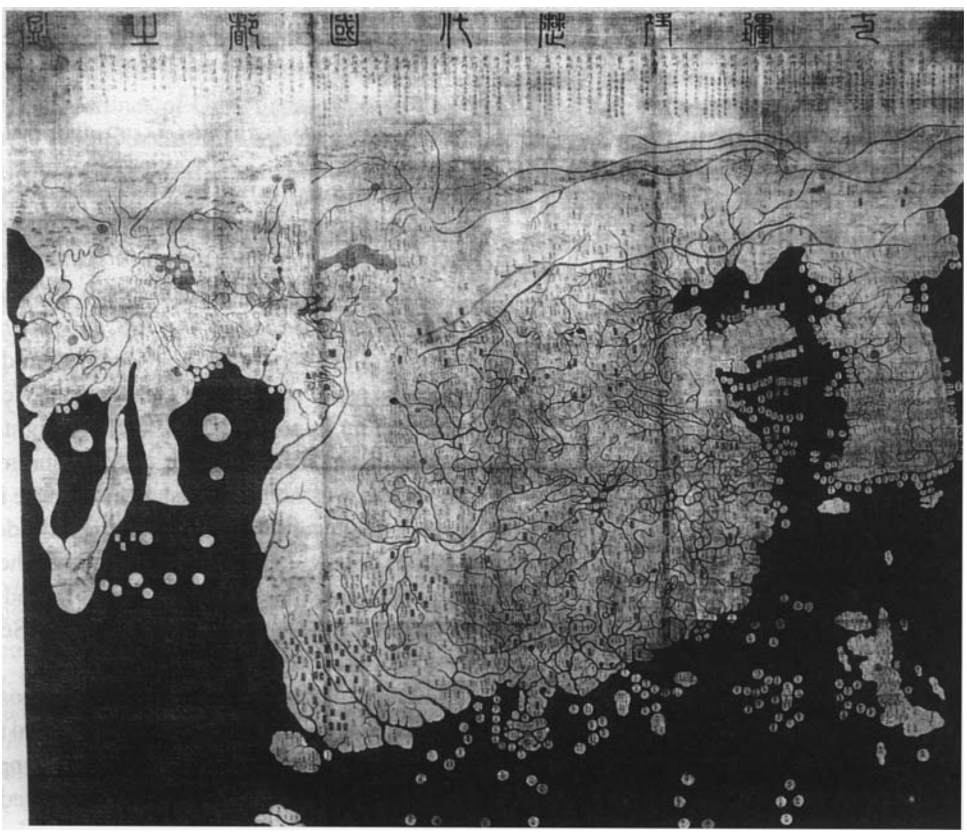
Korean Knowledge of Western Cartography

Jesuit missionaries, led by Matteo Ricci, began to introduce western maps of the world to China in the last years of the sixteenth century, and copies of printed editions of Ricci's world maps of 1602 and 1603 each reached Korea within a year of their publication. In 1708, a royal order was given to copy a variant version of the Ricci map, and this occasioned a Korean essay on Western cartography. Western maps continued to be imported throughout the eighteenth and early nineteenth centuries. A Jesuit-directed summation of mathematics and astronomy published in Chinese in 1723 updated Korean understanding of geographic latitude and explained methods of calculating longitude through the observation of eclipses, and Jesuit determinations of latitude and longitude for major Chinese centers and even for Seoul itself were found in the same source.

In spite of this more than passing exposure to western maps and mapmaking, one can find no visual trace of western influence on Korean maps themselves. An apparently Anglo-Chinese map from the 1790s was even printed by woodblock in Korea, in 1834, by the greatest Korean cartographer of all, Kim Chŏngho, yet Kim's own maps stay completely within the Korean tradition. On the other hand, there is abundant evidence that by the eighteenth century, Koreans were systematically compiling latitude and longitude data for their country, and although no indication of it is found on any Korean map of Korea, a kind of geodetic measurement did play a role in the accuracy of the data used to make the maps.

The Kangnido

The first rulers of the Chosŏn dynasty sponsored a number of projects designed to strengthen their legitimacy. Among these were a recarving on stone of a seventh century Korean star map and a terrestial map of the world. The star map reflected a very ancient Chinese astrographical tradition long superseded in both China and Korea, but the terrestial map, the *Honil kangni yŏktae kukto chi to* (Map of Integrated Lands and Regions and Historical Countries and Capitals) was based on two fourteenth-century Chinese maps. In 1402, Kwŏn Kŭn (1352–1409), a Confucian scholar and royal advisor, was ordered to supervise the compilation of a world map based on these two sources. The actual drawing was the work of Yi Hoe. To his images of China and the greater world, Kwŏn and Yi added Yi's own map of Korea and a recently imported image of Japan, thus, in their understanding, bringing the map to completion (Fig. 1).



Maps and Mapmaking in Korea. Fig. 1 *Honil kangni yŏktae kukto chi to* (Map of Integrated Lands and Regions and Historical Countries and Capitals). By permission of the Ryukoku University Library, Kyoto, Japan.

While this original *Kangnido* was lost long ago, a Korean copy made around 1470 and seized by Japanese invaders in the 1590s has survived in Japan. This copy contains Kwŏn Kŭn's original preface, which details the source materials.

At first glance, the *Kangnido* seems a collection of distortions. China and India make up a dominating, undivided mass in the center, while Europe and Africa hang from the western side and Korea hangs from the eastern as if these two masses were geographically equal. An upended Japan floats uncertainly in the East China Sea. The *Kangnido* was a conflation of other maps, with considerable relative distortion of the land masses, rather than cartography in the strict sense. As the first East Asian map to include Europe and Africa, and such features as the Mediterranean and Black Seas, the Arabian peninsula and the Persian Gulf, the Nile and the Red Sea, as well as to add Korea and Japan on the east, the *Kangnido* is an epochal achievement in Korean as well as world mapmaking.

Popular Cosmography: The Ch'ŏnhado

The *Kangnido* was in Korea too exotic to pass unrevised into the mainstream of Korean mapmaking. The unpronounceable names, in many cases Arabic originals filtered through Chinese transcriptions; the unimaginable distances; strange countries of which in many cases nothing was known – very little of this related to the concept of the world known in Korea. This world was essentially of Chinese definition. It was the *tianxia* (*ch'ŏnha* in Korean pronunciation) or "all under Heaven" that was at peace during the reigns of sage emperors, or that fell into disorder during the rule of bad ones. The geography of this world could be known through the Chinese classics and through the geographical sections and accounts of foreign countries in the long chain of Chinese dynastic histories that began to be compiled in the first century BCE. In addition there was the more fantastic and whimsical geography recorded in the *Shanhai jing* (Classic of Mountains and Seas), the older parts of which date from around the second century BCE but which evoke even more ancient myths and traditions. This source added to the classical geography such imagined places as the "Land of the One-armed," the "Country of Women," "Mount Incomplete," and many more. This mix of ancient historical places and imagined fantastic ones constituted the world that was mapped in the *ch'ŏnhado* (world maps) (Fig. 2).

Although based almost completely on Chinese source material, the numerous examples of *ch'ŏnhado* constitute a completely Korean genre of map. An inner continent dominated by China, with the Korean peninsula always clearly depending from the eastern side, is surrounded by a sea full of kingdoms, which itself is surrounded by a circular land strip with even more amazing places. The eastern and western sides of this ring feature trees near which the sun rises and sets.

The origins of the *ch'ŏnhado* genre are unclear. A number of scholars have believed that these maps were Buddhist in origin, and some have thought that the basic shape of the map could have been derived from geographic theories popularized by the Chinese naturalist philosopher Zou Yan (fl. third century BCE). While morphologically plausible, it is impossible to find any cartographic link over the nearly two millennia that separate Zou Yan from the emergence of the *ch'ŏnhado* in the sixteenth century.

I believe that the core of the *ch'ŏnhado* – its inner continent – evolved from the *Kangnido*. In addition to many geographical and morphological considerations, the Tenri *Kangnido* is also chronologically congenial to this theory, since it contains place names that fix its copying no earlier than 1568, making a plausible bridge to the sixteenth century *ch'ŏnhado*.

Korean National Maps

Under King Sejong (r. 1418–1450), the Korean court pursued a wide range of technical and scientific projects in astronomy, calendrical science, horology, musicology, pharmacology, agronomy, and geography and cartography. Distances between Seoul and the seat of each district, and between the districts themselves, were carefully measured and recorded. Polar altitude observations determined the latitude of the capital and of the extreme northern and southern frontiers, permitting an accurate estimate of the length of the country. Sejong also gave serious attention to the montane structure of the nation, collecting and studying data on the nation's mountain "arteries" and river "veins." King Sejo (r. 1455–1468), Sejong's son and follower, ordered the complete mapping of the country, including not only a national map but maps of each of Korea's eight provinces and approximately 330 counties.

The national map that resulted from this preparation was the *Tongguk chido* (Map of the Eastern Country), which was presented to King Sejo in 1463 by his two chief cartographers, Chŏng Ch'ŏk (1390–1475) and Yang Sŏngji (1415–1482), but is thought to be principally the work of the former. The general outlines of the peninsula's coastline are astonishingly suggestive of those on modern maps, while the shapes-and-forces treatment detailing the nation's mountain network and watersheds provides a rich appreciation of its physical geography. Every district of the kingdom is indicated, along with its distance from Seoul and its provincial affiliation. Equally distinctive is the map's chief flaw, an unduly flattened northern frontier. Early Korean mapmakers appear to have had considerable

Maps and Mapmaking in Korea. Fig. 2 *Ch'ŏnhado* (Map of the World). By permission of the National Central Library, Seoul.

difficulty in grasping the outline of the northern frontier, which was defined by the Amnok and Tuman (internationally, Yalu and Tumen) rivers that respectively flowed off the western and eastern slopes of Mount Paektu. It was not until the eighteenth century that this problem was essentially solved. So for about three centuries the conventional shape of the country was associated with Chŏng Ch'ŏk's outline, and cartographers now refer to such maps as in the Chŏng Ch'ŏk style.

The great summation of the administrative geography promoted by the fifteenth century Korean courts was the *Sinjŭng Tongguk yŏji Sŭngnam* (Complete Conspectus of Korean Territory, newly expanded), which was first drafted in 1481, and went through several revisions before the final one of 1531. Called the *Sŭngnam* for short, this work detailed the administrative history of Korea's provinces and districts. It connected each district to its earliest known organization in earlier dynasties; clarified its rank and position in the administrative and military chains of regional governance; listed its schools, monasteries, Confucian shrines, post stations, signal-fire stations, natural and economic resources, famous native sons and virtuous women; and concluded with a sampling of literature associated with its history and public and private institutions. The final edition of the *Sŭngnam* was so thorough and so well done that it was never supplemented or re-edited.

We know that the cartographer Yang Sŏngji, whose work over the years for Kings Sejo and Sŏngjong (1469–1494) had laid the foundation for the *Sŭngnam*, was well known for his strict views on defense and national security. He argued that maps should not circulate outside of a few designated government offices. These views may have been a factor in the spareness of detail on the *Sŭngnam* maps that appeared later in Sŏngjong's reign. Another important change on the *Sŭngnam* maps concerned the shapes-and-forces treatment. Even the *Kangnido*'s representation of Korea had displayed the principal mountain ranges of the kingdom. But on the *Sŭngnam* maps, shapes-and-forces indications completely disappeared. The reasons for this change are not clear.

During the first half of the eighteenth century there were new developments in the mathematical and observational sciences which had a strong impact on the maps of the later Chosŏn period. Much of this was connected with western knowledge, which had begun to flow steadily into Korea from Jesuit sources in China. Jesuit participation in the national mapping project of the Kangxi Emperor (1661–1722), which took place from 1709 to 1716, brought Jesuit cartographers who were mapping Manchuria to Korea's borders, and in 1713, Jesuit-trained Manchu and Chinese specialists made surveys and observations within Korea itself. The concepts of latitude and longitude, and related observational and mensurational techniques, were clearly described in Sino-Jesuit manuals which were introduced into Korea at least by 1715. A dramatic improvement in spatial representation is found on Korean maps that were developed during the following 30 or 40 years.

The man responsible for this cartographic revolution was Chŏng Sanggi (1678–1752), a brilliant scholar who labored for decades in the privacy of his home. He developed what he called the "hundred-*li* foot" (*paengni ch' ŏk*), a 100-*li* visual scale bar (metaphorically a "foot," I will call his unit a "scale-foot") calibrated in 10-*li* (4.3 km) intervals, which he inserted just after his introduction to his maps. Chinese books of that period specified a ratio of 200 *li* to one terrestial degree of latitude or longitude. This ratio was cited and used by late-eighteenth century Korean mapmakers (although the Korean *li* was considerably shorter than the Chinese), and calculations based on their maps show that they probably followed such a formula to determine geodetic distance. Perhaps Ch'ong Sanggi had used the same procedure.

Shapes-and-forces cartography made a strong return on Chŏng Sanggi's maps, and the vernacular painting style of the day depicted the mountain ranges in an attractive manner that created both cartographic clarity and an aesthetic dimension. A variety of symbols marked military bases, post stations, and other facilities Some copies of Chŏng's map's are works of art as well as cartographic masterpieces. His sons and grandsons continued to be active in cartography throughout the eighteenth century.

The Maps and Writings of Kim Chŏngho

In 1791, the Korean government sponsored the creation of a national grid for the purpose of complete cartographic standardization. While details of this project are uncertain, several albums of local maps copied on standardized *sŏnp'yo* (line guides) survive. Evidently the grid coordinates of each district seat were determined with reference to copies of Chŏng Sanggi maps owned by the government, and then marked on uniform line guides which were sent to district magistrates for development into standard district maps. The detail of these is astonishing. Every river and stream, every principal road and bridge, every public facility and many private ones such as schools, monasteries, and shrines, are indicated.

In 1834, an obscure cartographic genius named Kim Chŏngho (fl. 1834–1864) developed one of these national collections of district maps into a uniform national album, in which he re-edited hundreds of local maps into standard rectangular sheets. This national grid map was called the *Ch'ŏnggudo*, or Map of the Blue Hills, after an ancient poetic sobriquet for Korea.

Kim Chŏngho was himself a professional woodblock carver. It is not known whether he became one in order to market his maps, or began as a blockcarver and branched out into mapmaking. But it is as a blockcarver that he first comes to notice, in 1834, preparing for a famous scholar, Ch'oe Han'gi (1803–1875), a woodblock of a Chinese copy of an English hemispheric map of the world. Ch'oe obligingly returned the favor, writing an enthusiastic preface for the *Ch'ŏnggudo*. But this contact represents the only instance when the Korean world is known to have given any documentary notice to Kim's activities. This is in spite of the fact that in 1861, Kim would produce an even more remarkable national grid map that would bring him enduring fame. He must have been of very humble social status. We have no indication of his ancestry or native place. Traditions speak of endless trips throughout the country to check details and redo existing maps, and of a faithful daughter who took care of him and helped with the blockcarving. The traditional story holds that he was arrested in 1864, supposedly for endangering national security by revealing the nation's geography to potential enemies. But scholars doubt this, reasoning that such a grave incident would surely be reflected in official records, and noting that too many copies of the 1861 map (and of an 1864 recut edition) survive to permit belief that such a thing could have occurred. The 1860s were a time of great tension, with foreign incursions and a large-scale persecution of the country's Catholic community, which had been growing since 1784 in spite of many purges and constant suppression. Could Kim's printing of a foreign map of the world in 1834 have been taken against him? Ch'oe Han'gi, the actual patron of that project, had no problem with this, but then he was an upper-class scholar of influence and repute. Kim had no such insulation, and could have been the victim of petty policemen far down in the official structure. Whatever the reason, he disappeared in 1864 without a trace.

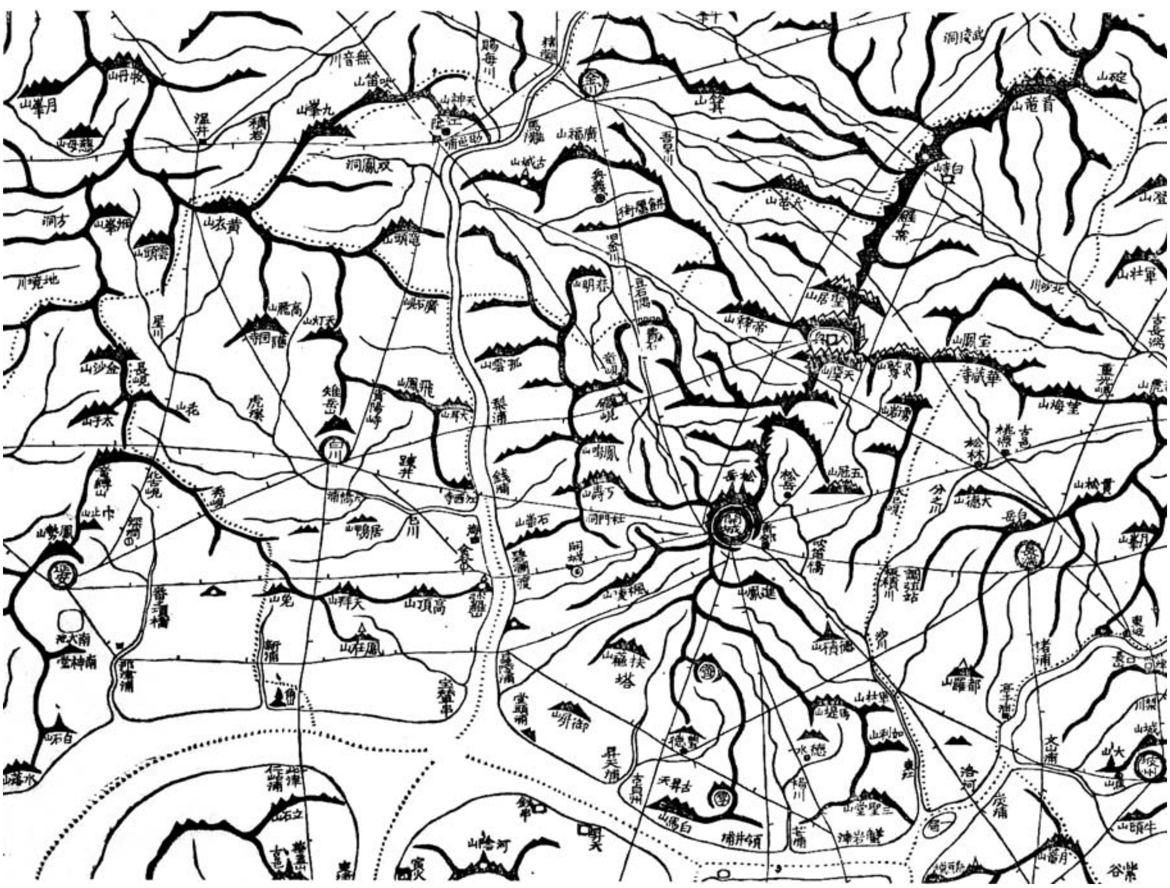
However humble Kim's status may have been, his writing shows that he was an accomplished scholar and a respectable writer of classical Chinese. From 1834 to 1861 his doings and whereabouts are completely unknown. In 1861, under the pseudonym Kosanja (The Master of Old Mountains), a second grid map appeared entitled *Taedong yŏjido* (Terrestial Map of the Great East (Korea)) Fig. 3. Kim's short preface deals mainly with the importance of maps for military affairs.

The *Taedong yŏjido* was a completely reconsidered cartographic image of the country. The shapes-and-forces treatment received here its greatest representation. Mountain ranges were now represented by a solid black line, thinner for lower ranges, thicker for higher ones, with special jagged teeth on the line to represent particularly rugged stretches, or white peaks to indicate snowy heights. The clarity of the overall effect is impressive. With the *Taedong yŏjido*, a complete union of cartographic display and woodblock publishing technique was achieved. Kim seems to have wished to present simply the earth and its natural and human features, with the cartographic structure left, so to speak, underground.

The complete printed *Taedong yŏjido* is likely to have been very expensive. To make his vision of Korea more cheaply available, Kim produced a single sheet version which put the whole nation on a rectangle of about 115 × 76 cm, giving it the title of *Taedong yŏji chŏndo* (Complete Terrestial Map of the Great East (Korea)). The short text that filled the Bay of Wonsan gave the map something of the quality of a patriotic morale poster. After introducing Mount Paektu as "the grandfather of Korea's mountain arteries," giving the dimensions of the seacoasts and northern rivers, and proclaiming the greatness of the nation's legendary founders Tan'gun and Kija, he concluded with his ringing climax: "'Tis a storehouse of Heaven, a golden city! Truly, may it enjoy endless bliss for a hundred million myriad generations! Oh, how great it is!"

The District Map

We have seen that in the late eighteenth century, the Korean government had taken special measures to see that all the districts of the country were uniformly mapped. Although the purpose of this program was to create a national standard, in fact local maps reflected the distinctive features of the district. These highly



Maps and Mapmaking in Korea. Fig. 3 *Taedong yŏjido* (Terrestial Map of the Great East (Korea)). Courtesy of the East Asian Library, University of California at Berkeley.

skilled, uniform maps of districts could not displace the traditional local maps in popularity.

The traditional local map must properly be called a map-painting. It was composed and executed by a practiced painter rather than by a mapmaker, and it set the community into the surrounding landscape in the manner of a landscape painting. The village was seen from a fixed orientation, most commonly with north at the top, and usually in bird's-eye view; roads, rivers, and walls divided up the space in realistic proportions. Distances were indicated by short notes inserted at a focal point in the road. Houses were nestled together in homey elevation, smoke rising from the chimney, a chicken pecking at the ground by the wall. The village well was in its proper place, but visited by ladies and water-boys. The school house with its surrounding pines was a miniature all by itself. In the distance, tucked into the hills, were the familiar shrines and monasteries. In Korean, as in the other East Asian languages, the word for "picture" and "map" was the same, and traditional Korean map-paintings exactly reflected that ambivalence.

City Maps

Seoul was the nation's first city, and was the home of virtually all of the nation's prominent people. Those who lived there seem to have been very fond of maps of the city mounted on folding screens in one of the principal rooms of the house. Although these maps often showed the close urban detail of streets and buildings, one does not get the feeling that those who bought them did so in order to find their way around. The city was large enough so that a bird's-eye view would be unable to reveal the order and scale of its streets and alleys. Thus most maps of Seoul are executed in aerial plan, although the surrounding mountains were characteristically drawn in pictorial elevation.

P'yŏngyang is Korea's oldest city. Once a capital of the ancient kingdom of Koguryŏ, it was always an important regional center in later dynastic days. As the capital of P'yŏng'an Province on Korea's northwestern border facing China, it had great strategic and commercial significance. Maps of the city are commonly encountered and must have always been a popular souvenir. Although maps in aerial plan are known, the favored orientation for its mappers was a bird's-eye view looking toward the city over the Taedong River from the east. More than maps of Seoul, those of P'yŏngyang took on many of the qualities of the map-paintings of smaller towns.

Defense Maps

After the invasions of Korea by the Japanese in 1592–1598 and the Manchus in 1627 and 1637, Korean statesmen adopted policies that put a high emphasis on defense and military preparedness. Thus for the years of the seventeenth through the nineteenth centuries, a great variety of defense maps (*kwanbangdo*) were produced. Most of them are unique and few were ever copied, accounting for the fact that most of those surviving today are original works. Some, such as the *Yogye kwanbang chido* (Map of the Defenses of the Liaoji Area) are vast panoramas that stretch from the northeastern coast of Korea northward toward the Amur River and westward to Beijing itself. Others show particular sections of the northern frontier. There are many having the character of charts that map Korea's coastal areas. There are detailed paintings of mountain fortresses. One sees in these works a great variety of styles, media, and painting skills. These maps, which in their day were in the category of classified information, are now prized for their unique approach to national and international cartography, and in many instances also for their highly stylized and artistic manner of execution.

Though one of East Asia's smaller countries, and always the object of Chinese cultural influences, Korea has had a proud and distinguished tradition of mapmaking all its own, and not a small number of unique cartographic achievements. The *Kangnido* is East Asia's oldest surviving world map, and by world standards at the time of its composition in 1402, one of the best realizations of world geography known from that time. The *Ch'ŏnhado*, though it reflects only Chinese geographic views and source material, is a map that China itself never produced. Chŏng Sanggi's maps of Korean provinces achieved a high standard of cartographic excellence and artistic distinction. Kim Chŏngho produced two great grid maps of Korea, and achieved a standard of cartographic imagination and excellence. Korea's great corpus of maps, now in Yi Ch'an's magnificent album, are deserving of serious attention and the further research efforts of the world's cartographic historians.

Maps and Mapmaking: Marshall Island Stick Charts

William H. Davenport

The so-called stick charts of the Marshall Islands in the Pacific Ocean are a rare instance in which a kind of cartography was developed in a nonliterate culture. Their designation comes from the fact that they are constructed of slender sticks and twigs, and sticks lashed together into complex patterns. These patterns represent what occurs when mature ocean swells sweep past one or more of the coral atolls that make up the Marshall Island chain. The charts are not carried to sea, but are used as illustrative devices to train young men in the skills of piloting canoes through the archipelago, out of site of land, by noting various swell phenomena.

The basic concepts that are illustrated on the charts are refraction and reflection of ocean swells. When well-defined swells approach a shore they are bent according to the angle the swell line encounters when it reaches shallow water and the shore. This occurs because the portion of a swell slows down as it encounters shallow water, while the offshore, deep water part continues unaffected. This is wave refraction (Fig. 2).

Refraction occurs as long as a swell is in contact with shallow water and with a small roughly circular atoll this may be entirely around it. As a result, the surface waters off the protected side of the island will be confused by the intersections of opposed arms of the refracted swells. Further off the protected shore the swells reform as they continue on their course.

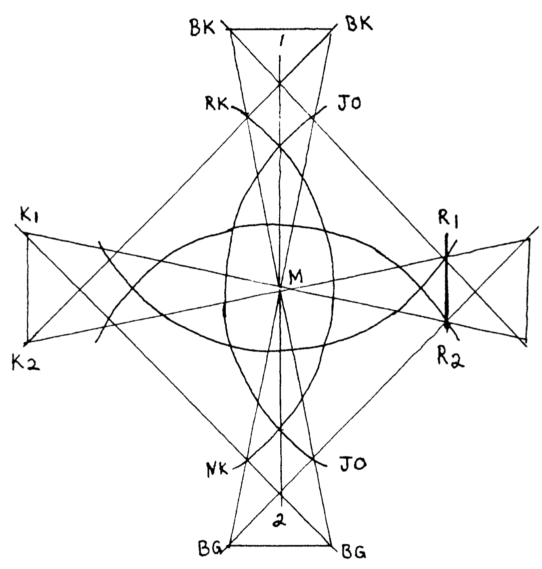
Wave energy is also reflected from a shore line which sends a smaller reflected wave back at a complementary angle, just as light striking a reflective surface or a ball striking a hard surface bounce back.

The Marshallese stick charts represent these phenomena: one or several lines of ocean swells approaching an island, their refracted and reflected swells, and the interactions of these with each other. The stick patterns on a chart can be quite intricate when more than one island and more than one swell system is depicted. In such cases a cardinal direction (rear) is indicated, which is the one generated by the north Pacific tradewind system, *rilib* (backbone), that strikes the Marshall Islands from a northeasterly or easterly direction.

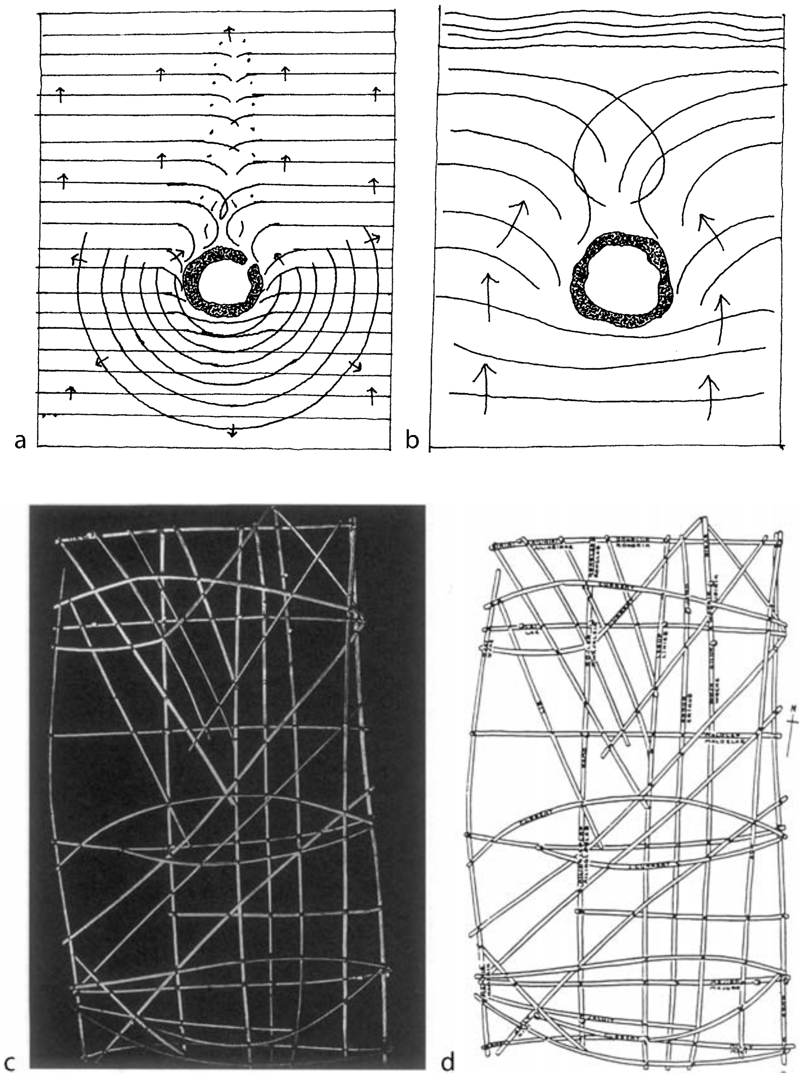
There are three kinds of charts: the *mattang* which illustrates the general principles of swell refraction and the intersection of swell lines; the *meddo* (sea) which depicts the relative positions of more than one island, wave data, and sometimes other pertinent hydrographic information; and the *rebbelith* which is like the *meddo* but includes many islands or most of the group, and has less detailed swell information. Sometimes shells are used to designate islands. There are some indications that the *rebbelith* type may have developed after Marshallese sailors learned about European nautical charts (Fig. 3).

A partial interpretation of the schematic diagram shown here (Fig. 1), taken from an actual *mattang*, will illustrate most of the wave phenomena used by Marshallese navigators. The center intersection of the chart (M) represents any island; at the right the vertical line R/1–R/2 represents the cardinal direction (rear) and dominant east-to-west swell (*rilib*). As *rilib* encounters island M it is refracted, the upper (northern) refracted arm (RK) is called *rolok*, the lower (southern) refracted arm (NK) is termed *nit in kot*. Opposing *rilib* is a weaker west-to-east swell called *kaelib*, both refracted arms of which are termed *jur in okme* (JO). Two other, usually weak, swell systems, one from the north called *bundokerik* (BK), and its opposed system, called *bundokeing* (BG) are also indicated as they are refracted by island M.

At sea where the *rolok* (RK) or *nit in kot* (NK) arms intersect at a certain angle with *jur in okme* (JO) as well as at other similar intersections of reflected and refracted swells their combined energies cause the water surface to peak up in a characteristic way and briefly break, producing a distinctive kind of white cap. This visible sign is called a *bot* (node). The narrow sector of sea in which *bot* are visible is termed the *okar* (root), because it leads to a tree, i.e., to land where trees grow. In the diagram, the line 1–M–2 represents the



Maps and Mapmaking: Marshall Island Stick Charts. Fig. 1 Schematic diagram of a *mattang* chart.



Maps and Mapmaking: Marshall Island Stick Charts. Fig. 2 a, Wave reflection and refraction around an atoll. b, Wave refraction around an atoll. c, Meddo chart, collected by Robert Louis Stevenson. From the University of Pennsylvania Museum of Archaeology and Anthropology (negative number S8-140153). Used with their permission. d, Key to the Robert Louis Stevenson chart.

northern and southern *okar* of the *rilib* and *kaelib* swell systems. In following the *okar*, the navigator notes the change in angle of the intersecting swells, if the angle increases (because the refraction is greater) he is getting closer to land, and the converse. Usually, however, dead reckoning has been good enough for the navigator to know which side of an island he is on.

It is well to keep in mind that a coral atoll is a very low-lying island, and from a distance the trees growing on it are its most conspicuous feature. Even so, from a canoe, atolls are not visible for more than a few miles away. Actually, there are other useful signs that indicate an atoll over the horizon. Among them are flight directions and patterns of certain birds, high accumulations of overhanging clouds, colored reflections from lagoons on the undersides of cumulus clouds, and floating vegetation, and navigator's rely heavily upon them. However, at night and in situations of poor visibility the information derived from swells can be critical. The Marshallese navigator does not use the information from swells only for making direct landfalls. Rather, on a voyage which passes in the vicinities of intervening islands he can mark his progress toward his destination by noting the reflected and refracted wave signatures of unseen islands as he passes by them.

Maps and Mapmaking in Mesoamerica

Barbara E. Mundy

When Spanish conquistadores first set foot in Mexico in the early sixteenth century, they found that many of the indigenous peoples they encountered made maps – graphic records of space. Since Mesoamericans had no previous contact with civilizations outside the New World, their mapping traditions developed independently and thus were distinct from those of Europe and Asia. Maps from central Mexico depended upon pictographic writing to convey place names and geographic information, and they were often drawn on native paper or cloth. Frequently, territorial maps would include historical narratives, also written with pictographic symbols. With the Spanish Conquest, the isolation of Mesoamerican mapping came to an end as it came under the sway of European forms and style. However, native peoples have continued using and making maps that are indebted to the native tradition.

Because preconquest Mesoamerican maps were frequently perishable, few such territorial maps survive today. Scholars therefore depend upon eyewitness Spanish accounts of native mapping in the decades after the Conquest as well as "pre-Hispanic-style" maps – those made in the decades after the Spanish Conquest that show little European influence – to reconstruct Mesoamerican mapping in the century or so before the Conquest. Unfortunately, the maps and mapping of earlier Mesoamerican civilizations – the Olmec, the Classic Zapotec, and the Classic Maya – are lost to time.

Nahua, or Aztec, maps are best known because Nahuatl speakers dominated central Mexico at the time of the Conquest. Nahuas also had the greatest degree of interaction with colonizing Spaniards. Many pre-Hispanic-style maps from the Nahua heartland in the Valley of Mexico (the site of the present-day Mexico City) survive. These maps had practical uses within Nahua society. For individuals, Nahua mapmakers carefully measured house lots, orchards, and gardens to make large-scale maps that documented their property. For neighborhoods, they drew up maps so that ward leaders could apportion lands and collect tribute. For towns, they created cadastral records that included individual maps of each family's plot. Not all Nahua maps showed such familiar territory: Nahua military spies mapped the layouts of foreign cities to help army commanders in planning their battles of conquest.

In the densely settled Valley of Mexico, scale-model maps were of some importance. Here, precise ways of measuring plots of land using ropes and measuring sticks were in evidence in the years after the Conquest. Two basic units of measurement coexisted in the Valley: the *quahuitl*, measuring about 2.5 m, and the *cemmatl* (which ranged from 2.5 to 1.77 m). Lines, representing one linear unit, and dots, representing 20, were used as counters. Fractions of the basic units could be shown with glyphs representing arrows (*cemmitl*), hearts (*cenyollotli*), bones (*omitl*), or hands (*cemmatl*). In some maps, area is also calculated and recorded in square *quahuitl*. Such measured precision in maps and specialization among maps may have been unique to the urbanized and hierarchical Nahua.

The Nahua were, however, very much like other Mesoamericans in making community maps, which were perhaps the most ubiquitous maps in the pre-Hispanic world. They are sometimes called *lienzos*, after the Spanish word for "linen," since many are painted upon cloth. These maps often showed the boundaries or extent of territory of a native city–state that the Nahua called an *altepetl*. To make community maps, mapmakers used pictographs arranged on a paper or cloth sheet to mimic the distribution of places and geographic features in space. Mapmakers did not carry out specific measurements of the contours of the landscape, but rather used symbols standing for the names of both places and physical landmarks, placing them relative to each other on the sheet. Thus community maps depended upon a mapmaker's knowledge of names – rather than absolute geography – to define the landscape. These community maps aimed not only to map territory, but also to record history. Given the primacy of the oral tradition in Mesoamerica, the maps may have functioned as mnemonic devices, designed to accompany the historian's account. The map's historical narrative, written in pictures and in pictographs upon the surface of the map, would often tell of a community's travels to reach its present territory. It might also show the battles a community fought and alliances it struck in order to cement its rights to lands. The Codex Xolotl of ca. AD 1540 is perhaps the earliest of such map histories known from the Valley of Mexico; the Mapas de Cuauhtinchan nos. 1–4 are notable map histories made outside of the Valley near the important pre-Hispanic center of Cholula.

The mapping by the Mixtec, who live in the modern state of Oaxaca, centered on community maps similar to those made by the Nahua, their northern neighbors. Since Mixtec communities tended to be small and independent, never coalescing into the complex hierarchical states of the Nahuas in the Valley, they had little need for the same kind of property, ward, and war maps. The community maps they made in abundance brought together spatial records with historical narratives, again recorded with pictures and pictographs. While Nahua community maps focused on peregrination and conquest, Mixtec ones emphasized genealogy – specifically the genealogy of each community's ruling family. In a characteristic community map, the Lienzo of Zacatepec of ca. AD 1540–1560, the boundary markers of Zacatepec's lands are written down with pictographic place names to create an inner frame within a rectangular sheet of cloth. Within this boundary map, the important ancestors of Zacatepec's rulers are shown with figures and named with pictographs.

While the Spanish Conquest inexorably changed Mesoamerican culture, native communities continued to make traditional maps to document their boundaries vis-à-vis those of adjacent communities and to keep records of community history. While these maps are best known from Nahuatl- and Mixtec-speaking communities, other ethnic groups in Mexico had their versions of community maps. Among them were the Otomí, Zapotec, Totonac, Huastec, Chinantec, Cuicatec, and Mazatec. Today, many towns and villages in Mexico still hold community maps. While these maps may have been redrawn and reinterpreted in the past five centuries, their roots remain in the native traditions of the preconquest period.

Less is known about the history of Maya mapping, even though the Classic Maya of AD 300–900 left us a rich record, written in a partly phonetic script, of their dynastic histories. Existing Maya maps from the postconquest period show the heavy influence of European forms and convention. These Maya maps use the European, not the Maya, alphabet to write place names. And other Maya records of territory take the form of written records rather than maps. Such quick conversion of Maya maps to European forms is perfectly understandable: having a writing system of their own, the Maya could easily adapt a foreign one to create territorial records that took a written, rather than a map form. In addition, the few Maya maps that we know of were probably not created to be used among the Maya, but to be presented to Spaniards in courts. Thus the effectiveness of these maps in proving territorial claims was only increased by shedding native conventions and adopting European ones.

Maps and Mapmaking of the Native North Americans

G. Malcolm Lewis

When considering the topics of maps and mapmaking in native North America, Europeans and nonnative North Americans have until recently tended to treat them as either novel and exceptional or inferior equivalents of their own cartographies. This is particularly so in writings before the last quarter of the twentieth century. Unconsciously but repeatedly, they imposed their post-Renaissance categories in trying to understand facets of cultures epistemologically different from their own. There is no direct evidence that before the encounter and associated acculturation, any of the native North American languages and dialects had lexical equivalents of "map" and the probability of there having been any seems decreasingly likely.

During the last quarter of the twentieth century increasingly rigorous research focused on the artefactual maps past and present, with an inevitable emphasis on those made in the encounter context. For the most part, native North Americans were either unable or unwilling to participate in this research. From their perspective they could claim to have been uninvited and unaware of it. Most of the research was by historians of cartography, untrained in and largely unaware of cultural and social anthropology, ethnohistory, native North American studies, etc. For the most part they saw themselves as contributing primarily to the understanding of a supposedly universal cartography. The materials they studied were surviving native artefacts or, more usually but less satisfactorily, transcripts and accounts made by earlier generations of Europeans and nonnative North Americans. Almost inevitably, there was a tendency to compare and contrast with what they assumed to be the norms established by post-Renaissance cartography. The following text first summarizes their achievements before attempting to detect early twenty-first-century trends and anticipate future developments.

At or soon after their first encounters, Europeans reported that native North Americans made maps. Most of the early reports were of maps made for Europeans to communicate geographical information, as for example a map of the lower Colorado River made by a Halchidhoma Indian in 1540. Ever since, Europeans and nonnative North Americans have continued to solicit and receive geographical intelligence in this way, whether they were explorers, traders, soldiers, settlers, missionaries, government agents, field scientists, or cultural anthropologists. It was, and until very recently remained, an important aspect of frontier information exchange. Natives communicating in this way included men of every social status, less frequently women, and occasionally even children. It occurred in every culture area and in most, if not all, tribes. Because of the publicity given to nineteenth-century Arctic exploration, it has sometimes been assumed that the Inuit were particularly skilled mapmakers. There is, however, no evidence that the maps they made for Europeans were either better or significantly different from those made by Indians.

In the encounter process, most maps were made with pencil on paper. Occasionally, however, more traditional materials were used, e.g., bark, textile, skin, hard animal tissue, three-dimensional models, and even rock. The distinctive characteristics of these encounter maps were, however, neither the media nor the mapmaking processes. Although Europeans were slow to recognize it, the natives' maps differed fundamentally from their own in three important ways. The geometry was topological, a product of cultural tradition, individual experience, the shape and size of the medium, and the purpose for which the map was made. Unlike European maps, it was not a consequence of plotting locations on a graticule selected to conserve particular properties at the expense of others. They conserved neither scale, direction, nor shape, except for very small areas.

The second important difference was in the categorization and magnitudinal ordering of the phenomena represented. Whereas most European maps were general, serving a range of functions and a diversity of users, each native map was made for a specific purpose and audience. These determined content and emphasis and only the essentials were represented. Hence, large physical features occurring within the area mapped were frequently either omitted, diminutive, or highly generalized, whereas small but contextually significant features were included and perhaps exaggerated. Thus, a large, complexly shaped lake might be represented by a simple circle, ornamented perhaps by a detailed representation of one culturally or contextually significant peninsula. Similarly, an essentially straight line might represent a long, complex, maritime coastline.

The third important difference was in the natives' use of pictographs as the approximate equivalent of the Europeans' combination of words, toponyms, and conventional map symbols. Pictographs were constructed according to culturally established principles to communicate complex mixes of information about size, importance, number, relationships, time, distance, direction, and events, as well as material and organic phenomena. Richer and far more flexible than the symbols on European maps, their information content was rarely intelligible to the aliens. Indeed, when, as they so frequently did, European's copied natives' maps, they often omitted or generalized the pictographic content. Regrettably, most extant examples of encounter maps are contemporary transcripts or, worse still, printed engravings: a small, debased sample of the many that were made, now scattered in archives, museums, libraries, government departments, and private collections in Europe as well as North America. Nevertheless, in their time, this type of native map served the aliens well; they helped them to open up their *terrae incognitae*, locate resources, plan military campaigns, etc. Though usually unacknowledged, they were frequently incorporated into the first generation of maps made by the aliens. Sometimes, misinterpretation and insensitive incorporation resulted in gross errors on maps made by Europeans, as with the Great River of the West, the Long River, and the gross westerly displacement of the mouth of the Mississippi River on printed eighteenth-century maps.

For some parts of the non-Eurasian world there is uncertainty as to whether precontact natives did or did not make maps. Each culture had a strong oral tradition, an important part of which was concerned with landscape, place, and spatial relations. Place – and feature – names were the "survey pegs" of spatial memory. This was almost certainly so among pre-Columbian North Americans, but there is considerable direct and indirect evidence that they also expressed their oral maps cartographically. For example, in 1540, Francisco Vásquez de Coronado discovered a painted skin in an abandoned Zuni pueblo. The pueblo was the first of the Seven Cities of Cibola ever to be seen by Europeans, and the painting represented their relative sizes and a route, probably the one linking them. Although difficult to date, much, if not most, North American rock art predates contact with Europeans. A very small proportion of these works have map-like appearances, at least when viewed from the European cultural perspective. Lacking texts, however, and in the light of the characteristics of native maps as now known, proof is difficult. Establishing similitude between a topological representation and its referent is much more difficult than for a projectively constructed map. Some celestial paintings on the roofs of rock overhangs in the Southwest undoubtedly represent exceptional astronomical juxtapositions known to have occurred at precisely established dates in pre-Columbian times. Others, like Map Rock, Idaho (a name given by the earliest white settlers in the lower Snake valley, because the engraving on it looked to them like a map), do appear to represent topologically and pictographically the pattern of geographical features in the regions in which they are sited. These, however, are exceptional cases and irrefutable evidence for terrestrial maps in precontact rock art has still to be established, though the case for plans of small areas and features is much stronger.

Ironically, the strongest evidence for mapmaking in precontact times is afforded by very early postcontact accounts by Europeans of the indigenous use of maps, usage of a kind that could not have been derived from European practices. It is debatable whether at the time of first contact any of the native languages contained nouns equivalent to map, though at later stages many of them certainly did. Nevertheless, some Indians certainly possessed an ability to read network patterns as maps. Montagnais and Naskapi divination by scapulimancy involved inducing random patterns of cracks by heat or percussion on mammalian bones, and these were sometimes interpreted to be maps of actual river systems. Likewise, the women of these tribes sometimes read as trail networks patterns made by biting folded pieces of birchbark, especially when the patterns had emerged in mistake for something else intended. Maps inscribed or painted on the inner surface of birchbark (or on growing trees from which the bark had been conspicuously stripped) were frequently positioned at conspicuous or strategic sites in the Northeastern forests to convey to friends – and sometimes enemies – spatially organized information about recent events or planned activities. There are accounts of maps being made by older men to instruct young braves about to undertake long journeys for the first time. Map modeling with whatever materials were at hand was sometimes a cooperative activity, at its best leading to a geographical consensus prior to military plannings and strategic briefings. Cosmological maps were common and usually combined geographical with mythical elements, the former most frequently near the center. Where geographical features were endowed with religious meaning, they might be topologically displaced. For example, on Lakota maps of the Black Hills, the Devil's Tower, located 60 mile to the northwest, was placed within the so-called Race Track that circumscribed them. Southern Ojibway birchbark midé-migration scrolls preserve the tradition as to how the tribe received its religion: from the east via a great waterway. At the left end of some of the scrolls, the waterways of part of Minnesota are readily interpretable. A little to the right, Lake Superior is highly stylized, but further to the right (east) it becomes increasingly difficult to relate the linework to the Great Lakes–St Lawrence River waterway.

By the beginning of the twenty-first century understanding of the nature and roles of native North Americans maps was diversifying. There were at least three reasons. First, and most importantly, the ferment of ideas generated by Columbus' quincentenary scholarship had begun to influence the field. Secondly, scholars outside the field were focusing attention on often long-known but superficially less map-like evidence, especially behavioral, including ceremonial. Thirdly, least obviously, but hopefully in the longer term most importantly, a younger generation of researchers was beginning to emerge, of which some were native North Americans. It is still too soon to predict all the consequences of these factors but overt recognition of the following would seem to be very likely:

1. Native North Americans often expressed spatial arrangements other than graphically on flat surfaces.
2. Even when expressions of spatial arrangements were graphical, their geometry was not even approximately Euclidean.
3. Spatial arrangements were often expressed in nonmaterial modes, e.g., speech, gesture, and ceremony. Others in material modes were hitherto unrecognized except by a few specialists, e.g., landscape design and architectural space.
4. A given spatial expression was not necessarily restricted to one discrete world of European epistemology – geographical, celestial, or cosmographical, as reconstructed or remembered from the past, perceived in the present, or envisaged in the future. It could include elements of two or more of these.
5. The determinants of silences in a spatial expression were neither of scale nor metrical magnitude but unimportance in the context of the specific purpose for which it was made.
6. Like all their spatial expressions, geographical maps made for Europeans and Euro-Americans were always made for a specific purpose but they were the graphical components only of a much richer multimode repertoire. Behavioral modes, if any, used in conjunction with them were either misunderstood by or unintelligible to the aliens and were either unreported or misreported.
7. Woodward and Lewis (1998) have provided a platform on which to base comparative studies of native North Americans' maps with those of traditional peoples elsewhere.
8. Geographical Information Systems (GIS) technology will become a powerful tool in studying the geometrical structure of native North Americans' graphical maps.

Most native maps represented relatively small areas and/or were linear, but a few embraced areas as large as one-third of a million square miles. The information upon which a map of a very large area was based could not have been derived from the direct experiences of an individual or even the cumulative experience of one group. Most of the content must have been based on information received by gesture and speech, perhaps over several generations.

Potentially, at least, maps made by native North Americans are significant in four broad contexts: legal, historical, anthropological, and scientific. Though lawyers have been slow to recognize it, an understanding of the fundamental differences between native and Euro-American maps helps, in some cases, to explain disputes between the two cultures concerning treaty and land sale agreements. Likewise, but with a few notable exceptions, archeologists and historians have been slow to recognize the significance of maps made by natives in such contexts as exploration, mapping, locating resources, place – and feature – naming, etc. Similarly, cultural anthropologists have been slow to explore the relations between maps and other graphical forms or to use them as evidence in establishing worldviews, reconstructing lifestyles, etc. Scientists, including linguists, have not even begun to recognize their potential significance in such contexts as human cognition, genetic epistemology, information exchange, language, categorization of phenomena, etc. These failures stem, in part, from the absence of a cartobibliography to the primary materials. Furthermore, scientists remain unaware of the now considerable body of secondary publications that, for the most part, is confined to the literature of the humanities.

Maps and Mapmaking in Asia (Prehistoric)

CATHERINE DELANO SMITH

There is plenty in Asian prehistoric art to interest the historian of cartography. It is sometimes difficult to draw a line between a picture of a place and a map of a place and it is, of course, impossible to know the original meaning of any graphic representation made in the period before writing. Nevertheless, there is a great deal of evidence that prehistoric people had both the mental capacity and the communicative and graphic skills to make maps. Such depictions were made on a variety of surfaces and in various ways but most commonly as paintings or engravings (petroglyphs) on boulders, rocks, cave walls, and cliff faces as well as on artifacts (bone, pottery, bronzes, etc.).

The earliest recognizable representation of spatial relationships involves: in Asia as in Europe, a continuous line – representing a boundary or enclosure – within which an event (animal trapping or herding, people standing or dancing) is taking place. For example, a painting on the wall of a Mesolithic rock shelter in Bhimbetka (Madhya Pradesh, India) shows, in profile, a family group mourning a dead child. The scene is placed in a hut, or some special place, which is represented by the encircling line. Similarly, a rock-carved enclosure from Mongolia (Bayan Khongor Province) provides a close parallel with enclosures in the Paleolithic art of the Franco-Cantabrian region of western Europe that have been identified as "hut or game enclosures." Yet another Asian parallel comes from Armenia. In this case, the enclosure depicted, possibly as early as the third millennium BCE, bears a marked resemblance to an early historic petroglyph from Jordan carved into a large stone with a text on another side referring to the enclosure as an animal pen.

Picture Maps

In all these examples, only one element of the composition, the enclosure, is rendered in plan (i.e., viewed from above); all other figures – persons, huts, and animals – are shown in profile (i.e., as seen from ground level). It is the defined space of the enclosure, however, that provides the cartographic key, the intended spatial relationships of the figures. These spatial representations are very simple as graphic compositions. Nevertheless, they contain the essence of a map and can be thought of as simple picture maps. In contrast, one of the most detailed prehistoric depictions of a village fails to meet the criteria for even a picture map, for there is nothing in it to suggest the critical *spatial* element. The petroglyphs in question, the Boyar *pisanitsas*, are found high on a cliff near Minusinsk, overlooking the Yenesei River in Siberia. They are thought to date from the last millennium BCE. The main assemblage is nearly 10 m long but nowhere in it is any feature or figure shown in plan. Nor is it easy to be certain, especially in the absence of an enclosure or frame, that the array of huts and scatter of human figures were created as an assemblage and are not merely a palimpsest of engravings made on quite different occasions, perhaps separated by long intervals of time.

However, another highly detailed rock painting, one of many on the cliffs at Cangyuan (Yunnan Province,

M

China) dating from the last millennium BCE, can be thought of as a picture map. Not only are the huts neatly and obviously deliberately positioned along the perimeter of a circular enclosure, but also their arrangement is topologically consistent: the huts on the far side of the enclosure from the viewer have been drawn upside down in order to maintain the relationship between the piles supporting each hut and the line that represents the village boundary or fence. Other lines project from the central enclosure like paths and indeed there are figures, human and animal, shown in profile, walking along them.

Plan Maps

The identification of objects and landscape portrayed from above is always difficult and the more so in rock art where all external evidence is lacking and diagnosis has to rest on intrinsic visual characteristics. However, the visual similarity between certain landscape features, when viewed from high above (i.e., in plan) and some of the rock art found in Asia, suggests that such examples were intended to be mimetic. Thus, included in the assorted petroglyphs of Mugur Surgol (upper Yenesei) are representations of the local herders' huts (yurts) and their surrounding stockyards. Four different sets of rock markings – "map signs" – are involved: solid outlines (squares or rectangles), rectangular outlines with internal subdivisions or compartments, rectangular outlines filled with stippling, and empty outlines, also rectangular or subrectangular. Each of the petroglyphs in question usually comprises one solid or compartmentalized shape and one or more stippled, or empty, rectangular or subrectangular shapes. These assemblages have been interpreted by archaeologists as plans of the Mongolian-type yurts found among the local Tuva, together with the yards and enclosures around them. Similar "hut and yard" markings are found in the Altai Mountains. All these are strikingly like those dating from the end of the Neolithic and, especially, the middle Bronze Age (third and second millennia BCE) found in the western Alps, as for example in Mont Bégo, France. Another category of plan map is more typical of Mongolian rock paintings. In these, assemblages comprising relatively large rectangles, usually stippled within, associated with human or human-like figures and the outline of a bird (eagle) with wings outstretched, have been interpreted as representations, rich in religious symbolism, of local graves, again as seen from above. This style of burial is known to be ancient and both graves and grave plans may date from the late Bronze Age.

Celestial Maps

Given the long history of astronomy in many parts of Asia, prehistoric representations of at least the major constellations might be expected. Certainly by the end of the last millennium BCE, the period of the Han Dynasty in China, the use of "ball and chain" patterns to represent groups of stars was evidently an already established tradition. Fully fledged prehistorical celestial maps, however, have yet to be discovered, in the literature or in the field. There are indications of what is to come. In 1990, the discovery of a very early historical map painted on the vault of a tomb was reported (*The Times*, 1 February 1990). It shows the heavens divided into 28 lunar mansions, seven for each of the cardinal points, which are personified as a Daoist deity. The map, executed in pastel polychrome, matches the description given by the Han historian Sima Qian (ca. 145–87 BCE). Elsewhere in Asia, representations of constellations, as well as "ingenious calendars" and the solar and lunar motifs associated with cosmologial myths, are said to be common in the rock art of Armenia. This rock art dates largely from the third millennium BCE, the date also of an astronomical observatory that was excavated at Metsamor (Armenia). Similar motifs may also be found in the pottery decoration of the period.

Cosmological Maps

It would be surprising if cosmological maps were not proven to be by far the most important category of Asian mapping in prehistoric times, just as they have been throughout the historic period (prior to European involvement). A preoccupation with the origin and structure of the universe, and above all with the afterlife and its location, is a fundamental attribute of human life – a manifestation of humanity's "cosmic anguish." Most, if not all, prehistoric rock art would have been associated with religion, and much of it must have reflected various aspects of local belief. Those responsible for the paintings and peckings, often made in virtually inaccessible places, would have been shamans or members of a priestly élite. One notable characteristic of prehistoric rock art, in Asia as in Europe, is its concentration into what are best seen as former ritualistic or holy places, on or at the base of a particular mountain peak, in or within a close radius of a high mountain pass, for instance, or associated with burial places. Thus the "hut and yard" maps should be seen as a record of a fossilized prayer, perhaps for the safety or prosperity of the homestead and its inhabitants, and represented as an icon rather than as an exact configuration of a nearby homestead, yet to be uncovered by archaeologists. As the Chinese tomb painting already described demonstrates, celestial cartography and cosmological cartography often overlap in their religious significance. Individual cosmological motifs are widespread in Asian rock art, such as those relating to the structure of the cosmos (the Tree of Life or *axis mundi*) or to access to the next world (boats, ladders).

They are also found in certain types of decoration, such as the bronze drums from Borneo and other parts of Indonesia. However, examples of cosmological maps from the prehistoric period, as opposed to these individual motifs, are few. One Mesolithic rock painting from Madhya Pradesh, India, is thought to represent, with its three bands, the three parts of the cosmos (water, air, and earth).

At present, information about rock art in general in Asia is both chronologically and geographically patchy. Some localities – for example in central and southern India, the peripheral provinces of China and Mongolia, the upper reaches of the great rivers of Siberia (Ob, Yenesei, Lena, Amur), around the high passes of the Pamirs, and the mountains of Armenia in the vicinity of Uchtasar – are comparatively well known, but such regions are separated by vast areas of ignorance, either through lack of exploration or through lack of reporting, especially in literature accessible to western scholars. Undoubtedly, though, future research and the wider reporting of new discoveries will yield a wealth of prehistoric maps and map-like representations throughout most of Asia, characterized by strong regional traditions, most of which will have a close counterpart elsewhere in the world.

Maps and Mapmaking in Southeast Asia

Joseph E. Schwartzberg

Indigenous maps from Southeast Asia were drawn for a multitude of secular and religious purposes and exhibit remarkable diversity in respect to medium, style, and content. Even within individual countries and cultures the surviving cartographic corpus is likely to be quite varied, though Burma and Vietnam were moving toward a national style in recent centuries. Broadly speaking, maps fall within four main traditions:

1. Tribal, for groups that never came under the cultural dominance of the great traditions of Hinduism, Buddhism, or Islam
2. Hindu–Buddhist, for cultures primarily shaped by influences emanating from India
3. Sinic, for the Vietnamese
4. Malay, for Islamicized peoples in what are now Indonesia and Malaysia

The number of surviving maps is great for Burma and Vietnam, and relatively few for Thailand (largely because of the Siamese tradition of purging documents that were no longer of current utility), Cambodia, Indonesia, and Malaysia. For Laos and the Philippines, indigenous maps are not known to exist. The corpus of known indigenous maps, however, is not a reliable guide to past cartographic output, since the accidents of preservation and documentation depend in large measure on the attitudes of colonial powers and individual scholars with respect to indigenous culture. It is likely that many maps still await discovery, especially in Buddhist temples and monasteries on the Southeast Asian mainland.

Tribal maps are documented mainly for the Sakai, an isolated Negrito people of West Malaysia, the Bataks of Sumatra, and various Bornean groups collectively known as *Dayaks*. For all of these the traditional medium was bamboo, into which designs were etched to create the map image. For the Sakai the mapped images served as magical charms to help insure success in hunting, fishing, and other activities in the places depicted or to ward off diseases and natural hazards associated with those places. Batak maps were mainly cosmographic or divinatory. Dayak maps, the most recent of which are exceedingly vivid designs on paper (supplied and preserved by missionaries), relate mainly to mortuary cults and relate to routes taken by the dead to reach the netherworld or the upper world and to the activities that take place therein. Dayaks also had a system of reading pigs' livers as if they were maps to discern auguries of good or bad outcomes for contemplated actions in particular places. There are no reliable guides to when mapping commenced among Southeast Asian tribal groups.

Hindu–Buddhist maps were drawn on palm leaf, indigenous bark paper (often assembled accordian-style in long folding manuscripts), cloth, and other media. In dealing with maps in this tradition it is necessary to distinguish between essentially religious and secular productions. The former are largely cosmographic, most depicting all or part of the Buddhist cosmos. Maps of the terrestrial plane, centered on Mount Meru, the *axis mundi*, generally utilized a planimetric perspective. Those that also showed the manifold heavens

M

and hells normally depicted the universe as if seen mainly in frontal elevation, but sometimes rotated the horizontal terrestrial plane 90° so as to maintain the traditional planimetric view for that region. Other Meru-centered maps show the mountain and its seven rings of surrounding mountains in vertical profile. One such depiction, more than 10 m in height, is carved into a cliff in Central Myanmar (Burma). A sumptuously illuminated cosmographic narrative, quite popular in Thailand, is the *Trai Phum* (Story of Three Worlds, *Traībhūmikathā* in Sanskrit). This work, compiled in ca. 1345, is a variant on the Jataka tales, relating to the past lives and wanderings of the Buddha. It has gone through a number of recensions and exists also in modified form in Myanmar and Cambodia. The longest manuscript, dating from BE 2319 (AD 1776), provides a continuous picture on 272 folding panels with an overall length of 32 m. Six of these panels depict Asia from the Arabian Sea coast to Korea. No surviving manuscript predates the sixteenth century. Hindu cosmographies were probably also painted in Southeast Asia, but apart from one attributed to Cambodia, none is known to survive on the mainland. Complex cosmographic works, however, continue to be made in various media in Bali.

The oldest known geographic map in the Hindu–Buddhist tradition, dating from the late seventeenth or early eighteenth century, is a long folded-panel work showing ecclesiastical and other property holdings in what is now southern Thailand. Thereafter, there is a long hiatus in Siamese secular cartography, but the period of the Chabri Dynasty, 1782–1851, saw a following of mapmaking under royal patronage. Maps then produced were mainly topographic and covered much of Southeast Asia. Some related also to maritime commerce, one extending as far as Japan, while others were strictly military. The maps were painted both, incorporated many standardized conventions, and were often quite large, the largest measuring S17 by 416 cm. (roughly 16 × 14 ft). Known Burmese secular maps do not predate the latter half of the eighteenth century. But one may safely assume that the mapmaking was by then a well-established art. Numerous maps, many covering rather large areas, were drawn for Francis Hamilton during his sojourn in Burma in 1795 and attest to the geographic sophistication of educated Burmese at that time. During the nineteenth century, if not earlier, the Burmese state engaged official surveyors and cartographers. Maps on European paper and cloth became increasingly common with the passage of time. Burmese maps were drawn largely for military and political intelligence purposes, sometimes to plan or to document specific campaigns. Others, showing property holdings and types of land use, were used for purposes of taxation. Many were used as aids for laying out new cities, monastic complexes, irrigation systems, and other public works. A common feature of Burmese maps was the use of a regularly ruled grid, very likely to transfer a sketch from one scale to another, though maps were never drawn to a uniform scale. Many of the maps from what is now Myanmar were actually drawn by ethnic Shans (a Thai people) and other ethnic groups within the Burmese political orbit. From insular Southeast Asia, only one presumably geographic map in an essentially Hindu tradition is known. Drawn on a batik shawl, this ornate and enigmatically patterned work probably dates from the early nineteenth century. It has no text, but is believed to relate to the former princely states of Surakarta and Yogyakarta, which, though ruled by Muslim sultans, maintained a largely Hindu court style.

Vietnamese cartography was mainly secular and, as in Burma, drawn for the military, administrative, and other political needs of the government. (Cosmographic maps did exist, but these were mainly in the Hindu–Buddhist tradition previously described.) The oldest textual references indicate that secular maps existed as early as the late eleventh century, though mapping appears not to have become a serious concern until the government was reorganized along Sinic bureaucratic lines some four centuries later. Thereafter, the map style was a regional variant of a general Sinic tradition, though changes were evident from one period to another. Many of the maps were bound, after the Chinese fashion, into atlases, which, with their abundant text, served also as gazetteers. The oldest atlas, made in the 1270s, related to a royal inspection tour of the then relatively circumscribed Vietnamese state, but it does not survive and its form is not known. In addition to atlases and regional maps, the Vietnamese drew route maps, maps of river systems and coastal maps to facilitate navigation; city plans, some of which were remarkably detailed; maps of individual forts and other edifices; and maps documenting tribute missions to the Chinese court in Beijing.

Surviving maps from the Malay cultural realm, though few in number, are quite diverse. The oldest, dating from the late sixteenth century, is a large cloth map covering the western third of Java. Most of the map space is given over to the depiction of the small chiefdom of Timbanganten, whose prince commissioned the work. The symbolization on this map is particularly distinctive and has no close analog in any other known work. All the remaining maps show varying degrees of European influence. A map of the Bornean Sultanate of Pontianak and another of part of East Central Java apparently related to administration and/or taxation. Others related to navigation and trade. One shows ports and commercial products of the Malay Peninsula. The others, covering most of Southeast Asia, are detailed hydrographic charts, copied onto cowhide, from an early nineteenth-century Dutch original, but with adaptations indicating independent depth soundings and new coastal observations.

These maps were drawn and used by wide-ranging Bugi pirates and contain abundant text written in the Bugi script, though Roman numerals were used to indicate ocean depths. Apart from the surviving nautical maps, there are textual and other grounds for supposing that Indonesians made use of maps in long distance navigation prior to the advent of Europeans in the region.

Maps and Mapmaking in Tibet

JOSEPH E. SCHWARTZBERG

For purposes of this article Greater Tibet includes not only the present Autonomous Region of Tibet, within China, but also the Chinese provinces of Qinghai and Sikang, the Indian regions of Ladakh and Sikkim, much of Nepal, and Bhutan, which have all been, greatly influenced by Tibetan Buddhism and other aspects of Tibetan culture. Despite its small population, this region has given rise to a remarkably rich and varied cartographic tradition. Moreover, that anciently rooted tradition still survives, despite attempts by the West, China, and India to impose political and cultural hegemony over the lands of its development.

Given the pervasive role of religion in Tibetan culture, it is hardly surprising that maps serving a variety of religious functions form the greater part of the region's cartographic corpus. These are commonly painted on cloth *thaṇkas*, which frequently occupy a focal position in family and monastic altars. The most abstract of Tibetan religious maps are *maṇḍalas*, which are regarded as representations of the cosmos and serve as objects of meditation for clergy and laity alike. These assume many forms, in both two and three dimensions, and utilize a wide range of media. Elaborate *maṇḍalas* fashioned from colored sand or carved in yak butter may be created over a period of weeks, but are kept for even less time than it took to construct them, thereby demonstrating the transience of all earthly existence. Many cosmographic maps were divinatory. Others were didactic, for example, paintings of the *bhāvacakra* (wheel of life) depicting the various realms of existence through which souls may transmigate on the path to *nirvāna* (the ultimate aim of existence in which the soul is liberated from the painful round of rebirth). Other forms of didactic painting are essentially hagiographic, showing various incarnations of the Buddha, *bodhisattvas*, or revered lamas surrounded by collages of sacred landscapes depicting particular places associated with their existence, both on earth and in nonterrestrial portions of the Buddhist cosmos. Though largely mythic, such places are often shown with a considerable sense of verisimilitude. Maps showing the cosmos as a whole or major portions of it are numerous. Some of these are large mural paintings. A particularly vivid set of fresco murals in Bhutan shows the evolution of the cosmos as a succession of disaggregations of terrestrial and extraterrestrial elements in space–time as described in various Indian and Tibetan Buddhist texts dating back to the fifth century. In these and many other cosmographic maps Mount Meru, the *axis mundi*, and four principal surrounding continents in the terrestrial plane figure prominently. Maps of other continents are also painted, two of particular note being Sukhāvatī (the Western Paradise) and the mountain-girt utopian realm of Śambhala (whence James Hilton's "Shangri-la"). Bards used to wander about Tibet illustrating stories of the way to Śambhala with map scrolls on which routes began in recognizable places, but led ultimately to mythic space. To devout Tibetans, however, the distinction between the real and the mythic would seem a false dichotomy.

Geographically identifiable locales do figure prominently in Tibetan religious maps. Many show individual religious edifices and centers such as the Potala and Tashilunpo, the residences of the Dalai and Panchen

M

Lamas, respectively; Lhasa and Shigatse, in which those two residences are, respectively, located; or Samye, Tibet's oldest monastic complex. Others show sacred landscapes in which groups of such centers, especially those proximate to Lhasa, are clustered. Some maps focused on Mount Kailas, in western Tibet, viewed as the earthly manifestation of Mount Meru, around which a complex of sacred pilgrimage places developed. Large sacred maps were displayed along the walls of the monasteries where they were held during certain holidays, when pilgrims would flock to major religious centers. One such painting, displayed annually in the Nepali town of Patan, has a length of more than 25 m and provides a rich panoramic view of the Vale of Kathmandu. Maps were made not only to serve the needs of pilgrims, but were also commissioned to commemorate pilgrimages completed. A particularly beautiful example, dedicated in AD 1802, depicts the patron and his entourage at many of the major pilgrimage places in central Nepal.

When Tibetans began to make maps is not known, but the roots of Tibetan cartography run deep. One of the most remarkable maps, depicting the anciently known world, appears in a modern recension of a dictionary of the Zang Zung language (probably Indo-European), formerly spoken in western Tibet. Though the places shown, reaching as far west as Egypt and Greece, were compressed into the form of a rectangular *maṇḍala*, thereby losing much of their geographic logic, most could be related to the period of Alexander the Great (late fourth century BCE). The map itself focuses on Parsogard, the Achaemenid capital from 550 to 522 BCE. There are grounds to believe that some version of this map was transmitted from antiquity to the present, despite the fact that no premodern version is known to survive. Another simpler, but equally cryptic, surviving world map was brought to Japan in AD 891.

Apart from the two world maps just noted, one map of Nepali provenance (but stylistically akin to Tibetan maps) covers a very large region of Central and Southwest Asia, with western limits at Baghdad and the Russian city of Saratov, on the Volga River. It has been argued that this map was commissioned ca. 1860 in relation to a contemplated, but never consummated, grand alliance to drive the British from Asia. This richly detailed map, despite its late date, includes numerous features that are essentially mythic.

A remarkable series of maps is that of the so-called Wise Collection in London's India Office Library. Wise's identity has not been established; but there are grounds to believe that the maps were prepared by Buddhist recruits (later dubbed *pundits*) from India's Himalayan territories who traveled over much of Tibet in disguise to gather intelligence. British training notwithstanding, the style of these maps is distinctly Tibetan.

With the aforementioned exceptions, regional maps from Tibet seldom cover more than a few thousand square kilometers. None is known to predate the late eighteenth century. As a group, the maps in question are remarkably detailed and utilize a well-developed set of symbolic and color conventions. They typically combine diverse perspectives: planimetric, high oblique, and frontal, depending on the features shown. Important buildings are sometimes shown as if seen from several sides simultaneously. There is no consistent orientation. Regrettably, only a few Tibetan maps have yet been studied as such by scholars with the needed cultural sensitivity and linguistic skills.

Maps and Mapmaking in Vietnam

John K. Whitmore

The tradition of mapping began in Vietnam just over half a millennium ago. As the state of Dai Viet, led by the young king Le Thanh-tong (1460–1497), adopted the administrative model of the Ming dynasty in China and became more centralized, mapping served as one of the procedures to that end. The new bureaucratic structure placed officials in the provinces and districts and ordered that these officials gather and relay information to the capital of Thang-long (now Hanoi) on the land and people within their jurisdictions. Maps were part of the required information, and they led eventually to an atlas covering the entire country. This atlas and its maps in the Chinese mode set the pattern of administrative cartography well into the nineteenth century.

The same reign also saw the extension of Vietnamese territory to the south as Thanh-tong crushed the forces of Champa in 1471. A map showing the stages of the expedition became the model for military and commercial cartography in the following three centuries. As these centuries were a time of military and commercial expansion, particularly of the *Nam Thien* (Southern Push) further down the east coast of mainland Southeast Asia through Champa and into Cambodia, this style of map came to reflect the dynamics of the Vietnamese population.

International contacts in the late eighteenth and early nineteenth centuries led to a new style of administrative mapping which combined a more realistic Western (particularly French) style with stronger Chinese elements. Yet, by the end of the nineteenth century, as French colonialism controlled the Vietnamese state, there appeared a shift toward a more complete Sinic [Chinese] mode of illustrating maps.

No technical study of Vietnamese maps based on the original documents exists. Looking at reproductions, mainly in black and white, yields the following observations. The maps available to us are almost entirely hand drawn in black ink, some with added color to emphasize their features. Only in the mid-nineteenth century did printing begin to play a major role in cartography here.

The earliest extant map, most likely from the sixteenth century, is quite simple in form and style. Lines were drawn to show the rivers and the land separating them. Nothing indicates water in the streams, and the standard Chinese three-ridge pattern for mountains served to suggest the highland regions above the plains. Names (in Chinese characters) marked location with no other symbol employed.

This changed in the seventeenth century as the earliest existing major corpus of indigenous maps appeared. They had become more artistic. Water was drawn in the streams and off the coast (river currents and roiling sea waves). Mountains retained the same style, but more accurately designated Vietnam's uplands. In addition, palaces, temples, and walls appeared (in frontal elevation), while jurisdictional locations were marked by written characters in rectangular boxes with little sense of hierarchy among them. Other characters showed the locations of natural features and additional human constructions.

In the eighteenth century, Vietnamese cartography took on in places a more artistic and Sinic mode. This change appeared particularly in the style of portraying the mountains. In place of the simpler three-ridge style, there came to be a more naturalistic landscape mode which well fit the vertical karst topography of northern Vietnam (and southern China). In addition, waves lapped on the shore, and temples and walls received a more Sinic treatment. The maps were drawn in black ink with colors (red, gray, and blue, for example) used to highlight roads, buildings, and mountains.

The nineteenth century saw more sophisticated international influences appear in Vietnamese mapping. Southern political forces had contact with French military figures and adopted the Vauban style of fortification. Simultaneously, the new Nguyen dynasty chose to hew more closely to the contemporary Qing dynasty of China. Though elements of the old Le style would continue, more realistic elements appeared on Vietnamese maps within the context of Chinese forms. A regional division of the country led the north to maintain the old style as French forms appeared in the south. The central region around the capital of Hue gradually forged a national style which, by 1840, showed the country of Dai Nam and its hydrographic complexities in a European perspective.

While becoming more realistic in outline, the artistic style shifted from the earlier sketchiness to a more specifically Chinese mode. This change appeared particularly in the mountains with their vertical and naturalistic mode, continuing to match the karst topography of the north. The new international style developed through the nineteenth century until the French conquest in the 1880s. Thereafter, in the early years of the twentieth century, the reaction against French rule among Vietnamese literati led to the greater emphasis on the Chinese style over the realistic mode.

The first centuries of Vietnamese mapping (fifteenth to eighteenth) produced two different genres: one administrative, the other military/commercial. The first, the atlas, originated in Le Thanh-tong's governmental transformation of the 1460s. In it, each of the thirteen provinces had a map showing the location of its prefectures and districts and a list of the types and numbers of villages contained therein. In addition, the atlas included a map of the country, noting the location of each province, and a map of the capital Thang-long. Despite originating in the fifteenth century, the earliest extant atlas, the *Hong Duc Ban Do* (Maps of the Hongduc Era), comes from the mid-late seventeenth century. As noted above, a single map of the country, showing its administrative units, does seem to be from the sixteenth century. In the atlases, natural features, particularly rivers, and some human construction like city walls and temples were also noted. The maps generally are seen from the sea (the east) and hence have a Western orientation. Since the Le dynasty (1428–1787) rose from the then southern provinces of Thanh-hoa and Nghe-an, these two maps came first after those of the country and the capital.

The other genre involved itineraries of different kinds, each a series of maps showing the way (usually from the capital region around present-day Hanoi) out to a distant location. The genre seems to have originated in Le Thanhtong's major campaign south against Champa in 1470–1471. Again, the earliest extant example comes from the seventeenth century, the *Thien Nam Tu Chi Lo Do Thu* (Book of the Major Routes of Thien Nam). At that time, the southern route was joined to three shorter routes to China: northeast, northwest, and north (the standard route to Beijing). These maps, and particularly those of the southern route, provide much more detail of daily life than does the atlas. They illustrated features of the land, the rivers, and the sea as well as elements of Vietnamese common and commercial life (markets, inns, temples, military installations, etc.). Another seventeenth-century itinerary, the *Binh Nam Do* (Map of the Conquest of the South), comes from the southern regime of the Nguyen and takes us through their territory of central and southern Vietnam to Cambodia. It shows the path of the Southern Expansion (*Nam Thien*) of the Vietnamese people then taking place.

The eighteenth century produced new, more artistic versions of the seventeenth-century atlas and itineraries. In addition, a new itinerary appeared in various forms – that of the Vietnamese embassy north to the Qing capital of Beijing in northern China. Once across the Chinese border, the delegation traveled mainly by river and canal, and these sets of maps were drawn from that perspective, showing the mountains and villages stretching away from both sides of the route. Finally, at the end of the century, there appeared the only known map of the brief Tay-son dynasty (1788–1802), a single page showing Siam (Thailand) and the routes through it from north to south. This map, like all other pre-1800 ones, had very little sense of the river systems to the south, particularly the Mekong Delta and the Great Lake of Cambodia.

Three major developments led to cartographic change in the nineteenth century: the international context, the initial regional control of the country (north, center, and south), and the borrowing of the Chinese geography form. The combination of these three brought the gradual emergence of a new form of mapping. This single form, the geography with maps accompanying the text, replaced the Le atlas as an administrative tool. Curiously, the genre of the itinerary disappeared, continuing only in the reproduction of earlier texts.

Just as the northern and southern regional autonomy was finally integrated into the central government during the 1830s, so their styles merged with that of the center and its usage of European and Chinese elements, as seen in the *Dai Nam Toan Do* (Complete Map of Dai Nam). The map of the entire country, now stretching from China to Cambodia, in particular took on a more Western form. The coast and the southern rivers, even the Great Lake of Cambodia, appear much more familiar, and the provincial maps are more realistic in our eyes, showing rivers in a dendritic manner for example [having a branched form].

Blending the new maps with the geography form of the Chinese *yi-tong-zhi* (Vietnamese *nhat-thong-chi*), Nguyen cartography reached its peak first in the *Dai Nam Nhat Thong Du Do* (Maps of the Unity of Dai Nam) of 1861 and finally in the imperial geography, the *Dai Nam Nhat Thong Chi* (Record of the Unity of Dai Nam). The latter, compiled and printed between 1865 and 1882, is a text describing the country of Dai Nam, its capital of Hue, and the 29 provinces and presenting maps of each of them. Even though the French had already seized the six provinces of the south, the Tu-duc Emperor kept this section in the geography together with those of the center and north as a symbolic representation of the whole.

Mapping of the nineteenth century was thus almost entirely involved with administrative matters, like the old Le atlas. The only itineraries were copies of the seventeenth- and eighteenth-century maps. The country map in the administrative collections did, however, provide a broader international setting than had occurred under the Le. This was done in a form similar to the European mapping of the time.

The major new form of map in the nineteenth century was part of the *dia-bo*, the land registers. Recording the land plots of each village, these documents show them in outline and provide their dimensions and type. The government produced these maps in a number of survey (and resurvey) campaigns through the first half of the century. Another new form of map was the symbolic diagram of the imperial tombs. The resulting drawings emphasized the symbolic relationships of mountains and water, and show the strongly Chinese style adopted by the Nguyen dynasty.

Vietnamese mapping was mainly the result of 400 years of administrative effort. Beginning with Le Thanh-tong's reforms in the 1460s, the need to know the bureaucratic jurisdictions and their villages led to the Le atlases and the Nguyen geographies. The fifteenth-century military campaign began the Vietnamese itinerary which to all appearances became commercial. The Vietnamese cartographic tradition was almost entirely internal, not external. Until the 1830s maps rarely showed much beyond their borders, the major exception being the eighteenth-century embassies to China. In addition, all the routes illustrated were by land, not by sea.

Marāgha

GREGG DE YOUNG

The observatory, located just outside Marāgha, the capital of the Ilkhānid kingdom, represents one of the most comprehensive examples of an astronomical research institution within the context of Islamic civilization. It is reported, on the authority of Naṣīr al-Dīn al-Ṭūsī, its first director, that construction of the observatory began under the patronage of Hūlāgū, Mongol conqueror of the region, in 657 AH/AD 1259. The remains of the observatory buildings still occupy a hilltop position near the city in Azerbayjan.

Construction at the site was overseen by Mu'ayyad al-Dīn al-'Urḍī, who wrote a treatise describing his efforts. In addition to the main observatory building, the site included a mosque and a residence for Hūlāgū, who took an active part in the work of the astronomers. The main building was described by contemporary witnesses as "huge" and there are reports that its library exceeded 400,000 treatises. There is also a report of a "high tower," as well as a domed structure which may have been the central building of the observatory. The dome was pierced, allowing sunlight to enter for the determination of equinoxes, as well as for measuring solar mean motions and elevations. There are still traces of a massive masonry-mounted mural quadrant, probably having a radius of more than 4 m, outside one of the observatory buildings.

Al-'Urḍī also had charge of constructing the observational instruments for the observatory, although it is doubtful that he would have constructed them all personally. He reports completion of their construction during 660 AH/AD 1261–1262. In addition to the mural quadrant, which was used to determine the latitude of the observatory as well as the obliquity of the ecliptic, the observatory included other large instruments: (1) an armillary sphere, consisting of five rings and an alidade (or sighting devise), and having a maximum radius of about 1.6 m, (2) a solstitial armilla, a bronze circle with diameter of about 1.25 m equipped with an alidade, which was placed in the plane of the ecliptic for determining solstice points, (3) an equinoctial armilla, similar to the solstitial armilla but with a second ring that could be aligned with the plane of the equator in order to determine equinoxes accurately, (4) an instrument with two holes on a sighting rod used to determine the apparent diameters of the sun and moon, as well as for observing eclipses, (5) an azimuth ring equipped with two quadrants and two alidades to measure angles of elevation, (6) a parallactic ruler which could make measurements equivalent to those made on a circle with a radius of 2.5 m, (7) an instrument for measuring azimuthal altitude and the sine of the complement of that angle of elevation, (8) a similar instrument to measure the azimuthal altitude and the sine of the angle of elevation, and (9) an instrument similar to a parallactic ruler, but not fixed in the meridian plane. In addition to these large instruments, there were many smaller ones, including planispheric astrolabes and quadrants, terrestrial and celestial globes, timekeeping devices, star charts, maps, and representations of the heavenly spheres.

Not only the observatory was the best equipped of the medieval period, but also it was the best staffed. In addition to Naṣīr al-Dīn al-Ṭūsī and Muʾayyad al-Dīn al-'Urḍī, such luminaries as 'Alī ibn 'Umar al-Qazwīnī, Fakhr al-Dīn al-Akhlātī, Fakhr al-Dīn al-Marāghī, Muḥyi al-Dīn al-Maghribī, Quṭb al-Dīn al-Shīrāzī, Shams al-Dīn al-Shirwānī, Najm al-Dīn al-Qazwīnī, 'Abd al-Razāk ibn al-Fuwwatī (the librarian), Kamāl al-Dīn al-Ayta, Athīr al-Dīn al-Abharī, al-Ṭūsī's two sons – Aṣīl al-Dīn and Ṣadr al-Dīn – and even a Chinese astronomer, Fao Mun Ji. (The presence of the latter indicates a growing interaction between the Islamic and Chinese astronomical traditions made possible and encouraged during the period of Mongol domination.) The activities of the scholars were supported by a full complement of technicians, instrument makers, and administrators.

The major result of the activities of the observatory was the production of a new set of astronomical tables, the *Zīj-i Ilkhānī*, completed in 671 AH/AD 1272, nearly 12 years after the observatory opened. Although the treatise contains many new observations, it did not incorporate any of the sophisticated critiques of the Ptolemaic cosmology being developed at that time in the observatory. The tables were widely used and frequently cited. The organization of the treatise (chronology, movements of stars in longitude and latitude, determination of times of ascendants, and astrological predictions) often served as a model for later zīj literature.

It was generally argued by astronomers that, in order to produce a full set of astronomical tables, observations should be made over a 30-year period (the time for Saturn to complete one revolution around the sky).

Most observatories prior to Marāgha had been forced to adopt less ambitious research programs, for they did not long survive the death of their founding patron. The Marāgha observatory is a notable exception. Hūlāgū, its royal patron, died in 663 AH/AD 1265 and al-Ṭūsī, the founder, died in 672 AH/AD 1274. After al-Ṭūsī's death, the observational activities continued at a somewhat slower pace under the leadership of Ṣadr al-Dīn al-Ṭūsī. Thirty years later, al-Ṭūsī's younger son, Aṣīl al-Dīn, was named head of the institution. This marks the last recorded activity on the site. Thus, this observatory continued to function for nearly five decades before being abandoned and falling into ruins.

One possible reason for the extraordinary longevity of this institution is the use of *waqf* funds to support the operation of the observatory. (A waqf is a grant of property in perpetuity for the support of religious or charitable institutions. Thus, not only many mosques are supported by income derived from waqf properties, but also orphanages, soup kitchens, hospices, schools, libraries, hospitals, and other public service institutions. The Marāgha observatory seems to be the only example in which an observatory receiving waqf support.) Several sources indicate that al-Ṭūsī, in addition to directing the observatory, was also charged with administering waqf funds throughout the state. Some sources indicate that about a tenth of all waqf revenues was earmarked for expenses of the observatory. It is not clear whether this unusual use of waqf funds generated any sort of public outcry. If nothing else, it seems to indicate that the work of the observatory was intended to be ongoing, not merely an intense short-term effort.

Perhaps the use of waqf funds to support the observatory was easier to justify in light of the extensive instructional activity carried on within its precincts. It was not uncommon to endow a *madrasa* (an institution of learning, usually focused on religious and legal sciences) with waqf funds. Our sources tell us that the observatory was a center of teaching in mathematical, astronomical, and related sciences. The educational program was apparently organized analogously to that of a madrasa, although the accounts in our sources are too vague to be certain.

In addition to teaching the classics of the ancient mathematical and mathematical astronomy traditions, the Marāgha observatory was also a focus for an important movement to criticize and reform Ptolemaic (Greek) astronomical theories. Ptolemy was perceived to have disregarded the essential sphericity and uniformity of the celestial motions postulated by Plato and other earlier thinkers. Ptolemaic theory described each planet as carried daily from east to west across the vault of the sky by the motion of the sphere of fixed stars. This diurnal motion is complicated by the observation that each planet sets a bit late in relation to the fixed stars and the planet moves across the heavens in a path not parallel to the fixed stars. Moreover, most of the naked-eye planets seem, from time to time, to slow to a stop and temporarily reverse their direction of motion (retrograde motion). To account for these observations, the Greeks had assumed that each planet must be fixed to a small sphere (epicycle) whose center is carried around by a larger sphere (the deferent), whose axis does not coincide with that of the fixed stars, and whose proper motion of rotation (zodiacal motion) is contrary to the east to west direction of the fixed stars and their diurnal motion. The motion of the epicycle center as seen from earth was not fully uniform, however, implying that the earth must not be at the geometric center of the motions on the deferent. The distance of the earth from the center of the deferent sphere (the eccentricity) was established by observational considerations. When this distance is determined, however, the observed angular velocities are only about half what is predicted. To remedy this problem, Claudius Ptolemy had postulated that uniform angular motion took place about a point (equant) located twice the value of the eccentricity from the earth along the line from the earth through the center of the deferent sphere. This postulate allows uniform motion in the sense of sweeping out equal angles in equal time increments when observed from the equant, but uniform motions in the sense of equal arcs traversed in equal increments of time does not occur. Herein lies the central problem that the Marāgha school of cosmography tried to resolve: how to construct a physical model of the spherical universe that fits the assumptions of uniform circular motion in both senses of that term and that gives predictions with the same level of accuracy as did Ptolemy's equant model.

Al-Ṭūsī, assuming that Ptolemy's circular motions were intended to be performed by true physical spheres and not just mathematical spheres, developed a system of spheres rolling inside one another to account for the observed zodiacal motions of the planets. The result of these motions, each truly uniform and circular in the Platonic sense, is that the planet follows the spherical path required by Greek cosmography while displaying the observed variations in velocity, thus overcoming the fundamental conceptual disjunction that Ptolemy had introduced by separating the circularity from the uniformity in the motions.

Al-Ṭūsī is best known among historians of science for his modification of a theorem of Proclus which demonstrates that when a circle, whose diameter is equal to the radius of a larger circle, rolls inside the circumference of the larger while rotating on its axis in the opposite direction with the same velocity, a point on the circumference of the smaller circle will execute a simple harmonic oscillation along a diameter of the larger circle. Al-Ṭūsī used his device, now known as a "Ṭūsī Couple," to describe the anomalous motion of the equant in Ptolemy's description of Mercury's motions.

It was further exploited by al-Ṭūsī's pupil, Ibn al-Shāṭir, and others at the Marāgha observatory.

Copernicus employed an essentially similar geometric device more than two centuries later in constructing his lunar model. This striking similarity of technique has led to questions concerning the originality of Copernicus. Arabic manuscripts describing al-Ṭūsī's model are known to have been in the Vatican Library by the time Copernicus journeyed to Rome, and some bear Latin annotations. Moreover, a late Byzantine Greek manuscript with a detailed exposition of al-Ṭūsī's scheme was also present in Italian libraries while Copernicus studied there. Tantalizing as such evidence may be, it is still not possible to determine with certainty whether the intellectual antecedents of the Copernican geocentric hypothesis may lie in Marāgha.

Māshāʾallāh

Richard Lemay

Māshāʾallāh ibn Atharī was a Jewish astrologer who was born in the southern city of Basra ca. 730 in the later Umayyad caliphate and survived till ca. 815. If he was ever converted to Islam, as his name Māʾshāʾallāh seems to imply, it is not made clear in any of the original sources such as the *Fihrist*. His respectful tone toward the Caliphs in his *Fī qiyām al-Khulafāʾ* would certainly befit a Muslim more than a Jew. At any rate he wrote extensively in Arabic, and he was called upon by the second Abbasid Caliph al-Manṣūr (754–775) to assist in the laying of the foundations of Baghdad in 762. Hence by that time he was surely a well known astrologer active in the Babylonian region, representative perhaps of the Jewish culture long settled in the area.

A celebrated astrologer in his time, Māshāʾallāh was either the founder or a leader of a school of Jewish astrologers in Mesopotamia. Apart from his participation in the laying of the foundations of Baghdad, we know rather little of the circumstances of his life. Though sparse on biographical details, the principal Arab bibliographers al-Nadīm (*Fihrist*, AD 987) and Ibn al-Qifṭi (*Tāʾrīkhal-ḥukamāʾ*, ca. AD 1248) credit Māʾshāʾallāh with a sizeable number of works. On the other hand, the *Jewish Encyclopedia* confuses him in part with Maslama al-Majrīṭī, probably because of the similarity of names. Paul Kunitzsch has recently established that the Latin treatise on the astrolabe long ascribed to Māʾshāʾallāh and translated by John of Seville is in fact by Ibn al-Ṣaffār, a disciple of Maslama al-Majrīṭī.

In his astrological doctrine Māʾshāʾallāh seems to have depended principally on the Persian tradition, though a late Byzantine translation of one of his works shows that he could also quote from Greek authors such as Plato, Aristotle, and Hermes. Māʾshāʾallāh's works have not survived extensively in Arabic and it is thanks to the Latin translations, mostly by John of Seville in twelfth century Spain, that we have access to a large number of those ascribed to him.

Māʾshāʾallāh's contribution in Arabic astrology must be linked with the widespread use of astrological prognostication in the Mesopotamian area since very ancient times. The thirteenth century bibliographer Ibn Khallikān recalls the extensive use of this "projective tool" in the politics and social life of the early Arab empire. What has survived of Māʾshāʾallāh's works shows that the substance of his astrological knowledge owes but little to Greek philosophy proper. Assuredly, there flourished in Sassanian times a trend to borrow from Greek (Alexandrian) astrology, apparently only to consolidate a native tradition of learning. And it is this Sassanian lore above all that nourishes Māʾshāʾallāh's production. On the other hand, it is historically confirmed that the passion for Greek learning among the Arabs was engendered by the caliph al-Maʾmūn's (813–833) enthusiasm for the philosophy of Aristotle, too late for Māʾshāʾallāh to share significantly in this outburst. The fresh start taken by "scientific" astrology under al-Maʾmūn's prodding is noticeable in the works of al-Kindī, of Abū Maʾshar, and the members of the *Bayt al-Ḥikma* (House of Wisdom) founded by al-Maʾmūn. Compared with their works, those of Māʾshāʾallāh and of his generation show no clear and systematic use of the axioms of peripatetic philosophy to buttress the principles of astrological science as was done so decidedly a generation later.

Māʾshāʾallāh's reputation remained high in the following generation as witnessed by Abū Maʾshar's praise of him, according to the *Mudhākarāt* (Memorabilia) of Ṣaʾid ibn Shaḍān. Yet, it is mostly for one single astrological topic, the "projection of rays" (*matraḥ al-shuʿāʿāt*), that Abū Maʾshar lavishes praise on Māʾshāʾallāh.

An important historical factor affecting the preservation of Māʾshāʾallāh's works, and consequently of his reputation as a leader in Arab astrology, must be stressed at this point. As stated above, his works were virtually superseded in Arabic astrology by the works of the generation which followed his death. Why then do we possess so many of his manuscripts in Latin translation? This seems to have resulted from the special interest manifested in Māʾshāʾallāh's works by John of Seville (Johannes Avendauth, or Ibn Dawūd). Having set about to translate for the benefit of Latin scholars the works of the "prince" of Arab astrologers Abū Maʾshar (no Arab himself but Persian/Afghan since he came from the "Bactrian" city of Balkh), John enlarged his program of translation to include the corpus of Jewish astrologers of the early Abbasid era.

Within the scope of Arab astrological doctrines there developed a side which stemmed from the application of the scheme of planetary conjunctions in relation to the zodiacal signs and various triplicities in which they might occur. But it was Jupiter's special prerogative to foster religious life. The conjunction theory animating astrological history turned principally around the conjunctions of Saturn and Jupiter to signal the emergence, duration, and waning of sects (Arabic *milal*) when referred to religions, or of dynasties and empires (*duwal*) when applied to military domination. A basic element of the scheme was the association of each planet with what was classified as "great civilizations", mostly religions with cultures that set religion as their guiding light. Saturn as the most distant planet was appropriated to the Judaic faith, the Sun to the Roman Empire, and Venus to Islam. This was in a nutshell the astrological exercise of the "horoscope of religions" as it came to be known in the Latin West.

The most famous of such interpretations was embodied in Abū Maʿshar's *Great Conjunctions*. Associating the spread of the Judaic religion with the rule of the planet Saturn, the sway of the Roman Empire with that of the Sun, and of the Arab Empire with that of Venus, etc., the scheme thereby stressed the primeval character of the Jewish faith in accordance with the status of Saturn, the highest and most distant planet. The vicissitudes of planetary conjunctions thereafter unfolding along the variety of signs in which they occurred successively, rendered Judaic monotheism anachronistic. It was replaced in time by the Roman Empire, which in turn was displaced by "manicheism" when the prophet Mani appeared, until the rise of Islam.

In ninth-century Baghdad there was great concern among the Abbasid rulers and the Arab elites who were confronted with widespread social unrest among non-Arab subjects. One wave of unrest was further encouraged in *shuʿūbīya* (ethnic) groups by astrological predictions hinting at the impending end of Arab domination foreboded by planetary conjunctions. This was the occasion for the consolatory *Risāla fī mulk al-ʿarab wa-kammiyatihi* (On the Dominion of the Arabs and its Extent) which al-Kindī wrote for the Caliph, a consolatory Epistle in which he calculated that the conjunctions of Saturn with Jupiter held forth a total duration of 693 years for the Muslim Empire, which meant at that time four more centuries of Arab rule, whereas Abū Maʿshar's similar calculations in his *Great Conjunctions* foresaw only 310 years or so for it.

The association of Judaism with Saturn is not present in Māshāʾallāh's scheme of astrological history, although his interpretation of planetary conjunctions was extended to Islam and in particular to the rule of the Caliphs. Yet the status assigned to Judaic culture in the scheme of planetary conjunctions of Arab astrology stirred echoes in Jewish communities in Spain, inspiring their leaders in astrological science to use the scheme of conjunctions to confirm the unique "vocation" of Israel. This endeavor is at the core of the *Megillat ha-Megalle* by Abraham bar Ḥiyya of Barcelona. This book purports to illustrate the fate of Israel in the cosmic framework of universal history by referring to Holy Scriptures, Rabbinic literature, and philosophy. Yet the entire last chapter is devoted to the scheme of planetary conjunctions and its significance for the fate of Israel, confirming by "science" the data of sacred literature. The enterprise ostensibly aimed to counteract the "scientific" demoting of Judaic civilization to a lower historical role by Arab astrological writers. Another Jewish astronomer astrologer in Spain, Abraham ibn Ezra, also critiqued the theory of planetary conjunctions.

The medieval Anglo-Irish scientific literature used to include two versions of some work by Māshāʾallāh' in the form of Chaucer's *Treatise on the Astrolabe,* and an Irish tract following closely the text published by J. Heller in Nurnberg in 1549 under the title *De elementis et orbibus coelestibus*. Since the publication of Paul Kunitzsch's thesis, however, which shifts the authorship of the Latin source used by Chaucer from Māshāʾallāh the Jewish astrologer from Iraq, to Maslama, the eleventh century Arab astronomer from Spain, it would appear that this part of Māshāʾallāh's claimed influence upon Western literary tradition must be abandoned.

A compilation of Arab "authorities" in astrology called *Liber Novem Iudicum* (Book of the Nine Judges) included Māshāʾallāh as one of its principal authorities. The compilation of the Nine Judges did much to carry Māshāʾallāh's astrological rules and reputation to the four corners of medieval Europe.

Mathematical Texts in Egypt

Annette Imhausen

While there is only indirect evidence for mathematical techniques in the Old Kingdom (2686–2160 BCE) and the New Kingdom (1550–1069 BCE), we do have texts detailing specific mathematical procedures from the Middle Kingdom (2055–1650 BCE) and the Graeco Roman Period (332 BCE – 395 CE).

Hieratic Mathematical Texts

The sources of the Middle Kingdom (the Rhind mathematical papyrus was written in the 2nd Intermediate Period, but states to be a copy of a Middle Kindgom original) are (in order of their publication; for respective editions see Collier and Quirke 2004 and 2006, Glanville 1927, Peet 1923a and 1923b, Schack-Schackenburg 1900 and 1902 and Struve 1930; a source book uniting photocopies and translations of most sources is Clagett 1999, for colour photographs of pRhind see Robins and Shute 1987):

– the Rhind mathematical papyrus (BM EA10057/58)
– the Lahun mathematical fragments (UC 32107A, 32114, 32118, 32134, 32159, 32162)
– the Berlin mathematical fragment 6619
– the Cairo Wooden Boards (CG 25368/8)
– the mathematical Leather Roll (BM EA10250)
– the Moscow mathematical papyrus (E4676)

They are all written in Hieratic (►http://www.digitalegypt.ucl.ac.uk/writing/hieratic.html), a cursive form of hieroglyphs. Most of the above listed sources were bought on the antiquities market, so that their exact provenance cannot be ascertained without doubt. Exceptional in this respect are the Lahun mathematical fragments, which were found between 1889 and 1899 by W.M.F Petrie during the excavation of Lahun, the pyramid town of Senusret II (1877–1870) (►http://www.digitalegypt.ucl.ac.uk/lahun/index.html). Nevertheless the form and content of Egyptian mathematical texts often allows us to determine their original context with some certainty.

We can distinguish two types of mathematical texts (and the individual sources listed above are compilations of one or both types): problem (or procedure) texts and table texts. Egyptian mathematical problem texts begin by stating a mathematical problem and then providing step-by-step instructions for its solution. We can differentiate several sections of a mathematical problem text.

1. Title, often in the form '*tp n ir.t* ...' 'method of calculating...' and highlighted by the use of red ink.
2. Announcement of the given data of the problem often followed by an explicit question of asking what shall be determined. The data are concrete values.
3. Procedure to solve the problem. This is spelled out via step-by-step instructions using the concrete data. Each instruction usually comprises one arithmetic operation (addition, subtraction, multiplication, division, halving, doubling, etc). After each step we find an intermediate result provided (for a technical analysis of the procedures found in the hieratic problem texts see Imhausen 2003a).
4. The indication of the solution, which usually equals the result of the last step of the instruction.
5. Verification of the solution.
6. Working of some calculations indicated in the instructions (for a recent discussion of some aspects of Egyptian arithmetic see Collier and Quirke 2004: 85–86).
7. Sometimes a drawing, indicating the object and its dimensions.

The problems teach basic mathematical techniques (e.g., how to determine an unknown quantity from a given manipulation of that quantity and its result ['a quantity, its 1/7 added to it becomes 19']) as well as applied mathematical problems, i.e., mathematical problems with a practical background. Practical problems include for example calculating distributions of rations, slopes of pyramids, work rates, exchanges of bread and/or beer and volumes of granaries.

Thus it has been concluded that Egyptian problem texts come from an educational background and were used in training junior scribes in the mathematical practices that they would need in their daily working lives (Ritter 2000). This was confirmed by administrative and economic papyri, which display the use of the same mathematical techniques (Imhausen 2003b).

Table texts comprise mathematical information in tabular format. They are often simply lists of mathematical data. Tables include those for fraction reckoning (most notably the 2/N table preserved at the beginning of the Rhind mathematical papyrus and in the Lahun fragment UC 32159), but also tables for the conversion of different metrological systems. Note that multiplication in hieratic texts was often carried out in writing, which rendered multiplication tables for natural numbers superfluous. For a description of Egyptian tables (both hieratic and Demotic) see Fowler 1999: 268–276.

Demotic Mathematical Texts

The second group of Egyptian mathematical texts dates from the Graeco Roman Period, i.e., a time when several cultures (the native Egyptian culture and the Greek and Roman cultures) coexisted in Egypt (for a description of Demotic mathematics within this cultural context see Cuomo 2001) and after Egypt had been under Persian rule twice (525–404 BCE and 343–332 BCE). Presumably during this Persian occupation (or earlier), Mesopotamian mathematical knowledge was transmitted into Egypt (see Parker 1972: 5–6 and Høyrup 2002: 405–406).

These are the extant sources consisting of several papyri (in order of their publication; for their editions see Parker 1959, 1972 and 1975):

Papyrus Griffith Institute I E.7
Papyrus Cairo JE 89127-30, 89137-43
Papyrus BM EA 10399
Papyrus BM EA 10520
Papyrus BM EA 10794
Papyrus Carlsberg 30
Papyrus Heidelberg 663

Ostraca, i.e., stone or pottery sherds were also used as writing material (for a list of Demotic mathematical ostraca see Ritter 2000 :134, note 27). It is likely that further sources will be discovered, as collections of Demotic papyri are being edited only now. Demotic (►http://www.digitalegypt.ucl.ac.uk/writing/demotic.html) is the cursive penultimate stage of ancient Egyptian.

The Demotic mathematical papyri show some similarities with their hieratic predecessors. Again, there are problem (or procedure) texts and table texts, and mathematical techniques are expressed rhetorically using specific numerical examples. On the other hand, there are distinct differences. At least within the extant Demotic mathematical papyri, we find that calculations of operations indicated in the procedures are no longer carried out in writing within the texts. Moreover there is a multiplication table within BM EA 10520, and the instructions for performing a multiplication in the same text are strikingly different from the Middle Egyptian method. The types of problems also vary, including some well-known Mesopotamian problems like that of a pole leaning against a wall.

Historiography

Earlier historiography has operated on the now outdated assumption that mathematical techniques exist and develop independently from their social and cultural context. These earlier studies focused mainly on the similarities with modern mathematics, using modern mathematical terminology and concepts to analyse the mathematical papyri. In 1989, Jim Ritter made a new beginning, setting new standards for the field (including the knowledge of Egyptian language and culture so the mathematical papyri can be studied in their original form and context). For an English translation see (Ritter 1995). A similar development has taken place for Mesopotamian mathematics pioneered by Jens Høyrup, Jim Ritter and Eleanor Robson. While older secondary literature is not to be discarded, it should be read carefully and the reader needs to keep in mind that significant progress has been made in Egyptology as well as in the History of Science (especially Gillings 1972 has to be read with this in mind) in the last 20 years.

Mathematics

George Gheverghese Joseph

A concise and meaningful definition of mathematics is virtually impossible. Mathematics has developed into a worldwide language with a particular kind of logical structure. It contains a body of knowledge relating to number and space, and prescribes a set of methods for reaching conclusions about the physical world. Also, it is an intellectual activity which calls for both intuition and imagination in deriving "proofs" and reaching conclusions. Often it rewards the creator with a strong sense of aesthetic satisfaction.

Mathematics initially arose from a need to count and record numbers. As far as we know there has never been a society without some form of counting or tallying, i.e., matching a collection of objects with some easily handled set of markers, whether it be stones, knots, or inscriptions such as notches on wood or bone. Also, it is precisely such an artifact that helps us to locate the early beginnings of mathematics.

High in the mountains of Central Equatorial Africa, on the borders of Uganda and Zaire, lies Lake Edward, one of the furthest sources of the River Nile. Though this area, Ishango, is remote and sparsely populated today, about 20,000 years ago a small community lived by the shores of the lake that fished, gathered food or grew crops depending on the season of the year. The settlement had a relatively short lifespan of a few hundred years before being buried in a volcanic eruption. Archeological excavations at Ishango unearthed a bone tool handle which is now on display at the Musée d'Histoire Naturelle in Brussels. The original bone may have petrified or undergone chemical change through the action of water and other elements. What remains is a dark brown object on which some markings are clearly visible. At one end is a sharp, firmly fixed piece of quartz which may have been used for engraving, tattooing, or even writing of some kind. Along the Ishango Bone, as it is now called, is a series of notches arranged in three distinct columns: first column contains four groups of notches with 9, 19, 21, and 11 markings; second column contains four groups of 19, 17, 13, and 11 markings; and third column has eight groups of notches in the following order: 7, 5, 5, 10, 8, 4, 6, 3, with the last pair (6,3) being spaced together, as are (8,4) and (5,5,10), suggesting a deliberate arrangement in distinct subgroups.

Conjectures based on underlying numerical patterns of the notches are well summed up by de Heinzelin, the archeologist who helped to excavate the Ishango Bone. The bone "may represent an arithmetical game of some sort devised by a person who had a number system based on ten as well as a knowledge of duplication (or multiplying by 2) and of prime numbers." Further, from the existing evidence of the Ishango tools, notably harpoon heads, northward up to the frontiers of Egypt, de Heinzelin supports the possibility that the Ishango numeration system may have traveled as far as Egypt to influence the development of its number system, the earliest decimal-based system in the world.

There is, however, another explanation which highlights a link that has played a crucial part in the historical development of mathematics. The close link between mathematics and astronomy has a long history and is tied up with the need for societies to record the passage of time, both out of curiosity as well as practical necessity. The alternative explanation is that the bone markings constitute a system of sequential notation – a record of different phases of the moon. Whether this is a convincing explanation would depend in part on establishing the importance of lunar observations in the Ishango culture and in part on how closely the series of notches on the bone matches the number of days contained in the successive phases of the moon. Marshak attempted to do both and concluded that the Ishango Bone, with its markings of different indentations, shapes, and sizes, was a lunar calendar where the different types of engraving indicate that it was also a calendar of events, probably of a ceremonial or ritual nature. There is still a good deal of controversy and interest around this bone.

One of the most ingenious methods of recording and storing information before the emergence of the computer is a *quipu*. The *quipu* (a Quechua word from the language of the Incas of South America) is an arrangement of colored wool or cotton cords with clusters of knots tied in the cords to represent numerical magnitude. In essence, it resembles a mop which has seen better days. It was widely used as a device for storing numerical and other information before the Spanish conquest in an area which would today include all of Peru, parts of Bolivia, Chile, Ecuador, and Argentina. A vast amount of information can be kept on a *quipu* using different colored cords for summation between and within categories and relative placement of the knots for indicating different numerical magnitudes. A *quipu* has been discovered which is a record of a census taken in 1587 of the Andean population of Lupaqa disaggregated by province, ethnic groups, size, and age/sex distribution of households, using cords of different thickness, color, and configuration. Altogether 46 different items of information were kept on this recording device no larger than an ordinary kitchen mop.

For a highly centralized society such as the Inca, an essential prerequisite for maintaining good order and efficient organization was the existence of detailed and up-to-date information (or government statistics, as we would describe such information today). A whole inventory of resources which included agricultural produce, livestock, and weaponry – as well as people – was maintained and updated by a group of specially trained officials known as *quipucamayus* (*quipu*-keepers). Each village under the rule of the Inca had its own specially trained *quipucamayu* and certain larger villages had as many as 30. One of the main tasks of the *quipucamayu* was to devise efficient and economical methods of storing information. The more the *quipucamayu* considered the pattern of distribution, taking account of the relative sizes and positions of different cords, the better the logical structure of the final representation. Cord placement, color coding, and number representation were the basic design features, repeated and recombined to define a format and convey a logical structure. This search for a coherent numerical/logical structure involves mathematical thinking reminiscent of database management in a modern computer and a study of spatial configuration structures of different *quipus* is a good introduction to a field of modern mathematics known as "graph theory."

It is possible to view the appearance of a written number (or numeral) system as a culmination of earlier developments. First was the recognition of the distinction between more and less (a capacity we share with certain other animals). From this developed first simple counting, then the different methods of recording the counts as tally marks, of which the Ishango Bone is one example. This progression continued with the emergence of more and more complex means of recording information, culminating in the construction of devices such as the *quipu*. Before the appearance of such devices, there must have existed an efficient system of spoken numbers founded on the idea of a base to enable numbers to be arranged into convenient groups.

There is ample historical and anthropological evidence indicating that a variety of bases for counting systems have been used over the ages and around the world. The base of a counting system tells how numbers are grouped and constructed. Our system, a decimal or base-10 system, has words for numbers from one to ten displaying no common root. Beyond ten, the number words generally show a variation of the unit word for the multiples of ten.

To illustrate, take the case of a few counting systems with different bases chosen from round the world. For an indigenous Australian group, the Gumulgal, counting proceeds as *urapon* (1), *ukasar* (2), *ukasar-urapon* (3), *ukasar-ukasar* (4), *ukasar-ukasar-urapon* (5),… to indicate counting by twos (or a base-2 system). In a Melanesian language, Sesake, counting proceeds as *sekai* (1), *dua* (2), *dolu* (3), *pati* (4), *lima* (5), *la-tesa* (6), *la-dua* (7),…,*dua-lima* (10),…,*dua-lima-dua* (20). This suggests a base-5 counting system where words for numbers six or seven use the roots for words one and two; ten is literally two-fives and twenty is two-fives twice. In a Micronesian language, Kiribati, counting proceeds as *tenuana* (1), *uoua* (2), *tenua* (3), *aua* (4), *nimua* (5), *onoua* (6), *itiua* (7), *wanua* (8), *ruainua* (9), *tebwina* (10), *tebwina-ma-tenuana* (11),…, *vabui* (20), *vabui-ma-tenuana* (21),…,*tebubua* (100),…, *tenga* (1,000),…,*tebina-tenga* (10,000),…,*tebubuna-tenga* (100,000). Here we have a straightforward base-10 counting system. In Kiribiti, number words also vary according to the object being counted. Thus the number word for 9 is *ruaman* when counting animals, *ruakai* when counting plants, *ruai* when counting knives, *ruakora* when counting baskets, and *rauawa* when counting boats. In certain other systems, such as the Aztec number system, the choice of the bases would depend on the type of objects being counted. Cloths or tortillas would be counted in twenties, while round objects such as eggs or oranges would be counted in tens.

Counting by tens has been the most widespread system probably because it is associated with the use of fingers on both hands. The other scale (base-20) had its most celebrated development as a written number system during the first millennium of the present era among the Maya of Central America. There have also been other base-20 systems, of which the Yoruba system from Nigeria and the Welsh system from Britain are two well-known examples.

An unusual feature of the Yoruba system is its heavy reliance on subtraction. The subtraction principle operates in the following way. As in our number system, there are different names for the number one (*okan*) to ten (*eewa*), the numbers eleven (*ookanla*) to fourteen (*eerinla*) are expressed as compound words which may be translated into "one more than ten" to "four more than ten." But once fifteen (*aarundinlogun*) is reached the convention changes, so that fifteen to nineteen (*ookandinlogun*) are expressed as "twenty less five" to "twenty less one," respectively, where twenty is known as *oogun*. Similarly, the numbers twenty-one to twenty-four are expressed as additions to twenty, and twenty-five to twenty-nine as deduction from thirty (*ogbon*). At thirty-five (*aarundinglogoji*), however, there is a change in the way the first multiple to twenty is referred to: forty is expressed as "two twenties" (*ogoji*) while higher multiples are named *ogata* ("three twenties"), *ogerin* ("four twenties"), and so on to "ten twenties," for which a new word *igba* is used. It is in the naming of some of the intermediate numbers that the subtraction principle comes into its own. To take a few examples, the following numbers are given names which indicate the decomposition shown on the right:

$$45 = (20 \times 3) - 10 - 5,$$

$$108 = (20 \times 6) - 10 - 2,$$

$$300 = (20) \times (20 - 5),$$

$$318 = 400 - (20 \times 4) - 2,$$

$$525 = (200 \times 3) - (20 \times 4) + 5.$$

All the numbers from 200 to 2,000 (except those that can be directly related to 400 or *iriniwa*) are reckoned as multiples of 200. From the name *egebewa* for 2,000, compound names are constructed for number in excess of this figure, using subtraction and addition wherever appropriate similar to the above examples.

The origin of this unusual counting system is uncertain. One conjecture is that it grew out of the widespread practice of using cowrie shells for counting and computation. A description of the cowrie shell counting procedure given by Mann in 1887 is interesting. From a bag containing a large number of shells the counter draws four lots of five to make twenty. Five twenties are then combined to form a single pile of one hundred. The merging of two piles of one hundred shells gives the next important unit of Yoruba numeration, two hundred. As a direct result of counting in fives, the subtraction principle comes into operation. Take the decomposition of 525, given earlier, as an illustration. We begin with three piles of *igba* (200), remove four smaller piles of *oogun* (20), and then add five (*aarun*) cowrie shells to make up the necessary number.

This complicated system of numeration in which the expression of certain numbers involves considerable feats of arithmetical manipulation has certain advantages for computation. As an example of a calculation which exploits the strength of the Yoruba numeration to the full, consider the multiplication: 19×17.

The cowrie calculator begins with twenty piles of twenty shells each. From each pile, one shell is removed (−20). Then three of the piles now containing nineteen shells each are also removed. The three piles are adjusted by taking two shells from one of them, and adding one each to the other two piles to bring them back to twenty ($-20 \times 2 - (20 - 3)$). At the end of these operations we have

$$400 - 20 - (20 \times 2) - (20 - 3) = 323.$$

While the Yoruba system shows what is possible in arithmetic without a written number system, it is clearly impractical for more difficult multiplications.

However, there are other mechanical aids which are more versatile, such as the Chinese or Japanese abacus (*soroban*). In the speed of addition and subtraction, the abacus still holds its own against the electronic calculator. In a test problem consisting of: first, adding a column of eleven numbers and then subtracting four numbers from the result where there was no number of less than three digits and most contained four or five digits, a third-grade abacus operator in China or Japan (i.e., an operator possessing the minimum level of competence acceptable for employment in a bank or similar institution) performed this computation in 30 s. An operator using the calculator took 90 s. A first-grade abacus operator would have been expected to have finished the computation in 20 s. There is even the well-attested claim of an expert operator taking less than 15 s to add ten numbers each of ten digits!

There are two modes of performing arithmetical operations. The first arose in cultures which, either because of scarcity of writing materials or because of the limitation of their written number systems, resorted to physical devices such cowrie shells or an abacus to carry out multiplication. The second mode involves "paper-and-pencil" methods of written numbers. The origins of many of these paper-and-pencil algorithms are found in parts of the non-Western world which gave birth to different place value number systems: Babylonia during the third millennium BCE, China around the third century BCE, the Maya Empire around the beginning of the Common Era, and in India a few centuries later. And in the process of transmitting the Indian numerals westward some of the efficient algorithms, initially devised for these numerals, were lost.

To illustrate, consider multiplying 97 by 93. The method favored today involves two sets of multiplication, one requiring the "9-times table," then adding the results of the two sets of multiplication on paper to get the final answer: 90/21. Of course these days, one would use an electronic calculator but feel rather lost if the calculator was not readily at hand. But there is a startling simple yet mathematically profound method available from the distant past.

Take the problem: 97 × 93; 97 is 3 less than 100, 93 is 7 less than 100. Multiply the deficiencies 3 and 7 to get 21. Subtract from 97 the deficiency corresponding to the other number, 93, which is 7 *or* the other way round. Both subtractions will give 90. The final answer is the merging of the two parts: 90/21. This procedure can be mathematically "productive" if one then proceeds to answer the following "what ifs":

- What if both numbers to be multiplied are just over 1,000?
- Both just under 1,000?
- One just over and one just under 1,000?
- Both just over or just under 100?
- Or one just over and one just under 100?
- What about numbers near 50?
- Or near 20?
- What if they are not both within the range of the same base?

In all these cases, the procedures devised involve using the principal strength of our number system – the place value principle. An examination of why the method works leads us quite naturally to the interconnection of arithmetic, algebra, and geometry, and also a reminder that algebra is but a generalization of arithmetic. A method claimed to be as old as the Vedas (ca. 500 BCE), it is found in works of later Indian mathematicians, notably Brahmagupta (ca. AD 600) and Bhāskarāchārya (ca. AD 1100). It was known to the Arabs through whom our number system, which began in India, spread westward into Europe. Yet this method was lost and what we have in place are rather cumbersome procedures, some more suitable perhaps for multiplication with number systems without place value like the Roman numerals.

The rules devised by mathematicians for solving problems about numbers of one kind or another may be classified into three types. In the early stages of mathematical development, these rules were expressed verbally, and consisted of detailed instructions about what was to be done to obtain a solution to a problem, for which reasons this approach is referred to as *rhetorical algebra*. In time, the prose form of rhetorical algebra gave way to the use of abbreviations for recurring quantities and operations, heralding the appearance of syncopated algebra. Traces of such algebra are to be found in the works of the Alexandrian mathematician Diophantus (ca. AD 250), but it achieved its fullest development in the work of Indian and Arab mathematicians during the first millennium AD. During the past 500 years symbolic algebra has developed so that, with the aid of letters and signs of operation and relation $(+, -, \times, /, =)$, problems are stated in such a form that the rules of solution may be applied consistently and systematically. The transformation from rhetorical to symbolic algebra has been a long one and marks one of the most important advances in mathematics. It had to await the development of a positional number system (i.e., the Indian numerals) which allowed numbers to be expressed concisely and with which operations could be carried out efficiently.

As early as 1800 BCE, the Babylonians had developed sophisticated methods of solving equations, building on their invention of a positional number system. A 4,000-year-old Babylonian clay tablet, now kept in a Berlin museum, gives the value of $n^3 + n^2$ for $n = 1, 2,\ldots,10, 20, 30, 40, 50$, from which it is deduced that the Babylonians may have used these values in solving cubic equations after reducing them to the form $x^3 + x^2 = c$. Linear and nonlinear equations in two and three unknowns were also solved correctly within the framework of a rhetorical algebra.

Early Indian algebra also contained solutions of linear, simultaneous, and even indeterminate equations. An example of an indeterminate equation in two unknowns (x and y) is $3x + 4y = 50$, which has a number of positive whole-number solutions for (x, y). For example $x = 14$, $y = 2$ satisfies the equation, as do the solution sets (10,5), (6,8), and (2,11). But it is only from AD 500 that there emerged a distinctive feature – the use of symbols, such as a dot or the letters of the alphabet, to denote unknown quantities. In fact it is this very feature of algebra that one immediately associates with the subject today. A general term in Indian algebra for any unknown was *yāvat tāvat*, which was shortened to the algebraic symbol *yā*, In Brahmagupta's work, Sanskrit letters appear, which are the abbreviations of names of different colors which he used to represent several unknown quantities. Thus the letter *kā* stood for *kālaka*, meaning "black," and the letter *nū* for *nūlaka* meaning "blue."

The word *al-jabr* appears frequently in Arab mathematical texts that followed al-Khwārizmū's influential *Ḥisāb al-jabr w'al-muqābala* written in the first half of the ninth century AD. There were two meanings associated with *al-jabr*. The more common one was "restoration" as applied to the operation of adding equal terms to both sides of an equation, so as to remove quantities, or to restore a quantity which is subtracted from one side by adding it to the other. Thus an operation on the equation $2x + 5 = 8 - 3x$ which leads to $5x - 5 = 8$ would be an illustration of *al-jabr*. There was also another, less common meaning: multiplying both sides of an equation by a certain number to eliminate fractions. Thus, if both sides of the equation $9/4x + 1/8 = 3 + 5/8x$ were multiplied by 8 to give the new equation $18x + 1 = 24 + 5x$, this too would be an instance of *al-jabr*. The common meaning of *al-muqābala* is the "reduction" of positive quantities in an equation by subtracting equal quantities from both sides. For the second equation above, applying *al-muqābala* would give $18x - 5x + 1 - 1 = 24 - 1 + 5x - 5x$ or $13x = 23$. The words *al-jabr* and *al-muqābala*, linked by *wa* (and), came to be used for any algebraic operation, and eventually for the subject itself. Since the algebra of the time was almost wholly confined to the solution of equations the phrase meant exactly that.

Apart from giving the name to the subject, the great contribution of the Arabs to algebra was to devise an efficient system of classifying equations. Starting with al-Khwārizmū, they reduced all equations to six main types. For each type they offered solutions and when possible a geometric rationale. Their work culminated in ʿUmar al-Khāyyam's geometric solution of the cubic equation in the middle of the eleventh century AD. The Arab work on equations is one illustration of their ability to bring together two strands of mathematical thinking – the geometric approach which had been carefully cultivated by the Greeks and the algebraic/algorithmic methods which had been used to such effect by the Babylonians, Indians, and Chinese.

The development of Chinese algebra was a direct result of their number system – the rod numeral system. Apart from its notational facility, the rod numeral system was helpful in suggesting new approaches to algebraic problems, notably the use of a variant of the modern matrix method for solving simultaneous equations about 1,000 live hundred years before its so-called discovery in Europe and the "method of double false" which constitutes an important algorithm for solving higher order equations in the modern subject of numerical analysis.

The Chinese work on solutions of numerical equations of higher order has its origins in the method of extracting square and cube roots found in their premier text, *Jiuzhang suanshu* (Nine Chapters on the Mathematical Arts), written around the beginning of the Common Era. The combination of the root extraction procedure with the use of what we know as the Pascal triangle (although it was already known to the Chinese about 500 years before the seventeenth-century French mathematician, Pascal) meant that the Chinese were solving equations of the ninth degree (i.e., equations involving the term x^9) around AD 1250, using a variant of the Horner–Ruffini method which only came into modern mathematics at the beginning of the nineteenth century.

Any definition of the subject matter of mathematics would include activities that relate to spatial configurations or geometry. There are two theories regarding the origins of geometry. Herodotus, the Greek historian who lived in the fifth century BCE, wrote that geometry arose in ancient Egypt from the need to parcel out, in an equitable fashion, precious agricultural land whose boundaries were annually obliterated by the overflow of the River Nile. The ideas of the Egyptian surveyors (or "rope-stretchers") were eventually passed on to the Greeks who proceeded to build that most impressive edifice known as "Greek geometry." However, Egyptian geometry had shown the way, for in the Moscow Papyrus, an important source of Egyptian mathematics from about 1850 BCE, the correct rule for calculating the volume of a truncated pyramid appears.

An alternative explanation sees the origins of geometry in religion and ritual. A good illustration would be a class of ritual literature from ancient India, known as the *Śulbasūtras* dealing with the measurement and construction of various sacrificial altars. They also happen to be the earliest text of Indian geometry dated around 800–500 BCE. They provided instructions for two types of rituals, one for worship at home and the other for communal worship. Square and circular altars were sufficient for household rituals while more elaborate altars involved combinations of rectangles, triangles, and trapezia for public worship. The geometry of the *Śulbasūtras* grew out of the need to ensure strict conformation of the orientation, shape, and area of altars to the prescriptions laid down in the scriptures. They include a general statement of the so-called "Pythagorean theorem," an approximation procedure for obtaining the square root of 2 correct to five decimal places and a number of accurate geometric constructions including ones for "squaring the circle" (approximately) and constructing rectilinear shapes whose area was equal to the sum or difference of areas of other shapes. The earliest known demonstration of Pythagoras' theorem is found in an ancient Chinese text, *Zhoubi suanjing*, at least 300 years before Pythagoras (ca. 500 BCE). Over 1,000 years before Pythagoras, the Babylonians knew and used the result now known under his name.

To most of us geometry deals with lines, angles, circles, and polygons. These are the central concepts that appeared in the best-known text in geometry, Euclid's *Elements* (ca. 300 BCE). To these were subsequently added subjects such as symmetry, coordinates, vectors, and other curves. Many of these concepts appear in different cultures in a variety of contexts: in architecture, drawings, decorations, etc. Do such examples constitute mathematics or can they at best be used as no more than peripheral illustrations of certain geometrical notions? In 1986, Paulus Gerdes posed the following "nonstandard" problems to a workshop of mathematics educators who had some difficulty working them out, although artisans in Mozambique, some of them illiterate, solved them as a matter of course:

- Construct a circle given only its circumference: a problem in laying out a circular floor for a traditional Mozambican house.
- Construct angles that measure 90°, 60°, or 45° with only strips of straw: a problem in basket weaving.
- Fold an equilateral triangle out of a square: a problem in making a straw hat.
- Construct a regular hexagon out of straw: a problem in making a fish trap.

Does solving these problems involve mathematical thinking? It could be argued that the artisans who first discovered the optimal solutions to these problems were engaged in "creative" geometrical thinking. Mary Harris has extended this argument to tasks which are usually seen as women's work.

> Many of the male teachers are so unfamiliar with the construction and shape and size of their own garments that they cannot at first perceive that all you need to make a sweater (apart from technology and tools) is an understanding of ratio and all you need to make a shirt is an understanding of right-angled and parallel lines, the idea of area, some symmetry, some optimisation, and the ability to work from 2-dimensional plans to 3-dimensional forms … It is interesting to take Gerdes' analyses … and apply them … in the different context of women's culture.

All that is needed in many non-Western cultures is to "defrost" the frozen mathematics of the cultures contained in useful objects such as baskets, mats, pots, houses, sand-drawings, sculptures, fish traps, etc.

There is, however, a major stumbling block: the wide spread acceptance of the hegemony of a Western version of mathematics, following from the assumption that mathematics is largely a European creation. Two tactics have been used to propagate this Eurocentric myth.

The first is Omission and Appropriation. Prior to the "Renaissance," European acknowledgment of the debt it owed to Arab mathematics and its antecedents was fulsome both in words and deeds. Indeed the course of European cultural history and the history of European thought are inseparably tied up with the activities of Arab scholars during the Middle Ages and their seminal contributions to mathematics, the natural sciences, medicine, and philosophy. By the seventeenth century, however, the perception concerning the origins of mathematical knowledge had begun to change, due to the workings of a number of forces. With the European expansion in the American continents, the development of the slave trade, and the imposition of colonial rule in many parts of the world, the assumption of white superiority became dominant over a wide range of social and economic activities, including the writing of the history of mathematics. Moreover, the rise of nationalism in nineteenth- and twentieth-century Europe and the consequent search for the roots of European civilization led to an obsession with Greece and the myth of Greek culture as the cradle of all knowledge and values. This was despite ample evidence of significant mathematical developments in Mesopotamia, Egypt, China, pre-Columbian America, India, and the Arab world, showing that Greek mathematics owed a significant debt to most of these cultures. In recent years a grudging recognition of the debt owed by Greece to earlier civilizations and the important contribution of Arab mathematicians has led to some revisions to a "purely" Eurocentric trajectory of the historical development of mathematics. But the modifications still ignore for the most part the routes through which Hellenistic and Arabic mathematics entered Europe and take little account of the mathematical knowledge produced by India, China, and other cultures. Even those texts which include the Indian and Chinese mathematics often confine their discussion to a single chapter which may go under the misleading title of "Oriental" or "Eastern" mathematics. That these cultures contributed to the mainstream development of mathematics is rarely recognized, and little consideration is given to the mathematical research that is currently taking place in these and other non-Western regions.

The second tactic is Exclusion by Definition. A Eurocentric approach to the history of mathematics is intimately connected with the dominant view of mathematics as a sociohistorical practice and intellectual activity. Despite the development of contrary trends in the last two centuries, the standard textbook approach sees mathematics as a deductive system, ideally proceeding from axiomatic foundations and revealing, by the "necessary" unfolding of its pure abstract forms, the eternal/universal laws of the "Mind."

The Indian and Chinese concepts of mathematics were very different. Their aim was not to build an imposing edifice on a few self-evident axioms, but to validate a result by any method. Some of the most impressive works in Indian and Chinese mathematics (the summations of complex mathematical series, the use of Pascal's triangle in solutions of higher order numerical equations, the derivations of infinite series, and the "proofs" of the Pythagorean theorem) involve the use of visual demonstrations that are not formulated with reference to any formal deductive system. The Indian view of the nature of mathematical objects, like numbers, is also based on a framework developed by Indian logicians and linguists which differs at the foundational level from the set theory universe of modern mathematics.

The view that mathematics is a system of axiomatic/deductive truths inherited by the Greeks and enthroned by Descartes has been traditionally accompanied by a cluster of values that reflect the social context in which it originated:

1. An idealist rejection of any practical, material(ist) basis for mathematics: hence the tendency to view mathematics as value-free and detached from social and political concerns.
2. An elitist perspective that sees mathematical work as the exclusive preserve of a pure, high-minded and almost priestly caste, removed from mundane preoccupations and operating in a superior intellectual sphere.

Non-Western mathematical traditions have therefore been dismissed on the grounds that they are dictated by utilitarian considerations with little notion of rigor in proof. Any attempt at excavation and restoration of non-Western mathematics is a multifaceted task: confront historical bias, question the social and political values shaping the mathematics curriculum, and search for different ways of knowing or establishing mathematical truths found in various traditions.

Mathematics Communicating Across Culture and Time

Leigh N. Wood

> The truth is that history, as we commonly conceive of it, is not what happened, but what gets recorded and told. Most of what happens escapes the telling because it is too common, too repetitious to be worth recording…
>
> The business of making accessible the richness of the world we are in, of making dense and substantial our ordinary, day-to-day living in a place, is the real work of culture (Malouf 1998: 17).

Mathematics is a method for communicating ideas between people about concepts such as numbers, space and time. In any culture there is a common, structured system for such communication, whether it be in unwritten or written forms. These systems can form bridges of communication across culture and across time.

So, what is communication? Crowley and Heyer (1995: 7) describe communication as "… an exchange of information and messages. It is a process. About 100,000 years ago our early ancestors communicated through non-verbal gestures and an evolving system of spoken language. As their world became more complex, they needed more than just a shared memory"… this led to "the development of media to store and retrieve the growing volume of information." Communication is about an exchange of information and the techniques humans have developed to store and retrieve that information. It is not necessary to have writing, computer disks and so on: communication can be verbal (oral traditions), non-verbal (gestures, *quipu*), temporary (sand drawing) or more permanent (clay tablet, woven cloth).

Communicating in or about the field of mathematics involves taking part in mathematical discourse, whether by reading, writing, listening or speaking. Discourse is a broader concept than language because it also involves all the activities and practices that are used to make meaning in a particular profession. The discourse of mathematics includes all the ways that mathematics is done: through language, textbooks, mathematicians talking to each other and to a wider public, and through popularisation and application of mathematical knowledge (Wood and Perrett 1997).

Discourse does not see the terms *language* and *communication* as synonymous, although it certainly recognises language as a central resource for the communication process. This view sees language as a resource for making meanings within different situations (Halliday 1978; Kamp and Reyle 1993). Communication is seen as a complex process within which natural language supplies a major (but seldom the only) resource for making specific meanings within the framework of specific social practices or areas of knowledge. Readers who wish to know more about the complexities of natural language may consult texts such as Finegan (2003).

When we speak of making meaning within different areas of knowledge we are referring to different discourse practices. The language used in mathematical discourse is natural language but it is a language that has evolved in specialised ways to deal with the demands of expressing mathematical concepts. The most striking difference between mathematical writing and most other types of writing is the extensive use that mathematics makes of symbols and numbers. These are sometimes seen as alternatives to natural language, alternatives that mathematicians value as being more precise and more elegant than natural language. However the symbolic language of mathematics is an extension of natural language as much as a replacement for it, just as a pile of cowrie shells or a gesture can represent a number word. Natural language is used to complement the symbolic language of mathematics when mathematicians talk and write to each other and it has to replace the symbolic language when mathematicians communicate with non-mathematicians. Thus we would argue that natural language plays an essential part in doing mathematics.

All cultures are mathematised, in that people within any culture use ideas of mathematics in their everyday life. For this I will take a wide definition of mathematics to include concepts of number, space, chance, and time. A report of the Australian Academy of Sciences *Mathematical Sciences: Adding to Australia* (1996: ix) gives this description of modern mathematics:

> Mathematics is the study of measurements, forms, patterns, variability and change. It evolved from our efforts to understand the natural world…
>
> Over the course of time, the mathematical sciences have developed a rich and intrinsic culture that feeds back into the natural sciences and technology, often in unexpected ways. The mathematical sciences now reach far beyond the physical sciences and engineering; they reach into medicine, commerce, industry, the life sciences, the social sciences and to every other application that needs quantitative analysis.

This description takes mathematics back to its roots. Mathematics has been part of all societies, a part of every profession as well as being used in everyday life. Western mathematics became narrower with the insistence that only deductive mathematics from a set of axioms, following the Greek tradition, was *real* mathematics. The broader view of mathematics, especially with the consideration of computing, validates the work of non-European mathematicians. A majority of mathematicians today are working much closer to the way that Indian, Chinese and Arab mathematicians worked, as they focus on real applications and better computing algorithms (Horgan 1993).

Culture too can be viewed broadly. Asher (1991: 2) says "In any culture people share a language; a place; traditions; and ways of organising, interpreting, conceptualising and giving meaning to their physical and social worlds." David Malouf (1998: 17) describes the process of acculturation as, "The business of making accessible the richness of the world we are in, of making dense and substantial our ordinary, day-to-day living in a place, is the real work of culture." The description of mathematics above states that "The mathematical sciences have developed a rich and intrinsic culture".

Mathematics has often worked on many levels, as part of everyday culture and also as used by subgroups within the main culture. In the Inca culture only a small group would have been able to construct and interpret the *quipus* (knotted cords used by the Inca to convey data, Asher 1991). In the Babylonian culture of 3000 BCE few people would have been skilled in the algebraic and computational techniques required for commerce, as is evidenced by the many clay tablets which can be interpreted as instructional textbooks. In

Egypt, the Ahmes papyrus consists of instructional material for a mathematical subculture that would calculate the land areas after the annual floods and document commercial transactions. Indeed in many cultures, the mathematics of calendars and astronomy was in the hands of the priestly classes.

The mathematical subcultures communicated their knowledge to future mathematicians in a similar way to classes or apprentices today. Students worked through sets of paradigm problems designed to develop the calculating skills, ideas and language necessary for their future careers. Some of the ways that mathematics has been taught is remarkably similar across the cultures and centuries. The drill and practice examples on the Ahmes papyrus and some Babylonian clay tablets are close to the way mathematics is taught in many classrooms today (Fowler and Robson 1998: 369). Teachers wrote commentaries and extensions from previous texts. They improved algorithms and compared methods. Høyrup (1994) concluded that mathematics as a discipline began to be systematically organised with the need to teach it to professional scribes in about 3000 BCE.

Communication Without Written Language

We will examine some examples of mathematical discourse in cultures with no written language. We are dealing with speaking and listening, but also with art, artefacts and gesture. It is possible to consider the *quipu* (Asher 1991) for example, as a "written" number system, but for this essay I do not wish to include such artefacts as written language.

How were mathematics and mathematical ideas communicated within cultures without writing? Here we make the assumption that cultures that do not have written language (95% of cultures, Asher 1991: 2) communicate mathematics by methods that have been documented by outside observers. The reliability of the documentation varies greatly with the biases and the mathematical knowledge of the observer. These snapshots can nonetheless help to extrapolate back into history for cultures that have lived in isolation for some time. For example the counting system of the Gomileroi in South-Eastern Australia (Table 1) has been documented and I suggest that this number system has been in situ for thousands of years prior to the arrival of Europeans in Australia in 1788. Similarly the counting systems in Papua New Guinea, documented by Glendon Lean (summarised in Phythian 1997), would have been used for centuries before the arrival of Europeans and European mathematics. Richard Pankhurst (as cited in Zaslavsky 1973: 89) has made an extensive study of the measures, weights and values in use among the various Ethiopian peoples throughout their history.

Between the years 1968 and 1988, Lean collected and recorded data on the counting systems of Papua New Guinea and Oceania. There are 1,200 languages in the region and Lean collected data on nearly 900. He also discussed how the number systems were communicated through migration, wars and marriage. As these languages are not written, he made use of diagrams to show gesture counting and used phonetics to write down number words. His awareness of mathematics has meant that he was conscious of the 2, 5, 10 and

Mathematics Communicating Across Culture and Time. Table 1 Gomileroi counting system (as quoted in Petocz et al. 1992: 164 after consultation with elders)

Gomileroi words	English translation	
mal	Finger	1
bular	Two fingers	2
guliba	Three fingers	3
bularbular	Two fingers and two fingers	4
mulanbu	Belonging to one hand	5
malmulanbu mummi	One finger and one hand added on	6
bularmulanbu mummi	Two fingers and one hand added on	7
gulibamulanbu mummi	Three fingers and one hand added on	8
bularbularmulanbu mummi	Two and two fingers and one hand added on	9
bulariu murra	Belonging to two hands	10
maldinna mummi	One toe added (to two hands)	11
bulardinna mummi	Two toes added on	12
gulibadinna mummi	Three toes added on	13
bularbulardinna mummi	Two and two toes added on	14
mulanbudinna mummi	One foot added on	15
maldinna mulanbu	One toe and a foot added on	16

M

20 cycles that occur in counting systems and gathered enough data to be able to classify each system. From his study, Lean concluded that the counting and tally systems in Papua New Guinea could have covered a period of thousands of years. Due to the fact that many neighbouring languages have few number words in common, he concludes that there has been little contact. An extreme example of this is two languages Baruya (6,000 speakers) and Yagwoia (5,000 speakers). Baruya is spoken by people who live north of Marawaka in the Eastern Highlands and Yagwoia is spoken to the south. Table 2 gives a few examples of differences (Phythian 1997). Should these two groups meet, they would need to have a good gesture system or concrete materials to come to a mathematical understanding, despite living next to each other. The work of Glendon Lean is collected and available at ▶www.uog.ac.pg/glec/index.htm.

The detailed work in Papua New Guinea contrasts with the work of linguists in the 1800s who recorded Tasmanian aboriginal languages before they (the aboriginals and the languages) died out. Perhaps due to a lack of mathematical awareness they did not record details of the counting systems. Some words for numbers are recorded but not in a systematic fashion. For example, one Tasmanian aboriginal group use the word *karde* for 5 and *karde karde* for 10 (Roth 1899: Appendix B, xi, xvii) but only a few other numbers are recorded. So we have a tantalising suggestion of a base five systems but insufficient evidence to come to a conclusion. This lack of evidence for numbers contrasts with the detailed coverage of words for the male and female genital areas (Roth 1899). I think we can make some conjectures about these Victorian scientists and their cultural proclivities.

In *Hidden in Plain View*, Jacqueline Tobin (1999) records the oral history of several African American quilt makers. They described the meanings and detailed communication that could be passed on by the combination of colours, beads and knots. They could give routes, times, maps and instructions all through quilting. Thus they passed on their African history and made plans to escape from slavery, all under the noses of their masters. The following quote (Tobin 1999: 78) discusses the *lukasa*, the memory boards of the Central African Luba people.

> The use of stitches and knots, as a kind of Morse code in thread, along with fabric colour and quilt patterns, made it possible to design a visual language.
>
> The *lukasa*, or memory board is a mnemonic device used by the highest level of the Luba royal association. The lusaka contains secret mythical, historical, genealogical and medical knowledge. Beads on the front…Engraved geometric patterns on the back…All these serve to recall aspects of Luba history.

There are mathematical implications. The quilts are like computer programs displaying information graphically and can be read by those who understand the code. Fortunately the code in this case has been recorded. It is an example of how mathematical (and other) ideas can be hidden in plain view.

Aboriginal art is another area where mathematics has been overlooked by Western eyes. Michael Cooke (1991) spent 10 years in the Yolngu community in northern Australia and his principal sources were Yolngu teachers. He acknowledges that by taking some of the Yolngu world and fitting it with a Western idea of mathematics, he has lost the full significance of the meanings and some of the intricacy of the Yolngu world. His paper covers many mathematical aspects including how kinship relationships are depicted in song and painting (Cooke 1991: 38).

> For the Yolngu artist, painting is a means of schematising Yolngu world order in a way parallel to the Western mathematical theorist who constructs graphs and diagrams. Just as the Western mathematician seeks elegance, symmetry and aesthetic satisfaction in such work, so does the Yolngu artist. Both rely on extensive use of systems of symbolic representation in their abstract modelling of order…
>
> For the Yolngu it is the system of song cycles which provides the theoretical basis and rationale for the Yolngu system of order and relationship.

There are many other examples of mathematical discourse in cultures without a written language:

- *Finger reckoning*. Hand signals for numbers and number operations are used in many cultures. Examples in Africa are given in Zaslavsky (1973: 239–253) and for Papua New Guinea in Phythian (1997).

Mathematics Communicating Across Culture and Time. Table 2 Examples of Baruya and Yagwoia numbers (Phythian 1997: 66)

Baruya	Yagwoia	
da-`	ungwonangi	1
da-waai	huwlaqu	2
da-waai-da	huwlaqungwa	3
da-waai da-waai	hyaqu-hyaqu	4
at-i	hwolyem pu	5
at-iraai	hwolye kaplaqu	10

- *Weaving or patterns*. Northern Australian aboriginals use painting to illustrate kinship patterns (Cooke 1991; Harris 1987; Harris 1991).
- *Cowrie shells* for currency. Again there are many examples in Zaslavsky 1973.
- *Knotting, quipu of the Incas*. Much has been written on the quipu (such as Asher 1991: 16–27; Smith 1925: 196; Joseph 2000: 28–37) and it remains an important example of how mathematics and mathematical ideas can be communicated effectively without a written language or number system.
- *Classification*. For example, Yolngu Aboriginal culture divides the world into two parts, Yirritja and Dhuwa (Cooke 1991).

All these cultures communicated mathematical ideas without written language. Some of the ideas would have been accessible to all people within the culture, such as the counting systems in Papua New Guinea, and some of the ideas would be restricted to a privileged group, such as the *quipu* makers in South America.

Making meaning from artefacts left to us presents a difficult task. What meaning can a modern observer make of the Tasmanian Aboriginal rock carvings in Figs. 1 and 2? Is this a number system, a pattern of moon phases, a written language? Even the arrangement by the modern artist may influence our ideas. We are using our western-trained minds to classify and order the images to fit with our concepts of logic and pattern. Unfortunately there are no Rosetta stones or living speakers to assist with translation.

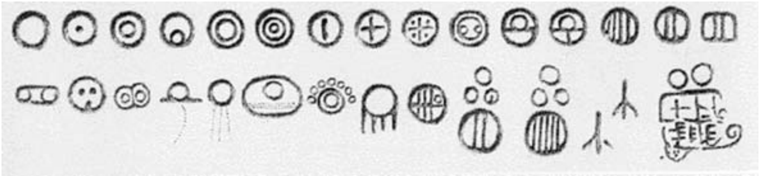
Cultures with Written Language

Making meaning from history involves examining the discourse of cultures from the information that is recorded and passed on. Written forms of mathematical discourse have largely formed the basis of modern mathematics: thus mathematical ideas have communicated across time. However, even with written records there are hazards to successful communication.

It is in part good management and mostly luck that written materials are available to modern readers, even though writers, such as Rashīd al Dīn (1971 translation) in thirteen century Persia went to great lengths to increase the probability that his work would not be lost. He made two complete copies of each work; each was translated into Persian and Arabic. Only the best quality paper and only scribes with the best handwriting were used. Even so, not all of his works exist today, but those that do give an insight into the mathematics in the lives of everyday people of that era. New materials, such as a letter of al-Kāshī on scientific life in Samarkand, described and translated in Bagheri (1997), are being added to our collection of records of mathematics. Translations, for example al Dīn (1971) make original works accessible to readers who are unable to read ancient languages.

Significant communication of mathematical ideas and techniques occurred between cultures in the past. An example of how commentaries and improved algorithms occurred between Arabic and Indian mathematicians is explained in Rashed (1994: 143–148) who showed that al-Bīrūnī (tenth century AD) was aware of

Mathematics Communicating Across Culture and Time. Fig. 2 Tasmanian Aboriginal rock carvings in situ (Clark 1986: 33).



Mathematics Communicating Across Culture and Time. Fig. 1 Symbols used in Tasmanian Aboriginal art (Clark 1986: 32).

Brahmagupta's methods of quadratic interpolation, used for trigonometry and astronomy.

However, as David Malouf (1988) states, much of what really happened is not recorded, and therefore must be inferred in the same way as for cultures with non-written languages. The information that is recorded is filtered through the eyes of the observer, who has his or her own cultural prejudices. Such cultural prejudices have caused criticism of non-European mathematics, in particular with the idea of proof. Modern mathematicians are in considerable conflict about the status and usefulness of proof (Horgan 1993) but some commentators feel free to criticise other cultures for not fitting within their own narrow definition.

Much has been made of the Greek concept of proof as the basis of modern mathematics to the extent that many writers (for example Kline 1972: 190, quoted in Joseph 1994: 194) have disparaged the Indians for their supposed haphazard ideas of proof. But as Joseph (1994) demonstrates, Indian mathematics does prove theorems though not in the same way as Greek deductions from axioms – in fact the Indian demonstrations are very similar to the way proofs are presented to students studying secondary and early tertiary mathematics. A broader idea of proof, such as that advocated by Mason et al. (1985) amongst others would include the demonstrations of Indian and Chinese mathematicians.

Another reason for miscommunication is error of interpretation. We mainly rely on translations of ancient texts. Translations are open to interpretation, compounded by time and cultural differences. Added to this, many translators are not mathematicians and so may miss subtle points which may be critical mathematically. This is not a criticism of translators but a criticism of commentators who do not take these difficulties into account when interpreting discourse over time and culture.

The mistranslation of one word can have critical effects. For example, the mistranslation of the word *asanna* in the translation of an Indian text has led to considerable misrepresentation of Indian mathematics. In verse 10 of the section entitled *Ganitapāda* from Āryabhata's *Āryabhatīya* (AD 499) appears the following: "100 plus 4, multiplied by 8, and added to 62,000: this will be the 'asanna' value of the circumference of a circle of diameter 2000." The Sanskrit word *asanna* has been translated as approximate, inexact, rough, crude and so on. On the basis of this translation, some Western historians of mathematics have concluded that Indian mathematicians did not realise the irrational nature of π.

George Gheverghese Joseph believes that the word *asanna* has a more fruitful meaning. It incorporates two different meanings that overlap with one another: "inexact" and "unattainable". The second meaning which is closer to the idea of irrationality is what Joseph thinks Āryabhata had in mind, and it was an extremely creative concept that gave the motivation to Kerala mathematicians to work on infinite series (Joseph, personal communication).

Reza Hatami, an Arab-speaking scholar working in Sweden, has translated sections of the work of al-Khwārizmī and ʿUmar Khayyām and has found similar difficulties with some of the standard English and Swedish translations (Hatami 1999).

Many translations are written in the modern discourse of mathematics and include use of symbols and algebra. The clarity of the symbolism in use today can cause us to underestimate the difficulties that mathematicians faced in the past. There is a good example of a theorem from Cardano (1545) that shows how mathematical writing has changed in the last 400 years. A comparison of this theorem with its modern equivalent shows how useful symbolic notation can be, and also illustrates the relationship of such notation to ordinary language (Smith 1997: 6). Cardano's intention was to provide a solution to the equation $x^3 + mx = n$, where m and n were implicitly assumed to be positive. However, even the *statement* of the theorem was different to modern language. Renaissance Italians referred to this equation as *a cube plus a first power equal to a number*. Cardano gave the solution as:

> Cube one-third of the coefficient of the unknown; add to it the square of one half the constant of the equation; and take the square root of the whole. You will duplicate this, and to one of the two you add one half the number you have already squared and from the other you subtract one half the same. Then, subtracting the cube root of the first from the cube root of the second, the remainder which is left is the value of the unknown.

Today we would write something like the following:

Theorem. *A solution of the equation* $x^3 + mx = n$ *is given by*

$$x = \sqrt[3]{\frac{n}{2} + \sqrt{\frac{n^2}{4} + \frac{m^3}{27}}} - \sqrt[3]{-\frac{n}{2} + \sqrt{\frac{n^2}{4} + \frac{m^3}{27}}}.$$

These examples show some of the difficulties of interpreting works from other cultures and times. The observer brings his or her knowledge and culture into the equation. I take issue with commentators, such as Kline (1980: 111), who make strident assertions about the mathematics of another culture.

> It is fairly certain that the Hindus did not appreciate the significance of their own contribution. The few good ideas they had, such as separate symbols for the numbers 1–9, the conversion from positional notation in base 60 to base 10, negative numbers, and the recognition

> of 0 as a number, were introduced casually with no apparent realisation that they were valuable innovations. They were not sensitive to mathematical values.

This is based on flimsy evidence and a very narrow view of mathematics. Notice the use of "mathematical values". Whose values? It may be that future commentators claim that strictly holding to the Greek view of deductive proof has seriously curtailed the mathematics of the twentieth century.

A Tenuous Link

> This art originated with Mahomet the son of Moses the Arab (al-Khowarizmi). Leonardo of Pisa (Fibonacci) is a trustworthy source for this statement (Cardano 1545, translation Whitmer 1968).

This is a lovely example of communication. Cardano has acknowledged the originator of his work, al-Khwārizmī, and the conduit of this knowledge, Leonardo Fibonacci.

The work of al-Khwārizmī (*ca*. 780–*ca*. 850), through the channel of *Liber abaci* (1202) by Leonardo Fibonacci became well known in Europe and became the basis of Cardano's work in 1545. This is just one example of how European mathematics was influenced by Arab mathematics, but it also shows how the European mathematicians readily acknowledged the prior work of non-European mathematicians.

Leonardo Fibonacci made considerable contributions to mathematics himself, notably in solving cubic equations, but it is his 1202 *Liber abaci* that was the most influential. Fibonacci travelled widely through Egypt, Syria, Sicily and Greece and came into contact with Arabic mathematics. He was convinced that the Indian–Arabic numerals and methods of calculation were vastly superior to the current methods in Italy (Eves 1983). *Liber abaci* can be considered the main reason why Indian–Arabic numerals and the achievements of Arabic mathematicians spread through Europe by the start of the Renaissance. How much would Cardano and others have achieved without al-Khwārizmī and Indian–Arabic numerals?

Making Meaning

Making meaning from the sources available to us leaves most unsaid and unwritten. Many of the ordinary day-to-day practices of mathematics are not recorded. The mathematical contributions of women, artisans and many workers are not represented. Many records have been lost. Of those discovered, there are risks of mistranslation, misinterpretation, or, in the case of the Tasmanian Aboriginal rock carvings, no basis for interpretation.

It is reasonable to expect difficulties with communication across time and cultures. Even within the same culture, recorders and observers often disagree. However there have been triumphs of communication across time and culture – Fibonacci's *Liber abaci* brought the ideas of algebra and Indian–Arabic numerals to Europe giving an excellent starting point for the work of Cardano and others.

Fibonacci displayed what many commentators have not: he displayed an open mind. Fibonacci was open to the work of other cultures and actively disseminated their ideas. Glendon Lean and Richard Parkhurst are more modern observers who have shown cultural sensitivity as well as keen mathematical knowledge.

As Zeilberger (1993) stated during a lively debate in the American Mathematical Society,

> Although there will always be a small group of "rigorous" old-style mathematicians... who will insist that the true religion is theirs and that the computer is a false Messiah, they may be viewed by future mainstream mathematicians as a fringe sect of harmless eccentrics...

Mathematics itself is not one culture with one discourse. The dominant paradigm in Western mathematics is shifting from Greek deductive proof to a more experimental and applied mathematics and with this comes a new discourse. A reappraisal of the contributions of non-European mathematics under the new paradigm will see a better valuing of their mathematical achievements and consequent changes in forms of mathematical discourse.

Let us look forward to a time when we can appreciate the mathematics of all cultures and the contribution of mathematical ideas to the "business of making accessible the richness of the world we are in, of making dense and substantial our ordinary, day-to-day living in a place – the real work of culture".

Mathematics, Practical and Recreational

Jens Høyrup

The geographical distribution of so-called "recreational" mathematical problems does not respect ideas about distinct mathematical cultures. The familiar conclusion is that they reflect "age-old cultural relations between Eastern and Western civilizations" (Hermelink 1978). This inference is indubitably true but does not exhaust the matter. The reasons that these kinds of problems reflect relations between civilizations that are less visible in other mathematical sources are informative, both regarding the conditions and nature of mathematical activity in different civilizations and about the sense (or nonsense) of the concept of distinct mathematical cultures.

"Recreational problems" are pure in the sense that they do not deal with real applications, however much they speak in the idiom of everyday (some examples will be cited later). Nonetheless, their social basis is in the world of know-how, not that of know-why (the world of "productive," not that of "theoretical" knowledge, in Aristotle's terminology). The distinction between these two orientations of knowledge is of general validity but has particular implications for mathematics.

Beyond this distinction between orientations, it is also useful to distinguish two main ways in which "productive knowledge" can be transmitted. One is through master-apprentice networks and on-the-job training. This type of knowledge, whose results may be labeled "subscientific," is explained later. The other is through institutionalized schools, where training is separated from actual practice and taken care of by teachers whose own connection to the practice for which they prepare is reduced; the outcome may be labeled "scholasticized knowledge."

It is important not to identify practitioners' knowledge (whether subscientific or scholasticized) with practical knowledge alone. The difference has to do precisely with the influence of the social systems which carry the knowledge in question.

The larger part of the practitioners' fund of knowledge is evidently applicable in practice, at least according to the convictions of the social totality within which they function (whether *we* regard the knowledge of seventeenth century physicians as medically useless is irrelevant to the seventeenth century existence and prestige of their profession). As far as this part is concerned, problems – the problems which the craft or profession is supposed to confront – are fundamental, and appropriate techniques have been developed which allow it to deal with these problems. But the training of future practitioners, even when done on the job, will have to start from simpler tasks than those taken care of by the master, in part from tasks which have been prepared with the special purpose of training the techniques which the apprentice should learn but which have no direct practical relevance. Here, techniques and methods are by necessity primary, and problems are secondary, derived from the techniques which are to be trained. Anybody familiar with schoolbooks on arithmetic will recognize the situation, and scholasticized systems are indeed those where problems constructed for training purposes dominate. Apprenticeship-based systems, for their part, tend to train as much as possible on real, albeit simple tasks.

Scholasticized systems often make some use of recreational problems as a means to create variation. However, the genuine basis for the invention and spread of these problems – problems that distort everyday settings so as to create a striking or even absurd situation – is what we can call the subscientific knowledge system. This system is oral in character, while scholasticized systems have always been geared to writing. Recreational problems are riddles for specialists, sharing with other riddles that eristic (given to dispute or argument) character which distinguishes oral cultures in general. Often, when they enter written problem collections or manuals, they contain phrases like "if you are an accomplished calculator, tell me..." – or they are presented as a way to impress the nonspecialists who do not understand. In the premodern world, this type of knowledge was neither "folk" nor "popular," but a possession of the few to a significantly higher degree than scientific knowledge today.

Phrases of this kind indicate how we are to understand the function of the "recreational" problems, which were not primarily recreational (whence the quotes) – no more recreational, indeed, than the potentially lethal riddle of the sphinx. They served as a means to display virtuosity, and thus, on one hand, to demonstrate the status of the profession as a whole as consisting of expert specialist, and, on the other, to let the single members of the profession stand out, and discover themselves, as accomplished calculators, surveyors, etc.

This function puts some constraints on the problems, which explains their character. They must arouse immediate interest, which explains the "recreational surface": if a camel is to transport grain from one place to another, being able to carry only one third of the grain in one turn, and seems as a consequence to devour exactly everything in the process, then the expert solution allowing a net transfer is impressive. A less striking formulation might provoke the reaction "so what?" The problems, furthermore, must appear to belong to the domain of the profession – skill in singing does not enhance the professional prestige of an accountant, since it does not demonstrate professional valor; according to their form, the problems have to be practical. But they must also be more difficult than the tasks that any average bungler in the profession performs without difficulty. This, together with the quest for the striking or absurd, is the reason that the problems are pure in substance, i.e., separated from real practice – and more truly so than the simplified problems of school teaching.

Like school problems, however, recreational problems are determined from methods, namely from the characteristic methods of the profession. Often they come from a peculiar trick (in the case of the camel, an intermediate stop and return) that will be known within the subculture of the profession but not outside.

Such tricks will often not be generalizable; moreover, as several mathematicians from the Islamic Middle Ages tell, the practitioners using them would often be ignorant of why their tricks worked. The purpose of posing and solving the problems is not to provide insight but to show off. The pure level of knowledge is thus neither a direct nor an indirect underpinning of practice, nor is it a critical reflection on the principles underlying practice. In this respect, it differs fundamentally from what Aristotle and al-Fārābī would speak of as theoretical knowledge and from what we call scientific knowledge.

But there is another point in the term "subscientific", namely that all levels of the subscientific knowledge system, the pure or recreational no less than the applied, have served as inspiration in the development of scientific mathematics. This process can be followed in the Greco-Islamic area (and its European offspring), in India, and in China; Japanese *wasan* may even offer an instance of direct transformation of a subscientific into a scientific system.

In the Greco-Islamic-premodern-European area (the most sensible delimitation of "Western" culture if the long historical run is considered), in contrast, the theoretical knowledge system may have been socially segregated from the subscientific systems to an extent which in other cultural areas was reserved for different domains, as courtly music in Japan, or poetry as bound up with the writing system in China. While the distinction between different orientations of knowledge systems and the effect of scholastization versus apprenticeship learning hold in general, the social segregation and the high social prestige falling to philosophical and scientific knowledge in this broadly defined Western culture have tended to make the rupture between scientific and practitioners' mathematics more visible than elsewhere and to hide the whole subscientific complex from view. Another reason for its invisibility in the contemporary European orbit is evidently that the originally autonomous subscientific traditions were displaced from the late Renaissance onwards by methods that were ultimately derived from scientific mathematics. Increasingly since the late nineteenth century, this process has occurred globally.

Few sources survive that tell how practical computation was performed in former times, in particular by practitioners not trained from school books. Moreover, most practical computations and geometrical constructions have relied on such simple techniques that questions of diffusion versus independent invention cannot be decided; this simplicity is precisely the reason that they could not serve as a basis for professional self-esteem. Even "wrong" formulae can be so intuitively near at hand that independent invention demonstrably happens time and again. For instance, Isabel Soto Cornejos observed when teaching illiterate peasants in Chile during the Allende era that they reinvented the "surveyors' formula" for approximately rectangular areas (average length × average width) spontaneously after having been taught how to calculate the area of true rectangles. Only problems that are complex enough to serve as display are by the very fact also so characteristic that they may function as index fossils. This is why the recreational problems are crucial for the understanding of the subscientific knowledge system and its relations to the scholasticized and scientific systems.

Often the recreational problems go together in clusters which, although some exchange takes place, are relatively closed. As an example we may look at a cluster – better documented than most others – which appears to be connected to communities of merchants interacting either along the Silk Road trading network or in the sea trade between China, India, the Near East, and the Mediterranean but which certainly also had an impact on local communities of accountants and calculators (whatever their social status and organization) wherever they were in contact with the merchants' communities.

One favorite problem from this cluster was the doubling of unity, repeated either 30 or 64 times and ending by a summation. The first occurrence is in a text from Mari (Northern Babylonia) from the eighteenth century BCE. Then it turns up in a papyrus from Roman Egypt, and next in a Carolingian problem collection (*Propositiones ad acuendos iuvenes*) based on material which had circulated since late antiquity in the Gallic region – all of these instances deal with 30 doublings. In the early ninth century, al-Khwārizmī wrote a treatise on the other (chessboard) variant, which appears to have passed via India, even though actual Indian attestations are later. In the following centuries, both versions are found in India, in the Islamic world, and from around 1200 even in Latin Europe.

Another problem from the cluster that was highly popular in the Islamic and European Middle Ages was the "purchase of a horse": three men go to the market in order to buy a horse. The first says that if he may have half the money belonging to the others he will be able to buy the horse; the second needs only one third, and the third only one fourth (the number of purchasers and the fractions may vary, but invariably they exhibit a striking pattern). Sometimes the price of the horse is told; sometimes the problem is left indeterminate and thus is not only striking but outright absurd (in the present case, any multiple of the set [10,22,26] will do for an answer). The earliest Western source to state the problem (without the equestrian dress) is Diophantos' *Arithmetic*; slightly earlier is an occurrence with a different dress in the Chinese *Shushu jiuzhang* (Nine Chapters on the Arithmetic Art, first century AD). A passage in Book I of Plato's *Republic*, however, reveals that the problem could be expected to be familiar for the Athenian public of the fourth (and probably the fifth) century BCE ("buying a horse collectively" is said to be a situation where one needs an expert).

A third problem from the cluster is "the hundred fowls": Somebody is to buy 100 fowls for 100 monetary units, given that (e.g.,) a rooster costs 5 units, and a hen 3, while chicks are sold 3 for 1 unit. It occurs in a Chinese fifth century source, as well as the Carolingian *Propositiones*, and Abū Kāmil describes it as widespread in his environment among people who do not understand the mathematical principles involved but just give one answer without adequate reasoning. A variant has been located by Jean Christianides in a Greco-Egyptian papyrus.

It is thus true that the distribution of these (and other) problems from the cluster bear witness of "age-old cultural relations between…Civilizations" (in Hermelink's words as quoted initially). It is no less true, however, that they highlight the absence of cultural relations at other levels. The *Nine Chapters* as well as Plato's remark and the reflections of the subscientific corpus in Diophantos' *Arithmetic* demonstrate that the literate cultures of China and of the Mediterranean world (to take these as the paradigm) knew about the anonymous tradition, and would take over appropriate material without credit. The wholly different methods applied by the Chinese mathematicians and by Diophantos to solve the same problems also show that what they took over was inspiration, in particular problems, and not full mathematical structures. The high cultures did not really communicate with the low oral culture (no more in mathematics than in other cultural domains); they drew on them and exploited them. Nor did they communicate with each other through the low cultures. Moreover, what happened at the level of oral culture may not be adequately described as cultural relations. The very possibility of distinguishing particular clusters shows that even oral cultures had their sharp boundaries across which only limited communication took place. But these boundaries did not coincide with the geographical boundaries between high cultures, and only in part were they at all geographical in nature. It was, so it seems, a common subscientific merchants' culture which inspired the Chinese and the Alexandrian mathematicians, and which thereby creates the illusion of general cultural relations (similarly, jugglers might move between China and ancient Rome; neither Roman nor Chinese gentlemen ever did).

The cluster just used as an example belonged with a calculators' and caravan merchants' culture. A cluster dealt with elsewhere in this volume, surveyors' "algebra", was carried by practical geometers from the Syro-Irano-Iraqi region. Even in this case, just enough evidence from the Greco-Roman world has survived to show directly that the tradition was known (one Greek papyrus, a problem in one agrimensor [surveyor] treatise). Indirect evidence shows that Diophantos drew inspiration even from this source, and that Book II of Euclid's *Elements* is closely connected to the tradition. For the present argument, however, the relation between surveyors' algebra and Babylonian scribe school algebra is more important, as an unusually articulate instance of the relation between subscientific and scholasticized mathematics.

According to what can be concluded from combination of the evidence presented by the various written traditions that it inspired, the stock of quasialgebraic recreational which problems that were current among the practical geometers of the region was quite restricted:

- to find the side of a square when the area; the diagonal; the sum of the area and the side; or the sum of the area and all four sides was known;
- to find the sides of a rectangle when the sum of its sides was known together with the area or the area augmented by the difference between the sides;
- when the difference between the sides together with the area or the area augmented by both or by all four sides; or
- when the diagonal together with the sum of or difference between the sides.

Each problem type was presented by only one or at most two examples, which would permit even those who did not understand to learn them by heart, and everything concerns the entities really present in the geometrical configuration – *the* area, not some multiple; the side, or the sides; etc. From indirect evidence, we may assume that the diagonal of the 10 × 10 square was taken to be 14.

The technique was taken over by the Old Babylonian scribe school and developed into its central discipline – a quasialgebra based on geometric cut-and-paste procedures. It still appears to have served professional self-esteem on the part of the scribes. But becoming a discipline (etymologically: a subject which is to be learned) it was systematized. We find texts which vary the coefficients of both the area and the sides systematically, others which replace the length of a rectangle with the product of the length and the ratio between length and width, and the width with the product of the width and the ratio between width and length (formally the outcome is a problem of the sixth degree; the solution combines a second-degree and a homogeneous third-degree equation, that is, well-known stuff), and still others where the geometrical entities represent prices in artificial commercial problems. Mathematical irregularities like the diagonal of 14 have been eliminated.

Beyond professional pride, this systematically drilled technique served the purpose of normal school mathematics: through the introduction of coefficients and other complications, the discipline could function as a training ground for the use of the sexagesimal place value system, which was fundamental for the daily engineering and accounting practice of scribes (while all second-degree problems were completely artificial and pure). On the same occasion, the problems lost most of their recreational character.

But the introduction of systematic drills and the elimination of mathematical irregularities were not the only changes. The sixth-degree problems, however much they constitute a trivial extension, and the use of the geometrical technique as a representation of nongeometrical entities, have to be understood as systematic attempts to test the carrying capacity of the professional tools, including the trick of the quadratic completion that was the basis even of the surveyors' algebra. The outcome may be claimed to be really an algebra, while the "surveyors' algebra" was not – an algebra being understood as the application of a functionally abstract standard representation (in terms of *x* and *y,* Greek *arithmós,* or Arabic *šay*' [thing] and *māl* [possession]) in the analysis of complex relationships involving entities of any kind. If the scribe school had possessed the intellectual drive for that, a transformation into scientific mathematics might have occurred, as it appears to have occurred in the case of *wasan,* and as it occurred – but then in interaction with already-present scientific mathematics – in the Islamic Middle Ages.

Lest anybody believe that the process of scholastization, with all its tediously repetitive drills, should be a characteristic of non-Western civilizations (or of some of them), one may point out that it reached a high point in the Humanist schools of the Renaissance and Early Modern period – the very cradle of the Western ideology.

Mathematics in Africa South of the Sahara

Paulus Gerdes

Most books on the history of mathematics devote only a few pages to Africa, and even then only to Ancient Egypt and to northern Africa during the Middle Ages. Generally they ignore the existence of mathematics in Africa south of the Sahara. They often deny that Egyptian mathematics is African. With the publication of Claudia Zaslavsky's *Africa Counts: Number and Pattern in African Culture* in 1973 this dominant Eurocentric view of the history of mathematics in Africa became challenged. When one uses a broad definition of mathematics – including counting, locating, measuring, designing, playing, explaining, classifying, sorting, etc. – it becomes clear that mathematics is a pan-cultural phenomenon manifesting itself in many ways. In African history, we have evidence of counting and numeration systems, games and puzzles, geometry, graphs, record-keeping, money, weights, and measures, etc. Mathematics in Africa may not be considered in isolation either from the development of culture and economy in general, or from the evolution of art, cosmology, education, philosophy, natural sciences, medicine, logic and language, graphic systems, and technology in particular. The application of historical and ethnomathematical research methods in recent years has contributed to a better knowledge and understanding of the history of mathematics in Africa.

In this article evidence for early mathematical activity in Africa will be given, followed by examples from geometry, games, riddles, and puzzles with mathematical "ingredients." Some topics for future research will be indicated and some comments about the development of mathematics south of the Sahara and in other regions, in particular northern Africa, will be presented.

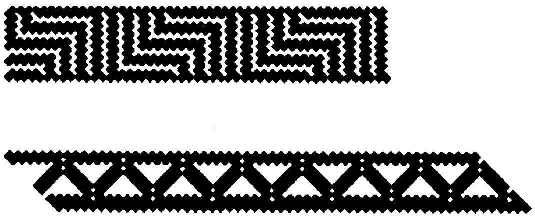
A small piece of the fibula of a baboon, marked with 29 clearly defined notches, may be one of the oldest mathematical artifacts known in the world. Discovered in the early seventies during an excavation of a cave in the Lebombo Mountains between South Africa and Swaziland, the bone has been dated to approximately 35,000 BCE. This bone resembles calendar sticks still in use today by the San (Bushmen) in Namibia. The San hunters developed very good visual discrimination and visual memory for survival in the harsh environment of the Kalahari desert. From the San in Botswana, information has been collected on their counting, measurement, time-reckoning, classification, and tracking. Well known as early evidence for mathematical activity in Africa is a bone now dated from about 8000 BCE to 20,000 BCE, dug up at Ishango (Zaire). The bone has what appear to be tallying marks on it, notches carved in groups that have been explained as early lunar phase count or as an arithmetical game of some sort.

Georges Njock has characterized the relationship between African art and mathematics as follows: "Pure mathematics is the art of creating and imagining. In this sense black art is mathematics."

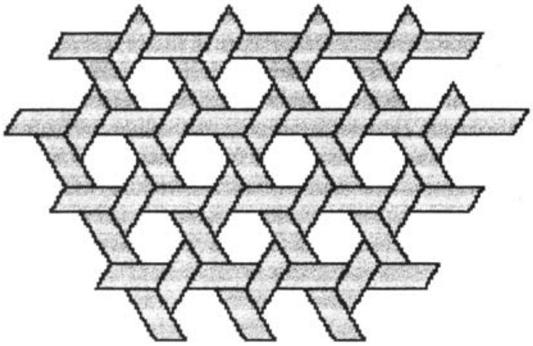
Mathematicians have primarily analyzed symmetries in African art. Symmetries of repeated patterns may be classified on the basis of the 24 different possible types of patterns which can be used to cover a plane surface (these are the 24 plane groups attributed to Federov). Of these, seven admit translations in only one direction and are called strip patterns. This classification has been applied to decorative patterns that appear on the raffia pile cloths of the Bakuba (Zaire), on Benin bronzes, and on Yoruba adire cloths (Nigeria), showing that all seven strip patterns and many of the plane patterns occur. The use of group theory in the analysis of symmetries in African art attests to and underlines the creative imagination of the artists and artisans involved and their capacity for abstraction. These studies do not focus, however, on how and why the artists and artisans themselves classify and analyze their symmetries. This is a field open for further research.

Why do symmetries appear in human culture in general, and in African craftwork and art, in particular? Paulus Gerdes analyzed the origin of axial, double axial, and rotational symmetry in African basketry. He showed how six and fivefold symmetry emerged quite naturally when artisans were solving some problems in (basket) weaving (see Figs. 1 and 2).

Beehive, conical, cylindrical, and rectangular shapes are common in African architecture. In West Africa the mathematician-scholar and the architectural designer–builder was often the same person. An example of geometrical know-how used in laying out the rectangular house plans in Mozambique is the following. Two ropes of equal length are tied together at their midpoints.



Mathematics in Africa South of the Sahara. Fig. 1 Two examples of woven strip patterns on baskets (Mozambique).



Mathematics in Africa South of the Sahara. Fig. 2 Hexagonal weaving pattern (Congo, Kenya, Madagascar, Mozambique).

A bamboo stick, whose length is equal to the desired breadth of the house, is laid down on the floor, and at its endpoints pins are hit into the ground. An endpoint of each of the ropes is tied to one of the pins. Then the ropes are stretched and at the remaining two endpoints of the ropes, new pins are hit into the ground. These four pins determine the four vertices of the house to be built.

The geometric shapes of pots, baskets, fishtraps, houses, etc. generally represent many practical advantages and are frequently the only possible or the optimal solutions of a production problem. Some scholarly research has been undertaken concerning knowledge about the properties and relations of circles, angles, rectangles, squares, regular pentagons and hexagons, cones, pyramids, cylinders, symmetry, etc. probably involved in the invention of the techniques (Gerdes 1992a,b). Themes for further research are the geometry of string figures, the geometry of settlement patterns in Africa, and the geometry involved in the ornamentation of the walls of buildings all over Africa (e.g., the attractive colorful patterns of the Ndebele in South Africa and the *litema* patterns drawn by Basotho women in Lesotho) (Fig. 3).

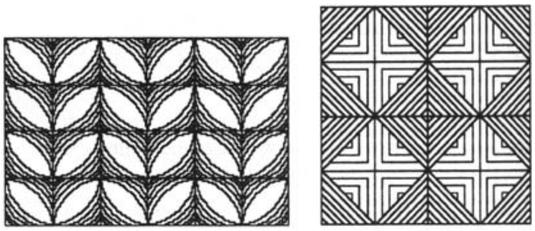
Games

Among the games with mathematical ingredients are counting rhymes and rhythms, arrangements, three-in-a-row-games like *Shisima* (Kenya), *Achi* (Ghana), *Murabaraba* (Lesotho), *Muravarava* (Mozambique), and games of chance. Board games like Mancala games, both two-row versions such as *Oware* (Ghana), *Awélé* (Côte d'Ivoire), *Ayo* and *Okwe* (Nigeria), and four-row versions such as *Omweso* (Uganda), *Tshisolo* (Zaire), and *Ntchuva* (Mozambique) also exhibit use of mathematical knowledge.

Recent research in Côte d'Ivoire showed that the rules of some games, like *Nigbé Alladian*, reveal a traditional and empirical knowledge of probabilities.

Riddles and Puzzles

From the Kpelle (Liberia) a riddle has been reported about a man who has a leopard, a goat, and a pile of cassava leaves to be transported across a river, whereby



Mathematics in Africa South of the Sahara. Fig. 3 Examples of *litema* wall patterns (Lesotho).

M

certain conditions have to be satisfied: the boat can carry no more than one at a time, besides the man himself; the goat cannot be left alone with the leopard, and the goat will eat the cassava leaves if it is not guarded. How can he take them across the river? This type of problem is also known from Ethiopia, Liberia, Tanzania, Uganda, and Zambia. More difficult to solve is the following puzzle from the Valuchazi (eastern Angola and northwestern Zambia) about three women and three men who want to cross a river in order to attend a dance on the other side. With the river between them there is a boat with the capacity for taking only two people at one time. However, each of the men wishes to be the only husband of all the three women. Regarding the crossing, they would like to cross in pairs, each man with his female partner, but failing that any of the other men could claim all the women for himself. How can they cross? In order to solve the problem or to explain the solution, the Valuchazi make auxiliary drawings in the sand.

The relationships between the development of mathematics in Africa south of the Sahara and the development of mathematics in Ancient Egypt, in both Hellenistic and Islamic northern Africa, and across the Indian and Atlantic Oceans, deserve further study.

Throughout history there have been many and varied contacts between Africa south of the Sahara and North Africa. Since the birth and spread of Islam, relations have been intensified and/or extended. *ᶜIlm al-isāb* (arithmetic), as part of the Islamic sciences was introduced some time after the eleventh century in Nigeria, first in Kanem–Borno and later, probably in the fifteenth century in Hausaland. Arithmetic was taught in both secular and Islamiyya schools, was used in the courts for the calculation of inheritance, and for collecting and distributing poor dues, business, and land surveying. A famous mathematician was Muammed ibn Muammed from Katsina (now northern Nigeria), who worked on chronograms and magic squares. He had been a pupil of Muammed Alwali of Bagirmi. He made a pilgrimage to Mecca in 1730, and he died in Cairo in 1741. Recently a manuscript of his was found in Marrakesh, Morocco. Magic squares were used in amulets among the Fulbe, and in Niger, Benin and Timbuktu (Mali). Formal logic was one of the fields of study in the economic and educational-scientific centre of Timbuktu, where recently three Arabic mathematical manuscripts were found in the Amad Baba Library. One of the three manuscripts, whose calligraphy is typical for Africa south of the Sahara, seems to have been written by a mathematician from Mali, al-Arwani. The other two contain references to medieval mathematicians from the Maghreb. Systematic research in libraries and archives will probably lead to the discovery of more mathematical manuscripts from Muslim scholars south of the Sahara.

What mathematics was brought to the Americas by the slaves? Which mathematical ideas have survived in one way or another? Mancala, and maybe other games with mathematical components, are played in the Caribbean and may be compared with their African "ancestors." In Africa the slave trade was extremely destructive of the existing mathematical traditions. This is because of breaking professional continuity and depriving Africa of bearers of mathematical knowledge and skills such as that of the drawing experts from Angola and Zambia and that of calculators like Thomas Fuller (1719–1790). Recent ethnomathematical research in Nigeria and Mozambique shows the survival, nonetheless, of a rich tradition of mental calculations among illiterate people.

The destructive impact of colonialism and the slave trade on Africa is one of the principal reasons Georges Njock gives to explain why mathematics in Africa has had a slower development in the last five centuries than in Europe. Other reasons he gives deal with the geography of the continent (migratory movement) and wars. This also constitutes an important research area that deserves further study.

Mathematics in Africa: West African Games

Salimata Doumbia

Exploring the sociocultural environment of Africa is an interesting way of learning about concrete mathematics. Games, always a popular childhood activity, should be studied with care in as much as they are a reflection of the society and its fundamental values. Today we are witnessing the introduction of “educational games” to the African continent, as if African games did not exist. In this article, we will describe several African games and the mathematics behind them.

Exhibition Games

In Africa there are games which have hidden underlying algorithms. The person who knows the algorithm is assured of winning, which makes him a “magician” or “sorcerer” to those who do not know it. The “sorcerer” often chants incantations or performs other magic tricks to show his power. We will study two of these games.

a. *The game of the sorcerer.* The game of the sorcerer is very old. Sorcerers perform it to demonstrate their supernatural powers. Forms of the game are played throughout Africa – in Senegal (Game of the Devil), in the bend of the Niger River (the Sorcerer’s Apprentice), in the Ivory Coast (*Lokoto*), and in Mali (*Gamma*) (Fig. 1)

There are two players: the sorcerer and his victim. The game is played on a board of 12 compartments set up in two rows of 6 and 48 beads.

Before beginning play, the players place four beads in each compartment. The sorcerer and the victim each take two stones from 11 compartments. From the 12th, the sorcerer takes three beads, the victim one (the sorcerer thus has two extra beads). He must now “magically” pass the two extra beads to the victim. He rubs the beads, chants incantations, blows on his thumbs, and then instructs the victim to fill the compartments with four beads each as he does the same. When the beads are redistributed, three beads are left in the victim’s hand, one in the sorcerer’s, and the trick is done.

If we analyze the mathematical aspects of the game, we see that it has two parts:

1. The taking of the stones (beads)
   The sorcerer: $2 \times 11 + 3 = 25$
   The victim: $2 \times 11 + 1 = 23$
2. The replacing of the stones
   Each player must put four beads in each of the compartments, filling as many as he can with the beads in his hand.
   The sorcerer: $25 = 4 \times 6 + 1$
   The victim: $23 = 4 \times 5 + 3$

After redistributing the beads, the victim has three beads in his hand and the sorcerer, one. The game works whenever the number of compartments is even.

b. *The game of the unknown stone.* The player asks a spectator to select in his mind one of 16 different stones. The player must discover the unknown, selected stone. First, he arranges the stones in two rows of eight. Then he asks the spectator to indicate the row that the unknown stone is in. Mentally the player makes two groups of four stones each from the stones in the indicated row. He rearranges them (or distributes each group on different lines) and asks the spectator again to indicate which row has the unknown stone. Upon the indication of the row he makes two groups of two stones each from one of the groups of four stones. Then he rearranges them again.

Again, the spectator indicates the row with the unknown stone. The player then redistributes the only two stones left, which could possibly be the unknown stone, into two different rows. The spectator again indicates the row with the unknown stone. Having identified the stone, the

M

player then collects all the stones together, mixes them up, pulls out the “unknown” stone, and the game is over.

The mathematics of this game shows that the player must divide the stones into two rows in order to locate the unknown stone.

$16 = 2^4$ where 4 is the number of times that the player must divide the 16 stones, two being the number of rows. More generally, if n is the total number of stones, and k is the number of times the player must divide the stones into two rows, then the following equation holds true: $n = 2^k$. Inversely, if one knows n, one can calculate k from the formula $k = \log_2 n$.

Games of Chance

Men have always played games of chance. In Africa, there are many situations in which chance is called into play: when one needs to make a hard choice (heads or tails, the short straw), or when one needs to be sure of winning. Games of chance are based on theories of probability.

The cowrie is a sea shell with two sides: a front and a back. In Africa, cowries were considered rare and valuable, and so played an important role in African life. Its form, similar to an aura according to the mystics, makes it an instrument of divination. Cowries also play a role in initiations, funerals, and engagements, and in certain regions of Africa, they were – and still are – used as a medium of exchange.

All the cowrie games are collective games. The number of players is two or more. The principle of the game is simple. Two players (or two representatives of two teams) throw the cowries at the same time. The cowries fall on the ground, landing on one of two sides. There are usually four shells. The configurations formed by the cowries are examined so that the results can be read. The results are interpreted according to pre-established rules: heads is given a +; tails is given a –.

Thus, when the four stones are thrown, there are five possible configurations:

Heads (+)	**Tails (–)**			
+ + + +	– – – –	10 points	– – – –	win
+ + + –	+ + + +	5 points	+ + + +	win
+ + – –	+ + – –	2 points	+ + – –	win
+ – – –	+ + + –	0 points	+ + + –	lose
– – – –	+ – – –	0 points	+ – – –	lose
Configurations	Example 1		Example 2	

The calculation of points varies. There are two ways to compute points, either numerically (Example 1) or not (Example 2). Generally, if points are calculated numerically, the winner is declared when a player reaches a certain total number of points, that number being fixed before play begins.

Word Games and Traditional Learning in Africa

In many African countries, traditional learning is oral. Information and wisdom are transmitted from generation to generation in the form of proverbs, stories, chants, riddles, and games. This provides real lessons in language, history, geography, natural science, arithmetic, measurement, cosmography, etc. Teaching is seen as the natural and traditional way of communicating the secrets of the adult world to a child. Following are some examples of counting games.

Cumulative Chants

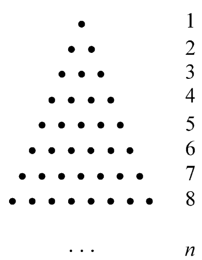
Memory Games: The Yé Gonan. The Yé Gonan is a children’s game from the Ivory Coast. There are two players, one who asks questions and one who answers. The players use eight stones and eight holes dug in a line in the sand, each one containing a stone. The player who is answering looks at the game and makes himself/herself acquainted with the rules. One of the rules is to retain correctly the sense of the course imposed by the questioning player. Then the answering player turns his back on the game. For each turn, the questioner taps on the hole and always asks the same question: “Am I taking a stone?” The answerer, who has his back to the game, can only answer “Yes” or “No, it’s empty.” Each time that he has taken a stone, the questioner comes back to the first hole. The answerer who reaches the eighth hole without making a mistake, wins the game. The players then change roles (Fig. 2).

The mathematical problem posed by the game is the following: when the questioner is at hole number n, which contains a stone, which is the total number Z_n of questions posed from the beginning of the game to the taking of that stone?

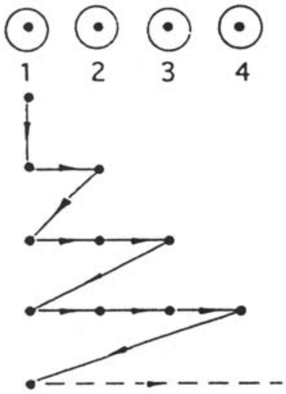
The answer is $Z_n = n(n+1)/2$.

It is a triangular number. For $n = 8$, one finds that: $Z_8 = 9 \times 8/2 = 36 = 6^2$. The number Z_8 is therefore a squared number: it is the smallest number that is, at the same time, both triangular and squared. The Pythagorean tradition considered the number $n(n + 1)/2$ as a secret value. It is interesting to find this same representation in the Pythagorean tradition both among the moors in Mauritania and the Wolofs in Senegal.

$Z_1 = 1$
$Z_2 = Z_1 + 2 = 1 + 2$
$Z_3 = Z_2 + 3 = 1 + 2 + 3$



$$Z_n = Z_{n-1} + n = 1 + 2 + \cdots + (n-1) + n$$



Mathematics in Africa: West African Games. Fig. 2 Cumulative chants diagram.

Riddle problems. In The Vultures, a shepherd, spending the night under a baobab tree, heard an old vulture pose the following riddle to some children: "There are 33 baobab trees; on each baobab there are 33 vultures; each vulture had laid 33 eggs; each egg yields 33 chicks; and each chick has 33 barbed feathers – How many barbed feathers are there altogether?" The shepherd, wanting to answer, fell dead. This is why, they say, the Fulani do not want to answer.

The solution to the problem lies in the calculation of powers. There are 33^6 vultures: $33^6 = 1{,}291{,}467{,}969$.

Magic squares. The Fulani are familiar with simple magic squares. They appear drawn with Arabic numerals as amulets. They are also used as a kind of game. Someone who knows the magic square proposes it to a group of people who then try to figure it out by putting stones, pebbles, or pieces of dung in a square drawn on the ground.

2	9	4
7	5	3
6	1	8

Saturn square (sum = 15).

21	26	19
20	22	24
25	18	23

Number of Allah (sum = 66).

23134	23137	23143	23127
23142	23128	23133	23138
23129	23145	23135	23132
23136	23131	23130	23144

The Four Angles (sum = 92541).

In a magic square, the sum of the numbers in each line, horizontal, vertical or diagonal, is the same. The number of Allah is 5 + 30 + 30 + 1 = 66. In the Square of Saturn, the total is 15, and in the Four Angels, the total is 92,541. Magic squares are well known in Muslim countries, as they are in China and Japan.

Mathematics and Astronomies of the Ancient Berbers

José Barrios García

Northwest Africa is an immense territory extending from the Mediterranean shores to the Niger River and from Libya to the Canary Islands. It is here where Berber culture began to develop about 10,000 years ago, and where it has continued to develop until the present.

Despite the antiquity and widespread diffusion of Berber culture, North African studies have traditionally understated its contribution to human history. Camps (1980) aptly summarized the situation in the title of his book: *Berbères: aux marges de l'Histoire* (Berbers: On the Margins of History). Although the overall situation has improved in the last decades thanks to the efforts of a new generation of scholars – one main outcome being the ongoing publication of the *Encyclopédie Berbère*, of which 27 volumes have already appeared – actual research on the mathematics and astronomies of the ancient Berbers remains scarce.

A faithful exposition of the situation must take into account two main areas of research, each one of them with its own scope, achievements and methodological problems: continental Berbers on the one hand, and Canary Islands Berbers on the other. While both areas are certainly unbalanced from many points of views, for our purposes they complement one another.

Continental studies are part of the ethnographic fieldwork performed in the nineteenth to twentieth centuries by European researchers, so they mainly provide information on modern Berbers. Most of these notices are related to astronomy through religion, calendar, and folklore, while those few dealing with mathematics mainly focus on numeral systems and their grammar. While some of the reported traditions are important and thought-provoking, little has been said on the technical aspects underlying them, nor on their supposed origin and extent. Besides that, some preliminary work has also been done on the astral aspects of the religion of the ancient Berbers, as well as on the astronomical orientation of a few archaeological sites.

Canarian studies deal with the Berber populations inhabiting the archipelago before the Spanish conquest of the Islands on the late fifteenth century. They mainly draw on a collection of written sources originating with the European rediscovery of the Islands in the early fourteenth century, complemented with archaeological, ethnographic, and linguistic data. Since written sources mostly apply to Grand Canary and Tenerife in the fourteenth to fifteenth century, I must restrict the evidence to both islands and this period of time.

Numeral Systems

Our knowledge of ancient Berber numerals comes from different sources, and all of them point to a pure 10-base system. The three oldest numeral lists are from the Canary Islands and are summarized in Table 1. The first one appears in a letter describing a Portuguese expedition to the islands in 1341, and seems to have been first studied by Costa de Macedo (1841). The second one appears in a play written in 1582. The third one appears in a chronicle of the conquest of Grand Canary preserved in a very problematic manuscript from 1682–1687; it is most probably a late compilation that dislocates the original list by erroneously introducing two Arabian numerals (*arba* and *canza*) and false forms for the tens.

Continental lists are considerably younger than the Canarian ones. The first one I can document was made by Domingo Badía in 1804 near Marrakech, and published under a pseudonym in Abassi (1814).

Generally speaking, the continental data show that the intense Arabisation process suffered by continental Berber speaking groups from the seventh century on led to three types of situations, summarized in Table 2:

a. Certain groups preserved a purely Berber numeral system (Tuaregs, Mzabits, etc.).
b. Certain groups completely lost the Berber numeral system, and counted with some dialectal variant of the Arab system.
c. Certain groups preserved the Berber numerals until a certain point and after that they counted with some dialectal variant of the Arab system. Among them were Kabylians (counting in Berber up to two) and Shilhs (counting in Berber up to nineteen).

Prasse (1974) undertook the reconstruction of the proto-Berber language. A comparison of his reconstruction with other relevant members of the Afro-Asiatic family can be seen in Table 3.

Astronomy, Calendars and Social Organization

The fieldwork of nineteenth to twentieth century ethnographers shows that northwest African peasants actually used several concurrent calendars. While the Julian calendar was the most used for agricultural purposes and the Hegira was mainly used in religious circumstances, the Gregorian calendar served to interact with administration and modern life, and was a common reference between the different systems.

Since these three calendars are non-Berber in origin and a summary of their local characteristics can be seen in EB–Gast–Delheure (1992), it is only necessary here to make a brief remark on their respective dates of introduction. Certainly, the Hegira was introduced after the Arab invasion in the seventh century and the Gregorian calendar after its inception in 1582, but there are good reasons to think that the Julian calendar is not a remnant of Roman domination, as is usually said. It seems to have been introduced by Coptic communities well after the Arab invasion and before the adoption of the Gregorian calendar (Servier 1985).

Besides the three mentioned calendars, a less evident but more profound and extensive astronomical tradition has been posed by two different and exhaustive studies carried out in the middle twentieth century by the French ethnologists Jean Servier and Viviana Pâques.

The Doors of the Year

Jean Servier travelled in North Algeria from 1949 to 1961 compiling information about the traditional thinking of Berber speaking peasants. His work (Servier 1962, 1985) describes a complex symbolic world superposed on an apparently simple material culture. He found that northern Algerian peasants mix a visible world with an invisible world. The invisible world would be related to their ancestors and the rhythms of nature as marked by the *tibburin ussegwass* (doors of the year). The doors of the year are the solstices and the equinoxes. In his opinion, this was part of an ancient system, which has disappeared in other parts of the circum-Mediterranean area, but is well preserved by traditional Berber peasants.

Canopus and the Cosmic Tree

From 1953 on Viviana Pâques researched in Fezzan, Sahara, Mali, Algeria and Tunis. She studied the spiritual world which enslaved Black people would have brought with them into these lands. Her results were presented in Pâques (1964). To her surprise, what she found was a conception of the world common to all peoples of North and West Africa, a conception as characteristic for an anthropologist as a typical biface would be for an archaeologist (Pâques 1964: 10).

Everywhere she found one or another variant of the following cosmogony:

1. God created the world by exploding Canopus, the primeval star. From Canopus exited the triple serpent it held in its matrix, which commands all divisions of the world by three. The explosion of Canopus gave birth to six other stars, which command all divisions of the world by seven.
2. The world turned back when a hero (sometimes a smith) decapitated the serpent, which was the prelude to all circumcisions.
3. The hero descended to the Earth through the triple cosmic tree formed by the body of the decapitated serpent.
4. The hero ascended the cosmic tree later, on the occasion of a second sacrifice of the serpent, which was the prelude to all marriages.
5. These mystic events occurred at a determinate point of the sky, at a moment when the sun was in a particular relation with Canopus, for the explosion, and with the Pleiades for the sacrifices. (On the planets' layout, the Pleiades are assimilated with Venus).

This myth defined the rules that organise every aspect of traditional North and West African life. From political, territorial and social structures to the division and rhythms of the heavenly movements, from the division of the agricultural year by means of certain constellations, to the design of clothes, shoes, coiffures and everything that could reflect this system in daily life.

The myth is deeply associated with three colours – white, red and black – respectively related to the triple serpent inside Canopus. Number 3 (and 60-based counts) is associated with women, while 4 (and 80-based counts) are associated with men. Number 7 (=3 + 4) represents the union of a man and a woman.

As to the origin of this African cosmogony, different opinions have been posed, ranging from a Mediterranean to an Oriental or Indian one. Nevertheless, the internal coherence, originality and distribution map of this myth make Pâques suggest that it originated at a very ancient date in some agricultural community living in a subdesert territory, perhaps around some of the Saharan oases where these conceptions are most fully preserved (Pâques 1964: 676).

What can be said about the astronomical and mathematical implications carried by the antiquity, originality and complexity of this cosmogonical system? This is probably one of the most interesting open problems for the history of ancient sciences, and the Canary Islands have something to say here.

The Canarian Evidence

In the fourteenth to fifteenth centuries AD, Grand Canary and Tenerife were inhabited by Berber populations – called Canarians and Guanches – coming from the nearby continent on different occasions between the first millennium BCE and the first millennium AD. These populations remained relatively isolated until the European rediscovery of the Islands in the late thirteenth century. At that time the population of each island was about 40–60,000, sustaining a developed agricultural (barley, wheat) and stock raising (goats, sheep, pigs) economy. The written sources point out the presence in both islands of a powerful priestly class, in whose religious system the sun, moon and stars played a very important role.

Grand Canary Island

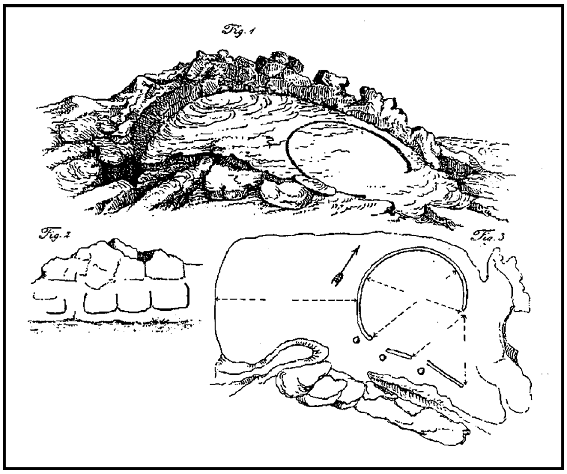
The Canarians used a synodic lunar calendar for daily life. The lunar year was adjusted to the solar year at the summer solstice. Although nobody mentions an intercalary moon, the first new moon after the summer solstice marked a new year and was feasted. Actual calendrical figures are very scarce but they mention a lunar synodic month of 29 days, a lunar year of 12 months, and a certain period of 520 days, which is an exact measure of one and a half eclipse years or three passes of the Sun by the lunar nodes (incidentally, this is the reason why eclipses are located in three fixed zones of the 260-day Mesoamerican sacred calendar). There are also notices about observation of rising and setting of stars. Sirius is the only explicitly mentioned star but there is a clear reference to Afarakrak, a Berber name of Canis Maior, in Facaracas, the preserved name of an important site where the nobility of the island used to meet.

Archaeoastronomical research undertaken from 1985 at the mountain of Cuatro Puertas (Four Doors) has revealed several methods for observing the solstices and other astronomical dates.

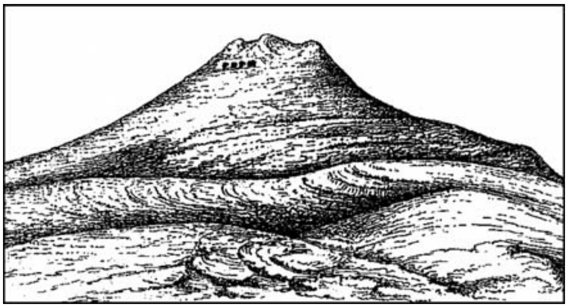
The mountain is an isolated arid volcanic semicone oriented east–west with an elevation of 319 m. above sea level. Seen from the north (Fig. 1) its slopes are smooth and rounded. All that stands out is the big artificial cave with four entries located near the top, which gives its name to the mountain. The precise orientation of these doors assures that sunlight only enters the cave at sunrise (Fig. 3) and sunset (Fig. 4) on a few days around the summer solstice.

Seen from south its appearance is diametrically opposed, plunging abruptly from its top to the bottom of a ravine. On this slope there is a group of spacious and sophisticated artificial caves excavated in the rock, among which stands out the Cave of the Pillars. This cave is fully illuminated by the rising sun on winter solstice days (Figs. 5 and 6).

At the top of the mountain there is a little ritual esplanade of some 10 × 5 m. partially excavated on the rock (Fig. 2). Open to the east and south, on the wall facing the east there is a carved sign about 2.4 m. long with JUUU form (Fig. 8).



Mathematics and Astronomies of the Ancient Berbers. Fig. 2 Ritual esplaaade at the top of Cuatro Puertas after Berthelot (1879).



Mathematics and Astronomies of the Ancient Berbers. Fig. 1 The mountain of Cuatro Puertas after Berthelot (1879).

Mathematics and Astronomies of the Ancient Berbers. Fig. 6 Winter solstice sunrise illuminating the cave of the Pillars. Photo by José Barrios García.

Mathematics and Astronomies of the Ancient Berbers. Fig. 7 Summer solstice sunrise from the sign of Cuatro Puertas. Photo by José Barrios García.

Every day at sunrise the silhouette of the rock located in front of the sign casts a certain shadow that changes its position day by day, reflecting the azimuthal change of the sunrise. The left edge of the shadow reaches the different strokes on determined dates, while the whole shadow fits the sign just on the summer solstice days (Figs. 7 and 8).

The Canarians used certain characters to record numerical, astronomical and calendrical data systematically. These figures were triangles, squares and circles painted in white, red and black on wood planks and on the walls of certain caves. The modern reconstruction of the decoration of the Painted Cave of Gáldar strongly suggests the use of a 3 × 4 chessboard, named *acano*, to represent 12 moons (Figs. 9 and 10).

A systematic analysis of the *acano* as a lunar calendar shows how the vertical numeration of its squares forces the solstitial, equinoctial and eclipse Moons to move across the board in very simple and stable patterns. These patterns provide a safe and clear mnemonic guide for performing on the *acano* an easy arithmetical calculus of seasonal and eclipse moons over extended periods of time. This calculus establishes the *octaeteris* and the 135-Moon eclipse cycle as basic periods of the *acano*.

Tenerife Island

The Guanches, as the Canarians, used a synodic lunar calendar for daily life, adjusting it to the solar year at the summer solstice. Also mentioned is the use of tally boards and small necklaces of clay beads for recordkeeping, although the absence of well-preserved examples in a reliable archaeological context impedes testing these accounts. Nobody mentions an intercalary moon, but the first moon of the year occurred towards the middle of August and was celebrated. This festival exists today in the traditions of the Virgin of Candelaria, patron of the island, whose apparition to

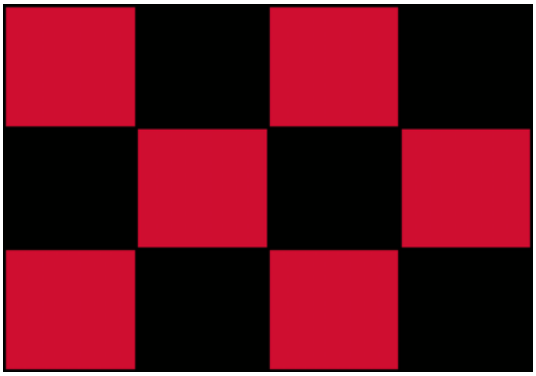
Mathematics and Astronomies of the Ancient Berbers. Fig. 9 The Painted Cave of Gáldar after Verneau (1889).



Mathematics and Astronomies of the Ancient Berbers. Fig. 10 The acano chessboard.

the Guanches is reported to have occurred about 100 years before the Spanish conquest in the late fifteenth century. A close analysis of these traditions shows that they match a Guanche cult to a stellar deity considered the "mother of the sun" as well as the "mother of the one who sustains the world."

Besides the main festival that occurred about the middle of August, there were two other important ones occurring in early February and late April, respectively. These three periods can be readily correlated with the heliacal rise, acronical rise and heliacal set of Canopus. On the whole the gathered evidence proves the presence in Tenerife of the Canopian cosmogonical system described by Pâques (1964).

Further evidence concerning the determination of the year of apparition of the Virgin to the Guanches supports the idea that the Guanches used a commensurability period of 19 solar years ≈21 sidereal lunar years in their calendrical reckonings.

Mathematics: Aztec Mathematics

Michael P. Closs

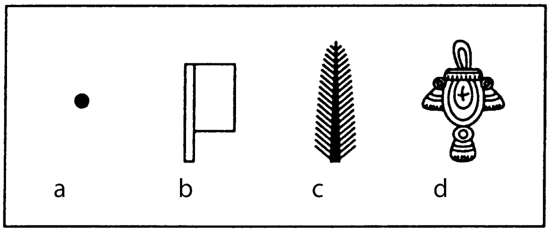
The tribal records of the Aztecs indicate that they left their legendary homeland in AD 1168 and founded their capital Tenochtitlan (present day Mexico City) in 1325. By the fifteenth century, their capital had become the center of an expansionist empire. When Cortés arrived in 1519, Tenochtitlan dominated all other cities and had reached the height of its power and magnificence. The language of the Aztecs, Nahuatl, is still spoken today in Central Mexico. An overview of the Nahuatl number sequence is given in Table 1.

Mathematics: Aztec Mathematics. Table 1 The Nahuatl number sequence

1	ce	
2	ome	
3	ei, yei	
4	nahui	
5	macuilli	
6	chicuace	(5) + 1
7	chicome	(5) + 2
8	chicuei	(5) + 3
9	chiconahui	(5) + 4
10	matlactli	
11	matlactli once	10 + 1
12	matlactli omome	10 + 2
13	matlactli omei	10 + 3
14	matlactli onnahui	10 + 4
15	caxtolli	
16	caxtolli once	15 + 1
17	caxtolli omome	15 + 2
18	caxtolli omei	15 + 3
19	caxtolli onnahui	15 + 4
20	cempoalli	one score
30	cempoalli ommatlactli	20 + 10
37	cempoalli oncaxtolli omome	20 + 15 + 2
40	ompoalli	2 × 20
60	eipoalli	3 × 20
100	macuilpoalli	5 × 20
400	tzontli	
401	centzontli once	(1 × 400) + 1
405	centzontli onmacuilli	(1 × 400) + 5
500	centzontli ipan macuilpoalli	(1 × 400) + (5 × 20)
8,000	cenxiquipilli	1 × 8,000

The term for five, *macuilli*, derives from *maitl* "hand", *cui* "to take" and *pilli* "fingers". It means something like "fingers taken with the hand". The term for ten, *matlactli*, comes from *maitl* "hand" and *tlactli* "torso". The term for 15 is a new basic word for which there is no known etymology. The vigesimal nature of the number system clearly shows up in the introduction of new basic terms for 400 and 8,000. The word for 400, *tzontli*, means "hair" or "growth of garden herbs". In either case, it signifies multitude or abundance. The word for 8,000, *xiquipilli*, refers to a "bag of cacao beans".

The Aztec had written numerals for the first four vigesimal powers: $20^0 = 1$, $20^1 = 20$, $20^2 = 400$ and $20^3 = 8{,}000$. These symbols are shown in Fig. 1: (a) a dot represents the unit 1; (b) a flag represents 20; (c) a hank of hair or garden herb represents 400; (d) a bag of cacao beans is used for 8,000. It can be seen that the symbol for 400 reflects the word for that number, *tzontli*, "hair" or "growth of garden herbs". Similarly, the sign for 8,000 reflects the word for that number, *xiquipilli*, "bag of cacao beans".



Mathematics: Aztec Mathematics. Fig. 1 Aztec numerals: (**a**) 1; (**b**) 20; (**c**) 400; (**d**) 8,000 (Drawing by Closs).

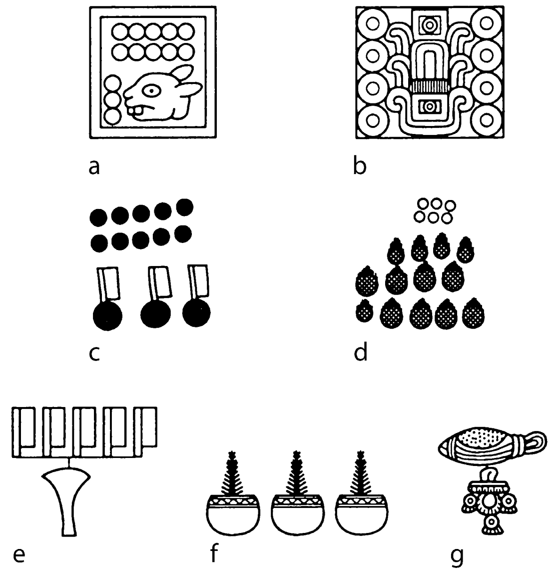
A tally of these four numerals was used to represent other numbers. Thus, quantities from 1 to 19 were represented by the appropriate number of dots or circles. In the same way, multiples of 20 less than 400 were represented by repeating the sign for 20 as many times as necessary. Similarly, the symbols for 400 and 8,000 were repeated to form multiples of 400 and multiples of 8,000, respectively. The largest number I have seen recorded with these numerals occurs in the Vatican Codex. It is composed of two signs for 8,000 and 9 signs for 400 yielding (2 × 8,000) + (9 × 400) = 19,600.

Numerals are found in a variety of contexts. One of the most common of these is as numerical coefficients in calendar dates. The Aztecs, along with other Mesoamerican cultures, employed two major calendrical cycles, a sacred almanac of 260 days called the *tonalpohualli* and an annual calendar of 365 days. The *tonalpohualli* was constructed from a sequence of numbers from 1 to 13 paired with a sequence of 20 day names. The 260-day and the 365-day calendars were combined so that each day could be specified by both a sacred date and an annual date. Since the least common multiple of 260 and 365 is 18,980 (= 52 × 365), the combined cycle of the two calendars repeats after 52 years of 365 days each. This 52-year period, known as the *xiuhmolpilli* "sacred bundle," played a significant role in Aztec religious life.

A given 365-day year was designated by the sacred almanac name of its 360th day. We refer to this name day of the year as the year bearer. Because of the structure of the calendar, only four day names could function as year bearers. The 13 numerical coefficients with the 4 day names yield 52 year bearers, one for each year in the 52 year period. In the Aztec codices and stone monuments, such years are frequently named. In these cases, the numerical coefficients are represented by a tally of from 1 to 13 small circles. Examples of the year bearer dates, 13 Rabbit and eight Reed, are shown in Fig. 2a and 2b.

The Aztecs also used numerals in chronological counts which varied from a few days to thousands of years. One section of the Mendocino Codex gives the different stages in the education that a boy or girl receives from its parents. The tasks which children must learn are depicted and their daily food ration is shown by a tally of tortillas that appears over their heads. The ages are indicated by a simple tally of blue disks representing the number of years. These run from three up to 14 as one progresses through the manuscript. The corresponding daily ration rises from half a maize cake to two per day. The largest chronological interval of this type is depicted in another portion of the Mendocino Codex where an elderly male and female are shown drinking a fermented beverage denied to those who are younger. Both persons are seventy years old and their age is indicated by a tally of ten blue disks together with three disks marked with the flag symbol for 20 as shown in Fig. 2c.

The Vatican Codex contains other chronological counts which measure far larger intervals. A count which refers to the years of the second age of the world is shown in Fig. 2d. Each of the cross-hatched disks with hair on top is blue in the original and represents a period of 400 years, being a conflation of the standard blue disk for the 365-day period and the numeral for 400. (In this regard, recall that the Aztec term for 400 is *tzontli*, "hair".) In the upper row is a tally of six smaller disks marking 6 years. The total count measures a period of (13 × 400) + 6 = 5,206 years.



Mathematics: Aztec Mathematics. Fig. 2 Contexts of Aztec numeral usage. *Calendar dates (year bearers):* (**a**) 13 Rabbit; (**b**) eight Reed. *Chronological counts:* (**c**) 70 years; (**d**) 5,206 years. *Tribute records:* (**e**) 100 copper hatchets; (**f**) 1,200 coarse clay pots; (**g**) 8,000 balls of unrefined copal (incense) wrapped in palm leaves (Drawing by Closs).

Some of the Aztec codices contain lists in which the quantities of the various tribute items to be received from conquered towns are recorded. In these documents, the towns are represented by hieroglyphic toponyms, the tribute items by hieroglyphic signs, and the quantities by numerals or by a simple tally of the items. If the total is less than 20, the item is often represented by a simple tally of the sign for the object itself or by a single depiction of the tribute item with an attached tally of numerals. For larger totals, a combination of the two types of tallies is often used. Some examples of tribute records are shown in Fig. 2e–g.

In the land documents of the Texcocan Aztecs a more concise and sophisticated system of numerical notation was employed. It was used for recording the measurements of perimeters and areas of land holdings in at least two locations in the Valley of Mexico. The system made use of only four symbols – a vertical tally stroke, a bundle of five strokes linked at the top, a dot and a corn glyph (*cintli*) – and position to indicate the value of measurements (Harvey and Williams 1980, 1986).

An example from the Códice de Santa Maria Asunción, dating from around 1545, is illustrated in

M

Fig. 3. The land record is divided into three parts. The first section (*tlacatlacuiloli, tlacanyotl*) contains a census by household. The name for each head of household is written in glyphic form beside a conventional symbol for household head. In the present example, the tlacatlacuiloli shows the head Pedro, his wife Juana, their two young daughters Ana and Martha, and the head's younger brother, Juan Pantli, his wife Maria and their son Balthasar. The shaded heads indicate that the individual is deceased.

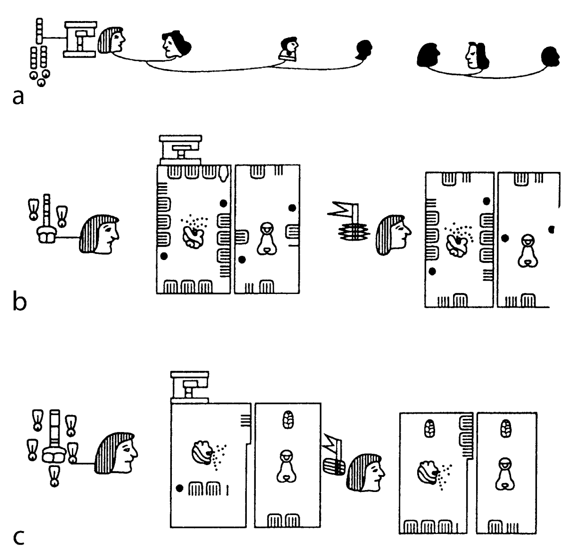
The second section (*milcocoli*) consists of a record of land parcels associated with each household. In this section, the scribe drew the approximate shape of each field. The measurement of each side was recorded using lines and dots, a line equal to one linear unit and a dot equal to 20. In the Texcocan area, the usual unit of linear measure was the *quahuitl* of approximately 2.5 m. Units less than one quahuitl were indicated by symbols such as a hand, an arrow, or a heart. The modern equivalents of these signs can only be estimated at present. In addition to recording linear measurements around the field perimeters, each field contains a hieroglyph in the center which indicates the type of soil. In particular, the milcocoli section for our example records the approximate shape, perimeter measurements, and soil type of four fields belonging to the household, two to the household head and two to his brother. The hand glyph in the first field indicates a fraction of a quahuitl.

The third section (*tlahuelmantli*) is a second record of the same lands as in the milcocoli section. However, in this case, the lands are shown in a stylized form as rectangles of the same size. Interestingly, the Nahuatl term *tlahuelmantli* literally means "smoothed, leveled, equalized." The majority of these fields have a protuberance in the upper right-hand corner. In addition to the standardized field shapes, the placement of numbers in the tlahuelmantli is different from in the milcocoli. The numerical quantities using lines and dots are entered either in the center or on the bottom line of the rectangle and in the protuberance. When numbers, never exceeding 19, are entered on the bottom line, a cintli glyph occurs near the top border of the rectangle. In addition, most fields contain a number ranging from 1 to 19 in the upper right corner of the protuberance. It has been determined that these numbers report the area of the field in square quahuitl by use of positional notation.

The system of recording area is dependent on three separate registers. The first register is located in the upper right protuberance and is used to record a unit count from 0 to 19. When the value of this register is 0, the protuberance is left empty or is not drawn. Otherwise, 1 to 19 strokes are recorded with groups of five being bundled together by a connecting line. The second register is the bottom line of the rectangle. It is used to record from 1 to 19 multiples of 20 (the vigesimal numbers from 20 to 380) by using a simple tally of 1 to 19 strokes. The third register is in the central portion of the rectangle. It is used to express higher multiples of 20, that is multiples of 20 which are greater than or equal to 400. In this register, a dot has value 400 and a stroke has value 20. The second and third registers are never used concurrently. If there is no entry in the third register, the cintli glyph is drawn toward the top of the rectangle. This may signify 0 in that register. In order to compute the area, the number in the second or third register is multiplied by 20 and added to the number in the first register.

In the example under consideration, the length of the sides, in quahuitl, of the four fields in the milcocoli section and the area, in square quahuitl, of the corresponding fields in the tlahuelmantli section is shown in Table 2.

The problem of how the areas in the tlahuelmantli were determined remains to be resolved. In general, the area of a quadrilateral cannot be determined from the



Mathematics: Aztec Mathematics. Fig. 3 A land record from the Codice de Santa Maria Asuncion (Drawing by Close from Harvey and Williams 1986).

Mathematics: Aztec Mathematics. Table 2 The length of the sides, in *quahuitl*, of the four fields in the *milcocoli* section and the area, in square *quahuitl*, of the corresponding fields in the *tlahuelmantli* section

	Sides	Area
Field 1	39, 15, 39, 15+	$(31 \times 20) + 4 = 624$
Field 2	25, 8, 26, 8	$(10 \times 20) + 0 = 200$
Field 3	38, 9, 39, 8	$(16 \times 20) + 13 = 333$
Field 4	20, 9, 20, 8	$(9 \times 20) + 0 = 180$

lengths of its sides. As a result, the information in the milcocoli section is not sufficient to obtain the true areas of the fields.

Mathematics in China

ANDREA EBERHARD-BRÉARD

Number System and Calculation Tools

Archaeologic finds from the Shang dynasty (fourteenth to eleventh century BCE) show the earliest number symbols inscribed on bones and tortoise shells. By then, different decimal and sexagesimal systems were in use. The use of rod-numerals is also attested on coins as early as from the Wang Mang period (9–23 AD). These are related to the instruments in use. For calculations, numbers were represented on a calculation surface by counting rods. The representation follows a decimal positional notation, where nine different signs for the numbers from 1 to 10 consist of either vertical or horizontal bars used to mark units, hundreds, myriads, etc. or tens, thousands, and other odd powers of ten. Three hundred twenty-six for example was thus put down in the following way: III = T. For negative numbers, black instead of red counting rods were used. In printed records (from the eleventh century onwards) they were marked by an oblique bar (Fig. 1).

"Brush calculations" written on paper and the abacus were widely spread by the sixteenth century, but the latter may have existed one or two centuries earlier. Procedures linked to abacus calculation are mostly written in versified form for easy memorization, and historians have shown how these evolved out of earlier procedures for counting rods (Fig. 2).

M

Textual Sources

The scope of research into the history of mathematics in China today is determined by the available source material transmitted to us. The early beginnings of mathematics are closely connected to astronomy. With its non-geometric formal methodology, astronomy in China was oriented towards calendrical calculations and numerical lists, but less concerned with the design of geometric models. The positions of the celestial bodies could be determined by a system of numerical constants derived from observation, interpolation algorithms and cyclical theories. But their choice was also influenced by numerological considerations and political events.

One of the earliest texts that has been preserved is the *Zhoubi suanjing* (*Mathematical Classic of the Gnomon of Zhou*) compiled towards the end of the first century AC. It is closely related to the cosmographic doctrine of the "Heaven as a chariot-cover" (*Gaitian shuo*), which was popular during the Han dynasty (206 BCE–220 AC). Among historians, it is mainly known for its proof of a statement analogous to the Pythagorean theorem (Fig. 3).

When the court astro loger Li Chunfeng (602–670) and his staff included the *Zhoubi* and its commentaries in a compilation of *Suanjing shi shu* (*Ten Books of Mathematical Classics*) for the government academy of the Tang dynasty, the text was elevated to the status of a mathematical canon as were the other nine contemporary or earlier treatises. The collection was first printed by the imperial library of the Northern Song in 1084, which is partly still extant from a 1231 reprint.

Mathematics in China. Fig. 3 Proof of Pythagorean theorem from the *Zhoubi suanjing*.

But there is another context in which mathematics played an important role and which shaped its methods of calculation and notation in China. The administrative tradition of registering numbers in the form of tables involved the calculation of the totals of sums or provided multiplication tables for fiscal purposes. Archaeologists found six manuscript sources, which attest of such mathematical activities, at the beginning of the twentieth century in the Buddhist Dunhuang Caves in Northwest China. They date from the 6th to the tenth century and are now stored in the National libraries of France and Great Britain. One of the manuscripts for example, which gives the date of the second year of the Guangshun era (952), tabulates the products in *mu* for the surfaces of all rectangular fields with the lengths of a side less or equal than 60 *bu* (1 *mu* = 240 square *bu*).

Equally important for our understanding of mathematical activities in early China is the recent excavation of a manuscript on 190 bamboo strips in a Chinese nobleman's tomb that was closed no later than 186 BCE. It represents the earliest document that has survived and provides us with a text outside the government sanctioned *Ten Books*. The stated problems and procedures show a certain connection to the foundational *Jiu zhang suan shu* (*Nine Chapters on Mathematical Procedures*) and its commentary by Liu Hui (263 AC), which were part of the *Ten Books*, yet this connection still needs to be explored.

The commentaries to the now still extant Song dynasty edition of the *Nine Chapters* also contain fragments ascribed to other mathematicians. Zu Geng (late fifth century to early sixth century), son of the famous Tang mathematician and astronomer, Zu Chongzhi (429–500), obviously knew Liu Hui's commentary, when he wrote his "sub"-commentary on the calculation of the volume of a sphere. Later editions contain commentaries by Jia Xian (first half of the eleventh century), which are based on the now lost *Huangdi jiu zhang suanjing xicao* (*Detailed [calculation] sketches for the Yellow Emperor's Mathematical Classic in Nine Chapters*).

Among other preserved Song dynasty commentaries on the *Nine Chapters*, we find Yang Hui's *Xiangjie jiu zhang suanfa* (*Detailed Explanations of the Nine Chapters on Mathematical Methods*) printed in 1261 and in 1408 for the copies of the Ming dynasty imperial library named the *Yongle dadian* (*Great Encyclopedia of Yongle reign*). The evidential research scholar Dai Zhen (1724–1777) compiled *Supplements of Diagrams and Errata to the Nine Chapters on Mathematical Procedures* when he worked on the edition of traditional Chinese mathematical sources to be included in the imperially commissioned *Siku quanshu* (*Complete Library of the Four Treasuries*). Since Dai Zhen's compilation project of the *Ten Books of*

Mathematical Classics, more than ten other editions of the *Nine Chapters* have been discovered.

The Foundational Mathematical Content of the Ten Books

Wang Xiaotong's *Ji gu suanjing* (*Mathematical Classic in Continuation of the Ancients*, compiled earlier than 626) played an important role in the development of numerical procedures for the solution of algebraic equations. It contains 20 problems, the first one of which concerns a calendrical calculation; problems 2–5 concern the construction of a geometric solid; problems 6–16 consider the construction of different types of granaries, and the (partially incomplete) problems 17–20 deal with right-angled triangles. All the procedures to solve problems 2–20 involve the solution of a quadratic or a cubic equation, which gives the treatise a certain coherence. Given the daily motion of the sun and the moon, the position of the sun on the ecliptic at the time of the new moon, and the time lapse between new year and new moon, Wang Xiaotong's first problem asks for the position of the moon on the ecliptic at the time of the New Year's new moon which should have ideally happened at midnight of the first day of the 11th month.

Commentaries by Chen Luan (fl. 566) and Li Chunfeng on *Sunzi suanjing* (*Master Sun's Mathematical Classic*, late fourth century) mentioned in the Tang dynastic annals are unfortunately lost. But *Master Sun's Mathematical Classic* itself is the earliest document on arithmetical procedures in China. It describes the positional arrangement of numbers represented by bamboo sticks, and gives detailed multiplication and division algorithms for these tools laid out on the positions of a counting board. The textual structure of the first part of the treatise is distinct from the usual arrangement in problem, answer and solution procedure. In sequential order, measures, weights, large numbers, and standard measure vessels are defined, before expounding the methods and positions for calculations with counting rods. The texts state in general terms, procedures for multiplication, and as its inverse counterpart, the procedure for division, followed by an ordered numerical list of multiplications, division, and summations.

Zhang Qiujian suanjing (*Zhang Qiujian's Mathematical Classic*), probably written between 466 and 485, can – taken in a large sense – be interpreted as a commentary to the *Nine Chapters*, since it recycles certain problems, for which the numerical solution is described through "detailed calculation sketches" by the Sui dynasty astronomer Liu Xiaosun (mid-sixth century). But *Zhang Qiujian's Mathematical Classic* also contains problem types which in later texts become themselves canonical models. For example, there is the "one hundred fowls" problem, in which somebody is to buy one hundred fowls for one hundred monetary units of several kinds. This requires the solution of an indeterminate system of equations. What is characteristic for this text is that problems from the *Nine Chapters* are often given in inverse formulation, which leads to inverse algorithms. In many cases this requires the solution of a cubic equation, which Zhang Qiujian solves with an extended procedure to the algorithm for root extraction found in the *Nine Chapters*. From the preface one can deduce, that Zhang Qiujian was familiar with other treatises from the *Ten Classics* and that his main mathematical activity was to rewrite their procedures. His textual work on Antiquity was thus not only limited to commenting on earlier writings, as he also combined and rewrote many of the problems found in the *Nine Chapters*, which gave rise to new mathematical objects.

The Song Yuan Period: Apogee of Mathematical Tradition in China

Judging from the available sources, the thirteenth century was a highly creative period for the development of mathematics in China. Numerous references to now lost treatises show that it was also one of the most productive periods as concerns the publication of mathematical treatises, although now only eight works by four mathematicians in all survive from the late Song to the early Yuan period in China. These are:

1. Qin Jiushao. *Shushu jiuzhang* (*A Mathematical Book in Nine Chapters*), 1247
2. Li Ye. *Ceyuan haijing* (*Sea Mirror of Circle Measurements*), 1248
3. Li Ye. *Yigu yanduan* (*Calculating with Segments in Extension of the Ancients*), 1259
4. Yang Hui. *Xiangjie jiuzhang suanfa* (*Detailed Explanations to the Mathematical Methods of the Nine Chapters*), 1261
5. Yang Hui. *Riyong suanfa* (*Mathematical Methods for Daily Use*), 1262
6. Yang Hui. *Yang Hui suanfa* (*Yang Hui's Mathematical Methods*), 1274/1275
7. Zhu Shijie. *Suanxue qimeng* (*Introduction to Mathematical Learning*), 1299
8. Zhu Shijie. *Siyuan yujian* (*Jade Mirror of Four Elements*), 1303

Yang Hui's writings record the traces of a geometric method that is at the basis of the algebraic method of the "heavenly element" (*tian yuan*), a method which circulated among authors in Northwest China. The latter allowed Li Ye to solve equations of higher degree in one unknown. To do so, the numerical coefficients were laid out in (ascending or descending) order on a calculation surface with counting rods. The position of

M

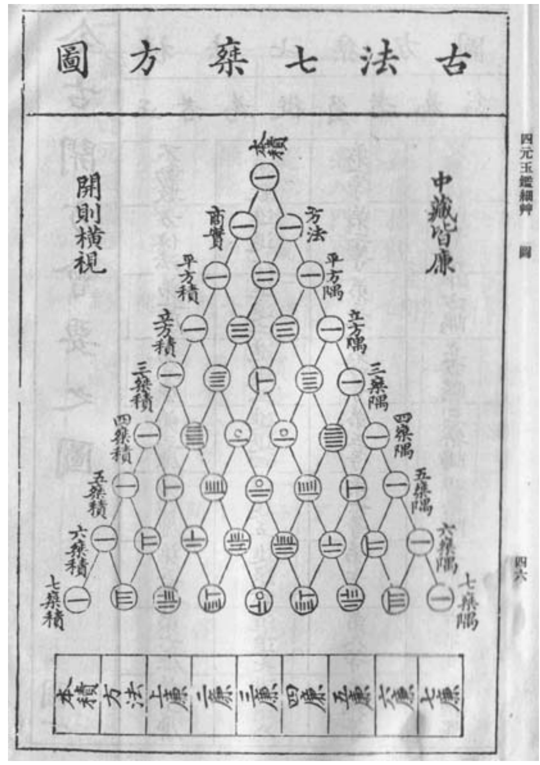
the constant term was either marked with the character *yuan* (element), or the coefficient of the linear term was marked with the character *tai* (supreme). In that way, the significance of each position was determined and the solution procedure could be performed.

According to the solution procedures cited in one of Yang Hui's texts, the *Tian mu bi lei cheng chu jie fa* (*Simple Methods for Multiplication and Division with Analogous Examples to the Categories of Field Measurement*, 1275), the algebraic *tian yuan* method evolved out of considerations of planes whose surfaces are known. In the related problem solutions, these surfaces are thought of as composed of segments, which are constructed with the given magnitudes of the problem and are in argumenative relation with the coefficients of the quadratic equation that needs to be solved.

In 1299 Zhu Shijie uses the *tian yuan* method systematically in the last chapter of his *Suanxue qimeng* (*Introduction to Mathematical Learning*) in diverse problems for plane surfaces and also for the first time for volumes. Only the first seven problems of that chapter do not require the layout of the coefficients for a polynomial equation in one unknown. These problems deal with the "opening of the square" that is the extraction of the square root of a given surface, volume, or high-dimensional surface-product. In problem 5 this requires the "opening of the triple multiplied side of a square," i.e., the extraction of the fourth square root of 1129458 511/625.

In the *Jade Mirror of Four Elements* (1303), famous for its earliest known drawing of the arithmetic triangle (or Pascal Triangle), Zhu Shijie uses in more than 200 problems the *tian yuan method* to solve equations in one unknown (Fig. 4). These problems were not limited only to applications on lengths of the sides or circumferences, and surfaces or volumes of geometric figures, but they also explored discrete cuts and accumulations that gave rise to investigations into arithmetical series. Zhu Shijie's solution procedures, however, do not contain any longer step-by-step deduction of the layout of coefficients. He merely indicates the choice of the unknown and the numerical values of the coefficients, which one obtains by an elimination method, related to the searching of "equal [surface-] products" (*ru ji*).

The *tian yuan method* had a great impact on the development of mathematics in other East Asian countries like Korea and Japan and gave rise to a large number of commentaries due to the transmission of Zhu Shijie's earlier book, the *Introduction to Mathematical Learning*. In Korea it was reprinted in 1433 under the reign of King Sejong (r. 1418–1450), and further transmitted into Japan by the end of the sixteenth century. Commentators then also started to see the limits of the *tian yuan* method, in particular for problems with two unknowns that could not be



Mathematics in China. Fig. 4 The arithmetic triangle as shown in Zhu Shijie's *Siyuan yujian*, 1303.

formulated by two independent equations in one unknown each. In China, Zhu Shijie and his precursors were already able to solve such problems (at least partially) with a method for up to four unknowns, but these writings had not made their way into Korea or Japan.

Zhu Shijie's *Jade Mirror* is now the only preserved witness of a solution procedure for higher degree equation systems with up to four unknowns. The first unknown remains the "heavenly unknown" (*tian yuan*), the other three are the "earthly" (*di yuan*), "human" (*ren yuan*), and "material unknown" (*wu yuan*). The coefficients of these unknowns are then laid out on a counting board as shown in the following illustration:

$$\begin{array}{ccccccccc}
d^m\cdot w^k & \cdots & d^2\cdot w^k & d\cdot w^k & w^k & w^k\cdot r & w^k\cdot r^2 & \cdots & w^k\cdot r^l \\
\vdots & \ddots & \vdots & \vdots & \vdots & \vdots & \vdots & \iddots & \vdots \\
d^m\cdot w^2 & \cdots & d^2\cdot w^2 & d\cdot w^2 & w^2 & w^2\cdot r & w^2\cdot r^2 & \cdots & w^2\cdot r^l \\
d^m\cdot w & \cdots & d^2\cdot w & d\cdot w & w & w\cdot r & w\cdot r^2 & \cdots & w\cdot r^l \\
d^m & \cdots & d^2 & d & {}_{t\cdot w}tai^{d\cdot r} & r & r^2 & \cdots & r^l \\
t\cdot d^m & \cdots & t\cdot d^2 & t\cdot d & t & t\cdot r & t\cdot r^2 & \cdots & t\cdot r^l \\
t^2\cdot d^m & \cdots & t^2\cdot d^2 & t^2\cdot d & t^2 & t^2\cdot r & t^2\cdot r^2 & \cdots & t^2\cdot r^l \\
\vdots & \iddots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\
t^n\cdot d^m & \cdots & t^n\cdot d^2 & t^n\cdot d & t^n & t^n\cdot r & t^n\cdot r^2 & \cdots & t^2\cdot r^l
\end{array}$$

This way of representation naturally limited the possibilities of solving certain types of equations. On the one hand, this is because not all theoretically possible products of unknowns could be represented;

on the other hand, a spatial extension was impossible. The possibilities of a two-dimensional layout were restricted to the four cardinal directions and thus to no more than four unknowns. Besides socio-political factors that influenced the transmission of mathematical knowledge and writings in Chinese society this was probably a structural reason for the end of the development of the *tian yuan method* after Zhu Shijie.

"Minor Traditions" as reflected in Printed Sources on Arithmetic

The commercialization of print since the Song dynasty brought about several other texts that were not printed under official auspices. The most widely circulating book was Cheng Dawei's *Suanfa tongzong* (*Systematic Treatise on Arithmetical Methods*, 1592), which was reprinted and very influential in Japan in the seventeenth century. It is structured into chapters according to the canonical categories of the *Nine Chapters* and three chapters on "difficult problems" (Fig. 5).

At the very end of Cheng Dawei's bestseller, we find a list of books of the time, but unfortunately nearly all of them are lost. But we learn from one comment and from a preface to Ding Ju's *Ding Ju suanfa* (*Arithmetical Methods*, 1355) that they might have been part of what was considered a "low" arithmetical tradition that coexisted in parallel with the tradition of the *Nine Chapters*. This parallels the historiographic trend to portray the Ming dynasty as a time of decline in scientific activity. Since the tradition was characterized by arithmetical procedures for abacus calculations, and often put in versified form, historians have paid little attention to Ming dynasty treatises and interpreted their content as folklore mathematics of little originality. Only Roger Hart has so far taken an opposite position on Ming dynasty trends. By analyzing Zhu Zaiyu's (1536–1611) *Yuelü quan shu* (*Complete Compendium of Music and Pitch*) and in particular the mathematics presented in his *New Explanation of the Theory of Calculation* (*Suanxue xinshuo*, engraved in 1604), he claims that Zhu's mathematics is perhaps some of the most sophisticated found in extant texts from the Ming dynasty. There the equal temperament of the musical scale is calculated to 25 decimal places using nine abacuses.

Foreign Influence in the late Imperial Era

The first wave of transmission of some elements of the European sciences to China, which started in the late sixteenth century, was a systematic enterprise of the Jesuit mission, who sought the support of the elite to evangelize from the top down. Matteo Ricci (1552–1610), the founder of the mission, identified the mathematical sciences as a field in which Chinese literati circles were interested. He translated, together with one of his convert students in mathematics, astronomy, hydraulics, and geography Xu Guangqi (1562–1633), the first six books of Euclid's *Elements* (*Jihe yuanben*, 1607). The translation was based on Christoph Clavius' (1538–1612) Latin edition and commentary (Rome, 1574) and aroused Chinese mathematicians and even the Emperor Kangxi's (r. 1662–1722) interest in Euclidean geometry (Fig. 6).

Several other treatises on geometry, trigonometry and methods of root extraction were then written in syncretistic style by Chinese literati, who attempted creatively to come to grips with the new learning. A series of mathematical textbooks was also translated into Chinese and eventually formed the basis of an imperially commissioned compilation on mathematics, the *Shuli jingyun* (*Essential Principles of Mathematics*, 1723), which played an important role into the mid-nineteenth century.

A second wave of translations of mathematical books related to foreign presence in China following the treaties concluding the Opium Wars. Protestant missionaries, foreign employees of the Imperial Maritime Customs Service connected to its Foreign Language Institute (*Tongwenguan*) in Beijing and private foreign enterprises to promulgate Western sciences in China were the driving agents in that movement in the second half of the nineteenth century (Fig. 7).

It was during that time that Chinese mathematicians started to introduce symbolic algebra into a renewed mathematical discourse. In the assimilation and translation of works on algebra, the late Qing mathematician Li Shanlan (1811–1882) played a key role. Not only he did derive new summation formulas for finite series based on traditional procedures (known as Li Jen-Shu's formula) and write commentaries on traditional algebraic methods, but also he was instrumental in the transmission of differential and integral calculus. In 1859 he translated, together with the British missionary Alexander Wylie (1815–1887), Elias Loomis' (1811–1889) *Elements of Analytical Geometry and of Differential and Integral Calculus* (1851) and Augustus De Morgan's (1806–1871) *The Elements of Algebra Preliminary to the Differential Calculus* (1835) which were reprinted in Japan in 1872 (Fig. 8).

Both algebra and calculus quickly found their way into late Qing curricula of mathematical education, in contrast to probability theory and statistics, which remained two applied fields of mathematics that had to wait for the 1930s – and for returned students educated abroad – to be fully understood. By then, the Chinese algorithmic traditional style closely related to the written classical language was abandoned. Texts were written in vernacular language and algebraic

symbolism was adopted as the universal scientific language. China's mathematicians for the first time had an institutional base, the Academy of Science's (*Zhongguo kexue yuan*) Mathematical Institute and several research centers in universities, where the emphasis was on number theory, operations research and closely related to it statistics and probability. The antirightist campaign of 1957 and the Cultural Revolution at its peak in 1966 involved a major disruption of intellectual activities in China. At the 1978 National Science Conference, Deng Xiaoping again allowed for the progress of all aspects of mathematical research by emphasizing science as one of the "four modernizations."

Mathematics Education in China

Mathematics, together with rites, music, archery, charioteering, and calligraphy, formed the *Six Arts* as defined by traditional Confucian learning. We know that Li Chunfeng's compilation project, the *Ten Books of Mathematical Classics*, was used as a textbook for the Mathematical Academy (*Suanxue guan*) founded by the Emperor Gaozong in 656. This academy was part of the "directorate of education" (*Guo zi jian*) responsible for the training of government officials. A "School of mathematics for the national youth" (*Suan li guozi xue*) had already existed since the Sui dynasty. It was taken over by the Tang, but we do not know about its curriculum and the manuals that were used. In Imperial China, there was no such profession as a mathematician; knowledge was mainly transmitted orally from teacher to pupil in private academies. We have little or no biographical information on those who wrote mathematical books except for court astronomers or those who held a government position, like Qin Jiushao in the Song administration. It was only during the late nineteenth century educational reforms that mathematics became part of the standard curriculum in schools and the first universities in China. By then, some government supported students returned from Japan, Europe, or the United States and served as teachers for Western sciences. But it was really only in the 1930s that effective schools were built up and that mathematical research started to be systematically institutionalized.

Mathematics in Egypt

James Ritter

By "Egyptian mathematics," we understand the mathematics developed in Ancient Egypt between the end of the fourth millennium BCE, when a centralized state came into being in the Nile Valley and a system of writing was invented, and 332 BCE, when Egypt was conquered by Alexander the Great and Greek cultural elements entered into the hitherto fairly autonomous development of Egyptian civilization. During these 3,000 years, the role of mathematics remained of central importance; the Egyptian educational system was geared principally to produce scribes who could count and calculate the work, rations, land, and grain of the State and the private landowner.

The judgments of Egyptian mathematics ordinarily to be found in histories of science fall into two main schools: either they are dismissive, claiming that mathematics in Egypt was merely of a "practical" or "trial and error" nature; or they are laudatory in the extreme, the Egyptians being seen as the precursors and inventors of all important concepts in mathematics. In fact, these two judgments share an identical misconception about mathematics itself, namely that it really exists only insofar as it corresponds to a particular Western image of theorem and proof. However recent interest in alternative (algorithmic and effective) methods in mathematics, as well as a better understanding of the complex and sophisticated nature of Egyptian civilization, has opened the way for a deeper comprehension of mathematics in the Nile Valley.

The real question is what mathematics represented for the Egyptians themselves, what they aimed at, what structural, intellectual, and sociological activities were connected with their mathematics. The Egyptians left us no philosophical or self-reflexive works commenting on their own activity; the nature and role of Egyptian mathematics must be pieced together from such texts as administrative and accounting documents, historical annals, and, above all, school texts.

We have, in fact, astonishingly few sources: the choice of excavation sites and the fragility of papyrus under humid conditions means that most written documents come, almost exclusively, from cemeteries and temples in the desert fringe along the Nile valley and only rarely from towns or cities in the fertile band around the Nile and its Delta. In addition, mathematical texts are particularly rare – some five papyri, mostly fragmentary, a pair of wooden exercise tablets, and a small inscribed stone flake. Moreover, with the exception of the last, all the texts are originals or copies dating from the same period, the Middle Kingdom between 2000 and 1700 BCE. The accounting documents are a little more plentiful and from a more balanced time span, but not all have been published and those that have still await a study of the mathematical techniques used in their fabrication.

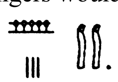
But there are some things that we do know. In Egypt, there were no centers of mathematical research in the modern sense, no journals or books exposing new results. There is not even an Egyptian word for "mathematics" in our sense: the only two Egyptian titles of mathematical school books that have come down to us are "The right method for entering into things, for knowing everything that is, every obscurity, …, every secret" (Rhind Mathematical Papyrus) and "The right method in matters of writing (?)" (Kahun Papyrus LV.4).

However, Egypt, like almost all societies, needed to create computational skills, to count and keep track of the collection and distribution of material wealth. Indeed, writing in Egypt was created precisely to make permanent records of these numerical data; the earliest signs were used to indicate metrological values along with the titles and proper names of those from whom came and to whom were to be delivered this wealth; mathematics and writing were linked from the very start and were the staple of Egyptian educational training. In particular, the mathematical texts we possess – including the Rhind Mathematical Papyrus – are school textbooks. So it is to the world of apprentice scribes and their teachers that we must look for an understanding of Egyptian mathematics.

Numbers

The third millennium had seen the development of some eight or nine distinct metrological systems – a discrete system, used for counting individual objects; a length system; an area system, used for measuring field surfaces; a distinct system for surfaces of linen; a capacity system for grain, and a weight system for measuring precious metals. The signs used to write the units of each system differed among themselves, as did the ratio between successive units in each system. In all cases though the Egyptians used an additive system of notation, in which a unit was repeated as many times as necessary to express the value desired.

For example, the discrete system is decimal in structure while the length system has four fingers to the palm and seven palms to the cubit. Thus whereas 14 goats would be written with 1 ten and 4 ones – written – a length of 14 fingers would have three palms and two fingers:



By the time of the Middle Kingdom, there is a distinct rationalization of these systems. Some, such as that for linen, simply disappear; some, such as that for lengths, are simplified. In the mathematical texts, all arithmetical operations are performed in the discrete system, now employed as a universal calculational system; an abstract concept of number is born. The discrete system being decimal, the base 10 became the standard. A significant part of mathematical training was devoted not only to learning how to perform mathematical calculations in the decimal system but also to mastering the conversions into and out of the surviving, nondecimal metrological systems.

The Mathematical Texts

The careful organization of the mathematical papyri reflect their pedagogic nature. They are constituted of numerical tables (to which we shall return) and solved problems: each problem is expressed in ordinary language with no symbols aside from the numbers themselves. The data and the results are given as concrete numerical values, and the solutions presented in the form of algorithms, that is a specific sequence of steps leading to the solution, generally followed by a numerical verification of the result obtained.

The subjects of the problems in the mathematical papyri touch on arithmetic calculations involving distribution of rations, work assignments, and the conversion of quantities of grain into beer and bread; mensuration problems involving the determination of volumes of circular and rectangular containers, areas of triangular, rectangular, and circular fields, slopes of pyramidal and conic constructions, and parts of ships, as well as others. The problems are roughly grouped by subject but, more precisely, by the type of algorithm used in their solution. Each group of problems is a series of exercises in the learning and use of an algorithm.

A typical example is given by the following Problem 26 of the Rhind Mathematical Papyrus; the words in red ink in the original are given in bold-face; the numbering of the steps of the algorithm and phrases in square brackets are my additions:

A quantity; its 1/4 is added to it. It becomes 15.

1. Calculate starting from 4; you will make its 1/4: 1.
2. [Add them together.] Total: 5.
3. Calculate starting from 5, to find 15.

   \1 5
   \2 10
   3 is the result.

4. Calculate starting from 3, 4 times.

   1 3
   2 6
   \4 12
   12 is the result.

The quantity: 12. Its 1/4: 3. Total: 15.
[Verification]

1 12
[1/2 6]
1/4 3
Total: 15.

It is important, in order to understand Egyptian mathematics, that each problem in a mathematical text operates on three distinct levels. The first is the global strategy used, embodied by the *algorithm* and is the same for all problems in a group. In our example it is the common Egyptian method, now called "false position." A (false) solution is supposed, in our example 4; the result of calculation with this value (steps 1 and 2) is compared to the true answer (step 3) and the original choice corrected by the necessary factor (step 4).

The second level is that of arithmetical *operations:* addition, subtraction, multiplication, division, square root extraction, etc., each of which corresponds to one step of the algorithm. It is introduced by a standardized formulation and includes a numerical computation. In our example, step (4) is a multiplication: as always indicated by "Calculate starting from *N*, *M* times"; likewise, step (3) is a division.

The third level is that of *techniques*, that is the set of means for carrying out the operation. Here the Egyptian scribe had a wide range of choices. For the simple operations of addition and subtraction (see step 2 in the example), no details were shown; the scribe was presumed to be able to do these without such aids. In the case of multiplication and division, the computations show what was done.

The multiplication of step (4), in our example, 3 × 4, is carried out in the following manner: starting with the first multiplicand, 3, in the right-hand column and 1 in the left, the scribe seeks the value of the second multiplicand, 4, in the left-hand column (since this is multiplication); in this case, the scribe obtains the columns directly by two successive uses of the same technique, namely *doubling*. The 4 is marked and the answer, 12, read off in the opposite column.

The division of step (3), 15 + 5, is carried out by putting the divisor 5 in the right-hand column, facing 1, and then, after a single doubling, finding the dividend, 15, in the right-hand column (since this is division), the sum of the two entries. Both are checked and the answer, 3 = 1 + 2, read off as the sum of the corresponding entries in the left-hand column.

Note that though the two operations, in the particular case treated here, are the inverse of each other, the only technique used to effect both of them is doubling. However, the Egyptian scribe was not limited to this single technique; others, such as halving (illustrated in the verification step of our problem), multiplying or dividing by 10, multiplying by 2/3, inversing, etc. were equally available. Given a particular arithmetic operation, the scribe chose the set of techniques appropriate to the numerical values in play.

Tables and Fractions

Fractions played a particular role in Egyptian mathematics. A fraction was viewed as the inverse of an integer; there could thus be only one fraction associated with a given integer *N:* namely, what we call the "unit fraction" 1/*N* – there being a single exception, the fraction 2/3. These fractions were manipulated in precisely the same way as integers, using the same panoply of techniques.

Only one fraction of a given kind could be used in the writing of a given number. Thus, for example, the double of the number 1 + 1/5 was not written 2 + 1/5 + 1/5 but rather 2 + 1/3 + 1/15. Finding such expressions is a centrally difficult problem: it occurs each time it is necessary to double an "odd" fraction, calculate two-thirds of a fraction, or add fractions together. It constitutes the core area of Egyptian mathematics, and furnishes the content of Egyptian mathematical *tables*. Such difficult calculations could be done once and for all and the results simply copied and looked up when the need arose in the solution of a specific problem.

The problems in Egyptian mathematical texts were chosen in order to cover the domain of the possible by a *network of typical examples*, a process which permitted the student (and later the practicing scribe) to place any new problem in this framework. The Egyptian approach to the question of generalization was not the discovery and application of a "general formula" in which each case might be enveloped, but rather through interpolation in a pattern of known results – a method equally used in some branches of mathematics today.

If Egyptian mathematics is viewed not as a poor simulacrum of proof-oriented mathematics, but on its own ground, it will be seen as an adequate and rational response to the socioeconomic and educational needs of Egyptian society. Mathematics even provided a model of a rational practice, equally applicable to other domains, wherever an efficient mode of action on the world was needed. Egyptian medical texts, for instance, were constructed in the same manner, with tables of remedies and a systematic network of procedural prescriptions.

This approach was not unique to Egypt; one finds analogous underlying principles at work in the mathematics of other civilizations, such as Mesopotamia, China, and India. It is not a question of borrowing; the mathematical traditions in question developed too early and were too widely geographically spread for this. Rather it shows the success of this algorithmic approach to the solutions of the problems posed by sufficiently advanced societies.

These different civilizations differed in their choices of number system, of modes of writing, of arithmetical operations, as well as the techniques used to carry these out. And the differences determined in turn the very different paths of development that mathematics knew in each society. If similar needs led to similar responses on the fundamental level, the different ways of implementing them created very different mathematics.

Mathematics in Egypt: Egyptian Mathematics and African Predecessors – New Insights from Work Sites

Beatrice Lumpkin

Recent archaeological digs have uncovered Middle Stone Age (MSA) artifacts that root the origin of modern behavior in Africa. The MSA dates from 200,000 BP to 40,000 BP (Before the Present). These recent finds upset the textbook theory that places the origin of modern behavior in Southern France and Spain, only 30,000–40,000 years ago. Modern behavior includes abstract thinking and symbolic representation, essential features of mathematical thinking. It also includes designing sophisticated tools and making plans for the future.

Reports of these MSA finds include stone blades from Kenya by McBrearty (1995), basalt tools from Tanzania by Adelsberger (2002), barbed harpoon points from the Democratic Republic of the Congo by Yellen, Brooks et al. (1995) and engraved designs from South Africa by Henshilwood et al. (2002). The Kenyan stone blades came from a formation over 200,000 years old and were shaped before they were knocked off the rock core (Gutin 1995). This required planning by toolmakers who had an abstract picture in their minds of the desired tools. If the toolmakers were anatomically modern *Homo sapiens*, they were among the earliest of their species. Modern humans are believed to have evolved in Africa about 150,000–200,000 BP and migrated to Australia and possibly East Asia by 50,000 BP.

In about 200,000 BP at Laetoli, Tanzania, raw material used by "archaic" *Homo sapiens* was transported from sources at least 20–30 km distant. The ancient toolmakers made a round trip to obtain the stone or some type of trade took place. The basalt from the more distant sites provided a better cutting edge than the local finer-grained rock. The author of the study wrote, "…apparently the archaic Homo sapiens of the Laetoli region comprehended these attributes as early as 200,000 years ago" (Adelsberger 2002).

At the somewhat later MSA site of Katanda in the Democratic Republic of the Congo, archaeologist Yellen was disappointed when he found a barbed harpoon point. He had hoped the site dated back as far as 70,000 BP. But the bone point was so finely crafted that it resembled European harpoon points that were only 14,000 years old. Disappointment changed to joy when the bone point was dated to ca. 90,000 BP. The Katanda materials included barbed bone points, unbarbed points, and a flat dagger, products of a formal bone industry. Although the Yellen team used three different techniques to date their finds, some archaeologists continue to dispute the date (Yellen et al. 1995) (Fig. 1).

However, sophisticated tools may not be enough to identify modern human behavior. The record was missing what Christopher Henshilwood et al. described as "evidence of abstract or depictional images" (Henshilwood et al. 2002). In 2002, they recovered two engraved pieces of ochre from MSA layers in Blombos Cave in South Africa, dated to 77,000 BP. One piece is inscribed with a design, a row of cross hatches, framed by two horizontal lines and bisected by a third. The second piece has fewer lines but indicates that the design on the first piece is not unique.

Why was the African evidence for sophisticated tool technology in the MSA not discovered sooner? Archaeologists now working in Africa have a simple explanation:

Mathematics in Egypt: Egyptian Mathematics and African Predecessors – New Insights from Work Sites. Fig. 1 A barbed harpoon point from Democratic Republic of Congo. After Chip Clark. *Science* 268, 28 April 1965: 495.

M

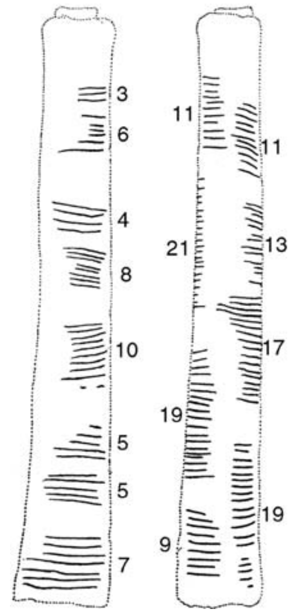
nobody had really bothered to look for it. "In France alone there must be three hundred well-excavated sites dating from the period we call the Middle Paleolithic," archaeologist Alison Brooks said. "In Africa there are barely two dozen on the whole continent" (Shreeve 1992).

Language is also a factor in the development of mathematics. The logical concepts needed for mathematics are built into all languages, as Karl Menger pointed out in his lectures. For example, all known languages have words for "or," for "and," and for counting numbers. By its nature, the development of language has left no records for archaeologists to excavate. However, numerical records have been found from soon after the MSA. The oldest known to date was found in Border Cave in Southern Africa and has been dated to ca. 37,000 BP. It is a fossilized baboon bone inscribed with 29 tally marks. Similar records are still made by San peoples of Southern Africa to record the lunar cycle (Bogoshi et al. 1987). Alexander Marshack gives examples of this type of tally record from many parts of the world (Marshack 1991). By the time anatomically modern humans left Africa, they may have been counting as well as making relatively sophisticated tools.

Trade played a very important role in the development of early mathematics. No direct evidence is known for a trade in chert, a flint-like quartz that was mined in large quantities in Southern Egypt ca. 33,000 BP. However, the quantities mined appear greater than the needs of local consumption. The miners used complex techniques not known in other parts of the world before 10,000 BP. Also, a grave at the mine site contained the remains of a young miner, buried with his mining tool. Burial goods and advanced mining techniques suggest cultural development at 33,000 BP (Vermeersch et al. 1984).

A Central African fossilized tally record, known as the "Ishango Bone," has excited discussion because it is more complex than the Border Cave fossil. First studied in 1950, the bone was recently redated back to 20,000–25,000 BP. The Ishango bone shows tallies on one edge for 3, 6, space; 4, 8, space; 10, space; 5, 5, space; 7. The other side is marked on one edge, 11, 13, 17, 19, and on the other edge, 11, 21, 19, and 9 (Zaslavsky 1999: 18). A number of hypotheses suggested that these number sequences were more than a simple count. Many harpoon points were also found at the site. This harpoon point technology spread to other parts of Africa, including the Nile Valley. Although not proof, it is suggestive of an Ishango input to the later Nile Valley civilizations (De Heinzelin 1962) (Fig. 2).

Some 15,000–20,000 years passed between the time of the Ishango bone and the first pharaohs who ruled all of Egypt. Although the record is sketchy, there were many advances made in the period before the pharaohs. Rock drawings from Nubia and Southern Egypt show ships with large crews, implying extensive trade. Evidence of early measurement systems predates writing and embodies a whole corps of mathematical knowledge. For example, Flinders Petrie reported a red limestone balance beam and sets of graduated weights from Southern Egypt, dated to Naqada I, 4500–4000 BCE. The weights are multiples of a base weight, showing that the concept of ratios was already well developed (Petrie 1920: 28, also 1926: 18).



Mathematics in Egypt: Egyptian Mathematics and African Predecessors – New Insights from Work Sites. Fig. 2 Ishango Bone, diagram (DeHeinzelin 1962: 114).

In 1998, archaeologists reported a 6,000-year old Stonehenge-type arrangement of large stones at Nabta Playa in Southwestern Egypt. They described a "calendar" circle with stones that align with the summer solstice of 6,000 years ago (Wendorf and Schild 2000). By 3200 BCE, hieroglyphic numerals were in use. An engraving on a knife handle clearly shows a numeral for 3,000 and other numerals are indicated (Williams and Logan 1987). The prehistory of Egyptian mathematics was coming to an end and the dawn of literacy had begun.

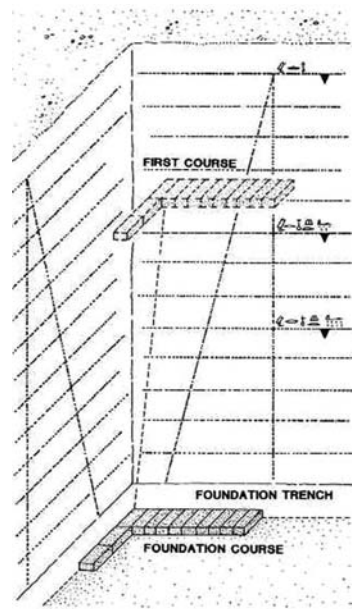
Egypt of the Pharaohs

The mathematical insights, discussed below, were gleaned from artifacts found at pyramid and temple work sites. They have not yet appeared in the textbooks on the history of mathematics. These insights include the use of rectangular coordinates and construction lines labeled with integers and a zero reference point. The same symbol used to label the zero reference point was later used to show zero remainders in a bookkeeping papyrus.

The period of building great pyramids began in Egypt ca. 2700 BCE. Thanks to the findings of Egyptologists such as Dr. Zahi Hawass and Mark Lehner, the Hollywood image of slave labor building the pyramids has been discredited. It is now known that the pyramid builders were well fed and were paid wages. There was a demand for mathematical and engineering skills. Scribes trained in mathematics kept accounts for thousands of workers, maintained the Egyptian calendar, and used a canon of proportions for paintings and statues of kings and nobles.

No mathematical texts are among the surviving papyri from that period. So we must study the pyramids, themselves, to learn about the mathematics used in pyramid design. Because they were so massive, pyramids and the large tombs called *mastabas* required careful leveling to prevent collapse. They also used deep foundations. For leveling purposes, the Ancient Egyptian architects created a system of guidelines with horizontal lines spaced one cubit apart. To locate exact distances below and above ground level, they placed a vertical line on the grid of horizontal lines. A zero reference level was used, often near pavement level, and labeled *nfrw*. (Egyptian hieroglyphic writing omitted vowels so the vowel sounds are not known.) Other points on this vertical line were labeled with the number of cubits above nfrw or below nfrw. In effect, these architects created a number line with a zero reference point and directed, or signed integers.

An example of these number lines appears to the right. These lines can still be seen in a foundation trench at Mastaba 17 in Meydum, Egypt. Horizontal, leveling lines were drawn on the wall of the trench, spaced 1 cubit apart. A vertical line intersected the horizontal lines. Some points of intersection were labeled with “nfrw” for ground or zero level, “5 cubits below nfrw” and “8 cubits below nfrw.” No labels are seen for “above nfrw” because the higher lines were not preserved. But at the nearby Meydum pyramid, there are leveling lines marked “6 cubits above “nfrw” and “8 cubits above “nfrw.” Dieter Arnold believes the vertical lines were “used not only for horizontal measuring, but also for marking directions” (Arnold 1991: 17, 18) (Fig. 3).



Mathematics in Egypt: Egyptian Mathematics and African Predecessors – New Insights from Work Sites. Fig. 3 Construction lines with zero reference (Arnold 1991: 12).

These findings contradict the oft-repeated statement that, “The Egyptians did not have a zero” (Bunt et al. 1976: 7). It is true that Egyptian numerals were additive, without place value. There was no need of a zero placeholder. But nfrw for zero level was noted by Egyptologists 100 years ago. Also, the related Egyptian word, *nfr*, was used for the zero remainder on the balance sheets of a bookkeeping papyrus. That papyrus is now known as Bulaq 18, written by the scribe Neferhotep, ca. 1700 BCE.

Neferhotep and his assistants recorded each day’s receipts and disbursements of supplies for the Pharaoh and his traveling court. For each type of goods, the sum of the disbursements was subtracted from the sum of the receipts to get the balances. On Day 1, Month 3 of this account, disbursements equaled receipts in four of the eight columns. Subtraction left zero remainders. The scribe wrote the zero quantity as nfr. Nfr had several meanings. In notes collected by Egyptologist Aayko Eyma, he writes:

> This nfr particle means ‘be at an end,’ ‘finished,’ ‘be zero(?),’ and occurs in constructions like nfr n (+ verbal form) ‘not,’ r-nfr n ‘so that not,’ and nfr pw ‘there is not.’ Some think the word nfr, ‘beautiful,’ ‘good,’ is unrelated but others believe that it may be related, in the sense of ‘perfect,’ ‘ultimate’ or ‘final state’ (Lumpkin 2003).

Scharff, the first European to publish Bulaq 18 (in 1922), translated the Egyptian numerals as Indo-Arabic numerals. Naturally, he knew that 52–52 left a remainder of 0 and that 7–7 = 0. But instead of writing zero, he wrote nfr, with no translation. In his comments, he described these remainders as “*das glatte Aufgehen*,” the flat or even outcome (Scharff 1922). Perhaps he did not want to challenge the established belief that “the Egyptians did not have a zero.” The great Egyptologist, A. Gardiner, in 1927 gave “zero” as the meaning of nfr(w) and “perhaps” zero as a meaning of nfr (Gardiner 1978: 266, 574). A later writer, Spalinger, had no problem with translating the nfr balances as “0” in his 1985 translation of Bulaq 18 (Spalinger 1985: 12). It appears that the Egyptians had a zero, after all.[1]

Few construction plans have survived the thousands of years since the time King Djoser’s step pyramid was built at Saqqara ca. 2700 BCE. Fortunately, an architect’s detail was found next to a domed structure inside the pyramid complex. The plan, inscribed in red ink on a limestone flake, shows a curve. Evenly spaced vertical lines, a cubit apart, give horizontal coordinates while hieroglyphic numerals state the vertical coordinates for points on the curve. Archaeologist Gunn plotted these points and connected them with a smooth curve. He reported in 1927 that the curve matched the curvature of the domed structure nearby (Gunn 1926). Somers Clarke and Engelbach, in their classic on Ancient Egyptian construction, called this early use of coordinates “of great importance” (Clarke and Engelbach 1930: 52–3). To date, this achievement remains little known, perhaps because it does not appear in the surviving papyri (Lumpkin 2002).

Pairs of construction guidelines may have provided axes for rectangular coordinates to locate points on pyramid walls. As early as 1865, Richard Lepsius recorded such systems of horizontal and vertical guidelines. The horizontal guidelines were labeled with the number of cubits from “a foundation line,” much as at Mastaba 17, shown in Fig. 3. In a chamber at Khufu’s great pyramid, Lepsius noted a pair of vertical lines intersecting a horizontal line. The line to the left was marked “3.” In fact, that line measured 3 cubits from the vertical line to the right (Lepsius Trans. 2000: 11–13). Since there were both horizontal and vertical reference lines, it is possible that rectangular coordinates were used to locate points of interest during the construction.

Khufu’s pyramid at Giza presents a special challenge in the study of the mathematics and technology used in construction. It is best know for its massive size, covering an area as large as eight football fields. The pyramid measured over 230 m each side and stood 146 m high. Many wonder how these pyramid builders, without modern machines, moved more than two million stones, some weighing 50 tons. But the greater challenge is to explain the extreme accuracy of the 90° angles that varied less than 1/15 of 1°. And what technology did they use to level the foundation platform to within 2.1 cm? How were the walls so closely aligned to the cardinal points?

Egyptologists are divided about how the builders found true North, whether they used star light or sun shadows. Either method required an accurate circle and bisection of an angle. Writers have suggested that leveling was accomplished by flooding the area inside a closed wall. But the pyramid was built on a sloping plateau with a rocky massif that became part of the pyramid. Leveling by water was not an option, Lehner concluded. He studied a double line of holes parallel to the sides of Khufu’s pyramid. It is possible, Lehner writes, that stakes were placed in these holes to support a cord used as a reference level (Lehner 997: 214–219).

Many have tried to explain how the Egyptians achieved such accurate square corners. Some Mozambicans and the Kpelle of Liberia compare the length of the diagonals of the base to check square corners for their traditional homes. But the rocky massif precluded this method at Khufu’s pyramid. It is possible that the pyramid builders used the right-triangle theorem to set nearly perfect square corners. There are reports of 3–4–5 triangles in the design of Old Kingdom temples but Lehner finds the evidence inconclusive.

Some have suggested that intersecting arcs were used to construct a perpendicular, using a cord as a compass. The accuracy of this method has also been questioned. Another method relies on tools invented by Ancient Egyptians. These included square levels, set squares and plumb bobs. A rough perpendicular line could be drawn with the set square. Flipping the square around that line would give a slightly different perpendicular. A more accurate perpendicular would be the line halfway between the two rough perpendiculars. Again, many believe that this method could not produce the accuracy achieved by the Ancient Egyptians.

Another difficult problem solved by Egyptian pyramid builders is less obvious. How did they manage to bring the four sides to a central point at the top? Knowledge of the slope of a pyramid is well attested in the *Rhind Mathematical Papyrus*, Problems 56–60. Actually, they used inverse slope, the ratio of run to rise. For Khufu’s pyramid, it was 14–11. This ratio must be kept constant to achieve the smooth sides of the pyramid. Lehner writes, “There is evidence that guidelines marking the plane of the pyramid face were cut into each casing block...” Also, Lehner has found possible postholes for markers to serve as backlights to align the pyramid axes and diagonals. This followed an earlier suggestion by Clarke and Engelbach. Further mapping of holes and marks around the pyramid may supply more insight into the Egyptian method of controlling the run to rise ratio (Lehner). It is hoped that continued exploration of African work sites will yield other exciting discoveries about our mathematical forerunners.

[1] Bulaq 18 is discussed in more detail in Lumpkin 2002. I thank Frank Yurco for his kind help with Bulaq 18 and other sources for the zero concept in Ancient Egypt.

Mathematics in Egypt: Mathematical Leather Roll

Milo Gardner

Henry Rhind purchased the 10″ × 17″ leather roll in 1858. It was sent to the British Museum in 1864, but was not chemically softened and unrolled until 1927 (Scott and Hall 1927).

Middle Kingdom hieratic characters were written right to left. There are 26 rational numbers listed. Each rational number is followed by a series of equivalent unit fractions.

There are ten binary rational numbers: 1/2, 1/4 (twice), 1/8 (thrice), 1/16 (twice), 1/32, and 1/64. There are seven other even rational numbers: 1/6 (twice – but wrong once), 1/10, 1/12, 1/14, 1/20, and 1/30. Finally, there are nine odd rational numbers: 2/3, 1/3 (twice), 1/5, 1/7, 1/9, 1/11, 1/13, and 1/15.

The British Museum examiners found no introduction or description of how and why the equivalent unit fraction series were computed (Gillings 1981: 456–457). A series of equivalent unit fractions is associated with the fractions 1/3, 1/4, 1/8, and 1/16. There is a trivial error associated with the unit fraction series total of 1/15. It is listed as 1/6. A serious error is associated with the rational number 1/13, a problem that the examiners did not resolve.

The *British Museum Quarterly* (1927) naively reported the chemical analysis to be more interesting than the Egyptian mathematical leather roll's (EMLR's) additive contents.

The binary fractions are now seen to be restatements and improvements to the older Horus-Eye numeration system. Horus-Eye arithmetic employed an infinite series numeration system that used "decimal fractions" similar to our present decimals (Ore 1948: 311–325). Note the Horus-Eye definition for the number 1

$$1 = \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \frac{1}{64} + \cdots,$$

with the last term 1/64th being thrown away (Gillings 1972: 210).

Another Middle Kingdom text, the *Rhind Mathematical Papyrus* (RMP), mentioned the use of six additional significant digit fractions, called *ro*. Ro units were used in volume calculations reducing the Horus-Eye error to 1/4,096.

Note that Babylonian scribes wrote in an expanded base 60 system before the Egyptian hieratic system appeared. Babylonian numeration also used properties of "decimal fractions." Babylonian numeration was written within a positional notation similar to the modern decimal system. Babylonians attempted high accuracy, minimizing error to 1/3,600 for two terms and 1/216,000 for three terms. However, for inverse prime numbers, Babylonians rounded off when writing their equivalent unit fraction series, thereby seriously degrading their system's accuracy (Robson et al. 2003).

Because the Middle Kingdom arithmetic was written in an unusual exact series context, modern researchers frequently minimized the EMLR's significance. One minimal aspect is that the older Horus-Eye system's accuracy may at first have been superseded in only special situations. Several ancient texts, the Akhmim Wooden Tablets, Berlin, Kahun, Moscow, and Reisner papyri, are read in this low content manner. However, the EMLR and RMP demonstrate generalized ways to convert any rational number to a concise unit fraction series. Therefore, the EMLR and RMP abstract arithmetic could have been seen in 1927 as having been standardized, thereby superseding both its additive Horus-Eye parent and its nearby competitor Babylonian base 60. Arguably the more accurate system provided more than "bragging rights" to Egyptian science and trade.

Restating the problem of fairly reading the EMLR, a process that took over 75 years, the majority of its early examiners strongly suggested that it contained only simple additive information. Over 60 years would pass before a higher systemized form of arithmetic began to be parsed from the EMLR and RMP data (Gardner 1995, 2002).

The following chronology shows several of the events along the road to understanding Egyptian abstract arithmetic.

For example, Ahmes, the RMP scribe, mentally computed:

$$
\begin{aligned}
&2/(pq) = 2/21, \text{where } p = 3,\ q = 7,\ A = (3+1)\\
&\text{such that}: 2/21 = 2/(3+1) \times (3+1)/21\\
&\qquad = 1/2 \times (3/21 + 1/21)\\
&\qquad = 1/2 \times (1/7 + 1/21)\\
&\qquad = 1/14 + 1/42
\end{aligned}
$$

Cryptanalysis has parsed five categories (a–e) from the EMLR's 26 equivalent unit fraction series. Three are identities (a–c) and one (d) is a remainder. The first four categories have been basically understood since 1927. However, one (e) is an algebraic identity. The algebraic identity form had escaped detection and confirmation for over 75 years. The five methods are explained below (Gardner 2002).

For example, the EMLR student set $p = 1$, $q = 8$, $A = 25$ such that

$$
\begin{aligned}
1/8 &= 1/25 \times 25/8\\
&= 1/5 \times 25/40\\
&= 1/5 \times 5/8, \text{ with}\\
5/8 &= 1/5 + 1/3 + 1/15 + 1/40
\end{aligned}
$$

may have been mentally computed by:

$$
\begin{aligned}
5/8 - 1/5 &= (25 - 8)/40\\
17/40 - 1/3 &= (51 - 40)/120\\
11/120 &= (8 + 3)/120\\
&= 1/5 \times (1/5 + 1/3 + 1/15 + 1/40)\\
&= 1/25 + 1/15 + 1/75 + 1/200
\end{aligned}
$$

Interestingly, the EMLR's four values for A (4, 5, 7, and 25) did not optimize its fraction series in a manner comparable to the RMP 2/*n*th table's entries. The EMLR's partitioning *A*s are therefore considered to be a RMP training technique. The serious error 1/13th could have been resolved by methods (c), (d), or (e). The error was related to a failed attempt to apply method (e). Math historians have titled a closely related "pick a number" method, found in the RMP, as "false position" (Eves 1961: 40).

The EMLR has been proven to be a student's introduction to an innovative numeration system. The improved Middle Kingdom arithmetic easily converted any rational number, after employing a factoring process, to a concise, optimal and exact series of unit fraction statements. This subtle conclusion was difficult to reach for a number of reasons, the greatest one being the small collection of surviving fragments of Middle Kingdom texts. Seen in its most basic terms, the EMLR was the most elementary of the 2000–1650 BCE abstract arithmetic texts.

Mathematics of the Hebrew People

TONY LÉVY

A "Hebrew mathematical text" is any text or work whose language is Hebrew (usually written in Hebrew characters), and whose content is mathematical in a narrow sense, that is, does not include astronomy (apart from relevant mathematical sections), astrology, or calendar calculations.

Apart from a few passages that are to be found in biblical and postbiblical (rabbinical) literature and which are relevant to the history of mathematics (number words and fraction words, practical rules of geometry), the oldest mathematical tract in Hebrew is the *Mishnat ha-Middot,* by an unknown author. This tract gives practical rules for the measurement of areas and volumes, and then deals with the measurements (*middot*) of the Tabernacle erected by the Jews in the desert. It has been recently shown that its composition was probably influenced by the geometrical part of al-Khwārizmī's *Algebra.* This tract remained unknown to most medieval Jewish scholars and its Hebrew mathematical terminology was of no consequence.

Two famous scholars are central in the eleventh and twelfth centuries in Spain: Abraham bar Hiyya (ca. 1065–ca. 1145) and Abraham ibn Ezra (1092–1167). This period saw the actual birth of Hebrew mathematics.

Abraham bar Hiyya, also called Savasorda (latinized from the Arabic *Ṣāḥib al-shurta*), flourished in Barcelona in Christian Spain, but was probably educated in the Arabic kingdom of Saragossa. Bar Hiyya wrote books in Hebrew on mathematics, astronomy, astrology, and philosophy. He clearly indicated that his Hebrew compositions were written for Jews living in southern France (in Hebrew, *EreṣSarfat*) who were unacquainted with Arabic scientific culture and unable to read Arabic texts. Bar Ḥiyya can thus rightly be considered the founder of Hebrew scientific culture and language, and specifically the father of Hebrew mathematics. We know of two mathematical compositions by Bar Ḥiyya: the extant parts of a scientific encyclopedia and a geometrical compilation.

The first of these books, *Yesodey ha-Tevuna u-Migdal ha-Emuna* (The Foundations of Science and the Tower of Faith), is presumably an adaptation from some unknown Arabic composition; the geometrical and arithmetical parts are extant. The study of its content sheds some light on eleventh century mathematical literature in Western Islamic lands and its diffusion.

The *Ḥibbur ha-Meshiḥa we ha-Tishboret* (The Composition on Geometrical Measures) enjoyed a very large diffusion as the *Liber embadorum* in its Latin translation by Plato of Tivoli (1145). Much has been said by ancient and modern scholars concerning the importance of this text for traditions of practical geometry in Europe.

Abraham ibn Ezra was born in Tudela in Aragon. Raised in Arabic culture, and probably knowing Latin, Ibn ᶜEzra spent the last part of his life traveling over Europe. He was a poet, a grammarian, an astronomer–astrologer, and a biblical commentator of great reputation. Ibn Ezra, one generation after Bar Ḥiyya, also created a new scientific language, different from that of his predecessor, closer to biblical Hebrew and less influenced by Arabic. His mathematical work consists essentially of the important book *Sefer ha-Mispar* (The Book of Number), but numerous arithmetical and numerological remarks are scattered in his others works, including his biblical commentaries.

His *Book of Number,* written probably before 1160, expounds for the first time the decimal positional notation including zero. The foundations of arithmetic are then discussed in the following order: multiplication, division, addition, substraction, fractions, proportions, and square roots.

In the thirteenth and fourteenth centuries, the works of both Abrahams opened up to the Jewish communities unfamiliar with Arabic access to basic mathematical knowledge. They obviously mention the names of classical authors, Greek or Arabic, and of their works, but these works themselves only became partly available in Hebrew during the thirteenth century. This first major period of translations continued until the first third of the fourteenth century.

Several of the translators were members of a single family of scholars. The first, Yehuda ibn Tibbon, left Granada in the middle of the twelfth century, at the time of the arrival of the Almohads in al-Andalus, and settled in Lunel in the south of France. There, he undertook the translation into Hebrew of ethical and philosophical works written in Arabic by Jewish scholars from Spain. His son, Samuel ben Yehuda, translated the famous *Guide for the Perplexed* of Maimonides from Arabic into Hebrew. The third and fourth generations of this family include translators of scientific works.

Thus, Jacob Anatoli (ca. 1194–1256), working in Italy under the patronage of Frederic II of Sicily, translated Ptolemy's *Almagest* and Ibn Rushd (Averroes)' *Compendium on Astronomy,* lost in the Arabic original. According to recent findings, he is perhaps the first translator into Hebrew of Euclid's *Elements.* Moses ben Samuel ben Yehuda of Montpellier (active between 1240 and 1283) translated, among others things, works by Euclid (*The Elements*), Theodosius (*Sphaerics*), al-Fārābī (The Commentary on *The Elements*), Ibn al-Haytham (The Commentary on *The Elements*), and al-Ḥaṣṣār (The so-called *Arithmetic*) Lastly, Jacob ben Makhir of Montpellier (ca. 1236–1305) also translated works by Euclid (*The Elements,* the *Data,* and perhaps the *Optics*), Autolycus of Pitane (*On the Moving Sphere*), Menelaus (*Sphaerics*), Jābir ibn Aflah (*Astronomy*), and Ibn al-Haytham (*Astronomy*).

To this period belongs a Jewish scholar from Toledo, who also had contacts with Frederic II of Sicily during the first half of the thirteenth century. Yehuda ben Solomon ha-Kohen (probably b. 1215) wrote in Arabic a (lost) encyclopedia of sciences, which he translated himself into Hebrew, *Midrash ha-ḥokhma* (The Learning of Wisdom). This book includes a redaction, or free translation, of Euclid's *Elements* (Books I–VI and XI–XIII).

A generation after Jacob ben Makhir, Qalonymos ben Qalonymos (Maestro Calo) of Arles (b. 1287) translated Archimedes (*The Sphere and the Cylinder* and the commentary upon it by Eutocius, perhaps also *The Measurement of the Circle*), Nicomachus of Gerasa (a lost Arabic paraphrase of the *Introduction to Arithmetics*), Thābit ibn Qurra (on the *Figura Sector* of Menelaus), Jabir ibn Aflaḥ (on the same problem, a text apparently lost in Arabic), and Ibn al-Haytham (a part of the commentary on *The Elements,* already translated in part by Moses ibn Tibbon). Qalonymos also translated several texts for which the original Arabic has not yet been identified, or is now lost: thus we have important fragments of a *Treatise on Cylinders and Cones* by Ibn al-Samḥ of Granada (eleventh century), perhaps extracted from a larger book of this Andalusian scholar. Qalonymos is also probably the author of an important mathematical and philosophical composition on the nature of numbers, the *Sefer ha- Melakhim* (The Book of Kings).

Thus, we possess more or less complete Hebrew versions of the treatises of the following classical authors: Euclid, Archimedes, Autolycus, Theodosius Menelaus, Ptolemy, Nichomacus. The conspicuous absence of the name of Apollonius does not mean that he was not known to the Jewish scholars.

The diffusion of the Hebrew versions of important mathematical works created the conditions for the composition of original works by Jewish scholars who were also excellent astronomers. This, at least, is the case of two scholars that we will mention here, as much for the depth of their talent as for the importance of their works. Levi ben Gershon, also called Gersonides (1288–1344) is the author of an important mathematical work. His writings on harmonic numbers (extant only in a Latin translation), on arithmetic and combinatorics (*Ma'aseh Ḥoshev,* Work of the Reckoner), and on the geometry of Euclid have been recently studied from the point of view of their contents, of their Arabic and perhaps Latin sources, and their possible influence on later works.

Immanuel ben Jacob Bonfils of Tarascon, one generation after Gersonides, must be mentioned in connection with two mathematical areas: that of the introduction of decimal fractions, and that of calculations related to the measurement of the circle. The sources and the scope of his developments in both areas have not yet been fully investigated.

In fifteenth-century Italy, there were a number of translators and commentators of note. The movement toward Italy is not only geographical: the Hebrew texts which we possess, and which have been only partially studied, show an increasing influence of Latin and also the vernacular languages.

Mordekhai (Angelo) Finzi of Mantua (active between 1441 and 1473) is without a doubt the best known of these translator–scholars. He translated several compositions of Abū Kamīl (a tenth-century Arabic scholar); he seems also to have been the translator (or perhaps the author) of a compendium on geometry in eleven chapters. Finzi is the author of a *Ma'amar be-Ḥeshbon Medidut ha-Gigiyyot we ha-Ḥaviyyot* (Treatise on the Measurement of Buckets and Barrels) in which he quotes Bar Ḥiyya and "the masters of the abacus," and whose analysis should yield useful clues on the history of stereometry before Kepler. Finally, we must emphasize Finzi's role in the diffusion of algebraic knowledge: in addition to Abū Kamīl's *Algebra,* Finzi translated from Italian or Latin into Hebrew the noteworthy algebraic composition of a certain Maestro Dardi of Pisa (who wrote in the fourteenth century), dealing with complex equations involving powers up to the twelfth degree.

The contacts of Jewish scholars in Italy with those in Constantinople, especially after the arrival of the Ottomans, constitute perhaps one of the channels by which ideas or texts of the Arabic East diffused.

There is also some mathematics of note in the Judeo–Byzantine scholarly world of the fifteenth to sixteenth centuries. The specific interest in studying this scholarly milieu – besides the talents of its representatives – lies in the use made therein of a triple heritage: that of texts available in Hebrew (Bar Ḥiyya, Ibn ʿEzra, the Greek and Arabic classics in translation, Gersonides, etc.), Arabic texts (sometimes not extant in Arabic) not translated into Hebrew but quoted in Hebrew compositions, and finally the Greek–Byzantine texts.

From this point of view, attention of scholars must be drawn to the mathematical works of Mordekhai Komtino (1402–1482) and of his two students Kalev Afendopulo (1460–1525) and Eliahu Mizraḥi (1455–1526).

The *Sefer ha-Ḥeshbon we-ha-Middot* (Book on Reckoning and Measurements) of Komtino shows a direct knowledge of ancient Greek sources such as Hero, and probably also of Byzantine–Greek texts. The *Sefer ha-Mispar* (The Book of Number) by Mizraḥi of which extracts were published in Latin in the sixteenth century, should be analyzed in the light of recent studies on the history of Arabic and Greek–Byzantine arithmetic. Finally, the commentary by Afendopulo of the Hebrew version of Nicomachus' *Introduction to Arithmetics* is a long text which includes several excursuses on philosophy, astronomy, and astrology.

In this very brief – and far from exhaustive – survey of Hebrew mathematics, an attempt has been made to indicate the importance of these texts and to describe their transmission as a general set of mathematical ideas of Hellenistic origin between the eleventh and the sixteenth centuries, that is, before the rediscovery of Greek original texts and the relaunching of activity in the Renaissance.

Mathematics in India

George Gheverghese Joseph

A widely held view is that Indian mathematics originated in the service of religion. Support for this view is sought in the complexity of motives behind the recording of the *Śulbasūtras,* the first written mathematical source dated around 800–500 BCE, dealing with the measurement and construction of sacrificial altars. This view ignores the skills in mensuration and practical arithmetic that existed in the Harappan (or Indus Valley) culture which dates back to 3000 BCE. Archaeological remains indicate a long established centralized system of weights and measures. A number of different plumb-bobs of uniform size and weights have been found that could be classified as decimal, i.e., if we take a plumb-bob weighing approximately 27.534 g as a standard representing 1 unit, the other weights form a series with values of 0.05, 0.1, 0.2, 0.5, 2, 5, 10, 20, 50, 100, 200, and 500 units. Also, scales and instruments for measuring length have been discovered, including one from Mohenjo-Daro, one of the two largest urban centers, consisting of a fragment of shell 66.2 mm long, with nine carefully sawn, equally spaced parallel lines, on average 6.7056 mm apart. The accuracy of the graduation is remarkably high, with a mean error of only 0.075 mm.

A notable feature of the Harappan culture was its extensive use of kiln-fired bricks and the advanced level of its brickmaking technology. While 15 different sizes of Harappan bricks have been identified, the standard ratio of the three dimensions – the length, breadth, and thickness – is always 4:2:1, considered even today as the optimal ratio for efficient bonding. A close correspondence exists between the standard unit of measurement (the "Indus inch" (33.5 mm) and brick sizes, in that the latter are integral multiples of the former. (An Indus inch is exactly twice a Sumerian unit of length (*sushi*). Twenty-five Indus inches make a Megalithic yard, a measure probably in use north-west Europe around 2000 BCE. These links have led to the conjecture that a decimal scale of measurement originated somewhere in western Asia and then spread as far as Britain, Egypt, Mesopotamia, and the Indus Valley.)

This relationship between brickmaking technology and metrology was to reappear 1,500 years later during the Vedic period in the construction of sacrificial altars of bricks. However, a most intriguing suggestion of Subbarayappa is that the Harappan numeration system contains certain similarities with the Kharoṣṭhī and the "Aśhokan" variant of the *Brāhmi* numeration systems which emerged in India about 2,000 years later. He notes the following similarities:

There are identical symbols for the numbers 1–4 and for a 100 in all three numeration systems.

All three were ciphered systems employing a decimal base.

He suggests that deciphering the inscriptions on the large number of excavated seals and other artifacts require that they be recognized as numerical records rather than as literary passages. Given the failure so far to decipher the Harappan script, this approach is certainly worth further examination.

The earliest written evidence in India of a recognizable antecedent of our numeral system is found in an inscription from Gwalior dated "Samvat 933" (AD 876) where the numbers 50 and 270 are given as  and . Notice the close similarity with our notation for 270 showing in both an understanding of the place value principle as well as the use of zero. There is earlier evidence of the use of Indian system of numeration in South East Asia in areas covered by present-day countries such as Malaysia, Cambodia and Indonesia, all of whom were under the cultural influence of India. Also, as early as AD 662, a Syrian bishop, Severus Sebokt, comments on the Indians carrying out computations by means of nine signs by methods which "surpass description" (Joseph 1993).

The spread of these numerals westwards is a fascinating story. The Arabs were the leading actors in this drama. Indian numerals probably arrived at Baghdad in 773 AD with the diplomatic mission from Sind to the court of Caliph al-Manṣūr. In about 820, al-Khwārizmī wrote his famous *Kitāb ḥisāb al-adad al-hindī* (Book of Addition and Subtraction According to the Hindu Calculation, also called just Arithmetic), the first Arab text to deal with the new numerals. The text contains a detailed expositioṇ of both the representation of numbers and operations using Indian numerals. Al-Khwārizmī was at pains to point out the usefulness of a place-value system incorporating zero, particularly for writing large numbers. Texts on Indian reckoning continued to be written, and by the end of the eleventh century this method of representation and computation was widespread from the borders of Central Asia to the southern reaches of the Islamic world in North Africa and Egypt.

In the transmission of Indian numerals to Europe, as with almost all knowledge from the Islamic world, Spain and (to a lesser extent) Sicily played the role of intermediaries, being the areas in Europe which had been under Muslim rule for many years. Documents from Spain and coins from Sicily show the spread and the slow evolution of the numerals, with a landmark for its spread being its appearance in an influential mathematical text of medieval Europe, *Liber Abaci* (Book of Computation), written by Fibonacci (1170–1250), who learnt to work with Indian numerals during his extensive travels in North Africa, Egypt, Syria, and Sicily. The spread westwards continued slowly, displacing Roman numerals, and eventually, once the contest between the abacists (those in favor of the use of the abacus or some mechanical device for calculation) and the algorists (those who favored the use of the new numerals) had been won by the latter, it was only a matter of time before the final triumph of the new numerals occurred, with bankers, traders, and merchants adopting the system for their daily calculations.

The beginnings of Indian algebra may be traced to the *Śulbasūtras* and later Bakhshālī Manuscript, for both contain simple examples involving the solution of linear, simultaneous and even indeterminate equations. An example of an indeterminate equation in two unknowns (x and y) is $3x + 4y = 50$, which has a number of positive whole-number (or integer) solutions for (xy). For example, $x = 14$, $y = 12$ satisfies the equation as do the solution sets (10, 5), (6, 8) and (2, 11).

But it was only from the time of Āryabhaṭa I (b. AD 476) that algebra grew into a distinct branch of mathematics. Brahmagupta (b. AD 598) called it *kuṭṭaka gaṇitā,* or simply *kuṭṭaka,* which later came to refer to a particular branch of algebra dealing with methods of solving indeterminate equations to which the Indians made significant contributions.

An important feature of early Indian algebra which distinguishes it from other mathematical traditions was the use of symbols such as the letters of the alphabet to denote unknown quantities. It is this very feature of algebra that one immediately associates with the subject today. The Indians were probably the first to make systematic use of this method of representing unknown quantities. A general term for the unknown was *yāvat tāvat,* shortened to the algebraic symbol *yā.* In Brahmaguptas's work Sanskrit letters appear, which are the abbreviations of names of different colors, which he used to represent several unknown quantities. The letter *kā* stood for *kālaka,* meaning "black," and the letter *nī* for *nīlaka* meaning "blue." With an efficient numeral system and the beginnings of symbolic algebra, the Indians solved determinate and indeterminate equations of first and second degrees and involving in certain cases more than one unknown. It is likely that a number of these methods reached the Islamic world before being transmitted further westwards by a similar process and often involving the same actors as the ones that we discussed earlier in the spread of Indian numerals.

The beginnings of a systematic study of trigonometry are found in the works of the Alexandrians, Hipparchus (ca. 150 BCE), Menelaus (ca. AD 100) and Ptolemy (ca. AD 150). However, from about the time of Āryabhaṭa I, the character of the subject changed to resemble its modern form. Later, it was transmitted to the Arabs who introduced further refinements. The knowledge then spread to Europe, where the first detailed account of trigonometry is contained in a book entitled *De triangulis omni modis* (On All Classes of Triangles), by Regiomontanus (1464).

In early Indian mathematics, trigonometry formed an integral part of astronomy. References to trigonometric concepts and relations are found in astronomical texts such as *Sūryasiddhānta* (ca. AD 400), Varāhamihira's *Pancha Siddhfāntạ* (ca. AD 500), Brahmagupta's *Brāhma Spuṭa Siddhānta* (AD 628) and the great work of Bhāskara II called *Siddhānta Śiromaṇi* (AD 1150). Infinite expansion of trigonometric functions, building on Bhāskara's work, formed the basis of the development of mathematical analysis – a precursor to modern calculus to be discussed later.

Basic to modern trigonometry is the sine function. It was introduced into the Islamic world from India, probably through the astronomical text, *Sūryasiddhānta,* brought to Baghdad during the eighth century. There were two types of trigonometry available then: one based on the geometry of chords and best exemplified in Ptolemy's *Almagest,* and the other based on the geometry of semichords which was an Indian invention. The Arabs chose the Indian version which prevailed in the development of the subject. It is quite likely that two other trigonometric functions – the cosine and versine functions – were also obtained from the Indians.

One of the most important problems of ancient astronomy was the accurate prediction of eclipses. In India, as in many other countries, the occasion of an eclipse had great religious significance, and rites and sacrifices were performed. It was a matter of considerable prestige for an astronomer to demonstrate his skills dramatically by predicting precisely when the eclipse would occur.

In order to find the precise time at which a lunar eclipse occurs, it is necessary first to determine the true instantaneous motion of the moon at a particular point in time. The concept of instantaneous motion and the method of measuring that quantity is found in the works of Āryabhaṭa I, Brahmagupta and Muñjāla (ca. AD 930). However, it was in Bhāskara II's attempt to work out the position angle of the ecliptic, a quantity required for predicting the time of an eclipse, that we have early notions of differential calculus. He mentions the concept of an "infinitesimal" unit of time, an awareness that when a variable attains the maximum value its differential vanishes, and also traces of the "mean value theorem" of differential calculus, the last of which was explicitly stated by Parameśvara (1360–1455) in his commentary on Bhāskara's *Līlāvatī.* Others from Kerala (South India) continued this work with Nīlakaṇṭha (1443–1543) deriving an expression for the differential of an inverse sine function and Acyuta Piṣāraṭi (ca. 1550–1621) giving the rule for finding the differential of the ratio of two cosine functions.

However, the main contribution of the Kerala school of mathematician–astronomers was in the study of infinite-series expansions of trigonometric and circular functions and finite approximations for some of these functions. The motivation for this work was the necessity for accuracy in astronomical calculations. The Kerala discoveries include the Gregory and Liebniz series for the inverse tangent, the Liebniz power series for π, the Newton power series for the sine and cosine, as well as certain remarkable rational approximations of trigonometric functions, including the well-known Taylor series approximations for the sine and cosine functions. And these results had been obtained about 300 years earlier than the mathematicians after whom they are now named. Referring to the most notable mathematician of this group, Mādhava (ca. 1340–1425); Rajagopal and Rangachari (1978) wrote: "(It was Mādhava who) took the decisive step onwards from the finite procedures of ancient mathematics to treat their limit-passage to infinity, which is the kernel of modern classical analysis." The growing volume of research into medieval Indian mathematics, particularly from Kerala, has refuted a common perception that mathematics in India after Bhāskara II made "only spotty progress until modern times" (Eves 1983).

Mathematics in Islam

JAN P. HOGENDIJK

Roughly speaking, one can distinguish two types of mathematics in Antiquity and the Middle Ages: one is "practical" (or subscientific) mathematics, concerned with practical calculation, administration, trade, land measurement, tax collecting, etc. The other is "theoretical" mathematics, studied either for its own sake, or connected with astronomy, philosophy, or religion.

The following survey of the history of mathematics in Islamic civilization will concentrate on "theoretical" mathematics. "Practical" mathematics in Islamic civilization is of great historical interest, but until recently the subject has received less attention than it deserves, perhaps because this kind of mathematics is less exciting from an intellectual point of view. Therefore it is not yet possible to give an adequate survey of its history.

The history of theoretical mathematics in Islamic civilization is intimately connected with astronomy. In Iran there was a pre-Islamic astronomical tradition which simply continued after the country was conquered by the Muslims. When the Abbasids came to power in 750, an interest in astronomy, and hence mathematics, developed in the new capital Baghdad. Iranian astronomy was influenced by Indian astronomy, and around 775 Indian astronomers and mathematicians were received at the court of the Caliph, and Sanskrit astronomical works were translated into Arabic. After 800, the Greek mathematicial and astronomical works became increasingly popular, and many of these works were translated into Arabic, including the *Elements* of Euclid and the *Almagest* of Ptolemy, an astronomical compendium full of very complicated mathematics. In the rest of this article, the term "Arabic" will be used in a linguistic sense, referring to Arabic as a scientific language. Thus "Arabic mathematics" is mathematics written in the Arabic language; an "Arabic mathematician" is a mathematician writing in Arabic. The reader should bear in mind that a large number of these "Arabic mathematicians" were actually Persians.

The most important traces of the Indian heritage in the Arabic tradition were the system of numbers and the sine function (which replaced the Greek chord in trigonometry). It is possible that early Arabic algebra was influenced by India to a much greater extent than is recognized today by most modern historians, many of whom assume a Babylonian influence, transmitted in some unknown way. However, the Greek influence was predominant in Arabic mathematics. It was a living continuation of Greek mathematics. New areas of mathematics were developed (algebra, trigonometry), new problems were solved (such as the *qibla* problem, determining the direction of Mecca), and a lot of creative work was done. However, there was no "revolution" in Arabic mathematics comparable with, for example, the development of analytic geometry and calculus in seventeenth-century Europe.

Arithmetic

Various systems of numeration were used by the Arabic mathematicians and astronomers. Many mathematicians and astronomers used the *abjad* (alphabetical) numeration. In this system, the letters of the alphabet have numerical values 1, 2, …, 9, 10, 20, …, 90, 100, 200, …, 900, 1,000. Almost all astronomical calculations were performed in a sexagesimal system in which the sexagesimals were denoted in the abjad system. The Hindu–Arabic system, consisting of nine symbols and a zero, was introduced into the Arabic world by al-Khwārizmī around AD 830, but it was not received with much enthusiasm. It was only used for large numbers, for example the tangents of angles near 90°. In algebraical works, al-Khwārizmī and others did not use numbers but words, for example "three squares and four is equal to seven things" (meaning: $3x^2 + 4 = 7x$ in modern notation). Fractions were denoted in various complicated ways, often without any symbolism. In the tenth century, al-Uqlīdisī used decimal fractions and a symbol equivalent to our decimal point.

Algebra

The name of this part of mathematics is derived from al-Khwārizmī's *Kitāb fī'l-jabr wa'l-muqābala* (Book on Restoration and Confrontation). In this treatise al-Khwārizmī gives a systematic treatment of linear and quadratic equations. The contents were not new, because the Babylonians in Iraq were able to solve quadratic equations 2,000 years before al-Khwārizmī. However, the treatise is very well written and al-Khwārizmī gives many worked examples. He treats the reduction of any linear or quadratic equation to one of six standard forms $ax = b$, $ax^2 = c$, $ax^2 = bx$, $ax^2 + bx = c$, $ax^2 + c = bx$, $ax^2 = bx + c$, and he then gives the solution of each of these forms: first the procedure for finding x, and in the case of the last three forms, also a geometrical motivation using rectangles and squares. The operation *al-jabr,* which gave its name to the whole field of solving equations, means the "restoration" of a negative term (example: $3x^2 - 7x = 4$ is "restored" to $3x^2 = 4 + 7x$). After al-Khwārizmī, Abū Kāmil solved complicated quadratic equations with irrational coefficients. In the tenth century, al-Karajī treated various properties of quadratic irrationals, which Euclid had proved geometrically. Al-Karajī also discussed cubic irrationalities, and he explained the extraction of the root of a polynomial (which is assumed to be a perfect square). In the tenth and eleventh centuries, cubic equations were solved geometrically by the intersection of conic sections, for example by ʿUmar al-Khayyām, and the theory was perfected by Sharaf al-Dīn al-Ṭūsī. A few mathematicians worked on equations of degree higher than three, but most of this work seems to be lost.

Theory of Numbers

Some Arabic mathematicians were interested in indeterminate equations, i.e., equations with an infinite number of solutions. The solutions had to be rational numbers (in the way of Diophantus of Alexandria, whose *Arithmetica* was translated into Arabic) or integers. Examples of the last kind are: find integers x, y, and z such that $x^2 + y^2 = z^2$ (such numbers x, y, and z are the sides of a right-angled triangle); or the famous problem of "congruent numbers": find numbers which are the surface area of a right-angled triangle whose sides are all integers. In the tenth century it was believed that no numbers x, y, and z such that $x^3 + x^3 = z^3$ existed, but it seems that this fact could not be proven by means of the mathematical methods then available.

Some progress was made in the theory of perfect and amicable numbers. A number is perfect if it is equal to the sum of its own divisors. Euclid had proved a formula for even perfect numbers, and four such numbers were known in antiquity: 6, 28, 496, and 8,128. In or before the thirteenth century, three more were found by Arabic mathematicians: 33,500,336; 8,589,869,056, and 137,438,691,328. Two numbers are called amicable if they are the sum of the divisors of each other. The example 220, 284 was known from antiquity. Thābit ibn Qurra discovered and proved that if p, q, and r are three prime numbers of the form $P = 3 \cdot 2^{n-1} - 1$, $q = 3 \cdot 2^n - 1$, $r = 9 \cdot 2^{2n-1} - 1$, then the numbers $2^n \ldots pq$ and $2^n \ldots r$ are amicable. Examples are the pairs 200, 284 ($n = 2$) and 17,296, 18,416 ($n = 4$). Perhaps the subject of amicable numbers was popular because of its magical applications, and such applications may also explain the interest in magic squares, which continued throughout the Arabic tradition.

The reader should bear in mind that the ancient and medieval concept of "number" is not necessarily the same as the modern one. In ancient Greek mathematics, a "number" was always a positive integer number, or a fraction (i.e., a ratio between two positive integer numbers). The Greeks knew that there were proportions in geometry which could not be expressed by this limited concept of number (such as the ratio between the side and diagonal of a square, that is $1 : \sqrt{2}$). Nevertheless, they did not extend their concept of number to include the modern idea of an irrational or real number. The reason is that this involves difficulties with the infinite, which they would have avoided (and which are carefully hidden in naïve presentations of the concept of real number in school mathematics). Instead of working with real numbers, the Greeks developed a theory of proportions of geometrical magnitudes (for example, line segments). This theory is found in Book V of Euclid's *Elements*, which was widely studied by the Arabic mathematicians. In astronomy, one has to calculate the (approximate) length of segments, which cannot be represented as a number according to the orthodox view. Thus it is understandable that the Arabic mathematicians, most of whom were also astronomers, came closer to the naive concept of real number, as it is nowadays taught in schools. Many mathematicians, such as Sharaf al-Dīn al-Ṭūsī, continued to believe that any rigorous treatment of numbers and algebra had to be based on the Euclidean theory of proportions.

Geometry

The basic geometrical work in Arabic mathematics was the *Elements* of Euclid (ca. 300 BCE). This work was very thoroughly studied, and more than fifty commentaries in Arabic were written, most of which have not been studied in modern times. Euclid's parallel postulate was one of the main points of attention. Most Arabic mathematicians found this unsatisfactory, and attempts were made, by Ibn al-Haytham, Naṣīr al-Dīn al-Ṭūsī, and others, to replace it by a more appropriate axiom. Many other Greek geometrical works were translated into Arabic, so the Arabic literature is an important source of new information on Greek geometrical works which are now lost.

The Arabic mathematicians were very interested in geometrical constructions. Such constructions should preferably be made by ruler and compass, that is to say, by successive intersections of straight lines through two known points and circles with known centers and radii (the intersection of such known figures produces new known points). The most interesting problems from Greek geometry (trisection of the angle, construction of two mean proportionals, etc.) cannot be constructed in this way. The Arabic mathematicians also used conic sections as means of construction.

Some of the mathematicians were clearly aware that they progressed beyond the ancient Greeks, and there was a feeling that the authorship of a geometrical construction added to one's prestige as a mathematician. Some mathematicians even plagiarized others' works, as in the case of the regular heptagon. This figure cannot be constructed by means of ruler and compass, but the Arabic geometers knew an ancient construction (attributed to Archimedes) by means of a straight line which had to be moved in an unclear way until two triangles are equal. Around 968 Abū'l-Jūd proposed a ruler- and compass construction of the heptagon. The elementary error in this construction was soon discovered by al-Sijzī. The missing link was filled by al-ᶜAlā' ibn Sahl by means of conic sections, and this was then plagiarized by al-Sijzī (who repented later) and also by Abū'l-Jūd. Other constructions of the heptagon were found by al-Qūhī (ca. 970) and Ibn al-Haytham (ca. 1000), who were both very proud of their achievement. Most mathematicians felt that the heptagon had not really been constructed by the ancients, and thus the "moderns" had gone beyond the level reached by the Greeks. A similar problem was the inscription of an equilateral pentagon in a given square. This was solved by al-Qūhī, who stressed that this problem had not been solved by the ancient geometers.

An important branch of geometry was spherical trigonometry. In the eighth and ninth centuries, spherical trigonometry developed rather chaotically, in the context of astronomy and on the basis of a mixture of Indian and Greek methods. In the tenth century the field became an independent subject of study, and special treatises were devoted to it. The Arabic mathematicians studied the spherical triangle, that is a triangle on a sphere, such that the "sides" of the triangle are arcs of great circles (i.e., circles whose center is the center of the sphere). In the tenth century, "angles" were also defined in a spherical triangle, so that a spherical triangle has six elements, three angles and three sides, like a plane triangle. The main problem of spherical trigonometry could now be phrased thus: if three elements are given, how do we compute the rest? Treatises on this problem were written by Naṣīr al-Dīn al-Ṭūsī and the eleventh century Spanish mathematician Ibn Muᶜādh.

The determination of the *qibla* (direction of Mecca) from a locality with given geographical coordinates can also be regarded as a problem of spherical trigonometry. In the eighth and ninth centuries only approximate solutions of the problem were known, but exact solutions were found in the ninth century, and tables were computed in the twelfth century and later.

The Arabic mathematicians devoted much time and energy to the computation of trigonometrical tables (sines and tangents) with ever increasing accuracy. The main difficulty is the determination of the sine of one degree; since this quantity cannot be expressed in square roots of rational numbers, the standard approximation methods fail. Around 1420, al-Kāshī found a method to approximate the sine of 1° with any degree of accuracy, using algebra. Al-Kāshī was able to express this as a root of a cubic equation with known coefficients, and he developed a very fast algorithm to approximate the root. He also computed the number π to 16 decimals.

Mathematics and Astronomy

It is historically impossible to separate Arabic mathematics from Arabic astronomy. Astronomy was the main field of application of mathematics, and calculations that were done by the astronomers vastly surpassed those of "practical mathematics" (commerce, administration, etc.). Many people studied mathematics in order to become astronomers (or astrologers). One finds a lot of very interesting mathematics in astronomical handbooks (*zījes*). The astronomical problems were sometimes too difficult to be solved by the methods of medieval mathematics, or, in cases where the problems could be solved, the computations were sometimes too complicated to be performed in a reasonable amount of time. Therefore, such computations were often simplified by clever approximation devices, which presuppose considerable numerical insight.

Mathematics was also important for astronomy on a more philosophical level. The philosophical foundation of Ptolemy's astronomical models was unacceptable for some Arabic mathematicians (such as Naṣīr al-Dīn al-Ṭūsī) because some of the circular motions in his theories of the moon and the planets were nonuniform.

The later Arabic mathematicians sought to remove these flaws by adding one or more circles to these models, producing the same effects as Ptolemy in a philosophically acceptable way. The most famous device is the so-called Ṭūsī couple, consisting of a circle of radius *r,* which rolls along the interior of a second circle with the double radius 2*r*. As a result of this motion, any point on the first circle oscillates on a fixed straight line.

Transmission

Arabic mathematics influenced the development of mathematics in medieval Europe in various ways. In the twelfth century, some Arabic mathematical works (such as the *Arithmetic* and the *Algebra* of al-Khwārizmī) and Arabic versions of Greek mathematical and astronomical works (such as Euclid's *Elements* and Ptolemy's *Almagest*) were translated into Latin, mainly in Spain. These translations were the beginning of the development of mathematics in Christian Europe. The thirteenth century European mathematician Leonardo Fibonacci learned mathematics in the city of Bougie in Algeria and during his travels to other Islamic countries, and he then wrote various influential mathematical works. The transmission of mathematics from Arabic to Latin was far from complete, and until 1450 the level of mathematics in Europe was below that in the Islamic world.

Mathematics in Japan

Jean-Claude Martzloff

At various stages of Japanese history, mathematics developed as a direct consequence of contacts with foreign cultures, both Chinese and Western. Five successive waves of cultural influx may be delineated (1) Chinese wave I, from the seventh to the end of the ninth century; (2) Chinese wave II, from the end of the sixteenth to the mid-nineteenth century; (3) Western wave I, 1543–1639; (4) Western wave II, 1720–1854, and (5) Western wave III, from 1854 onwards.[1]

As far as may be surmised, the two Chinese waves developed independently and were separated by an interim period of semi-seclusion from continental influences during which Japanese mathematical activity subsided.

During Chinese wave I, Japanese mathematics did not depart significantly from that developed in China during the same period. This was also the case in Sui (589–618)[2] and Tang (618–907)[3] China. Japanese imperial authorities are said to have founded an elite school for training future accountants, fiscal officers, surveyors, calendar makers, and other such practitioners. The teaching of mathematics was based on the Chinese *Suanjing shishu* (The Ten Computational Canons) and not on Japanese autochthonous manuals. During that period and the following centuries, mathematics never developed beyond the rudiments. Fragmentary records such as those of a priest from the Kenninji temple show that ca. 1311, the Chinese *Jiuzhang suanshu* (Computational Prescriptions in Nine Chapters) from the Han dynasty was studied in Kyoto. Certain texts known as *oraimono* (didactic exchanges of letters) contain, nonetheless, a number of mathematical recreations such as the problem of *mamakodate* (lit., the standing stepchildren). In this problem, a mother has 15 true children and 15 stepchildren; she must eliminate the latter by placing them in a circle in such a way that starting from some child and counting clockwise she eliminates every tenth child until at last only the true children are still

[1] This mode of periodization is borrowed from Sugimoto and Swain (1978).

[2] The short-lived Sui dynasty inaugurates a period of relative stability characterized by the unification of China after several centuries of disunion.

[3] The Tang dynasty is one of the most brilliant in Chinese history where the Chinese were able to extend their influence all over Asia, from Iran, Central Asia, India, and of course Japan.

standing. This problem is reminiscent of the Josephus puzzle, where children are replaced by Turks – to be eliminated – and Christians.

During Chinese wave II, a number of Chinese mathematical texts were imported into Japan on the occasion of the Japanese military expeditions in Korea of the 1590s.

One of them, the *Suanfa tongzong* (Comprehensive Treatise on Arithmetic), was a compendium of commercial arithmetic. First published in China in 1592, this manual was mostly intended for abacus calculations and was very often reprinted in China and Japan until the twentieth century. However, although strongly influenced by its Chinese model, Japanese arithmetic began to develop on its own. In particular, arithmeticians devised a new type of abacus (*soroban*). It was composed of five balls for the representation of the decimal digits of each order of units, instead of seven in the Chinese case. There were four balls valued at one unit each and one ball valued at five units, instead of five balls valued at one unit and two balls valued at five units. For the first time, the Japanese also wrote arithmetical books in their own language. One of them, the *Jingōki* (Treatise on Numbers Ti and Huge) of Yoshida Mitsuyoshi (1578–1672), first published in 1627, became so popular that hundreds of plagiarized versions were published. In its 1641 version, the author included 12 problems left unsolved and bequeathed to posterity (*idai keishō*). Subsequently, this kind of challenge was often issued and played an important role in the development of Japanese mathematics. At first, the custom was limited to more or less trivial arithmetical problems, but gradually amateur mathematicians imagined complex problems relating, for example, to the volume of intricate solids (such as those defined by the intersection of two other solids), or to chains of circles or spheres tangent to other circles, spheres, ellipses, or ellipsoids, respectively. When solutions were found, the solvers published them and in their turn propounded new enigmas.

A development in mathematics more sophisticated than arithmetic, however, was triggered by the introduction into Japan of the *Suanxue qimeng* (Introduction to Computational Science), a Chinese algebraic textbook by Zhu Shijie published in 1299 in Yuan China. Subsequently forgotten in China for five centuries, but universally considered by present historians of Chinese mathematics as representative of the golden age of Chinese mathematics, this manual was first reprinted in Korea during the fifteenth century and in Japan in 1658. At first, the part of this text devoted to *tianyuan* (celestial origin) algebra was not well understood.

This Chinese medieval technique was presented using a series of artificial problems, with some intermediary computations and a few cryptic and terse sentences apparently having more to do with magic than mathematics. Moreover, known and unknown quantities were not distinguished from each other by special symbols but only by the relative position of numbers on the counting board, so that mere numbers in all cases equally represented both kinds of quantities. Yet, 20 years later, certain scholars began to crack the code and realized that Zhu Shijie's algebra was in fact a powerful weapon capable of mechanically solving all sorts of intricate problems and particularly those of the *idai* new tradition. What is more, these efforts at last enabled Seki Takakazu, also called Seki Kowa[4] (ca. 1742–1708), the son of a samurai who became a chief Palace accountant, to develop algebra well beyond the state he had found it in Zhu Shijie's manual.

Seki was so successful as a mathematician that he was retrospectively considered the father of a national tradition called *wasan*. Wasan is literally Japanese (*wa*) and mathematics (*san*). That is in contrast with *yōsan*, Western (*yô*) mathematics; these two terms were coined ca. 1870. Although strongly influenced by Zhu Shijie, and more generally by Chinese models, Seki's work marks a certain rupture with mathematics conceived as collections of isolated problems. Concerning the elimination of unknowns between polynomial equations, he imagined a general method which resulted in an invention of determinants independently of Leibnitz. He also systematized the Chinese Hornerian methods for the numerical evaluation of the roots of polynomials, computed the decimals of π, and used what we now call the Bernoulli numbers. Last, but not least, he created a kind of notational algebra whose symbols consisted of dissections of Chinese characters which enabled mathematicians to perform literal (and not merely numerical) computations in writing rather than by using counting-rods as the Chinese did. In fact, Seki's algebra was not so different from that of Vieta. Seki Takakazu's collected works were published in 1974 (Hirayama et al. 1974).

Later mathematicians improved all this. In addition, questions relating to the precise evaluation of the circumference, arcs, and chord lengths became so important that they were conceived as a single domain called *enri* (circular principles). Later, this domain was generalized to the computation of all sorts of infinite series and to various curves in a way which more or less evokes Western calculus.

However, Chinese mathematics was not the sole source out of which Japanese mathematicians developed their own mathematics. During Western wave I, a very limited amount of mathematical knowledge of Western origin (consisting perhaps only of some mathematical recreations) was introduced into Japan as a consequence of the diffusion of Catholicism by Jesuit missionaries. But edicts against Christianity were issued as early as 1612, and in 1630 a ban on the

M

importation of Western books was decreed. During Western wave II, the ban was progressively removed and Western mathematical knowledge gradually permeated into Japan. In the period from 1720 to 1730, elementary geometry, plane and spherical trigonometry, and even logarithms became accessible through the medium of Chinese adaptations of European works such as the *Chongzhen lishu* (Chongzhen Reign-Period Compendium of Mathematical Astronomy), an encyclopaedic work which marked the start of the reform of Chinese astronomy in 1644 on the basis of European knowledge. Later, the Japanese also came into contact with Western works written not in Chinese but in Dutch, the language of the Dutch merchants, the sole Westerners who had relations with Japan. This initiated the development of a new branch of knowledge called *Rangaku* (Dutch learning). A consequence for mathematics of this new learning was the importation of the Dutch version of John Keill's (1671–1721) commentary on Newton's *Principia*.

Consequently, elements of European mathematics were integrated into wasan and new results were discovered. For example, Takebe Katahiro (1664–1734) developed an infinite series of the square of the arcsine. Takebe was a disciple of Seki and a Shogunal advisor also responsible for new developments in geography and astronomy. Ajima Naonobu, another distinguished wasan scholar, independently solved celebrated geometrical problems such as those of Steiner's chains of circles (circles mutually tangent inserted between two non-concentric circles situated one inside the other) or the so-called *Malfatti's problem* about three circles mutually tangent and inscribed in a triangle. Less anecdotally, Ajima and later Wada Yasushi (1787–1840) also elaborated methods for calculating areas and volumes as limits of infinitesimal rectangles or parallelepipeds in a way which is reminiscent of the construction of definite integrals. The achievements of Japanese autochthonous mathematics were thus quite high. A fundamental difference between Western and Japanese mathematics stems from the fact that the latter was essentially algebraic and developed independently of axiomatic–deductive reasoning.

While the search for general and systematic methods concerned more and more mathematicians, an opposite trend towards solving highly artificial problems conceived as isolated puzzles became still more prominent. In fact, mathematics was mainly practiced by 'hobbyists', members of rival schools or even mathematical sects. Works of wasanists were thus not much diffused. Original manuscripts were often copied by the disciples of some master (like Seki) and kept secret. Consequently, no consensus towards uniforming mathematical notations and concepts ever emerged, even though towards the end of the eighteenth century some mathematical works were eventually printed. More importantly, wasan studies were often condemned by Confucian elites who judged them 'mental acrobatics' and thus futile and socially useless. No official schools devoted to the study of wasan were ever created. During the whole Edo period (1698–1868), wasan was often practiced by *rōnin* (lordless samurai) who travelled all over Japan and earned their living by teaching wasan in private academies or becoming private tutors at the service of rich merchants. Unexpectedly, owing to a surprising alliance between mathematics and religion, wasan became more and more visible even in the Japanese countryside. From the end of the seventeenth century, wasan adepts advertised the achievements of the groups they belonged to by means of votive tablets (*sangaku*). Hung in public view in Buddhist temples and Shinto shrines, these wooden tablets generally displayed problems and beautifully engraved geometric figures (often consisting of mutually tangent figures, especially circles and triangles) with numerical solutions but no intermediary calculations. Hundreds of tablets have survived, and it is still possible to admire them everywhere in Japan. Moreover, printed anthologies of such tablets have been published. Such a practice is unattested anywhere else in the world outside Japan.

Until 1853, despite the importation of a certain amount of knowledge from China and Europe, Japan essentially remained isolated. But the partisans of isolation did not succeed in imposing their policy after Commodore Matthew C. Perry of the United States had forced open Japan's ports. As early as 1855, an Office for Occidental Learning (*Yōgakusho*) was created; one year later, this office was renamed Office for Investigating Barbarian Documents (*Bansho shirabesho*). There, government-appointed students learned to apply mathematics to navigation, shipbuilding, armaments, and other military matters. But radical changes had to wait the Meiji restoration of 1868. With the advent of this utterly new era, Western learning was no longer confined to military affairs and other utilitarian goals. Wasan was completely abandoned to Western mathematics. In 1877, the University of Tokyo was founded. At first, four out of five professors were foreigners (one American and three French). The Japanese professor was Kikuchi Dairoku (1885–1917) who later became Minister of Education. Kikuchi was an outstanding student who had been trained at the *Bansho shirabesho* and sent to Cambridge University; he gave his mathematical lectures in English. A few years later, however, the best students of mathematics were appointed professors in their turn. In 1877, the Tokyo Mathematical Society was founded. Japanese mathematicians rapidly attained the same level as that of Western researchers. Many mathematicians, such as Takagi Teigi (1875–1960) who contributed to class-field theory and gained worldwide fame, were trained during this period.

Extra: Seki Takakazu's Works

Seki Takakazu's collected works were published in 1974 (Hirayama, A., K. Shimodaira, and H. Hirose. *Takakazu Seki's Collected Works Edited with Explanations*. Osaka: Osaka Kyoiku Tosho, 1974). This thick volume has 871 pages comprising (1) various preliminary data concerning Seki Takakazu: a chronology, his biography, his disciples, a critical note on his portrait, the location of his tomb, his mathematical achievements; (2) the main text of his original works, printed or manuscripts (most often) (576 p); (3) a presentation of the main text in Japanese (216 p); and (4) a presentation of the main text in English (83 p). Given the seminal importance of Seki Takakazu for Japanese mathematics, it is worthwhile to describe his collected works briefly here.

The collection contains the following 29 original works:

1. *Kiku yōmei sampo* (1683) [Essential Methods of Calculation with the Compass and T-Square]. This is his earliest work. It gives simple calculations concerning the circle, arc of circles and the sphere; it has only ten pages and contains the first known Japanese proof of the Pythagorean theorem, in the form of a Chinese-like dissection.
2. *Ketsugishō tōjutsu* [Solutions *Tō* (in the form of *jutsu*, i.e. 'prescriptions') – the Japanese *jutsu* is the same as the Chinese *shu* – [of the 100 unsolved problems] from the *Ketsugishō*]. Here, the *Ketsugishō* is the title of a previous work, published in 1659; the expression *ketsugi* means 'omitted', i.e. the original solutions were not given. *Shō* = manuscript. For example, the fourth problem asked for the dimensions of a right-angled triangle given the sum of its three sides and the difference between the hypotenuse and the shorter side. Other problems are more complex and involve square and inscribed circles in a triangle and solid figures such as wedges, pyramids, or trunks of a cone. The last problem is about the construction of a 19 × 19 magic square. Most are solved using the algebraic technique known as *tengenjutsu*, a variant of the Chinese *tianyuanshu*.
3. *Futsudankai tōjutsu*. *Futsudankai* is the title of a previous manuscript (1673) containing unsolved problems. The expression *Futsudankai* means 'do not be afraid to change (the answers)'. This is again a collection of specific problems but they are much more complex than the two preceding ones. Sometimes, dissections of plane or solid figures into several pieces of unknown dimensions are given. Again, Seki provides algebraic solutions depending on the establishment of a polynomial, often of high degree, with coefficients composed of ten or more digits.
4. *Hatsubi sampō*. Once again, this work is based on a previous collection of problems. Here, *Hatsubi* means something like 'disclosing subtle [elements]' and *sampō* is exactly the same as the Chinese *suanfa*, 'computational methods' or 'mathematics'. Here the problems have several unknowns and the solutions involve their elimination.
5. *Kaihendai no hō* [Method of Solving 'Transparent' Problems]. This covers the area and volumes of simple plane figures and solids.
6. *Kaindai no hō* [Method of Solving 'Opaque' Problems]. This work is more theoretical than the previous ones. It does not consist of a list of problems but explains how to set and manipulate algebraic equations. A technique of solving polynomial equations analogous to Horner's method is also given.
7. *Kaifuku dai no hō* [Method of Solving Dissimulated Problems]. Here the expansion of determinants in relation to the process of elimination of polynomial equations is given.
8. *Kaihō honhen no hō* [Method of Solving Various Cases of Root Extractions]. This covers the tentative classification of polynomial equations and the study of elimination procedures.
9. *Daijutsu bengi no hō* [Method for Differentiating Problem Statements and Solutions]. This contains a method of successive approximations.
10. *Byōdai meichi no hō* [Method for Clarifying Flawed Problems]. Here one problem has an imaginary root and its statement is modified in order to let it having a computable root.
11. *Hōjin no hō*, *ensan no hō* [Methods for Magic Squares and Circles].
12. *Sandatsu no hō*, *Kempu no hō*. These two titles refer to the Japanese equivalent of Josephus's problem (called here *sandatsu*, i.e. enumerating a series of elements, *san*, while skipping some of them in the count, *datsu*) and another mathematical game consisting of remembering letters written on cards.
13. *Kyûseki* [Finding Volumes and Areas]. These include the area of an ellipse, analogous to the theorem of Pappus–Guldin. It also contains a problem concerning the intersection of a torus and a cylinder.
14. *Kyûketsu henkei sō*. A draft (*sō*) concerning the intersection of solids.
15. *Kaihō sanshiki* [Computational Configurations for Root Extractions]. This describes a technique for obtaining several roots of an equation with an approximation technique equivalent to Newton's method of approximation.
16. –19. *Katsuyō sampō*, 4 vols. [A Compendium of Mathematical Methods]. This contains a finite summation formula for the sum of powers with the discovery of the coefficients usually known as *Bernouilli's numbers*. A method for solving simultaneous congruences of the first degree (Chinese remainder theorem) is also included, as well as a systematic derivation of polynomial equations for calculating the length of the side of regular polygons, from the equilateral triangle to the 20-sided polygon. The compendium also offers inter alia a derivation of the result $\pi = 3.14159265358$.
20. *Happō ryakuketsu* [Abbreviated Mnemotechnical Tricks Concerning Eight Methods]. The content of this book is simpler than the preceding ones; it deals with the equivalence and conversion of units of length, weight, and volume.

The following seven treatises concern astronomical calculations:

21. *Juji hatsumei* [An Elucidation of the *Shoushi li*]. Here, the *Shoushi li* is a set of calendrical and astronomical official techniques, adopted in China from 1281 to 1368, and from 1368 to 1644 with some minor modifications. Seki explains the Chinese approximation method for the mutual expression of the arc and sagitta, by means of special approximation techniques.
22. *Juji rekikei rissei no hō* [Methods for Astronomical Tables in the *Shoushi li* Canon]. Introduction to the question of the tables for the motion of the sun and the five classical planets.
23. *Juji rekikei rissei* [The Astronomical Tables of the *Shoushi li* Canon]. Here the tables are fully reproduced.
24. *Seiki teisho* [Chinese Texts Corrected by Seki]. The text in question is the *Tianwen dacheng jiyao* (An Abridgment of the Great Sum of Astrology), a Chinese astrological treatise published in 1659.
25. *Siyō sampō* [Methods of Calculation of the Four *Yō*]. The 'four *yō*' are four invisible and imaginary celestial bodies used in Chinese astrology.
26. *Shukuyō sampō* [Calculation of the Astrological Chinese Mansions].
27. *Temmon sûgaku zatcho* [Various Mathematical and Astronomical Works]. Various notes, mainly on eclipses, with numerous geometrical drawings.

M

Lastly, the collection also contains the following:

28. *Sampō kyojō* (Mathematical Diploma). This is an attestation awarded by Seki to one of his disciples, in 1704. The document gives a list of all the subjects mastered by him.
29. *Hatsubi sampō endan genkai* [Explanation of the *Endan* Methods of Solution Concerning Subtle Computational Methods]. Here, the *endan* is a special algebraic notation borrowing its name from Chinese mathematics, but it is more complex than the original since the unknowns are denoted by special expressions (Chinese characters) and not only by the relative positions of numbers.

The reader will find many more details in the aforementioned book, with some examples of problems and mathematical techniques fully worked out.

Mathematics in Korea

Kim Yong-Woon

During the Shilla dynasty (59 BCE–AD 935), in AD 682, Korea established its official mathematical system under the influence of the mathematics of China (Tang dynasty) whose primary structure was algebra (theory of equations) and whose philosophical background was *yin-yang* theory. It was an educational program designed to train professional mathematicians, and it prescribed the number of mathematicians to be trained and the length of study and curricula, and it remained the official mathematical system to the end of the Chosun dynasty in 1910.

The system soon died out in China. It was revived in the Song dynasty, but failed to become an official system again. Meanwhile, Japan set up its mathematics system under the influence of the Paekche and Shilla dynasties in Korea. The Taihorei of 710 clearly defined its contents, but this too soon became extinct. In China and Japan official mathematics ceased to exist, but civilian mathematics prospered. Korea, on the contrary, was fundamentally different from these two countries (see Table 1).

The arrangement of the Shilla curriculum here is hypothetical; originally only the names of the four subjects were given. The length of study for Korea, 9 years, is for classical studies; whether this applied to mathematics and other technical fields is yet to be explored.

In China during the Tang, there were different qualifications for the *guozixue* (National Academy) in mathematics and other fields. In Korea and Japan, qualifications also differed by field.

The Koryo dynasty (918–1392) continued using the Shilla mathematical system in a slightly changed version. Whereas the Koryo continued to use Nine Chapter Arithmetic, the Continuation Technique, and Three Opening Arithmetic, they discontinued Six Chapter Arithmetic and began to use Saga.

The Chosun dynasty (1392–1907) strengthened the system of its predecessors and the standard text books were completely changed. The texts include Sanmyon arithmetic, Yonghui arithmetic, Sanhak Kaemong arithmetic for bureaucrats, and arithmetic for surveying.

In the Chosun dynasty, the study of mathematics was encouraged to fill administrative needs and was incorporated into the official system. During the reign of King Sejong (AD 1419–50), a Bureau of Mathematics and an Agency for Calendars were created, and mathematics was revived to match the level of the Koryo dynasty (936–1392). The positions of *Sanhak*

Mathematics in Korea. Table 1 Mathematics education systems in Korea, China, and Japan around the seventh century AD

Country	Enrollment age	Admission qualifications	Subjects	Length of study
Korea (Shilla) AD 682	15–30	Taesa (grade 12 in a hierarchy of 17 grades) and those who had no official positions	Six-chapter arithmetic, nine-chapter arithmetic, three opening arithmetic, continuation technique	9 years or longer
China (Tang) AD 624	14–19	Children of grade 8, and lower-grade public officials	Nine-chapter arithmetic, calculation of distance to a far-off island, Sun Zi's arithmetic for five government bureaus, Zhang Guijian's arithmetic calculation and gnomon continuation technique, topics in number three standard mathematics	7 years
Japan AD 710	13–15	Children of grade 8, and higher-grade public and local officials	Nine-chapter arithmetic, calculation of distance to a far-off island, Sun Zi's arithmetic, three opening arithmetic, continuation technique, six-chapter arithmetic	7 years

paksa (Doctor of Mathematics), *Sanhak Kyosu* (Professor of Mathematics), and *Sansa* (mathematician) were created.

The Chosun dynasty attached great importance to mathematics from the beginning, and the bureaucrats in charge of the technical civil service examinations in 10 fields began to play a greater role, ultimately forming the new social class of *chungin* (middle men). The *chungin* class is considered unique in the history of the world. (The term began to be used officially during the reign of King Sukchong (1675–1720)). As technocrats, they were recruited through comparatively low-level civil service examinations. Most of them came from the *chungin* class. It does not mean that a son inherited his father's position; rather it seems that intermarriage among the *chungin* contributed to the preservation of the tradition. Among them, mathematicians showed an especially strong tendency toward preserving this hereditary tradition. The roster of successful candidates in the tests for mathematicians and the position of *Sanhak Sonsaeng* (mathematics teachers) list a total of 1,627 during 300 years from the fifteenth to the seventeenth centuries. Their fathers' occupations were as follows: 124 herbalists, 75 translators, and 6 astronomers; the rest were mathematicians.

The mathematicians of the *chungin* class lived in a very closed society. As many of the books they wrote have been lost, and only fragmentary information is available, it is difficult to evaluate their achievements, either as a group or as individuals. A typical mathematician of the *chungin* is Hong Chong-ha, a professor of mathematics, who wrote an eight-volume (plus a supplement) *Kuilchip* (Nine Chapters on Arithmetic in One) which is still extant today. He was born in 1684 into a typical *chungin* family of mathematicians; his father, grandfather, great-grandfather, and his wife's father were all mathematicians.

From his book, we find the following. First, mathematicians of the day were quite unfamiliar with the course of events in China, whereas the literati of the *yangban* class maintained direct contact with Chinese culture and with European culture through China. The mathematicians were bound by the old system and continued using only the traditionally handed-down manuals; they had no access to Chinese translations of Western mathematics books. Second, *tianyuan shu* (Horner's approximation theorem for an equation with real coefficients) and the calculation rod thrived in Korea throughout the Chosun dynasty, long after they had ceased to be used and had been replaced by the abacus in China after the establishment of the Ming dynasty. Japanese mathematics in the Edo period (1603–1867) is called *wasan*. The origin of *wasan* is Chinese mathematics, but the Japanese replaced the calculation rod with handwriting and eventually developed it into symbolic algebra. Korean mathematicians were then isolated from the outside world and from European mathematics which had already found its way into China, but they preserved traditional mathematics using the calculation rod.

One of the other mathematical trends in the Chosun dynasty was *yangbans* (nobles). Ch'oe Sok-chong was a mathematician of noble birth who was a great admirer of classical Chinese philosophy. As the author of *Kusuryak* (Concise Nine Chapter Arithmetic), similar in its style of description to that of early European monastic mathematics books, he was a "Boethius (480–525) of the Orient." Boethius's mathematics was theological, metaphysical, and number-theory centered. Both gave a touch of mysticism to numbers, and Ch'oe studied magic squares of various types: circle, square, hexagon, etc. The hexagon denotes "water" in Chinese traditional philosophy, and Korean mathematicians attempted to indicate some philosophical meanings by means of mathematics.

Culture and Mathematics

King Sejong wanted all the branches of Asian learning – Confucianism, linguistics, music, astronomy, herbal medicine, and agriculture – to be in the service of his country. Unlike the Greek system of learning that branched off into mathematics, natural sciences, and metaphysics, the Eastern system tended to integrate all fields of learning into a whole. This was typified by classical Chinese studies (compare this with the Western trivium and quadrivium). For example, in the reform of music and the creation of the Korean alphabet, King Sejong remained true to the orthodox Asian view of learning and was content with being a true inheritor of Eastern culture. His policy for the promotion of mathematics did not seek any new paradigm.

Sirak

Sirak is the Korean version of the neo-Confucian concept of "practical learning," similar in nature to *jitsugaku* in Japan and *shixue* in China. It was active for about 300 years, from the mid-sixteenth to the mid-nineteenth centuries. Descriptions of some of the prominent mathematicians and their works follow. Yi Sugwang (1563–1628) wrote *Chibong yusol* (Chibong's Miscellany) which treats astronomy, geography, bureaucracy, belles-lettres, human behavior, technology, and even birds, animals, and insects.

Typical of this encyclopedic coverage is *Ojuyon mun-jangjon san'go* (An Oju's Multitude of Articles and Essays) by Yi Kyu-gyong (b. 1788) in 60 volumes, which contained 1,400 entries relating to the problems of all ages and countries. He had a very practical outlook, and in a commentary on the original text of a geometry book, he regarded surveying as the primary purpose of its study.

Ch'oe Han-gi (1803–79) is said to have broken with the traditional position of neo-Confucianism and become an activist philosopher, adhering to thoroughgoing empiricism. But he too remained orthodox in his attitude to arithmetic, as is evident in his comment, "By the degree of knowledge one has acquired in arithmetic, we can judge one's insight; we can see whether one's attitude is reasonable or not by judging if one's reasoning is arithmetical."

In 1765 Hong Tae-yong (1731–83) visited a Catholic church in Beijing, China, and acquired first-hand knowledge of Western culture. He conversed with Hallerstein, the Chief Astronomer, and his deputy Gogeisl at a Chinese astronomical observatory, thereby broadening his knowledge of astronomy. His work *Tamhonso* (Tamhon's Writings) treats mathematics and astronomy in Vols. 4–6 of Book II. Hong consciously discussed the infinite; he was the first Korean to discuss an infinite Universe, and he also mentioned infinite decimals in discussing the value of π.

At the end of the Chosun dynasty a new movement in mathematics arose. Nam Pyong-gil (1820–1859) and Yi Sang-hyok (1810–), perhaps the two greatest arithmeticians at the time, did not belong to the *Sirak* school. None of the *sirak* scholars specialized in arithmetic. But Nam was born into a *yangban* family, and Yi was a professional arithmetician of the *chungin* lineage. They joined hands in the study of arithmetic.

Nam's works include many arithmetic books, but he made them look new by adding illustrated explanations. There is no trace of metaphysical view, a dominant characteristic of the works of other *yangban* scholars.

Yi Sang-hyok was a typical *chungin* arithmetician. After passing the national test, he was assigned to an astronomical observatory as a budget officer. Among his works are some astronomical books and the following books on arithmetic: *Iksan: Ch'agunbop monggu* (Winged Mathematics: Hypothetical Method for the Theory of Roots) and *Sanhak Kwan-gyon* (A Brief Survey of Arithmetic). The first title probably implies "mathematics of two wings," one wing referring to traditional arithmetic, and the other to modern arithmetic. *Ch'agunbop monggu* is an explanatory book on European algebraic equations, while *Sanhak Kwan-gyon* presents Yi's creative study of mathematics. Yi's single-minded devotion to higher mathematics, ignoring the traditional patterns of thought when classic arithmetic was reviving, leads us to assume that this type of mathematical research may have prevailed among *chungin* scholars at that time.

Classical official Korean mathematics maintained its continuity without any fundamental changes from the seventh century (Shilla dynasty) to the beginning of the twentieth (the end of the Chosun dynasty).

The Chosun dynasty had three groups of mathematicians: the *chungin*, the *yangban*, and the *sirak*. The *sirak* school searched for new mathematics as seen in collaboration between *yangban* and *chungin* mathematicians. But their study of European mathematics was limited to algebraic equations and geometry at best, and they never went much beyond the traditional Chosun dynasty mathematics even when they accepted European mathematics. The works of Hong Tae-yong, allegedly the most progressive of all *Sirak* mathematicians, differ from other classical manuals only in that they dealt with practical applications of old principles.

At the end of the Chosun dynasty, some of the *chungin* mathematicians attempted an original study in mathematics, breaking with the old traditions. But they too were limited by the prevailing intellectual climate, which hindered understanding and assimilation of modern mathematics.

Korean mathematicians made little effort to change fundamentally the mathematics which originated in China, they did not yield to foreign influence, and they maintained the classical mathematics of the East to the last (to the end of the Chosun dynasty) even when Chinese and Japanese mathematics underwent drastic changes.

Mathematics of the Maghreb (North Africa)

Ahmed Djebbar

In discussing the mathematical activity which occurred within the framework of Arab-Islamic civilization, it is not possible to speak of one specific tradition from the medieval Maghreb, nor still less of specific traditions from each of the three regions of the Maghreb-Ifrīqyā, the central Maghreb, and the far Maghreb. Indeed, there has been one Arab mathematical tradition, born and developed in the East, partially transmitted to the Muslim cities of the west of Central Asia and then, later, to southern Europe by the intermediary of Latin and Hebrew translations. This tradition was assimilated, revived, and enriched by different scientific milieux.

Mathematics in the Maghreb from the Ninth to the Eleventh Centuries

Considering the close economic, political, and cultural ties which linked the Maghreb with the Andalus, it is not possible to separate the mathematical activities which took place in these two regions of the Muslim West. Indeed, the period which extends from the end of the eighth century to the end of the eleventh was characterized by the development of two scientific traditions linked to each other and brought to life by scholars who, apart from social divisions and differences in laws and religion, were united by the cultural and scientific environment which was made up of exchanges between the Andalus and the Maghreb, and of frequent contacts with the cities of the east – Baghdad, Damascus, and, later, Cairo.

That being said, the beginnings of scientific activities in the Andalus and the Maghreb are not well known. Indeed, information on the earliest mathematical activities of the region is rare and not very specific. But it is reasonable to state that, during the period of installation and consolidation of Arab-Islamic power, the development of the study and teaching of the Arabic language and of the different religious sciences of the period probably favored the teaching of sciences like medicine and arithmetic, which answered the needs of certain fringes of urban society (in particular, caring for the wealthy and administrating the distribution of inheritances).

In the Andalus, it is likely that from the beginning of the ninth century, the first translations of Greek and Indian works appeared in Cordoba from the centers of the empire and served to bring scientific learning to everyone from children to rulers. This was the case, for example, for ʿAbd ar-Raḥmān II (822–852) who benefited from this education and, in turn, actively supported further scientific activity by financing the establishment of an important library with works bought in the East. But it was not until the middle of the ninth century that scientific centers began to exist independently, outside the walls of palaces and princely mansions, in Cordoba, Toledo, Seville, and Saragossa.

During the last third of the ninth century and throughout the tenth the activities of teaching and research in the different branches of mathematics were greatly stimulated by the patronage of two great

M

Umayyad caliphs, ᶜAbd ar-Raḥmān III (912–961) and his son al-Ḥakam II (961–976). These activities continued in the eleventh century with the blossoming of important scientific centers in capital cities of principal states which, in turn, stemmed from the brilliance of the caliphate of Cordoba.

The information which exists today about scientific activities in the Maghreb leads one to believe that the beginnings of mathematics, on the scale of all of the Maghreb, occurred in Ifrīqyā (present day Tunisia) as early as the end of the eighth century. Among the scholars whose names are still known is Yaḥyā al-Kḥarrāz, who had as a student Yaḥyā al-Kinānī (828–901), the author of the first book of *ḥis'* (control of weights and measures) written in the Maghreb.

From the ninth century, the name of only one mathematician remains, Abū Sahl al-Qayrawānī, of Iraqi origin. He is also the first Maghrebian mathematician whose book is known: *Kitāb fi al-ḥisāb al-hindī* (Book of Indian Mathematics). As the title indicates, the book was in the new Arabic arithmetical tradition, of Indian origin, which had been inaugurated by mathematicians in Baghdad at the end of the eighth century and the beginning of the ninth.

As in other regions of the Islamic world, patronage of scientific activity was prevalent in the Maghreb and functioned as it did in the great cities of the East, with the purchase of books, the financing of manuscript copies, grants to scholars, and the construction of schools and institutions. The only precise information we have is on the *Bayt al-ḥikma* (House of Wisdom) founded by Ibrāhīm II (875–902) in Raqqāda. This institution, which survived as a scientific center until the Fatimid dynasty, welcomed mathematicians, astronomers, and astrologers.

Maghrebian mathematical activity of the tenth century is not well known. It seems that the patronage initiated by the Aghlabids in the ninth century continued and that the study of mathematics and astronomy flourished, particularly in the course of the first two decades of the reign of the Fatimid Caliph al-Muᶜizz (953–975). But biographers have given us only a few names of people who were known for their mathematical activities or their interest in the discipline, such as Yaᶜqūb ibn Killīs (d. 990) and al-Huwarī (d. 1023). To these names must be added the names of scholars who came under the influence of the intellectual centers of the Umayyad Andalus or of Fatimid Egypt, like Ibn Yāsīn and al-ᶜUtaqī.

We are somewhat better informed about mathematical activity in the eleventh century, but information is still fragmentary. Some scholars of this period are well known, for example Ibn Abir-Rijāl (d. 1034–1035) and Abū'1-Ṣalt (1067–1134). They wrote on mathematics, astronomy, and astrology, but only certain of their works in the latter two disciplines survive.

Mathematics in the Maghreb in the Almohad Period (Twelfth to Thirteenth Centuries)

Much is known about the importance of the twelfth century in the political and economic history of the Maghreb. But the cultural and scientific history of that period remains a vast, unexplored field. For example, in the field of mathematics, only three scholars of this period have been the subject of research studies. They are Abū Bakr al-Ḥaṣṣār (twelfth century), Ibn al-Yāsamīn (d. 1204), and Ibn Munᶜim (d. 1228). These three scholars are important because of several factors. The first is that they were the first mathematicians in the Maghreb whose writings have survived.

The full name of al-Ḥaṣṣār is Abū Bakr Muḥammad ibn ᶜAbdallāh ibn ᶜAyyāsh al-Ḥaṣṣār. It appears that in addition to his mathematical activities, he was also a reader of the *Quʾrān* and a specialist in inheritances. It is also probable that he lived a long time and that he taught in Sebta, since he seems to have had ties with other mathematicians in that city. Only two of his writings have survived. The first, entitled *Kitāb al-bayān wat-tadhkār* (Book of Demonstration and Memorization) is a manual of calculation dealing basically with arithmetical operations on whole numbers and fractions. His second book is entitled *Kitāb al-kāmil fī ṣināᶜat al-ᶜadad* (Complete Book on the Art of Numbers). It was in two volumes, but only the first volume is extant. It takes up the themes of the first book, with new chapters on the breakdown of a number into prime factors, on common divisors, and on common multiples.

Reference to al-Ḥaṣṣār in two Andalusian works which are now lost leads us to the conclusion that, in one way or another, the Andalusian arithmetical tradition was present in the Maghreb in the twelfth century. This presence was reinforced, moreover, both by the direct diffusion of Andalusian works on algebra, geometry, and astronomy and by the utilization of the contents of the works of al-Ḥaṣṣār by later Maghrebian mathematicians like Ibn Munᶜim, Ibn al-Bannāʾ (d. 1321), and Ibn Ghāzī (d. 1513).

It appears that al-Ḥaṣṣār lived before Ibn al-Yāsamīn, but there is no way to verify that fact. However, the contents of their mathematical writings are quite similar insofar as they are written in the Andalusian tradition of the twelfth century, and they expand that tradition by the introduction of symbolism for certain objects and certain arithmetical operations and by the important development of a chapter on fractions.

We can say nothing about the works of Ibn Munᶜim on geometry or on the construction of magic squares, as they have not yet been discovered. But we are better informed about his writings on combinatory analysis, arithmetic, and number theory. The *Fiqh al-ḥisāb* (Science of Calculation), his only surviving text, contains the usual chapters of calculation manuals, dealing with the four arithmetic operations applied to whole numbers and to fractions, but also chapters at a higher level which deal with extraction of the exact or approximate root of a number, the properties of figurative numbers, the sum of series of whole numbers, and the determination of amicable numbers.

It is not known what the importance of mathematical activity in Marrakesh was at the time that Ibn Munʿim settled there. He himself is not specific about the Maghrebian mathematicians of his time or their predecessors. On the other hand, he refers very specifically to Andalusian scholars, citing their names, titles of their works, and even passages of their writings. This only serves to confirm the important scientific ties between the Maghreb and the Andalus, ties which were considerably strengthened in the fields of science and philosophy during the reigns of the first four Almohād caliphs, from 1130 to 1213.

It is important to note that the writings of al-Ḥaṣṣār, Ibn al-Yāsimīn, and Ibn Munʿim were not the only writings which were studied. Indeed, one can cite the names of several whose work may have been just as important: Abū'l Qāsim al-Qurashī (d. 1184) who taught algebra in Bougie, al-Qāḍī al-Sharīf (d. 1283) who was a student of Ibn Munʿim in Marrakesh, al-Qalʿī (d. 1271) who also lived in Bougie and who taught the science of inheritances, and Ibn Isḥaq al-Tūnusī (d. after 1218), who was known for important work in astronomy. Unfortunately, none of the mathematical writings of these scholars remains, and we cannot even speculate on their contents.

The Mathematics of Ibn al-Bannāʾ and Commentaries on His Work (Fourteenth to Fifteenth Centuries)

In the history of scientific activity in the Maghreb, the fourteenth century is a special time, not only because of the quantity of mathematical work, but also because of the content of that work and its influence on the teaching of mathematics in the Maghreb in the centuries to follow.

The majority of mathematical work done in this century was reviews, in the form of commentaries and summaries of work which had already been discovered or assimilated in the course of previous centuries. New contributions were the exception. The work of the mathematician Ibn al-Bannāʾ (1256–1321) becomes even more important in this light, since he was both one of the last innovators in the great Arab mathematical tradition and also one of the initiators of a new tradition in the teaching of mathematics.

Ibn al-Bannāʾ was born and raised in Marrakesh where he also died, but he also lived and taught in Fez for a period. He seems to have been one of the last scholars to have engaged in research activity in that he grappled with problems which were new at that time and to which he found original solutions, for example in combinatory analysis. He also introduced original ideas or processes in algebra (on the existence of solutions to a second degree equation) and in calculus (on nondecimal bases).

Ibn al-Bannāʾ was also notable for the richness and diversity of his work. In the inventory which Ibn Haydūr (d. 1413) made of his writings, he records 98 titles, 32 of which deal with mathematics and astronomy. This may have been the reason for the high social status he enjoyed, being honored by the highest authorities in the far Maghreb, which led him to leave Marrakesh and settle in Fez for a period of time.

Ibn al-Bannāʾ wrote on geometry and an important work on algebra which was used as a teaching text in the Maghreb until the fifteenth century. But it is his writings on the science of calculation which have made him famous. Three of them remain in existence: the *Talkhīṣ aʿmāl al-ḥisāb* (Summary of the Operations of Computation), *al-Qānūn fi l-ḥisāb* (Canon of Mathematics), and the *Rafʿ al-ḥijāb* (Lifting of the Veil).

While the third title is the most important in mathematical terms, it is the first which is best known. A manual on the operations of calculation, it is characterized by great conciseness, rigor in its formulation, and especially, by a total absence of mathematical symbolism. For these reasons, many mathematicians after Ibn al-Bannā have published commentaries on this manual.

A comparative study of the most important chapters of these commentaries leads to the following observations on their content and on the general level of mathematics at that time. First, that the level of mathematics was not lower than that of earlier periods but that certain themes which had been taught since the tenth century no longer appear. Second, there are no new contributions in the commentaries, neither on the theoretical level nor on the level of the applications of ideas or earlier techniques. The most significant innovation in the commentaries is in the progressive utilization of a relatively elaborate symbolism. This symbolism had already appeared in the writings of al-Ḥaṣṣār and Ibn al-Yāsamīn, but its use seems to have taken hold throughout the thirteenth century and the beginning of the fourteenth. It reappeared in certain commentaries in the fourteenth and fifteenth centuries, both in arithmetic and in algebra.

Mathematics in the Maghreb After the Fifteenth Century

The activities of mathematicians from the Maghreb who lived between the sixteenth and nineteenth centuries are not clearly known, but it is possible to get an idea of their contributions from the titles of

M

writings which still exist. The mathematical disciplines which were taught or treated in the writings are metric geometry and calculation. It is possible to affirm that the content of these works differs from that of earlier mathematical writing both in form and level. There are poems, for example, those of al-Akhḍarī (d. 1575) and al-Wansharīsī (d. 1548), glosses and commentaries like those of Ibn al-Qāḍī (d. 1616) and Muḥammad Bannīs (d. 1798), and summaries like those of Ibrāhīm al-Ribāṭī (d. 1926). But the level of these works is inferior to those of the fifteenth century, which are themselves much poorer than works of the thirteenth and fourteenth centuries, both in ideas and techniques. The same is true in other sectors of intellectual activity in the Maghreb which were characterized by a narrowing of the respective domains of investigation and an impoverishment of their contents. This situation, the result of a long process of decline, had an indirect effect in mathematics in a gradual reduction both of content and in the field of application. Thus, the only activities left to mathematicians, aside from teaching and editing manuals, were mathematical practices linked directly to activities or preoccupations of a religious nature, like the distribution of inheritance, and donations to rightful claimants, the determination of times for fixing moments of prayer, or the construction and use of astronomical instruments.

Mathematics: Maya Mathematics

Michael P. Closs

The common numerical notation of the Maya employed combinations of "bars", having value 5, and "dots", having value 1, to represent the vigesimal digits from 1 to 19. For example, the kneeling scribe in Fig. 1 appears on a Classic Maya vase dating from around AD 750. From his armpit emanates a vegetative

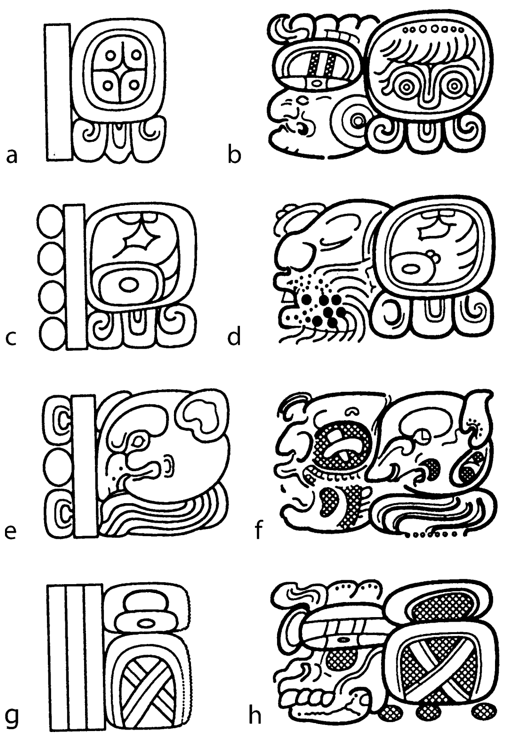
Mathematics: Maya Mathematics. Fig. 1 A kneeling Maya scribe (drawing by Closs after Clarkson, 1978).

scroll containing bar and dot numerals. Beginning at the armpit, the sequence of numerals runs 13, 1, 2, 3, 4, 5, 6, 7, 8, and 9. Often, non-numerical crescents or other fillers were used to create a more aesthetic balance for the numeral.

In some records, these simple numerals are used to count objects, in particular to specify the quantity of offerings of a particular type. However, the overwhelming usage occurs in calendrical and chronological contexts. In the former, the numerals appear as coefficients in the Maya calendars of 260 and 365 days. The former consisted of the cycle of numbers from 1 to 13 paired with a cycle of 20 day names. As the days went by, both the number and the day name would simultaneously advance in their respective cycles, thus generating a sequence of 260 distinct dates. The second calendar was a civil year composed of 18 "months" of 20 days each and a residual "month" of 5 days. The days within a given month were numbered consecutively from the first to the penultimate by prefixing the proper numeral to the appropriate month name. The last day was sometimes indicated by prefixing a special sign having the sense of "end" to the month name. However, the more common practice was to prefix a sign signifying "seating" to the following month and thereby identify the last day of one month as the seating day of the following month. Frequently, the Maya would describe a day by giving its dates in both the 260 and 365 day calendars. This generated a cycle of 18,980 paired dates known as the "calendar round".

A characteristic of Maya writing is that it often uses many distinct signs to represent the same linguistic value. This is the case with numerical terms where, in addition to bar and dot numerals, the Maya represented numbers by head forms and even full body figures. Some examples of bar and dot numerals in calendrical contexts, with alternative representations of the same dates using head variant numerals, are illustrated in Fig. 2. All of these examples come from the same ancient Maya city of Palenque and demonstrate the scribal variation to be found in Maya writing even at the same location. For a more extensive description and additional examples of Maya numeral forms, see Closs (1986).

The Maya frequently recorded the chronological interval separating two calendar dates. For this purpose they employed a vigesimal count of *tuns* (360 day periods) and separate counts of *winals* (20 day periods) and *k'ins* (days). A given interval would be expressed as a count of the respective time periods into which it could be minimally decomposed. Each of the time periods was represented by a characteristic sign and the appropriate count was indicated by a numerical prefix. In recording such chronological counts, it is necessary to have a symbol for zero so as to indicate an empty count of a particular period if this occurs. The Maya did have a zero symbol for that purpose. In fact, as with other signs employed in Maya writing, there are several variants of the zero symbol.



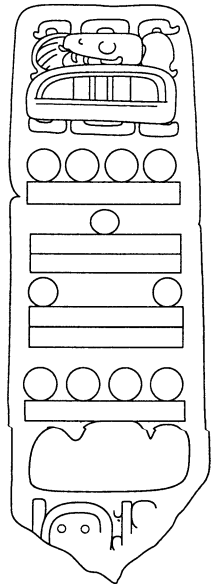
Mathematics: Maya Mathematics. Fig. 2 Maya numerals in a calendrical context. Dates in the 260-day calendar: (a) 5 Lamat, Palenque, Palace Table, R4; (b) 5 Lamat, Palenque, Tablet of the 96 Glyphs, D4; (c) 9 Manik, Palenque, Dumbarton Oaks Panel 2, J; (d) 9 Manik, Palenque, Tablet of the 96 Glyphs, H1. Dates in the 365-day calendar: (e) 6 Xul, Palenque, Palace Tablet, N15; (f) 6 Xul, Palenque. Tablet of the 96 Glyphs, C5; (g) 15 Uo, Palenque, Tablet of the Slaves, H5a; (h) 15 Uo, Palenque, Tablet of the 96 glyphs, G2 (drawing by Closs).

In many cases, and typically in the codices, Maya scribes would represent chronological counts using a system of positional notation. In this system, counts were written vertically with the lowest position being occupied by the count of *k'ins*, the next higher position by the count of *winals*, the next higher position by the count of *tuns*, and successively higher positions by the corresponding count of successively larger vigesimal multiples of the *tun*. Any chronological count could be recorded in this system by using the 19 vigesimal bar and dot digits and a symbol for zero.

In the monumental inscriptions, it was customary to indicate the interval between two successive dates of the text by recording the chronological interval separating them. Such chronological counts are referred to as "distance numbers" and might be added or subtracted to a given date to reach the following date. The initial date in an inscription is often anchored in an absolute chronology by recording the chronological count separating it from a common base date far in the past. These chronological records are referred to as Initial Series and have a characteristic format. An example of an Initial Series on Stela 1 at Pestac, employing positional notation and incorporating a zero, is illustrated in Fig. 3. It shows a count of 9 baktuns (=3,600 tuns), 11 k'atuns (=220 tuns), 12 tuns, 9 winals, and 0 k'ins (a total of 1,379,700 days or approximately 3,777 years) and leads to a date in AD 665. This is the oldest securely dated Maya text incorporating the system of positional notation with a zero sign.

In nonpositional contexts, the zero sign is found in Initial Series at a much earlier time. For example, the zero sign occurs on Stela 18 and 19 at Uaxactun, dating from AD 357. The most ancient nonpositional chronological count of this type, but without a zero, is found on Stela 29 at Tikal, dedicated in AD 292. It is interesting to note that the system of positional notation is very ancient in Mesoamerica and is found on monuments that predate those of undisputed Maya origin. However, none of them exhibit a zero sign. The oldest of these monuments goes back to 36 BCE.

In several instances, the Maya worked with negative chronological counts. These are used when counting backward from the zero point (base date) of the absolute chronology. They are distinguished from positive counts by a peculiar notation that has engendered the term "ring number". An example of a ring number from the Dresden Codex, one of the few surviving Maya



Mathematics: Maya Mathematics. Fig. 3 The front of Pestac, Stela 1, with an Initial Series of 9.11.12.9.0 employing positional notation and a zero sign (drawing by Closs).

Mathematics: Maya Mathematics. Fig. 4 A Maya ring number of 1.7.11 from the Dresden Codex, p. 58 (drawing by Closs).

hieroglyphic books, is illustrated in Fig. 4. The ring number of 1.7.11 is a negative chronological count with reference to the zero point of Maya chronology and leads to a mythological date.

Among the mathematical problems faced by the Maya were those of determining the calendar round date when a chronological interval is added to or subtracted from a given date and of determining the chronological interval between two given calendar round dates. The Maya also used other calendrical cycles of 4 days, 9 days, and 819 days. This led to other problems such as determining the station in the 819 day cycle closest to a given calendar round date. It is clear from artifactual evidence that the Maya performed their calculations using residue arithmetic.

The most sophisticated accomplishments in Maya mathematics are found in their arithmetically based astronomy. Here I will touch on three areas.

1. From the earliest days, the Maya scribes kept track of the moon through a lunar calendar. We have a large number of moon age records giving the current age of the moon within a cycle of 29 or 30 days. If a moon age was greater than 19 days, a special symbol for 20 was employed along with a regular bar and dot numeral to make up the balance of the count. Occasionally, a similar notation was used in the chronological counts discussed above. Since a lunation is around 29.5 days, the Maya used varying proportions of 29-day and 30-day months to keep their moon age records in agreement with astronomical reality. This gives an idea as to how the Maya avoided the necessity of fractions in their integer-based arithmetic. We have a few examples of moon age calculations from contemporaneous dates into mythological time, thousands of years earlier, from which it has been possible to recover the moon-age formulas that were used. These are formulas of the type "x moons = y days" where x and y are integers. Dividing through by x, one can say that a particular Maya formula is equivalent to estimating an average lunation as y/x days. This can then be compared with modern estimates and the precision of the Maya results can be recognized. Nevertheless, it can be misleading because the Maya did not look at things in this way.
2. The Dresden Codex contains a Venus table that permits the prediction of first appearance of the planet as morning star and as evening star over a period of about 104 years. The introductory page to the table has several features of mathematical interest. It has a mythological base date marked by a ring number. To this is added a companion number leading to a canonical base date of the table in the historic era. The companion number spans a period of 1,366,560 days (more than 3,741 years). It has the prime factorization $2^5 \cdot 3^2 \cdot 5 \cdot 13 \cdot 73$ and so is highly divisible into a product of relatively small prime numbers. This is fairly typical of other companion numbers associated with ring numbers in the Dresden Codex. It is a contrived number constructed using a knowledge of residue classes. The page also includes a table of multiples of 2,920 days. The importance of this number stems from the formula "5 Venus years of 584 days = 8 solar years of 365 days" commensurating the Venus and solar cycles. The existence of tables of multiples is

habitual in the Dresden Codex and indicates that the Maya worked from such tables rather than depending on algorithms for multiplication. The table of multiples and other calculation factors provide a mechanism for advancing from the canonical base date of the Venus table into the Venus table proper at a contemporaneous date. Still other calculating factors on the same page permit the Venus table to be recycled over time so that it maintains its astronomical integrity over several hundreds of years, much longer than the actual span of the table.

3. The Dresden Codex also contains an eclipse table that identifies dates of potential solar and lunar eclipses. It records a commensuration of the eclipse cycle with the sacred calendar of 260 days. This table also has mechanisms for recycling so that it can remain useful over many runs of the table. It is one of the great mathematical and astronomical achievements of the ancient Maya.

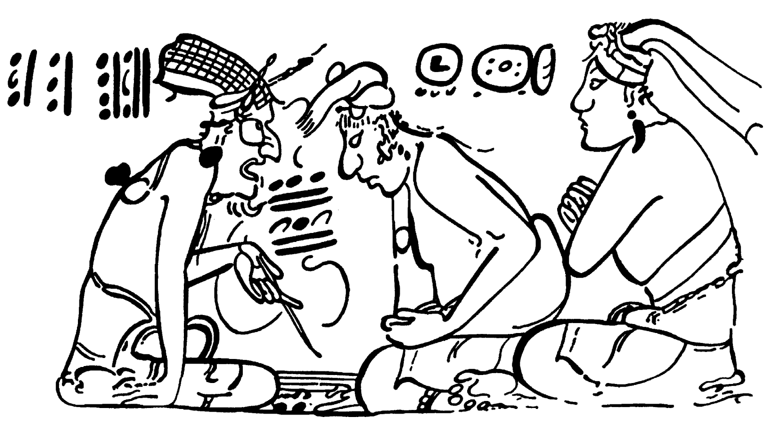
We also have some indications of geometrical knowledge among the Maya but nothing derived from written texts. Information that has been obtained comes from the study of architecture and site plans. For example, there are reasons to believe that an arrangement of three major temples at Tikal – at the vertices of an isosceles right triangle – is not coincidental. Many other alignments suggesting intentional geometrical concerns have been proposed at various Maya sites, but no adequate synthesis of the geometry involved has yet been achieved.

The idea of mathematics was sufficiently concrete in Maya thought that it has a presence in Maya art and iconography. In a number of almanacs in the Madrid Codex, deities are shown holding a vessel of black paint in one hand and a brush for painting or writing in the other. This type of scene is now known to depict the deity in the act of writing or painting. In at least two instances, an extra feature has been added to the scene. This consists of a scroll containing numbers issuing from the mouth of the deity. The added element indicates that the writing which is being performed is of a mathematical nature. By using this device, the Maya artist testifies to the visibility of mathematics as a discipline in Maya society.

The notion that mathematics was also considered a distinct discipline within the scribal curriculum is demonstrated on a Classic Maya vase (ca. AD 750). The scene on one side of the vase, illustrated in Fig. 5, shows a classroom scene in which Pauahtun, an aged god with a characteristic netted headdress, instructs two disciples in the mathematical art. Pauahtun, who is known to be a patron of scribes, is seated with a codex in front of him and a brush pen in his left hand. From his mouth issues a speech scroll containing the bar and dot numbers 11, 13, 12, 9, 8, and 7. The hieroglyphic caption behind the head of the first student is a name glyph. On the other side of this vase, there is a near identical classroom scene in which hieroglyphs are recorded in the speech scroll. In that case, the spoken text begins with a verb indicating "to teach."

A pair of deities in a detail from another Classic Maya vase is shown in Fig. 6. The god on the right has the facial features of a monkey and carries a codex in his right hand. An effigy head rests on top of the opened codex. The god on the left rests one hand on the back of the previous figure and holds a conch shell ink-pot in the other. Of special interest is a vegetative scroll, containing bar and dot numerals, which emanates from his armpit. There is also a curl, with single digits, running down from his cheek. Coe has suggested that these deities are patrons of mathematics and writing. The pairing of the two deities in this manner distinguishes between mathematics and writing in Maya thought. It reinforces the idea that mathematics was recognized as a separate discipline.

It is apparent that a scribe who was a mathematical specialist must have mastered calendrical and chronological calculations. The most detailed information on Maya civilization at the time of the Spanish conquest is



Mathematics: Maya Mathematics. Fig. 5 An ancient Maya mathematics lecture (drawing by Closs from Kerr, 1989).

Mathematics: Maya Mathematics. Fig. 6 Maya gods of mathematics and writing (drawing by Closs from Coe, 1978).

found in Bishop Landa's *Relacion de las Cosas de Yucatan*. This work was written shortly after the conquest and draws heavily on data provided by educated native informants, members of the former scribal class. Landa refers to the mathematical techniques of the Maya scribes as the computation of the katuns. He writes that this "was the science to which they gave the most credit, and that which they valued most and not all the priests knew how to describe it" (Tozzer 1941). This informs us that not all scribes were mathematical specialists and that those who were had greater prestige. It supports the idea that mathematical specialists were recognized as a specialized subgroup of the scribal class. In this regard, the situation at the time of the conquest seems to have been no different than it was during the Classic period.

Mathematics in Mesopotamia

SEMA'AN I. SALEM

"A mind that does not know accounting, is it a mind that has intelligence?" This ancient Mesopotamian proverb equates mathematical dexterity, to the exclusion of all other disciplines, with mental capability, and portrays the reverence the ancient Mesopotamians had for the field of mathematics. It is certainly true that the study of mathematics is an intellectual activity that requires both imagination and intuition.

Mathematics arose from the need to count and to record numbers. Many ancient societies had methods for tallying and counting. Thus, they developed a variety of counting systems used over the millennia around the world. Our base-10 system, the most common of all systems because of its association with the number of fingers on both hands, is but one of many.

A concise and meaningful definition of the field of mathematics is virtually impossible. The word was originally used to mean arithmetic. Then simple algebra was introduced, followed by plane geometry and other related concepts. At present, the word mathematics is defined as a language with a particular kind of logic. It contains a large body of knowledge often beautifully expressed in terms of equations, numbers, and symbols.

In this article, the word mathematics is used in its most general meaning.

Mesopotamia is a land that nurtured many civilizations – Sumerian, Akkadian, Babylonian, Chaldean, and later on Abbasid. It has a long list of achievements in astronomy and mathematics as well as other disciplines. The Mesopotamians' love for and interest in the study of astronomy led to their development of mathematics. The two fields, being interdependent, grew and prospered side by side.

Originally, mathematical calculations were used to count herds, livestock, produce, and people; later, they were used to help understand astronomical observations. Mesopotamian stargazers had a motto, "When it is clear, observe, when it is cloudy, compute." They observed for long periods of time; the longest uninterrupted period of astronomical observation, and this includes modern day observations, was carried out in Mesopotamia. To understand these observations, they performed very complex mathematical computations.

In this article we present some of the simple mathematical operations that were performed by early Mesopotamians. We will avoid the more complex calculations more suitable only to the experts.

The ancient Mesopotamians worshipped celestial objects as gods, and they believed that they were created for the purpose of serving these gods. To perform this function properly and to interpret the wishes of these gods, they studied their every move, chartered their paths, and calculated their positions as a function of time, thus creating a strong link between the study of mathematics and astronomy. This link played an important role in the development of both fields and later gave rise to the formulation of the Mesopotamian early calendars.

For our knowledge of Mesopotamian mathematics we are indebted primarily to the work of the Otto Neugebauer, who, between 1935 and 1937, studied all the known mathematical cuneiform tablets and published their contents in three volumes entitled *Mathematische Keilschrift-texte*. In these, he included photographs of original texts, transcripts, and translations into German. He also wrote a comprehensive commentary. A later publication by F. Thureau Dangin contains new transcriptions and French translations of most of the material published by Neugebauer, and a new and valuable commentary. For an extended period after 1937, Neugebauer continued his study of Mesopotamian mathematics; he kept translating and publishing articles about the subject, indicating what type of mathematics the Mesopotamians were interested in and how they solved some of the difficult and involved problems. And in 1945, he and Sachs published another collection – a supplement to Neugebauer's early work. In 1961, E. M. Bruins and M. Rutten produced a volume entitled *Textes Mathématiques de Susi* (Susa). The works of Otto Neugebauer, F. Thureau Dangin, and E. M. Bruins and M. Rutten are our main sources and best references to Mesopotamian mathematics.

The oldest mathematical symbols uncovered in Mesopotamia are Sumerian; they go back to ca. 3000 BCE. They are a short straight line, which stands for unity; a small circle darkened at the top which corresponds to 10; and a half-moon which represents 60. To add numbers, they wrote them next to one another; to multiply two numbers, they wrote one inside the other. For subtraction they had symbols that stood for the minus sign; to write 8, they wrote $10 - 2$.

With the advent of cuneiform, wedge-shaped signs replaced the old Sumerian symbols. A one wedge-sign by itself stood for unity, and two such signs placed next to each others meant two, and so on. The symbol for 10 was a small arc inscribed in an angle, and 60 was represented by a triangle. This retained the decimal/sexagesimal system.

Numerous clay tablets uncovered in Mesopotamia reveal that by 2000 BCE the Mesopotamians had a fully developed number system, which is partly decimal and partly sexagesimal. It has a symbol for 10, but instead of clumping together six such symbols to form 60, they had a unique symbol for 60. Although the ancient Egyptians are usually credited with the development of the decimal system, the Mesopotamians made partial use of such a system. These various notations were in use until the advent of the elegant, place-value system, a great leap in the advancement of mathematics. To differentiate between their numerous gods, the Mesopotamians assigned numerical values to these gods. Anu, the god of heaven, was allotted the number 60, and thus in their calculations, they used the sexagesimal system. That is, they used 60 the same way we use 10 in our decimal system. The influence Mesopotamian mathematics had on the Western civilization and mathematics is clear, as remnants of their sexagesimal system are still apparent in our method of measuring time (60 min to an hour and 60 s to minute) and in measuring angles (360°, 6×60, in a complete circle, and there are 60′ to a degree).

True to their sexagesimal system, they wrote all their fractions out of 60, the way we write our fractions out of 10. Thus, to write one half, they wrote a symbol that meant 0.30, the way we write 0.50 to mean a half.

Place-Value Numeration System

In our decimal system, if we desire to write eleven, we do not need to write 11 straight line scratches next to one another, we simply write 11 – the one in the first column to the right stands for unity, and the one in the second column stands for ten, and when they are placed together they represent 11. Similarly if we write one hundred and eleven starting from right to left, we have

M

1, 10, and then 10^2 giving the desired number of 111. Every time we move one column to the left we multiply by 10. In the sexagesimal system, the second column is 60, the third is 60^2, and every time we move one column to the left we multiply by 60. With the advent of cuneiform and the place-value numeration system, there was no further need for a symbol for 60. It was dropped, but the symbol for 10 was retained.

This system, which was conceived by the mathematicians and astronomers of Mesopotamia toward the beginning of the second millennium BCE, was a giant step in the annals of mathematics. To comprehend the importance of this giant step and how much simpler it is to perform mathematical operations using the place-value system, one ought to try to multiply two numbers using present-day Roman Numerals. The following table illustrates the use of place-value in the sexagesimal system (Table 1).

As the Mesopotamians had only two symbols to work with, the separations between successive symbols indicate different columns and a multiplication by 60 of the left column, instead of a simple addition of the two symbols. In solving one problem, another was created. The scribes had to determine how wide or how narrow the spaces between the columns ought to be. According to Mesopotamian understanding, if the spacing was too narrow, the two numbers must be added instead of multiplying the one to the left by 60 then adding. Thus making a symbol for zero became a necessity.

The astronomers and mathematicians of Mesopotamia had to contend with this difficulty for some 1,500 years, before they introduced a sign for zero. It took that long because it is difficult to think of "nothing" and even more difficult to find a symbol that represents "nothing." But in spite of the shortcomings of their numerical system, they were able to perform sophisticated calculations.

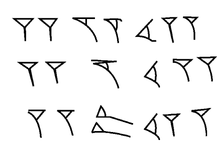
A Symbol for Zero

The history of the development and use of zero played a crucial role in mathematics and was the subject of several scientific publications, papers, and books. In a recently published book, *The Nothing That Is: A Natural History of Zero*, Robert Kaplan wrote that the earliest evidence of the use of zero was found on Sumerian clay tablets uncovered in southern Mesopotamia. The Sumerians, around 3000 BCE, inserted a slanted double wedge between numerical symbols to indicate the absence of a number. This date, if true, corresponds to the earliest use of mathematical notations by the Sumerians, and it comes only a couple of hundred years after the Sumerians invented writing.

It is possible that a symbol for zero was used by one civilization, got lost then rediscovered by another. Kaplan adds that the zero made its way into the Babylonian Empire and from there to India. In the Greek culture, the zero appears only occasionally, and there is no trace of its use during the Roman Empire. Arab scholars and merchants introduced the zero to the West, providing the earliest steps in the crucial role the zero plays in the world of mathematics. Note that the English word "cipher," meaning zero, has its origin in the Arabic word *sifr*, meaning empty. Finally, at a date not precisely determined, but either late in the sixth century BCE or early in the fifth century BCE, the Babylonian mathematicians, to indicate the absence of a sexagesimal unit, used a true sign for zero and spread its use over their vast empire and into the Indian subcontinent.

To avoid the difficulty encountered by leaving spaces to indicate zero or the absence of a number, they inserted between the columns one of the following signs:

For example 132 was written in one of the following ways:



That is $2 \times 60 + 12 = 132$.

Mathematics: Maya Mathematics. Table 1 The place-value numeration system

	is 5
	is 64
	is $60 \times 60 + 60 + 1 = 3661$
	is $60 \times 60 + 20 \times 60 + 15 = 4815$

When cuneiform writing became obsolete in the first half of the first century AD, the Babylonian signs for zero were lost with it. But the great mathematician, Muḥammed ibn Mūsā al-Kwārizmī (ca. 800–847), working in Baghdad, reestablished a sign for zero and introduced it into his mathematical computations (Fig. 1).

Recreational Mathematics

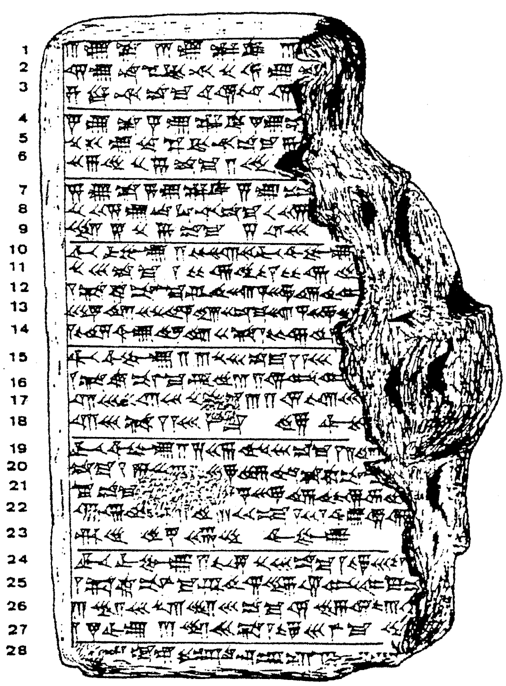
Most ancient mathematicians were interested in the solution of practical problems such as dividing geometrical figures into two or more equal parts, or multiplying two numbers to determine the area of a field. Such knowledge was used to divide properties among inheritors. For similar practical reasons they worked out the volumes of various solids to measure and store grains and other crops.

The Mesopotamians' interest in mathematics took them beyond its practical aspect and into its recreational, or what we call today pure mathematics. They worked out equations with two and three unknowns, they found solutions for quadratic equations, and they worked on problems such as, "Given the product of two numbers and either their sum or their difference, find the numbers." For most of their mathematical operations, the Mesopotamians constructed tables; they had tables of multiplication, division, squaring, and extracting square and cube roots. They also had tables of reciprocals, i.e., sexagesimal fractions. They went beyond all that and constructed tables for the summation of geometrical progression, such as

$$1 + 2 + 4 + \cdots + 2^9 = 2^9 + (2^9 - 1).$$

They also calculated the time required for the alignment of the sun–earth–moon to determine the time of lunar and solar eclipses. They were able to predict these eclipses with great precision.

A truly dramatic clay tablet, written in 568 BCE during the reign of Nebuchadnessar, states that a lunar eclipse predicted to take place on the 4th July 568 BCE (the date was recently calculated from an ancient Babylonian calendar) "failed to occur." Modern astronomers have verified that a lunar eclipse did take place on that date, but during the day, when the moon was not visible in Mesopotamia.



Mathematics: Maya Mathematics. Fig. 1 This mathematical clay tablet was uncovered in Uruk. It dates from either the late third or early second century BCE. It contains the earliest known signs of the Babylonian zero (Musée du Louvre, Paris). Used with the author's permission, from his article in *Dahesh Voice* 8.4 (2003): 14–9.

Influence on Greek and Western Mathematics

The first known Ionian astronomer, Thales of Miletus (ca. 625–545 BCE) was a statesman fond of traveling. While in Babylon, he obtained lists of observations of the heavenly bodies. From these lists, Babylonian astronomers had already deduced the periodicity of eclipses, and had accurately predicted several solar and many lunar eclipses. With these lists in his possession, Thales returned to his hometown of Miletus. It was reported there that he predicted a solar eclipse that took place in 585 BCE. But Thomas Martin, in his book *Ancient Greece, from Prehistoric to Hellenistic Times*, writes, "Modern astronomers doubt that Thales could actually have predicted an eclipse" (Martin 1969: 91).

Greek tradition indicates that it was customary for young Greek scientists to visit Mesopotamia in search of knowledge. One of the famous Greek scientists, who made the journey, probably after being deported from Egypt, was Pythagoras of Samos (d. ca. 497 BCE). He may have become acquainted with Mesopotamian mathematics, and most certainly with the theorem that bares his name, and which states that in a right triangle, the square of the hypotenuse is equal to the sum of the squares of the two other sides.

Neugebauer (vol. II, p 53 and vol. III, p 22) states that a cuneiform tablet, also belonging to the Old Babylonian period, contains extensive values of the sides of right triangles that satisfy the above-mentioned theorem. And Neugebauer and Sachs collection (pp 38–41) contains an extensive table of "Pythagorean Triplets." In addition to the theorem itself, right triangles, which obey the theorem, are also known as "Pythagorean Triangles" and the sets of numbers such as 3, 4, 5 and 6, 8, 10 and 12, 16, 20, etc. which satisfy the theorem are known as "Pythagorean Triplets or Pythagorean Triads." The theorem, the triangles that obey the theorem, and the sets of numbers that satisfy the theorem should be named Babylonian instead of Pythagorean.

This is not an isolated case. Through the work of Neugebauer, it became clear that the work of the mathematicians and astronomers of ancient Mesopotamia greatly influenced the mathematics of the Greeks, and through them that of the Western world.

In Babylonian algebra, quadratic equations of the four standard types occur frequently:

$$X + Y = A, \quad XY = B,$$
$$X - Y = A, \quad XY = B,$$
$$X + Y = A, \quad X^2 + Y^2 = B,$$
$$X - Y = A, \quad X^2 + Y^2 = B.$$

They also appear in Euclid's *Elements*: Theorem 5–6 and 9–10 of Book II without reference to their origin, and Neugebauer pointed out that the Greek geometrical solutions of these equations were exactly the same as the Babylonian algebraic solutions; for example, whenever the Babylonians wrote, "Take the square root of A." The Greeks changed it to read, "Take the side of the square of area equal to A."

The great interest the Mesopotamians showed in the solutions of pure mathematical problems – recreational mathematics, which has no practical applications – indicates that they viewed this endeavor as a mental exercise. This kind of mathematical intelligence greatly benefited both the Mesopotamians and the civilizations which followed them.

Mathematics in Native North America

Michael P. Closs

The mathematical development of the Native American peoples is highly variable among different cultural groups. In this article, I will treat two areas of interest: the wonderful diversity in the formation of number words and the use of tally systems to record information. Other articles in this volume give more explicit details on the mathematics of two particular indigenous groups, the Aztec and the Maya.

Number Words

Often numbers have a digital origin, indicating that counting began, or at least was remembered, by finger counting or by counting on the hands and feet. Here, I look at only a few examples. For a more extensive treatment, see Closs (1986a, b).

The relationship between the method of finger counting used and the creation of number words may be very explicit. The Bacairi of Mato Grosso in Brazil have the number sequence shown below:

1	*tokale*	
2	*ahage*	
3	*ahage tokale*; *ahewao*	2 + 1; 3
4	*ahage ahage*	2 + 2
5	*ahage ahage tokale*	2 + 2 + 1
6	*ahage ahage ahage*	2 + 2 + 2

The second of the number words for 3 is not used more often than the form made up of 2 and 1, nor is it used in the formation of any of the higher number words. The word for 1 comes from the word for bow. It has been suggested that since each man has only one bow but many arrows, the bow came to exemplify 'oneness'. The word for 2 and the word for 'many' derive from the same source. Thus, the two basic terms in the number vocabulary have a non-digital origin. The number sequence is an example of an additive 2-system, i.e. a system in which the terms are formed by using addition (implicitly) and groups of twos.

In finger counting, a Bacairi starts with the little finger of the left hand and says *tokale*, grasps the adjacent finger and joins it with the little finger and says *ahage*, goes to the middle finger and, holding it separately beside the little finger and the ring finger, says *ahage tokale*, goes to the index finger and joining it to the middle finger says *ahage ahage*, grasps the thumb and says *ahage ahage tokale*, places the little finger of the right hand along side it and says *ahage ahage ahage*. He then goes to the remaining fingers of the right hand and touches each finger in turn while saying *mera* 'this one'. He continues by touching the toes of the left and right foot and each time says *mera*. If he is still not finished he grasps his hair and pulls it apart in all directions. The number 6 marks the end of the use of 2-groups in finger counting. Nevertheless, the finger counting still continues on to 20 by a straight one-to-one correspondence without the use of number words.

Number words are not always derived from words associated with counting on the fingers. Frequently, the meaning of even relatively small number words is transparent. In some languages the word for 1 is related to the first person pronoun. Often the word for 2 comes from roots denoting separation or pairs. Moreover, not only large numbers but also small ones may be formed by using arithmetical principles. In the simplest case, this takes the form of doubling but there are instances in which addition, subtraction, multiplication, and division are used. Number words may also be created in more exotic ways (see Table 1).

Larger number words may be formed by using superlatives or other expressions which are indefinite (see Table 2).

There are many number systems developed in the New World that follow unusual principles of grouping. The number sequence of the Coahuiltecan of Texas shown in Table 3 exhibits an extensive use of additive and multiplicative principles early in its development. It is also very unusual in the heavy reliance it places on 3-groups.

The word for 3 is an additive composite of the words for 2 and 1. That pattern, seen in the earlier 2-system, is not continued and new words are introduced for 4 and 5. The number 6 is expressed in two ways, either as a composite of 3 and 2 or by a new word. The next new term introduced is for 20. The number sequence rises from 6 to 20 by a regular use of 3-groups and the use of the arithmetic operations of addition and multiplication. Below 12 the development of the

64	omahat-tc-am-op	'four-pile-at'

number system is not consistent. The Coahuiltecan sequence might be classified as a 2–3–20-system.

The number systems employed within closely related linguistic groups may also exhibit considerable variation. For example, the four Yukian languages of California belong to the same family but have very different number systems. In three of the four, the numbers up to 3 are related. However, from 4 on all the languages employ composite number terms whose meanings are completely different. Moreover, the methods of forming the numerals also differ since one of the four is an 8-system, two others are 5–10-systems, and the fourth is a 5–20-system.

The number sequence of the Round Valley, or Yuki proper, dialect is shown in Table 4, together with an analysis of the numerals.

The Yuki number sequence is inextricably linked to their method of finger counting. Rather than counting the fingers themselves, the Yuki count the spaces between the fingers, in each of which, when the manipulation is possible, two twigs are laid. Except for the words for 1 and 2, common to all the Yukian languages, and the word for 3, common to all but one of the Yukian languages, the number words are descriptive of this method of counting. The number words have no relation to those used in the other related languages. From 9 to 15 the number words are formed by addition to a base of 8. Those from 10 to 15 include the term *sul* 'body', suggesting that 'body' represents the full count of 8 spaces between the fingers.

Many of the terms given for the larger numbers are residue representations as can be seen below:

$$16 = (8) + 8, \quad 24 = (16) + 8,$$

$$17 = (8) + 9, \quad 26 = (16) + 10,$$

$$18 = (8) + 10, \quad 35 = (16) + 19,$$

$$19 = (8) + 11, \quad 51 = (2 \times 16) + 19,$$

$$20 = (8) + 12.$$

The above terms suggest that 16, as well as 8, may be used as a base for constructing the higher numbers. Indeed, the term for 64 is literally '4-pile-at' and 64 would be 4 piles of 16. It has been reported that 64 is also used as a higher unit in the Yuki count. This has been taken as evidence that the Yuki had evolved a pure 8-system. Nevertheless, because of the term for 64, it seems better to classify it as an 8–16-system.

The Yuki number sequence illustrates that one may employ the fingers and hands in counting and not end up with a decimal or vigesimal system. This lesson could also have been drawn from the finger counting of the Bacairi who evolved a 2-system. It can also be seen that the Yuki had precise concepts of number and counting which went far beyond their formal number sequence. The existence of variant terms for the same number and the use of residue expressions for larger numbers attest to this.

The facility with which different indigenous peoples dealt with large numbers also shows considerable variability across the Americas. The Pomo of California have a deserved reputation as great counters. Large counts were commonly performed by them at the times of deaths and peace treaties. An example of such a count is related in a Pomo tale about the first bear shaman who gave 40,000 beads in pretended sympathy for the victim whose death he had caused. One investigator reports that his informant has observed counting in excess of 20,000.

Although the Pomo were able to express numbers reaching into the tens of thousands, the published lists of Dixon and Kroeber contain numbers which do not exceed 200. From these lists, I present the number sequence of the Eastern Pomo which is shown in Table 5. The second last column gives a simple analysis of the number words while the last column gives a second-order arithmetical analysis so as to exhibit the structure of the numerals more simply.

It can be seen from the above number list that the Eastern Pomo employed a 5–(10)–20-system. The term '1-stick' is used to represent 20. The phenomenon of overcounting (i.e. referring a count upwards to the next higher level) is also employed. For example, 50 is expressed as 10 towards 60, and 70 is expressed as 10 towards 80. Fortunately, the absence of higher numbers in the list has been remedied by Edwin Loeb. He provides the sequence for large counts among the Eastern Pomo in Table 6.

The Pomo number words are closely connected with the method of counting. For example, in counting small amounts, the word for 20 is *xai-di-lema-tek*, 'full stick', and when that number is reached a stick is laid out for this primary unit. When 20 such sticks were accumulated they formed a larger unit of 400 that also was represented by a stick.

There is evidence that 1-stick represents counts of 20, 40, 80, or 100 in different Pomo number sequences. This simply indicates that variant grouping practices prevailed in different Pomo areas at different times. Using different sizes of groups to represent 1-stick would yield different number sequences even though

Mathematics in Native North America. Table 5 The number sequence of the Eastern Pomo

17	xomka-mar-na-xotc	3-mar + 2	(3 × 5) + 2
18	xomka-mar-na-xomka	3-mar + 3	(3 × 5) +3
19	xai-di-lema-com	stick-di-5-less	20 − (1)
20	xai-di-lema-tek	stick-di-5-full	20
21	xai-di-lema-na-kali	stick-di-5 + 1	20 + 1
30	na-hadagal	na-10	(20) + 10
40	xotsa-xai	2 sticks	2 × 20
50	hadagal-e-xomka-xai	10-e-3-sticks	10 towards (3 × 20)
60	xomka-xai	3 sticks	3 × 20
70	hadagal-ai-dola-xai	10-ai-4-sticks	10 towards (4 × 20)
80	dol-a-xai	4 sticks	4 × 20
90	hadagal-ai-lema-xai	10-ai-5-sticks	10 towards (5 × 20)
100	lema-xai	5 sticks	5 × 20
200	hadagal-a-xai	10 sticks	10 × 20

M

Mathematics in Native North America. Table 6 The number sequence of the Eastern Pomo for large counts

80	dol-a-xai	4 sticks	4 × 20
100	lema-xai	5 sticks	5 × 20
200	hadagal-a-xai	10 sticks	10 × 20
300	xomka-mar-a-xai	15 sticks	15 × 20
400	kali-xai	1 (big) stick	400
500	kali-xai-wina-lema-xai	1 (big) stick + 5 sticks	400 + (5 × 20)
800	xote-guma-wal	2 (big sticks)	2 × 400
2,400	tsadi	6 (big sticks)	6 × 400
3,600	hadagal-com	9 (big sticks)	9 × 400
4,000	hadagal	10 (big sticks)	10 × 400

the same techniques of stick counting were applied. There is evidence for distinct Pomo systems which may be classified as 5–20–400, 5–40–400, (5)–80–400, and (10)–100–400.

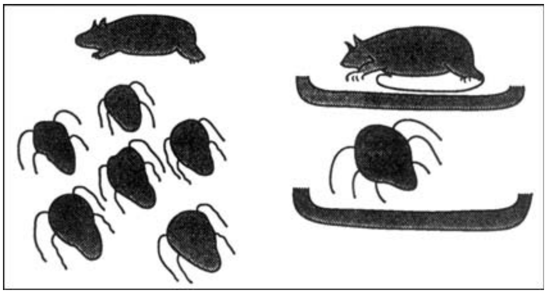
Tally Records

A tally is a simple method of representing the cardinal number of a group of objects by making a one-to-one correspondence between the objects being counted and special marks made by a counter. Today, many tallies are made by using automated counted devices. However, throughout history, tallies were made by more personalized methods such as marking vertical strokes on a flat surface, cutting notches on a stick, tying knots on a string, or placing pebbles in a bowl. It is the most ancient form of record keeping used by humans.

Biographical and chronological records formed of strings with simple knots tied in them existed among the interior Salish and neighbouring tribes of southern British Columbia and the region about Yakima, Washington. More sophisticated knotted string records, *quipus*, were used by the Inca.

For this discussion, I consider three types of tally records employed by the Ojibway:

1. The pictograph in Fig. 1 was transcribed from the sides of a blazed pine tree found on the banks of a tributary of the Upper Mississippi in 1831. On the upper right is the totem of an Ojibway hunter who had encamped at that spot. It represents a fabulous animal called the *copper-tailed bear*. The two parallel lines beneath it, curved at each end, represent the hunter's canoe. The next sign, on the same side, below, is the totem of his companion, the cat-fish, and below that a representation of his canoe. The upper figure on the left represents the common black bear, the six figures below it denote six fish of the cat-fish species. The interpretation is this: the two hunters, whose totems were cat-fish and copper-tailed bear, while encamped at the spot, killed a bear, and captured six cat-fish in the river.

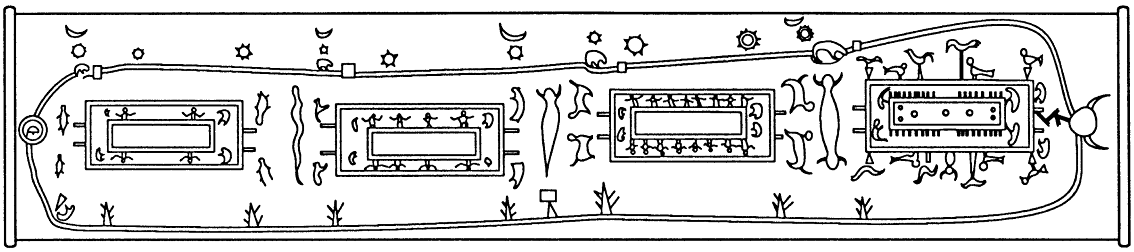


Mathematics in Native North America. Fig. 1 An Ojibway pictographic record (drawing by M. P. Closs from Schoolcraft 1851).

The record was designed to convey this piece of information to any of their people who should pass the locality.

2. Tally records were also carved on Ojibway grave posts. Babesakundiba, or Man with Curled Hair, was the ruling chief of the Sandy Lake band of the Ojibway on the Upper Mississippi. He died in the late 1840s, after a long life of usefulness and honour, and was buried on a prominent elevation, on the east bank of the river, where his grave and an ensign which waved over it were visible to all who navigated the stream. A drawing of his inscribed grave post is shown in Fig. 2.

The upside down bird denotes his family name, or clan, the crane. Four transverse lines above it signify that he had killed four of his enemies in battle. This fact was declared by the funeral orator at the time of the deceased's interment. At the same time, the orator dedicated the ghosts of the four men, whom the departed had killed in battle, and presented them to the dead chief, to accompany him to the land of the spirits. The four lines to the right and also the four corresponding lines to the left of the central marks denote eight eagle feathers and are commemorative of his bravery. Eight marks made across the edge of the inscription board signify that he had been a member of eight war parties. The nine other transverse marks



Mathematics in Native North America. Fig. 2 The grave post of Babesakundiba (drawing by M. P. Closs from Schoolcraft 1851).

below the sign of the crane signify that the orator who officiated at the funeral and drew the inscription had himself participated in nine war parties.

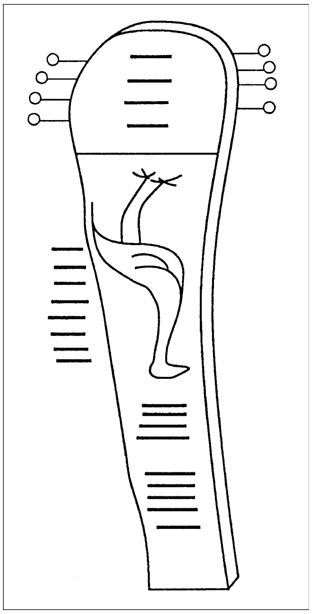
3. The Midéwewin was a set of ceremonials conducted by an organized group of men and women among the Ojibway people who had occult knowledge of ‘killing’ and ‘curing’ by the use of herbs, missiles, medicine bundles, and other objects which possessed medicinal properties. The records and teaching of the Midéwewin were inscribed on birchbark scrolls. These form a body of pictographic material in which one can find various tallies and graphic notations exhibiting a ritual use of number among the Ojibway.

The scroll depicted in Fig. 3 was used for instruction in the lore and rites of the Midéwewin. It is characterized by four rectangular floor plans corresponding to four lodges (and degrees of initiation) which a candidate had to pass through before achieving the status of a Midé master.

The inner rectangle in each lodge represents the path that is followed when processions are made around the interior of the lodge. There are four bear *manitos* (archetypal spirits) in each lodge, two guarding each entrance. In addition, there are 4 officials shown in the first lodge, 8 in the second, 16 in the third, and 36 in the fourth.

Lurking between the lodges are evil manitos that block the entrances. The first three lodges are each blocked by four manitos, two near each entrance. The fourth lodge is uniquely surrounded by 12 bird-like figures, possibly sky manitos, with an additional horned figure and two bear figures. These seem to be beneficent entities.

The network of lodges is bordered by the Ojibway universe. It begins with a small circle containing Bear and terminates with the horned symbol of Everlasting Life. Along the upper border, close to the upper left-hand corner of each lodge, is a figure of Bear seated before his sacred drum. Outside of this border are lunar and solar symbols. Along the lower border is a sequence of trees which represents a forest.



Mathematics in Native North America. Fig. 3 The Midé master scroll kp-1 (drawing by M. P. Closs from Dewdney 1975).

The scroll emphasizes the number 4, sacred to the Ojibway, in many ways. It is the number of lodges, the number of bears in each lodge, the number of evil manitos adjacent to the entrance of the first three lodges, the number of bear and drum figures on the boundary, and the number of lunar signs. Also, the 12 bird manitos about the fourth lodge and the series of officials in the sequence 4, 8, 16, and 36 are based on multiples of 4.

Mathematics in Oceania

Nicholas J. Goetzfridt

The historical and contemporary practice of mathematical concepts in Oceania and their intentional and unintentional expression in various fields of written literatures negates, from the start, the possibility of pinning down their elements entirely. This is to be expected since a bibliographic tour is not only limited to what writers have thought relevant or important enough to mention since the start of anthropological inquiries into Pacific societies. It is also limited to depictions of real life, culture, and society in written words. But the available representation of these concepts throughout the past several decades nevertheless allows one to grasp ethnomathematical essences in their indigenous contexts – such as the application of knotted plants or leaves for mnemonic purposes or for the determination of one's fate using a system of 256 possible results originating from the sky god *Supwunumen* who bore the destiny faces of *pwee* before allowing them to emerge into 16 human forms. They then descended in a heavenly constructed canoe to teach the art of knot divination to a few select men in the Caroline Islands. The two major schools of the art of the *pweewunus* were distinguished by whether one conceived of the celestial canoe as having been a sailing canoe or a paddling canoe (Goodenough 2002).

Knots for memorization or recall take several forms throughout the Pacific, although none of the forms serves as a society's definitive method of memorization. They instead reflect environmental needs and practices, such as the tying and untying of knots to mark the passage of days before a particular event in Papua New Guinea (Blackwood 1935) or, in "former times," the tying and untying of knots on various types of leaves and strands for deaths and the successful revenge for each death among the Parevavo people of Papua New Guinea (Hallpike 1979 and Wolfers 1971). In 1832, Typerman and Bennett described the practice of a Hawaiian "tax-gatherer" in the district of Waerua who kept "very exact accounts" of each inhabitant's tax debt on a line of cordage of four to five hundred fathoms in length and which were individually distinguished with "knots, loops, tufts, of different shapes, sizes, and colors" (p.71). While knotted cords were used in the Marquesas Islands to measure time, record genealogies, and as mnemonics for the singing of religious songs (Barthel 1971), one women in Papua New Guinea kept track of the number of times her husband beat her by tying knots in a leaf cord and eventually presented it to authorities as concrete proof of his treatment of her (Hallpike 1979).

Of course people count objects using base systems, terms, objects, and even themselves (most extensively practiced in Papua New Guinea) for transaction and gifting practices (each society having particularly prominent objects to enumerate – pigs and yams, for example, in Papua New Guinea), for the distribution of food and objects in accordance with statuses or roles, and for the counting of material objects and people for other reasons. Objects themselves can take on quantifying terminology separate or derived from words that form base systems unique to societies as well as those acculturated through time from neighboring villages and islands. Among Elsdon Best's condescending though detailed work on Maori society in the 1920s is a reference to a system used by the Maori people in the Waikato district for counting eels (Best 1921) (44 eels forming the smallest unit for tallying large numbers of eels (Best 1929)), and the encapsulating of four birds in a single brace or *pu* (Best 1924). Koch (1983) notes terms used in Tuvalu for bundles of 10 coconuts (*fui*) and a larger bundle ranging from 10 to 70 coconuts (*fikau*) while MacGregor (1937) cites use of terms for units of ten recently harvested coconuts in counting coconuts to 1000. Fox (1931) observed that among the Arosi people, Solomon Islands, counting was sometimes done "by ones, sometimes by pairs, sometimes by fours, sometimes by fives; the pair, or four or five being reckoned as a unit and given a distinct name" with numerous object centered variations and terms existent for yams, coconuts, banana-shoots for planting, pigs, dogs, fish, breadfruit, dogs' teeth, and shell currency.

These distinctions evolved in the context of counting systems and their bases that, as Lean (1991) demonstrated primarily in Papua New Guinea, extend from a vast array of counting systems in numerous languages. Lean classified these systems into several distinct types with a particular emphasis on a number system's expression of its "frame pattern" and "cyclic pattern" although others before and after Lean used other organizational standards. (See for example Berndt 1954, Joseph 2000, Philip and Kelly 1977, and Laycock 1975.) Descriptions (sometimes with illustrations) of body-part counting systems of indigenous peoples of Papua New Guinea, based on the extent of numbers before an extension beyond that number is employed, sometimes note a reversal in counting direction (characterized further by descending or ascending directions) or the use of another body in this relatively unorganized literature.

These descriptions appear to be characterizing these societies in an ethnomathematical context, as does a perhaps peculiar concern with indigenous Pacific peoples' abilities to count to large quantities and with their concepts of infinity. Although Clark maintained in 1839 that Hawaiians "seldom had occasion for any complex combination of numbers" (a perception usually tossed at atoll inhabitants in Micronesia as well), he still intermittently listed Hawaiian words for 4 (considered to be "the lowest class or collection of numbers") to 400,000 as well as a word for four million. He maintains however that this number "is not often brought into practice as their minds become confused with so great a number as is implied by the meaning of the word [*nalowale*]. A great but indefinite number is expressed by the repetition of the word *kini*, or *lehu*, as *kinikini*, *lehulehu*." Other, at least partial, depictions of the numerical extent of counting systems usually have indigenous counters falling off at a certain numbers (the highest numbers usually thought to be employed infrequently) and into a shout of the greatness of quantities that are like sands of the beach, stars in the sky, etc. (See for example Beaglehole and Beaglehole 1938, Elbert and Pukui 1979, Taylor 1957, Kaleva 1995, Seidenberg 1962). The Beagleholes (1938: 354) maintained in their study of the ethnology of Pukapuka that it was "a little hard to see the function of high numerical concepts in an atoll culture" although such large numbers "indicate not so much a definite number as a progression of increased greatness that is more sensed or felt than definitely apprehended." Drawing from his own experiences in learning mathematics in Papua New Guinea schools and his knowledge of the Wisai language from the Buin district of Bougainville, Kaleva (1995) also notes that while the word for a chicken represents 1000, and for 2 chickens 2000, and so on, there comes a point at which this numerical progression ceases and people say that "the chicken went into the bush and never came back" (Beaglehole 1938: 144) – a phrase Kaleva also identifies as an expression of infinity.

Numerical, spatial, and linear elements common to the western assigned cultural boundaries of Melanesia, Polynesia, and Micronesia vary in accordance with both the demands and the nurturing characteristics of the distinctive environments and social and cultural histories embodied in these boundaries. Arguing that the counting systems and their bases have developed and changed from indigenous environments and not from some Babylonian or other Western source (as Pospisil and Price (1966) suggested but which Bowers (1977) strongly rejected), Lean's extensive study of these systems throughout Papua New Guinea and into the Pacific islands demonstrates the depth to which functionality in an environment characterizes the individual elements of ethnomathematical concepts and practices in these three vast regions of the Pacific. While the existent literature (scattered with unintended and sometimes unindexed mathematical references) might enable one to identify Melanesia with the presence of counting systems, linguistic structures and principles of terminology, measurement, agricultural and lunar based calendars, and methods of conveying currency values for exchange (buoyed in particular by studies done in Papua New Guinea), ethnomathematical practices in the far flung atolls of Micronesia are much more distant and spatial in nature. Most aspects of counting, measuring, astronomical methods of determining time and creating the calendar, the intentional expression of geometric forms, determination of distance and numerous other elements of ethnomathematical practices span across Oceania. But each of these three Pacific regions originally created by European cartographers has its own physical circumstances and historical connectedness to make, for example, Papua New Guinea the central area for expanded enumeration concepts but Polynesia (and particularly Hawai'i and Easter Island) for past practices of aligning stone structures with stars to mark the occurrence of the equinox and solstice. Meanwhile in Micronesia, linear concepts in voyage dead reckoning, using what is often considered to be a dividing of a voyage into segments via linear associations of stars with an out-of-sight reference island en route through the *etak* concept, are generally lacking in Polynesia. While this *etak* concept is absent in Papua New Guinea (where some interesting topographical associations with ancestors and directions are reminiscent of Australian Aboriginal practices), it is also absent in island Melanesia.

Here we are again dealing also with the limitations not only of what has been of interest to writers – and particularly the earliest writers in the case of Polynesia – but what was accessible to them. Perhaps Captain Winker's tenacious but sidetracked attempts (1901) to comprehend the then secret essences of Marshallese stick charts and their use for interpreting swells refracted by atolls is somewhat demonstrative of this now incurable problem. Centuries of interaction between Papua New Guinea tribal peoples and the centrality of exchanges and gift protocols, the impacts of indigenous diffusion where it occurred, as well as the contemporary acculturation of contact with Europeans has its passages and forms in the many enumeration systems Lean examined. Enumeration descriptions occur elsewhere in this literature but not anywhere to the degree that it has in regards to Papua New Guinea. There are nevertheless a few examples available for Micronesia. Alkire (1970), for example, describes how Woleai's enumeration bases of four and eight not only reflect dualism in Woleai (central Caroline Islands) concepts of enumeration but also emphasizes their importance in the knot diviner's interpretation of 256 knot combinations (ultimate destinies) formed by knots representing those 16 traditional divination spirits whose two pairs of leaflet knot quantities do not each exceed four. In a somewhat sensationalized note, Ballinger (1978) discusses the recording by the 1908 Thilenius South Seas Expedition of a "mysterious" counting system on the atoll of Faraulep in the central Caroline Islands with its "regular, stepped, series of 'characters'" representing numbers from 100,000 to 60,000,000 (again noted as being unpractical for an atoll environment) and symbols being used with no apparent derivations from other Pacific islands. And while noting that the "ethnonavigators" of the Caroline Islands, in contrast to Western navigational practices, employ rigid spatial concepts that close off the potential for new information to be introduced into this nongeometrical or nonalgebraic system, Freedman (1980) still pointed out the Pukapuka system of numerals running from 1 to 12 and extending by 100s to 2,000 along with its quantitative class names for the counting of specific objects.

The presence of Polynesian enumeration in the literature (comparably marginal when referenced against the literature on enumeration in Papua New Guinea) in Polynesia either reflects a lack of attention by European writers, the long and early impact of European acculturation on enumeration systems, or both. We have Conant's 1893 survey of "primitive number systems" (including Polynesia) whose origins of numbers among "the savage languages of the human race" are unknowable as well as Thomas' attempt to link the Marquesas Islands to India via Malaysia through the presence of vigesimal systems of enumeration.

Even so, mathematical characteristics in each of these three giant regions of Oceania were and are expressible on the basis of the environments that have prompted and sustained them. It is clear, for example, that the large ocean areas separating small atolls and higher level islands, the relatively recent scholarly interest paid to the prehistoric exploration and settlement of the Pacific, and the remaining availability of indigenous, noninstrumental navigational techniques on the Caroline atolls of Polowat and Satawal in a larger context of the importance of such exploration and techniques to contemporary Pacific cultures, all make distance and linear associations prominent in Micronesian ethnomathematics. These distances are inherently linear in a forward moving fashion. A universal kind of fascination with the capacity of indigenous navigators to maintain and essentially harness distance in movements from one point to another is energized by both scholarship and cultural pride. The concept of *etak* as a technique for segmenting these voyages into manageable parts (as well as at least one alternative explanation that dismisses this segmentation (Hutchins 1983) and the expression and explanation of wave refraction and interpretation in the linear expressions of the Marshallese stick charts remain prominent parts to this literature on Micronesian mathematical ideas and practices.

On the other hand, spiritual, material, and societal needs have also encouraged recognition and study of land-based uses of mathematical concepts. The knot divination practices passed on by the sky-god *Supwunumen* to determine the outcomes of certain events and the 256 possible fates of people for days and years to come probably registers as the most unique mathematical element in Micronesia. However, measurement concepts that may employ a small variation of lengths by the use of the same body part but from different bodies for canoe and house construction, axis concepts, calendar development (primarily lunar and somewhat stellar referenced in Polynesia and Micronesia but more agriculturally based in Melanesia), circular displays and conceptualizations, cosmology, and geometric concepts and applications are generally found in the written literature on all of Oceania although each region has its distinctive marks. Late nineteenth and early to lower-mid twentieth century literature on Hawaiian cosmology and lunar calculations of the days and thus the months are, for example, coated with Hawaiian genesis traditions of the cosmos and the role of the Pleiades and the moon. Chauvin (2000: 116) notes that, "the Hawaiian names for the thirty nights of the moon indicate an ancient ability to make accurate naked-eye observations of lunar phases and then to record those observations in descriptive appellations. Thus the first appearance of the waxing crescent moon in the west marking the first night of the month was called Hilo – meaning 'twisted' or 'threadlike,' as a braid."

There is very little mention of base properties in Micronesia (as compared to their propensity in writings on Papua New Guinea enumeration systems), little or no recognition of any body part counting practices, no references to archaeoastronomy research (in comparison to those available for Easter Island, Hawai'i, and, to a lesser extent, Tonga), very little concern with any mathematical elements of debt calculation and payment or base properties (again, in comparison to a much stronger presence in the literature on Papua New Guinea), and no mathematical elements of birth order names. However, the presence of horizontal concepts and their role in dealing with ocean distances are far more present in the literatures on Polynesia and Micronesia than for Melanesia and specifically Papua New Guinea. Horizontal lines on the tattoos of an elder Marshallese man in Barclay's novel (2002) on the Marshall Islands have numerous horizontal elements which themselves are intended to reflect their conceptual presence at sea. The earth's horizon itself often figures prominently not only in relation to stellar references to cardinal points (see Brower (1983), Finney (1998), and Babayan (1987) for examples) but it also has a crucial role in traditional Hawaiian and Chuukese conceptualizations of a series of domed heavens. (See Chauvin 2000 also for their Hawaiian expression in a gourd.) Chuukese conceptualizations of these layered heavens involved paths for the dead where the "Singing Place" (*Neechiichi*) level or path tended to turn these voyaging souls toward irresponsible dance and song, thus distracting them from their final abode. Riesenberg (1972) focuses on the centrality of metaphor in several categories of mnemonic navigational knowledge on Polowat and the expression of relationships between real and mythical geographic elements and star courses. Riesenberg also examines the importance of the horizon in stellar courses that are thought of in terms of navigators pursuing a reef fish from one island to another with their associated stellar alignments. The Breadfruit Picker (*fééyah*) category of courses, Riesenberg notes, "are not necessarily on a straight line under the star named in the directions but include one star to each side of it, thus covering a sector of the horizon three stars wide" (Riesenberg 1972: 24).

The ethnographic and anthropological literatures of Melanesia, Polynesia, and Micronesia all have seemingly inevitable references to the triangular or rectangular or square joining of cross beams, weaving threads, planks, and canoe pieces that emerge from practical applications but which would not only be difficult to isolate entirely (and what would be the point?) but would probably also be difficult to align with conscious ethnomathematical concepts. The appearance of squares, circles, and triangles in the numerous available descriptions of string figure practices in the Pacific are likewise natural consequences of string designs with a few exceptions of figures named after geometric shapes and the direct intent to convey these figures in the end result of the dexterity of string and fingers. One might point to these natural consequences of material needs as being indicative of the ultimate weakness with which bibliographic overviews of subjects are not only guided by the literature that is actually available but more importantly, by the human dynamics of history that will always defy anything resembling a complete inventory.

Thus environmental factors and geographic realities (linear spaces associated with stellar concepts in Micronesia, enumeration systems for social traditions of exchange and possession in Papua New Guinea) serve to define and stress the kinds of mathematical concepts employed in different Pacific societies. The piecemeal fashion with which these concepts have been identified and extended in both scholarly and contextual terms actually underlines the intricate place of ethnomathematical practices in individual cultures. Their emergence comes and came over the past several decades through their sometimes chance recognition in other ethnographical terms, the scholarly concerns that happen to be prevalent for given societies, and of course the extent to which access was allowed to outside observers. At times it was the particular practice wrapped up in ethnomathematical principles that was the primary reason for an ethnographic focus – such as Bernard A. Deacon's detailed descriptions (1934) of the geometrical sand drawings from Malekula (Vanuatu) and most notably that which the *Temes Savsap* ghost half erased and expected the dead souls traveling to the afterlife to reconstruct before passing on or face being devoured – for a particular society. The same was true for selected other works on mathematical principles. Price and Pospisil's theory (1966) of a Babylonian influence on enumeration structures among the Kapauku people in Papua New Guinea was strongly rejected by Bowers (1977) while conjectures by Ross (1936) and Heyerdahl (1961) that an apparent presence of two distinct counting systems on Easter Island at the time of early European contact was indicative of outside, non-Polynesian influences were challenged by Métraux (1936). Works on Papua New Guinea enumeration systems sometimes draw from previous works while scholarship on the challenges Papua New Guinea students face in successfully comprehending and using Western enumeration and mathematical principles – particularly in the acknowledged context of their social and environmental origins – represent the pocket of literature on the presence of Pacific ethnomathematical principles that is most responsive to the works of others.

While arguing that a predominant belief in Western worlds of the universality of mathematical principles underlines the ongoing use of these principles "as one of the most powerful weapons in the imposition of western culture," Bishop (1990: 60) also recognizes the nebulousness of the term "ethnomathematics" itself. Perhaps, he suggests, "it would be better not to use that term but rather to be more precise about which, and whose, mathematics one is referring to in any context." This issue of the foremost inclusion of contextual realities stresses the "humanly constructed" nature of mathematics – a nature that Bishop maintained can be imperialistically manipulated as reflected for example in the fact that the 180° sum of the angles of a "perfect triangle" was predetermined by a dominant western epistemology. In extending linear and horizontal concepts to a Micronesian concept such as *etak*, to the practice of backsighting against prominent points of an island as it sinks below the horizon, and even to the "linear series" of ancestral and contemporary movements that embody a "lineal segmentation" from a point of unity (Rumsey 2001), one speaks directly to the representation of cultural ideas and realities subverted by the idea of there being a universal and culturally free field of mathematics to which all can refer. The interpretations of mathematically related ideas throughout the Pacific and the anthropological and other literatures that have attempted by happenstance or intent to express them have always prompted the possibilities and appropriateness of this extension. The legitimacy that they are afforded speak not only to Bishop's concerns but to the relevancy of practices that in many cases have become more "past" through colonial hegemony as well as an acculturation that was once more indigenous in nature but of course finds its niche in the far reaching influences of western society.

This is where, however, the depiction of "real life" in specific societal and cultural dynamics resides when lineal and spatial manifestations from that life are acknowledged in their own right. In Rumsey's examination of "topographic objectification" in a landscape of totemic references in the Morehead River area of Papua New Guinea and among the Iatmul people of Sepik, the concept of spatial unity derived from ancestral tracks that emanated from a featureless pit at the beginning of the world and from which ancestral movements in space and associated phenomena designated clan properties, features linear and spatial ideas and actions of both practical and spiritual value. The difference between this kind of ancestral tracking and that of Australian aboriginal peoples is the greater abstraction of actual places from the empowering force of their names in Morehead River cosmology than is true of Aboriginal approaches to such inscriptions. However, admitting these ideas of spatial unity and ancestral tracks and property segmentation into ethnomathematical levels of describing societies bodes well for their relevance in the intricate nature that mathematical ideas in a society play in understanding social structures, values, and perceptions. Perhaps we can be reminded here of Bishop's suggestion that even a universal term such as "ethnomathematics" for indigenous contexts may not serve the Sepik and Morehead River areas (or those of Maekula or perhaps of any other area discussed above) very well. Environmentally based concepts of lines, distances, division and segmentation, topographical and oceanic references (both practical and mythical), enumeration by systems of indigenous diffusion and acculturation (and now those of an influential western world), perceptions of space and measurement, and any number of mathematical principles that have emerged from various literatures on the Pacific clearly underline the centrality of these cultural contexts.

Mathematics in Vietnam

Alexei Volkov

Traditional Vietnamese mathematics has never been studied systematically. Rare mentions of Vietnamese mathematical works are either written by nonspecialists or based on second-hand information. No systematic efforts were made by modern researchers to locate, publish, or study the corpus of extant Vietnamese documents concerning mathematics. General works by colonial French scholars, such as the book by Huard and Durand (1954: 120, 144) or the paper by the modern Vietnamese author Tạ (1979) contain only scarce and sometimes unreliable information on the traditional Vietnamese mathematics (Volkov 2002: 375). Similarly, no more than a short paragraph was devoted to the topic in the recent book *A history of Chinese mathematics* by Martzloff (1997: 110).

The first attempt to study the extant materials on Vietnamese mathematics was made by the Chinese mathematician and historian of science, Zhang Yong 章用 (1911–1939). In 1938 Zhang Yong visited Hanoi and explored the collection of books of the French

School of the Far East (École française d'Extrême-orient) (Li 1954). In 1939, soon after his travel Zhang Yong passed away and his findings were not published. Only recently Han Qi provided a brief introduction to the extant Vietnamese astronomical and mathematical texts written mainly on the basis of his study of the partial copies of Vietnamese treatises made by Zhang Yong in Vietnam and preserved in Beijing (Han 1991). Recently the author of these lines published several papers (Volkov 2002, 2004, 2005, 2006) on the basis of his preliminary investigation of the original mathematical treatises preserved in Vietnam and in France.

Vietnamese Mathematics: An Outline

Vietnam gained independence from China in the tenth century AD; the country was united and proclaimed an Empire in 968. At that time the Vietnamese state took shape based upon the blueprint of its Chinese counterpart, and a State University (*Quoc tu giam* 國子監, Chinese *Guozi jian*, literally Directorate of Education for Sons of the State), an equivalent of the Chinese University of the Tang dynasty, was established early in the eleventh century. There are records about the metropolitan examinations in "counting" (*suan*, Viet. *toán* 算) that took place in 1077, 1179, 1261, 1363, 1404, 1437, 1472, 1505, 1698, 1711, 1725, 1732, 1747, 1762, 1767, and 1777. In a record of 1762 the mathematics examinations were ordered to be held every 15 years.

The official mathematics examinations were suspended in China by the end of the Tang dynasty (618–907) and reintroduced during the Song dynasty (960–1279). The mathematical textbooks were reedited and block-printed in 1084; the examinations were held in 1104, 1106, 1109, and 1113 (Hucker 1985; Martzloff 1997: 82). It may be therefore assumed that in the eleventh century the Vietnamese mathematics education and examination system functioned following the Chinese tradition of the late first millennium AD. However, the oldest mathematical textbooks supposedly used in Vietnam were lost, most likely, prior to the mid-fifteenth century. One of the possible reasons for the loss was the massive destruction of books during the war with Champa (1371) and during the Chinese occupation in the early fifteenth century (Tran 1938: 43–45; Cadière and Pelliot 1904: 619, n. 3). In 1460–1497 two successive orders of the newly established Lê 黎 dynasty prescribed to look for ancient books all over the country and to deliver them to the court, yet there is no available information concerning any mathematical or astronomical books found during these campaigns. The state of mathematics and mathematics education in Vietnam of the eleventh to fifteenth centuries thus cannot be reconstructed, at least on the basis of the available sources.

The state mathematicians and astronomers in the seventeenth century Vietnam are mentioned in the records of the Jesuit scholars, Christoforo Borri (1583–1632), Julien (Giuliano) Baldinotti (1591–1631), and Alexandre de Rhodes (1591–1660). In his book *Relation on the New Mission of the Fathers of the Company of Jesus to the Kingdom of Cochinchina* published in 1631, Borri describes in great detail his predictions of the lunar and solar eclipses on December 9, 1620 and on May 22, 1621 he used to convert Vietnamese functionaries (Borri 1631: 178–190, 1931: 372–381).[1] Borri mentions that the court astronomers of the Nguyen Lords (who at that time reigned over the Central part of the present day Vietnam) were usually calculating eclipses with the accuracy of 2–3 h (Borri 1931: 378). In his book Baldinotti mentions the discussions he had with the "King of Tonkin" (i.e., Northern Vietnam) about "the Sphere" (Baldinotti 1629: 196); most likely, he refers to the treatise *Tianwen lüe* 天問略 (Brief account on the Questions concerning the Heaven), a compendium of Ptolemaic astronomical theories compiled by Manuel Dias in 1614 (Dudink 2001: 201). In turn, A. de Rhodes visited Northern and Central Vietnam in 1624–1640 and mentioned in his book the numerous discussions of astronomical topics he had with local astronomers and geomancers (whom he indiscriminately calls "mathematicians") as well as with the rulers of the both parts of Vietnam (de Rhodes 1854: 111–113, 185). All three accounts suggest that by the early seventeenth century Vietnamese mathematical astronomers and high-rank officials were capable of conducting sophisticated astronomical calculations and were aware of contemporaneous Chinese (and, therefore, European) astronomical theories.

It appears that the state mathematics education survived in Vietnam at least until the early nineteenth century. The reign of the Emperor Minh Mệnh (Minh Mạng) 明命 (Nguyễn Phúc Đảm 1791–1841) was the time when traditional Chinese scholarship of the Ming dynasty (i.e., prior to the Manchu invasion and the rule of the Qing dynasty, 1644–1911) was highly appreciated, and even though the European mathematics and astronomy, as suggested above, may have been known to Vietnamese court astronomers beginning from the early seventeenth century, the Vietnamese treatises of the nineteenth century and even early twentieth century still looked similar to Chinese texts prior to the early seventeenth century (see below).

The list of the Chinese books on mathematics and mathematical astronomy preserved in the imperial library in Hue in the nineteenth century reconstructed

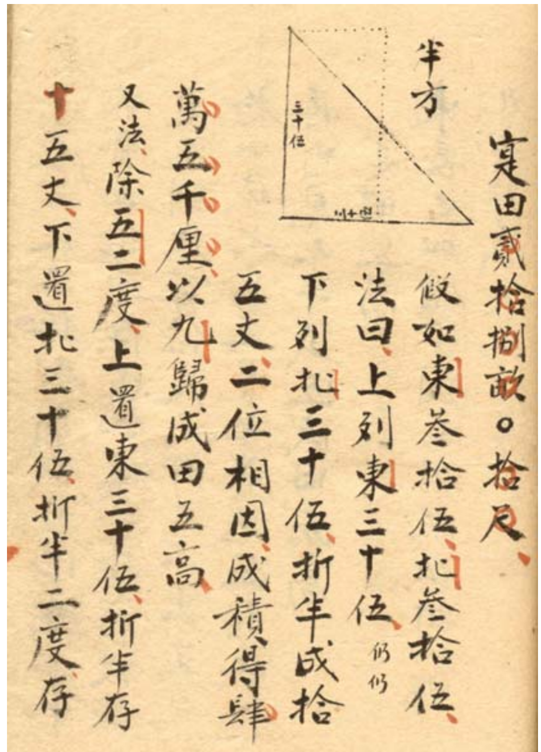
[1] It is possible that the way in which Borri used his astronomical expertise to convert the Vietnamese functionaries was known to the Jesuit Ferdinand Verbiest whose prediction of a solar eclipse in 1669 played a crucial role in the history of the Jesuit mission in China.

on the basis of the extant catalogs includes 59 titles. The list shows that the collection of mathematical books in the library (presumably accessible to the officers of the Astrological Bureau) contained mainly pre-Qing and early Qing mathematical treatises not influenced by European mathematics. It remains unknown whether this was the result of a deliberate choice of the authorities made in attempt to restore classical Chinese scholarly tradition.

The Extant Vietnamese Mathematical Treatises: A General Outline

The number of extant treatises representing Vietnamese mathematical tradition amounts to 19, yet only seven of them (nos. 1–7 below) can be dated. Their list reads as follows:

1. *Toán pháp đại thành* 算法大成 (Great Compendium of Mathematical Methods). By Lương Thế Vinh. Location: The Institute of Han-Nom Studies, Hanoi.
2. *Cửu chương lập thành toán pháp* 九章立成算法 (Ready-made Computational Methods of Nine Categories). By Phạm Hữu Chung 范有鍾, 1713. Location: The Institute of Han-Nom Studies, Hanoi; Paris, Bibliothèque Nationale de France; The National Library of Vietnam, Hanoi.
3. *Chỉ minh lập thành toán pháp* 指明立成算法 (Guide for understanding of the Ready-made Calculational Methods). By Phan Huy Khuông 潘輝框, 1820. Location: The Institute of Han-Nom Studies, Hanoi, Vietnam; The Institute of Information on Social Sciences,[2] Hanoi; Ecole française d'extrême-orient, Paris (microfilm).
4. *Ý Trai toán pháp nhất đắc lục* 意齋算法一得錄 (A Received Copy of the Computational Methods of Ý Trai). By Nguyễn Hữu Thận 阮有慎 [=Nguyễn Ý Trai], 1829. Location: The Institute of Han-Nom Studies, Hanoi.
5. *Cửu chương toán pháp* 九章算法 (Computational methods of Nine Categories); another title: *Cửu chương toán pháp lập thành* 立成 (Ready-made Computational methods of Nine Categories), 1882. Location: The Institute of Han-Nom Studies, Hanoi; The Institute of Information on Social Sciences,[3] Hanoi.
6. *Bút toán chỉ nam* 筆算指南 (Compass of Handwritten [lit. "Brush"] Computations). By Nguyễn Cẩn 阮菫, revised by Kiu Oánh Mậu 喬瑩懋, 1909. Location: The Institute of Han-Nom Studies, Hanoi; Ecole française d'extrême-orient, Paris (microfilm).



Mathematics in Vietnam. Fig. 1 Page 75 of the *Thống tông toán pháp* 統宗算法 (Systematic Treatise on Computational Methods). By Tạ Hữu Thường 謝有常. Picture coutresy of the National Library, Hanoi.

7. *Toán pháp* 算法 (Computational methods). By Nguyễn Cẩn 阮菫, revised by Kiều Oánh Mậu 喬瑩懋. Location: The Institute of Han-Nom Studies, Hanoi.
8. *Đại thành toán học chỉ minh* 大成算學指明 (Guidance and explanations for the Great Compendium of Mathematical Learning). By Phạm Gia Kỷ 范嘉紀; revised by Phạm Gia Chuyên 范嘉瑼. Location: The Institute of Han-Nom Studies, Hanoi.
9. *Lập thành toán pháp* 立成算法 (Ready-made computational methods). Location: The Institute of Han-Nom Studies, Hanoi; the Institute of Information on Social Sciences, Hanoi;[4] the Institute of History, Hanoi.
10. *Thống tông toán pháp* 統宗算法 (Systematic Treatise on Computational Methods). By Tạ Hữu Thường 謝有常. Location: The National Library, Hanoi (see Fig. 1).
11. *Toán điền trừ cửu pháp* 算田除九法 (Nine methods of division for computations [related to] fields). Location: The Institute of Han-Nom Studies, Hanoi.

[2] According to Tran and Gros (1993).
[3] According to Tran and Gros (1993).
[4] According to Tran and Gros (1993).

M

12. *Toán học để uẩn* 算學底蘊 (Reaching the Depths of the Science of Computation). Location: The Institute of Han-Nom Studies, Hanoi.
13. *Toán học tâm pháp* 算學心法 (Mental Methods of the Science of Computation). Preface 1850. Location: The Institute of Information on Social Sciences, Hanoi.
14. *Toán học cách trí* 算學格致 (Exploration [of Things] and Extension [of Knowledge] in the Science of Computations).[5] Location: The Institute of Han-Nom Studies, Hanoi.
15. *Toán pháp* 算法 (Computational methods).[6] Location: The Institute of Han-Nom Studies, Hanoi; The Institute of Information on Social Sciences, Hanoi;[7] Ecole française d'extrême-orient, Paris (microfilm).
16. *Toán pháp đề cương* 算法提綱 (Presentation of the Key Points in the Computational Methods).[8] Location: The National Library, Hanoi.
17. *Toán pháp ký diệu* 算法奇妙 (Mysteries of Computational Methods). Location: The Institute of Han-Nom Studies, Hanoi.
18. *Tổng tụ chư gia toán pháp đại toàn* 總聚諸家算法大全 (Great Compendium of the Computational methods of All Schools). Location: The Institute of Information on Social Sciences, Hanoi;[9] the Institute of Han-Nom Studies, Hanoi.
19. *Trùng dính Toán học chỉ nam tân biên* 重訂算法指南新編 (New Edition of the Re-established [text of the] *Compass for Method of Computations*). Location: The Institute of History, Hanoi.

The book conventionally considered the oldest, the *Toán pháp đại thành*, is credited to the authorship of one Lương Thế Vinh 梁世榮 (1441–1496?), a high-rank official of the Lê 黎 dynasty (1428–1789), yet the authorship of Lương is problematic (see below). Another book (no. 2 in the list) was compiled in the early eighteenth century, and three (nos. 3–5), in the nineteenth century, while the last of the dated books (no. 6) was published as late as the early twentieth century. Since the compilers of the book no. 7 are the same as of the book no. 6, one can conjecture that the latter was also compiled in the late nineteenth–early twentieth century. None of the remaining 12 books are mentioned in the bibliographic chapter of the *Đại Việt thông sử* (Complete History of the Grand Viet) accomplished in 1749 by the famous Vietnamese *literatus* Lê Quý Đôn 黎貴惇 (1726–1784?), and one can be tempted to date all the books not earlier than the late eighteenth century (Gaspardone 1934: 149; Tran 1938: 97–98). On the other hand, the mathematical contents of the books are similar to that of Chinese mathematical treatises antedating the introduction of European mathematical methods to China by the Jesuits in the early seventeenth century.

The Structure of a Mathematical Treatise: The Example of the *Toán pháp đại thành*

There are two manuscript copies of the treatise *Toán pháp đại thành*, both found in the Han-Nom Institute, Hanoi; their call numbers are VHv 1152 and A 2931. When manuscript A 2931 was produced is unknown (but it certainly happened prior to 1934), while the date when the copy VHv 1152 was made (1944) is written on its front page; a comparison of the copies suggests that the MS VHv 1152 is a copy of A 2931. Neither manuscript has a preface or a postface, or any other data which would suggest the date when the treatise was compiled or would specify the identity of the author(s). The name of the presumed author ("Doctor Lương Thế Vinh") is written only on the first page of each manuscript next to the title; however, it is possible that this page was added later (see also Gaspardone 1934: 149, n. 1).

The treatise is compiled in the traditional "Chinese" way, as a collection of problems with numerical answers given along with the procedures (algorithms) for their solution. There are also several procedures that do not correspond to any particular problems; most probably this is the result of loss of parts of the text containing the corresponding problems and answers. The total number of problems in the treatise amounts to 138. Some geometric problems are not explicitly stated, but introduced with a diagram of a figure with given dimensions. In one case neither numerical data nor a problem accompanied an algorithm, yet the algorithm may well be a fragment from the famous Chinese "Sunzi remainder problem."

The text of the treatise can be subdivided into eight parts:

Part 1 (problems 1–35) contains problems devoted to partitioning, and, in particular, to division. Part 2 (problems 36–42) contains problems devoted to the calculation of the areas of plane figures: a square, a rectangle, a figure approximated by the area of a trapezium, a circle, and a segment of a circle. Part 3 (problems 43–69) contains problems devoted to proportions, the rule of three, and the rule of double false position, as well as to rather simple cases of

[5] The book is listed in Tran and Gros (1993) under the title Toán pháp 算法 (Computational methods).
[6] The original title of the book remains unknown; the title "Computational methods" was apparently given to a manuscript with missing first pages on the basis of its contents.
[7] According to Tran and Gros (1993).
[8] This is *not* the title of the book. The first page(s) of the manuscript is (are) missing and the subtitle of its first section is used as its title in the catalogue of the National Library.
[9] According to Tran and Gros (1993).

multiplication and division. This part also includes a method for calculating the height of an object when the height of another object and the length of the shadows of both objects are given. Part 4 (problems 70–85) contains problems devoted to root extraction and to an auxiliary algorithm used for the conversion of monetary units of one type into another. Part 5 (problems 86–93) is a sequel to Part 3. The reader is asked to solve problems on the calculation of interest and on multiplication and division. However, there is a problem devoted to the calculation of the volume of a solid figure and a fragment on divination. Part 6 (problems 94–131) is related to various subjects, such as calculations of the areas of various figures. Here one finds such shapes as rectangles, circular segments, a "horn of the bull," circles, "drums," ellipses, rings, an "eye-lid" (or "eye-brow," that is, the intersection of two circles), an isosceles triangle, a rectilinear figure composed of several adjacent trapezia, a trapezium, a quadrilateral with four given sides, and the figure formed by two adjacent squares. The remaining problems in this group are devoted to the extraction of square roots, calculation of the volumes of rectilinear solids, and to the conversion of metrological units. Part 7 does not contain mathematical problems; this is a large independent text devoted to land taxation. Part 8 (problems 132–138) embraces various problems devoted to "numerical divination," the calculation of the height of a tree when the length of its shadow is given, a rhymed solution to a problem of indeterminate analysis, and the calculation of the area of a quadrilateral.

Several "earmarked" mathematical problems and methods found in the *Toán pháp đại thành* studied in order to suggest the possible origins of the contents of the treatise were discussed in (Volkov 2002). The analysed topics included: (1) the counting instruments to be used; (2) the 9 × 9 multiplication table featured in the treatise; (3) the lists of the so-called "large numbers"; (4) rhymed algorithms for computation of areas; (5) problems of remote surveying; (6) problems related to numerical divination; and (7) problems on indeterminate analysis. The results of the comparison of the above-mentioned mathematical methods, problems, and instruments with their Chinese counterparts can be summarized as follows (for more details see Volkov 2002):

1. The lack of explicit references to the abacus in the treatise suggests that either the *Compendium* was compiled *before* Vietnamese mathematicians were acquainted with any Chinese books devoted to abacus calculations, or it was compiled later solely on the basis of Chinese and Vietnamese mathematical books written prior to 1573 when the first extant Chinese mathematical treatise devoted especially to the use of the abacus, Xu Xinlu's 徐心魯 *Counting procedures for Pearls on a Plate* (*Panzhu suanfa* 盤珠算法), was published.
2. The text of the treatise does not contain any information confirming that it was indeed authored by Luong Thế Vinh, the fifteenth century *literatus* and official.
3. It is not impossible, however, that the book may well have been a compilation made exclusively on the basis of mathematical treatises compiled in China prior to the late fifteenth century and later available in Vietnam. However, the compilation of the treatise involved a substantial "localization," that is the adaptation of the problems and methods to local measure units, currency, tax system, as well as to the names of specific local objects mentioned in the problems (plants, drugs, kinds of food, animals, etc.).
4. The seeming similarity between certain methods in the *Compendium* and in the Chinese treatise *Suanfa tongzong* 算法統宗 (1592) by Cheng Dawei 程大位 does not necessarily mean that the Vietnamese text was compiled on the basis of the book of Cheng. The similarity can be explained by the fact that Cheng himself based his manual on numerous mathematical texts compiled in the thirteenth to sixteenth centuries available to him, firstly and most importantly, the treatises of Yang Hui 楊輝 (fl. ca. 1275) and Wu Jing 吳敬 (fl. ca. 1450). It is not impossible that the compilers of the *Compendium* also had access to these treatises, or to other older Chinese treatises containing similar materials and later lost.

The preliminary exploration of the contents of the Vietnamese treatise *Toán pháp đại thành* presented in (Volkov 2002) thus did not permit a clear picture of its origins. The exploration of the materials related to the life and activity of its presumed author, Lương Thế Vinh, thus appeared necessary to establish the origins of the book. The obtained results of this exploration (Volkov 2005, 2006) are summarized in the following section.

Lương Thế Vinh: The Case of a "Mathematical Agiography"

The biographies of Lương can be provisionally subdivided into two categories, the "historical biographies" and the "legendary accounts." The "historical biographies" of Lương Thế Vinh are found in the collections of biographies *Đăng khoa lục* 登科錄 (*Records of successful examinees*) by Nguyễn Hoãn 阮俒 (1712–1791) et al., in the manuscript entitled 登科錄抄本 (Manuscript copy of the *Records of successful examinees*), and in the treatise *Lịch đại đại khoa lục* 歷代大科籙 (Records of Great Examinations

M

Through Generations). All these texts present rather short descriptions of Lương's official career and specify his birthplace and his official duties within the Hàn lâm 翰林 Academy. Second and third treatises mention a mathematical book he wrote, yet provide different titles for the book. The second and the third biographies mention that Lương's diplomatic activities, the details of which, however, remain unspecified.

The second group of the extant Lương's biographies focus primarily on the supernatural circumstances of his life and death. The following four collections of biographies of successful examination candidates contain his biographies including "supernatural" elements that slightly differ from source to source and are sometimes placed in different order:

1. The *Đăng khoa lục* 登科錄 (Records of successful examinees) by Nguyễn Hoản.
2. The *Đăng khoa lục sưu giảng* 登科錄搜講 (Investigation and discussion of the *Records of successful examinees*), by Trần Tiến 陳瑨 (1709?–?).
3. The *Đại Việt đỉnh nguyên Phật lục* 大越鼎元佛錄 (*Records of the Successful Candidates and of those who attained Buddhahood in the Great Viet [=Vietnam]*).
4. The *Nam sử tập biên* 南史輯編 (Histories of the South [=Vietnam], collected and edited), by Vũ Văn Lập (1896).

A short description of the "supernatural" biographies is found in (Volkov 2005), and the translation of one of them is published in (Volkov 2006). The preliminary analysis of the legends suggests that the early legends of Lương were created in two nonintersecting social circles (that can be dubbed "Palace" and "Village"), yet both groups of legends portrayed him as possessing supernatural powers or divine origin. One can conjecture that the reason why he became associated with mathematics may have been related to his official duties during his lifetime such as, for example, his participation in diplomatic activities and in military operations against the Cham, his work in cartography, etc., briefly mentioned in his biographies. His legendary capacities of "counting" and "measuring" (in a broader sense) in this case would have merged with his established status of supernatural being and thus may have made him the patron saint of professional mathematicians by the early eighteenth century (Volkov 2005).

The temple devoted to Lương Thế Vinh 梁狀元祠 located in his native village Cao Hương (Nam Dinh Province, Vu Ban district) hosts the statue of Lương, his portrait, details of his official costume (boots and hat), and a number of Imperial edicts related to the establishment and functioning of the temple (Volkov 2005). The official portrait of Lương preserved in the temple (Fig. 2) depicts him as a state functionary without making any visual reference to the miraculous circumstances of his birth and life; only one inscription mentions a mathematical work he presumably authored.

Mathematics in Vietnam. Fig. 2 The portrait of Lương Thế Vinh preserved in his temple, Cao Hương village.

The *Chỉ minh lập thành toán pháp* and the Model Examination Paper

The mathematical treatise *Chỉ minh lập thành toán pháp* 指明立成算法 (Guide for Understanding of the Ready-made Calculational Methods) was compiled by Phan Huy Khuông 潘輝框 in 1820 (Tran and Gros 1993; 1: 258). The last, fourth chapter of the book contains a model examination essay that spreads over almost six pages. This unique document is particularly interesting for the history of mathematics education in Vietnam and China.

The text of the model examination work written by Phan Huy Khuông contains a rather simple problem: three categories of officials, A, B, and C have to be remunerated with $N = 5{,}292$ *lương* of silver; the ratio of the amounts of silver to be given to the functionaries of the three ranks is $a{:}b{:}c = 7{:}5{:}2$, and the numbers of functionaries of each category are A = 8, B = 20, and C = 300. The question is to find the "scaled distribution" for them, i.e., the amounts of silver x, y, z given to each functionary of the categories A, B, and C, such that $x{:}y{:}z \therefore a{:}b{:}c$, and $\mathrm{A}x + \mathrm{B}y + \mathrm{C}z = N$. The problem of this type are found as early as in the *Suanshu shu* (prior to the early second century BCE) and in the *Jiuzhang suanshu* (the first century AD), and are also found in a large number of medieval Chinese mathematical treatises. To solve the problem, the imaginary model candidate has to use the method based on the following idea: since $x:y:z \therefore a:b:c$, the ratio of the magnitudes $Ax + By + Cz$ and $Aa + Bb + Cc$ will be the same as $x:a = y:b = z:c$. This latter ratio can easily be found: since $Ax + By + Cz = N$ is given, $x:a = y:b = z:c = Ax + By + Cz:Aa + Bb + Cc = 5292:(56 + 100 + 600) = 5{,}292:756 = 7:1$, hence the solution (Volkov 2004).

The solution of this particular problem is not as important as the very form of the essay suggested by Phan Huy Khuông, most likely an instructor of an educational institution. Firstly, the candidate is supposed to check the data proposed in the problem; secondly, he has to find a solution to the problem. The basic algorithm is certainly known to the examinee, he is not supposed to invent it anew. Yet he has to apply it correctly to the given data and to make sure that it works and that the obtained solution satisfies the original conditions. This style of the "model" examination work found in the nineteenth century Vietnamese mathematical treatise thus was essentially the same as that of the mathematics examinations papers of the Tang dynasty (Siu and Volkov 1999).

Conclusions

The available materials do not suggest any reliable picture of the traditional Vietnamese mathematics prior to the fifteenth century, and no information is available concerning the transformation of the system of mathematics education that most likely resulted from the Chinese occupation of Vietnam in the early fifteenth century. However, numerous sources suggest that mathematics and mathematical astronomy occupied in Vietnamese society a position similar to that of its Chinese counterpart in the first millennium AD and remained a discipline supported by the state until the early twentieth century.

The extant Vietnamese mathematical treatises were produced, most likely, in the early eighteenth–late nineteenth centuries on the basis of older Vietnamese mathematical treatises drawing upon their Chinese counterparts of the Ming dynasty. Their preliminary investigation suggests that the Vietnamese mathematicians were not willing to include the elements of the contemporaneous Western mathematics introduced by Western missionaries in China in the early seventeenth century. The Vietnamese mathematical treatises appear rather similar to the Yuan and Ming dynasty corpus of the "practical" or "popular" Chinese mathematical treatises (dramatically different from the high-level mathematical texts devoted to the higher degree polynomial algebra of the late Song–early Yuan dynasties). In the Ming dynasty China (1368–1644), the traditional mathematics was transformed into an applied discipline used for practical ends by low-level state officials, merchants, artisans, etc., while remaining the subject of the research conducted by isolated scholars without the ideological or material support of the state who were interested in what would be called nowadays intellectual history; it was no longer one of the subjects of the state examinations, as it used to be during the Tang (618–907) and Song (960–1279) periods. In Vietnam, on the contrary, the discipline remained embedded in the framework of the old Chinese-style state education, employed traditional didactic practices, and was linked to the bureaucratic hierarchy via the institution of mathematics examinations.

Mathematics of Yolngu Aboriginal Australians

Helen Verran

Yolngu Aboriginal Australians live as members of around 20 different clan groups in northeast Arnhem Land in Australia's Northern Territory. They organise their collective and individual lives through a mathematics system very different to the modern system of abstracting through number and quantification. The modern system is incorporated as a subsidiary to their indigenous mathematical system. The Yolngu form of indigenous mathematics can be understood as exemplifying the many similar systems that have life in hundreds of Aboriginal Australian communities.

To consider notions of Aboriginal mathematics usefully in a short space we need to avoid the academic controversies over what mathematics is about and how we know it, while still demonstrating something held in common between the two arenas we identify as Western and Yolngu Aboriginal mathematics. Before we can say anything about mathematics in the life of Aboriginal Australian communities it will help to look briefly at the cluster of meanings associated with the term 'mathematics' in Western life.

Bowing to the antiquity of the notion of mathematics we can note the Greek origins of the words mathematics and mathesis/mathetic. This cluster of words coming to us in English through Latin carries original ideas of learning, seeing and mental discipline. To these are added overtones of systematicity: arithmetic, geometry and reasoning. Western mathematics involves rigorous and systematic ways of seeing and working things out, and is intimately tied up with the constitution of the social order at both the macro- and micro-level. That much is uncontroversial. But asking about the objects which constitute mathematics brings us to less solid ground. Most people want to answer that mathematics is constituted of abstract objects. But constrained to ask what abstract objects are, we find ourselves amongst the disagreeing philosophers and mathematicians and in the realm of metaphysics.

The objects of Western mathematics are forms that inhabit an arena seen as somehow beyond the concrete here-and-now. Those mathematical forms, glimpsed through material objects and arrangements, are usually taken as representations of mathematical objects. In contrast the objects of Yolngu Aboriginal mathematics have life in the concrete here-and-now in that they are performed or enacted. In their being performed or collectively enacted, 'The Dreaming' or *Wangarr*, which is the origin of Yolngu mathematical objects, is remade in the present. There are significant differences between Western mathematics and Yolngu Aboriginal mathematics at the metaphysical level. I will not explore those differences here. Rather I look for a similarity that can be seen as lying within this overarching difference.

A commonsense way of beginning is to take numbers as representative of the sorts of objects we find in mathematics. Many of us are comfortable with seeing numbers embedded in very practical matters like tallying with fingers or stones. We continue to talk of 'digits' alluding to a historical role for fingers, and perhaps for toes. We do not, however, expect that numbers should remain tied to those practical origins. Most people are quite comfortable with numbers being highly mobile, working so as to pattern and order, in almost any situation. Of course, there are many mathematicians and philosophers who would disagree with this way of coming up with a working definition of mathematical objects because it seems to downgrade the significance of numbers and other mathematical objects, a significance deriving from their proper status as 'abstract'.

My approach emphasises instead the ways numbers are embodied and embedded in ongoing collective life, irrespective of whether that is the rarified halls of university departments of mathematics, or the aisles of supermarkets and the anxiety ridden rooms of weight-loss clinics. Nevertheless taking this everyday collective and materialist understanding of number as a mathematical object seriously I suggest that it can provide a minimalist basis for comparing and contrasting Western mathematics with the mathematics in Aboriginal Australia.

Can we identify an arena of collective Aboriginal Australian life with the characteristics of rigor and systematicity, which is tied up with the working of entities involved in patterning and constituting order in multiple heterogeneous contexts? We could point to any Aboriginal Australian community and identify just such an 'Aboriginal mathematics', although it is likely that among the many different Aboriginal Australian communities such an arena would go under different names. Here I confine myself to considering some mathematical elements in the life of contemporary Yolngu Aboriginal Australians. We look at *gurruṯu* a mathematical-like discourse and set of practices embedded in Yolngu life. In Yolngu life, *gurruṯu* is expressed in the many and heterogenous material practices of doing kinship relations, including land ownership, although to render the term *gurruṯu* in English is just as difficult as expressing mathematics in the cluster of Yolngu languages. This mundane way of describing *gurruṯu* would not satisfy my Yolngu friends. However, recognising that caveat while putting it aside, just as I have put the concerns of mathematicians aside, I go on to explore some interesting similarities between Western and Yolngu Aboriginal mathematics. I begin by speculating about possible material origins of the contrasting mathetic objects in Western mathematics and *gurruṯu*.

A familiar story about origins of numbers in Western mathematics sees them as originating in the practices of material tallying. This is modeling an event or episode in the world with a material encoding process. We can see this as using a finger to encode the passing of a sheep through a gate, the placing of a pebble to encode the pointing at a soldier, or the engraving of a line on a bone or a piece of wood to record the filling of a vessel with grain. This imagines the involvement of fingers and toes in tally keeping in a non-linguistic way. One separated digit codes for one separated item. But if we then extend the coding operation and say a word which codes for the finger or toe, we have done something much more complex and ended up with a code which is much more useful than the material code of fingers and toes or display of objects like dropping stones into a bucket or adding another shell to the pile.

In saying a word as a finger is held up to code for an item involved in some event we understand that the word we say does not name either the item or the finger. It names a position in a progression. Numerals are words that code for a position in a series. A set of number names, a numeral system, is characterised by having a sequential base pattern and recursivity. Numerals constitute an infinite series by having a base about which repetition occurs, and a set of rules by which new elements are generated. The contemporary numeral system which has developed in association with Indo-European languages like English has ten as its base; in other words ten is the point in the series which marks the end of the basic set of numerals. As each ten is reached, the basic series is started again, each time recording in the numeral how many tens have been passed. The rule by which new elements are devised is addition of single units and base ten units.

A similar story can be told of origins of one set of mathetic objects in Yolngu Aboriginal life. Imagine Yolngu people plotting the spatial pattern of land sites owned by related groups of people. Stones and shells might be taken to represent positions in the mesh of family relations and the sites owned by the various groups. The shells/stones symbolise the links between people and land, and placed on sites through which land is owned they both express and demonstrate the pattern of the network of linkages between related groups of people and their lands. Naming can codify the relations, just as position in a sequence can be codified by names in numbering. But codifying relations with names is more complicated than codification of an event signalled with a finger. In fact two contrasting relations need to be encoded to begin. In *gurruṯu* the relation between brother and sister is contrasted as a formal opposite to that between husband and wife. By positing an ideal form of marriage a system of reciprocal names can be devised. So just as we find human bodies embedded in Western mathematics through numbering, so too we find human bodies embedded in *gurruṯu*. On biological grounds of life expectancy we could expect a way to express family links which recognises the presence of three generations; necessarily these will be differentiated along matrilineal and patrilineal lines.

The first mathetic objects are moieties. Brother and sister belong to the same moiety. Husband and wife belong to opposite moieties. In Yolngu life these formal opposites are named *Yirritja* and *Dhuwa*. This formal opposition of the organising categories of Yolngu life – patrilineal and matrilineal lines allows a matrix in which everything can be located with respect to all other things. Humans and non-humans, living and non-living, material and non-material, everything is locatable – people, places, concepts, images, languages, animals and plants.

The matrix is elaborated in naming a series of family relations. Reciprocal pairs of names code for relative positions in the kinship mesh. They do not name individual people or clans or places, but relations between them. *Gurruṯu* names are code for positions in a formal series, but not a series with a linear form as in numbers. This is a series with the form of a net or a matrix.

Gurruṯu is a form which is primarily a formal map. Just as the number series is used to 'reveal' value in the material world, the *gurruṯu* matrix is used to reveal relative location in the material world. For example it codifies the location of places in the landscape. Table 1 is a list the eight reciprocal pairs which constitute the base of the *gurruṯu* recursion. The easiest way to begin to understand these categories is to personalise them in terms of my kin relations.

Or I could do it the other way around: the person I call *gathu* (child) calls me *mukul bapa* (aunty – father's sister) and so on through to the person I call *dhuway* (husband) who calls me *galay* (wife). The dual names in some rows on the left-hand side of the pairs represent male and female holders of a position, necessarily brother and sister. Each of those pairs has the reciprocal relation of *yapa* (sister) and *wawa* (brother). The reciprocal pair *yapa* and *wawa* enable the pattern of names to work as a true recursion; they are not themselves members of the base set of reciprocal name pairs. Elaborating the list of names of *gurruṯu* relations is analogous to listing the set of numerals from one to ten. In that set zero holds a pivotal position, enabling iteration of the number pattern. Zero is not itself a member of the base set of names and can be understood as having a similar function to *yapa* and *wawa*. In just the same way as number, the name series of *gurruṯu* constitutes a recursion where elements, i.e. positions constituted in the series, provide the basis for further constitution of elements.

The matrix formed by naming these relations is understood as re-emerging across history. But the image of time embedded in history here is not linear; it is not the form of time Westerners are familiar with. For Aboriginal Australians time is cyclical. History accretes in place in going through the cycle mapped out by the matrix of *gurruṯu*. The cycle of the *gurruṯu* matrix can be mapped by the ideal cycle of marriage and child bearing in Yolngu life. This cycle is shown in diagrammatic form in Fig. 1.

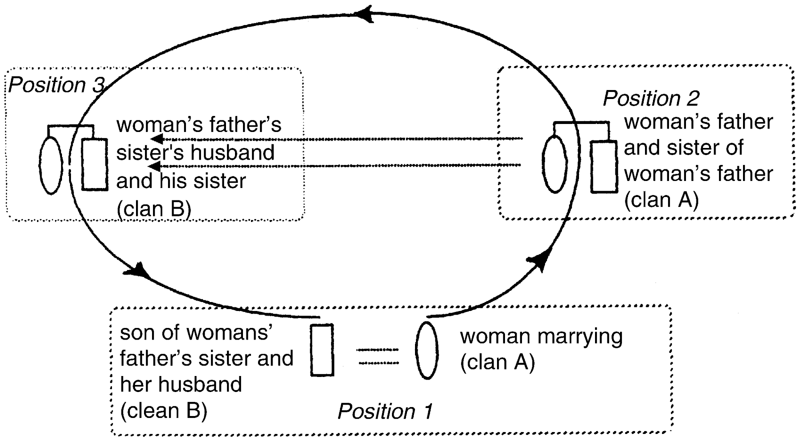
The father of the man marrying (and the father's sister) constitute one position (clan A – moiety 1), the mother of the man marrying (and her brother) a second position (clan B – moiety 2) and the wife (and her brother) of the brother of the mother of the man marrying constitute a third position (clan C – moiety 1). In the Yolngu case, the pattern of this geneological ideal implies either two *Yirritja* clans and a *Dhuwa* clan, or *Yirritja* clan and two *Dhuwa* clans.

One way to begin describing the structure of this matrix is to map it in the conventional form that anthropologists map genealogies. The basic unit in this map is the hypothetical ideal family tree shown in Table 2. This 'ideal unit' illustrates the fundamental contrast between the two different sorts of relations which constitute the *gurruṯu* system of relations: that between wife and husband and brother and sister.

Exhaustively specifying the primary positions generated in this genealogical ideal across the generations from grandchild to grandparent, constitutes eight reciprocal pairs, 16 positions: two groups and three reciprocal positions in each: two sets of two to the power of three. Naming this set of 16 positions constitutes a primary

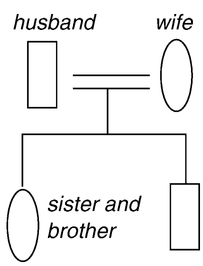
Mathematics of Yolngu Aboriginal Australians. Table 1 Kin relations

The person I call	Calls me
bäpa (man) – father	*gäthu* – child
mukul bäpa (woman) – father's sister	
ngäṉḏi (woman) – mother	*waku* – child
ngapipi (man) – mother's brother	
märi'mu – father's father and father's father's sister	*marratja* – grandchild
ngathi (man) – mother's father	*gaminyarr* – grandchild
momu (woman) – mother's father's sister and simultaneously father's mother	
märi – mother's mother and mother's mother's brother	*gutharra* – grandchild
mumalkur (woman) – mother's mother's brother's wife	*dhumungurr* – mother's brother's mother-in-law
ngathiwalkur (man) – mother's mother's brother's wife's brother	
mukul rumaru (woman) – mother's brother's wife	*gurrung* – mother-in-law
maralkur (man) – mother's brother's wife's brother	
galay – mothers' brothers' daughters and sons simultaneously brother's wife and her brothers	*dhuway* – sister-in-law



Mathematics of Yolngu Aboriginal Australians. Fig. 1 Pattern on a Yolngu genealogical idea.

Mathematics of Yolngu Aboriginal Australians. Table 2 A conventional genealogical map of the basic elements in Yolngu *gurruṯu*



template, just like naming the set of ten fingers constitutes a primary template. The eight pairs of reciprocals name across generations or across matrilineal or patrilineal lines. The brother/sister reciprocal pair completes the set of named relations and enables continuing iteration. Together the names and rules of generation form an infinite series. When we map the series of eight reciprocal kin relation pairs with this unit we get this diagram of the relations named (Table 3).

Laid out in this way it becomes obvious that in the *gurruṯu* system where every person and everything is exhaustively located with respect to every one else and everything else has a three generational interval known as the *mari–gutharra* (grandmother/father–granddaughter/son) relation.

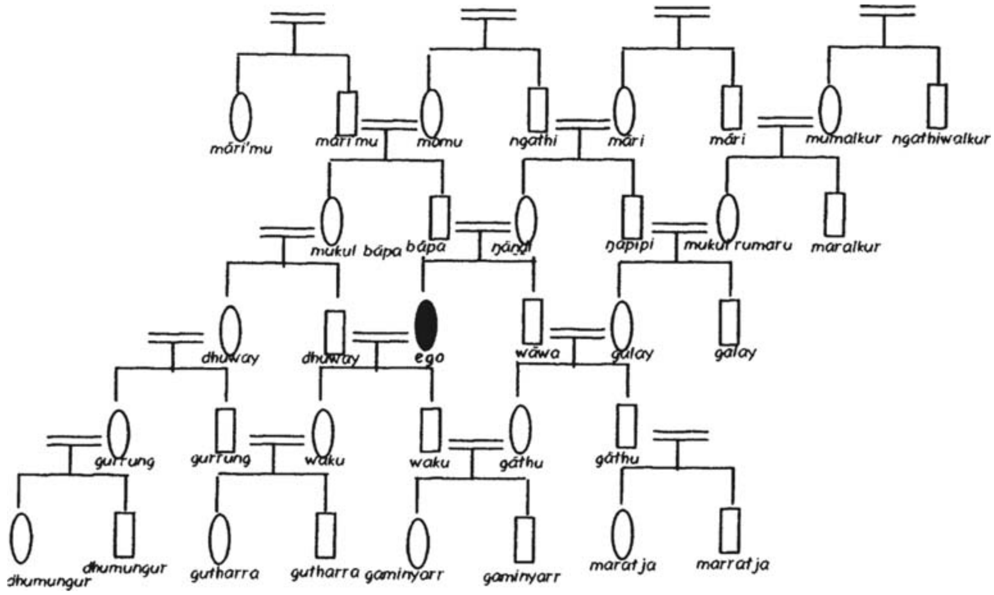
The triple generational/dual moiety recursion constitutes an encompassing pattern of Yolngu life and social order. Right from the beginning of their lives, Yolngu babies are instructed on the relation that this or that person has to them. The set of relations involve notions of hierarchy and equivalence, but not as a single-centralised hierarchy. Each position plays different roles in several different hierarchies; the many hierarchies are woven together to form a decentralised orderly mesh of hierarchies. *Gurruṯu* carries a powerful ideology; it achieves a general ordering of both the social and the natural world. It maintains an image of continuity and permanence across both time and space. And it is not only people who have *gurruṯu* positions; all entities in the Yolngu world have positions in the *gurruṯu* matrix.

I am presenting the number and *gurruṯu* recursions as analogous, but they are very different in their content. Should that worry us? These two great recursions – the tallying recursion codified in counting, and the genealogic recursion codified in ordering descent and ancestry – are of a kind, albeit different in form. They differ in structure: each number has one direct antecedent and one direct successor, and each *gurruṯu* position has two direct antecedent positions and one successor position. However the two systems are characterised by recursive definition. A recursive definition formalises the idea of 'and so on'. We can define *gurruṯu* positions as the members shared by all classes that contain a *gurruṯu* position, and the successors of all their own members. Similarly we can define the natural numbers as the members shared by all classes that contain one and the successors of all their own members.

Both these recursions are manifest to varying extents in all human societies. By noting the emphasis on the genealogic system in Yolngu society I am not saying that the tallying recursion is entirely absent from Yolngu life; it is not. Nor, in noting the predominance of tallying in European derived Australia, I am saying that the genealogic recursion (arranging matters on the basis of close and distant kinship) is entirely absent from Western life. What I am saying is that in Yolngu life the tallying recursion does not carry the ordering burden that the genealogic recursion carries. Conversely in Western society the genealogic recursion carries very little by way of ordering knowledge or productive processes.

Nor I am suggesting that the 'great recursions' operate quite independently of one another. In the Western world the tallying recursion predominates; it is

Mathematics of Yolngu Aboriginal Australians. Table 3 A genealogical mapping of the base set of *gurruṯu* elements



the recursion by which most social relations are effectively ordered. This is not to deny the influence that the genealogic recursion retains. Yet genealogic classifications are not exhaustive and applicable as objective classification throughout the community as we see them in Yolngu life. In Western life kinship classifications are discontinuous and discrete. They are variously regarded as important or not. Westerners can reject their genealogy and invent ancestors with impunity. They can lie about their genealogic relations. The genealogical recursion is taken as significant only in the biological sense. In the social sense people can choose to invoke or not to invoke the recursion.

In contrast to the dominant place of the tallying recursion as a foundation for reasoning in Western life, it is involved in Yolngu life in only a secondary way. Distributive arrangements for turtle eggs invoke an indigenous tallying recursion; here a recursive material arrangement – base 5 is engaged and linguistically encoded (each group of five is one *rulu*). In contemporary Yolngu society the use of base 10 tallying recursion predominates when the community or individuals are dealing with the white social order, but in exchanges involving only Yolngu the tallying recursion, as expressed in money for example, is subordinate to the working of the *gurruṯu* system. It does not carry the deterministic weight, the aura of inevitability it carries in non-Aboriginal Australia. People can choose or not to invoke quantification.

We should not go away with the idea that all genealogic recursions of Aboriginal Australia are worked in exactly the same way. Just as the tallying recursion can be worked differently for different purposes and by different groups, so Aboriginal Australian communities work with the genealogic recursion in different ways. In Yolngu life there are two distinct genealogical recursions which serve distinct functions. The distinction between them is something like the distinction between ordinal and cardinal numbers.

Juxtaposing number and *gurruṯu*, the primary principle embedded in these contrasting forms becomes evident. The primary principle for manipulating the categories constituted in the patterns derives ultimately from the practical, material system which formed the template of the recursion in its symbolic constitution. Going back to numbers we can see that the primary rule of that recursion is a version of the process of holding up another finger as another sheep leaps through the gateway. The important thing about this operation from the point of view of recursion is that each finger is exactly equivalent to each other finger. And any collected set of fingers has a precise and identifiable relation to any other collections of fingers; they relate to each other as a specific ratio. The primary principle of the number system is the principle of ratio: the ratio of any term to another is determined by the number of times one contains the other.

The primary principle of working the set of mathetic objects in *gurruṯu* is quite different. Going back to the ideal marriage arrangement which underlies *gurruṯu* we can see that an inherent reciprocity marks the form. Husband taker and wife taker are reciprocally related. Clan A and clan B together constitute a unity – the offspring of the marriage. This is an instantiation of the principle of reciprocity – two opposing elements constituting unity. A reciprocal is an expression so related to another that their product is unity. It is the inherent opposing duality constituting a unity, which is the fundamental principle of *gurruṯu*. Every position in the *gurruṯu* matrix is necessarily constituted by a two-way naming. The elements of the recursion must be specified from both ends before they come to life as an entity within the recursion.

Reciprocity can be pictured as two sides of a coin. On the old Australian penny (which had the head of the current king or queen of England on one side and a kangaroo on the other), 'head' and 'tail' constitute reciprocals, and together constitute a unity. The notion of reciprocal is often difficult for learners of Western mathematics centred around numbers to understand; they need to understand fractions before it is possible to understand reciprocals in a rigorous manner.

In *gurruṯu* reciprocity is primary. If you take any base family relation as a unit, for example *mari–gutharra* – the matrilineal relation across two generations (mother's mother or mother's mother's brother) – you can understand it as constituted by the mutual engagement by both sides. The descendant and the grandmother/great uncle are equally important in constituting the unity described by *mari–gutharra*. Each side is necessary to constitute the unity held between them. And just as reciprocity can be secondarily derived in the system of numbers pivoting around ratio, similarly the notion of ratio can be secondarily derived in *gurruṯu*. *Milmarra* is a name given to this way of rendering *gurruṯu*. A simple ratio involves juxtaposing a *yothu–yindi* (mother–child) relation with *a mari–gutharra* (child–mother's mother) relation: "If the two clans of the *yothu–yindi* are A and B, what is the Mari clan?" There is always only one correct answer which can be understood as expressing the ratio of the two reciprocals. Such puzzles are often set for learners of the *gurruṯu* system.

Number and *gurruṯu* are contrasting generalising logics. Perhaps the most challenging aspect of this is the notion that there are contrasting generalising logics in a contemporary way of life. Such a situation implies the need for continual translation between logics in that lifeway. Recognising that need opens the possibility for reflexive consideration of how different peoples might collectively go on, doing their differences, including their different generalising logics, together.

Mean Motions in Indian Astronomy

George Abraham, J. Samuel Cornelius, N. Gnanamalar David

This article is a follow-up of a very important contribution to the understanding of Indian astronomy by Billard (Billard 1971, 1977; van der Waerden 1980, 1988) who has calculated the mean longitudes of the sun, moon, moon's apogee and node, and those of the five known planets, from the numerical data in the main astronomical texts. The errors of these longitudes are determined by comparing them with the results of the modern formulae.

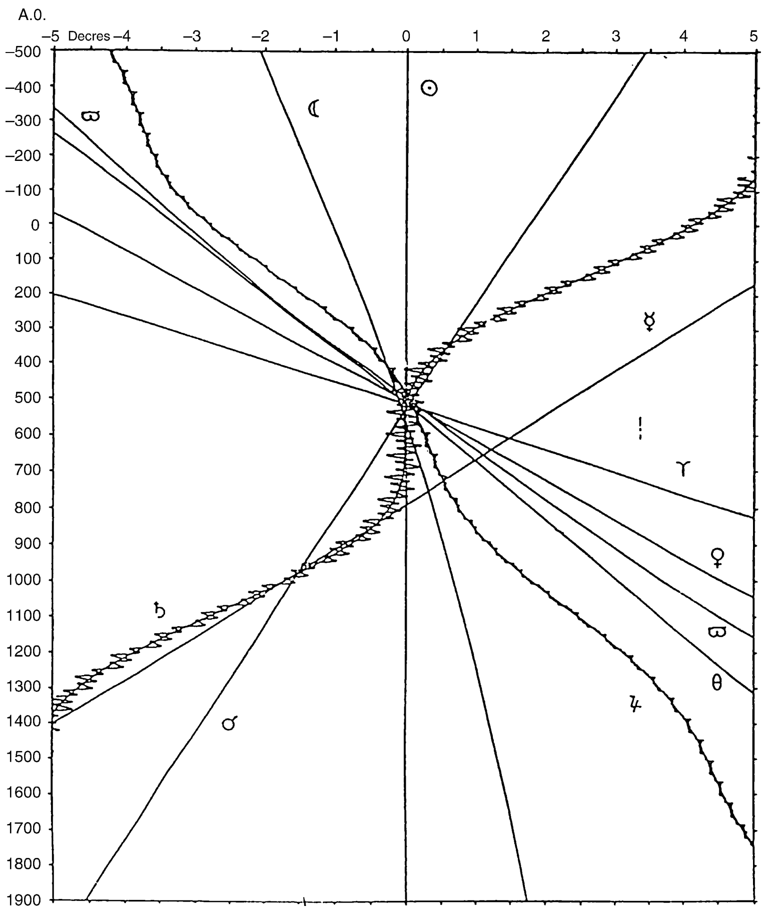
Billard uses the methods of mathematical statistics to find the most probable dates of the observations. His graphs, in which the errors of the longitudes are plotted against time from BCE 500 to AD 1900, illustrate his most important conclusions. For example, the Āryabhaṭa graph, Fig. 1, of this article, (Fig. 6 in Billard's book) shows that he made accurate observations at about AD 510. The error lines are for the Sun (☼), Moon (☾), Moon's apogee and node (ω, θ), Mercury (☿), Venus (♀), Mars (♂), Jupiter (♃), and Saturn (♄). There are large errors on earlier and later dates, showing that the rate of change of longitudes, the mean motions, are far from correct.

The synodic graphs of Lalla and Nīlakaṇṭha Somayāji (our Figs. 2 and 3 and Figs. 18 and 42 of Billard's book) stand out conspicuously, compared to the other graphs, because as many as six lines are close to the zero-line for most of the time span; therefore their mean motions are very accurate.

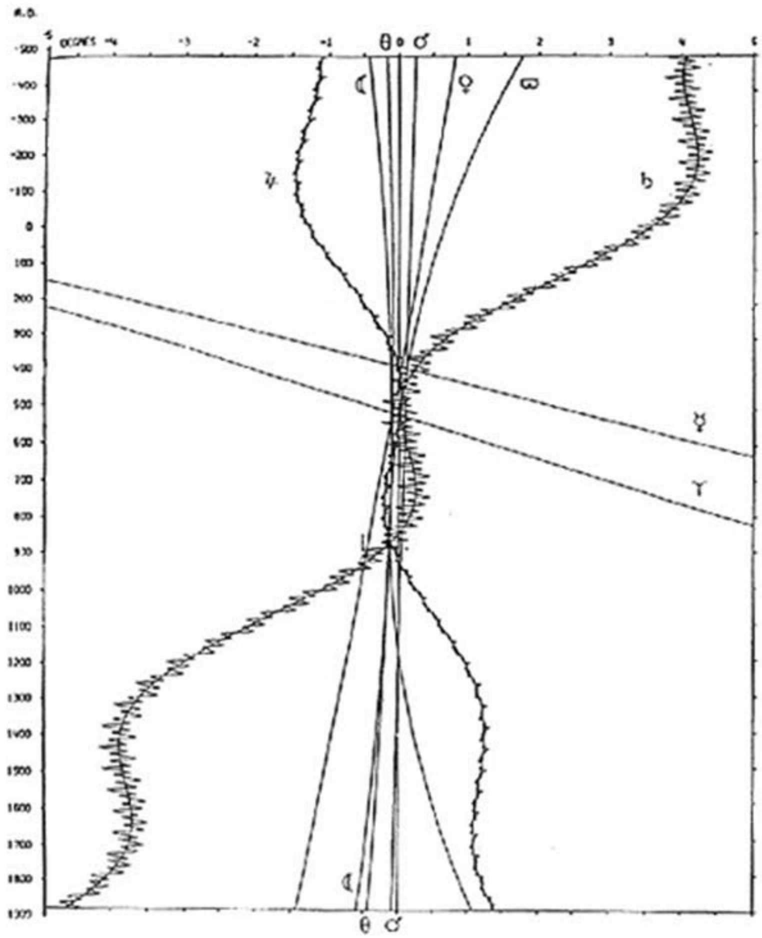
Another important finding of Billard, strongly supported by Raymond Mercier (1993) is that the date of the *Mahasiddhānta* is the early sixteenth century, against the AD 900 estimate of Dikshit (1985).

In this article, the focus is on mean motions, instead of longitudes. To begin with, we consider the following Babylonian period relations (Table 1) (Neugebauer 1975):

From these relations, we can calculate the ratios of the velocities of the Moon and planets to that of the Sun. The resulting numbers are in the first row of Table 2, denoted by O_1. The next row M_1 are the corresponding



Mean Motions in Indian Astronomy. Fig. 1 K. Āryabhaṭa.



Mean Motions in Indian Astronomy. Fig. 2 K. Lalla.

ratios calculated from modern theory of Simon et al. for the year BCE 300 (Simon et al. 1994). The third row numbers are the errors defined by

$$E_1 = \frac{|O_1 - M_1|}{M_1}$$

We now compare these Babylonian values to those of Ptolemy. His daily motions of the Sun, Moon, and planets are given in Billard's book (1971: 53). From these velocities, we calculate the same ratios as for the Babylonian observations and the resulting numbers, denoted by O_2 are in the fourth row of Table 2. The fifth row M_2 are from the modern theory (Simon et al. 1994) for AD 150 and the errors E_2, defined in the same way as in (1), are in the last row.

The mean values of the Babylonian and Ptolemy's errors are $\overline{E}_1 = 18.7$, $\overline{E}_2 = 5.8$. The reciprocals of these numbers are plotted in Fig. 4. Ptolemy is more accurate by a factor of about 3.

In an earlier paper, we calculated the errors of the mean lunar and planetary motions of Ptolemy and the most prominent Indian astronomers, Āryabhaṭa, Brahmagupta, Lalla, and Nīlakaṇṭha Somayāji. We now extend our investigation to include another seven Indian canons, which have been analysed by Billard. These are listed in Table 3. The first two columns give the names and the page reference in Billard's book (1971); the next column gives the approximate dates. The fourth column has the three lunar errors E_1^1, E_1^2, E_1^3 (synodic, anomalous, draconitic) and the errors E_2^2 to E_2^5 of the synodic daily motions of the five planets. The last column gives the mean lunar and planetary errors $\overline{E_1}$ and $\overline{E_2}$.In Fig. 5a,b we have plotted the values of $1/\overline{E_1}$ and $1/\overline{E_1}$, which are a measure of the accuracy of the Indian observers. The corresponding numbers for Ptolemy are also shown, based on the errors calculated in the earlier paper (Abraham 2003). In these figures P stands for Ptolemy and the 11 Indian canons are numbered 1–11 as in Table 3.

In Fig. 5a,b Ptolemy, Lalla and Nīlakaṇṭha Somayāji's *k.TantraS* are the most prominent. Their accuracy is the result of their own observations, also taking into account

the observations of others, spread over a long period of time. Āryabaṭa's poor mean motions are due to his assumption of the conjunction of planets, at the beginning of the Kaliyuga (van der Waerden 1988).

The *Pancasiddhantika*'s corrections to the *Sūryasiddhānta*'s planetary motions make a significant improvement, indicating further accurate observations.

The improvements of the later *Sūryasiddhānta* over the earlier version, and of Siddhantasiromani's *k.BrSpS2* compared to that of Brahmasphutasiddhānta are insignificant.

Mean Motions in Indian Astronomy. Fig. 5 (a) Lunar accuracy, (b) Planetary accuracy.

The planetary motions of the later *Sūryasiddhānta* and those of Parameshwara's *Drgganita* are remarkably close as pointed out by David Pingree (1987: 613), leading to the same errors in our approximation. The lunar motions of the two canons are slightly different, perhaps due to Parameshwara's new observations.

Meat Preservation in Ancient Egypt

SALIMA IKRAM

The ancient Egyptians consumed all types of meat: mammalian, piscian, and avian. It was an important source of protein, but one that was not always equally available to all levels of society. While piscian and avian meat sources were readily obtainable through fishing, hunting, and trapping, mammalian meat was sometimes harder to acquire due to restrictions on hunting wild game and the expense of killing livestock. Thus, mammalian meat tended to be more frequently consumed by the wealthy elite, although it would have been consumed by other social classes on feasts or at festive occasions.

Once slaughtered, the meat had to be consumed immediately to prevent spoilage, or it had to be processed and preserved for later use. There were several ways of preserving meats available to the ancient Egyptians – drying, salting (dry and wet), smoking, a combination of any of these methods, pemmicaning, or using fat, beer, or honey curing. Preserved meat provided a supply of protein for lean times, a commodity that could be traded, as well as a convenient food to take on all types of expeditions, whether exploratory, military, or commercial.

The evidence for the different types of meat preservation in ancient Egypt comes from two- and three-dimensional representations, mummified and preserved meat that comes from tombs, and artefacts, such as labeled pottery jars pertaining to meat. Additional information can be gathered from ethno- and experimental archaeology.

Drying

Drying is the easiest and most common way to preserve meat. Pieces of meat are cut from the carcass and hung in the sun to dry. The entire animal can be preserved in this way, although certain cultures seem to prefer specific cuts for drying. Drying time depends on the temperature and the thickness of the cut; generally it takes between 1 and 3 weeks. Dried meat can last up to 2 years, depending on storage conditions. Artistic and archaeological material shows evidence of such preservation practices.

Pounding meat before it is hung up to dry is a variation on this process. Some representations found in tombs support the idea that such a method was used to preserve meat in ancient Egypt. The pounding of the meat forces out the liquid in it that could cause spoilage, thereby making it possible for the meat to last longer. As a further protection, salt can be rubbed into the meat before it is dried. The term, *iwf ḏr*, suggests this method of preservation for meat.

Dried meat can also be prepared by boiling small pieces of meat, and then putting these in the sun to dry. This method tends to lower the nutritive value of the meat.

Fish can also be dried very effectively. Tomb representations show fish being cleaned, opened, and dried. Actual examples of these have been found at Deir el-Medina, and there are several references to dried fish found in Egyptian literature.

Birds were probably not generally dried. Only a handful of images suggest that poultry was dried, but these are inconclusive.

Salt

Salt curing is a simple and effective means of preserving meat, and salt was readily available in ancient Egypt. Both dry and wet (brine) salting would have been possible in ancient Egypt, but it is more probable that the former method would have been more commonly used. The basic idea was to immerse the meat in salt or brine, and then to seal it. The salt not only draws out the liquids in the meat that could cause spoilage, but also deters bacteria. This was the same precept governing mummification. Salt curing was faster and more efficient than simple drying, and the meat thus preserved would have lasted longer than dried meat.

Archaeological and artistic evidence suggest that dry salting was the most common method of meat preservation employed by the ancient Egyptians. Meat, fish, and poultry were all dried and salted. Scanning Electron Microscopy carried out on samples of preserved meat found in tombs supports this theory. Drying and salting fish is the most common way to preserve fish, actual examples of which were recovered from the tomb of Kha, and references to salted fish appear in texts, notably in the tale of Wenamun. Salt fish continues to be a staple of the modern Egyptian diet, especially for peasants. Mullet roe, the earliest caviar, also used to be preserved in salt and is still kept in this way today. Birds were also salted, and examples of these have been recovered from Kha's tomb.

Smoking

Although smoking meat in order to preserve it was hypothetically possible, it is unlikely that this method was used in ancient Egypt. The main reason for not using it was the relative paucity of wood, especially wood of any aromatic nature.

Fat

Animal fat is commonly used to conserve meat. Goose, mutton, or cow fat could have been used for this. Meat was cut up and then cooked with fat and salt and then placed in a container. Once cool it would have been sealed. This method, called *lahma mahfooz*, is still in use in Egypt today.

Honey

Honey might have been used to preserve food in ancient Egypt. Certainly, honey has preservative qualities. Indeed, Alexander the Great's body allegedly was preserved in honey. However, it is unlikely that this would have been used, as honey was a valuable commodity and the only sweetening agent available to the Egyptians.

Thus, although a significant variety of technologies were available to the ancient Egyptians, it is clear that drying and salting meat were the ones that were most commonly used.

Mechanical Technology and Instruments of China

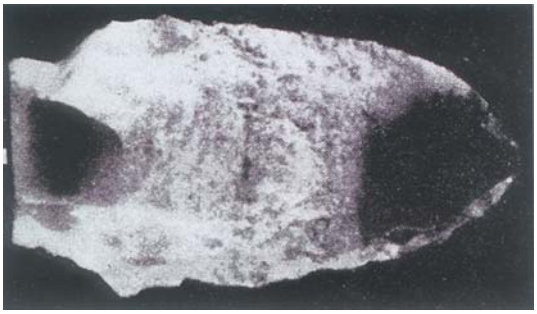
Tong Qingjun, Feng Lisheng

China was among the earliest countries to develop mechanical technologies, and its long history is full of achievements in technology for mechanical engineering.

Archeological work since the twentieth century has unearthed a large amount of prehistoric relics that provide a wealth of information about the evolution of technology for manufacturing tools and instruments in antiquity.

Paleolithic artifacts were mainly made of stone and wood, although sometimes bone was used. They were mostly chipped stone vessels that were formed by hammering and primary truing. Later, polished stone vessels were shaped to serve as tools that could chop, break, or scrape. Hammers, knife-edged tools, spheres, spears, and arrowheads made of stone can also be seen from this period. Arrowheads were found in a late Paleolithic site in Zhiyu, Shanxi province, that dates to about 28,000 years ago (Fig. 1) (Du 1984: 6) and the appearance of arrows themselves indicates that a relatively high level of mechanical technology had been attained. Also at the site are wooden sticks and polished needles made of other materials.

Neolithic artifacts were mainly made by a polishing technique that demanded selecting, cutting, polishing, and boring the stones. Copperware also appeared at this time. A sword and some fragments made of copper were unearthed in the early layers of Majiayao, Dongxiang, Gansu province, and date to 2575–2500 BCE according to carbon-14 analysis. Some scholars consider the sword to be the earliest bronze in China (Shen 1987: 919), but others have disagreed (An 1993). Plenty of tools for production – including adzes, axes, shovels, chisels, millstones, burnishers, pestles and mortars, spinning wheels, plows, swords, and hoes – have been found from this period, when the types of tools increased considerably and had special uses (Fig. 2). Also at this time, such complex machinery as original textile machines and pottery wheels appeared.



Mechanical Technology and Instruments of China.
Fig. 1 A stone arrowhead unearthed in Shuo County, Shanxi Province (from Hua 1997).

Mechanical Technology and Instruments of China.
Fig. 2 A tool to level soil, unearthed in Qiansanyang, Wuxing, Zhejiang Province (from Du 1984).

From the late Neolithic to the Western Zhou Dynasty (1046–771 BCE), animals and wind were used as the main sources of energy, as attested to by chariots and sails from these times. There is little evidence to demonstrate a relationship between the chariots of China and those of Western Asia, and although the earliest appearance of chariots has been recorded differently in the literature, we can conclude that two-wheel wooden carriages were used as early as the Shang Dynasty (ca. 1600 BCE, Fig. 3). Carriages of this time commonly had two wheels, a rectangular or square wagon box, a single thill (one of two shafts extending from the body of a cart or carriage on either side of the animal that pulls it), a crossbar, yokes at either side of the crossbar, and leather straps for pulling the cart. Cattle were used to cultivate the land, plows were widely used, but the agricultural machines and devices varied a lot. Booms, windlasses, and other such composite machines also existed in antiquity.

Bronze tools and instruments began to be widely used during the Shang Dynasty, and the techniques for smelting metals and casting utensils were at their highest even before the Western Zhou. Having begun with small-sized implements that had single-side and double-side patterns, the Shang eventually yielded large implements with composite patterns around a core, while advanced techniques such as separate casting were widely used in the middle of the dynasty and pottery patterns became more complex in its later stages. The largest known bronze vessel is the Simuwu Ding, which was unearthed in Wuguan village, Anyang, Henan province in March 1939. It weighs about 875 kg and embodies the high level of casting under the Shang. Fig. 4 shows the large-scale bronze wine table (*jin*) with a cloud design that was unearthed in Xichuan

Mechanical Technology and Instruments of China. Fig. 5 A page from the *Kaogong Ji* (from Hua 1997).

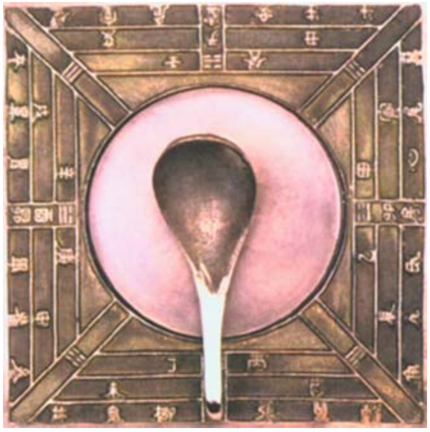
Mechanical Technology and Instruments of China. Fig. 6 A Western Han bronze clepsydra (from *Zhongguo Gudai Keji Wenwu Zhan*).

county, Henan province in 1978 and is the earliest known product cast according to the so-called "lost-wax process" (*shi la fa*) (Hua 1986: 231–232).

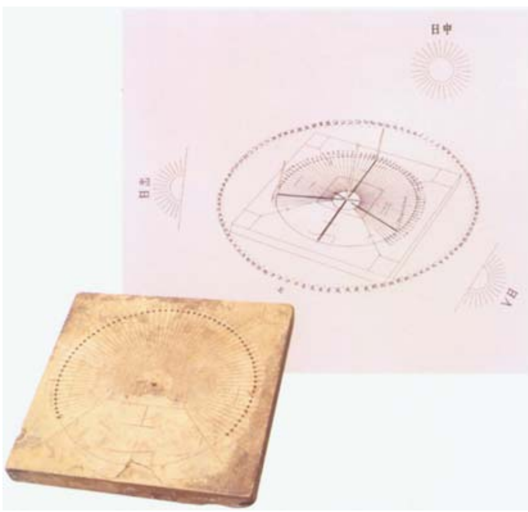
Ironware has been in use since the Spring and Autumn (Chunqiu) Period (771–476 BCE). The appearance and development of techniques for ironware casting made it possible to produce tools that were highly efficient. Techniques such as founding, forging, and softening that employed heat developed rapidly during this time, when many kinds of machines and devices, especially farm implements, were made from cast iron. In the Warring States (Zhanguo) Period (475–221 BCE), techniques for softening cast iron were developed.

The *Kaogong Ji* (Records of the Artificers, Fig. 5) is the earliest literary work on the techniques used in the handicraft industry in China. Most of it was compiled in the late Spring and Autumn and the early Warring States Periods, but some parts were added late in the Warring States. It includes information about how to manufacture carriages, weapons, sacrificial vessels, bells, and chime stones, as well as about architecture, hydraulics, dyeing, and techniques for other handicrafts (Dai 2003). Such problems as the elasticity of bows, rapidity of arrows, and stability of flight are also addressed thoroughly.

Many instruments for astronomy originated in early China. The gnomon, which utilizes directions and lengths of the shadow of the sun to determine south and north as well as the seasons, existed under the Shang and Zhou. Water clocks which measured time by means of the liquid were first developed in the Spring and Autumn or the Warring States Period (Fig. 6). An intact bronze clepsydra which was unearthed in Inner Mongolia in 1976 has a year engraved on it that dates it to the Western Han Dynasty (206 BCE–8 AD). Instruments utilizing lodestones that pointed to the geomagnetic poles were called *si nan* by the ancients



Mechanical Technology and Instruments of China. Fig. 7 A *si nan* (from *Zhongguo Gudai Keji Wenwu Zhan*).



Mechanical Technology and Instruments of China. Fig. 8 A solarium from the Han Dynasty (from *Zhongguo Gudai Keji Wenwu Zhan*).

(Jin 1999: 103). According to the reconstruction by Wang Zhenduo in Fig. 7, a natural lodestone shaped like a spoon was placed on a plate with the directions labeled, and the handle of the spoon when stabilized would point to the south. From the Qin or early Han Dynasty, the solarium with a graduated circle to indicate the time according to the position of the sun, and based on the gnomon, became widely used (Fig. 8). Furthermore, astronomical instruments such as armillary spheres and celestial spheres designed according to mechanical principles appeared in the Han Dynasty, and according to the *Tianwen Zhi* (Records of Astronomy) in the seventh-century *Jin Shu* (History of the Jin Dynasty), the armillary sphere and celestial

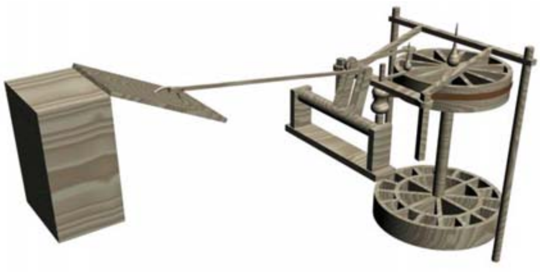
Mechanical Technology and Instruments of China. Fig. 9 Bronze chariots and horses, unearthed from Qin Shihuang's tomb (from *Qin Shihuang Ling Tongchema Fajue Baogao*).

sphere made by Zhang Heng during the Eastern Han Dynasty (25–220 AD) were of a fairly high level. The celestial sphere was in a closed box, was driven by water, and indicated the time that stars appeared and disappeared according to astronomical observations.

Mechanical technology during the Qin and Han Dynasties also progressed in other respects. The bronze chariots, warriors, and horses unearthed from the tomb of Qin Shihuang (r. 221–210 BCE) demonstrate a high level of mechanical fabrication, and their scales were one half of reality for the chariots and lifelike for the horses (Fig. 9). Even such details as the wheels that allow the chariots to move, the horse gear, and ropes were molded in realistic shapes. These artifacts are not only unrivalled throughout the world but also outstanding examples of mechanical engineering under the Qin. When hydraulic power came to be added to wind and animals as a form of energy in the Han Dynasty, water-driven machines and devices that included such mechanical breakthroughs as gears, cams, and toggle levers were created. Among the machines and devices were the waterpower reciprocator, hydraulic trip-hammer, south-pointing carriage, incense burner, and Zhang's armillary sphere and seismograph, all of which reflected quite a high level in mechanical engineering.

The earliest records related to bellows driven by water power are in the *Du Shi Zhuan* (Biography of Du Shi), in the fifth-century AD *Hou Han Shu* (History of the Eastern Han Dynasty), which notes that a water-power reciprocator (*shui pai*) had been invented, while the *San Guo Zhi* (History of the Three Kingdoms) records that Han Ji made *shui pai*. Besides an explanation of the structure of a *shui pai*, the *Nong Shu* (Book on Farming) by Wang Zhen includes illustrations to show the structure and how it operated. A *shui pai* (Fig. 10) included two horizontal wheels that were connected by a shaft, and when the lower wheel was driven by flowing water, the upper wheel rotated and, via a driving-belt, moved a pulley that was set with an eccentric lug or crank to move a connecting rod. This rod pushed two levers back and forth to make

Mechanical Technology and Instruments of China.
Fig. 10 Model of a south-pointing carriage (from *Zhongguo Gudai Keji Wenwu Zhan*).



Mechanical Technology and Instruments of China.
Animation 1. A *shui pai*.

a piston rod move. The effect was that the rotation of the lower horizontal wheel was linked to the reciprocating motion of the piston rod (Animation 1).

The south-pointing carriage (*zhi nan che* or *si nan che*) was said to have been invented by Huang Di – the Yellow Emperor – or Zhou Gong. In the *San Guo Zhi*, a person called Ma Jun from the state of Wei (220–265 AD) is noted as having manufactured a south-pointing carriage, while Zu Chongzhi, Yan Su, and Wu Deren are known to have made such a carriage later. Only for that by Yan, however, are there extant, detailed records about the shape and inner structure (Fig. 10).

The south-pointing carriage by Yan was driven by four horses and had two wheels and a rectangular wagon box. Inside was a gear linkage system that had nine gears in all, five serving as a transmission. In the box and connected with the other gears was a big horizontal gear, at the center of which stood a pole with a wooden person on top. Whenever the carriage moved, the hand of the person always pointed to the south, mechanically made possible by the automatic clutch system for the gears.

Mechanical Technology and Instruments of China.
Fig. 11 Model of a *li*-recording drum carriage (from *Zhongguo Gudai Keji Wenwu Zhan*).

Fig. 11 shows a drum carriage that recorded *li* (a distance of about half a kilometer) and was refitted from a drum carriage dating to the Han Dynasty. Mechanisms such as the decelerating drive gears and cam-and-lever devices were installed inside. As the carriage moved one *li*, the cam and a cord caused a wooden person to beat the drum with its right hand. The *Yu Fu Zhi* (Records of Carriages and Dresses) in the *Nan Qi Shu* (History of the Qi Dynasty) has a record of the *li*-recording drum carriage, the *Kui Tan Lu* (Records Ashamed of Tan) by Yue Ke of the Southern Song Dynasty (1127–1279 AD) records and explains how the gears worked, and the *Yu Fu Zhi* in the *Song Shi* (History of the Song Dynasty) has details about the devices and how motion was generated.

Zhang Heng is noted in the *Hou Han Shu* as having invented the machine known as "Chang's seismograph." According to the restoration by Wang Zhenduo, its inside structures include a pole, with a thick upper part and a thin lower part in the center, and eight curved levers around. The upper part of each lever is connected to the upper jaw of a dragon, whose lower jaw holds a brass ball. When the earth shakes, the pole falls down in the direction of the earthquake and presses the lower part of the corresponding curved lever, causing the upper jaw of the dragon to open and the ball in its mouth to drop down to a toad's mouth that is facing it. This makes it possible to recognize the direction from which the earthquake came (Animation 2).

Agricultural machines and implements developed rapidly during the Han Dynasty. The three-legged seed plow and the fan wheel (Fig. 12), which was a highly efficient processor of grain, were other noteworthy inventions. Other grain processing machines such as mills and trip-hammers not only appeared but also were improved. Mills with transmission gears and pestles driven by waterpower appeared during the Eastern Han Dynasty, and moldboards appeared under the Western Han, when the design of the plow was finalized. Hand reeling machines, looms, jacquards, and other important machines were also invented, while techniques for building ships during this period were highly developed. Such components of ships as sculls, helms, and sails became well established, and large ships with upper decks as well as warships were easily made at the time of the Han.

Mechanical Technology and Instruments of China. Animation 2. Chang's seismograph (from *Zhonghua Keji Wu Qian Nian*).

In this period, many kinds of machines and devices used natural rather than artificial power, and their operation changed from direct to indirect means. Transmissions of power and movement were completed by the machines and devices themselves, while the control of the machines by humans became indirect. Machines and devices such as the *shui pai*, pestles, and the *ma pai* (horse-powered reciprocator) were provided with three basic composite elements – prime motors, actuating mechanisms, and operating mechanisms – and their appearance demonstrates that the mechanical system had reached a high level of development. From the subsequent Three Kingdoms Period (220–280 AD) until the Yuan Dynasty (1206–1367 AD), the overall technical level of traditional machines and devices progressed considerably.

From the Three Kingdoms Period into the Sui (581–618 AD) and Tang Dynasties (618–907 AD), the techniques were substantially developed. Forged implements became dominant among the tools for farming, and as founding techniques developed, large-scale casts appeared. Progress was made in hydraulic machines, while the Jin Dynasty (265–420 AD) saw the appearance of automatic mill wheels (*mo che*), pestle-wheels (*chong che*), and water mills (*shui nian*). The water-lift chain-pumps (*fan che*) invented during the Eastern Han Dynasty were improved and popularized. Tools for irrigation such as a "noria for high lifts" (*gao zhuan tong che*; Fig. 13) were also invented, while the structure of the plow was improved under the Tang, and movable plow pan devices appeared. Shipbuilding techniques developed further, and paddleboats were invented.

Mechanical Technology and Instruments of China. Fig. 12 A fan wheel (from *Tiangong Kaiwu*).

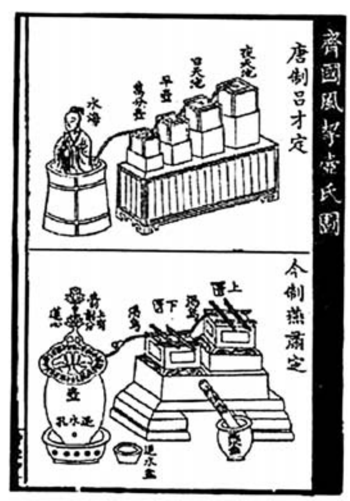


图1 《六经图》中的齐国风挈壶氏图

Mechanical Technology and Instruments of China. Fig. 13 A *gao zhuan tong che* (from *Nong Shu*).

Mechanical Technology and Instruments of China. Fig. 14 The "*Qi* Guo Feng *Qiehushi Tu*"(Illustration of the official who lifts the water clock according to the *Balladry* of Qi) in *Liu Jing Tu.*

Moreover, developments could also be seen in astronomical instruments. The *Tian Wen Zhi* in the eleventh-century *Xin Tang Shu* (New History of the Tang Dynasty) has detailed records about such an instrument designed by the monk Yi Xing and Liang Lingzan in the thirteenth year of Kaiyuan (725 AD). It had two wheel rings to represent the sun and the moon as well as a celestial sphere that was driven by waterpower. Two puppets inside marked the time by beating its drum and striking its bell. Earlier in the Tang Dynasty, Lü Cai (ca. 600–650 AD) had improved the water clock by adding several compensating clepsydras above the main clepsydra to make the time more accurate. Thereafter, Yan Su of the Northern Song Dynasty (960–1127 AD) created a lotus clepsydra (*lianhua lou*) which was widely used at that time. Fig. 14 shows the style of these water clocks as presented in an illustration in the *Liu Jing Tu* (Illustrations to the Six Classics) by Yang Jia and printed in 1153.

Incense burners made of silver or gold have been found in several tombs from the Tang Dynasty (Fig. 15). Among them are the elaborately constructed, elegantly encased ones unearthed at Shapo village, Xi'an in 1963 and from the Famen Temple in Shaanxi province in 1987. Incense burners were first recorded in the *Mei Ren Fu* (Ode to Beauty) of the Western Han Dynasty by Sima Xiangru (179–117 BCE) and the *Xi Jing Za Ji* (Miscellanies of the Western Capital) of the Jin Dynasty by Ge Hong (284–364 AD). There were two or three concentric rings between the outer shell and the hemispherical body for burning the incense in the center. This hemispherical body had minor axles at both ends of its diameter so that, supported by the two radial holes of the inner ring, it was capable of moving freely. The inner ring was supported by the outer ring, which itself was supported in the same way by the inner wall of the outer shell. The supporting axles for the body of the burner, the inner ring, and the outer ring were perpendicular to

Mechanical Technology and Instruments of China. Fig. 15 Incense burner (from Hua 1997).

M

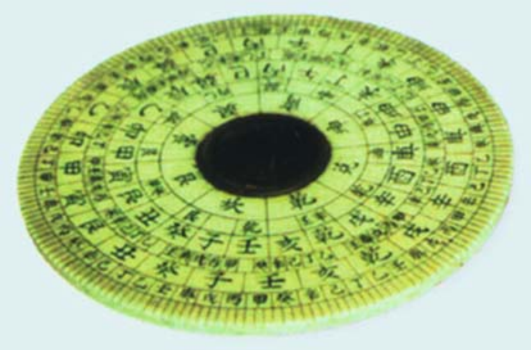
each other, and because of the force of gravity, the burner remained horizontal at all times regardless of how the shell rotated.

During the Song and Yuan Dynasties the development of traditional machines and devices in China peaked, and a great deal of progress was particularly made in those for agriculture. The plow colter (the cutting arm of a plow) appeared under the Song, and new farm implements like cramp irons (*tie da*) and hoof plows (*ta li*) were widely used while many kinds of hydraulic machines became more widely used. Among the monographs on agricultural machines that were published, the nonextant *Nong Qi Pu* (Book of Faming Implements) by Zeng Zhijin of the Song Dynasty discussed various kinds of farming implements. The *Nong Qi Tu Pu* (Illustrations of Faming Implements) in the *Nong Shu*, by Wang Zhen during the Yuan Dynasty, introduced and explained contemporary agricultural machines and many tools for production, making the work a base for later research and records. Weaving machines had also been developed, while the spinning wheels driven by waterpower, foot-powered wheels for spinning cotton, and other machines in the *Nong Shu* reflected the high level of such contemporary machinery.

Techniques for manufacturing weapons developed rapidly and included new weaponry such as tubular firearms and jet-fire arrows. While shipbuilding became more sophisticated, breakthroughs were made in instruments for astronomy to bring their traditional development in China to a peak. Among the different kinds that appeared were lotus clepsydras, Taiping armillary spheres (*tai ping hun yi*), "pseudo astronomical instruments"(*jia tian yi*), a water-driven astronomical clock tower, and "simplified instruments" (*jian yi*). Among the other important inventions at the time, typography, a two-way ram-acting air box, and cold-forging and cold-drawing techniques should be noted.

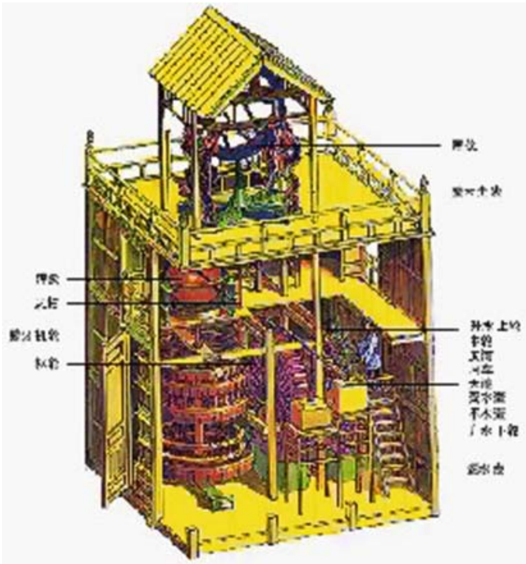
The magnetic needle was an instrument made by utilizing the property of lodestones to point to the geomagnetic poles. Early needles were simply made with natural lodestones and were improvements on the *si nan*. In the *Wu Jing Zong Yao* (General Military Principles), compiled by Zeng Gongliang in the early Northern Song Dynasty, is a record of how to construct a south-pointing fish that was precise whenever it was placed on a surface of water. The manual method of rubbing lodestones to magnetize steel needles was developed during the Northern Song Dynasty, when carved wooden south-pointing fish or tortoises with magnetized needles in their stomachs became rather popular. The dry land compass with a fixed point of support was invented in the Southern Song Dynasty, but water compasses which made use of buoyancy remained in general use (Figs. 16 and 17).

Mechanical Technology and Instruments of China. Fig. 16 A floating magnetic needle (from *Zhongguo Gudai Keji Wenwu Zhan*).

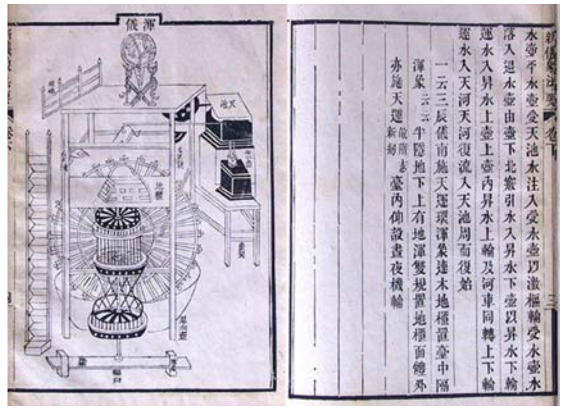


Mechanical Technology and Instruments of China. Fig. 17 An ivory water compass dating to the Qing Dynasty (from Jin 1999).

The water-driven astronomical clock tower in Animation 3 was the earliest astronomical clock in the world. Having included an armillary sphere, celestial sphere, and water clock, and being the work of Su Song in the seventh year of Yuanyou (1092), it was a square platform-like wood construction that measured about 12 m in height and 7 m in width. Its upper part was narrower than the lower part, and it had upper, middle, and lower layers. At the top was the coppery armillary sphere that illustrated observed celestial bodies, in the middle was the celestial sphere which marked about 1,400 stars and was used mainly as a planetarium, and at the bottom was the mechanism for indicating time. The machine was driven by a gear system which was assisted by chain drives (or a high ladder) and levers. "Celestial balances" (*tian heng*) and



Mechanical Technology and Instruments of China. Animation 3. Su Song's astronomical clock tower (from *Zhonghua Keji Wu Qian Nian*).



Mechanical Technology and Instruments of China. Fig. 18 A page from Su Song's *Xin Yixiang Fayao.*

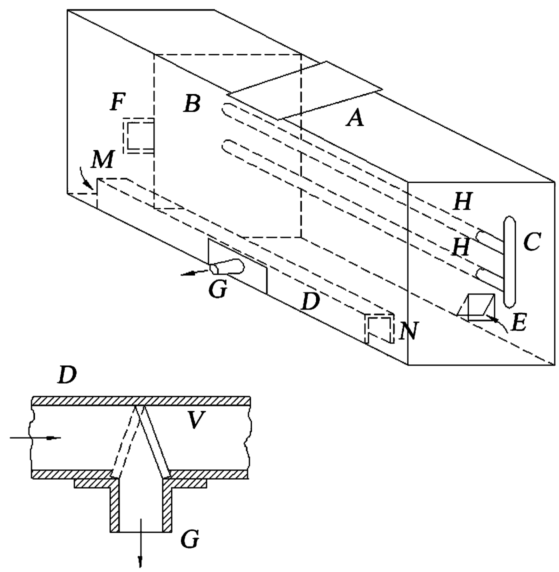
driving wheel (*shu lun*) comprised the coordinated escapement, which as a whole is regarded as a remarkable invention in mechanical history.

The driving wheel was the principal component of the clock tower, with 36 water boxes (*shou shui hu*) along the circumference. When the water in the box reached a certain weight, a series of control systems would be triggered, causing the driving wheel to rotate intermittently. The rotation was transmitted to the "celestial pole" (*tian zhu*) by the "terrestrial hub" (*di gu*), and then to the operating mechanisms by a drive system.

There was an escapement mechanism designed to keep the driving wheel rotating isochronally.

The astronomical clock tower was destroyed in the war between the Northern Song and the Jin in 1127. Fortunately, Su wrote the book *Xin Yixiang Fayao* (New Design for an Astronomical Clock, Fig. 18) after the instrument was completed in the early years of Shaosheng (ca. 1094–96 AD). Because it is the most detailed extant monograph on astronomical instruments and has illustrations of the clock tower as a whole as well as of its components, spare parts, and star images, it has been possible to recreate the astronomical clock.

The air-blast apparatus was first a leather bellows, then a *ma pai* and a *shui pai*, and finally an box-bellows with piston. As shown in Fig. 19, the piston-bellows was made of wood and had a blowing piston-board (B) in the middle and a square tube at the lower left. Two holes (M, N) were connected to the box, with a flow mouth (G) pointing outward in the middle. The free



Mechanical Technology and Instruments of China. Fig. 19 A box-bellows.

valve inside the tube could connect either part of the tube with the flow mouth freely, as illustrated below. The two free valves (E, F) at both ends of the box could only open inward, making the outer air flow into the box when the handle of the piston-board was pushed forward. Since the air behind the piston-board is of lower pressure, the air outside presses valve E inward and flows into the box. At the same time, the air in front of the board is of higher pressure, so valve F gets closed. The air before the board therefore flows into the tube and pushes the valve to move backward, causing the air to flow into the smelting furnace through G. As the handle moves forward and backward, the

Mechanical Technology and Instruments of China. Animation 4. How the box-bellows works.

higher-pressure air flows almost continuously and keeps the fire burning. Animation 4 shows how the box-bellows works.

The machines and devices of this period not only reached a high technical level, but they were also varied and many resulted from especially creative talent. Among their many makers were Ma Jun, Zu Chongzhi, Li Gao, Zhang Sixun, Yan Su, Su Song, Guo Shoujing, and Wang Zhen, and many Chinese machines and devices spread to other countries.

From the late Yuan Dynasty into the Qing (1616–1911 AD), there were a few developments in traditional machines and technology. Still, there were fewer great inventions in this period, although traditional mechanical technologies were still progressing. Cold-forging and cold-drawing techniques were improved during the Ming Dynasty (1368–1644 AD). The *Tiangong Kaiwu* (Exploitation of the Works of Nature) by Xu Guangqi records the cold-forging technique for making saws and the cold-drawing technique for making steel needles, while the many kinds of wrought products that existed demonstrate the development of forging techniques. In the Ming Dynasty there was one called “cold quenching,” which suggests that the understanding of quenching had advanced. Weapon-making techniques improved quickly as many kinds of weapons appeared and monographs on weapons such as the *Huolong Jing* (Book of Fire Dragon) and *Huolong Shenqi Zhenfa* (Array of Magic Instruments of Fire Dragon) were published, while shipbuilding continued to develop as China became a powerful maritime country. Furthermore, it was during this time that the hourglass, an important marker of time, was invented.

Toward the end of the Ming and into the Qing Dynasty, missionaries from the West brought Western science and technology to China. Machines and devices were also imported, and translations of works on machinery such as the *Yuanxi Qiqi Tushuo Luzui* (Illustrated Books of Western Magic Instruments) were published. From early in the eighteenth century to the 1840s, however, the Qing government opted for a policy of seclusion and broke communications with the Western world. The development of machinery in China then stagnated, and there were no notable inventions for more than a hundred years. Because it was at that time that the Industrial Revolution took place in the West, mechanical science and technology developed there rapidly and took the West far beyond the level of Chinese technology.

Medical Ethics

Robert M. Veatch

The medical ethics of non-Western cultures are not as cleanly differentiated from the rest of their religious and cultural value systems as they are in the West. There the traditional medical ethic of organized professional medicine is summarized in the Hippocratic Oath and the tradition surrounding it. This ethic that guides health care professionals is often in conflict with religious and philosophical traditions that provide more general ethical frameworks. By contrast, in non-Western cultures, medical ethical questions are often addressed in the core ethics literature of the group, such as religious texts and philosophical writings.

The ancient cultures of Asia provide an example. Generally, they turn to classical texts for their medical ethical insights.

China

Although Chinese medicine has a history of at least 2,000 years, the first explicit medical ethical writing is usually attributed to Sun Simiao (also called Sun Simo, ca. AD 581–682). His "On the Absolute Sincerity of Great Physicians," which is part of the massive *Qianjin Yao Fang* (Important Prescriptions Worth a Thousand Pieces of Gold, or the Thousand Golden Remedies), is sometimes referred to as the Chinese Hippocratic Oath. Sun Simo, who is primarily associated with Daoist thought, but who also reflects Buddhist influences, is credited with differentiating medicine from more general social practices by demarcating a core group of "Great Physicians." This core group is held out as the normative ideal. The emergence of this concept of the great physician is thought to be the beginning of the professionalization of medicine.

Great Physicians practice the virtues of compassion and humaneness. They are committed to preserving life, a traditional Daoist moral orientation. In a manner typical of ancient Chinese medical ethical writings, but normally omitted from the Greek Hippocratic tradition, Sun Simo says that the Great Physician "should not pay attention to status, wealth, age, neither should he question whether the particular person is attractive or unattractive, whether he is an enemy or a friend, whether he is Chinese or a foreigner, or finally, whether his is uneducated or educated. He should meet everyone on equal ground" (Unschuld 1979). Paul Unschuld argues that this professionalization of the practice of medicine begins the effort to control the practice of medicine and its material and nonmaterial rewards.

About 150 years later, Lu Zhi (AD 754–805) provided a Confucian response in his *Luxuan Gonglun*. It also emphasizes the virtues of humaneness and compassion, but, according to Unschuld's interpretation, the classical Confucian perspective resisted the professionalization of medicine, holding that medical skills and knowledge should be distributed among all people, not just specialized professionals. The theme of the duty to treat all in medical need, regardless of status and concern over elitist professionalization, occurs throughout ancient Chinese medical ethics. In the seventeenth century Li Ting (fl. AD 1615) wrote his often cited *Ten Maxims for Physicians; Ten Maxims for Patients*, which repeats these themes, beginning with the necessity of mastering Confucian teachings. While the Daoist and Buddhist strands of Chinese thought have reflected strong prohibitions on killing, generally including condemning of abortion and insisting on prolongation of life, Confucian views have been more tolerant of such practices.

India

India, like China, incorporated its medical ethical teachings within its classical philosophical/religious literature. Among the Vedic texts, the *Āyurveda*, initially developed beginning in the first millennium BCE, contains the most important medical writings. Three such texts, the *Carakasaṃhitā*, the *Suśrutasaṃhitā*, and the *Vāgbhata*, include medical ethical writings. The first two also include oaths of initiation taken by students of medicine when they began their training.

The oldest, the *Carakasaṃhitā*, dates from the first century AD, but contains older material. Like the Hippocratic Oath, it requires the student to pledge loyalty to his teacher, to "dedicate thyself to me and regard me as thy chief." Reflecting Hindu reverence for animal species, it requires praying for the welfare of all creatures beginning with cows and Brahmanas, a large domestic fowl. In an unusual provision, though one understandable given the Hindu doctrine of karma, in which a person's conduct during the successive phases of his existence determines his destiny, the student pledges not to treat those "who are hated by the King or who are haters of the King," or those "who are extremely abnormal, wicked, and of miserable character and conduct." It also proscribes treating "those who are at the point of death." In spite of this reluctance to treat those who are dying, Hindu medical ethics stresses the importance of the proscription against killing.

The Hindu notion of *ahiṃsā*, the avoidance of suffering, is another central theme in Hindu medical ethics. It is sometimes interpreted as requiring caution in order to avoid injuring, a concern often reflected in Western medical ethics with its slogan *primum non nocere*, first of all do no harm.

Buddhist Culture

Some of these notions are also reflected in the Buddhist medical ethic of various Asian countries. The prohibition on killing, the concern about *ahiṃsā* and a commitment to veracity all contribute to the Buddhist tradition of medical ethics. These commitments are often in tension both with indigenous pre-Buddhist religious traditions (Confucianism and Daoism in China, Hinduism in India, and Shintoism in Japan) as well as with modern Western culture. Ratanakul (1988), commenting on the penetration of traditional Thai Buddhism by Western individualism, traces conflicts over four central themes of Buddhist medical ethics: veracity, noninjury to life, justice, and compassion. Hippocratic Western medical ethics has never manifested commitments to any of these until recent efforts have begun reflecting them at least in a modest way.

In Japan, Buddhist thought has provided the foundations for medical ethical thought. For example, in the sixteenth century a school of medicine, commonly known as the *Ri-shu* school, manifested classical Buddhist commitments. Students in this school were bound by *The 17 Rules of Enjuin*. Killing of any creature was proscribed. Even hunting and fishing were not acceptable. In contrast to the Hindu *Carakasaṃhitā*, the duty to rescue was extended even to those whom the physician disliked or hated. But virtuous acts were to be performed secretly so that they did not become known to people. Doing good deeds secretly was considered a part of virtue. In a fashion similar to the Hippocratic Oath, students were sworn to secrecy, being prohibited from disclosing any medical knowledge to outsiders. Unless a successor trained in this school was found, those of the Ri-shu school were even required to return all medical books to the school when a disciple ceased to practice.

In Japan, Buddhist medical ethics has survived in an uneasy tension with both modern Western thought and indigenous beliefs known as *kami no michi* (the way of Kami), or Shinto, according to the Chinese. For example, while killing is clearly condemned according to Buddhism, suicide and mercy killing receive more sympathetic assessment both by some proponents of the patients' rights movement imported from the West and by those reflecting traditional Shinto openness to *jyoshi* (love suicide) and *shinjyu* (group suicide). It is these latter influences that undoubtedly account for what could be called mercy killing in Japan.

The traditional influence is also seen in the resistance of Japan to the Western brain-oriented definitions of death. Japan is the only country that has not adopted such a legal definition. It is argued that the traditional Japanese notion of a life force penetrating the entire body clashes with Western notions of life related to brain or mental function.

The Near East

Near Eastern cultures have perspectives on medical ethics that date back at least to the second millennium BCE. Zoroastrianism of ancient Persia saw the physician as a force for good in the struggle between good and evil. It is suggested that this provides a foundation for a medical ethic that would oppose euthanasia. In both Assyria–Babylonia and in Egypt, suicide was proscribed. There are records of abortifacient remedies in ancient Egypt, but there is doubt concerning abortion's legality. It was, however, by the middle of the second century BCE prohibited by Assyrian law as it was in Persia.

The Babylonian Code of Hammurabi (1727 BCE?) provided stiff penalties for incompetent surgery. The surgeon's hand was to be severed if surgery was performed on a nobleman that resulted in death or loss of an eye. If death was caused by a medical procedure on a slave, the physician was obliged to replace the slave. This "sliding-scale" punishment was matched with a similar sliding-scale fee structure in both Assyro-Babylon and Persia. The higher the status of the patient, the higher the fee.

In Islam, medical ethics is grounded in the *Qurʾān*. A ninth century work, *Adab al-tabib* (Practical Ethics of the Physician, by al-Ruhawi) reflects the Islamic synthesis of Hippocratic, Greek, and Arabic medicine. In the thirteenth century an Arabic version of the Hippocratic Oath is found in *Lives of Physicians* written by Ibn Abī Uṣaybiʾah. Nevertheless, the core of Islamic medical ethics is explicitly grounded in the *Qurʾān* and its central teaching, "There is no god but Allah, and Muhammad is Allah's Apostle." This has sometimes given rise to a kind of fatalism in Islamic folk medical ethics. It is sometimes reported that Muslims oppose medical manipulations such as birth control for this reason. But a sophisticated ethical framework in Islamic medical ethics includes a rigorous commitment to the preservation of life, and opposition to all killing including killing for mercy and abortion.

> Whoever killeth a human being for other than manslaughter or corruption in the earth, it shall be as if he had killed all mankind, and whoso saveth the life of one, it shall be as if he had saved the life of all mankind (*Qurʾān* 5:22).

Islamic medicine, in contrast to Western Hippocratic medicine, is thoroughly theocentric.

This is reflected even in contemporary Islamic medical ethics. In January of 1981 Muslim scholars from throughout the world gathered in Kuwait at the First International Conference on Islamic Medicine. They produced the "Kuwait Document," a now-definitive Islamic Code of Medical Ethics. It contains 12 chapters outlining in detail Islamic positions supported by reference to the *Qurʾān*, culminating in "The Oath of the Doctor", a summary of the code. Among the prominent characteristics are a pledge to "protect human life in all stages and under all circumstances, doing my utmost to rescue it from death, malady, pain and anxiety." It also includes an exceptionless pledge of confidentiality that stands in contrast to the Hippocratic provision, which implies that some information ought to be disclosed to others. It also embodies a commitment to provide medical care for all, "near and far, virtuous and sinner and friend and enemy." Other chapters include an explicit recognition of the duty of the Islamic physician to society (a contrast to the exclusive focus on the individual in traditional Hippocratic medical ethics), further expounding on the sanctity of human life (including prohibitions on all abortion and mercy killing), and a full endorsement of the legitimacy of Islamic involvement in new biotechnological advances including organ transplantation. This last provision contrasts with the folk ethic that sometimes reflects a kind of fatalistic yielding to the power of Allah.

African Societies

Many African cultures have taken positions on matters related to medical ethics. Unfortunately, with the exception of ancient Egyptian views, relatively little is known about their specific medical ethical stances. In some sub-Saharan African tribal groups understandings of moral conduct related to life and death are closely tied to the religious culture (*Wiredu*). Since the cultures and languages are so diverse, it would be a mistake to assume that all African societies hold the same medical ethical views. Nevertheless some common patterns are reported. Although euthanasia is not widely discussed, it was and is reportedly practiced by family relatives for incurable and distressful mental illness and severe congenital malformations in many African societies. Likewise, abortion, though viewed with moral skepticism, appears to be practiced as it is elsewhere in the world.

Pre-Columbian Western Hemisphere

Among the most poorly understood medical ethical systems are those of the pre-Columbian Western hemisphere. There has never been any formal analysis of the medical ethics of the great Inca, Aztec, or Maya cultures or of the Native American tribal groups of North America. Most of what is known pertains to views about abortion, suicide, human sacrifice, and related practices.

The Incas viewed children as an asset, and, while abortion was known (by means of fetal massage, beatings, and special drugs), it was punished by execution of both the woman who aborted and those who aided her. Nevertheless among the Inca human sacrifice was practiced. Male children could be demanded for sacrifice, although the practice was apparently rare. Sacrifice of one's young children was reportedly a last resort to attempt to win the favor of the spirits. The yearly sacrifice of two infants was a part of the ritual of the most important temple. In contrast to Greek and modern infanticide, Inca sacrifices had to be of children without blemish.

Human sacrifice was also practiced by the Mayas, either by "heart-rending" or by throwing the one to be sacrificed into a cenote or large sink hole. The Mayas also offered sacrifices of their own blood by piercing their cheeks, tongues, or lower lips. The blood was considered to express "vital principles". Suicides were held by the Mayas to be sacred, deserving of their own special heaven. Human sacrifice was more common among the Aztec as it was in the society of the Caribs. By contrast in these pre-Columbian cultures, there are few reports of killings of either infants or adults for the purpose of euthanasia or the sparing of the afflicted. The close integration of religion, magic, and medicine in these cultures makes the differentiation of a uniquely medical ethic implausible.

Inca doctor–sorcerers, called the *camasca*, or *soncoyoc*, are said to have employed deception in their practice of medicine. They earned entrance into the profession by telling stories of vivid dreams or miraculous recoveries from fatal diseases. Once they had obtained the status of *camasca* or *soncoyoc*, they staged dramatic procedures. One example is surgery in which the doctor would claim that he had removed worms and stones – the supposed causes of disease – from the patient's body, when in actuality, he had recovered said items from no other place than his own pocket, using sleight of hand to make it seem as though they were being extracted from the body. In addition, the Inca physicians would create mixtures of herbs that they claimed to be deadly, in order to generate fear – and revenue – from their clientele. Despite all of this activity, to kill with magic charms was considered a serious crime. Like healers in many cultures, the practitioners were very exclusive about the practice of medicine, claiming that only they, the chosen ones, could practice it properly. Another source says that in some tribes, as in ancient China, herb healers were family based, and all professional information as to the nature of different herbs was kept as a family secret.

Medical ethical stances are derived from more general systems of ethics and belief. It is not surprising then to find that there are as many medical ethical systems as there are systems of ethical thought. To say that behavior in the medical sphere is ethical is, after all, simply saying that the behavior is ethical – at least according to some standard of ethics. Even those practicing medicine within Western culture will inevitably encounter patients who come from other cultures whose medical ethical values and beliefs may be quite different. Only by knowing the range of medical ethical systems will one's own positions be brought into focus.

Medical Ethics in China

Angela Ki Che Leung

For most pre-modern civilizations with a certain degree of cultural sophistication, medical ethics were strikingly similar: hard work and concern for the poor and needy. A good doctor not only excelled in his medical skills, but also cared for the sick and poor. Material benefits should not be his major pursuit. In the West, such tenets naturally conformed to Christian morality; in China, Confucianism, Buddhism, and Daoism mostly contributed to the formulation of such ethics.

Despite the universality of these basic ethical requirements, there were specific features in the historical development of Chinese medical ethics which can be said to have gone through several stages of formation: the mythical period of Antiquity (ca. 771 BCE–AD 265); the period of Buddhist and Daoist influences of the early medieval era (265–960); the period of medical professional maturity of the late medieval era (960–1368); and lastly the late imperial period of Confucian influence (1368–1911).

In the period of Antiquity some of the basic tenets of medical ethics were put forward. From some of the earliest records of Chinese oracle bone writings and other texts, we know that medicine was then mixed with divination and magic. The shaman/doctor had a relatively high social position and a respectable one should, according to opinion of the time, have the quality of perseverance or stability (*heng*).

With the gradual emergence of professional doctors around the sixth century BCE, clearer notions of medical ethics appeared. In the *Huangdi Neijing* (Yellow Emperor's Inner Canon) attributed to the mythical Yellow Emperor, the basic medical classic compiled throughout a period of not less than 400 years beginning in the Warring States period (475 BCE–221 BCE), qualities such as erudition, rich experience, wisdom, humility, and hard work were evoked as necessary for a good doctor. Renowned doctors of this period were reputed to have most or all of such qualities.

Another major quality said of the early doctors was their concern for the poor and lowly. They did not only cure the wealthy and the powerful, and profit was never their major pursuit.

Prominent doctors of this period, such as Bian Que (fifth century BCE), Chunyu Yi (b. 205 BCE), Zhang Zhongjing (second to third centuries AD), and Hua Tuo (d. ca. 208), were later to be venerated as deities of the medical profession, and symbolized the very virtues of good doctors. The deification of these doctors, especially Hua Tuo, was based not only on their exceptional medical skills, but also on their outstanding and legendary morality.

In the Early Medieval period, Buddhism and Daoism had a marked influence of, not only on medicine itself, but also on medical ethics. For many modern historians of Chinese medicine, true medical ethics were not systematically composed in China until the seventh century, when one of China's greatest doctors Sun Simiao (also called Sun Simo, 581–682) wrote systematically on the duties of a physician in his book *Qianjin Bao Yao* (The Thousand Golden Remedies). In this work Sun not only reiterated the qualities already mentioned for model doctors of Antiquity, but also emphasized the importance of retribution as a safeguard for good virtues: "Lao Zi, the father of Daoism, said, 'Open acts of kindness will be rewarded by man while secret acts of evil will be punished by God.' Retribution is very definite. A physician should not utilize his profession as a means for lusting. What he does to relieve distress will be duly rewarded by

Providence." The notion of retribution, though here thought to be essentially Daoist, was in fact much influenced by Buddhism in this period.

The medical ethics put forward by Sun Simiao reflected other aspects of Buddhist–Daoist influences: to attend to all patients equally, disregarding their social and economic position, their age, and their physical appearances. Enemies and friends, foreigners and Chinese, the stupid and the wise should all be treated alike. All these categories should be considered as one single, general class by the doctor. This "equality" before medical care was something unfamiliar to Confucian morality but which has remained significant in medical ethics since the seventh century.

In the Late Medieval period, Chinese medicine reached maturity, both as an institution and a clinical art. The formal division of medicine into different branches or specialties (notably *fuke*, the branch of medicine specializing in women's diseases; *erke*, in children's diseases; and *waike*, in bone fractures and operations) implied a finer division of labor amongst physicians, and this was also reflected in a more elaborate and systematic training program for officially approved doctors in this period, and increased state intervention in the management of medical resources. Though some scholars think that in this period medicine was "a respectable field of study…but as a career and mode of life was highly controversial," one can still see the emergence of a certain medical professionalism, and with it, new elements in medical ethics.

One such element was the frequent caution against *yongyi* (common practitioners). The term was frequently evoked in Song medical texts. A *yongyi* is the antithesis of a *liangyi* (fine doctor), comparable to a *liangxiang* (fine minister). This comparison was first put forward by the famous Song minister Fan Zhongyan (989–1052), who had once considered becoming a doctor himself. The medical profession in the Song period took greater pains than before to draw lines between good and bad doctors, reflecting the emerging professional consciousness of doctors of the period.

However, the reputation of a fine doctor was not entirely based on his curing skills. A fine doctor now combined the religious selflessness and charity of the early Medieval period, as well as neo-Confucian ethics. One of the greatest *fuke* specialists of the Song, Chen Ziming (1109–1270), wrote that he came from a family of three generations of doctors, with an excellent private library of medical books. But his appetite for prescriptions and medical texts was so large that whenever he traveled in the southeast, he collected large quantities of texts which he studied in his free time. Obviously, a good doctor was now likened to a good Confucian scholar, for whom family tradition and textual learning were considered essential for professional success.

The increasing influence of Confucian morality on medical ethics was yet to be seen in the late imperial period. This was a period of relative political continuity and economic prosperity, accompanied by a significant growth in medical knowledge. However, this period was not one of institutional renovation and regulation in medicine. Consequently medical professionalism, in the sense of the maturation of a completely independent professional category, might have suffered. As Unschuld (1979) has said, "The Chinese physician as a definable entity did not exist." The respectability of a physician was, besides his curing technique, increasingly linked to Confucian morality.

One prominent sixteenth century physician, Xu Chunfu (1526–1596), wrote in his major work *Gujin Yitong Daquan* (Medical Tradition of the Past and of the Present) that "Confucianism and medicine cannot be separated." His contemporary, also a famous doctor, Gong Tingxian (1522–1619), put forward ten requirements for physicians, the first two being to cherish kindness and to understand Confucian principles. Another doctor, Li Ting (d. 1619), in his *Rules for Medical Studies* stated from the outset that, "Since medicine comes from Confucianism, unless one studies and understands the [basic] principles, one remains mediocre, vulgar and stupid…" At the same time, detailed instructions on treating female patients were increasingly provided in order to avoid transgressing the Confucian principle of the separation of the sexes.

However, it was also prominent "Confucian doctors" of this period that further defined medical ethics in more systematic ways. The above-mentioned Xu Chunfu was among the first to list the main "vices" of *yongyi*, including taking on the appearances of good doctors with a few tricks, extorting money out of patients, and freeing themselves of responsibility by any means in case of misdiagnosis leading to death. Another famous doctor of the seventeenth century wrote the first Medical Code in 1658. Yu Jiayan (ca. 1585–1664) wrote detailed technical diagnostic guidelines for professional doctors. He made the doctor responsible for all avoidable diagnostic errors, and in so doing, attempted to draw a clearer line constructed on technical considerations between a *liangyi* and a *yongyi*. In other words, development, though limited, was still perceptible in the professional consciousness of doctors despite the overwhelming influence of Confucianism in this period.

However, the incomplete growth of an autonomous medical profession inevitably left areas of ambiguities in medical ethics. One such is the transmission of "secret prescriptions." For some historians of medicine, "the dispensing of secret prescriptions was never considered to be unethical in China. Some even deemed it an honor for a physician to know a secret formula." However, there are indications that not all approved of this attitude. Among others Xu Youzhen (1407–1472), a scholar-official, accused contemporary doctors of preserving secret prescriptions for private profit. For him, effective prescriptions should be published in order to save more lives and to be passed onto posterity. An early nineteenth century physician, Bao Xiang'ao, wrote in the preface of his compilation of "effective prescriptions" that those who did not make effective prescriptions public were despicable.

This ethical ambiguity of the necessity of keeping prescriptions and healing techniques secret obviously was a consequence of the basic structure of the medical institution in late Imperial China: the lack of centralized control in the production of medical knowledge, either by the state or by a self-regulatory medical corps, and the accompanying uncontrolled distribution of medical resources in society. Each family or school of medicine thus had to preserve its share of the resources in order to be competitive in the field, though morally such an attitude was obviously questionable. Such a characteristic only encountered effective challenge when western medicine was introduced into China in the late nineteenth century, together with its ethics and institutions.

Medical Ethics in India

Prakash N. Desai

The origins of medicine in India stretch back to antiquity. The Harrapan city culture flourished in and around the Indus Valley ca. 2500 BCE; it is known for its elaborate bathhouses and drains and sewers built under the streets leading to soak pits. In the second millennium BCE, the northwestern parts of India were host to a series of Indo-European immigrants and invaders from Central Asia. With them began the classical culture of India. Vedas, the sacred lore of the Indo-Europeans, celebrate the *Bhesaj*, one knowledgeable in medicinal herbs. One of the four Vedas, the *Atharvaveda*, contains many chants, mantras, and herbal preparations to ward off evil, enemies, and diseases. The priest–physicians prescribed preparations of plants and herbs, and prayers and fasts for their patients. The Indian medical tradition, *Āyurveda*, meaning the science of vitality and long life, is considered a limb of the *Atharvaveda.*

A more formal system of medicine evolved from around the time of the Buddha (ca. 500 BCE). It became organized in textual form in the first century AD, and reposes in a vast body of literature redacted and updated from that time to the present. There are six principal texts of the Āyurveda. The older three are the two compendia, *Carakasaṃhitā* and *Suśrutasaṃhitā*, named after the two legendary physicians, Caraka and Suśruta, and the *Aṣṭāṅgahṛdaya*, the eightfold essence attributed to an eighth century physician named Vāgbhaṭa. The younger three are the *Mādhavanidāna* (ninth century), *Śārṅgadharasaṃhitā* (thirteenth or early fourteenth century), and *Bhāvaprakāś* Bhāvamiśra (sixteenth century). The word *caraka* also means one who moves about, and may have referred to the itinerant Buddhist and Jain monks who played a pioneering role in the evolution of the Indian medical tradition. In the realm of King Aśoka (273–232 BCE), who embraced Buddhist ideals, Buddhist monasteries served as institutions, like hospitals and hospices, for the care of the sick and the dying.

The earliest medical writings known as the Bower manuscripts, discovered in a Buddhist Stupa in Kashgar (modern China), and translated by Rudolph Hoernle, are considered to have been written by Buddhist authors around AD 450. These texts contain medical treatises which describe the virtues of garlic in curing diseases and extending the life span, elixirs for a long life, ways of preparing medical mixtures, eye lotions, oils, enemas, aphrodisiacs, and procedures for the care of children. Early Indian medicine was carried to Tibet along with Buddhism and was best preserved there, as well as in China. Travelers to and from China, Greece, Persia, and Arabia contributed to the spread of Indian medicine outside India.

The basic assumptions of Indian medicine are rooted in the religious and philosophical traditions of India. Early developments exhibited great diversity in opinion and formulation in keeping with the diversity in Indian thought, tied to Hindu, Buddhist, or Jaina philosophies in various measures. Similarly the system allowed for significant geographic variation as knowledge spread through the subcontinent over a long period of time.

The medical ethics which are closely linked to these religious and philosophical perspectives (*darśanas*) reveal variable, shifting, and accommodating attitudes.

Āyurvedic constructs of the body and the self, central to the medical enterprise, grew in tandem with the faith traditions. The primary vehicles of ayurvedic pathophysiology are the *doṣas* (humors): *vāyu* or *vāta* (wind), *pitta* (bile), and *kapha* (phlegm), and the *dhātus* (body substances). The three humors represent movement, heat, and moisture, respectively, in the body. The primary body substance, *rasa*, organic sap, is derived from food, moves throughout the body, is stored in various reservoirs, and is finally excreted as waste products. In processes of sequential transformation, the *dhātus*, flesh, fat, bone, marrow, and semen, are derived, semen being the purest and most vital product of this process.

The Indian system of medicine views health as a state of balance of body substances, *dhātusamya*, and illness as a state of disequilibrium. The body responds to many kinds of inputs: physical, as in food and drink, psychological, as in emotions of anger or jealousy, and social, as in affection, praise, or scorn. Each input is a potential source of a disease or a cure.

The theory of *guṇas* (lit. strands or qualities) introduces the notion of ethics as a material basis in the ayurvedic pathophysiology. Inherent and substantial, *sattva* (goodness), *rajas* (vitality or activity), and *tamas* (inertia) are qualities or traits found in all substances in various combinations. The balance determines the overall dispositions of persons, foods, activities, bodily substances, and so forth. *Sattva*, which is cool and light, produces calmness, purity, or virtue; *rajas*, which is hot and active, produces passion, happiness, or sorrow; and *tamas*, which is dark, heavy, and dull, produces sloth, stupidity, and evil. Contemplation, meditation, silence, devotion, and fasting promote goodness; love, battle, attachment, pleasure seeking, and emotionality enhance vitality. Sleep and idleness increase inertia. In a hierarchy of values, the *sattva* categories reign supreme and become less material, closer to the idea of *sat* (truth or essence), and often the same as the mind or self. The object of the therapeutic is to transform a person from lower to higher strands or qualities, which is accomplished through the prescription of foods and activities which build goodness. Thus the therapeutic and the ethical become coterminous.

In the Indian view life is not the opposite of death; birth is the opposite of death. Life begins when an embryo is formed out of the union of male and female germinal substances. Defining when human life begins was neither easy nor uniform and straightforward. Some texts maintained that life began with the aforesaid union, and others at the moment of quickening or the descent of the fetus into the pelvis; the latter was more frequently understood as a point of viability. Abnormal pregnancies, congenital deformities, multiple pregnancies, and infertility were explained in terms of defective germinal substances, unnatural coitus, failure in nourishment, or disturbances in humors in the mother or the fetus.

Among the religious obligations, having male progeny was imperative in order to secure a passage to the land of forefathers through the performance of funerary rites. In situations in which a woman failed to have a son, the man was to take another wife, or otherwise adopt a son. If the problem appeared to be male impotence or infertility, the husband's younger brother or another suitable man was to impregnate the wife (a custom called *niyoga*). Early medical texts elaborate on the ways of enhancing conception, and later texts discuss problems of contraception. Mythology also testifies to in vitro fertilization and embryo transfer.

The *Suśrutasaṃhitā* describes various forms of arrested fetal development or obstructed deliveries and describes ways of inducing labor and/or destroying the fetus, especially in the case of danger to the mother's life. A seventeenth century text also describes ways of inducing labor for purposes of abortion in cases of women in poor health, widows, and women of liberal morals.

In contemporary problems of medical ethics, no problem has caused as much furor as has amniocentesis. Preference for a male child, with an easily available technology to determine gender prenatally, has resulted in inordinate and indiscriminate use of abortions. Some states in India have enacted laws to restrict the scope of indications and use of amniocentesis.

There are three categories for the etiology of diseases in *Āyurveda.* External or invasive diseases are caused by foreign bodies, injuries, infestations, and possession by evil spirits. Internal diseases are disturbances of humors, in part caused by lapses in discretion, as in faulty or unseasonable diets, overexertion, sloth, sexual indulgence, or mental disturbances. In either case, the final pathway for the pathology of a disease is an imbalance of humors. The third category contains the diseases which are the fruits of *karma*, the operative principle of Hindu ethics. A very simple explanation might be "every action has a reaction" or "as you sow, so shall you reap," but the logic extends beyond one life. In *karma* theory, when a person dies his self moves to the other world, enveloped in the part material and part ethereal covering which carries the traces of all actions performed, and comes to determine its condition in the next life. Thus some diseases are the fruits of actions from past lives. The unseen hand of *karma* is invoked to explain the not so easily explicable. Events like epidemics and disasters are a result of bad actions of a whole community or the actions of a king.

Mental illnesses also arise from these etiologies: possession states, disturbances in humors, and lapses in discretion. Some disease states are also seen as the workings of time, as in aging.

Physicians in ancient India did consider *karma* in etiology, but they agreed that the passivity that results from assumptions of predetermination made the whole medical enterprise meaningless. Human effort was always a factor in the workings of *karma*, and caring and healing must be actively pursued by the physician. There was also a recognition of incurable diseases, in the face of which human effort was futile. The physician was prudent if he avoided heroic efforts to prevent the inevitable, which not only led to loss of income but also loss of prestige. If the case was hopeless, the physician was to do no more than attend to the nutrition of the dying patient, and even that might be withdrawn at the request of the family.

A category of "willed death" was also recognized in the various religious traditions and was understood to be different from suicide. Suicide was regarded as an act of desperation and willed death an act of determination. It involved permission of the religious order and was resorted to only when the quality of remaining life was likely to be poor.

The ayurvedic physician, called a *vaidya*, was esteemed for his powers but also shunned because of his contact with impurities such as body products, suppurative lesions, and corpses, and his mingling with common people. Taboos around touching ultimately resulted in palpation falling into disuse.

The physician was enjoined to strive constantly to acquire new knowledge, advance through practical experience, and enter into learned dialogues with practitioners from other places. His education began as an apprentice, with the teacher and pupil choosing each other. A good teacher was free of conceit, greed, and envy, and a student had to be calm, friendly, and without physical defects. Later on the *vaidya* became a subcaste or occupational division, and the profession passed from father to son.

The *Caraksaṃhitā* contains an extensive list of ethical directives in the form of an oath to be taken by one entering medical practice. Among these were injunctions never to abandon a patient even if that interfered with one's livelihood, to be modest in dress and conduct, gentle, worthy, and wholesome. A physician must not enter a patient's house without permission, and be mindful of the peculiar customs of a household. He was to avoid women who belonged to others and maintain confidentiality.

Quacks and charlatans were known by their pretense and arrogance, boastfulness and superficial knowledge. The fate of their patients was worse than death. The *Caraksaṃhitā* says that one can survive a thunderbolt but not the medicine prescribed by quacks.

Medical ethics was an integral part of ancient Indian medicine. The texts addressed ethical issues that arose at both ends of life, birth and death. Their approach was pragmatic and flexible, and the purpose of alleviating an illness was always considered in the context of geographic locale, time (the era and the stages of a patient's life), and the particularities of a person. The physician's conduct was also to be always above reproach both in his professional and personal conduct.

Medical Ethics in Islam

Azim A. Nanji

The ethical assumptions underlying the practice of medicine in Islam are inspired by two foundational texts: the *Qurān*, the divine message revealed to the Prophet Muḥammad; and the *Sunnah*, the paradigmatic life of the Prophet Muḥammad which complemented and exemplified the Quranic message. A secondary source of influence resulted from the Muslim conquest and expansion of the seventh to the eleventh centuries, when the cultural and scientific heritage of Antiquity was translated into Arabic and came selectively to be appropriated, refined and developed by Muslims. The integration of this heritage into Muslim civilization led to a new synthesis, not only of the science of medicine but also of the moral values supporting it. Although some of the medical traditions and values of Antiquity were sustained, they were set in Islamic contexts which allied their meaning and purpose to different goals.

The early centuries of Islam also represented a tremendous flowering of intellectual sciences. Muslims were encouraged by their faith and by the *Qurān* to engage actively in the pursuit of knowledge. This impetus translated itself into significant advances in the study of the natural sciences, cosmology, geography, mathematics, history, law, languages, and medicine to name some of the major disciplines. The emergence of Muslim medical ethics has to be situated within this matrix of scientific interest and intellectual commitment.

Muslim views regarding medicine evolved from that of a predominantly Arab cultural setting to that of a diverse and cosmopolitan civilization. The reconstruction in Muslim thought of a prophetic medicine, emphasizing the spiritual dimension and the role of faith in healing, represented an attempt to associate with the Prophet those practices of human life and healing promoted by the rise of a tradition of scientific medicine. The perception of Muslim adherence to prophetic medicine has often been misconstrued as promoting a kind of fatalism, but it would be misleading to extend this interpretation to the whole spectrum of medical ethics and values among Muslims. Prophetic medicine developed alongside professional medicine, which cultivated its own frame of reference for integrating ideas.

Adab is the Arabic term that best describes the pattern of medical ethics and conduct which evolved as a result of the synthesis of the Islamic message and Hellenistic thought. The term represents a set of cultural and moral assumptions articulating the linking of knowledge to appropriate behavior. Ishāq ibn ʻAlī al-Ruhāwi, a ninth-century Christian physician, translated one of the earliest texts dealing with medical ethics into Arabic. His work already reflects the vocabulary of Islam and a heritage of Prophetic religion integrated within a moral framework attributed to Galen and the ancient philosophers. According to al-Ruhāwi, medicine is a divine art granted to humanity by the Creator, whose healing role the physician imitates. Prayer, as the first and last act of the day, is recommended as part of the personal conduct and moral beliefs of physicians.

Within the larger harmony of moral and religious principles is the ethical concept of moderation. Muslim medicine did not accept the body/soul distinction of the Greek tradition but conceived of human beings as entities formed in symmetry and harmony. One of the most illustrious physicians of early Muslim history, Abū Zakariya al-Rāzī (Rhazes) argued for a healthy, moral life based on moderation between excessive indulgence and abstinence and an adherence to a life of knowledge pursued to balance physical, moral, and intellectual needs.

The *Qurān*'s message of social justice, developed into the notion of public welfare and charitable works toward the poor, influenced medical values in ways quite different from that of the Hippocratic tradition. The hospital, founded through royal acts of patronage or endowments, is an Islamic institution traceable to the eighth century. This larger social role, engendered by Islamic values of concern and care for the indigent, represents perhaps one major difference with the practice of Antiquity, where the emphasis lay mostly on the physician's concern and relationship with an individual patient.

The rise of the physicians and the medical ethics that guided the emergent profession in Muslim society cannot be separated from the general tenor of the civilization and the polity that had emerged after the founding and spread of Islam. The moral discussions and intellectual forces that emerged stimulated a concern for how moral and religious perspectives could be reconciled with intellectual modes of inquiry. But professional medicine was only one of several therapeutic systems available. As Sufism, the mystical and spiritual dimension of Islam, grew in influence and became institutionalized through a system of orders, the heads of these organizations came to be regarded as having the power to intercede in moments of crisis, including disease. In time this led to an extensive use of amulets, granting of prayers and recitations from the *Qurān* as aids to healing. Such traditions and practices came to occupy a relatively prominent place beside that of professional medicine during the premodern period, and continue to be influential in many Muslim societies.

Whereas the eighteenth and nineteenth centuries marked a new impulse in medical and ethical thinking in Europe, the events leading to the encounter of modern Western culture and political power with the world of Islam created a different context for the assimilation and practices of modern medicine. Muslims were faced with new tools and methods of healing which called into question all of the normative assumptions that previously had been integrated into their *adab* of medicine. The institutionalization of Western medical practices also resulted in moral and ethical consequences. Muslim responses reflected all of the ambiguities in the face of the challenge the new authority and its civilization brought. For some, Islam would serve as a moral sanctuary from which to combat secular ways of staving off disease. For others, it led to an acceptance of modernity and provided the impulse to shape it in conformity with the sources and perceptions of their past heritage. The process of change as it affected medical practice and value thus cannot be separated from the larger issues entailed by the colonial encounter and the patterns of medical education and practice, as well as attitudes to disease and healing that came in the wake of Western contact and influence. The measures instituted through European doctors and medicine eventually received acceptance by a new generation of professional physicians and led to the assimilation and emulation of the new practitioners and their values. The duality that resulted caused a failure to ground the new training and knowledge within Muslim theological moral and cultural contexts and separated the "new" physicians from traditional counterparts and their moral world. In many ways, this sense of duality and the effort to recover the center constitute the story of ethical issues facing twentieth and twenty-first century Islam. The most important challenge however remains the formulation of an *adab* that will guide the practice of medicine while remaining engaged with its past ethical underpinning and taking account of the dramatic changes brought about by population growth, poverty, and national policy.

In the field of medicine as in other scientific and technological areas, Muslims are faced with complex choices and newly emerging issues that raise moral dilemmas. There is a greater need to harness resources that advance skills in moral reasoning and enhance sensitivity, and to integrate these into perspectives of medical education, institutional development and the Islamic commitment to ameliorate poverty and disease.

Medical Paintings of Tibet (*Sman thang*)

Zhen Yan

Sman thang is the abridged form in the Tibetan language for Tibetan medical painting, in which *Sman* stands for medicine, while *thang* refers to *thangkha*, a hanging scroll commonly mounted on a piece of silk with vignettes of various backgrounds.

There is no definite conclusion as to exactly when the *Sman thang* appeared in history. However, in so far as the painting art of *thangkha* is concerned, there are some studies written by scholars outside China. The prestigious Italian Tibetologist, G. Tucci, provided very detailed descriptions on these works of art (1949).

Generally, it is claimed that the *thangkha* originated from religious demand, beginning with the painting of Buddhist icons. The paintings, in addition to the main Buddhist icons, provided contrasts with other items such as clouds in the sky, trees, birds, or beasts; later, landscape painting also appeared. Such primitive religious paintings were owned by lamaseries, and were hung in the Buddhist hall for worship by monks and devotees. Sometimes, the secular population also used them when storytellers were narrating their tales, so as to keep the attention of the audience and strengthen its attraction. Scholars claimed that the modern *thangkha* was systematized and flourished under the auspices of the Sa skya sect of Lamaism from the thirteenth century. This is based on Tucci and Pal's descriptions. The provenance of Tibetan medical *thangkha* might be so early, based on our investigation on the whole series of modern *Sman thang* and the in-depth study of the history of Tibetan medicine as a whole.

In the mid-seventeenth century, during the reign of the fifth Dalai Lama, because of the diversity of various patterns and styles of earlier *Sman thang* painting, there are differences regarding the recognition of Tibetan drugs, therapies, and moxibustion points. The Regent of Dalai Lama made up his mind to rearrange and systematize the existing *Sman thang*. After approval by the Dalai Lama, Sde srid sangs rgyas rgya mtsho used his *Baidurya sngon po*, the most prestigious commentary on the medical canon, *Rgyud bzhi*, as a basis, and painted a new whole series of *Sman thang*. Altogether 60 paintings were completed in the year 1688.

But the Regent was not satisfied, considering there was a need to further expand the series. With the members of the original team, based on some new materials, including the diagnosis and points for moxibustion included in *Sman dpyad zla ba'i rgyal po* of the Tubo Dynasty, drugs newly discovered and applied to different points and vessels for moxibustion and bloodletting in both Northern and Southern Schools, new *Sman thangs* were drawn. Ultimately, in 1703, the total number increased to 79. This might be the mother *Sman thang* series of modern colored *Sman thang* series.

When the fifth Dalai Lama died, 50 of the paintings were used as funeral objects and buried in the *chod rten* (mausoleum), since they had been viewed as treasures by the ruling class. New versions were duplicated during the reigns of the sixth and seventh Dalai Lamas.

The 13th Dalai Lama (reigned 1895–1933) also treasured the *Sman thang* series, which were reproduced, either individually or in a series, in 1918, 1923, and 1933 separately.

In 1923, the then director of the Sman rtsi khang (now Traditional Tibetan Hospital of Tibet Autonomous Region) painted a new *Sman thang*. Being the 80th in the whole series, this *thangkha* is very unique and different from the others. It is entitled "famous physicians of successive ages." Altogether 12 physicians are included. On the back of this *thangkha*, the date of printing was given, which was never seen in the previous ones.

The total number of the whole series of *Sman thang* is 80. It deals with the whole picture of Tibetan medicine based on the *Baidurya sngon po*. This includes the history of Tibetan medicine, the physiology, anatomy, pathology, diagnostics especially pulse taking and urinalysis, medical instruments, all clinical aspects, including the causes, manifestations, treatments of all diseases in internal medicine, sensory organs, gynecology, pediatrics, dermatology, Tibetan *materia medica*, recipes, drug forms, all sort of therapies, medical ethics, and macrobiotics.

All paintings in the current series were not painted at the same time, so the paintings in the whole set are not identical in their sizes. Some might be smaller, others bigger, measuring 75.0–86.0 × 58.0–68.0 cm in size. All the illustrations contain vivid Tibetan characters, architecture, clothes, natural scenes, and folk vignettes. A few special points need to be pointed out here.

First, the reader can learn the wisdom of the ancient Tibetan people and their customs and habits. The paintings contain such elements as national clothing, especially the special hairstyles and decorations with which comparative studies on clothing of ancient and modern periods can be made.

The expression of the Tibetan language throughout the *Sman thang* is unique. As shown in the second, third, and fourth *thangkhas*, there are special manifestations of a tree, the so-called "base wood," "allegorical," "unfolded," or "wish-fulfilling" tree. Of course, it is hard to say that the trees in these paintings are exactly the base wood; however, it is quite similar to the actual tree (referring to the original paintings, not to the reproductions drawn elsewhere). Through the roots, trunks, branches, leaves, flowers, and fruits of these trees and so on, the physiology, pathology, diagnosis, and treatment of Tibetan medicine are fully laid out. Through this imagery, it is easier to remember the three-factor theory, the seven materials and the three excreta, the etiology and causes of diseases, and the transmission routes, locations of lesions and the rules governing them, the sequelae, classification of diseases and causes of death, all kinds of diagnostic methods, food and drink, daily life, treatment, medication, and topical therapies. In short, by these three base woods, all the contents of Tibetan medicine are included, embodying the wisdom of the Tibetan people.

The application of a measuring system by ancient Tibetan people is, again, a unique one. The unit for anatomical measurement, for example, is *tong shen cun* (homophysical inch), namely, applying the length of certain part of the patient's own body as a unit for measurement, such as the finger or the fist, the thumb, or the two points between the ends of the radial creases of the second phalanges when the middle finger is flexed.

There are some very interesting paintings. In the painting of embryology, two points must be mentioned. First, the painting shows the development of an embryo beginning from the combining of the father's semen and mother's blood. The simple fertilized ovum develops gradually into a complex structure and increases in size and changes its structure gradually. Unlike some ancient embryologists who claimed that an embryo is nothing but a miniature baby that simply increased in size, without any other changes which is the so-called "preformation theory," popular at the time before being superseded by the scientific embryological theory of the modern age, Tibetan embryology is rather scientific as compared with the Western theory. Another point is that the painting shows that during the developmental processes of an embryo, there are three stages through which it should pass. These stages are called fish stage, tortoise stage, and pig stage. The ancient Tibetan embryologist might recognize this problem on the basis of the morphology of the embryo. Whatever the condition, this idea is exactly in line with the theory of modern embryology which claims that the human embryo is developed as a miniature of the evolutionary process of the animal kingdom, moving from simple water-borne organisms through the early stages of vertebral animals living in water and then passing on through the birds and mammals, until a human being was finally formed. The description in the painting, therefore, coincides with modern embryology, a very high achievement of Tibetan medicine.

Painting no. 51 is an anatomical illustration. In this painting, there are six illustrations. Among them, four show a sitting position, while the remaining two depict a standing position. The two sitting pictures at the center show an anterior and posterior view. The anterior view shows the internal viscera. The key points are the position and the contour of the heart. Here, the heart is in the shape of a lotus flower bud, with the round end situated in the middle lower part of the chest, while the sharp end is pointing upward, which is based on the description in the *Rgyud bzhi*, saying that “the heart is sitting on the throne like a king.” Hence it is sitting solemnly in the middle of the chest with its tip pointing upward.

This goes against the actual structure of the body in which the heart is situated in the left middle part of the chest, with the tip pointing leftward and downward instead of upward. During the reign of the fifth Dalai Lama, Lho brag sten zin nor bu, a physician and painter, through observation of cadavers, found the actual condition of the anatomical structure and produced a drawing to check the errors, declaring that this was “what I witnessed.” He also produced drawings of the gallbladder, lungs, stomach, intestine, bladder, kidneys, liver, and *bsam se’u*, all appended at the sides of this *thangkha*.

This painting is the most unique one in the whole series. It is evident that this *Sman thang* was prepared by at least two persons: an anonymous painter for the original painting and Sten zin nor bu for the revised one. This is the only case of its kind in the whole series and is of utmost scientific importance.

During the reign of the fifth Dalai Lama, Tibet was still a society ruled by a unified political-religious system, Lamaism, with Tibetan Buddhism being the highest ruling spiritual discipline, and the Dalai Lama being the secular and religious head. He was in the position as shown in the painting as the King of Tibet sitting in the middle.

To change this situation of supremacy according to the actual conditions, the painter risked being accused of blasphemy. The formal drawing of this *Sman thang* demonstrates, on the one hand, that the fifth Dalai Lama was open-minded enough to tolerate and respect natural science in order to publicize the real situation to the populace, and Sten zin nor bu was brave enough to insist on upholding this scientific spirit and the truth. This explains, at least, that, by then, anatomical science was respected and its dignity and purity was protected.

People now call *Sman thang* the gem of Tibetan medicine; and it is treasured by people all over the world. This whole series of paintings have been now published in atlases or albums in several languages with elaborate commentaries.

Medical Texts in China

Richard Bertschinger

The texts of Chinese medicine are extremely voluminous. They have a continuous history of more than 2,000 years, of which little is known in the West. Standard works up to AD 1900 number around 190, and if popular writings are included this rises to at least 1,500. There has been great activity since the 1949 establishment of the New China, and a modern dictionary of traditional Chinese medicine written in Shanghai in 1988 refers to over 4,000 individuals and 8,000 works. And yet there are barely a dozen translations of these texts. The whole corpus also includes works on massage, diet therapy, and therapeutic exercise similar to the contemporary popular *Taiji Quan* (Supreme Ultimate Boxing) and *Qi Gong* (Breathing Therapy). These have been largely omitted from the following entry, which describes, in chronological order, the most important texts on medical theory, acupuncture and moxibustion, and herbal medicine.

The earliest extant systematic writings, which formed the cornerstone for all medicine in China, Japan, Korea, and the Far East, are collected in the large compilation made during the Han dynasty (202 BCE–AD 220), named the *Huangdi Neijing* (The Yellow Emperor’s Inner Canon). Extracting itself from the notion of ancestral curses and demonic attacks as the cause for illness, the reasoned tone of this compilation (and it is only one of many Han classics) laid a foundation for the next 2,000 years of medical writing, and its influence soon spread to Korea, Japan, and beyond.

The basic theory of Chinese medicine, as spoken in the *Huangdi Neijing*, involves the interplay and interfusion of *yin* (quiescent) and *yang* (active) forces, producing both health and disease. This alternation occurs both within the human body, and between the body and the natural world. Chinese medicine pays particular attention to natural rhythms and the *wuxing*, five fundamental elemental associations of vegetation, fire, soil, minerals, and fluids (wood, fire, earth, metal, and water), both within the natural world and as symbolic agents of change within the body. Illness is seen as a disorder of the *qi* (vital energy), perhaps enhanced by some external factor but primarily involving a deficiency within the individual.

The *Shennong Bencao* (Shennong's Herbal) appeared soon after the *Huangdi Neijing*. It is the earliest surviving materia medica, believed to have been compiled during the first century BCE. In this work 365 kinds of medicinal substances are listed and divided up into three classes: major remedies, medium remedies, and minor remedies.

An almost contemporaneous and equally important text is the *Shanghan Lun* (Discussion on Cold-Induced Disorders) which was written by Zhang Zhongjing (ca. AD 150–219) at the close of the Han, and which has proven to be one of the most influential texts in Chinese medicine. This was the first to advocate the analysis of medical conditions in accordance with the six channels (*taiyang*, *yangming*, *shaoyang*, *taiyin*, *shaoyin*, and *jueyin*) and eight syndromes (*yin*/*yang*, outer/inner, hot/cold, and excess/deficient). Along with the *Huangdi Neijing*, it formed a straightforward basis for the development of traditional Chinese medicine. Its companion text is the *Jingui Yaolue Fang Lun* (Concise Prescriptions from the Golden Casket, ca. 220), also by Zhang Zhongjing.

The importance of these two texts, the *Huangdi Neijing* and the *Shanghan Lun*, is that they illustrate the building up of a well worked out and heuristic, classificatory framework, involving the *yin* and *yang*, the five phases, the six channel types, and the eight principle syndromes of diagnosis, into which the results of any doctor's medical observations could be fitted.

The first textbook on acupuncture and moxibustion was the *Zhenjiu Jiayi Jing* (A–Z of Acupuncture and Moxibustion), written by Huangfu Mi some time around AD 280. Much of this text actually repeats verbatim the *Huangdi Neijing*, but it also gives the first systematic description of acupuncture points, each listed according to its position on the body, and also their function. In addition, the first book on pulse diagnosis, the *Mai Jing* (Pulse Classic, ca. 300), appeared during this period. The author, Wang Shuhe, perfected the art of pulse taking, describing in detail nearly 30 separate categories of pulse. This work, along with Li Shizhen's *Binhu Maixue* (Pulse Studies of Master Binhu), written later during the Ming, formed the core texts for this unique method, which is characteristically Chinese.

It is recorded in the Tang dynasty histories that the Imperial medical colleges based their teachings upon the *Huangdi Neijing* and Huangfu Mi's *Zhenjiu Jiayi Jing*. Among the books also at their disposal would have been the famous, and charmingly titled *Zhouhou Beiji Fang* (Emergency Remedies to Keep Up One's Sleeve, ca. 340), by the ardent Daoist Ge Hong. Ge Hong was also the compiler of the early alchemical and dietetic work *Bao Pu Zi* (The Work of Master Puzi).

Sun Simiao (also called Sun Simo), in 652, published the *Qianjin Yao Fang* (Remedies Worth their Weight in Gold) and its sequel the *Qianjin Yi Fang* (More Remedies Worth their Weight in Gold). These two volumes were extremely diverse, and together they summarized the medical achievements of the Tang, including practices as diverse as incantation, prayer, love philtres, exorcism, dietary restraints, as well as acupuncture and herbal remedies. They also contain the first known charts of the channels and points of the human body, with front, side, and back views. Sun Simiao's work also contains the early *Yinhai Jingwei* (A Detailed Study of the Silver Sea) which describes 81 eye conditions and their treatment, although this work has also been attributed to an author from the Yuan dynasty.

During this period, the earliest official pharmacopoeia ever to be published was sponsored by the Tang government, based upon the work of the earlier Shennong Herbal. The *Tang Xinxiu Bencao* (Tang Newly Compiled Materia Medica) was complied by Su Jing along with 22 other scholars, and it lists some 844 medical substances.

In AD 1027, at the establishment of the Song dynasty, two bronze statues were cast by edict of the Emperor, fashioned by a doctor, Wang Weiyi, who incorporated into them all the known acupuncture points. These statues were accompanied by his *Tongren Zhenjiu Shuxue Tu Jing* (Illustrated Canon of Acupuncture Points based upon the Bronze Figures, 1026). This text is still popular and used for point-location in acupuncture colleges throughout the world. Also around this time appeared the earliest work on bone setting, the *Lishang Suduan Mifang* (Secrets of Treating Wounds and Bone-Setting, ca. 946), put together by Lin Daoren. This outlined the use of traction, fixation, reduction, and reunion for fractures and dislocations.

The fixed attitude to traditional knowledge began to subside gradually during this period. With greater political stability and urbanization, medicine became more intensive and specialized. The number of medical publications during the Song exceeded those of all previous ages put together, and it is largely the Song view, and Song editions of texts, which are now extant. The work begun by Lin Yi, with his editing and reprinting between 1068 and 1077, produced the classical editions most in use today. This was also the century which initiated the massive Daoist patrology, the *Dao Zang* (Storehouse of the Dao).

The monumental *Shengji Zonglu* (Imperial Encyclopedia of Medicine), complied by a board of physicians under the emperor around AD 1111, was composed of 200 volumes. Other specialized works include the small pamphlet the *Yanglao Fengjin Shu* (Looking After the Aged, early eleventh century) by Chen Zhi, on the care and feeding of old people, and the famous monograph on beriberi, the *Jiaoqi Chifa Zongyao* (Every Essential on the Treatment of Beriberi, 1078) by Tong Zhi.

During this time, another influential book was the *Sanyin Jiyi Fang Lun* (Discourse on the Three Causes Ultimately for Any One Disease, 1174) by Zhen Yan. In this the cause of disease was seen as belonging to one of three categories: either internal (including emotional disturbances), external (climatic change), or neither (malnutrition, over-feeding, animal or insect bites and stings, wounds, hoarseness through shouting, drowning, etc.). There was also the gynecological *Furen Da Quan Liang Fang* (Collection of Excellent Prescriptions for Women, AD 1237) by Chen Ziming, consisting of 260 articles in eight divisions, and numerous books on children's illnesses and surgery. One of the earliest was the *Xiaoer Yaozheng Zhijue* (Treatise on Pediatric Pharmaceutics, 1119) by Qian Yi. This small book exerted a profound influence on pediatrics, giving valuable insights into measles, scarlet fever, chickenpox and smallpox, along with innovative methods of diagnosis and treatment. Also, in 1461, the Dr. Gou Bing produced the *Quan You Six Jiao* (Directions for Those Working in Pediatrics), in which indigestion or wrong feeding was held to be the probable cause of most ailments. The first treatise on forensic medicine also was published at this time, the *Xiyuan Jilu* (Instructions to Coroners, 1247), written by Song Zi. This too proved to be a foundation text.

Around this time medical colleges became well organized, and this setting of academic boundaries resulted in differing schools of thought. One considered disease to be caused by excessive heat in the body and advocated cooling medicines; another emphasized the use of purgatives and emetics; another extolled the use of tonics. The most influential book surviving from these debates was probably the *Piwei Lun* (Treatise on the Stomach and Spleen, ca. 1230) by Li Dongyuan, who put all disease down to disorders in life style and the digestive tract. Also notable is the *Rumen Shiqin* (A Literati's Dutiful Care of His Parents) by Zhang Zihe (1156–1228), which advocated the use of sweating, emesis, and purgation.

Arriving at the Ming dynasty (1368–1644) we find scholarship bearing remarkable results. The *Bencao Gangmu* (A Materia Medica Compendium, 1590) by Li Shizhen (1518–1593) is one of the most important works ever produced in China. It was a gigantic text in 52 volumes, listing nearly 2,000 medical substances, including plants, minerals, and animal products, with over 10,000 prescriptions. It detailed the appearance, properties, methods of collection, preparation and function of each substance. This was a truly encyclopedic work commenting on all branches of natural history, botany, zoology, mineralogy, and metallurgy. Mention should also be made of its forerunner, the *Puji Fang* (Prescriptions for Universal Relief, 1406), produced by Teng Hong, which contained an astonishing 61,000 prescriptions.

Great textbooks on acupuncture also appeared during the Ming. Again these were truly comprehensive, reproducing the best of the old along with reworkings and selections from the new. Most notable are the *Zhenjiu Daquan* (Acupuncture and Moxibustion in its Grand Entirety, 1439) by Xu Feng, the skillfully compiled *Zhenjiu Juying* (Gatherings from Outstanding Acupuncturists, 1537) by Gao Wu, and the last in this tradition, the monumental *Zhenjiu Dacheng* (Acupuncture and Moxibustion, the Grand Compendium), written by Yang Jizhou in 1601 – a book "still of the highest usefulness today" (Needham 1980).

Mention should also be made of the reordering of the *Huangdi Neijing*, the *Lei Jing* (Classified Classic) by Zhang Jiebin, which appeared in 1624; with this work, and its illustrated appendices, the summit of *Neijing* scholarship had been reached.

During the later centuries little work of influence appeared. An exception is the *Yizong Jinjian* (Golden Mirror of Medicine, 1749) by Wu Qian. It is mostly made up of extracts, revisions, and corrections of earlier writings. A government decree in 1822 actually eliminated acupuncture from the medical curriculum. And, although China's indigenous medicine survived, it met with disfavor from the established government until, as late as 1929, the Guomindang banned traditional Chinese medicine altogether. However, that same year, Mao Zedong wrote that both Chinese and Western medicines should be used to serve the population, and this has been the prevailing view ever since.

Since the founding of the People's Republic (1949) several medical colleges have been established, combining modern Western and traditional Chinese medicine, and an increasing number of texts have been reedited and published. Many new areas of research have been opened up: acupuncture anesthesia, ear-needling, the discovery of new points; and the translation of texts has begun. Finally, to appreciate the resilience and accuracy of Chinese medical texts we can compare two extracts.

One is from the first page of the first acupuncture book ever produced for the West (Beijing 1980):

> The theory of Yin and Yang holds that every object or phenomenon in the universe consists of two opposite aspects, namely, Yin and Yang, which are at once in conflict and in interdependence; further,

> that this relation between Yin and Yang is the universal law of the material world, the principle and source of the existence of myriads of things, and the root cause for the flourishing and perishing of things.

The second is from the *Huangdi Neijing* (ca. 100 BCE):

> Yin and Yang are the grand method of heaven and earth, the rule and pattern of the ten-thousand things, the father and mother of change and transformation, the fundamental origin of living and killing… (Ch. 5).

The continuously resilient nature of Chinese medical texts could not be more clearly shown.

Medicinal Food Plants

Nina L. Etkin

The connection between diet and health is recognized by all human societies, and for many, healthful eating is a pivotal construct of their medical ideologies. How central a role food plays in disease prevention and therapeutics ranges along a continuum, one pole of which represents such indefinite notions as "healthy foods." This is a feature of all cuisines, although which particular foods are so regarded varies with both place and time. Toward the other end of the continuum, more specific explanations of the healthful nature of foods are based both on physical characteristics or effects and on abstract qualities.

Among the abstractions that people apply in their assessment of medicinal foods are paradigms of binary opposition such as heating/cooling and wet/dry, representations of intangible qualities that are not related to actual thermal or hydrous states. These are expressions of health conceptualized as a balance between certain key qualities that can be mediated by diet. In China, for example, cooling foods such as carrot and seaweed restore equilibrium in the case of rash, constipation, and other hot disorders. This general kind of food therapy also characterizes the medical traditions of India, Southeast Asia, Latin America, the Near East, parts of Africa, and much of Europe, although the attributes ascribed to particular foods and diseases vary across, and even within, cultures. In China these binary oppositions intercalate with older traditions that symbolize the more cosmic *yin/yang* philosophy, take into account the theory of Five Phases (*wuxing*: earth, metal, fire, wood, water), and address the concept of *pu* (strengthening, patching up). These statements oversimplify, but they make the point that the healthful qualities of foods are manifold and are integrated in complex ways into different food cultures.

Regarding the physical characteristics of medicinal foods, the cultural dicta by which people interpret the appearance, taste/smell, or physical effects of foods are as varied as the religious beliefs, languages, marriage customs, etc. that distinguish societies from one another. A common link between food plants and diseases is the taste that defines their curing properties. Consider this complex example. The medical tradition of a Hausa population in northern Nigeria advises that the treatment of measles be aimed at several stages, beginning with efforts to expel disease substance from the body's interior. As soon as the measles spots appear, bitter and astringent foods and medicines are sought to chase out internal sores so that the rash matures. Foods and medicines that occur later in the therapeutic progression are cold and aromatic because the illness likes those qualities. In the event that nausea and fever accompany the rash, acid/sour tastes are indicated, to calm and cool. When there is evidence that all sores have been externalized (that is, when other internal signs such as fever and lymphatic inflammation have subsided), the rash is treated with astringent and emollient medicines, no longer with medicinal foods. In this example, taste features prominently in the selection of medicinal foods.

Among another physical attributes by which people identify foods for medicinal use, color, location, texture, and shape may be evoked as part of a "doctrine of signatures." This fundamental tenet in plant selection maintains that these attributes are signs of a plant's intended use. Some of these associations conform as well to theories of sympathetic magic, which is based on the idea that like affects like. Thus, for example, in US Colonial and Chinese medical traditions, the shape of walnut kernels suggested their effectiveness as a brain tonic, in Taiwan red foods such as tomato, red crab, and carrot are considered nutritious because red symbolizes prosperity and good fortune; in several Southeast Asian cultures, where red protects against spirits, red eggs are used to ensure fertility; and in Ecuador the red flowers of the amaranth plant are made into a beverage to restore menstrual regularity and purify the blood. That other medical traditions identify plants with red flowers or leaves to fortify blood finds a parallel in the US, some decades ago, when "good red meat" (beef) defined the core of an "all American," healthy cuisine. Similarly, yellow plant foods are designated for such liver disorders as jaundice in which the skin and white of the eye take on a yellowish tone, and plants whose leaves are shaped by several lobes are used in the treatment of lung disorders. These associations are not as simple as outlined here, because although appearance and other physical attributes are presented as the primary distinguishing feature of certain medicinal foods, they are understood to protect or interfere with disease processes in variable and complicated ways that bear on other characteristics that different medical cultures describe through such metaphors as "strength," "neutralization," and the like.

By the same token, foods also have negative health connotations, many of which have been systematically codified as food taboos, the symbolism of which is especially rich. Food prohibitions play a pivotal role in the traditional medicine of Thailand where there are five general taboo units: meats (cow, water buffalo, pig, and chicken; frogs and scaleless fish); seafood; pickled food; and certain vegetables (cucumber, gourd, and jackfruit). Further, specific foods and beverages are prohibited in particular conditions, and specific tastes such as sweet, fat, and sour are additionally proscribed in certain instances – for example, sour is discouraged because it is understood to result in the accumulation of pus, which should be avoided when one is treated for wounds. Similarly, for Hausa in Nigeria, food plants (e.g., okra, cat's whiskers) that are otherwise appreciated for the gelatinous quality they impart to soup, are avoided when one has congestion from flu, and in the case of certain backaches that are understood to be caused by an accumulation of phlegm within the body. For altogether different associations, Hausa understand that peanuts aggravate leprosy and offset the effect of medicines for anemia.

The cultural and social aspects of medicinal foods are especially apparent in circumstances in which their consumption extends beyond the sick person to include others. Among the Nekematigi of New Guinea, for instance, ceremonial therapeutic meals are shared by the entire community and consist of all purpose medicinal foods – ginger, for example – that are intrinsically healthful regardless of the cause of illness, and specific antidotes against the acts of enemy sorcery that account for most sickness in this society and that always originate from outside the village. If the illness persists, the meal is repeated, again involving the community and thus reaffirming solidarity in the face of malevolence introduced from outside the social body. Conversely, for Nigerian Hausa, whereas healthy foods such as fish and peanuts are shared among family members who eat from the same pot, specific medicinal foods are consumed only by the sick person. In other medical traditions the healer and patient consume the medicinal foods, usually at the same time, both to cement the therapeutic relationship and to empower the healer's empathy toward the patient.

Since people everywhere recognize the relationship between a mother's health and that of her nursing infant, one is not surprised to find, as among Hausa, that when a baby is ill, medicinal foods are also consumed by the mother, and exclusively so if the infant has not yet begun to eat solid foods. And on the Western Pacific island Espiritu Santo (Vanuatu, formerly New Hebrides), food taboos for children who have become ill as a result of malevolent magic are extended to the parents. The general point made here is that the consumption of medicinal foods occurs in a variety of social contexts that range cross-culturally along a continuum of inclusiveness with respect to patients, their families, and their communities.

The interpretation of these cultural expressions by social and health scientists has largely replicated a central idiom in Western thought – i.e., that food and medicine are separable categories. This is apparent, for example, in studies that inventory medicinal or food plants, overlooking the possibility that plants are not simply one or the other. In this way, whether or not a food is considered healthful depends on its intrinsic nutritional value. For the first half of the twentieth century nutrition scientists concentrated on identifying the nutrients that help the body's immune system fight infectious disease and whose deficiencies result in such discrete disorders as scurvy (vitamin C), rickets and osteomalacia (calcium, vitamin D), and beriberi (thiamin). (This can be related to the Chinese example above through observation that insufficiency of the vitamins found in carrots and other cooling vegetables typically eventuate in skin disorders.)

During the latter 1900s nutritional scientists focused on foods linked to chronic disorders, some revealing negative associations: foods high in salt, sugar, and fat have been implicated in hypertension, diabetes, and cardiovascular disorders, respectively. Conversely, other nutrients have healthful effects on chronic diseases: dietary fiber – such as provided by whole-grain cereals, fruit skins, vegetables, legumes, and nuts – has been linked to diminished risk of colorectal and stomach cancers, high blood pressure, diabetes, high cholesterol, atherosclerosis, and coronary heart disease. Vitamin A – present in yellow and orange fruits and vegetables (carrots, bell pepper) and dark green leafy vegetables (spinach, kale) – has been reported to protect against lung and prostate cancers and to decrease the severity of measles. Vitamin E (found mostly in green leafy vegetables) and C (high in fruit, especially citrus) both have been linked to lower cancer risks as well.

In sum, to date the frame of reference has been the nutritional composition of medicinal foods, and apart from the conventional nutrients – vitamins, minerals, protein – foods have been regarded as chemically inert, thus of no salience to specific disease processes. But foods are not chemically mundane. Most people are aware of toxins in potentially nutritious foods, so why not drugs? The line between toxin and medicine is in any case an uncertain one – toxic in what dose, and for whom? Many of the toxic "secondary" metabolites produced by plants are a primary defense against fungi and bacteria, microorganisms not unlike the pathogens with which human societies contend. Accordingly, people have taken advantage of these characteristics of plants, in some cases modifying that chemistry through selective breeding and special planting of food plants to exaggerate certain features and to reduce or eliminate others.

In view of this, a more recent development in medicinal food study is to focus on the drug-like qualities of plants. Attention has been paid especially to spices, perhaps because their role in the early history of Western medicine has made this category of plants the more likely subject of pharmacologic inquiry. In a biomedicine so strongly informed by the germ theory of disease, the antimicrobial action of many spices merits attention; and because spices – like pharmaceuticals – are small (in quantity) and powerful (in smell, taste), they fit an allopathic model of healing. Evidence for pharmacologic activity in spices includes: capsaicin in chili pepper diminishes risk of cluster headaches and stomach cancer; sulfides in garlic and onion inhibit blood clotting and promote cardiovascular integrity; West African black pepper has anticonvulsant activity; ginger is effective in the treatment of motion sickness and nausea; cricetine in saffron has antiatherosclerotic activity; vanillin and catechin in vanilla have, respectively, liver protective and anticariogenic actions; and caffeine, theophylline, and theobromine in chocolate elevate mood.

More recently attention has been directed as well to more ordinary foods: sulforaphane in broccoli protects against certain cancers; gamma-amino butyric acid in tomatoes is hypotensive; rhubarb has antibacterial activity; epicatechin gallate from tea leaves lowers serum cholesterol; and pigeon pea is helpful in diminishing the symptoms of sickle cell anemia.

These catalogs offer only an incomplete story of the medicinal potential of food, since much of what is reported is based only on laboratory studies of purified substances and/or on animal studies using healthy subjects. Thus, although some medicine-like action may be confirmed, one cannot be certain that this will indeed be the outcome when the plants are ingested by sick humans. One gains more insight by considering food use in its broadest physiological and cultural contexts, in order to take into account preparation and incidence and quantity of consumption.

In many traditional societies the same plants are used as both food and medicine, their function and preparation depending on how they are identified for a specified context of use. Over the last two decades, anthropologists have been especially adroit in detailing how foods and medicines overlap. This is significant on at least two levels. First we recognize that the use of plants in more than one context extends the range across which people are exposed to active constituents. Second, we begin to appreciate how very complex human–environment interactions are. For the latter it signifies that foods tend to be prepared in ways that diminish the risk of toxicity, especially cooking, thereby allowing the consumption of otherwise potentially dangerous foods in relatively large volume and at regular intervals. The same plants intended for drug use may be prepared differently – neutralizing pharmacologically active constituents only partially or not at all – and are consumed in small quantities, allowing the action of toxin against pathogen or symptom without overwhelming the human host.

Hausa people of northern Nigeria are a case in point that food plants overlap conspicuously with medicines. Ninety-six per cent of the 119 plants that one Hausa village identify as foods number as well among the 374 plants that make up the local pharmacopoeia. Hausa clearly distinguish foods from medicines by parts used, preparation, and, especially, intended outcome (nutritive or preventive/therapeutic). Further, Hausa have much more to say regarding the healthful qualities of a medicine compared to a food. While medicines address specific symptoms, dislodge phlegm, expel spirits, and so on, foods simply strengthen, fortify blood, or promote growth. Extending overlapping use beyond foods and medicines reveals that all of the 20 plants used cosmetically have medicinal uses, five are foods as well; of the 16 plants used in personal hygiene, all are used as medicines, six are foods, and three are cosmetics. The point, again, is that attention to the different contexts of plant use accounts most fully for the range of people's exposure to the drug-like actions of botanicals.

An interesting question is raised in the rank ordering of use: medicine first or food first? These are not, of course, mutually exclusive positions; pharmacopoeias and cuisines are created in increments, not all at once, so that one pattern or another may apply for a given plant. A sizeable number of plants used today as food were first appreciated for their medicinal qualities. Throughout the Andes and Mesoamerica the ritual and medicinal uses of red amaranth pigments were once more common than the use of these plants as a source of food grain. In the Mediterranean and Near East licorice was domesticated for medicinal use (it has estrogenic and antimicrobial activities), as were a variety of other plants that are used today as flavorings. Soybeans and *Mo-er* (black tree fungus) of Chinese cuisines were first cultivated as medicines. The latter demonstrates the kind of antiplatelet activity that might provide protection against atherosclerosis. In light of the especially uncertain distinction between medicine and food in Asian cultures, other plants also are likely to have been cultivated first as medicine. Drawing attention again to Hausa in Nigeria, a significant number of their wild plant foods have been "identified" first as medicines. This is revealed by the inventory of Hausa medicinal plants, which is considerably more inclusive of local flora than lists of Hausa foods and other useful plants; the list of medicines includes all plants from those other categories, whereas the reverse is not the case. Hausa oral tradition further reinforces the primacy of medicinal use over food use for some plants. This perspective cannot be applied wholesale to all societies, since the cultural and environmental circumstances under which pharmacopoeias and cuisines are created involve different patterns of need and knowledge about particular plants. But this does challenge a conventional, unidirectional view that people learn about medicines only secondary to their search for food.

A comprehensive perspective on plant use better characterizes the interconnected histories of human food and medicine, and accommodates both nonfood first and food first models to explain the development of botanical knowledge. Thus, whereas it is customary to talk about the "traditional" medicines and foods of a people, region, or religion, in fact therapeutics and diet are dynamic. Transformations in the content and intent of medicines and diet are shaped in part by shifting concerns with health.

Today, in the West, an analogue to medicinal foods exists in the growing popularity of food supplements. This term is apprehended by the consuming public as a range of products that include conventional supplements (e.g., vitamins) and extend as well to a great diversity of plant and animal products. The popularity of these products bears on several interrelated issues – dissatisfaction with biomedicine and the search for holistic and natural medicines; patients' seeking agency in their own health care; and the commodification of health and healing.

Finally, a timely issue relates the topic of medicinal foods to concern with environmental protection. Contemporary debates on the preservation of global biodiversity have focused on plants that development planners and national polities identify to be at risk. This cross cuts other international efforts directed at alleviating or preventing the effects of famines and lesser food shortages. Collectively these programs highlight staple foods in their efforts to assure that "important" and varied foods are available to the world's peoples, or that other "interesting" plants are preserved for their potential contribution to the pharmaceutical industry of the West. Thus, Western scientific paradigms and various economic and political agendas have been instrumental in shaping the direction of environmental protection and restoration efforts. These programs should be credited with the results achieved to date, as well as with their more recent inclusion of local populations in the planning of sustained efforts. In light of the present discussion of medicinal foods, one might wish to add certain refinements that assure that local cognitive categories and the specific contexts of plant use are given attention, including an examination of what the existing or restored diversity affords in human cultural terms. More specifically, to the extent that the same plants serve dietary and medicinal objectives, their significance to local populations is greater than what development planners might have considered; additional contexts of use elevate the local value of those plants even further.

Medicine and Colonialism in India

RANÈS C. CHAKRAVORTY

Ancient India

The Indian subcontinent was well inhabited by the first millennium BCE. The inhabited territory extended west into areas that today are in Pakistan and Afghanistan. These ancient Indians had a well-developed system of medicine termed Āyurveda (The Science of Life). Ayurvedic physicians practiced medicine and to a lesser extent, surgery. The system and its practitioners were held in high regard and Indian physicians are known to have been in the courts of the Muslim rulers. Some of the Ayurvedic texts were translated into Arabic early in the history of Islam.

The basic thrust of Colonialism is to exploit the colonized for the benefit of the colonizers. Usually after a long period of colonization the two groups come to a situation of better parity. Both these phenomena are well illustrated in the colonization of India.

Muslim Invasion

From the early eighth century, India was invaded by the Muslim kings ruling in the west across the Himalayas. Initially these Muslim pockets were small and often short-lived. By the twelfth century, a Muslim kingdom had been established in Delhi, though the ruler(s) recognized their western center outside India as the capital. By the thirteenth century Muslim occupation in India had become permanent, and ultimately the Muslim rulers assimilated into the Indian culture. The Turk, Babur, established his capital in Delhi in 1526, though it was not until his grandson, Akbar (1556–1605) ruled, that the Mughals considered themselves Indians. The Muslims had brought with them the Islamic system of medicine, Unani or Tibbi, based largely on translations of Greek Medicine. However, Āyurveda was also in use, not only in the Hindu population, but also among the Muslims.

With the arrival of the Europeans, European physicians also practiced in India though in small numbers. From the time of Shahjehan, Akbar's grandson, some European physicians are known to have practiced in royal courts. Thus, Niccolo Manucci (1639–1717) was an artilleryman to Shah Jahan's eldest son Dara Shukoh. He later took up the profession of medicine (even though untrained) and practiced both professions (!) in various royal courts. Manucci's memoirs name some other European physicians practicing in India. François Bernier, a Frenchman with a medical degree from Montpellier, served Dara Shukoh and later his brother, the Mughal emperor Aurangzeb (Majumdar et al. 1994).

European Colonization

Portuguese

From the middle of the sixteenth century, European nations turned their eyes eastward for territorial expansion and trade. The Muslims had established themselves in the Middle East from today's Syria southwards to Egypt and across North Africa to the southern half of Spain. Trade with India and further East had become dangerous and expensive. There was also the need to spread Christianity.

The first to arrive in India was the Portuguese Vasco da Gama who landed at Calicut (now Kozhikhode) in southwest India on 20 May 1498. By 1510 the Portuguese had an established presence in Goa on the west coast. Goa remained a Portuguese possession until 1949 when it joined the Republic of India. In the 450 years of its association with Portugal, Goa became a medical center of sorts. It had the oldest European-style hospital and medical school in the East.

The Royal Hospital was started in 1510 and by about 1546 western medicine was being taught. The Hospital was fully supported by the Portuguese rulers and was a showpiece in its time. The continuing rivalry between the Dutch and the Portuguese, however, caused a decline in Goa's prosperity and the Hospital started to decline by the mid-seventeenth century. In order to have a cadre of assistant physicians, non-Portuguese natives were taught the rudiments of medicine.

Some Portuguese physicians and apothecaries traveled to Goa and some even stayed behind. The most prominent among them was Garcia d'Orta. A converted Jew, Garcia d'Orta was born to Jewish parents who had been expelled from Spain in 1492. They were converted to Catholicism but were always looked down upon. D'Orta studied medicine in Spanish universities and returned to Portugal in 1523. He then joined the faculty at the medical school in Lisbon. In 1534 he left for Goa with his friend, who was to become the Governor-General of Goa and the Portuguese territories in India.

D'Orta became a very successful practitioner, not only for the rich Portuguese in Goa, but also for the rulers of neighboring Hindu and Muslim kingdoms. (Other Portuguese physicians also became court physicians and many rich Indians came to Goa for treatment.) D'Orta is remembered today for his book *Coloquios dos Simples e Drogas da India* – an Indian materia medica, which was published in 1563, in the first printing press in India. The book gained great renown and was very popular in Europe. D'Orta died in 1568, probably quite poor as the Catholic hierarchy had turned against him. His bones were burnt at an auto-da-fe in the cathedral in Goa some years after his death. D'Orta remains the first author of a western-style medical book from India.

A woman medical doctor, Dona Juliana, came to Goa and later on moved to the court of the Great Mughal

M

Akbar. Nicolau Manucci, mentioned above, came and practiced in Goa for a short while but was then thrown out by the authorities.

Around 1842 a formal medical school, Escola Medico-Cirurgica de Nova Goa was established in Goa. The number of graduates (strictly limited to Christians) from this school was never very high, though many of them went on to achieve professional distinction in Goa, in India and in the Portuguese territories elsewhere (Pandya 1982). The school was discontinued at the time of Goa's admission to the Republic of India.

Following the Portuguese, the French, the Dutch, and the Danes established trading centers in India. The latter two countries had undistinguished and short stays in India. The French remained in Chandernagore, Pondicherry, Mahe, Yaman, and Karikal, all isolated enclaves until Indian independence in 1947. During this period they had no significant medical establishments either as medical schools or hospitals.

Medicine and Colonialism in India. Fig. 1 The tombstone and epitah (in English and Arabic) of William Hamilton in St. John's church, Kolkata, India (Photograph by author).

British

Starting with small trading posts in the seventeenth century, the British ultimately occupied all of the Indian subcontinent and the history of colonial medicine in India is almost exclusively that of the development of medicine during British rule (1857–1947).

Medical practices under the British will be described in two phases. The first was under the East India Company, the next under the British crown as a part of the Empire.

Phase 1: The East India Company

The East India Company was a profit-making body administered by local administrators in India. In theory the Board of Governors in England were responsible for the supervision with some generally minimal oversight by the British Parliament. Under the Company, fortune making and profiteering were rampant and generally tolerated. Only a very few people were ever brought to justice in the courts or impeached in the Parliament. The entire western-style medical setup was for the British, largely the armed forces; the native population depended upon the indigenous medical systems.

Each ship coming to India had a (naval) surgeon on board.[1] They sometimes deserted (often without punishment when captured), settled as surgeons to the trading settlements on land and not infrequently fought as soldiers in the many and frequent battles between the British, the French (the Carnatic and Mysore Wars),[2] and the native Indians.

While a number of the naval surgeons were of great service to the British, two are of special interest, signifying different aspects of the duties of the navy surgeon. William Hamilton of Dalziel in Scotland is hardly remembered today Fig. 1. However his epitaph (still to be seen in the graveyard of St John's Church in Kolkata, India) states "…his Memory ought to be dear to this Nation for the Credit he gained ye English in curing FERRUKSEER the present king of Indostan… by which he made his own name famous at the court of that great monarch; and without doubt will perpetuate his Memory in Great Britain as well as in all other Nations of Europe." Hamilton was apparently trained as a surgeon and did not have a university degree in medicine. He was attached to the small Company trading post in Calcutta. The Company had been trying to get a *firman* or permit to carry on trading with the local populace under advantageous terms and lowered customs duties. The Company sent a delegation to the Surman Embassy to the court of Farrukhshiyar, the reigning Mughal monarch in Delhi. On arrival at Delhi, the delegation found that Farrukhshiyar was seriously ill with infected lymph nodes in the groin. He had been

[1] The training and career of a naval surgeon of the times are well detailed in *The Adventures of Roderick Random* (1748) by Tobias Smollett (1721–1778) who was himself a physician trained at the University of Aberdeen.

[2] The Carnatic and Mysore Wars were fought in the latter half of the eighteenth century by the British against the Marathas, rulers of Mysore, and the French to establish British power in southern India.

treated by the court (native) physicians unsuccessfully. Hamilton treated the emperor (apparently lancing the boils) which resulted in rapid recovery. The emperor also had an anal fistula that Hamilton successfully treated.

The grateful monarch issued a firman in favor of the British, munificently rewarded the young surgeon, and wanted him permanently in his employ. Hamilton died soon thereafter and was buried in the Company cemetery in Fort William, Calcutta (Wilson 1911).

John Zephania Holwell (1711–1798) was quite a different type of physician. Born to well-established parents (his father was a timber merchant in London) Holwell studied in England and Holland and trained as a surgeon in Guy's Hospital, London. He came to India in 1732 and to Calcutta, which had the most important British factory in India, in 1736.

In 1756 the British settlement in Calcutta was attacked by Siraj-ud-Dowlah, the ruler of Bengal. The Governor left the Fort with all the ladies and most of the men for a safe refuge on the river Ganges. Holwell remained as the governor of the fort, put up a stiff fight, was defeated and captured. He with the 156 other captives was put in a small chamber termed the "Black Hole." Only 23 survived the night (Holwell's description of this event has been seriously criticized. Probably the numbers reported were exaggerated though the confinement did happen. A monument erected by Holwell to recall the event was later removed but can still be seen at the back of St John's Church.)

Holwell became the temporary Governor of Bengal after Robert Clive's return to England and finally returned to England in 1761. He wrote a number of books on his experience, knew a number of languages including Arabic, and was one of the first to study Hindu antiquities.

Phase 2: The British Raj

In 1857, there was a revolt by some of the Indian regiments and Indian rulers against the East India Company. Known variously as the Sepoy Mutiny (by the British) and the First War of Independence (by the Indians) the immediate result of this conflict (which the British won) was the takeover of the Indian territories by the British Government. The Government sent representatives of the Crown (Governor Generals) to rule over the Indian territories.

Even though the Government was mainly geared to British interests, there was some beginning interchange between the Indians (mainly the Hindus) and the British rulers. Calcutta remained the capital and the seat of government (until 1911) so most of the action occurred there (Bala 1991; Arnold 2000).

With the establishment of the Raj, the early British officials were very interested in native customs and learning. In 1776, (Sir) William Jones, a superb linguist, and a Judge of the Calcutta High Court, established the Royal Asiatic Society of Bengal with the support of the Government specifically for oriental studies and research. Both he, Warren Hastings, and other high-ranking officials encouraged the study of the Indian systems, and this helped establish the Calcutta Madrassah for the study of Arabic and Persian and the Sanskrit Colleges of Calcutta and Benares for the study of Arabic (Majumdar et al. 1979).

Because of the lack of practitioners trained in Western medicine, the local British physicians would train their assistants for 1 or 2 years and then certify them as being capable of practicing western medicine independently. In order to increase the number of better-trained medical practitioners and the number of assistants to the European physicians, the Government started a Native Medical Institution in 1824 in Calcutta (and later in Bombay) mainly to produce assistants, dressers, etc. Auxiliary Medical sections were also established at the Sanskrit College in Calcutta where Āyurveda was taught together with some western medicine. (A hospital with 30 beds was started for these students in 1830.) At the Calcutta Madrassah, rudiments of western medicine were taught together with Unani or Tibbi – the Arabic medical system. The western system had a therapeutic armamentarium that was possibly inferior to the native systems. Its nosology (classification of diseases) was different but not much better; the main difference was in the study of human anatomy by dissection and surgery (without anesthesia).

A Bengal Medical Service had been started in 1763 – similar provincial services started in Madras and Bombay. Membership was limited to the British for many years and when Indians started to be admitted to the Indian Medical Service they were usually assistant or subassistant surgeons. Created to serve the needs of the Empire, the IMS had a prime responsibility to the armed forces and military matters; service to civilians was secondary.

Arrangements for the institutionalized treatment of the employees of the East India Company and the soldiers and sailors had existed from the beginning at the three main British centers – Calcutta, Madras, and Bombay. Madras had a hospital since 1664. A hospital for Europeans was started near St John's Church in Calcutta in 1707. In 1768 a General Hospital for other Europeans (including indigents) and visiting European sailors was started in Calcutta. This Presidency General Hospital still exists.

Lord William Bentinck was the Governor-General from 1828 to 1835. He was convinced that education was to be Europeanized. In 1835 the Native Medical Institution and the medical sections of the Sanskrit College and Calcutta Madrassah were abolished. The Bengal Medical College was opened in Calcutta with three British and one Indian faculty (Anon 1935). The

M

Indian, Madhusudan Gupta had been a student (and later a teacher) of the Vaidyaka Sreni or medical section of the Sanskrit College. A remarkable person in all respects, Gupta initiated cadaver dissection in 1836 (Chakravorty 1997) Fig. 2. In 1857, with the establishment of the University of Calcutta, the College changed its name to the Calcutta Medical College. The Madras Medical College also started in 1835. Amongst other achievements, this institution was the first to formally train women in medicine. The Grant Medical College of Bombay was started in 1845.

Women

The first special attention paid to native women by the British physicians followed a law enacted in Britain. From 1805 to 1833 and again from 1868 to 1880, venereally infected prostitutes and soldiers were kept in "lock hospitals." Christian women missionaries from the west played a large role in looking upon native women's health, although the main object was probably conversion to Christianity (Balfour 1929). The first was Clara Swain, who in 1869 established the American Methodist Episcopalian Mission in Bareilly. Here she also trained Indian women in nursing and midwifery. Many women missionaries came from Great Britain, Canada, and the United States to render service to native women and men.

Ida Scudder, an alumna of Cornell University Medical School, opened a medical college and hospital for women in Vellore, Madras Province. In 1945 the college was opened to men also. Today it is the biggest Christian hospital in the world and one of the best-teaching institutions in the country. India was a haven for women medical graduates from the British Isles. They had problems in being accepted in Great Britain but had much better opportunities in India.

Medicine and Colonialism in India. Fig. 2 Painting by Madhusudan Gupta by Mrs. Belnos in the Anatomy Department, Medical College, Kolkata, India (Photograph by author).

A specialized case was that of Lady Dufferin's Fund (Lal 1994). Initiated by the wife of the Viceroy, Lord Dufferin, this organization collected donations to start hospitals for women and train nurses and midwives. Though always short of funds, the Fund played a significant role in women's health care. It also helped establish the Lady Hardinge Medical College for Women in Delhi in 1916.

As in all other countries, women had difficulty in receiving formal education in medicine. Among the first woman physicians of India was the English woman (Dame), Mary Scharlieb who was the wife of a prominent lawyer of Madras. Her husband's family was well known to the Governor and the Superintendent of the General Hospital in Madras. She first took courses in midwifery but later with three other Anglo-Indian ladies was allowed to attend classes and sit for the final Licentiate examination in 1878. Of her colleagues, Dora White became a physician to the Nizam's Government in Hyderabad and D'Abreu (who had come to Madras as she had not obtained admission in Calcutta) became a medical missionary. She later returned to England and became very well known as a physician.

The first Indian woman to graduate was Kadambini (Basu) Ganguli (1861–1923). She was the first woman to get the Bachelor's degree at Calcutta University (together with Bidhumukhi Bose). She obtained her licentiate from Calcutta University in 1886. Later she went to Great Britain and obtained degrees from Glasgow and Edinburgh. She was a very successful practitioner of medicine, obstetrics and gynecology, and surgery.

Anand(a)ibai Joshi of Pune graduated from the Women's Medical College of Pennsylvania in 1886. She returned to practice in India in charge of the Female Ward of the Civil Hospital in Kolhapur, Maharastra, but died of tuberculosis soon thereafter.

Diseases, Public Health, and Research

India has its own spectrum of diseases, many of which were unknown to westerners. I will discuss only three of the most devastating.

Malaria had been a devastating disease in India and the countries around the Mediterranean for centuries. Because of the lethality of malarial fever, the British Indian authorities had established a Fever Commission (of which Madhusudan Gupta – see above) was a member. Later "Burdwan fever" – a malignant febrile illness, generated a great deal of discussion, without any effective resolution of its nature and treatment. The use of Jesuit's Bark, Cinchona (quinine), was known and in fact had been used by Ayurvedic physicians since 1860. However it was not until Ronald Ross (1857–1932) working in the Presidency General Hospital in Calcutta established the life cycle of the malarial parasite in the mosquito that the disease was finally understood. Born in India and educated in England, Ross joined the Indian Medical Service in 1881. He was awarded the Nobel Prize in 1902. He left India for England in 1901 and died there in 1932.

In 1859, the prevalence of infectious diseases and a high mortality amongst Europeans in India had resulted in the formation of a Royal Sanitary Commission with Dr John Snow (who had written the book *On the Mode of Communication of Cholera* in 1855) as its chairman. In 1863 a Commission was setup to inquire into the Cholera Epidemic of 1861 in Northern India. With Robert Koch's identification of the causative organism in the water of a reservoir in Calcutta in 1884, the possibility of controlling cholera through sanitary measures became practicable. (Koch became a Nobel Laureate in 1905.)

Smallpox had been a devastating disease all across the world for centuries. Variolation – the introduction of live smallpox from a patient to a healthy person by scarification had been used for immunization for centuries. The Indian Medical Service accepted and used this method till the discovery of vaccination (the introduction of cow pox by scarification) by Edward Jenner (1749–1823) in 1796. Both variolation and vaccination were used in India for immunization for a while until the Smallpox Commission in 1850 stated that the latter was superior and safer than the former.

Research

Though Ronald Ross was the physician to get the highest accolades, the members of the Indian Medical Service carried on investigations into common local diseases. In later years some Indians (outside the IMS) also became well known for their research findings. Thus Sir U. N. Brahmachari discovered the cure for Kala-Azar (Leishmaniasis), and Sir K. N. Das was a pioneer obstetrician who wrote a classic text on the discovery, development, and use of the obstetric forceps.

In the 190 years of British occupation of India, the relationship between the colonizer and the colonized had equalized considerably. In 1887, Dr R. G. Kar and colleagues started the Carmichael Medical College as the first non-Government Medical College in the country. Today the R. G. Kar Medical College is one of the prime teaching and research institutions in the country. In the earlier half of the twentieth century, the medical programs in the country were more and more in the hands of the Indians, though postgraduate education abroad, especially in the British Isles was almost mandated for a teaching position and even for successful private practice. Indian physicians today occupy many prestigious chairs outside India, especially in English-speaking countries. This is one of the legacies of colonial medicine in India.

M

Medicine and Colonialism in Sri Lanka

Soma Hewa

It is generally accepted that Western medicine introduced by European colonizers and missionaries saved millions of lives in Africa, Asia, and the Americas (Comaroff and Comaroff, 1992). In this context, Western medicine represented a higher civilization and social order that lifted people to modern ways of life. David Livingstone, known for his religious zealotry, chose a medical career to heal the suffering of Africans: "In the glow of love which Christianity inspires, I soon resolved to devote my life to the alleviation of human misery… and therefore set myself to obtain a medical education, in order to be qualified for that enterprise" (Livingstone 1858; Moffat

[3] A number of publications in Bengali have significant information on this subject. They have not been mentioned here.

1969). Medical missionaries believed that the eradication of fatal diseases among the indigenous people would encourage the "heathens" to embrace Christianity. Commenting on the effort to establish a public health department in India by the British colonial government in the mid-nineteenth century, Florence Nightingale observed that "it was not only a noble task but also a part of a mission to bring a higher civilization into India" (Cook 1914). Even though Western medicine was regarded as an integral part of culture, medical services were rarely extended to the masses without reservations.

Several studies have argued that medicine and medical services in the colonies evolved in response to political and economic needs of Western imperialism. They suggest that medicine played a critical role in the expansion of imperialism in the late nineteenth and early twentieth centuries (Headrick 1981; Arnold 1988). Medicine, as it was introduced to non-Western societies by imperial forces, was an instrument of political, economic, and cultural domination. With the expansion of European colonialism in Asia, Africa, and Latin America, the threat of "tropical disease" became a major obstacle to colonial rule. New medical sciences were developed to deal with diseases such as cholera, malaria, dysentery, and yellow fever for the protection of the European troops and administrators from diseases originating in the indigenous communities (Kavadi 1999). Radhika Ramasubban, who has done an extensive analysis of the origin and the development of Western medicine in British India, suggests that the main concern of British colonial policy was to protect the health of the British army and the European civilian population living in India. As a result, colonial medical policy in India created medical "enclaves," leading to the exclusion of local populations. Such policies were justified by the colonial administrators who contended that the Indians were "superstitious and backward," and would not accept modern medicine even if it were offered (Ramasubban 1988).

In the larger context of colonial rule, medicine and medical services were important political and psychological tools that bolstered the colonial grip over local populations.

1. It became clear that the health of the European personnel, particularly members of the military, could not be protected by measures directed at them alone when there were epidemic diseases among the native populations (Worboys 1988; Turshen 1984).
2. The increased trade and political interactions with the colonies led to a heavy traffic of people and materials across the continents. As a result, the increased vulnerability of Europe itself to epidemic diseases stemming from the tropics became a matter of concern (May 1958).
3. The supply of raw materials for the industries in Europe and North America were dependent upon the productivity of the colonial labor force. Therefore, to sustain the capitalist economic development in the West it was necessary to improve the productivity of the people in the colonies (Emmanuel 1982).
4. The expansion of the market and future investments by the industrialized countries in these colonies were dependent upon the receptiveness of the masses to Western cultural and social values. Hence, the ability of Western medicine to eradicate diseases in these societies would "reduce the cultural autonomy of the agrarian people and make them amenable" to Western values and life-styles (Brown 1976).

Against the background of these recent interpretations of the role of medicine in colonial rule, we examine the impact of British colonial economic policies on the health of the colonial labor force in the plantation sector of Sri Lanka (formerly known as Ceylon) as a case study. The laissez-faire policy of the colonial government enabled the British planters to ignore even the most basic sanitary requirements such as latrines on the plantations in order to maximize profit. As a result, the plantations became breeding grounds for many parasitic and infectious diseases found on the island during the late nineteenth and early twentieth centuries. When the International Health Board (hereafter IHB) of the Rockefeller Foundation arrived in Sri Lanka in 1916 to set up a hookworm control campaign, there was an epidemic of hookworm infection on the plantations and the neighboring villages.

Historical Background

The British captured the Kandyan Kingdom of Sri Lanka in 1815, slaughtering thousands of natives and destroying scores of villages (Marshall 1846). Dr. Henry Marshall, a senior medical officer of the 89th Regiment that led the war against the Kandyan Kingdom, wrote that "the incursions of our troops into the Kandyan territory... were calculated to fill the population with the most unfavorable opinions of our justice and humanity, and to confirm the worst prejudices against the European race." As Marshall predicted, the bitterness of the war persisted among the Kandyan Sinhalese for a long time. When the British established plantation industries in central Sri Lanka during the mid-nineteenth century, the Kandyans refused to work on the estates. To fill this deficit, laborers were brought from the southern Indian state of Tamil Nadu for the year-round work in the plantation industry. Unlike in other British colonies, such as Mauritius and the West Indies, where the Indian labor had been employed since the early nineteenth century, the colonial government never directly participated in the recruitment of Indian estate labor for Sri Lanka. The authorities maintained that Sri Lanka was close enough to India to leave such recruitment to private economic enterprises (Kodikara 1965). The estates' agents, or *Kanganies*, recruited the laborers in India. The number of laborers recruited gradually increased with the expansion of the plantation industries: coffee in the years 1841–1880, tea in the years 1890–1910, and rubber in the first two decades of the twentieth century. By the turn of the century, about 100,000 workers and their families arrived annually in Sri Lanka (Heiser 1936; Philips 1955).

According to the contract, the planters provided living and hospital care for the workers (Chattopadhyaya 1979). The workers lived in barrack-like "lines" that were constructed of temporary materials. Each family was given two small rooms and as many as twelve people lived in a 8 × 10 ft room. One of the unhealthiest aspects of the living conditions on the estates was that the lines were not provided with latrines (Rockefeller Archive Center 1914, hereafter RAC). The workers had no choice but to relieve themselves wherever they felt the inclination. As a result, the sanitary conditions on the estates were deplorable (RAC 1914). The lack of government regulations over the affairs of the plantation industry made it easier for the planters to maximize their profit at the expense of the basic needs of their workers. In the extremely poor sanitary conditions on the plantations, immigrant workers and their families faced the threat of a wide range of diseases such as hookworm infection, malaria, smallpox, and cholera, which often became epidemics in many parts of the country. S. V. Balasingham, a Sri Lankan historian, describes the desperate conditions of the immigrant workers as follows: "The spread of epidemics, like cholera and smallpox in certain years in Ceylon has been traced to these immigrants and epidemics of either disease are reported to have carried away large numbers of the immigrants themselves.... There were reports in the Ceylon Times of starvation among these laborers and sale of children owing to the impossibility of maintaining them on the low wages of 6d a day" (Balasingham 1968).

The Prevalence of Hookworm Disease

Hookworms are tiny, slender parasites from one-half to three-quarters of an inch in length. Although parasitic in the bowel, the worm does not gain entrance through the mouth but through the pores of the skin when it comes in contact with polluted soil. The hookworm infection causes under-nutrition, anemia, and lassitude. The victims of hookworm infection sometimes die because the worms literally suck away the blood necessary for life. Usually, however, death occurs because—drained of blood—the sufferers are too weak to resist new infections (Cort 1921).

The hookworm infection (anchylostomiasis) first appeared in the administration report of the Principal Civil Medical Officer (hereafter PCMO) of Sri Lanka in 1888, when 31 cases were diagnosed at General Hospitals in Colombo, Badulla, and Kurunegala (Sri Lanka National Archive 1888, hereafter SLNA). This number increased rapidly, and by 1899 about 239 deaths from anchylostomiasis had been reported in the island. According to Allan Perry, PCMO, over 80% of the reported cases were immigrant workers, and the rest were people living in the neighboring villages of the plantation areas. "The greatest number of cases occurring in the planting districts... Yet other provinces show some cases, notably the Northern, which returned 57 cases for the year" (SLNA 1899). Although, the authorities were fully aware of the cause of the spread of the disease, they were reluctant to interfere with the private economic decisions of the planters (SLNA 1916). Consequently, by 1916 the hookworm infection had reached epidemic proportions; more than 90% of the population in the plantation districts was infected with the disease. Although the main cause of the spread of disease was the poor sanitary conditions in the plantation areas, the economic interest of the planters took precedence over the health of their workers (RAC 1914). Even though a large number of the immigrant laborers arriving in Sri Lanka each year seldom lived more than "a couple of monsoons," the planters were not concerned with the high death toll. According to K. M. de Silva, in the years 1841– 848, about 70,000 (10,000 per year) or 25% of the immigrant workers died of various causes. These figures, according to de Silva, had been published by *The Colombo Observer*, a leading newspaper of the day, which argued that the death toll in Sri Lanka was much higher than that of Mauritius, where Indian laborers received relatively better treatment (de Silva 1965). Particularly, with the proximity of Sri Lanka to South India and the large reserve of cheap labor there, the planters never felt any economic urgency to take the hookworm epidemic seriously. Moreover, the Kanganies who recruited laborers for the estates were always willing to bring as many laborers as the planters required. According some observers, "Kanganies" who recruited laborers in India acted as leaders of each gang of up to one hundred workers. In addition to their salaries for working as supervisors, the Kanganies received 2 cents per day from each laborer's wage under their supervision. Further, they received a bonus when their workers turned up, and therefore they made every attempt to bring as many workers as possible to the plantations (Chattopadhyaya 1979).

M

Philanthropic Medicine

The Rockefeller Foundation initiated the hookworm control campaign in the early 1900s, when the disease was a major health problem in the southern United States (Fosdick 1952). The public health program was started in the South for the purpose of integrating its

[a]Population figures for the Island and the Plantations are based on the 1900, 1911, and 1921 census. Department of Census and Statistics. *Census Data, Ceylon Year Book*, Colombo 1970; Rockefeller Archive Center, *Ceylon Population*, 4, 1914, Record Group 5, Series 2, Box 47; Sri Lanka National Archive, *Ceylon Administration Reports, Vital Statistics: Report of the Registrar General of Ceylon* (1900–1922).

agricultural territory into the more stable, industrial economy controlled by the capitalists in the North. John D. Rockefeller Sr. and his close advisors believed that the disease, illiteracy, and unemployment in the South were not only causing political and civil unrest, but also contributing to the sluggish economy. By improving the health and education of the whole population, beyond racial boundaries, the Rockefeller Foundation expected to expand its industrial and commercial base in the South (Brown 1979).

The political and economic interests of the Rockefeller philanthropists were certainly not limited to the United States. They clearly recognized the interrelationship between their own personal economic interests and those of the capitalist class and the global economy in general. Consequently, with the experience of controlling hookworm infection in the South, the International Health Board of the Rockefeller Foundation (hereafter the IHB) willingly extended its capital to other countries, particularly to the British Empire. Frederick T. Gates, who was one of the architects of the Rockefeller philanthropies, wrote to John D. Rockefeller Sr. in 1905 stating that the hookworm control campaign was one of the “special programs that has direct physical and economic benefits, and a means of creating and promoting influences” (Brown 1976). The “concept” of health, for the Rockefeller philanthropists, was clearly an economic term embedded in the capitalistic pursuit of global economic and political domination. They had the foresight to understand that disease has no geographical or cultural boundaries. In relation to the hookworm control program in Sri Lanka, Dr. Victor Heiser, the director of the public health program of the IHB in the East, maintained that “disease never stays at home in its natural breeding place of filth, but is ever and again breaking into the precincts of its more cleanly neighbors.... It should also have been evident to employers of colonial labor that human life had a direct monetary value... even though it might vary greatly with age and race” (Heiser 1936). The Rockefeller philanthropists believed that if health could be achieved in the British colonies, which included the largest share of the global market, Western industrial capitalists could not only expand their trade to those countries, but also influence the national political affairs of those nations. In this context, they expected that medicine would help unify and integrate the emerging industrial economies and their social and cultural values with those of less developed agrarian societies and legitimize capitalist activities by diverting attention from structural and other environmental causes of disease (Brown 1976).

When the IHB began the hookworm control campaign in Sri Lanka in 1916, the United States was already an emerging superpower with an established military presence in the East. Following the Spanish-American war in 1898, the United States was in control of the Philippine Islands (Wolff 1961). While the U.S. Army Board of Health was responsible for the overall public health activities of the islands, the Rockefeller Sanitary Commission was engaged in some philanthropic work in the field of tropical sanitation. Sri Lanka was a special interest case for the IHB in the East for specific reasons pertaining to the long-term objectives of the Rockefeller Foundation. Wickliffe Rose, the director of the IHB, pointed out that Sri Lanka was a key location in Asia where a successful public health program could attract a great deal of interest in the whole region (RAC 1915). Among some of the specific reasons that he indicated for the choice of Sri Lanka were:

1. The government offered a favorable administrative framework,
2. The agricultural industry provided an effective economic medium,
3. The island delimited a large, but discrete, area,
4. The geographic location of Sri Lanka in the East might tend to help spread the new knowledge and its benefits (Philips 1955).

By implementing a hookworm control program for a selected group of people in the country, the IHB expected to achieve high visibility and recognition in the international community. Furthermore, by eradicating hookworm infection among the workers in the plantation industry the Health Board believed that it could help increase productivity (Brown 1976). In his speech to the Planters' Association in Kandy on May 12 1916, Dr. Howard, a project advisor of the hookworm control campaign in Sri Lanka, specifically mentioned the economic benefits of the hookworm campaign: "it is of immense importance to the planters and estate owners since their profit must be dependent upon the efficiency of the labor with which they operate. Further, not only would the efficiency rate of the treated laborers increase by 20–40%, but also they were less likely to return to India necessitating the importation of others to replace them" (RAC 1916).

The cultural and political aspects of the location of Sri Lanka were equally important for the Rockefeller Foundation. Sri Lanka, as the center of Theravada Buddhism in the East, was identified as an important cultural "laboratory" for a public health campaign of Western medicine, the success of which could be used by the Rockefeller Foundation as an example to highlight the benefits of Western culture (Jayawardena 1988).

Organization of the Project

The project was begun in 1916 under the direction of an American doctor, John E. Snodgrass, who reported both to the IHB of the Rockefeller Foundation and to the PCMO of Sri Lanka. All the other subordinate staff working in the project was selected locally. The immediate objectives of the project were outlined as follows:

1. To reduce the cost of annual recruitment of new workers by reducing morbidity and mortality
2. To cut down hospital expenses by reducing the rate of hospital occupancy
3. To increase the rate of fertility among female workers and to produce a native-born permanent labor force by treating anemia and
4. To increase daily productivity by reducing the number of sick workers (RAC 1916).

By the end of 1922 over 600,000 people had been treated. The rate of infection dropped dramatically, and hookworm related deaths in the island declined to their lowest level of 415 per million persons in 12 years. The reduced hospitalization among workers showed the planters the economic benefits of the campaign. Annual reports emphasized the increased productivity and the reduced absenteeism. "There have been indications that the health of many has improved since the treatment. There has been an increased capacity for work" (RAC 1918). Reports were carefully worded to avoid any misunderstanding that could jeopardize the confidence in Western medicine or the work of the Rockefeller Foundation. For example, in the case of death following treatment, the locally recruited dispensers were accused. "Careless administration of treatment... may have caused one or two deaths in the hookworm campaign. There were mistakes and instances of irresponsibility on the part of some of the local staff, but all known emergencies were met by the doctors with an almost perfect record of medical success" (RAC 1917). American doctors working in the field often interviewed plantation management to get their reaction to the increased productivity as a result of the treatment. One planter reported that "the whole labor force is healthier... there has been very little sickness lately and... one outcome of the treatment is the pending heavy increase in the birth rate. My coolies on the whole have great faith in the treatment" (RAC 1918).

The increased productivity immediately after the treatment created a great deal of enthusiasm among planters as well as the Rockefeller field doctors. Almost every communiqué from the field doctors to the IHB officials clearly emphasized the fact that the laborers were healthier and working hard. But this enthusiasm was not translated into fundamental sanitary reforms on the plantations. Although the field doctors insisted upon the establishment of latrines in workers' lines, it was beyond their power to impose such orders on planters. With the experience of reinfection under poor sanitary conditions in other countries, the field doctors made a number of appeals to the Planters' Association

Medicine and Colonialism in Sri Lanka. Table 2 Persons Examined and Treated for Hookworm Disease by the International Health Board, Sri Lanka, 1916–1922

Year	Persons Examined[a]	Percentage Found Infected[a]	Persons Treated[b]	Percentage Cured[b]
1916	7,645	96.3	6,752	82.5
1917	42,828	97.2	35,675	82.5
1918	26,424	97.0	50,374	88.9
1919	15,542	77.5	88,602	77.9
1920	16,961	75.5	126,529	76.2
1921	497	84.9	117,209	n/a
1922	7,137	83.7	262,545	n/a

and colonial government for constructing latrines in the workers' lines. They recommended the following steps for permanent control of hookworm infection on the plantation:

1. The construction and improvement of latrines and line compounds in order to meet basic sanitary requirements,
2. The mass treatment of all employed laborers annually until the re-infection declined to a negligible level,
3. The establishment of quarantine camps in South India, where the plantation workers originated, to treat them before leaving for Sri Lanka (RAC 1925).

The Rockefeller Foundation's hookworm control campaign on the plantation began with the understanding that the planters would take the appropriate measures to improve the sanitary conditions on the estates. However, these preventive measures required some spending which the planters did not want to undertake. As a result, the rate of reinfection continued to increase in the plantation areas. In one district alone (Matale), a year after the workers had been cured, the rate of re-infection was 88% among a total of 3,000 persons examined (RAC 1920a). The field doctors reluctantly admitted that the planters were unwilling to improve sanitary conditions, though they were happy to see that the laborers were being treated. In their annual reports, they recommended sanitary reforms as a fundamental requirement for the prevention of the disease. However, these cogent recommendations of the field doctors were not matched by sufficient will on the part of the IHB officials, whose mandate it was to negotiate with the government and planters. For political reasons financial contributions were approved so long as good will continued to prevail between these parties. For instance, in recommending $5,000 for a plantation company to provide treatment for their laborers, Dr. Jacocks, a senior representative of the IHB in Sri Lanka, wrote to the New York office, "I asked Dr. Rutherford [PCMO] for his opinion as to whether the granting of such a contribution by the Board at Government's request would help to "heal the break" [original emphasis] between Government and the planters. He said that he thought it would, as it should be evident to planters that the aid could not have been granted without Government consent. He thought further that a more kindly reciprocal feeling between planters and Government would follow" (RAC 1920b). Perhaps even in a more crucial ideological sense, presented with the choice of pressing for fundamental sanitary development or continuing medical treatments, the IHB officials consistently authorized the latter, which it favored due to its bias towards curative medicine. Instructing on how to spend the $5,000 grant, Dr. Jacocks stated, "this sum to be used for post treatment as well as first treatment" (RAC 1920b). Despite the apparent failure of the hookworm control campaign on the plantations, the IHB felt it had achieved its goal by demonstrating the relationship between the treatment for hookworm disease and increased productivity. Therefore, in 1922, the IHB decided to close its program on the plantations (Hewa 1995).

While medicine and medical services were developed to overcome the threat of tropical diseases, these medical services were not extended to the people of the colonies until it was realized that the repeated outbreak of epidemics in the colonies would not spare the European troops and administrators. Moreover, the diseases in the colonies eventually found their way to Europe through trade. For example, the spread of cholera from India to Europe between the period of 1816 and 1880s was a major concern that directly influenced the scientific research of John Snow, Louis Pasteur and Robert Koch (May 1958). While the health of the Europeans was always the first priority of colonial policy, the health of the indigenous people, as long as it did not threaten the economic and political interests of the empire, was ignored. Indian labor was exploited extensively for the expansion of the empire in

Asia, Africa and the Pacific in the same manner as African slavery was used to build the colonial economy in America and the Caribbean.

As shown, the hookworm epidemic in Sri Lanka was the result of a colonial labor policy which compromised the basic sanitary requirements of the workers for the purpose of maximizing profit. Although there was nothing inherently evil in the medical services provided by the IHB in Sri Lanka, or anywhere else for that matter, the predominant interests of the IHB–as epitomized by its partiality for curative medicine - effectively precluded the success of their campaign to cure disease at their source. This curative bias of the IHB official changed overtime as they continued to work in Sri Lanka. This was evident in the subsequent Health Unit Program (Hewa 2005) begun in the late 1920s that became the foundation of the primary care system developed in the last 75 years in Sri Lanka.

Medicine of Tibet

Robert William Prasaad Steiner,
Yangbum Gyal

How can we understand the practical applications of healthcare systems from different cultures? This chapter about the theory and practice of traditional Tibetan medicine (TTM) attempts to point to possible answers to that question.

Traditional Tibetan medicine approaches health from the perspectives of balance, synergy and integration of multi-dimensional aggregates that span body and mind, simultaneously and without distinction. The emphasis of TTM involves dealing directly with the nature of imbalances among the aggregates that result in the appearance of signs and symptoms of disease and illness. The approach includes dealing with issues of mind – including conflicting emotions and mental afflictions – as well as dealing with the external influences that adversely affect a person's specific constitution and condition. TTM avoids the schism of mind and body that is so prevalent in western medical care.

His Holiness Dalai Lama XIV offered a statement about the utility of TTM at the First International Congress of Tibetan Medicine in 1998 (Dalai Lama 1999):

> As an integrated system of health care, Tibetan medicine can offer allopathic medicine a different perspective on health. However, like other scientific systems, it must be understood in its own terms, as well as in the context of objective investigation. In practice it can also offer Western people another approach to achieving happiness through health and balance.

Dalai Lama states a position of cultural relativism – that opportunities are present to study culturally different traditions of healthcare that may benefit people in western cultures. This is possible if the native culture is understood and examined from its own premises, rather than maintaining an ethnocentric position. His Holiness also points to a priority of TTM – a primary goal of healthcare is to attain happiness. This goal is often not considered in western biomedical traditions of healthcare, where there is more emphasis on materialistic aspects of technologic interventions to overcome disease.

The notion of disease can be viewed as a culturally bound concept – one that depends upon assumptions, motivations, and selective attention of the people in that tradition. Disease is a reified concept, based upon meaning and interpretations assigned to patterns of the subjective symptoms and experiences of illness and concurrent objective symptoms (Kleinman 1981). One intention of this chapter is to examine the premises underlying the theory and practice of TTM, so that the engrained approaches of western biomedicine may become more accessible, understandable, and meaningful by comparison and contrast (Leslie and Young 1992).

Anatomy and Physiology in Tibetan Medicine: Aggregates and Elements

Maintaining balance among the three aspects of bodily constituents (Tibetan: *Nyipa sum*) is the goal of Tibetan medicine (Dhonden 1977, 1986, 2000). The three aggregates are complexes of mind-body that include physical, personality, and spiritual aspects. The three aggregates are *rlüng*, *mKhris-pa*, and *Bad-kan*, often collectively translated as "humors" and translated as "wind," "bile," and "phlegm". However, these terms do not accurately portray the unified and multi-dimensional nature of these aspects. Alternatively, the terms "rlüng, mKhris-pa, and Bad-kan" can be translated as "subtle energy, transforming energy, and supportive energy." These alternative terms convey the qualities of functional interactions that are prominent within Tibetan medicine. The term "aggregates" will be used in the remainder of this chapter, in place of the more common translation as "humor."

The aggregates of TTM are composed of elements. The elements that comprise the ordinary physical body in TTM are translated as space, air, fire, water, and earth (*nam mkha*, *rlüng*, *me*, *chu*, and *sa*). The five sensory consciousnesses (hearing, touch, sight, taste, and smell) each correspond to the same respective elements. Thus, each element is a metaphor, or "sphere of influence" (Porkert 1974), representing the many dimensions of life experiences. For example, space represents formless potentiality (e.g., consciousness) and air is associated with subtle movements (e.g., conduction of impulses in the nervous system, circulation, respiration, or intuition). Fire represents active transformation (e.g., digestion of food into nutrients or intellectual discourse), while water represents cohesion and communication (e.g., empathy, lubrication, or feelings), and earth is manifest form (e.g., anatomic structure or physical sensations). Each element is

Medicine of Tibet. Table 1 Five elements and their cellular, tissue, and physiological functions

Elements	Physiological functions
Earth	Muscle tissues, bones, nose, and sense of smell
Water	Blood, body fluids, tongue, and sense of taste
Fire	Body temperature, complexion, eyes, and sense of sight
Air	Respiration, skin, and sense of touch
Space	Body cavities, ears, and sense of hearing

Medicine of Tibet. Table 2 Relationship between the five elements, aggregates, and three poisons

Element	Three aggregates	Three poisons (mental and spiritual)
Earth and water	Phlegm (Tibetan: Bad-kan)	Delusion, ignorance
Fire	Bile (Tibetan: mKhris-pa)	Aversion, hatred
Air and space	Wind (Tibetan: rlüng)	Attachment, passion

Medicine of Tibet. Table 3 Characteristics and functions of three aggregates

Aggregates	Characteristics	Functions
Wind (Tibetan: rlüng)	Rough, light, cold, subtle, hard, and mobile	Physical and mental activities, respiration, urination, defecation, development and delivery of the fetus, menstruation, spitting, burping, speech, clarity of the sense organs, sustain life by acting as a medium between mind and body
Bile (Tibetan: mKhris-pa)	Oily, sharp, hot, light, fetid, purgative, and fluid	Hunger, thirst, digestion and assimilation, promote bodily heat, gives luster to body complexion, provides courage and determination
Phlegm (Tibetan: Bad-kan)	Oily, cool, heavy, blunt, smooth, firm, and sticky	Firmness of the body, stability of mind, induces sleep, connects bodily joints, generates tolerance, and lubricates the body

associated with a sense organ and sensory perception, emotions, sacred images, and more (Tables 1–3).

The elements combine to form the aggregates that represent a person's constitution (Tibetan: *Rang bZhin*). Space and air together comprise rlüng (Sanskrit: *vata*). Rlüng is traditionally considered the most important aggregate in Tibetan medicine, since movement is so basic to all vital functions. Consequently, rlüng conditions are highly prevalent. Fire is the primary element in mKhris-pa (Sanskrit: *pitta*) constitution, while water and earth combine to form Bad-kan (Sanskrit: *kapha*) (Lad 1984).

Usually one aggregate predominates as a person's constitution. The aggregates can also combine so that primary and secondary aspects are present. For example, primary rlüng and secondary mKhris-pa constitutions (and vice versa) allow for refined behavioral and medicinal prescriptions. When all aggregates are afflicted simultaneously, a condition known as *mug-po* is present. The Tibetan elements differ from the five-phase theory in the traditional Chinese medical model (Porkert 1974).

An example of the explanatory model for aggregates in Tibetan physiology may be useful. When we eat, the nutrients go to the stomach where Bad-kan helps to mix them (lubrication function). Then the mKhris-pa will help to digest them (transformation activity), and the rlüng will help to separate the essential nutrients from the waste products (movement metaphor). The essences of the nutrients eventually form blood, and in a cascade of events, the essence of blood forms muscle tissue, the essence of muscle tissue forms fat, the essence of fat forms bones, the essence of bones forms marrow, and the essence of bone marrow forms the regenerative fluids. The qualities of the regenerative fluids are responsible for the radiant glow of good health (Sanskrit: *ojas*). When the three aggregates are balanced, then the seven bodily sustainers mentioned above are also balanced.

Functional relations are emphasized more than physical anatomy in Tibetan medicine (Rechung 1976). From the spiritual perspectives of Tibetan Buddhism and in the context of TTM, the organs, their functions, and elements are each related to a particular wisdom portrayed in sacred iconography (Lauf 1976: 117–137). Each bodily structure is also associated with meditational deities and sacred sounds (*mantra*). Each element and aggregate is related to aspects of mind, sensory perceptions and emotions and modes of cognition. Body and mind, mundane, and spiritual are fused within Tibetan medicine. Thus, health and disease are multi-dimensional, including spiritual dimensions.

Clinical Diagnosis in Tibetan Medicine

A Tibetan physician employs his own senses to examine the patient's general balance of health. There are three main methods of diagnostic examinations in Tibetan medicine: questioning, observation, and palpation. Interactive and subjective clinical assessments are the essence of the diagnostic method. Objective technologies for clinical diagnosis are practically non-existent in TTM. There are modern clinical survey instruments to assess Ayurvedic constitution (Sachs and Rapgay 1995; Chopra 1991), but no psychometric studies are readily available to validate their clinical utility.

Diagnosis by Questioning

Questioning is based on a series of 29 items that help to identify the nature of the imbalance in constitution and condition (Clark 1995). Questioning is analogous to taking a clinical history in western medicine, whereby signs, symptoms, patient perceptions, and meanings are elicited. For example, the cause of disease may lie in consumption of unwholesome foods or improper behaviors. Asking about specific signs and symptoms assists the physician in understanding the imbalances among the three aggregates. (Finckh 1988) When assessing constitution and condition, the qualities that the patient exhibits in responding to the questions are as important as the content of the answers.

Diagnosis by Observation: Urine and Tongue Diagnosis

The urine is examined to assess constitution, condition, and response to treatments. For constitutional assessments, the patient is instructed to refrain from eating spicy foods, drinking alcohol, performing unusual strenuous activity, and having sexual intercourse on the day before the examination. The physician examines the first early morning urine sample by stirring it in a small bowl with a clean stick and then examining the color, vapor, odor, bubbles, sediments, and scum.

The color of urine is determined by the intake of food and drink, seasons, diseases, and imbalances. In general, a reddish color with a small volume of urine indicates a hot disorder, while whitish clear urine with a large volume indicates a cold disorder. For the patient with rlüng, the urine is clear like water and it has many big bubbles that may last only a short time. The urine from a person with mKhris-pa constitution is a reddish-yellow color, with a very strong odor, and moderate-scant volume. The Bad-kan patient has urine that is clear in color, with little odor, large volume, and small bubbles that often last a long time. Repeat urine analyses are used to gauge the accuracy of diagnosis, the efficacy of the treatment and as a guide to refining the treatment.

The Tibetan doctor may view the patient's tongue to provide additional clinical information. For example, the rlüng patient will probably have a red, dry, and rough tongue. The patient with mKhris-pa constitution will likely have a tongue with a thick yellow coating. The tongue of a Bad-kan patient is white, smooth, and wet. Tongue and pulse diagnosis may also prompt additional questioning to support or reject clinical assessments.

Diagnosis by Palpation: Pulse Diagnosis

Examination by touching includes palpation of the body parts to assess temperature, areas of tenderness, tightness, weakness, or abnormal growths. Pulse diagnosis is a key method for assessment (Dhonden 1986; Dhonden and Topgay 1980; Finckh 1978; Steiner 1987–1989). The physician interprets the waveforms of the patients' radial arteries to assess ongoing physiologic processes and relationships between body parts and aggregates. Patients are instructed not to engage in sexual intercourse on the day prior to the pulse reading, not to consume alcohol, eat excessively, or engage in strenuous activities. These recommendations are intended to normalize the three aggregates by minimizing extraordinary external influences. The assessments of constitutional pulses are typically performed during the early morning, while the patient's stomach is empty.

The physician palpates the radial pulses on both wrists, while the patient is in a comfortable and quiet environment (Fig. 1). The left hand is slightly flexed, so that the wrist creases are clearly visible. A special pillow may be used to rest the wrists during this part of the examination. The doctor places the fingers of his right hand on the left radial pulse of the patient, so that the right index finger is proximal to the wrist crease, at a distance about as wide as the patient's distal thumb. The second and third fingers then fall naturally along the artery. The three palpating fingers generally do not touch one another unless the patient is small in stature. The patient's right radial artery pulses are palpated in a similar manner. The physician may examine the pulses on one wrist at a time, or he may examine both wrists simultaneously. The radial pulse is palpated with increasing pressures at each site proximal to the wrist crease.

Medicine of Tibet. Fig. 1 Positions of the physician's fingers for reading the pulses.

Each of the physician's palpating fingers can assess the functional characteristics of specific physiologic systems form the observed and interpreted qualities of the pulses. It is again important to note that although the names for organ systems are used here, these terms are metaphors for the mind-body functions associated with the elements and aggregates. According to the text, the heart and small intestine are assessed at the first position on the male patient's left hand, the spleen/pancreas and stomach with the second palpating finger, and so on. Similarly, the pulses at the first position on the male patient's right radial artery correspond to the lungs and large intestine. Liver and gall bladder pulses are located at the second position, and right kidney and urinary bladder are at the third position.

The pulses of women are reversed at the first position only, so that the heart and small intestine are assessed at the first position on the woman's right hand and the pulse for lungs and large intestine is read on a woman's left radial pulse. The reason for the switch is due to slight differences between genders for the apex of entry for consciousness that enters the heart, although no physical differences in the anatomy of the hearts is present. This is consistent with teachings of Tibetan embryology.

There is a complex system for interpreting the qualities of the pulses at each of the 12 sites on the radial arteries. For example, floating, irregular or intermittent beat qualities may be present in the pulse in the presence of disorders of rlüng. This finding often indicates the presence of pain symptoms that may radiate or have a breaking quality in specific sites indicated by the pulse. Rlüng symptoms have a tendency to change or be fleeting. Protruding and rolling pulses in the proximal sites are often present in early pregnancy, a finding attributed to the excess blood from the fetus (Bad-kan condition). Fast or jumping qualities indicates excess heat (mKhris-pa). Underlying patterns within the pulses can be discerned; this allows the physician to select various medicines in accord with their taste, potency, and site of action (Fig. 2).

Medicine of Tibet. Fig. 2 A Tibetan physician reading the radial pulses.

Constitution Analysis and Treatment Methods

The first priority in Tibetan medicine is to restore harmony to each person in the context of his or her life experiences. Symptoms are a result of an imbalance caused by disturbances in circumstances such as diet, lifestyle, and seasonal and mental conditions. Treatment depends on the total situation rather than the individual symptom; therapy varies with constitution and condition. Two people with the same symptom may be given very different advice and treatment, if constitution and condition differ.

Tibetan medicine provides a systematic approach to treatment and prevention. There are four methods of intervention: diet, behavior modification, medicine, and physical therapies. The three constitutions (rlüng, mKhris-pa, and Bad-kan) each have patterns of symptoms, preferences, and tendencies that can be remedied with categoric therapies. If the illness is not serious, diet and behavioral advice may be sufficient; otherwise, prescriptive medicines may be needed.

However, the best use of medical treatment cannot provide good health through physical means alone; a healthy mind is needed as well (Tai Situ Rimpoche and Terhune 1992: 21). Tibetan medicine gives priority to psychological and spiritual factors in its definition of health. It teaches that we can make peace with the disease once we know and understand it. The literature is rich with specific meditation techniques used to restore balance (Rimpoche 1996; Sachs and Rapgay 1995; Tulku 1979; Thondup 1998; and many others). Each constitution and typical treatments are discussed below.

Constitution and Conditions in Tibetan medicine: rlüng

The physical characteristics of rlüng constitution typically include an asthenic body (lacking strength or vigor), sensitivity to cold, and a talkative and lively personality. Rlüng people are easily aroused from sleep, tend to eat small amounts of food frequently, and work hard but sweat little. They are prone to worry and sorrow. Symptoms of excess rlüng tend to be worse during cold and windy climates, during summer, or during early morning and/or late afternoon. Aging tends to produce imbalances in rlüng, so that these conditions are more common among the elderly.

From the spiritual perspective, egocentric mind is the usual source for imbalances of rlüng. Relational issues about attachment, sometimes translated as passion, essentially characterize people with rlüng constitutions (Sachs and Rapgay 1995). Ego, in this context, is the identifying with the false concept that each person is separate and independent from the world in which we live. In Tibetan medicine and culture, ego is viewed as

M

a limitation to be overcome, rather than a psychological resource to be enhanced. Ego is synonymous with self-clinging habitual patterns of mind, and so it is viewed as an obscuration to the clarity of the self-liberated mind. Ethical motivations and meditative practices with an experienced teacher can be an aid to realizing and dissolving such barriers.

Diagnosis by observation of a person with excess rlüng shows a tongue that is rough and dry (Fig. 3). Pulse diagnosis shows qualities that are irregular, empty, or floating. Urine is clear and has many large or variable size bubbles that last only a short time (Fig. 4). Diagnosis by questioning may reveal symptoms that are worse with ingestion of foods with light or rough potency and symptoms that change quickly over time. Typically, symptoms worsen when the patient is hungry and they may be relieved with foods that are oily, hot, or heavy. Symptoms tend to have a breaking quality, particularly in the bones and joints and in the lower body. Nervous symptoms including anxiety are common in this group.

Medicine of Tibet. Fig. 3 Wind tongue is dry, with a red tip.

Medicine of Tibet. Fig. 4 Wind urine is clear with lots of large bubbles that do not last long.

Patients with excess rlüng are typically instructed to rest – both physically and mentally. Minimizing anxiety and worry is important, since this psychic discord is a basic manifestation of rlüng. They can be advised to stay in comfortable, quiet, dimly lit, warm places. Company with a few close friends is beneficial, as are small amounts of alcoholic drinks. Patients should avoid excessive indulging of strong coffee and black tea, cold or refrigerated food and drinks, smoking, unripe fruits and vegetables, bitter gourd, junk foods, pork, foods and drinks with bitter and astringent tastes. Patients are encouraged to eat sweets, protein and nutritional foods and drinks, oily and warm foods and drinks, warm milk, butter, wine, garlic, caraway, leek, onion, sesame, cauliflower, radish, nuts, pomegranate, strawberry, apple, nutmeg, flax seed, clove, star anise, cabbage, mushroom, mustard, sunflower seed, cinnamon, and soya bean.

Patients with rlüng disorders are asked to pay special attention to regulating their lifestyles (e.g., eating, sleeping, and excretory function), to find time for calm activities and socializing, and to exercise in ways that promote good overall circulation, using techniques such as hatha yoga exercises and pranayama (yogic breathing). External cautery, similar in principal to traditional Chinese or Mongolian moxibustion (the application of burning moxa or other combustible materials at the acupuncture points) may be used to heat the body. Figures 5 and 6 show some typical herbal ingredients used to diminish excessive rlüng.

Constitution and Conditions in Tibetan Medicine: mKhris-pa

People with mKhris-pa constitution may be very ambitious; they tend to be active and may try to control situations physically or through positions of power. They tend to be keen thinkers and may have extraordinary motor skills. Yet control and aggression are sources of suffering for them. Spiritually, people with mKhris-pa constitutions can be characterized by aggressive behaviors sometimes translated either as “hatred” or “aversion.” The attitudes and behavioral characteristics of mKhris-pa also rest upon a false sense of ego-clinging identity, just as was present among those with rlüng. However, the varieties in constitution and condition allow for different manifestations of this basic ignorance.

Patients with mKhris-pa constitutions are typically medium size, muscular, with a yellowish tinge to the skin. They are frequently hungry and/or thirsty, sweat easily, and they like activities and challenges. They are prone to annoyances and anger. Symptoms of excess mKhris-pa tend to be worse during hot and dry climates, during autumn, or during midnight and midday hours. Imbalances in mKhris-pa tend to occur among middle age groups.

Medicine of Tibet. Fig. 5 Clove or Eugenia caryophyllata, an ingredient of Sem-De, a traditional herb medicine to reduce excessive rlüng.

Medicine of Tibet. Fig. 6 Nutmeg or Myristica fragrans, an ingredient of Agar 8, a traditional herb medicine to reduce excessive rlüng.

Diagnosis by observation of a person with excess mKhris-pa shows a tongue that is coated with a thick, yellowish substance (Fig. 7). Pulse diagnosis shows qualities that are fast, strong, and jumping. Urine is yellowish-red, with a strong odor and small bubbles (Fig. 8). Diagnosis by questioning may reveal symptoms that are worse after eating, especially after foods with sharp or hot qualities. Symptoms may include a bitter taste in the mouth, a sense of heat or fever within the body and aches in the middle and upper parts of the body. Ingestion of cool foods may relieve the symptoms.

Therapy for mKhris-pa is directed to foods and medicines that are sweet, bitter and astringent in taste and cool, smooth and blunt in potency. Patients with an imbalance in mKhris-pa should eat beef, vegetables, butter, low fat cheese, cow's yogurt and buttermilk, and drink weak tea or spring water. A simple vegetarian diet is suitable, including legumes, potatoes, artichokes, bitter vegetables (e.g., dandelion), and turnips that may

Medicine of Tibet. Fig. 7 Bile tongue with yellow coating.

be seasoned with cumin, coriander, or fenugreek. Foods that are heating in nature should be avoided, including peanut butter, mustard and hot spices, garlic, ginger, onion, alcohol, grilled meats (esp. lamb), oily and greasy foods, and soups made with bones.

Syrups and powders are traditional types of prescribed Tibetan medicines for mKhris-pa. Purgatives and strong laxatives are used to reduce the excessive amount of heat in the body. Behavior changes include the use of cold baths and showers, sitting in shaded

Medicine of Tibet. Fig. 8 Yellow, foul smelling urine for case with excess mKhris-pa (bile).

Medicine of Tibet. Fig. 9 Herbal remedy for excessive mKhris-pa (bile) is *Saussurea lappa*, an ingredient of Tik-Ta 8.

places, walking by the sea and cooling scents such as sandalwood. Individuals suffering from a mKhris-pa disorder should avoid situations causing conflict and direct, excessive exposure to the sun. Physical activities that are relaxing are encouraged; an environment that is conducive to calmness is beneficial. External treatments may target the production of sweat and may also include bloodletting. Typical herbal ingredients for excess mKhris-pa are shown in Figs. 9 and 10.

Constitution and Conditions in Tibetan Medicine: Bad-kan

The physical characteristics of Bad-kan constitution are typically a large or tall body, someone who can endure hunger and thirst well, who shows a pleasant, easy going and friendly personality. People in this group tend to sleep soundly, eat too much and too quickly, and wear clothing that is insufficient to keep them warm. Excessive sleeping can worsen conditions. Bad-kan people tend to be slow, persistent, and methodical in daily routines. Cultivation of good habits can be beneficial and enduring. Established routines are easily maintained, but changing habits can be difficult. Changing unhealthy habits may call for exertion that may initially make the person uncomfortable. This information is part of the prescription for health for this constitution. Babies and young children tend to have imbalances in Bad-kan.

The spiritual dilemma of people with Bad-kan constitutions can be characterized by ignorance, also known as delusion or confusion. Ignorance is one of the three poisons. It means not relating to self and others with a proper view. Ignorance has no relationship to intelligence, as we use the term in western societies. As such, it cannot be remedied with more studies or acquisition of mundane knowledge. Spiritual insight is the key to resolving the dilemma of ignorance.

Medicine of Tibet. Fig. 10 Herbal remedy for excessive mKhris-pa (bile) is *Rosa sericea* Lindl., an ingredient of Tri-Nam.

Diagnosis by observation of a person with excess Bad-kan shows a tongue that is moist, smooth, glistening with a thick gray lusterless coating (Fig. 10). Pulse diagnosis shows qualities that are slow, weak, sinking, or deep. Urine is usually clear, with little odor and few bubbles that last a long time (Fig. 11). Diagnosis by questioning shows that symptoms are worse after eating, especially after heavy foods, and relieved after warm or hot foods. Symptoms include a sense of discomfort, heaviness or coldness in the upper body or a sense of heaviness in the mind (Fig. 12).

Therapy is directed to foods and medicines that are pungent, sour and astringent in taste, with potencies of sharp, rough, and light. Patients should adopt a heating diet with respect to both the nature and the temperature of the food. For example, they are encouraged to consume a traditional diet to counter excess cold and retention of fluids, including: hot water,

Medicine of Tibet. Fig. 11 Excessive Bad-kan (phlegm) tongue is wet and coated white.

Medicine of Tibet. Fig. 12 Excessive Bad-kan (phlegm) urine is clear with small bubbles that last a long time.

cooked foods, mutton, fish, barley, pomegranates, sheep cheese, yogurt, ginger, radish, honey, garlic, and wine. They should avoid cold drinks and raw foods such as salads, potatoes, tomatoes, eggplant, bell peppers, and sugar.

Patients with Bad-kan disorders may be instructed to keep warm and perform vigorous exercise such as running or dancing. Swimming in cold water is not appropriate for Bad-kan conditions. Periodic emetics (e.g., induced vomiting) are recommended as part of a traditional health maintenance routine, since this reduces the excessive amount of cold and damp that tends to accumulate in the body. An environment that is conducive to heat producing activities is beneficial, including lots of exposure to warm sun and fires burning in the home. External treatments may target the

cautery and other forms of heat. Traditional herbal remedies to reduce excessive Bad-kan are shown in Figs. 13–16.

Pharmacology in Tibetan Medicine

Natural herbal preparations are a large part of therapy in Tibetan medicine. The goal of herbal remedies is to restore balance among the constituents of the body-mind complex. The medicinal effects associated with Tibetan preparations are not due to the presence of a specific ingredient, as in western pharmaceuticals. Rather, the herbal combinations act on the body-mind aspects of the afflicted aggregates and elements to restore balance. Remedies act on the specific imbalance, while other ingredients support the aggregates that are not maligned during the period of the intervention, although they may be challenged during the dynamics of therapy and healing (Fig. 17).

Medicine of Tibet. Fig. 15 Saffron, an ingredient of Dhe-Nyom.

Medicine of Tibet. Fig. 16 A medical student gathering herbs.

Medicine of Tibet. Fig. 17 Medical students cleaning gathered herbs in Northern India.

Most of the ingredients in the Tibetan *materia medica* are herbs and plants. There are eight categories of natural substances used in preparing prescribed therapeutic remedies: precious metals and gems, stones, earth medicines, trees, resins, plants, herbs, and animal products (Clark 1995; Clifford 1990; Dash 1976). The remedies can take ten forms: decoction, pills, powder, gruels, medicinal butters and calxes, concentrated extractions, medicinal wine, herbal medicine, and gems as medicine. Enemas, especially if oily, mild, and soothing, are useful for rlüng imbalances. Purgatives reduce the heat in mKhris-pa conditions. Emetics reduce water and mucous associated with excessive Bad-kan.

Tibetan herbal pills are often complex, with 3–150 herbs per formula. Each herbal formula is prescribed to fit the manifestation of the disease and the evolving condition of the individual patient. The herbs are often sought from natural settings, often harvested from a great distance or requiring expertise in climbing or other skills to access the plants. The plants are gathered under specified circumstances, including time of day, phase of the moon, etc. Special mantras are often recited during collection of the herbs, during preparation and after the pills are formed, to imbue the remedies with healing qualities.

The physician often starts with less potent preparations and advances to stronger forms if necessary. Typically, two to four formulas are prescribed for each day at specific times. Morning remedies commonly include those for Bad-kan disorders or digestive disorders. Afternoon remedies are typically used to treat mKhris-pa disorders. Remedies given in the late afternoon or evening are usually given to treat rlüng disorders. Herbal remedies are often modified at each visit (Figs. 18 and 19).

The substance in which a medicine is dispensed is called the medicine horse (*Men-Ta*) (Burang 1974). Typical carrier agents include water, alcohol, sugar, treacle, or honey. According to tradition, sugar is the men-ta for dispelling mKhris-pa, treacle is the carrier for reducing rlüng, and honey is selected for

Medicine of Tibet. Fig. 18 Modern methods for making TTM pills.

Medicine of Tibet. Fig. 20 Various forms of modern Tibetan medicines.

overcoming Bad-kan. The compounded remedies are sometimes coated with resins, so that they pass through the stomach and into the intestine where they are integrated into the body in accord with traditional concepts of physiology (Fig. 20).

The art and science of preparing TTMs is based on tastes and potencies. The tastes are associated with medicinal properties. Each taste is present as the result of interaction between two or more elements. Specific tastes can increase or decrease the activity of specific aggregates. The text says that sweet, sour, and salty tastes overcome (reduce) rlüng. Likewise, bitter, sweet, and astringent abate excessive mKhris-pa, and pungent, sour and salty tastes counter Bad-kan (Table 4). These same tastes also describe the medicinal properties of common foods and spices.

The properties of herbal remedies and traditional medicines can be determined by the refined sense perceptions of Tibetan doctors. The tastes and actions of therapeutic agents on specific parts of the tongue correspond with medicinal properties at specific parts of the body. For example, medicines with astringent tastes that influence the sides of the tongue may be useful for treating imbalances that adversely influence the gallbladder organ and associated dimensions, including some migraine headaches. Knowledge about tastes and medicinal actions of therapeutic agents is embodied in a cultural tradition of health care, known as microsystems of anatomic correspondence (Porkert 1974).

Typically the Tibetan pharmacist is also a physician. Preparation of botanical medicines involves collection of specimens, drying, cleaning, storage and preparation, detoxification and neutralization, and compounding. Various parts of plants are gathered at different seasons – fruits in the autumn, leaves during the summer, branches and barks during the spring, and roots during the winter. Mantras to invoke the Medicine Buddha and other deities are often recited during the time of collecting and during other stages in processing to imbue the remedies with additional potency (Fig. 21).

One fundamental difference between modern biomedical sciences and TTM is the notion about the interdependent nature of reality. Interdependent realities include the participatory awareness of an observer in interactions with the relative world of appearances, including measurable phenomena. The perceiver, the object of perception, and the sensory faculties for perceptions are all interdependent. From this perspective, to exclude the observer from an investigation and analysis of phenomena is akin to making an artificial reality. Experiential qualities of relationships are valued as much in TTM as are objective measures of form.

Indeed, one of the strengths of TTM is that mind and body, and mundane issues and spiritual aspirations, are each intimately linked with one another. The perspective of TTM and Tibetan Buddhism pose that the world we experience exists only in the context of our human presence and interactions. In short, the world is an aspect of Mind. Questions posed by western health scientists tend to assume that the nature of reality is independent of the observer. This positivist view typically

M

Medicine of Tibet. Table 4 Influence of tastes and qualities on the aggregates (adapted and modified from Clifford 1990: 120; Lad 1984; and others)

Elements	Taste	Qualities	Food and spices	Aggregate increased	Aggregate decreased
Earth–water	Sweet	Cooling	Wheat, rice, peppermint	Bad-kan	Rlüng; mKhris-pa
Earth–fire	Sour	Heating	Yogurt, cheese, lemon, rose hips	mKhris-pa; Bad-kan	Bad-kan
Water–fire	Salty	Heating	Salt, kelp	mKhris-pa; Bad-kan	Rlüng
Water–wind	Bitter	Cooling	Dandelion, turmeric	Rlüng	mKhris-pa; Bad-kan
Fire–wind	Pungent	Heating	Onion, radish, ginger, garlic	mKhris-pa; rlüng	Bad-kan
Wind–earth	Astringent	Cooling	Unripe banana, persimmon, goldenseal	Rlüng	mKhris-pa; Bad-kan

Medicine of Tibet. Fig. 21 Monastic community rituals for blessing TTM medicines.

asks questions about form and status of external phenomena – the “what” of measurable components of nature. Thus, western sciences seem to be bound and limited by concept, form and reliance on objective measurements. TTM defers involvement of the inherent mind-body split of western science and medicine by defining mind as part – if not the source – of reality.

Thus, the very notion of disease and clinical reality as we know it in western biomedicine are challenged in TTM. TTM addresses the process-oriented issues about “how” more than “what.” For example, “How might we live within this precious human birth in a manner that brings happiness to ourselves and all sentient beings?” is a basic motivation among practitioners of TTM. The focus is more on the dynamics of process and relationship, rather than on the parts to be measured. Yet form is not ignored in TTM – it is recognized as simply one mode of perception and relationship among many other possibilities. The dynamics of subtle anatomy and the interactions among the elements and aggregates are the core methods for identifying imbalances to be addressed through traditional methods of TTM.

Thus, a tension is acknowledged between biomedicine and TTM, where TTM focuses on processes for realizing subjective well being for all involved in life experiences, while modern biomedical care seems intent upon attaining disease-free states of objective health status for specific individuals. Yet, perhaps each health care system makes sense when viewed from its unique perspective. Each system is logically consistent within itself.

Does TTM offer any opportunities for new understandings of health and well being among people in western societies? That may depend upon the willingness of western scientists to overcome some engrained notions about the nature of reality and the nature of mind (e.g., of the observer–participants) in scientific investigations. Valid research methods to investigate culturally different health care systems may make use of hypothesis generation from the traditional perceptive, with psychometrically examined key measures that support the traditional view, complemented by known biomedical measures (Anderson 1992; Steiner 2003). Such methods for cross-cultural research, including hypothesis generation from the traditional perspective, may yield new insights about best practices in medical care.

Traditional Tibetan medicine offers an alternative view to health and healthcare, as well as a choice to western scientists. That choice is to consider complementing the focus of western sciences on measurable phenomena with an inward investigation about the nature of mind of the perceiver. In some Tibetan schools of mindfulness training, the inwardly directed investigations are initially analytic and conceptual in nature, but proceed to realizations about the nature of mind itself that are embodied within our human experience – but are not limited by ordinary dualistic conceptual thinking (Thondup 1998; Wallace 1996). That choice is available for any person who is willing to focus on the mindfulness of life experiences, as offered through the guidance of lineages and teachings of wisdom traditions from Tibet, including TTM. The study of TTM offers an opportunity to examine a participatory universe. In short, entering the path of health, healing and well being in accord with principles of TTM, is a choice.

Medicine in Africa

JOHN M. JANZEN, EDWARD C. GREEN

Health and healing practices in sub-Saharan Africa have evolved over three millennia in constant interchange with those of other world regions. The medicine of Ancient Egypt shaped ideas of the civilizations around it, including the medicine of classical Greek and Roman Antiquity. This complex in turn spread to African regions, through the influence of Islamic Medicine. Another dimension of Islam, "prophetic medicine," brought notions of health and healing to Africa from Persia and Arabia.[1] Christian faith healing, which spread first with early Christianity across North Africa and Ethiopia, later was part of European colonial expansion to sub-Saharan Africa. Post-Enlightenment scientific medicine, building upon ancient medicine, brought its ideas of public health and curative medicine. All these perspectives coexist in the early twenty-first century with African perspectives on health, sickness, and healing.

M

[1] The term "Islamic medicine" encompasses the traditions of medical theory, practice and literature that have been developed in Islamic cultural contexts and expressed most commonly in the languages of Islam, principally Arabic, Persian, Turkish, and Urdu. There are two medical traditions that developed in Islamic contexts. One ultimately derives its authority, and many of its theoretical and practical components, from ancient Greek and Hellenist sources, called in this essay Islamic medicine; the other encompasses traditions associated with the Prophet Muhammad, or prophetic medicine.

What then is African healing and medicine? Africa is of course a vast continent with a multitude of societies of great diversity, and we admit a certain hubris with the very idea of generalizing about it. We will focus our attention on the ethnolinguistic group known as Niger-Congo, within which we have ourselves had most of our experience.[2] This group of societies is geographically widespread and numerically large, covering sub-Saharan Africa from the Wolof of Senegal to the Swahili of coastal East Africa, and down to Southern Africa. The Niger-Congo grouping relates the Bantu-speaking peoples of the Congo basin and southeastern Africa historically and culturally to the dense population of West Africa. All of these societies share, in addition to historically related languages, "attitudes about God, religion, kinship, the nature of the world, and life" (Murphy 1972: 179), and within them, health-related practices and beliefs.

Tools and Perspectives for the Historical Study of Changing Healing Traditions

Ecologically distinctive zones of the rainforest, savanna, and desert have shaped both health and adaptive responses by human communities. The modes of living – hunting and gathering, cultivation, herding, and then urban societies – also shaped the underlying determinants of health.

Hunters and gatherers, for example, such as the remaining Khoisan speakers of Southern Africa in the early twentieth century, practiced infanticide for population control and birth spacing of up to 4 years between children. They also picked up camp whenever diseases broke out, in order to reduce deaths in the settlement. Given their small population concentrations, contagious diseases did not have a chance to take hold and become endemic. The health of the band was promoted through spirit healing ceremonies led by leading healer-singers (Katz 1982; Katz et al. 1997).

Both the West African and the Bantu-speaking civilizations, defined primarily by sedentary agriculture, have also been cattle herders and pastoral nomads throughout their histories. Where the tsetse fly has been absent – as across the Sahel, the eastern Sudan, in the lake region of East-Central Africa, and into moderate Southern Africa – pastoralism has brought with it a distinctive set of ideas about health, sickness, and medicine.

As livestock herding spread southward about six millennia ago, it skirted the rainforest area. This created at the center of the African continent a vast population without domestic large animals. As a result, this population is unable to digest animal milk – a condition known as lactose intolerance. The boundary between pastoralist and nonpastoralist societies has historically been that between rainforest and wet savanna on the one hand and the dry savanna and the desert on the other. On the one hand, the pastoralists have had to manage their herds, concentrating on good breeding, learning the politics of being good neighbors (or superior raiders) on their annual transhumance treks to find seasonal pasture, and understanding the danger zones of the tsetse fly's habitat. On the other hand, the cultivators without large livestock have had to emphasize crop fertility, soil fallowing, irrigation and water management, and the importance of rainfall.

In West Africa, the domestication of plants and animals in sedentary settlements was well underway by 4000 BCE. Urban centers and stratified societies emerged in the West African and the Sudanic savanna by the early centuries of the first millennium AD, and trade routes linked West Africa with the Mediterranean and Europe. By the early second millennium AD the influences of Islam and Arabia were felt in the savanna, but pre-Islamic healing rituals or therapeutic practices were not fully supplanted.

The spread of food cultivation and sedentary social modes southward through and around the equatorial rainforest has come to be associated with the spread of the Bantu, Cushitic, and Nilotic cultures and languages. Perhaps as early as 1000 BCE the Bantu languages had begun to spread from the region that is now Cameroon and Nigeria. These languages ultimately came to be spoken throughout the whole of Central, Eastern, and Southern Africa, facilitating exchange of ideas and practices, including those related to healing. Food production and iron working spread rapidly through this area during the first millennium AD. The sedentarization of community life in sub-Saharan Africa and the domestication of food plants and livestock provided a moving threshold that also affected health and healing. With the transition to cultivation and larger, sedentary communities, new diseases appeared. There was sleeping sickness (endemic in the rainforests, a major threat to pastoralists), malaria (endemic in rainy forested areas), and smallpox (endemic once population concentrations emerged). Together with widespread environmental risks such as poisonous vipers, these diseases offer examples of health threats that encouraged the creation of "medicines" directed at them. They also show the vocabulary of health-related terms and concepts in a common linguistic and cultural background.

Language history – along with archeology and the study of the distribution of cultural practices including uses of plants, animals, and other natural substances – offers one of the most promising avenues for the study

[2] For Janzen, Central Africa (specifically, the Western southern savanna and Kongo coastal regions, the Great Lakes region, coastal Tanzania), and Southern Africa (Swaziland and Capetown); for Green, Swaziland, Mozambique, Southern Africa, East and West Africa.

of the history of African medicine and health related practices (Ehret 1998; Janzen 1992; Schoenbrun 1998; Vansina 1990). Analysis of the words and their meanings and uses by language family permits the determination of which concepts, practices, terms, and phrases are part of the institutional infrastructure of these varied adaptations. Language analysis assists in determining which are inventions along the way, and which are borrowed from elsewhere. Language history also allows the reasonable dating of the origin and spread of specialized institutions, practitioners, techniques, concepts and ideas, and materia medica.[3]

The common vocabulary of the Bantu expansion from about 1500 BCE includes terms for suffering (*-*duaad*-), healer (*-*ganga*-), medicinal plant (*-*ti*-), the power of words and will to affect health in social relationships (*-*dog*-), and song–dance ceremonies of trance and healing (*-*goma*-) are found throughout Equatorial, Central, East and Southern Africa (Janzen 1992; Vansina 1990).[4] Such a constellation also characterizes medicine on the Guinea coast and West Africa. As this cultural complex moved eastward to the Great Lakes region, the basic term for healer became bifurcated and the root term for "big man" or chief (*-*kumu*-) came to be applied to diviner (*-*mufuumu*-), suggesting the importance of the diviner in social control (Schoenbrun 1998).

Profound transformations were brought to African medicine by the mercantile trade of the sixteenth to the nineteenth centuries, and then by nineteenth and twentieth century European colonialism. Foreign trade, technology, ideologies, and social forms were often imposed by force. New ideas about health were part of this colonialism, ideas that discredited African medical systems. Missionaries and colonial regimes came to evangelize Africa. Just as Islamic crusaders had attacked "pagan" African forms of healing and religion, so Western Christian missions discredited the basis of knowledge as the overall approach to ritual healing. At a time when early positivist science was analyzing the causes of contagious diseases and public health campaigns were being waged to make Africa safe for "progress," assumptions that social dynamics could cause sickness were dismissed as witchcraft. Since they had cures for diseases such as yaws, leprosy, and later malaria and dysentery, Christian missions and their hospitals contributed to the conversions of many Africans. Although Christianity gained widespread following in sub-Saharan Africa, many of the marks of the African worldview of misfortune have been reincorporated or persisted quietly in private. In the postcolonial era – generally from 1960 on – the process continues of sorting out what indeed were precolonial health codes and realities and evaluating what in them is of importance and might be endorsed, revived, and further developed.

The latest economic and health crises lent an immediacy to these debates. African traditional medicine continues to be widespread, as biomedicine is expensive and often locally unavailable. The epidemic crisis of HIV/AIDS has revived the question of whether the African pharmacopoeia has something to offer. Such pressing issues have again raised questions about the fundamental character of African medicine and its ideas of health.

Interpreting Practical Applications of Materia Medica

Examples of pragmatic and empirical solutions to health threats include diagnoses and interventions for

> bone-setting, midwifery, and a host of specific interventions for such ailments as fever, rheumatism, intestinal disorders, parasites, lactation deficiency, earache, toothache, headache, epilepsy, menstrual disorders, and more. Most of the African pharmacopoeia under discussion here is derived from plants, but medicines from animal parts, sea shells, coral, soils and other substances of natural origin may also be used. Medicine may be drunk as herbal decoctions, or they may be ingested through inhalation, vaccination (dermal incisions), enemas, vaginal infusions, massage, bathing, or fumigation, in forms that include powders, porridges, soups, ointments, smoke, fumes, or eye drops (Bibeau 1980).

These medications variously reflect the desert, savanna and rainforest ecologies and pastoral and

M

[3] One of the best methods for reaching back through contemporary and recent African experience to find the faint images of ancient thought and practice is to follow the widespread vocabulary having to do with health, the nature of disease, and the ideas and techniques of healing. Sub-Saharan healing is not codified in written texts, but it is transmitted through rich oral instructions from generation to generation. These texts and their vocabulary are as persistent and more durable – in the tropics – than papyrus or parchment. Historical linguistics is based on the premise that core vocabulary in language remains relatively constant and can be traced by comparing languages with a historical affinity. Core vocabulary shows both lexical and phonetic change at a rate of about 20% per millennium. Thus, if two languages are shown to have a 60% common core vocabulary and related phonetic structure, they are about 2,000 year apart in their history. Newer techniques, ideas and related terms will show a different distribution, whose origins can sometimes be traced by examining the distribution and the phonetic transformations they have undergone. Phonetic changes occur in certain directions within the basic human sound-making potential. This "historical linguistic" methodology permits scholars to study concepts at a depth of up to 5,000 year.

[4] A term headed by an asterisk (e.g., *-*ganga*-) indicates that it is a widespread cognate in either the proto-Bantu or proto-regional reconstructed core of verbal concepts.

farming ways of life. Following are two examples of pastoral knowledge of sleeping sickness and its vector the tsetse fly. The early nineteenth century Nguni king Mzila, as he was expanding his territory in Southeastern Africa, concentrated his people in large settlements and had them garden close-in territories; then he sent his hunters out to kill all large wildlife in the savanna forests at a greater distance before allowing his herdsmen to take the cattle into those areas (Swynnerton, in Ford 1979). The Turkana pastoral nomads of northern Kenya are well aware of the dangers posed by the sleeping sickness bearing tsetse fly to their cattle and themselves during the rainy season, especially in the lush grasses near streams. Therefore they send out young herders with the least valuable animals to graze in those sites to establish their safety from the tsetse before bringing in fertile cows. (Gray 1997, based on fieldwork with the Turkana in Kenya).

Malaria is an endemic disease over much of Africa. It is usually that variety of malaria for which the Anopheles mosquito serves as vector. It became a problem for West and Equatorial African cultivators at the time they settled into sedentary communities and began to clear forests for crops. A genetic adaptation to the high death rates occurred soon after, in the form of the blood cell sickling that in its heterozygous form created immunity to malaria (although proving lethal in its homozygous form). Clearly no one was aware of the genetic structure of this adaptation to malaria. However, settlers preferred to build villages and towns on breezy hillsides rather than in the quiet thickets. Thus, before quinine and the late nineteenth century association of mosquitoes with malaria, breezy hilltops were the preferred settlement site, provided they were near sources of good water.

Smallpox too has been a scourge in sub-Saharan Africa since the advent of cultivation and large concentrations of people (Dawson 1992: 90). The central placement of Ipoona, the god of smallpox, in the pantheon of Yoruba (and other West African) societies, suggests that it has a history of millennia rather than centuries. In addition to the sacrifices made to the angry god Ipoona, who could kill, a pattern of actions during smallpox epidemics suggests pragmatic public health consciousness as well. Examples include the separate burial of victims, the abstinence from mourning in close proximity to the victims, and quarantining infected households or settlements. Most intriguingly, they refer to attempts to immunize those not yet infected by taking pus from the poxes of infected individuals and introducing it into scratches in their skin.[5]

Immunization as seen in the case of smallpox may be part of a broader principle of confronting the evil of disease or threat. Several kinds of poisonous vipers have posed a serious problem in the lands of the Nyamwezi and Sukuma peoples of Western Tanzania. Organizations of snake handling experts actively promote the encounter with these poisonous vipers and other snakes through public dance performances in which they demonstrate that they can come to terms with the threat. The demonstration includes allowing the otherwise venomous snakes to bite them. However, the snake handlers have been inoculated with small doses of venom that they have milked from the vipers. This understanding of immunization is mainly available to those who have been appropriately initiated to the Snake Handling Order. These examples of immunization to smallpox and snake venom are part of the much wider notion of the need to incorporate or confront the threat in order to overcome it.

Curative plants are central to African medicine. Two examples illustrate the ways in which specific problems were, and are, approached with the curative powers of plants and techniques. Mirau, a herbalist of the Meru people studied by Finnish ethnographer Harjula (1980) who records many of the healer's herbal treatments as one-disease, one-plant related, practices a widespread treatment for intestinal microorganisms. Although this conveys a somewhat simplistic picture of African herbalism, it does permit a clear examination of Mirau's work from the outside. One of Mirau's 200 single-plant treatments is for children's diarrhea, a serious problem in many regions of the continent where infant mortality often reaches more than 100 per 1,000 births. Using the plant known locally as *mamiso* (*Bidens pilosa L.*), Mirau takes 15–20 flowers and boils them to obtain one dose, which is given twice daily as oral medicine. According to Watt and Breyer-Brandwijk's (1962) massive compilation of East and Southern African medicinal and poisonous plants, this plant carries antibacterial substances against microorganisms, including five enteric pathogens. The same plant is reported in use against dysentery and colic in other regions of East and Southern Africa.

In another well-documented study from the national Zairian Research Institute (Bibeau 1980), the work of six healers in Kinshasa was examined for effectiveness in 22 diabetes cases. Independent examination of blood sugar levels revealed an average glycine rate of 500 mg/108 ml of blood. After treatment, which lasted a week or longer, 17 of the cases experienced a decline of glycine levels to an average of 100 mg/108 ml of blood. Although a surprisingly large diversity of plants was used in preparation of the oral medications, several plants stand out for their repetition from healer to healer, including *Crossopteryx febrifuga* (Rubiaceae), *Nauclea latifolia* (Rubiaceae), *Anchonames difformis* (Arceae), and *Bridelia feruginea* (Euphorbiaceae), the latter of which is used in Ghana for diabetes therapy.

[5] See Green 1999: 69–70 for such evidence in southern Africa.

Some of the Kinshasa treatments were accompanied by dietary proscriptions for salt, ripe mangoes, pepper, beer, manioc, and mushrooms.

Thus far these treatments have appeared to be of the empirical type that scientifically oriented Westerners would recognize. However, in classical African medical thought the added dimensions that Westerners might call "symbolic" or "social" are added without a conceptual break. In the next two examples of treatment with materia medica the fusion of the natural and the human dimension is evident; they deal with two types of bodily swelling.

Mama Mankomba of Mbemba village in the Luozi region of Lower Zaire was well known for her treatment for bodily swelling. She distinguished between two types of swelling, the first thought to be due to heart congestion, the second to poisoning, the result of anger growing out of animosity. Simple swelling was dealt with by an initial emetic from the drops of sap of the finger cactus (*diza kia nlembo*, *Euphorbia tirucalli L.*) with a soapy base to keep the poison from harming the body. This was followed by a potion made from the roots of six savanna plants taken three times daily (*Nlolo, Annona arenaria Thonn, Annonaceae; Mumpala-mbaki, Crossopteryx febrifuga* (*Afz. ex G. Don*) *Benth*. = Rubiaceae; *Nkizu, Syzygium guineense* (*Willd.*) DC. = Myrtaceae; *Votila, Psorospermum febrifugum Spachh*. = Guteriferaceae; *Luvete, Hymenocardia acida Tul*. = Euphorbiaceae; *Kinsangula, Maprounea africana Muell. Arg*. = Euphorbiaceae). Dietary restrictions against sugar, salt, and pepper were also imposed. Poisoning cases received the same initial purge, but were followed by a second purge of the bark scrapings of only the kinsangula plant with salt and palm oil to provoke diarrhea and vomiting. Although Mama Mankomba treated the physical manifestations of anger illness, she refused to become involved with the deeper causes of anger which required conflict resolution and judicial action (Janzen 1978).

The use of multiple plants and techniques not only introduces a degree of complexity from the botanical and chemotherapeutic compound involved, but also adds to these symbolic classifications, names, songs, and other ritual connotations and devices, and above all, the human dimension in health and disease. Studies of plant uses in circumstances where both chemotherapeutic and consciously exercised symbolic principles and human issues are at work need to be examined further (Figs. 1 and 2).

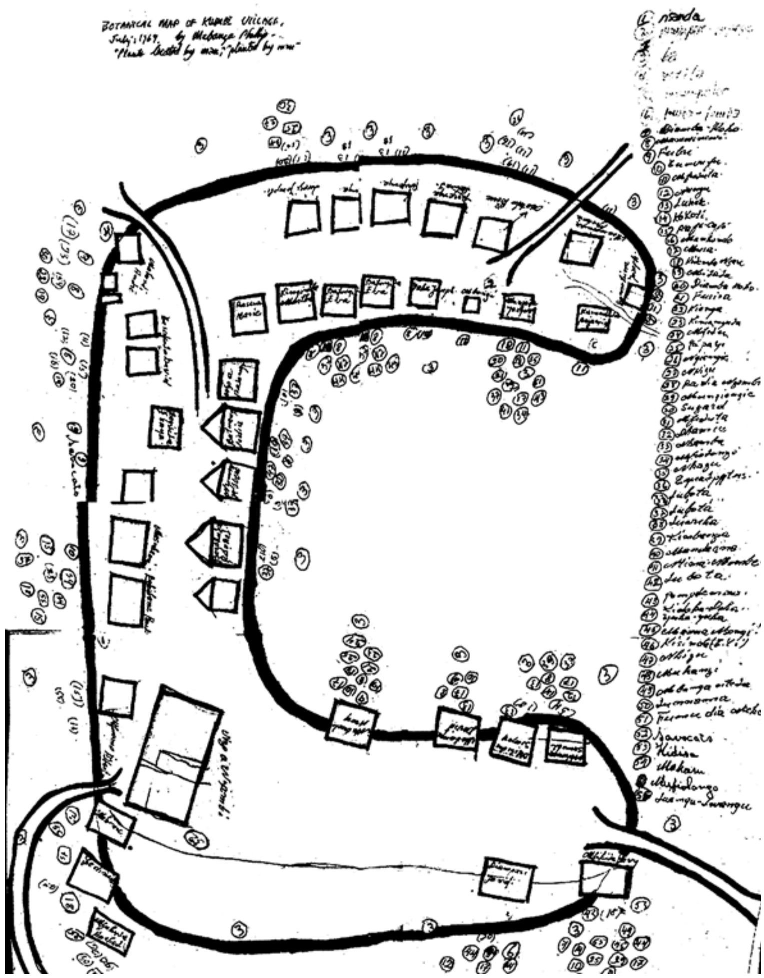
Divination: Differentiating What "Just Happens" from "Agency-Caused" Misfortune

As important as practical medicines is the pervasive concern that Kongo therapy managers spoke of as "something else going on" (Janzen 1978). There is a shift from pragmatic to ritualized therapy that occurs because the misfortune or affliction is perceived to be fraught with anxiety and fear of pollution by both human and superhuman conflict (Janzen and Prins 1981). This shift amounts to a purposeful amplification in practical care with affective symbols referring to the human dimension, to spirits, and to efforts to manipulate them. Usually only consecrated persons are considered capable of handling such powerful therapies as the purification of polluted persons and settings, making sacrifices to ancestors or neutralizing menacing spirits.

Medicine in Africa. Fig. 1 Kongo healer-herbalist Kitembo of Balari commune in North Manianga stands in a forest clearing with a handful of leaves collected from wild plants, as is most of his pharmacopoeia. However, other Kongo healer-herbalists tend botanical gardens for their most frequently used herbaria. (Photo by Janzen.)

The pervasiveness of divination in treating African sickness and misfortune attests to the importance of causation, especially the suspected shift in cause from a mundane to a highly charged cause in the human or spirit realm. Usually consultation with a diviner is not undertaken until there is sufficient reason in the kin group of the sufferer to suspect causes other than natural ones. Such a precipitating factor may be the worsening turn of a sick person, a sudden and mysterious death, the coincidence of a sickness with

M



Medicine in Africa. Fig. 2 A 1969 botanical survey map by Mabanza Philip of "plants planted by man" in Kumba village in North Manianga, Lower Congo, Democratic Republic of Congo. The map shows 56 varieties of shrubs and trees for food, medicinal, ritual, and other purposes. The *ba*, oil palm (3) part of the ancient West African domestic plant set, is used for cooking oil, palm wine, and raffia fiber. Others, such as *payi-payi* (25) and avocado (52) are much cherished edible plants. *Kienga* (22) and *lubota* (42) are potent medicinal plants; *lemba-lemba* (6) is a sedative and a symbolic plant of the entrances; *mpese-mpese*, a poplar, used to outline chief's courtyards, here marks the men's lodge. *Kidiza* (53) is a cactus whose poisonous sap is used to catch fish and for emetics. The *nsanda* fig tree (*Ficus bubu*, sp. = Moraceae) (1), a harbinger of water, thus of a good village site, is said to be the first planted to determine the quality of the site. A botanical map such as this reveals the 2000-year history of plant domestication and agriculture, just as the illustration of healer Kitembo with wild plants in his hand suggests the continuing history of foraging. Both modes of making a living are joined in Kongo culture and medicine.

a conflict in the close social environment of the sufferer, or the paradoxical occurrence of a disease on only one side of a family. In such cases the clients are looking for answers to questions not only of "Why did it happen?" but "Why did it happen to us?" and possibly "Who caused it?" and "What should we do about it?"

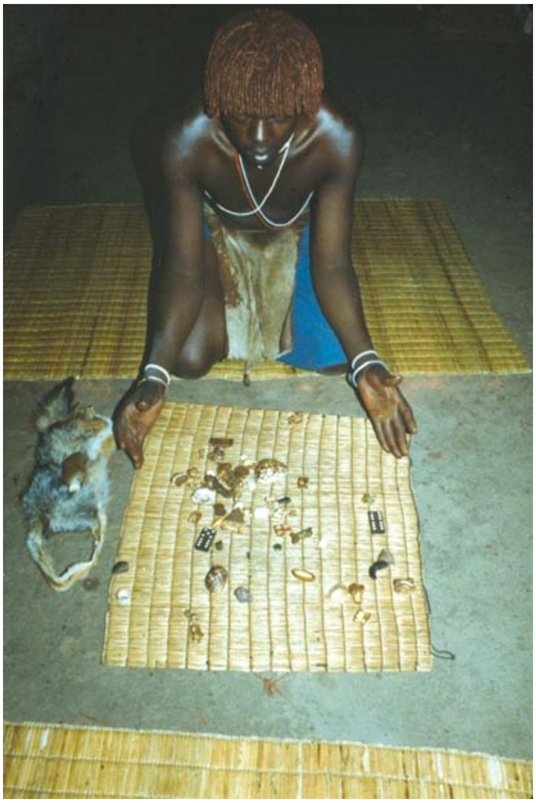
Scientific explanations of health may not necessarily lay to rest these questions, which are of a different order from the ideas in natural causation. A community may know very well that the spirochete transmitted by the bite of an anopheles mosquito causes malaria in the blood of a human. But the diviner may shed light on the question of why some people are infected and not others, or why some died when all were infected. Divination may also clarify the human causes behind accidents or provide a pattern with which to explain them. Western medicine is often good at answering "why?" but not "why me?"

In the broad West Africa belt from Central Nigeria to Ghana, the prevailing mode of divination is known as Ifa. A cup bearing a set of usually 16 cowries or pods is thrown out into a tray. The combination of "ups" and "downs" is coded to indicate a set of verses, numbering in the thousands, which illuminate the life situation involved in the affair before the diviner. The tray or the cup usually bears the image of Eshu Elegba, the trickster, who is believed somehow to hold in his hands individuals' and families' fortunes. At least he attempts ceaselessly to surprise humans with contradictory and unintended turns of events, often for the worse. Thus he and his character of trickery, deceit, and surprise embody the essence of what divination seeks to illuminate (Pemberton, in Pelton 1980: 136).

On the Southern Savanna, from the Atlantic coast southeastward to the Copper Belt, the Ngombo basket mode of divination is common. Its thorough integration into the societies suggests that the genre may be a thousand years old. Carved figurines and natural objects, representing human situations and predicaments, lie together in the basket. As the basket is shaken, one of the objects emerges at the basket's rim between two lumps of clay, one red, and the other white. This "gateway" of white and red suggests the liminality of the threshold between the visible and the invisible spirit world. The diviner reads the case before him in the light of the emergent object or the constellation of objects in the basket (Turner 1975: 315–316).

In Southern Africa a common mode of divination is a bag of animal bones and perhaps seashells (brought or traded from coastal areas) which are shaken out and thrown onto a mat before the diviner and the client (Fig. 3). The bones, whose constellation represents issues in human life, relationships, and the world of spirits, may be combined with trances to indicate a complex hierarchy of causation behind the surface realities of a misfortune.

These and many other types of divination in sub-Saharan Africa are predicated on the assumption that sickness or other misfortunes may be caused by an untoward turn of events in the human or related spirit world. The immediate cause or agent such as the sign or symptom of disease is thought to require interpretation in the light of ultimate natural, human or spirit agents. Thus, despite widespread acceptance of modern science, divination continues to be a common method for discerning the dividing line between that which "just happens" and the human or mystical factor that is seen as important in the pattern of misfortune.



Medicine in Africa. Fig. 3 Divination by means of throwing "bones" in Swaziland. (Photo by Green.)

Science or Magic? A History of Scholarly Debates About Etiology in African Medicine

Anthropologists and other scholars have debated the nature of African medicine and thought ever since David Livingstone published his debate with an Mbundu rain maker (Janzen 1978: 38–40), designed to show that the latter, although rational, was arguing with false premises. All participants in the anthropological debates accept empirically effective medicines, as mentioned earlier. The debate focuses on the nature of the other logic – the human and spirit logic – and the relationship between these and the empirical or "natural" realm of causes and cures. The arguments range along a spectrum from prioritizing the empirical treatments to charging that witchcraft overrules other causalities in African medical thought. A range of terms has been put forward to identify the several logics that work together in African healing thought, as for example naturalistic, personalistic, God-caused, or human-caused.

Many scholars of African medicine today would not be likely to use Foster's global distinction between "personalistic" and "naturalistic" treatments (1976: 775), because it just does not fit well. Illnesses that "just happen" – we would say naturally – are attributed to God, a personalistic force. Nor would this dichotomy very readily do justice to impersonal ideas of pollution brought about by exposure to the dead, to certain diseases, and brushing one's feet against polluting substances. Similarly, few would accept Murdock's global survey of theories of illness, in which African societies, based on the survey's reading of available ethnographies, demonstrated a prevalence of supernatural (including fate, ominous sensations, contagion, mystical retribution, soul loss, spirit aggression, sorcery, and witchcraft)

M

over natural (including infection, stress, deterioration, and accident) etiologies (1980: 48). Nevertheless, British anthropologist Pool, who has studied Cameroonian societies (1994), has joined Murdock and scholars of other disciplines, missionaries, travelers, government administrators (pre- and postcolonial, foreign and African), doctors and health officials, and economic development professionals, who have simply taken these simplistic dichotomies and characterized African health beliefs as operating primarily, or solely, in the domain of "personalistic" or "supernatural" shaped witchcraft, sorcery and/or spirits.

Evans-Pritchard's classic on Azande ideas of misfortune (1937: 67) would seem to endorse their views. Yet Evans-Pritchard has been much misrepresented by his excerpt on the Azande granary's collapse being attributed to witchcraft rather than natural causes. A careful reading of Evans-Pritchard reveals that he describes a "hierarchy of resorts ranging from simple to serious, with recourse first to empirical treatments, then to magical interventions" (Janzen 1981: 188–189). Yet many scholars of African healing and religion, who have experienced attributions to witchcraft for events Westerners would say were caused by gravity, germs, or sheer coincidence, prioritize this explanation over one in which events merely occur because they occur (e.g., see Turner on the Ndembu 1967: 300–301).

A third group of anthropologists began to find evidence of empiricism and rational, logical thought in African ethnomedicine (Horton 1967; Fortes 1976; Yoder 1982; Morris 1998). Horton in particular sought parallels between African and Western thought, including in the domain of health and illness. Anthropological opinion has changed considerably since the 1970s, in part because of the involvement of anthropologists in applied research of infectious diseases such as child diarrhea and sexually transmitted diseases (Inhorn and Brown 1990; Green 1999).

For example, recent research suggests that while magico-religious or supernatural ideas may often be associated with mental illness and certain other conditions, naturalistic etiologic notions rooted in empiricism are often found to underlie the infectious and contagious diseases that have always accounted for the greatest morbidity and mortality (Green 1999). Diseases such as malaria, tuberculosis, schistosomiasis, cholera, amoebic dysentery, AIDS and other sexually transmitted diseases, typhoid, acute respiratory infections including pneumonia, yellow fever, leprosy, and dengue tend to be understood within a framework that may be called indigenous contagion theory. In this analytic framework, one becomes ill because of impersonal exposure. One comes into contact with something that anyone could come into contact with, not because an avenging spirit or an ill-intended person singles one out for misfortune in the form of sickness (Green 1999).

A fourth and final group of scholars have sought to formulate the relationship between disparate types of logic and misfortune causation in African thought. Morris notes that Chewa medicine includes an "empirical herbalist tradition, based on a belief in the intrinsic efficacy of certain plant and animal substances." Yet it also includes "a cosmological tradition, which sees the human subject as a microcosm of the world and in which health was seen as restoring a balance or mix between certain vital 'humors' or principles, and a tradition that focused on 'communal rites of affliction,' and involved spirit healing" (Morris 1998: 86). How do these multiple realms of African healing relate to each other?

The late Rwandan scholar and physician Pierre-Claver Rwangabo offers an insight into contemporary African thinking on the question. Even though not all aspects of the Rwandan medicine system are amenable to modern science, Rwangabo believes that it is a part of modern reality rather than a fossil. He divides the causal domains of Rwandan medicine into "physical" and "mystical" causes. Diseases range across a variety of types which may be attributed to either causal category or to both. Rwangabo's medical training is evident in his listing of disease classes that include: parasitic diseases, microbial diseases, systemic diseases and bodily accidents, gynecological and obstetrical diseases, and psycho-mental and behavioral diseases. But under the latter group he identifies current psychopathologies that entail abnormal behavior as understood in traditional thought and diseases believed to be caused by broken prohibitions and beliefs about ancestors (*abazimu*) and other spirits (*ibitega, amahembe, nyabingi, amashitani, amajini*) which often are identified in relation to mental illnesses. "Poisoning," the result of human aggression, is a major aspect of the human source of misfortune. Misfortunes brought on by the breach of social rules also have a mystical though not necessarily mysterious causal character. Rwangabo's insight into the character of traditional medicine lies in the observation that most pathologies may have both a physical and a mystical dimension. This affects the way therapy will be arranged. The decision to seek physical or other therapy has to do with the context in which it occurs, its severity, the suspected human etiology, and response to treatment.

This emphasis on the context of the causal attribution makes all the difference in how sufferers, their therapy managers, diviners, healers and medical practitioners will treat illness. If the misfortune is considered to be ordinary and predictable, it will be seen along the lines of the material world. If catastrophic forces or circumstances have precipitated it, or if it seems to be the result of the chaos of underlying affairs in the human and mystical realm, it must be handled differently. Thus the same condition may need to be treated with different medicines. The first realm we might term "natural," the second "unnatural." But this dichotomy requires closer examination so as not simply to read into it influences of Western thinking.

In widespread sub-Saharan African parlance in the twentieth century, the natural realm is associated with God, or caused by God – the God of the created universe (Turner 1969: 52; Orley 1970: 137; Swantz 1970; Ngubane 1977: 22–24; Gilles 1976: 358–369; Janzen 1978: 44–49; Davis 2000: 94–5), not the God of a mechanistic Enlightenment world nor the God of puritanical retribution for human sin, as in the African Islamic or Christian view. Rather, God-caused misfortune is widely seen to be the created order of things such as the seasons and rhythms of birth and death in society and in the surrounding world. The death of an elderly person would be "in the created order," whereas the death of a child-bearing mother, for example, would be seen as "unnatural," or caused by some other human or spirit force. The unnatural source of misfortune – which may be manifested in an otherwise scientifically understood disease – may be attributed to human error or malicious motive, arising from the many inconsistencies inherent in human society, or the deceptive, antisocial nature of some individuals. This view of humanity often includes the ancestors or demigods who have a vested interest in the outcome of human affairs, especially in their clans and localities.

Paradigms in African Medical Thinking

Sub-Saharan African understandings of health, sickness and healing are often couched ideas about the nature of the world and life within it, ideas or images which offer powerful metaphors with which to make sense of suffering and uncertainty. These ideas are discernible in verbal concepts that have a deep history and broad geographical and cultural distribution and a continuing use in diagnosis, the formulation of the sickness experience, and in therapies.[6]

The first organizing idea defines an ordered structure of the body. Any disruption, negation, or distortion of this ideal suggests sickness, as expressed in a verbal cognate that extends from West to Equatorial Africa – *eela* or *ele* in Yoruba of Nigeria (Buckley 1985); *beela* in Kongo of Western Zaire (Janzen 1978, 1992). This notion often relates to a nonverbal code of three or more colors and related substances used in medicine and ritual to situate the body within a wider cosmology. Chalk or kaolin from stream banks is used to represent purity and wholeness; camwood or other red is used to represent transition and danger. Charcoal or a substitute represents human chaos. White is associated with goodness and the legitimacy of the created order. Chalk is the most widespread of these colors used in healing and ritual. For example, chalk is smeared onto the face and body to represent the presence of ancestors, white beads are strung around the body or head to represent spirit possession, flour or another white powder is used to trace the outlines of sacred space, and white sap may allude to milk or semen as sources of life. Whiteness represents the realm of the water, the spirits, and the beyond. It usually stands for the clarity and goodness of the spiritual world where human life is rooted. Usually, the colors are used in combination. Redness, smeared on the face and body, dyed into cloth, or covering a ritual object, appears alongside whiteness to suggest the juxtaposition of "the white" with transition and danger. The combination suggests power that can build up the created order but can also destroy it. Hierarchies of spirits may appear represented in these two colors. Charcoal, the remains of fire, represents the chaos and destructiveness of human life left to itself. In association with white, this chaos and energy is balanced by the clarity, legitimacy, and order of spiritual truth. Turner wrote the classic study of this color code in sub-Saharan African ritual about the Ndembu of northern Zambia (1967: 59–92).

In a second idea, balance or harmony is necessary to a state of health in the relationship between an individual and the people surrounding him or her, as well as between the human community and the natural and spiritual environment. The verbal concept *lunga* refers to a principle of health in the Zulu society of South Africa (Ngubane 1977) and the Kongo society of Western Congo (Janzen 1978) and to a type of healer in the Luba-influenced Tabwa culture of the western shores of Lake Tanganyika (Davis 2000). In regions influenced by Galenic humoral theory via Islamic medicine, balance may have the connotation of an equilibrium between the humors and between heat and cold. Balance between opposing humors or fluids leads to health, imbalance to disease.

The idea of balance or harmony often extends to relations with kinsmen, neighbors and others with whom people come into regular social contact. Social disharmony leads to resentment, anger, envy, evil-wishing, cursing, and gossip, and often finds expression in sorcery and witchcraft. Cases of illness or misfortune that seem particularly dramatic or ambiguous are commonly a cause for divination.

A third concept is that of "coolness" as grace and health, in contrast to the "heat" of conflict and ill-health (widely distributed in sub-Saharan Africa under the term *-*pod*- in connection with cooling down, being cured). Conflict and anger are often associated with heat and fire that like energy out of control can cause

M

[6] This is the most recent of a series of formulations of such broad ideas in sub-Saharan African medicine. The present essay is particularly informed by "sub-Saharan African Healing" (Janzen 1997).

great destruction, disease, and death (among the Ndembu of northern Zambia, Turner 1969: 27–31; among the Tabwa of eastern Congo, Davis 2000: 58–60). Medicines that extinguish the fire or cool the situation or sufferer are administered as an antidote to the dangerous condition. A balance between the extremes of fire and the cold of death are regarded as important for health and life (in the widespread *ngoma* ritual of healing, Janzen 1992; among the Hemba of eastern Congo, Blakeley and Blakeley 1994). The sub-Saharan African concept of the "cool" extends an aesthetic notion widely seen in the arts and in human relations into a definition of health.

Fourth, the widespread concept of "flow and blockage" is the closest to a classical African anatomy that inspires clear ideas about health and infuses numerous therapeutic practices. The prevalence of purgatives and emetics, fertility medicines, and herbal drinks in the African tool kit reflects this conceptual scheme (Janzen 1978: 170). However, the physiological coordinates are usually linked to the wider world of a person's relationships in society, if not to society itself as a body. In fact, an outside observer sees a clear homology between the physical realm of the body and exchanges in society. Both are seen as needing to flow openly to thrive. Just as food and fluids need to be ingested for the physical body to be healthy, so the body social needs to be fed with reciprocal gifts and gestures of good will. Grudges, envy, and ill will in the social body are seen to cause blockage in the physical body (Taylor 1992).

A fifth idea expresses purity, a ritual state in which the dimensions of the human world are in order; its opposite is a state in which these affairs are out of order, causing ritual pollution or sickness. Several Africanists have noted the importance of the antonymous concepts of pollution and purity and have noted practices related to these ideas in widely distributed Bantu-speaking societies (e.g., among the Kongo of Western Equatorial Africa, Janzen 1982; the Lele of southern Congo, Douglas 1966; among Nguni-societies of southern Africa, Hammond-Tooke 1981; Ngubane 1977; and in Mozambique and elsewhere, Green 1999). Pollution commonly results from mystical contamination, which in turn is caused by death (including abortion) and women's reproductive processes (birth, menstrual blood, breast milk). The distinguishing feature in all of these examples seems to be an absence of an absence of spirits, witches or other malevolent humans as the cause of distress. Pollution is an impersonal condition that can be righted by purification rituals or curative interventions. In the course of years of applied ethnomedical research in Africa, Edward Green came to believe that purity and pollution concepts represent a traditional set of natural contrasts that may have served in the past as a foundation for ideas of health and disease prevention.

Finally, sixth, there are the related notions of contagion and protection, or immunization. That microorganisms can spread diseases is in fact a relatively old idea that goes back well before the theory of microbial vectors of disease. It is a widely held notion in African thinking about health, although that which is believed to spread and infect may include ill will, poison, malefic medicines, and a variety of forces which may cause harm. A well-known example of this idea is the case of precolonial Kenya, where smallpox-infected communities were quarantined as a health measure and the healthy were immunized with a bit of fluid from the pustule of an infected individual (Dawson 1992: 96).

In most societies where this theory is found, the agents of infection are described as worms or tiny insects, e.g., *kadoyo* among the Bemba (Zambia), *iciwane* among the Zulu (South Africa), *liciwane* among the Swazi (Swaziland), *atchi-koko* among the Macua (northern Mozambique), *khoma* among the Shona (central Mozambique), and *kokoro* among the Yoruba of Nigeria (Green 1999; Foster et al. 1996). Sexually transmitted diseases are often thought to involve such infection agents.

Some scholars speak of African contagion as mystical, comparing it to pollution (cf. Murdock 1980). Yet it is not so mystical when closely examined. People become ill as a result of contact with, or contamination by, a substance or essence considered dangerous because it is unclean or impure. Africans considered in an unclean or polluted state are often kept apart from other people, since they are considered contagious until ritually purified. In central Mozambique, people believe that several kinds of child diarrhea and/or dehydration are caused by contact with polluting essences (or by eating bad or spoiled food). One source of pollution that may appear mystical is unfaithful behavior on the part of a parent: if a mother or father commits adultery, he or she acquires a contaminating essence that makes the child sick. The immediate cause is physical contact with the child, or drinking "hot," "spoiled" or "contaminated" breast milk. This belief reinforces the importance of fidelity in marriage (Green 1999: 13).

A third component of contagion theory, environmental danger, is based on the belief that elements in the physical environment can cause or spread illness. One expression of this is the notion that contagious illness can be carried in the air or wind. For example, the Bemba of Zambia believe that tuberculosis is an "illness in the air," spread by inhalation of unclean dust carried by the wind. The Bambara of Mali classify smallpox, measles, and other contagious illness as "wind illness," because only wind has sufficiently widespread contact with the body to cause outbreaks (Imperato 1974: 15). *Tifo temoya* (illness in the air) is a general Swazi term denoting illnesses that are contracted through inhalation. Colds, influenza, tuberculosis, severe headaches (probably malarial) and some types of contagious child diarrhea are examples (Green 1999: 189–90).

Recognition of this sort of contagious disease, along with sound preventive practices, can also be found in indigenous African veterinary practices. McCorkle and Mathias-Mundy (1992: 67) have noted:

> African herding strategies often reflect a highly sophisticated understanding of contagion and immune responses. For example, Fulani may move upwind of herds infected with hoof and mouth disease in order to avoid contagion; or they may move downwind so as to expose their animals to the disease, knowing that a mild case confers immunity.

Health in the Social Fabric: Shrine Communities and Cults of Affliction

The texture of society is extremely rich in sub-Saharan Africa. Social codes and the power of words are considered important to shaping health. A widespread verbal concept whose root is reconstructed as **-gidu-* refers to the role of social prohibitions, taboos, and the consequences of their violation. This is mentioned with reference to the restriction on eating or killing one's clan or individual totems and familiars. Other observers note that these prohibitions help individuals adhere to social codes in general, including health promoting restrictions on such things as overconsumption of alcohol, overeating, or health destroying excesses of any kind (Rwangabo 1993).

Another aspect of the social dimension of health is bound up in the role of human agency in sickness or misfortune, in the action of anger or ill will in a relationship, and the action or gesture to harm the other, be it an injurious word, a blow to the head, or a bit of poison in the drink or food. The single root that most frequently refers to this "human cause" of misfortune is **-dog-* or **-dok-* (part of the Proto-Bantu lexica of at least 3,000 years ago), modern derivations of which are found from Cameroon and the Kongo coast in the west (KiKongo: *kuloka*), Central Africa (Kinyarwanda: *kuroga*); to the Nguni-speakers in South Africa (Zulu: *kuthaka*).

In contemporary diagnoses of misfortune, victims will often identify a string of misfortunes and try to recall the exact words spoken by others prior to or in association with the events, drawing the logical inference that these utterances had caused, or could have led to, the bad luck. Words of warning or injurious words spoken in anger are especially suspect. Therefore, in divination, these moments are recalled so that the individuals or the relationships may be repaired. Without treating the root cause, the surface signs and symptoms cannot be permanently overcome.

There have been collective healing rites based on common afflictions or groups of devotees identified with gods or spirits considered to be the cause or medium of these afflictions. Such communities or orders have arisen and declined over time as particular constellations of afflictions have occurred. Often they have been a kind of barometer of the major dislocations and diseases in a region.

In West Africa, shrine communities and cult memberships were often associated with major shrines and cults to the earth, to the water, to nature, and to the sky, as well as to the rulers of local cities and states. Some shrines were addressed to specific conditions, such as twinship (as in the Ibeji of Yorubaland), or particular diseases, such as the very widespread shrine complex to the god of smallpox (variously Ipoona, Shapanna, Shapata). On the Guinea coast forms of gender-divided societies developed around the female Sande association and the male Poro association. These addressed many aspects of health and the public good such as instruction of youth, midwifery, social control, and hygiene. These shrine societies and cults of West Africa may well have been part of very early agrarian society, having become an integral feature of the cycles of celebrations and sacrifices.

Across Equatorial Africa this type of therapeutic ritual assembly often centers around particular issues as well, such as fertility, twinship, women's reproductive issues, the health and well-being of infants and children (Turner 1968, 1975; Devisch 1993; Spring 1978), debilitating chronic conditions, fortune and misfortune for men in hunting, mental illnesses, the survival of kin groups (Janzen 1992; Nisula 1999), and a range of social and environmental issues (Janzen 1992; Van Dijk 2000). Membership was usually made up of the afflicted and formerly afflicted, who underwent a therapeutic initiation with stages from sufferer-novice to healer-priest. These "drums of affliction," as Turner (1968) dubbed them, are often associated with the voice of the ancestors and spirits which inhabit the celebrants and are expressed in the song-dances at the core of the ritual performances. Sometimes the mark of growth or healing in the sufferer-novice is the creation of a personal song based on the ordeal of suffering, a dream/vision, or other moving experience. Such a song constitutes a unique set of powerful words, recalling the cognate *dok*, that offset and overcame the destructive forces of disintegration, misfortune, sickness and chaos of the previous period of the individual's life. Where such a "drum of affliction" addresses community issues, the healing ritual may be directed to the community, and society becomes the body that is cured (Fig. 4).

These cults and shrines have related to Christianity and Islam for centuries. Sometimes the African institution has absorbed the outside idea or symbol, in other cases Christian and Islamic institutions have recreated the African forms and substance. Especially widespread in sub-Saharan Africa are the Independent African Churches, many of which encourage healing, exorcisms, and various kinds of incorporating rites of purification, protection, and sanctification (Sundkler 1976; Jonker 2000). Prophet-founders play the role of ancestor-mediators, while prominent or talented members assume the diagnostic role of diviners.

Although orthodox Muslims frown on blending Islam with African indigenous religion, the interpenetration of Islam and African ritual healing is extremely common (among Hausas of Northern Nigeria, see Abdullah 1992; Wall 1988). *Jin* and *amasheitani* spirits widely cohabit the spirit worldviews of ngoma associations in Eastern and Central Africa. Muslims healers of the Swahili coast have long practiced ngoma as part of their medicine kit, along with reading the Koran; the purification symbolism of African healing merges with that of the ritual ablutions of Islam in connection with prayer. In northern Swahili towns such as Lamu, early twentieth century ngoma Maulidi was introduced for performance in the mosque; its songs celebrated the prophet Mohammed, much to the chagrin of fundamentalist Muslims.

New Health Crises and the Relegitimization of African Medicine

The financial crises of African societies, and the search for an infrastructure of health, have led planners to take a second look at African institutions such as cults of affliction and the education of healers. By 1998, findings from a survey by the World Health Organization's Regional Office for Africa showed that a national management or coordination body for traditional medicine activities existed in 17 of 30 countries surveyed. Twenty-two indicated that associations of traditional healers had been established, and ten said that a national directory existed. Four countries reported that a training program for healers existed (the actual number would surely be higher) and 17 countries had such programs for traditional birth attendants. Twenty countries indicated that institutions in their country were carrying out research related to traditional medicine. Fifteen reported that there was local production of indigenous medicines, and 17 countries reported having botanical gardens or arboreta for cultivating medicinal plants (WHO 2000).

Research related to the medicinal value of plants in the African materia medica is important for several reasons related to public health (1) achieving community or national self-reliance in health by promoting locally available and already-accepted herbal medicines; (2) developing an indigenous pharmacological industry, based on local plants, that reduces national dependence on expensive, imported drugs; (3) promoting natural health care and reducing the iatrogenic effects of modern medicine; (4) finding out what traditional healers are using and, if medicines are found to be dangerous and highly toxic, trying to persuade healers to substitute safer plants or at least reduce dosages; or (5) finding an effective-seeming indigenous medicine for the symptoms of a high-priority illness such as child diarrhea, then finding ways to promote more widespread use of the medicine (Green et al. 1994: 44).

Medicine in Africa. Fig. 4 (Continued)

Medicine in Africa. Fig. 4 "Doing ngoma" in Guguleto Township, Capetown, South Africa, 1982. This composite shows the essential elements of a very widespread Central and Southern African therapeutic ritual. Lower left, two novices provide the drum rhythm; upper left, other novices sing-dance and "confess their dreams" to novices and a few senior healers; right, a trained graduate of ngoma leads this particular event with her bold sure step and her colorful clothing and beadwork, which represents her well-developed sense of self in contrast to the novice-sufferers, who are entirely "white." (Photo by Janzen.)

Preliminary pharmacological research is showing that phytomedicines (medicines derived from plants) used by African healers may indeed be effective for diseases in three of the most severe current public health crises: schistosomiasis and childhood diarrhea.

Ndamba et al. (1994) analyzed the most commonly used plants used to treat schistosomiasis by 286 traditional healers in Zimbabwe, administering the crude extracts orally to hamsters infected with *S. haematobium cercariae*. It was found that plant extracts from *Abrus precatorius* (Leguminosae), *Pterocarpus angolensis* (Leguminosae) and *Ozoroa insignis* (Anacardiaceae) were lethal to adult schistosomes. In a study of HIV-positive Ugandans with Herpes zoster, herbal mixtures used by healers were found to be at least as effective as biomedical treatments, including the antiviral drug acyclovir, in treating symptoms (Homsy et al. 1999).

Recent phytochemical research has shown that the roots of *Mirabilis jalapa*, used in South Africa as a purgative to treat some child diarrheas, in fact exhibit antibacterial activity against an impressive range of diarrhea-causing pathogens: *Staphylococcus aureus, Streptococcus pyogenes, Escherichia coli, Enterobacter sp., Vibrio cholerae, Shigella flexneri* and *Salmonella typhi* (Chifundera et al. 1991).

At the World Health Organization Forum on Traditional Medicine in Health Systems held in Harare in 2000, the African Regional WHO office expressed keen interest in the mass production of phytomedicines for the treatment of malaria, AIDS, and other diseases identified as priority diseases by member states. It is a strategic objective of the WHO to develop a framework for the integration of traditional medicine into national health systems. The idea is to encourage local industry to invest in the local production of indigenous medicines and make them commercially viable. Governments were urged to create policies related to conservation, safety and toxicity, and regulation in order to assist a local production industry (Green 2000) (Fig. 5).

Mass production, promotion, and distribution of African phytomedicines have begun. For example, Nigeria has developed medicines for ulcers, anemia, contraception, malaria and HIV, and it now holds patents for some of these in several countries. In late 2000, Nigeria became the first African nation to officially promote a plant medicine for the treatment of HIV/AIDS.

The ratio of traditional healers to the general population of various African countries seems to be in the range between 1:200 and 1:800, based on surveys and censuses (cf. Green 1994: 19 for a review of studies). In Mozambique, a doctor theoretically serves about 10,000 people. In practice, coverage is even less. Most doctors live in larger cities, while most rural Africans are lucky if they live within 5–10 km of a clinic staffed by a minimally trained nurse, where medicines may or may not be available (Fig. 6).

It is widely accepted that at least 80% of Africans rely on traditional healers for much or all of their health care. This had led some that work in public health to think that healers ought to play a role in curbing the spread of infectious disease. From a public health viewpoint, this would seem to make sense. Healers are found everywhere; they are culturally acceptable; they explain illness and misfortune in terms that are familiar.

M

Medicine in Africa. Fig. 5 An example of African medicine given a modern scientific basis and commercialized. Dr. Byamungu Lufungula, left, French trained pharmacist, stands before instruments in his laboratory in Bukavu, Kivu, Eastern Congo. In 1994 his enterprise, SODIPHAR, employed 25 workers. Pharmacies in Goma, Bukavu, and Uvira sold about 20 products, all based on laboratory tested traditional medicines obtained in collaboration with herbalist healers. Byamungu is the author of *Les Plantes Médicinales, Les Rites Therapeutiques, et Autres Connaissances en Médicine des Guérisseurs au Kivu*, 1982.

Medicine in Africa. Fig. 6 Indigenous South African healers collaborating in public in AIDS prevention program, 1993. (Photo by Green.)

Medicine in Africa. Fig. 7 South African diviner-mediums (traditional healers) teaching each other biomedical ideas about HIV/AIDS, in a USAID-sponsored workshop in Tsitsikama, South Africa, 1993. (Photo by Green.)

In the 1970s there were several collaborative programs involving traditional healers in areas such as child diarrheal disease and family planning (e.g., Green 1987, 1996; Good 1987; Warren 1989) (Fig. 7).

With the explosion of HIV/AIDS in east and southern Africa, an even greater number of collaborative programs developed. In southern Africa, once they had participated in workshops on AIDS and sexually transmitted diseases (STDs), healers proved willing to promote condoms and safe sex. Once it was accepted that standard STDs facilitate the transmission of HIV, it occurred to some that healers ought to be involved in STD treatment programs – at least through referrals to clinics – since patients with STDs so often consult healers. Moreover, avoiding AIDS by sticking to one partner usually made sense to healers because they already interpret locally recognized sexually transmitted illness as resulting (at one level at least) from violations of the codes that govern proper sexual behavior and exposure to essences believed to be polluting (reproductive fluids, death). They feel encouraged to learn that their own governments as well as the international community *also* wish to warn people against having sex with "just anyone," with too many people, with strangers, with prostitutes, or with someone other than one's wife or husband. Finally, with drugs and hospitals in short supply, healers are already caring for a large proportion of those already infected with HIV. UNAIDS, the United Nations agency for coordinating HIV/AIDS programs, recently published an official "Best Practices" paper summarizing the role of healers in HIV/AIDS prevention and support programs, which concluded that they have made a substantial contribution (King 2000), although the situation regarding HIV in Africa remains grim.

Medicine in Ancient Egypt

Hedvig Győry

In pharaonic time people saw their everyday life as a mixture of rational facts and supernatural phenomena, and the healing texts and the relating archaeological artefacts reflect a similar double-sided medical attitude as well. According to their beliefs, each illness had two causes. One was of direct origin, caused by an invisible pathogenic material personified, such as a disease-demon, an evil spirit or an animal, or an object of the material world. The other was of indirect origin, caused by a god or goddess who was malevolent or who punished the patient, or by a curse invoked by individuals. This meant that the curing process had to be directed both to the physical and the divine world. One had to appease (*sḥtp*) the appropriate god or exorcise the evil spirit or demon by religious or magical means and to fight the physical symptoms by the application of a remedy or physical treatment.

As the Egyptian themselves summarised, "Magic is effective together with medicine. Medicine is effective with magic" (Eb.2).

Sources

The study of ancient Egyptian medicine is based on various sources. The most complex are the ancient Egyptian texts from the pharaonic period, which instruct us not only about the scientific knowledge of the time but also about the way of thinking and the results physicians expected of their intervention. The medical anthropological study of human remains demonstrates the level of efficacy of ancient medications together with the general state of health of the population. There is also a good deal of analysis of the chemical–physical properties of pharmaceutical preparations that were used or applied in given cures.

In addition, scholars are able to look at religious, magical, historical, sepulchral, epistolary, and other types of texts written either by Egyptian or foreign people, archaeological and art historical finds or buildings, and (paleo)ethnographical parallels. All these sources are, however, not enough to provide a detailed medical overview of the complex of medicine in any period of ancient Egyptian history. The best-known period is the New Kingdom as most of the Egyptian medical literature known today relates to it. By contrast, the scientific analyses of the mummies are performed on mostly Late Period or Graeco-Roman mummies.

Healing Papyri and Ostraca

The healing texts, known from papyri (see Note 1) and ostraca (a potsherd used as a writing surface), can be divided into medical and medicomagical (=iatromagical) ones. Iatromagical spells are constructed the same way and contain exactly the same expressions such as in any other type of traditional magical spell, but the purpose stressed is medical – the annihilation or elimination of a disease-demon, the invisible enemy of the health of the patient. There are also prayers to various deities. The term medical papyri means those texts which deal with the physical reality of a disease. The mixture of medical and iatromagical texts is also common.

Medical spells can have several genres. Most of the extant medical papyri consist of prescriptions (*pẖrt*), which just name the disease to be treated or say, "another one", followed by a list of materials and key words for the preparation process. These were sometimes finished by an evaluation such as "proved a million times". Texts relating to paediatrics and obstetrics often contain prognoses. Surgical case studies are documented in instruction form (*sšꜣw*), which contains both diagnosis and therapy, if needed.

The papyri are usually compilations of different "books", often comprising groups of prescriptions. The original books seem to be arranged by the parts of the body the therapy had to be directed to, but the extant papyri often contain several books (or parts of them) mixed in with each other. Thus they were copied from various scrolls for practical guides to medication or for teaching or reference purposes. Only a few might be a copy of one original book, centred around one medical topic, such as curing methods (trauma in the Smith papyrus) or treatment of the same part of the body (such as the Kahun papyrus).

Many tracts must have been destroyed down through the centuries, but, according to ancient Egyptian traditions, the earliest medical book – an anatomy – already existed during the reign of Djer or Dewen, kings of the first Dynasty. If this is so, it must have been a list of anatomical expressions. Recipes are also attributed to Old Kingdom persons, such as the mother of Teti, sixth Dynasty (Eb.468), and spells against snakebite are listed among the Pyramid texts. In the tomb of Uash-Ptah we can read on the wall that he collapsed in front of Noferirkare, king of Upper and Lower Egypt. The pharaoh then sent for a physician who returned with a book to look up a possible way to save him, unfortunately without success. The known medical papyri originate beginning with the Middle Kingdom, and the last we hear about are mentioned by Clement of Alexandria (second half of the second century AD). He knew about six Egyptian handbooks devoted to specific aspects of medicine such as anatomy, illnesses, surgical instruments, drugs, eye diseases and gynaecology.

Human Remains: Mummies and Skeletons

Paleopathology is a relatively new branch of science. For a long time it relied entirely on bones. Thus, it meant not examining the mummy, but during the autopsy everything was taken from the bones: wrapping, funeral goods, skin, soft tissues and muscles. The pioneer of its systematic application was Sir Marc Armand Ruffer, from the Cairo Medical School (1896–1917), who also changed to a scientific means of examination. He introduced regular X-ray examinations, which were first made for an Egyptian excavation in 1898, for Flinders Petrie. This is a non-invasive method to learn about possible diseases or fractures of the body, or to discover the cause of death. Even so, the destruction to artefacts and skeletons did not stop. Today's methods are much more subtle and much less harmful. This is especially the case with computer tomography, which also helps in reconstructing a "living picture" of the examined person. The aim is now to get maximum data with no or minimum destruction. With very few samples (taken for instance by fibre-optic endoscopy) it is possible to determine the blood group, the DNS/DNA or the antigens of various infections. Scientific examinations resulted in finding severe infections from worms such as taenia (tapeworm), ascaris (roundworm), draconculiasis (guinea worm), strongyloides, trichinella or schistosoma. Bacterial and viral infections, such as tuberculosis, variola (smallpox) and mastoiditis (middle-ear inflammation) are also attested.

The arteries reveal the existence of arteriosclerosis; mummified lung tissues reveal sand pneumoconiosis, pulmonary tuberculosis or (probably lobar) pneumonia. The alterations and deformations of the bones demonstrate arthritis, periostitis, ostitis, osteomyelitis, osteroporosis, osteochondrom, multiple basal-cell naevus syndrome, pelvic contraction or vesico-vaginal fistule, and several types of tumours. Growth disturbances (indicated by Harris lines) together with various types of distortions of the backbones reveal spondylitis, scoliosis or Pott disease. Different types of innate distortions of the skull point to acrocephaly and hydrocephaly; other bones indicate achondroplasy, Klippel-Feil-Syndrom, talipes equinovarus or other disorders. The teeth are usually worn out and abrased, or else they have tartar or abscesses, if they are not missing. Caries are present mostly from the Ptolemaic period. By the mummification of the inner organs it is also possible to examine the parts of the body, which show signs of anthracosis, silicosis, pneumonia, lung-emphysema; kidney hyperplasia, abscess, calculus, bladder stones; gallstones, cholecyctitis; liver fibrosis; megacolon, prolapsus recti and several other diseases.

To what extent did the ancient Egyptian prosthetic medicine work for living persons? Some mummies are outfitted with prosthetic devices. In cases of the nose or stick legs, they were probably made for the afterlife, but some others might have been used. This is the case with a woman, probably in her 50s, in the Theban T95 tomb from the twenty-first Dynasty, who had an artificial wooden big toe.

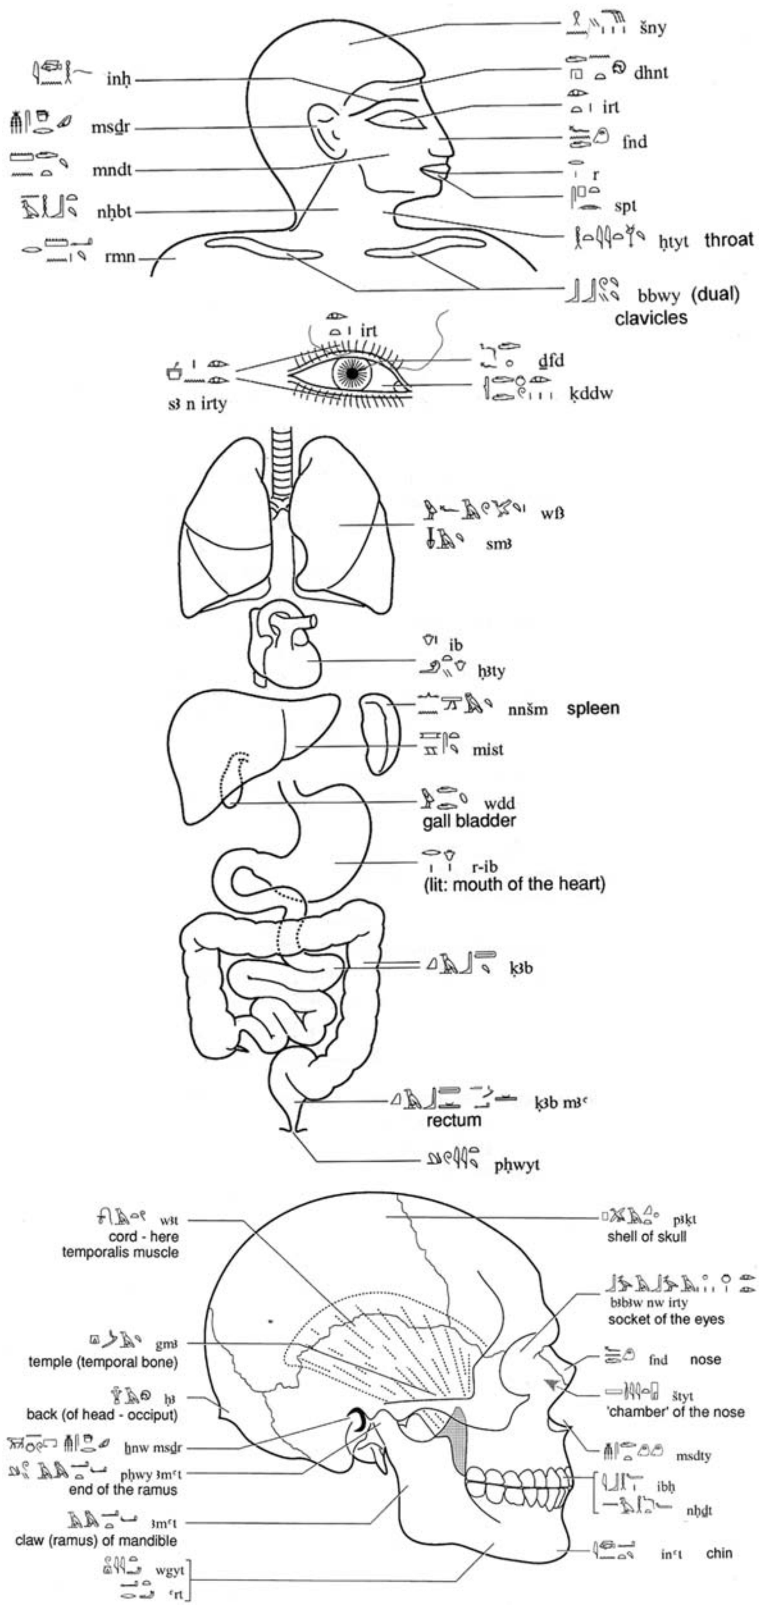
Theoretical Background

Anatomy and Physiology

Ancient Egyptians had advanced anatomical and physiological knowledge. It must have been due to extended observation but also to the custom of mummification. This was a completely different science in the pharaonic period, and according to the data known today, persons executing it were never healers and had no connections to physicians. Characteristic to Egyptian culture, both fields of science had many specialised books, which were kept in libraries – available for every professional, which might mean a reciprocity of giving and receiving knowledge by embalmers and healers. Another opportunity for gaining similar experience might be from accidents or battles. For instance, the process of emptying the skull through the nostrils (a route applied often in modern brain surgery) by means of a long hook attests to a good knowledge of the anatomy of the head and brain. The exact description of the latter is given very vividly in the Smith papyrus (Sm.6). They obtained reliable information about the meninges, the cerebrospinal fluid, and twitches and pulsations, and they noticed a connection between the state of the brain and body control, although they did not develop it into a theory. A similar feature can be observed at the spinal cord, the dislocation of which was connected to paralysis of the four limbs and incontinence (Sm.31), although the nervous system is not mentioned.

Their main concern was directed to the heart. Its position was described precisely, and some of its disorders, such as missed beats, were discussed. It was recognised as the centre of a circulatory system, where the various *mtw* – "canal" systems – met. They seem to have had two different schools for anatomical explanations (Eb.854, 856, Brl.163) concerning the numbers and roads of *mtw*. The *mtw* supplied the body with every substance it needed. They thought the blood vessels contained air in a healthy and blood in an ill state. Their vessels were thought to be hollow and have a mouth. The heart "spoke" through them, as they determined the pulse, and told the physicians at any part of the body about the general state of health of the patient. By this they recognised the peripheral pulses, but they were not aware of the circulatory system in a modern sense. All the fluids in the body, including air and blood, but also any type of body secretion, excretion and discharge flowed in a series of these interconnecting canals in the human body. The system was described based on everyday life: fluids and pathogens or even disease-demons were sailing there like Egyptian people were said to sail on the water of the Nile or its tributaries, with the Sun in the sky or on the river of the Afterworld. Thus *mtw* meant any blood vessel (veins and arteries), ducts or passages in the body, but they were also used as the technical term for muscles, tendons and nerves.

Ancient Egyptians sometimes used in the medical literature different words for a part of the body than were used in everyday life (for instance *wfꜣ* for *smꜣ* as lung). For the names of body members see Fig. 1a–c. The vocabulary was rich for external parts, but relatively few names remained for the inner parts of the body. For instance, the kidney is not mentioned at all, though some hieroglyphs show such organs (lung and heart as *nfr*, heart as *ib*, intestins as *pẖr*), but with



Medicine in Ancient Egypt. Fig. 1 Body members with their ancient Egyptian names. Source: Nunn J.F., Ancient Egyptian Medicine. British Museum, London, 1996, Figs. 3.3a,b and 3.4.

M

animal origins. They knew very little about their function. Regarding the respiratory system, they knew that the *tȝwnʿnḫ* (breath of life) entered through the nose, and then the heart and the lung gave it to the entire body (Eb.855a). There was another type of breath – the "breath of death" – which entered the body through the left ear (Eb.854f). The concept of the digestive system was also simple; food and drink went to the stomach, and part of it left through the anus. The details are unmentioned and, based on the treatments of the disturbances, they seem to not have been understood at all.

Pathology

Physicians often treated internal cases, where they could not see the alterations of the organs. They developed their concepts based on symptoms given by the patient and on exterior alterations of the body or of the given organ, experienced by palpation. Patients thought they had become ill because of an outside disease matter; namely the name of diseases was written in several cases by the figure of a god at the end. Among these "disease demons", as they are called today, an enigmatic one is the *wḫdw*. The verb *wḫw* means "to suffer". This pathogen afflicted many organs, causing suffering for the patient, and is a designation for all sorts of symptoms which changed their location. This meant that the *wḫdw* was wandering in the body (Eb.856). All the disease matters and demons entered the body from the outside world by natural or occasional openings. Thus, an important part of the cure and the prevention of morbidity was the physical and magical protection of the openings. A next step could be the cleaning of the *mtw*, the route of travelling of these elements. This theory is also the explanation of the frequent use of enema in treatments.

As the same treatment in a seemingly same case could end, however, with different results, they thought to seek for help in the divine world. This was important at each step of the treatment: from choosing the materia medica and the devices, preparing and administering the drug or performing the operation. This way they aided recovery not only by their medical knowledge but also by favouring the patients with psychological conditioning.

Medical Practice

Egypt was famous in the ancient word for its hygiene. Egyptians often cleaned themselves and their belongings. For this they used natron, ashes, or soda which are all good detergents and dissolve fatty matter. Probably it was also an important factor in the care of the sick. Another aspect is drug administration which was often carried out at home, without professional help. This is what Homeros hints at, saying that everybody living in Egypt is a physician, for the whole population there originates from Paieon (*Odysseia* IV, 231–232).

Medical practice included the use of herbal remedies, but also surgery, various types of physical treatments, religious invocations and as an essential part, magical incantations. For the cure, healers had to handle problems concerning medical history, examination, diagnosis, prognosis, and various means of treatment if they were general practitioners or specialised in various fields of medicine.

Way of Examination

Medical practice was performed in a systematic way. According to the available clinical descriptions, before any treatment could be administered, a detailed history taking and questionnaire took place. The first course of action for the physician was to make a diagnosis, employing his powers of observation and experience to detect as many symptoms and to elicit as many signs as he could for determining the nature of the disease. He referred then to the medical papyri to determine the most appropriate course of treatment. Normally, this would take the form of a potion, unguent, ointment, balm, pill, poultice, enema, suppository or an eye lotion comprised from a concoction of natural ingredients.

The case study comprised several steps:

1. Interrogation of the patient
2. Detailed inspection of the face and skin, smell of the body, urine and faecal matter, palpation
3. Percussion of the body and diseased organs, functional testing
4. Diagnosis and verdict ("An ailment which I will treat", "An ailment which I contend" or "An ailment not to be treated")
5. Treatment

Treatment

Contrary to the statement of Herodotos (II.77), physicians seem not to have been concerned so much with prevention of an illness, but rather with treatment of an ailment, using all the means at their disposal. And they had many. Unfortunately, we do not know details of them, as the texts are very limited. It is, however clear, that the physician gave patients medicaments, or he prescribed rest if needed (Kah 10). The duration of the treatment is often omitted, but it is sometimes specified by exact days (most frequently 4), or paraphrased (typical in the Smith papyrus: "until he recovers", "until the period of his injury passes by" or "until you know that he has reached the decisive point").

If medicine was prepared and administered according to the physician's teachings, he was exempt from all blame if the treatment did not work. However, if he deviated from the traditional remedies and tried to increase his knowledge through experimentation, he risked losing his life if it failed (Diodoros I.82). These principles may have hindered changes in the medicine of Ancient Egypt.

Drug Therapy

Drug administration was the most popular method; drugs were either prepared by the physician himself or followed according to his instruction by an apprentice. Most of the medical texts describe a sole treatment. Medicaments contained a multiplicity of drugs simultaneously. The choice of selection seems to have been influenced by magical considerations. As a vehicle they usually used wine, beer, mothers' milk, oil or grease (*mrḥt*) or honey; they used also active drugs in their own right; in addition to the most common, water. *mrḥt* came in many many varieties, according to the plant or animal it was extracted from or made of. The measures were usually given in units or fractions expressed by the drawing of the components of the *wedjat* eye. The means of their utilisation is usually very short. It was a secret science. The chemical knowledge of the Egyptian physicians was so vast that some would attribute the origin of the word "chemistry" to "Kemet", the ancient name of Egypt.

The preparation process not only had its own rules, but also the administration – method, timing or dosage – was sometimes also specified. Some of these were very complicated. Regulations adhered to the same guidelines physicians apply today. In some prescriptions even the dosage of the different drugs was adjusted to the patient's age: "If it is a big child, he should swallow it like a draught, if he is still in swaddles, it should be rubbed by his nurse in milk and thereafter sucked on 4 days" (Eb.273).

Surgery

Surgery was considered in trauma and in a few cases of tumour and swelling. Based mostly on the Smith Papyrus, the simplest repertoire of surgical procedure is known, but these reveal a remarkably scientific manner and clean environment. There is, however, no mention of any sort of anaesthesia. Bandaging, stitching, bounding with oil and honey belonged to the usual wound managing. Infection of the wound was regarded to be a normal step of recovery. Evidence of operation is very sporadically attested on mummies. Fracture reduction was found a bit more frequently, and it was often successful, as were dislocations – also healed according to Kocher's method.

Complementary Therapies

The ancient Egyptians practiced several other therapies. In the tomb of Anh-mahor (sixth Dynasty, Saqara) a sort of physiotherapy or reflexology might be inferred: the manipulating of fingers and toes were depicted. Chambers equipped with basins were found near Dendera temple, suggesting hydrotherapy in the sanatorium by the use of healing statues. Again they used the ultraviolet of the sunrays (heliotherapy) by exposing an anointed ill body in the sunshine. The treatment by mud and clay was also known (Eb.482).

Magical practices

One of the most powerful tools in the healer's armoury was magic. It was regularly used in conjunction with rational medical practices. Some materia medica seem to be chosen mainly on the magical character assigned to them, such as virgin's urine, crocodile excrement, black pieces of bull hair, or tortoise bile. The administration of the medicament, as with surgical intervention, was also accompanied by prayers and offerings or magical spells addressed to malign or angry deities. In addition, some objects sacred to certain gods or provided with supernatural properties or deemed as a reminder of a myth might give additional help in various other forms. They might be amulets, drawings, statuettes or tiny steles, or using an object as a model (e.g. crocodile statuette in Chester Beatty V. 4, 5–9) (Fig. 2).

If the medical treatments were deemed not to be working, the healer could call solely upon the divine world for destroying "the enemy". Predominantly benign deities, in particular Isis, Horus and Ra, were usually invoked. As expectations and environmental effects have measurable curative value, this was widely employed by ancient healers. Their emphasis on magic was an even more powerful psychological opportunity, the application of which improved therapeutic efficiency. In many cases, especially after attacks of animals such as snakes or scorpions, the spell casting activity of the healer–priest seemed to be decisive. It was thought to be the only treatment for a long while. After the publication of the Brooklyn Herpetological Papyrus, however, prescriptions became known which provided a very deep knowledge of snakes and the effects of their poisons.

Materia Medica

Pharmacology was a secret part of the physicians' studies and knowledge. There are a great variety of materials which cannot be identified, regarding the amount and quantity of usage, or time and way of gathering the raw material; these were guided by experience and theological concept. Physicians prepared the remedies themselves. They were made from natural ingredients, in raw or prefabricated conditions, such as:

- Small amounts of (toxic) *minerals*, like copper oxide, sulphate, antimony, zinc, lead, arsenic, malachite, natron, common salt, haematite, chalcedony
- Various parts of more than 200 *plants*, with about only a fifth identifiable with certainty. Among the

M

Medicine in Ancient Egypt. Fig. 2 Small Horus stele amulet in the Museum of Fine Arts, Budapest.

common plants were fenugreek, sycamore, castor oil, acacia gum, carob, wormwood, juniper, Cyprus grass, cinnamon, date, lotus or sycamore fig. Vegetal components were collected not only in Egypt itself, but were also imported (such as the mineral lapis lazuli)

- *Animal* parts (meat, milk, fat, blood, skin, hair, bile, liver, brain matter, urine, or excrement)
- *Human* body products, such as milk, sweat or blood

Ancient Egyptian prescriptions do not say which elements were expected to exert pharmacological effect and which were used as a vehicle, or added for taste or general conditioning capability. Some constituents were used very extensively in most cases, but the texts often do not give the reasoning. The choice of the material changed during the history of ancient Egypt, which is well reflected by a comparison between New Kingdom and Roman time medical papyri, but it is impossible to follow the process because of our lack in knowledge of the time in between.

Instruments

As medical treatments consisted of rational and magical components, they required both medical devices and magical instruments.

Medical Devices

Healers required some objects for storing substances (such as special milk jugs, kohl pots, jars) or for preparing drugs, such as perforated plates for straining (*ʿtḫ*), bowls for getting a homogenous mixture (*m ḥt wʿt*), pots for grinding (*nḏ*) and cooking (*ps*), small measures for volumes (the most convenient are *hnw*, approximately 450 ml and *ro*, approximately 14 ml) or sticks and spoons for the mixing procedures. For enema there were some sort of clysters; for fumigation there were burners. All the devices needed had to be packed in the house or sometimes in a bag to take to patients.

For the treatment of injuries we find “fire drill” which consisted of a stick and board used for starting fires by friction, as a cauterising tool, and various types of bandages. From the New Kingdom onwards, they used small metal knives as well as tools such as hooks, forceps, “disposable” lancets and blades fashioned from reed stems, spatulas and spoons.

In Kom Ombo, the Antonine (Roman) period inner decoration of the surrounding wall of the Sobek and Haroeris temple bears a table of surgical instruments, divided into four horizontal rows. The relief shows knife blades, a saw, spoons, spatulas, forceps, pincers, small bags, a small scale, specula and *wedjat* eye amulets. In the bottom register there are two round forms (possibly vases), a papyrus scroll, two packages for needles or small instruments, an oval object, needles and cleaning tools.

Magical Instruments

As magic and religion played a major role in treatment, magical instruments were also important. Amulets, models and other magical objects such as knots, magic wands, statuettes of gods and “concubine statuettes”, bowls, representations of symbols and scenes or various inscriptions were generally used. Some of them had a specific aim; others had a wider range of applicability. As these practices changed continually, we can specify the time of their use. For instance magic wands was used almost exclusively during the 12–13th Dynasties while the Horus-cippi, which repelled reptiles and cured people who had been bitten, started to appear during the eighteenth Dynasty and stopped after the end of the Ptolemaic era.

Diseases

Degenerative diseases tend to afflict people the same way; other diseases are dependent on environmental factors. These were different in antiquity not only because of the thousands of years during which the virulence and geographical boundaries of many pathogens (and hosts) could have changed significantly but also because of alternating ethnical mixtures of people and changes of life patterns such as diet, way of life, quality of air or geographical factors. There are some which are already extinct. Thus the pathogens were less or more different, and they could cause slightly different symptoms. Examinations of the human remains reveal, however, that diseases usually resulted in the same conditions as they do today.

About 300 diseases are mentioned in ancient Egyptian texts. They are very hard to identify, because the prescriptions usually do not give any or enough description. Moreover, several diseases mentioned are only signs or symptoms (heat, cough, vomiting, obstruction, voiding of blood), which can occur in many diseases. Disease descriptions are also inaccurate for today's diagnoses. For instance the so-called "Asian disease", described very vividly in H.170, has been interpreted differently: bubonic plague (Goedicke), leprosy (Bardinet) or smallpox (Győry). Ancient Egyptian medicine paid detailed attention to the anus. Nevertheless, it is difficult to find a technical term for constipation or diarrhoea, though many remedies cleared the bowels and stopped evacuation (*wsš*). There is no doubt in the meaning of *gs-tp* – "half head", modern migraine (Eb.250, ChB V.4), and the probability is high in the identification of the passage Brl.67 as facial nerve paralysis (Bell's palsy). Due to the widespread nature of dental disease, halitosis (bad breath) must have been a common complaint. A prescription has been discovered to combat this condition.

Another difficulty in understanding ancient Egyptian medical texts is that a lot of words have specific medical meanings, which are only rarely explained in a gloss. Some of them were not well understood even during pharaonic times. That is the reason we have glosses in the Ebers and Smith papyri. Thanks to them, we know much more about surgery and healing wounds than about any other medical cases. In the Smith papyrus, case 7 gives for instance a very plausible description of tetanus.

Prescriptions often speak about worms, as several disease terms are determined with the sign of a snake, the hieroglyphic sign also for worms. There seem to be only two, *ḥfꜣt* and *pnd*, with a sense of a specific worm. And there is no clue for the identification of these two. Several types of vermifuges were used against them, such as pomegranate or wormwood in medical texts or garlic, radish and onion in everyday life, but they are not specific. We have a nice description for the treatment of dracunculiasis (Eb.875), but the worm taken out over a painstaking month is not given a specific name. There is a possibility that the snakes for the emblem of Greco-Roman and modern medicine (caduceus) may be related to this procedure.

Ancient Egyptian representations could be a big help, because they were often accompanied by explications. The medical papyri are, however, not illustrated, and the reliefs on tombs give ambiguous information for medical interpretation. Servants are often represented as humpbacked. We do not know whether this represents poor posture or the result of a disease, such as Pott's disease, ankylosing spondylitis, porter's hump or a sort of fracture. The representations with gynaecomastia or elephantiasis are no better; they can be caused by several diseases, most often by schistosomiasis or filariasis. Similarly, the picture of the equine deformity of the foot of Rama can be the representation of either poliomyelitis contracted in childhood or a variety of clubfoot. The dilemma is the same with the mummy of pharaoh Siptah. The stela of Bak shows him with a high probability of having Simmer's fibrosis caused by schistosomiasis. The case of Seneb, who is sitting beside his wife on a statue from his tomb in Gisa, is a classic example for achondroplasiac dwarfism. But dwarfism was not considered a disease.

The Healers

Health was very important for ancient Egyptians. For many maladies, however, they needed special health care performed by specialised physicians who were remunerated for their services in barter and money-barter by the state or with gifts by private persons. They worked usually on their own, as pharmacists, nurses or midwives.

Herodotus (II, 84) attests in the fifth century BC that

> The practice of medicine is so divided amongst them that each physician treats one disease and no more. There are plenty of physicians everywhere. Some are eye doctors, some deal with the head, others with the teeth or the belly, and some with hidden maladies…

A similar picture is reflected by the medical titles of the Old Kingdom and Late Period among the *swnw*, the ancient word for physician (from the root word "*swn*" meaning "to suffer pain".) The hieroglyph contained the sign of an arrow, which might lead to a possible origin of the occupation such as removing arrows from the injured, or it might allude to Thoth, who not only gave written instructions but also cared for the wounded in battle.

Another type of physician were the priests of Sekhmet, the lion-headed goddess who dispensed disease especially at the end of the year, or cured it. They were called "the wab-priests of Sekhmet, who can dispel evil spirits". They are thought to have been surgeons and might also be veterinarians. A third type of healer was the magician, called *sꜣw* (the protector). These three main categories of healers might function simultaneously for a given patient. All of them could perform the classical medical examination, including palpation. The main difference among them was their way of approaching the disease and consequently the treatment. All three functions could be united in one person as is the case with Hery-shef-nakht (Hatnub, twelfth Dynasty).

The magician healer used mostly magic, which did not exclude operations or medicaments prepared according to the medical prescriptions. His fields were probably centred around fertility and severe illnesses hardly or not curable by physical treatments. They might also be specialised in some diseases; for instance, some healers of the first decades of twentieth century's Egypt (AD) only took out maggots from the eye. Very specialised, the *ḫrp Srḳt* (a sort of priest to the scorpion goddess Selket) dealt only with scorpion stings and snakebites by the recitation of spells and incantations. Surgeons used a "knife-treatment" operation for a wide range of cases, although the act was preceded and followed by religious acts such as offerings, prayers or incantations. The *swnw* were concerned with pragmatic medicine, but again with some divine help.

They adopted a rather elaborate hierarchy system for the health service, with titles such as:

- *swnw* – physician
- *ḥry-swnw* – one with authority over physicians
- *imy-r-swnw* – overseer of physicians
- *wr-swnw* – chief physician (possibly *smsw-swnw* – eldest physician in some cases)
- *sḥḏ-swnw* – inspector of physicians

During the Old Kingdom and Late Period there were many specialists in the different fields of medicine, such as the *swnw jrtj* (ophthalmologist), *swnw ẖt* (physician of the abdomen; i.e. gastroenterologist), *nrw pḥwy* (shepherd of the anus; i.e. proctologist), who probably administered enemas; or *jryw-jbw* (dentist) and *jr-jryw-jbw* (great of those who are concerned with teeth), first given to Hesy-Re in the royal palace of the third Dynasty. Besides the palace, the army also had its own physicians, as well as some social groups such as the royal tomb builders, or miners. Some physicians held several specialised titles, such as Ir-en-akhty (First Intermediate Period), who was both court physician and their inspector, as well as proctologist, ophthalmologist, gastroenterologist and *ꜣʿʿ mw m-ẖnw ntntt* (interpreter of the liquids in the intestines(?)).

The ancient Egyptian physician was generally educated and trained by his father and relatives or within the temple schools and libraries, the so-called *pr-ʿnḫ* (house of life). The most famous New Kingdom medical institutions were in the temples of Heliopolis and Sais. Pupils underwent a formal apprenticeship under an acknowledged master. Training was so successful that Egyptian physicians became renowned throughout the ancient world for their skill. For instance, at the request of Hattushili, Ramses II despatched a physician to the Hettite court and later, at the request of Cyrus Amasis II, sent an Egyptian ophthalmologist to the Persian court. Many Greek people wandered to Egypt to learn from the Egyptians. Even Hippocrates highly esteemed their knowledge; he used the same method of reaching a diagnosis and deciding on a plan of action.

The title of *swnw* was held in high esteem in Egypt itself. More than 150 names of *swnw* have survived. Being an overseer of these was an important rank: Mereruka (son-in-law of pharaoh Teti, sixth Dynasty) was proud of being *jmy-r gswy dpt swnw prʿꜣ* (overseer of the two sides of the boat of the physicians of the pharaoh). There is one story of a female physician: the mother of Akhet-hotep (fifth/sixth Dynasty) was their overseer – *jmj-r swnwt*. Moreover, two persons without known contemporary evidence of bearing this title – Imhotep, the royal chamberlain to Djoser (third Dynasty) and Amenhotep-son-of-Hapu, the royal scribe to Amenhotep III (eighteenth Dynasty) – were deified from the Late Period, the former one also identified with Asclepius by the Greeks (Fig. 3).

If one had to be ill in antiquity, ancient Egypt would be the preferred place. Although the basis of their medication was mainly empirical and aimed at the relief of symptoms, they thought to eliminate the cause of the disease by winning the gods' benevolence. The medical knowledge of their physicians was without equal at that time; their formal, structured and logical approach to the patient is unchanged in modern medicine; and their techniques and treatments are often comparable to today's medical profession.

Extra 1: The Most Important Medical Papyri

The earliest texts originate from the Middle Kingdom (Amenemhat III). The *Kahun papyrus* was found in the town of Illahun by Flinders Petrie in 1889, and is badly damaged (Griffith 1898; Stevens 1975).

Medicine in Ancient Egypt. Fig. 3 Bronze statuette of Imhotep. Dyn. 26. Source: 1. Nagay, Guide to the Egyptian Collection. Museum of Fine Arts, Budapest, 1999. p. 67.

All the paragraphs are gynecological, but the first half is written in instruction form, while the second 17 paragraphs are prescriptions or pregnancy prognoses. The 17 *Ramesseum papyri* were found in a magician-healer's tomb in the great temple of the Ramesseum, Thebes. They are also fragmentary and originate presumably from the 13th Dynasty. *Numbers 3 and 4* contain several prescriptions and also magical spells treating various parts of the body, though many deal with birth and babies or the eye. Scroll *number 5* is in the best state of preservation among them, and the writing suggests it to be the earliest copy. It collects cases concerning the *mtw* – that is the "canals" of the body – in this case usually muscles and tendons. The other Ramesseum scrolls are mostly magical.

The 4.5 m long *Edwin Smith papyrus* was purchased in Thebes in 1862 by its eponym, and published in 1932 by James Henry Breasted in two superb volumes. The recto gives an excellent insight into the surgical practice of ancient Egypt with the 48 trauma cases in instruction form. There are several corrections written in the paragraphs and explanations (glosses) appended behind them, which indicate that the original text was not understandable any more. Its language suggests a Middle Kingdom origin. It outlines procedures and techniques that are considered antecedents of modern surgical practice. The 48th case ended abruptly in the middle of a sentence. The verso was finished by another hand and consists of various medical paragraphs together with iatromagical incantations. The style of the writing dates the scroll approximately to 1550 BCE.

The longest medical papyrus is *the Ebers papyrus*, which was also bought by Edwin Smith in 1862. It was said to be taken from between the legs of a mummy in Assasif, Thebes. It measures some 20.23 m in length and 30 cm in height. A passage on the verso dates it to the ninth year of Amenhotep I. Georg Moritz Ebers published it in 1873. The recto contains 877 medical paragraphs of various topics arranged unsystematically in many books with some loose prescriptions and randomly placed glosses. The pages were numbered by the ancient compiler, who collected material from the ancient Egyptian medical literature – ophthalmology, obstetrics, contraception, dentistry, urinary and digestive system, psychiatry, etc. The "book of the stomach" (188–207) and the injury section (857–875) are in instruction form. It also contains two anatomical treatises (854–56) and a detail of a herbarium (251).

In 1901, a scroll of papyrus was presented at the Californian Phoebe Hearst expedition in Deir el-Ballas. The scroll, later named *Hearst Papyrus*, was written during the reign of Tuthmosis III and is a less systematically written compilation of several topics, probably a practicing physician's formulary. It is concerned with diseases of the urinary system, blood, hair, bites, etc. More than a quarter of the paragraphs are similar or very close parallels to the Ebers papyrus. The recto *of Chester Beatty VI* of the nineteenth Dynasty from Deir el-Medina consists of prescriptions for rectal ailments. The *Berlin Papyrus*, acquired by Giuseppe Passalacqua in Saqqara and sold to Friedrich Wilhelm IV of Prussia in 1827 for the Berlin Museum, bears a great similarity to the Ebers papyrus, and also contains an anatomical treatise (163). Beside the prescriptions for various illnesses there are also some birth prognoses. The paleography indicates that it is of the nineteenth Dynasty. Unknown is the origin of the badly damaged *Carlsberg Papyrus VIII* written by two different hands and dated to the nineteenth/twentieth Dynasties. Its language suggests a Middle Kingdom origin. The recto gives prescriptions for eye diseases and the verso prognoses for pregnancy.

The *Brooklyn Herpatological Papyrus* concentrates exclusively on snakebites and dates to the thirtieth Dynasty or Early Ptolemaic Period. It starts with a systematic description of the properties of 38 snakes and their bites (the first 13 were on the missing part of the papyrus), while the second section describes prescriptions to "drive out the poison" of snakes, scorpions and tarantulas and to "seal their mouths". The *Fayum Medical Papyrus*, originating from the library of the Sobek temple of Crocodilopolis in the second half of the second century AD, is a compilation of prescriptions for various diseases. Although it is written in demotic and the structure is traditional, it is completely imbued with the Mediterranean medical praxis and drugs.

M

Extra 2: The Most Important Mixed and Pure Iatromagical Texts

The provenance of the *London Medical Papyrus* is unknown. It was given to the British Museum by the Royal Institute of London in 1860. It is a palimpsest in very poor condition dealing with various topics such as gynaecology, ophthalmology or proctology. The earlier work dates to the reign of Tutankhamun. Of its 61 paragraphs, 25 are prescriptions; the others are magical spells. Among the 19 *Chester Beatty Papyri* given by Sir Alfred Chester Beatty to the British Museum, spells are often cast for unidentifiable diseases (*VI verso, VIII, XV*). Then again there are some systematic books – incantations against headache (*V.*) and scorpion stings (*VII recto*). The collection was found in a tomb at Deir el-Medina in 1928 and belonged to the archive of the family of the scribe Qen-her-khepeshef for over a century during the nineteenth Dynasty. The *Mother and Son Papyrus* in the Berlin Museum was auctioned from the Athanasi collection in 1843 as burial good from Memphis or Thebes. Written in two hands at the beginning of the eighteenth Dynasty, the papyrus contains three prescriptions for the newborn and 18 magical spells against children's illnesses or for delivery, mother's milk and the general safety of the child.

The *London-Leiden magical Papyrus*, which consists of a few prescriptions and many incantations for various ailments, was written in the third century AD. The two halves, sold first by Anastasi, the Swedish consul of Alexandria and aquired much later by the British Museum and the Dutch government, were discovered by the first publishers, Francis Ll. Griffith and Herbert Thompson. Although it is basically demotic, it also contains many Greek glosses, some coptic words and a few hieratic signs.

Typical pure magical texts were written against snakebites, and not only on papyri or ostraca but also carved on stone from the New Kingdom – mainly on *Horus-cippi*. Probably the most complete collections are the *Metternich stela* and the inscription of the *healing statue* of Hor-udja. These incantations often quote mythical events in connection with the child-god Horus or the goddess Isis. Other types of spells were cast over pain and aches in different parts of the body. The *Turin magical papyri* contains a large collection of these and snakebite spells.

Medicine in Ancient Mesopotamia

Semaàn I. Salem

The art of medicine is as old as humanity itself. Diseases must have existed as soon as life was formed and early human beings tried to rid themselves of the pain and discomfort they caused. This art is not restricted to human beings alone; many animals even some plants have ways to combat sickness.

Early people probably practiced two completely different methods of medication: a practical method originating from the obvious, and another resulting from combating the unknown and the mysterious. When a thorn or a similar object penetrates the flesh, removing it relieves some pain and discomfort and is therefore a cure. Pressing one's finger or hand on a wound stops the bleeding and thus is a form of medication. On the other hand a cure for a mysterious or a supernatural illness, such as a high fever or epilepsy, is not as obvious and therefore requires a supernatural treatment. Not knowing the nature of such mysterious illnesses or how they entered the body of their victims, early humans accused demons and evil spirits, and called on magicians and exorcists to chase away the offending demons. Thus to combat diseases, the help of a benevolent god was invoked either directly by prayers and sacrifices, or through a medium, an expert in communicating with such a super power. This type of treatment survives today, practically unchanged into the twenty-first century, in many places.

Most of the almost one thousand medical tablets uncovered in Mesopotamia treat most diseases in this fashion: a disease is the invasion of the body by an evil spirit or a harmful demon, and the cure is always described as a method to force the demon to leave the patient. This is accomplished either by a healing god, or by scaring, or disgusting the intruding demon. The evil spirit may become disgusted and forced to leave by feeding the patient repulsive materials, such as dirt or excrement. In Mesopotamia, the healing god was usually associated with a snake, the symbol of healing.

On one of the oldest Mesopotamian medical tablets, the Sumerians attribute numerous diseases to harmful demons and evil spirits and call upon their goddess for medical help. In their incantations, she is addressed by various names, such as Bau, Ninisinna, and Gula. An example of this kind of treatment is found on several tablets describing the disease that overwhelmed Tabi-utul-Enlil, the ruler of Nippur. He calls on various gods and goddesses, begging them to rid him of the evil demons that entered his body. There was no other cure mentioned.

An evil demon has come out of its (lair);
It struck my neck and crushed my back,
It bent my high stature like a poplar;
Food became bitter and putrid,
The malady dragged its course.
My flesh was wasted, my hands were wan.
All day the pursuer pursued me;
At night he granted me no respite whatever.

Then Tabi-utul-Enlil mentions how the diviner failed him and his gods deserted him.

The disease of my joints baffled the exorcist,
And my omens were obscure to the diviner,
The exorcists could not interpret the character of my disease,
And the limit of my malady, the diviner could not fix.

He was baffled by his punishment, as he was a pious ruler, who performed his duties to gods and men.

As though I had not set aside the portion for the god,
And had not invoked the goddess on the meal,
Had not bowed my face and bought my tribute;
And had not taught my people fear and reverence.
I thought that such things were pleasing to the gods.

Here, Tabi-utul-Enlil states that since he is such a pious man, he should not have gone through so much suffering. The good god should have prevented the evil spirits from entering his body. But he never lost faith in his benevolent god. Finally, the good spirit appears, and cures all his ailments; a mighty storm drives all the demons out of his body.

He sent a mighty storm to the foundation of heaven,
To the depth of the Earth he drove it.
He drove the evil demon into the abyss.
He tore out the root of my disease like a plant.

Cured, Tabi-utul-Enlil praises his god, offers sacrifices, and calls upon his subjects to have faith, and never to despair.

This piece of Mesopotamian literature provides a clear insight into Mesopotamian view of diseases and cures. There is no difference between demon and disease; the two words were synonyms. And so were the words god and cure. Many historians see similarities between Tabip-utul-Enlil's story and that of the biblical Job.

Although magical cures were prevalent in ancient Mesopotamian society, there are indications that even in the early stages of Mesopotamian development, plants, and other substances were consumed for medical purposes and some specialized medicine existed. A clay tablet, written toward the end of the third millennium BCE was uncovered in Nippur and brought to the Museum of the University of Pennsylvania, where it was translated by Samuel Kramer and Martin Levey. Considered the oldest medical document of record, this tablet describes over a dozen remedies extracted from plants such as myrtle and thyme, and from trees such as willow, pear, fir, fig, and date. It also mentions extraction from milk, snakeskin, and turtle shell as well as table salt and potassium nitrate. This tablet has two drawbacks: it fails to mention the diseases for which these remedies were intended or the quantities to be used in the treatment. Another clay tablet that dates to the middle of eighteenth century BCE mentions aloe as a cure for "anything that ails you." An Egyptian papyrus written around 1500 BCE confirms the Mesopotamian claim; it states that aloe relieves skin afflictions, infections, and constipation.

Modern scientific studies have confirmed what Mesopotamians and Egyptians knew some 3,500 years ago, that aloe has therapeutic powers; it heals burns, skin lesions, and frostbite; it reduces inflammation and enhances the immune response. If taken internally, certain components of aloe reduce stomach acids, relieve the pain of arthritis, and reduce blood sugar in diabetic patients.

The therapeutic effect of plants is also mentioned in one of the Sumerian creation stories. Uttu, the goddess of plantations, after being impregnated by her grandfather Enki (Lord-Earth), fulfilled her duty and created a variety of plants. Enki visited Uttu's plantations and, in an effort to determine their medical power, he ate some of them. The goddess Ninhursag (Queen-Mountain), enraged by what had happened, cursed Enki, who as a result, fell grievously ill. The Anunnki (Great Gods), troubled by Enki's illness, brought Ninhursag to Enlil (Air-God), their leader, who persuaded her to heal Enki. To perform that function, she placed the sick god close to her vulva and began to create a god (a specialist) for each of the diseases that inflicted him.

Ninhursag placed Enki at her vulva.
'My brother what hurts you?' – 'My tooth hurts me.'
'I have caused Ninsutu to be born for you.'
'My brother what hurts you?' – 'My mouth hurts me.'
'I have caused Ninkasi to be born for you.'
'My brother what hurts you?' – 'My rib hurts me.'
'I have caused Ninti to be born for you.'

M

The similarity between the creation of Ninti (Lady of the Life or Lady of the Rib) from the rib of Enki and the creation of the biblical Eve from the rib of Adam has been recognized since these verses were translated.

The therapeutic effect of plants was mentioned only rarely. The general public believed that demons and evil spirits caused all diseases, and magical cures were predominant. This led to devising and adopting various protective methods, such as hiding from the sight of evil demons, which in turn led to the use of masks and symbolic chains that protected loved ones from harmful contacts. Another way of hiding from evil spirits was by painting the patient in a variety of colors, and this is might be the origin of tattoos. Changing the patient's name was another way of fooling the evil spirits, preventing them from finding him.

Other forms of protection against harmful demons included the administration of seven drops of a liquid, the assistance of a special person – a child, a virgin, a firstborn – and a variety of amulets such as odd-shaped stones, and threads spun from a virgin kid. Such charms were attached to the head, neck, or limbs of the patient, or tied about his bed or at the entrance of his dwelling.

These ancient protective devices may be viewed as the precursors of ornaments or signs used today, such as the statues of Buddha, crosses, and small boxes containing Quranic verses, usually worn around the neck, and also the signs of the cross painted above the doors of certain homes and statements such as "God bless our home," hung on the wall.

In a society governed by demons, magic, and fetishes, individuals who possessed the power to pacify angry spirits and triumph over powerful evil forces became respected and admired. They were the priest–magicians–physicians, who rose to prominence, not only in Mesopotamia, but also in other societies. They called for the help of benevolent gods to frighten away evil spirits. In many instances they also foretold the future by observing the stars and other celestial phenomena, or by studying the liver of an animal or a fellow human being. They taught the people how to avoid forthcoming calamities. In modern religions, this function has been taken over by prophets, saints, and the clergy, who could intercede with God on behalf of people in need.

Mesopotamian society was host to such practices for some 2,000 years, from the early Sumerian period until Hammurabi's rule. During that long period, magician–priests were the dominant factor in medical practices. But astrology also played an important role. The conjunction of the stars at the birth of a child was thought to determine his lot all through life as well as the time and manner of his death. This belief is still held by many people, and many prominent newspapers still publish a daily astrological column. This is but one of many ancient myths still flourishing in our time.

Another magical concept came about from the belief that blood is responsible for all vital functions and for the continuation of life and must be provided with the proper nourishment. The liver was assumed to be the organ that receives the blood and was considered the seat of all life processes. Accordingly, when an animal was sacrificed, its liver was thoroughly examined for signs of destiny. Divinations were derived from its position, its form, and any irregularities it possessed. This concept passed unaltered from Sumerian medicine into Assyrio-Babylonian and then west into Canaanite, Hittite, and Etruscan medicine. In turn, the Etruscans passed it to the Romans. The Latin word for liver, *haruspex*, has its origin in the old Babylonian word for liver, *har*. Haruspicy, or divination using livers of animals of slain enemies, survived in Greece for several centuries after the advent of Christianity.

Various forms of magic were used to rid the patient of the invading demon. A magician–physician would wear a terrifying mask, cover himself with animal skin, and make wild noises, dance and jump, and rave until the patient laughed, a sign that the invading demon was frightened away. Did the ancient Mesopotamians discover the healing power of laughter? Another method to get rid of the demon was to set its image on fire. Often the image was shown bound, hand, and foot, its eyes pierced, and its tongues pulled out. Then the mutilated image was thrown into the fire.

Yet another method of extracting the demon from the body of the patient was to find a substitute: a lamp, a pig, or a bird. The chosen substitute was placed near the sick person, and then killed by tearing out its insides, enticing the demon to leave the patient and enter the body of the substitute. The animal was then offered to the gods as a sacrifice. Humans did not consume its meat. This notion of passing an unclean spirit from a person to an animal survived and spread west with Christianity as Jesus ordered the unclean spirit, Legion, to leave a mad man and enter a herd of swine (*New Jerusalem Bible*, Mark 5: 8–13). Based on the belief that the evil spirit could enter a person and drive him insane, many people so inflicted were chained and put in dark caves, dungeons, or locked in a cellar, barn, or an attic to force the evil spirit to leave them. This method continued to be practiced in Europe and the Middle East well into the nineteenth century.

All medical treatments were based on the notion of forcing the evil spirits to leave the body of the patient, and all cures, regardless of their nature, were effective because they performed that function. In time the approach did change; scaring or disgusting the invading spirits gave way to pleasing and appeasing them. This was accomplished by treating the patient and therefore the evil spirits with delicious drugs, such as honey, milk, and sweet smelling herbs.

Based on their experience with irrigation and the effect of sweet water on the growth of vegetation, the

Mesopotamians reasoned that water held healing powers. As this phenomenon was common and readily observable, many ancient civilizations reached similar conclusions, and sweet water became the medicine of choice, and the gods of healing in many civilizations were associated with sweet water. The Sumerian god Enki, whose abode was Apsu, the underground sweet water, was the god of healing, and so was the Babylonian god Ea, the god of the underground sweet water, and the wisest of all the gods. The Phoenician god of healing, Ashmun, was associated with the river and the pond that bears his name (the name has since been changed to al-Awwaly), and most of the Greek and Roman gods of the medical art were associated with sweet water. To wash away an ailment, the patient drank the water, sprinkled it over his head, or bathed in it. As a result many rivers, lakes, and pools became sacred and revered for their healing powers. Many still are.

When water was administered to relieve a patient from the clutches of demons, an incantation was usually chanted. One such incantation associated with the god Ea ritual reads:

With pure, clear water,
With bright, shining water,
Seven times and again seven times,
Sprinkle purify, cleanse!
May the evil Rabisyu depart!
May he step to one side!

The water was sprinkled seven times and again seven times because the number seven was considered sacred. The ancient use of sweet water as a healing commodity may have served as a prelude to Christian baptisms. Other rituals were later introduced. Among them was rubbing the patient with butter, milk, or oil while chanting the proper incantation.

During the golden age of Babylon, King Hammurabi put forth his code of law in which he detailed reward for various successful medical operations and describes penalties for failures. One such law reads, "If a physician performs a major operation on a nobleman with a bronze lancet and saves his life, or opens up the eye of a nobleman with a bonze lancet and saves the nobleman's eye, he shall receive ten shekels of silver." In Babylonian society there were three classes: nobility, commoners, and slaves. The eye of a commoner was worth half that of a nobleman's, and if a practitioner saved the eye of a slave, his reward was only two shekels.

To discourage imposters, Hammurabi put stiff penalties on failures. "If a surgeon shall make a severe wound with an operating knife and kill the patient, or shall open an abscess with an operating knife and destroy the eye, his hand shall be cut off." This was probably intended to prevent imposters from practicing medicine. Of course, penalties were less severe if the patient was a commoner or a slave. "If a physician shall make a severe wound with a bronze operating knife on the slave of a free man and kill him, he shall replace the slave with another slave. If he shall open an abscess with a bronze operating knife and destroy the eye, he shall pay half the value of the slave."

The fact that such legislation was needed in eighteenth century BCE proves that such operations were fairly common, and that the people of Babylon were enjoying the services of a class of able physicians. It also proves that empirical medicine was beginning to displace magic and exorcist medicine, but not to eliminate it. The two survived side by side for centuries, as they still do.

Medicine of the Australian Aboriginal People

Dayalan Devanesen, Patrick Maher

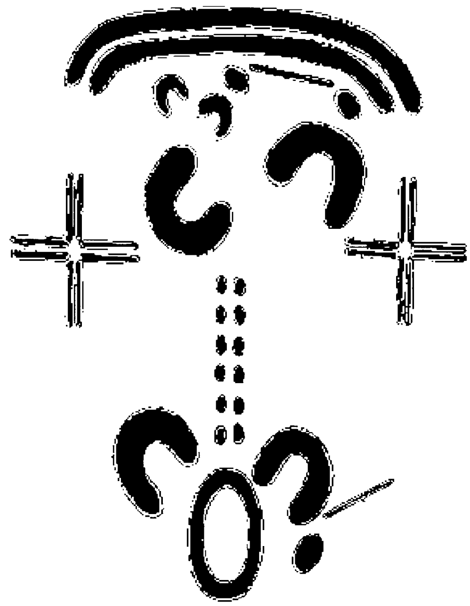
Australia is the only continent to have been occupied exclusively by nomadic hunters and gatherers until recent times. Carbon dating of skeletal remains proves that Australian Aboriginal history started some 40,000 years ago, long before Captain Cook landed on the eastern coast in 1770. This history is not completely lost. It is retained in the minds and memories of successive generations of Aboriginal people, passed on through a rich oral tradition of song, story, poetry and legend. According to Aboriginal belief all life forms, human, animal, plant and mineral are part of one vast unchanging network of relationships which can be traced to the great spirit ancestors of the Dreamtime.

The Dreamtime continues as the "Dreaming" or *Jukurrpa* in the spiritual lives of Aboriginal people today. The events of the Dreamtime are enacted in ceremonies and dances and chanted incessantly to the accompaniment of didgeridoo or clapsticks (Isaacs 1980). The Dreaming is the source of the rich artistry, creativity and ingenuity of the Aboriginal people.

In Australia, Western health services have been superimposed on traditional Aboriginal systems of health care. However, these traditional systems have survived despite the dramatic influence of cultural contact, and Aboriginal medicine is still widely practised in the Northern Territory today (Tynan 1979; Nathan and Japanangka 1983; Reid 1983; Soong 1983; Devanesen 1985; Maher 1999). The Northern Territory occupies one-sixth of the Australian land mass. It has a population of just under 200,000 of which 28% are Aboriginal. The vast majority of the Aborigines live in small remote communities scattered across the Territory.

Traditional Aboriginal medicine is a complex system closely linked to the culture and beliefs of the people, knowledge of their land and its flora and fauna. Its survival is explained by its "embeddedness" in the social fabric of Aboriginal culture. Reid (1983) has shown that, though Aborigines living at Yirrkala in the Northern Territory choose Western biomedicine to treat the majority of their sicknesses, they continue to explain the causes of these sicknesses through their traditional beliefs. This may be because the health beliefs continue to play a role in providing meaning to events and thereby helping people to cope with serious illness and death (Reid 1983).

The Aboriginal approach to health care is a holistic one. It recognises the social, physical and spiritual dimensions of health and life. Their concept of health in many ways is close to the World Health Organisation definition of health: "a state of complete physical, mental and social well being and not merely the absence of disease or infirmity". The Warlpiri Aboriginal tribe have described health as "life" or *Wankaru*. Their definition takes in a whole of life cycle. The front of their health centre at the Aboriginal settlement of Yuendumu is adorned with the painting in Fig. 1. It shows family life, food, shelter, warmth, water and exercise, all of which are essential for health (Devanesen 1983).



Medicine of the Australian Aboriginal People. Fig. 1 Health symbol for Yuendumu: Napangardi women's *Jukurrpa* or Dreamtime.

Traditional Indigenous Health Systems

The traditional health beliefs of Aboriginal people are interconnected with many aspects of Aboriginal life such as the land, kinship obligations and religion (Tynan 1979). The sociomedical system of health beliefs held by Aboriginal people places emphasises on social and spiritual dysfunction causing illness. This approach emphasises that "individual well-being is always contingent upon the effective discharge of obligations to society and the land itself" (Morgan et al. 1997: 598). A person's social responsibilities and obligations may take precedence over their own health because of the priority given to social relationships in this model.

Sorcery and supernatural intervention are part of the perceived reality of Aboriginal life (Waldock 1984), and in Aboriginal society explanations in terms of sorcery are often used. The deaths of infants or the very old or chronically ill are considered to be in the normal course of events, while deaths outside these groups may have a supernatural influence, especially if they are regarded as premature, unexpected and sudden (Reid and Mununggurr 1977).

There are many beliefs associated with supernatural interventions and sorcery:

- Sorcery exists in many forms. Its effect is to manipulate and alter behaviour and cause morbidity and mortality.
- Sorcerers can be specialists or non-specialists.
- Distant groups have the most virulent sorcery and are the most feared.
- Many diseases come from dangerous, secret sacred sites. They are manifestations of the forces or power emanating from those sites.
- Unskilled or uninitiated people may release forces from a dangerous site by disturbing the site.
- Sorcery is carried out in secrecy.
- Retribution sorcery is directed serially at members of a family or lineage. Therefore, the serious illness or

death of one member is followed by the illness and death of others.

- A traditional healer can apply counter measures to identify the cause and source of illness and death, but the healer should not interfere if it is the result of legitimate punishment (Biernoff 1982).

The ill effects of sorcery will not necessarily be felt only by the "offender", but may also be felt by his/her family and descendants. While the thought of sorcery is prominent in Aboriginal life, people do not live in constant fear of sorcery. Sorcery is usually an explanation that is applied retrospectively to explain deaths, serious illness or injury (Reid and Williams 1984).

The concept of supernatural intervention and sorcery plays an important function as "it explains why one person and not another died or became ill at a certain time and not at another" (Reid and Mununggurr 1977: 39). It provides the explanations of "why me" and "why now" which cannot be answered in terms of Western medical theory. It provides the answer to the ultimate cause of the event.

Many have acknowledged the cultural diversity, particularly in regard to health beliefs, between Aboriginal groups and communities (Reid 1983; Elkin 1994). We have therefore chosen to describe the features of the traditional indigenous medical system by particular reference to one tribe, the Warlpiri.

Traditional Health System of the Warlpiri Aborigines

The Warlpiri Aborigines comprise one of the largest tribes in the Northern Territory. They are scattered over many Aboriginal communities in the northwest of Central Australia. The main components of the Warlpiri health system are the *ngangkayikirili* or traditional healers, commonly referred to as *ngangkari* or *ngangkayi* (healing power), *Yawulyu* ceremonies; healing songs and herbal medicine. In addition there are laws governing behaviour that are aimed at preventing sickness.

Ngangkari

Traditional healers have a variety of roles, including providing strong spiritual and social support (Reid 1983; Soong 1983); determining the ultimate cause of a serious illness or injury (Nathan and Japanangka 1983; Reid 1983; Peile 1997; Tynan 1979); determining cause of deaths at an "inquest" (Nathan and Japanangka 1983; Reid 1983; Peile 1997; Tynan 1979); and employing counter sorcery to remove the evil influences causing illness (Reid 1983; Tynan 1979). They are believed to have many powers to undertake these roles and utilise numerous different healing techniques (see Table 1).

Professor Elkin (1994) referred to the traditional healers as Aboriginal men of high degree. The healers

M

Medicine of the Australian Aboriginal People. Table 1 The powers and healing techniques of Aboriginal traditional healers

Powers/capabilities	Healing techniques
• have assistance from the spirit world to assist healing • telepathy • divination • X-ray vision • clairvoyance • telesthesia • control the weather • mind reading • walk on fire • inserting healing objects into patient's body • magically heal wounds including internal wounds • travel at fast pace • protect people against attack from spirits via counter sorcery • commune with spiritual beings including the dead • manipulate a patient's spirit • spirit travel • able to project their spirit into the body of patient • able to replace patient's blood with their own • able to communicate with the spirit world	• provide positive emotional support • physical contact and touching • massage • extraction of objects causing illness from a patient's body via sucking, rubbing or massage • smoking used ritually (after initiation or death) or therapeutically for mothers and babies after childbirth • use of healing songs and chanting • counselling • using objects with healing powers • dreaming • cleansing the patients' internal organ(s) while they asleep

are kindred to Amerindian “men of power” and shamans. These healers are specially chosen and trained to remove the influence of sorcery and evil spirits and to restore the well being of the soul or spirit. Their role is extremely important because most serious illness is thought to be brought about by loss of a vital substance from the body (soul loss), introduction of a foreign and harmful substance into the body (spirit intrusion or possession) and violation of taboos or sorcery (singing). The traditional healers usually gain the power to heal through inheritance or through special spiritual experiences. They possess a spirit called *mapanpa* which is associated with healing power. This is different from the spirit that every Warlpiri person has “like a shadow” (Tynan 1979).

The traditional healer carries out a healing ritual which often includes sucking the sick person. After sucking, the healer usually spits out a wooden object called *yarda* which is covered in blood. The *yarda* represents the evil influence. Sometimes, the traditional healer massages the patient, manipulates the body or sings during the ritual. The traditional healer may diagnose the state of the spirit, e.g. *kurrunpa yulangu* (the spirit is sad). The traditional healers do not use herbal medicine in their practice.

Yawulyu Ceremonies and Healing Songs

Warlpiri women frequently perform *Yawulyu* ceremonies. These ceremonies improve the health of sick people but cannot remove the influence of sorcery. The ceremony consists of singing songs and painting designs on the sick person. These designs are derived from the power of the Dreamtime (see Fig. 2). Each ritual is carried out by the *kirda* (owners) or *kurdungurlu* (managers) of a particular “Dreaming”. Sometimes the songs and designs appear to the people in their dreams and are thought to be revealed by spirit creatures called *yinawuru* (Munn 1973). During the ceremony the sick person may be massaged with fat and red ochre. These materials derive special potency from the songs. In some cases senior men and women sing songs without the ceremony to strengthen sick people. Songs are sometimes sung to ensure safe childbirth. The *Yawulyu* ceremonies and songs assist in providing strong family support for the sick person.

Medicine of the Australian Aboriginal People. Fig. 2 *Yawulyu* designs on women – yam dreaming.

Herbal Medicine

Herbal medicine and knowledge of plants is not the domain of any particular group in the Warlpiri system. The whole family shares its knowledge and use. The Warlpiri have extensive knowledge of plants and have published their own book which lists several plants and their medicinal uses (Henshall et al. 1980).

Medicinal plants are mainly used symptomatically for coughs and colds, pains and aches. Some are used as dressings for wounds and sores. The main conditions that herbal remedies were used for reflect the types of sickness that Aborigines had before contact with Western society. They were joint and muscle pain, toothache and sore mouth, gastro-intestinal disorders, symptoms of colds and flu, e.g. fever, headache and ill-defined pain, congestion, cough, general malaise, sore throat, sores, boils, cuts, scabies, bites, stings, burns and major wounds, warts, allergy rash and itchy skin disorders, ringworm, other tinea form skin infections, eye disorders and fever.

Aboriginal expertise regarding plants has been acknowledged for many years. Webb (1969) has shown that many Aboriginal bush medicines contain biologically active compounds. Bitter Bark (*Alstonia constricta*), used to prepare a tonic, contains reserpine, a tranquilliser and antihypertensive. Plants used on sores and wounds contain proteolytic enzymes that help healing. Spilanthes, a native daisy used to treat toothache, has been shown to contain spilanthol – a local anaesthetic. Over half the world’s supply of the drugs hyoscine and scopolamine come from an Australian native tree Duboisia, which was used by Aborigines as an emu and fish poison (Pearn 1981).

Herbal medicine was the first component of the Warlpiri health system to be eroded by the introduction of Western medicine. However, the movement of the Warlpiri people back to their traditional land has led to a renewal of interest in the use of herbal medicine.

A program by the Northern Territory Department of Health that commenced in 1973 to collect information regarding the Aboriginal use of plants has helped non-Aboriginal staff to appreciate the great knowledge and complexity of the Aboriginal health system (Devanesen and Henshall 1982).

In 1995 staff at a remote health centre in the Northern Territory carried out a study to compare the effectiveness of wound healing by the use of a traditional remedy, Bauhinia root (*Lysiphyllum cunninghamii*) and a Western preparation in the treatment of boils, sores and scabies. The study concluded that the herbal medicine was as effective as the Western preparation. In addition the Aboriginal people felt more comfortable using the traditional remedies and felt a sense of pride in their own traditional knowledge and culture (McLean et al. 1996).

The Warlpiri Health System

The Warlpiri health system can be represented as in Fig. 3.

When someone falls sick, one of the three main components of the health system is tried. If it does not work, another component is used or the same component tried again until there is a definite outcome.

Preventing Sickness

Reid (1982) gives a good description of prevention at the level of personal relationship and religious injunctions:

> Preventive measures can include avoiding foods prohibited during ceremonies or life crises, obeying ritual proscriptions, taking care not to abuse ones' land or trespass on territories of others, avoiding prohibited sacred sites or approaching them with ritual protection, observing debts and obligations to others, containing anger, violence or jealousy, exercising caution in interactions with strangers and taking steps to avoid sorcery or often conflict with others.

The methods of preventing illness link in directly with what are regarded as the ultimate causes of illness under the Aboriginal model of causation of illness. In summary, good health is associated with strict adherence to approved patterns of behaviour and avoidance of dangerous places, people and objects (Biernoff 1982).

The Place of Western Medicine

Western medicine has been incorporated into this system at the same level as herbal medicine. By doing this, the Warlpiri are able to retain their belief in spirit causation of illness while using Western medicine for the relief of symptoms.

Changes are taking place in the illness-related beliefs of Aborigines in the Northern Territory. Reid's study at Yirrkala shows that this change is characterised by the "gradual addition of causes and elaboration of the existing causes within the aetiological domain". Reid lists three categories of causes (1) social and spiritual causes, e.g. sorcery or breaking the law; (2) causes other than social or spiritual, e.g. emotional state, old age, assault; and (3) emergent causes, e.g. alcohol, sin, smoking (Reid 1983).

Aboriginal people use the strategy of domain separation to divide illness into Aboriginal and Western causes. This involves thinking in terms of separated cultural or social domains and deciding when to apply the rules of each domain (Harris 1988). This strategy occurs not only in the area of health beliefs, but also in other areas to respond to cultural uncertainty, to reduce social complexity and stress and to deal with social dilemma (Harris 1988).

There are a variety of behavioural patterns of seeking medical assistance that traditional people use during illness:

- Sequential (use one practitioner then another kind, e.g. Western then traditional or vice versa)
- Compartmental (using traditional medicine for conditions which have established traditional explanations)
- Concurrent (concurrent use of traditional and Western forms of health care; Armstrong and Fitzgerald 1996)

Aboriginal people use all these patterns (Reid 1983; Peile 1997; Tynan 1979; Elliot 1984; Tonkinson 1982; Gray 1979; Berndt 1964). This model is best expressed in Fig. 4.

Generally combinations of traditional and Western medicines are used (Reid 1983; Tynan 1979). Western medicine may relieve symptoms and provide explanations to the mechanism of how something occurred while traditional explanations provide the reason why it occurred and are able to address the ultimate cause. In cases of supernatural intervention Western medicine is used to treat the symptoms and to hasten the cure, provided it does not conflict with traditional beliefs, but it is not able to remove the cause of the illness (Tynan

1979; Waldock 1984). In contrast only Western medicine can affect emergent Western illnesses (Waldock 1984; Scrimgeour et al. 1997).

In spite of this attempt to incorporate Western medicine into the traditional system, there are areas of conflict. Western medicine is based upon particular Western explanatory models. Variation in the underlying beliefs, assumptions and general medical information has been implicated as the basis for the conscious rejection of Western health care by some Aborigines (Hamilton 1974). It is well known that differences in underlying knowledge systems impede even willing compliance between culturally divergent groups. The lack of a common conceptual framework within which patient and practitioner can interact may result in decreased compliance and satisfaction (Maher 1999).

Development of Traditional Practice in Health Services to Aboriginal People

There has been government support with recognition for traditional Aboriginal medicine since the 1970s. A report on Aboriginal health by the Australian Parliament recommended that:

> Aboriginal cultural beliefs and practices which affect their health and their use of health services such as their fear of hospitalisation, their attitudes to pain and surgery, the role of traditional healers and the differing needs and roles of Aboriginal men and women, be fully taken into account in the design and implementation of health care programs (Commonwealth of Australia 1979).

Bicultural Medicine

Two-way medicine is the term that has been coined by Aboriginal health workers (AHWs) to describe a bicultural approach to health care. It is based on the principle that "if you can use what is best in modern medicine together with what is best in traditional healing, the combination may be better than either one alone" (Werner 1977). The Northern Territory Department of Health's first policy on Aboriginal health stated that "traditional medicine is a complementary and vital part of Aboriginal health care, and its value is recognised and supported" (Northern Territory Department of Health 1982). The Northern Territory Department of Health over the years has established several programs that recognise the traditional health system, Aboriginal values and beliefs.

Support for Traditional Healers/Ngangkari

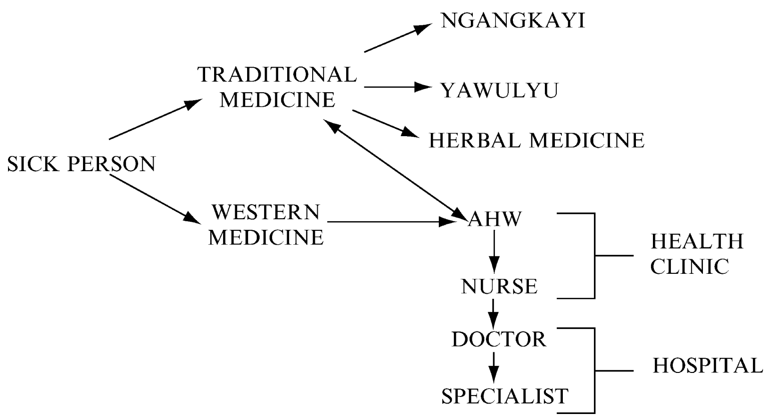
Traditional healers were employed by the Northern Territory Department of Health at various rural health centres in Central Australia in the early 1970s. While this practice has ceased, rural health centres continue to recognise and cooperate with traditional healers in the management of sick people, and some remote health centres run by Aboriginal Community Controlled Organisations have recommenced the employment of traditional healers. The healers often act also as consultants for determining culturally appropriate service delivery.

A meeting of Ngangkaris was held near Uluru, Central Australia, in April 2000. Over 40 Ngangkaris gathered together to discuss the production of an information manual about the work, history and traditions of Ngangkari (Mullins 2000).

A recent proposal to establish an Aboriginal Healing Centre close to the Alice Springs Hospital is being examined. The centre would develop a place to promote spiritual health supported by a network of traditional Aboriginal healers.

Aboriginal Health Workers

There are over 300 AHWs in the Northern Territory today. The AHW training program is recognised as one of the main strategies for improving Aboriginal health. AHWs are selected by their own communities and



Medicine of the Australian Aboriginal People. Fig. 5 Aboriginal medicine and Western medicine.

trained in various Western medical skills. They have proved highly successful in treating common health problems in Aboriginal communities, such as diarrhoea, chest infections, trachoma, and ear and skin infections. They also act as mediators between Western and traditional medical systems.

Aboriginal health workers bridge the "cultural chasm" separating the traditional and Western worldviews. They relate Western beliefs to an Aboriginal conceptual framework, making it possible for Aboriginal patients to understand what is being said and to assess the validity of the statements. They make it possible for the health centre teams to communicate with Aborigines in language and concepts that they understand. In most Aboriginal communities, the people's point of entry into the Western health system is through the AHW who may refer them to a nurse or doctor or back to the traditional system as shown in Fig. 5.

The Bush Food Program

Aboriginal people often view food as their medicine. Many foods are known to strengthen the body against sickness or promote healing. Some prized foods such as the witchety grub (*Xyleutes*) are crushed and used for treatment of burns and wounds. The grubs are nutritious as well, with protein (15.1%), fat (19.2%), 100 mg thiamine and 5 mg vitamin C per 100 g (see Fig. 6).

In 1981, the Northern Territory Department of Health launched the Bush Food Program which sought to establish a durable record of traditional Aboriginal food practices and beliefs and develop a more relevant and acceptable style of nutrition education.

A publication on the nutritional composition of 42 Bush Foods collected through this Program has some interesting results (Brand et al. 1983). The green plum (*Terminiala ferdinandiana*) contains 3,150 mg/100 g of Vitamin C, making it the richest source of Vitamin C in the world. The bush banana (*Leichardtia australis* and *L. leptophylla*; see Fig. 7) and the water lily root (*Nymphae macrosperm*) contain very high proportions of protein, and the list goes on.

The Bush Foods Program has led to the stimulation of reciprocal learning processes between two cultures and the self-examination of attitudes and values.

Medicine of the Australian Aboriginal People. Fig. 6 Witchety grub (*Xyleutes*).

Medicine of the Australian Aboriginal People. Fig. 7 Bush banana (*Leichardtia australis*).

M

The current health status of Aboriginal people is characterised by unacceptable levels of morbidity and mortality. Aboriginal life expectancy is 20 years less than other Australians; Western medicine has not solved many of the Aboriginal health problems.

Traditional medicine is part of Aboriginal culture. Its recognition can bolster the self-confidence of Aboriginal people and improve the delivery of health services to Aboriginal communities. Two-way medicine needs to be supported and developed with ongoing research to evaluate the therapeutic value of traditional medicine. The increasing worldwide popularity and use of complementary and alternative medicine may assist in the development and sustainability of Aboriginal traditional medicine and healing in Australia.

Medicine in China

CAI JINGFENG

The term Chinese medicine has a dual implication. It refers both to all medical systems prevalent in contemporary China and to traditional or indigenous medicine in its narrow sense (TCM for short). The former includes three medical systems: traditional, biomedical, or Western medicine as the Chinese call it, and integrated Chinese and western medicine.

Traditional Chinese medicine includes the experiences of fighting against disease, keeping fit, and seeking longevity. It was created by all nationalities of the Chinese people and is the synthesis of the medical systems of all ethnic groups. For historical reasons, TCM has been applied exclusively to the indigenous medical system created by the Han nationality. Logically, TCM should also include Tibetan, Mongolian, Korean, and Uyghur medicine and that of all other ethnic groups as well. Unfortunately, this interpretation would go against the common understanding of TCM. Hence, in this article we also use TCM in its narrow sense, referring to the Han-Chinese medical system only.

TCM has a history of at least three to four millennia. Archaeological findings reveal that the application of fire in the Paleolithic age not only brought warmth and cooked food, which was beneficial to health, but also resulted in the invention of moxibustion therapy. The Neolithic age also saw ancient Chinese people applying the stone knife and “needles” for treating some external diseases. These passed through a long process of evolution from stone to needles made of bamboo, wood, porcelain, bronze, and ultimately metal. Shining gold and silver needles over 2,000-years old have been unearthed. The last kind of needle, in fact, is the basis for the invention of the unique channel system, though other factors may also have contributed (Cai 2000). In terms of materia medica, legend has it that Shen Nong tasted and tried all kinds of plant herbs and other remedies from natural sources, beginning at the period of agriculture, about 7000 to 5000 BCE. People of other nationalities also discovered some effective remedies, such as wine from highland barley for stopping hemorrhages, which was used by Tibetan people, and Cistanche Salsa, Koumiss for nourishing the body, which the Mongolian people use (Cai 2000).

Early in the Xia and Shang Dynasty (twenty-first to eleventh centuries BCE) some 3,000 years ago, some characters related to medicine were inscribed on bone and tortoise shells as oracles, including *yi* (medicine), *bing* (disease), and up to several hundred archaic characters relevant to the healing art. As early as the Zhou Dynasty (eleventh century BCE–475 BCE), medicine in the imperial court was divided into four departments: internal medicine, ulcerative (external) medicine, dietetic therapy, and veterinary medicine. TCM had already applied the four diagnostic methods – inspection, auscultation and olfaction, interrogation, and palpation (looking, listening and smelling, asking, and feeling) – by this period. Of these, palpation is the most worthy of mention. Chinese ancient physicians may have been the earliest to apply the art of pulse taking for medical purposes. In the *Shi Ji* (Historical Record), compiled by Sima Qian (b. 145 BCE), the Herodotus of China, in the Western Han Dynasty (206 BCE–AD 24), it is recorded that the physician Bian Que of the Warring States Period (475 BCE–221 BCE) was the first one to apply pulse taking in clinical practice (Chen 1957).

The most famous medical classics were compiled in the Pre-Qin period (before 221 BCE) and completed around the Han Dynasty (206 BCE–AD 220). Among them, the most important and extant ones are *Huangdi Neijing* (*Yellow Emperor's Inner Canon*), *Shennong ben cao jing* (*Divine Husbandry's Classic of Herbology*), *Nan Jing* (*Classic of Questioning*), *Shang han lun*

M

(*On Diseases Caused by Cold Evil*), and *Jin gui yao lüe* (*Synopsis of Golden Chamber*). These lay the foundation for clinical science with definite treatment principles and diagnostics. Chunyu Yi of the Western Han (206 BCE–AD 24) Dynasty first formulated case records for the patients with a fixed pattern.

Chinese pharmacy reveals some outstanding achievements at this period. *Shennong's Classic of Herbology* presents many specific effective remedies. It sets up the theoretical basis of drug use, as well as describing collection, preservation, compounding, simple processing, and method of administration. Therapeutic effects of specific drugs, such as *rhei* for catharsis, coptis root for asthma, seaweed for goiter, mercury for scabies, and many others are mentioned (Anonymous, 1956). Their effectiveness has since been proved by modern techniques. The famous surgeon of the Later Han Dynasty (AD 25–220), Hua Tuo, first applied *mafei* powder as an anesthetic for some major operations, including abdominal surgery. As early as the third century AD, the *Mai jing* (*Classic of Sphygmology*), written by Wang Shuhe, recorded 24 kinds of pulse, touching the issues concerning heart rate, rhythmicity, condition of blood flow, texture of the artery, and the nature of blood itself such as viscosity and hemorrheology. Later, this Classic spread via Tibet and India to the Arabic countries, and it is not surprising to note that in the *Canon of Medicine* by Ibn Sīnā (980–1037), Arabic sphygmology has a lot of content in common with Wang Shuhe's. The *Classic of Sphygmology* has been translated into several foreign languages.

From the second century AD, medical disciplines were professionalized. The following are worth mentioning: *Zhen jiu jia yi jing* (*A–B Classic of Acupuncture and Moxibustion*) by Huangfu Mi, *Lei gong pao zhi lun* (*Master Lei on Drug Processing*) by Lei Xiao, and *Liujuanzi gui yi fang* (*Liu Juanzi's Recipes Bequeathed from a Ghost*) by Gong Qingxuan, a textbook of surgery in the fifth century. Clinical medicine developed tremendously during the period of the third to tenth centuries. Ge Hong (265–341) was an expert in clinical medicine and a famous alchemist. His work, *Zou hou bei ji fang* (*Handbook of Prescription for Emergency*), contained discoveries on tsutsugamushi (mite-borne typhus) and smallpox, inventions for the treatment of hydrophobia by applying the brain tissue of the mad dog, and treatment of malaria by the juice squeezed from the artemisia herb, resulting in the extraction of a new effective anti-malaria remedy which is called artemisinin in modern biomedicine. Moreover, new medical techniques such as abdominal paracentesis, catheterization, first aid therapy for foreign bodies in the esophagus, and chiropractic were also introduced (Cai 1984).

The Sui-Tang Dynasties (618–907) also saw several major medical issues. The Tai Yi Shu (Imperial Academy of Medicine) and the *Xin xiu ben cao* (*Newly Revised Materia Medica*) (659) are, respectively, recognized as the earliest medical university and pharmacopoeia. Several important medical works were compiled in this period, representing the improvement of medical science. Cao Yuanfang's *Zhu bing yuan hou lun* (*On Pathegenesis and Manifestations of All Diseases*) is the first elaboration on etiology, pathology, pathogenesis, and semiology in China. Sun Simiao's *Bei ji qian jin yao fang* (*Essential Recipes Worth a Thousand Gold*) contains a great thesaurus of valuable recipes for many diseases, some still in use today. Wang Tao's *Wai tai mi yao* (*Clandestine Essentials from an Imperial Library Curator*) records many effective recipes. During the Song Dynasty in the tenth to thirteenth centuries, a Jiaozheng Yishu Ju (Bureau for Reviewing Medical Publications) and Huimin Heji Ju (Bureau of Compounding Remedies for Benevolence) were set up by the Imperial Court. What should be mentioned here is the casting of two life-sized bronze human models for acupuncture and moxibustion in the year 1026, on which the acupoints and channels were cast on their surfaces. This is not only a valuable and sophisticated work for appreciation, but also a skilled model for intuition education which greatly enhanced the development of the art of acupuncture and moxibustion.

During the Jin-Yuan Dynasties (1115–1360), four main academic medical schools appeared, namely the Schools of Cold-favoring, Spleen-Stomach Benefiting, Drastic Attack, and *Yin*-nourishing. Each had its own emphasis and advocacy, both theoretical and practical. This greatly advanced the academic development of Chinese medicine.

The academic standard of Chinese medicine was further elevated in the Ming-Qing Dynasty (1368–1910). A new school, the Wenbing Xuepai (Warm Disease School) evolved from the traditional Shanghan Xuepai (School of Disease of Exogenous Cold Evil). This new school was devoted to acute infections. It successfully tackled many infectious diseases such as B-encephalitis, acute viral hepatitis, influenza, and other viral diseases. Another outstanding contribution of Chinese medicine in this period was the invention of a human pox inoculation (variolation) from which Edward Jenner's smallpox vaccination drew its inspiration. Variolation should share the merit with vaccination in the global campaign to eradicate smallpox. The naturalist Li Shizhen (1518–1593) contributed his pharmacological knowledge to opening a new era in the history of Chinese materia medica. His rich knowledge on natural science aroused the interests of the evolutionist Charles Darwin, who indirectly cited many biological examples as evidence supporting his theory of evolution.

Beginning with the middle of the nineteenth century, Western medicine, so-called by the Chinese people since it was introduced by Western medical missionaries, came to China, resulting in the formation of three different academic factions in the medical province: biomedical, traditional or indigenous, and integrative.

Through the ages, Chinese medicine applied and created a series of unique theoretical systems and practical techniques. The following is a brief introduction (Needham, 2000).

The philosophical concept of *yin–yang* is based on the observation of contradiction in nature. This was coordinated into a *yin–yang* theory for explaining the law of changes. In the medical circle, people made use of this idea to interpret the complex relationship between upper and lower, inner and outer, the body and nature and society. The equilibrium and harmony between these two aspects within the body is essential to and the base of the body's normal activities and functions. Conversely, once the harmony is broken, disorders of the body will develop, thus affecting normal physiological activities. Physiologically, *yin* refers to those tangible structures and *yang* to invisible functions. Thus blood itself belongs to *yin* while its circulation function falls under the category of *yang*. These, in TCM terms, fall under the categories of the so-called blood and *qi*. *Yin* and *yang* are mutually dependent. Without *qi*, blood will be stagnant and become a pathological entity, while *qi* attaches itself to the blood as its place to stay in. Without blood, *qi* will be "homeless." These ideas have direct bearing on the theory of treatment. Hence, *yin* and *yang* are mutually rooted, interdependent, and inversive.

Ancient philosophy states that the whole universe is constructed with five basic kinds of materials: wood, fire, earth, metal, and water. Each element has its own characteristics. As a microcosm, the human body, which is comparable to the universe, is also made up of these five elements. Like the universe, all the organs, tissues, functions, and systems can be compared with and assigned to one of the five categories. For instance, under the wood category, we have liver (*yin* viscera), gallbladder (*yang* viscera), eyes (sensory organ), sinews or tendons (tissue), sour (taste), wind (climatic factor), spring (season), anger (emotional state), and green (color). In the meantime, we have heart, small intestine, tongue, vessel, bitter, hot, summer, joy, and red under the fire category; spleen, stomach, mouth, flesh, sweet, damp, long-summer (the last month of summer), anxiety, and yellow under the earth category; lung, large intestine, nose, hair, pungent, dry, autumn, sorrow, and white under the metal category; and kidney, urinary bladder, ear, bone, salty, cold, winter, apprehension, and black under the water category. The five categories have a dynamic rather than a static relationship, the order being wood, fire, earth, metal, water, and wood. Each category can also be conquered or restricted by another category, the order being wood (restricted by) metal, fire, water, earth, and wood. Hence we have the title Five Phases or *wuxing* with its theoretical system.

Both the *yin–yang* principle and the Five Phases theory are applied clinically for directing and interpreting physiology, pathology, diagnostics, treatment, or even prognosis, and they were proposed and completed some 2,000 years ago. The *yunqi* (activity of *qi*) or the *wu yun liu qi* (five activities and six climatic factors) theory or hypothesis investigates the influence of astronomical, atmospheric, and climatic factors on the human body and the occurrence of diseases. By five activities, it refers to the cyclic activities or movements of the five phases – wood, fire, earth, metal, and water – within the four seasons, while the six climatic factors refer to wind, cold, damp, dry, hot, and fire. This theory estimates the law of disease occurrence and yearly changes of weather with astronomy and the calendar as its parameters. In general, the yearly weather changes are wind in spring, hot in summer, damp in long-summer, autumn dry, and winter cold. Thus liver diseases are apt to occur in spring, heart diseases in summer, spleen diseases in late-summer, lung diseases in autumn, and kidney diseases in winter. The theory stressed the relations between weather and disease which, though a bit mechanical and controversial, has something to do with chronomedicine. This theory reached its zenith a thousand years ago (Editorial Committee, 1992).

The theory of visceral manifestations deals with the physiology and pathophysiology of the five *yin* viscera: the heart, kidney, spleen, lung, and liver; the *six yang* viscera: the small intestine, large intestine, stomach, bladder, gall bladder, and triple *jiao* (pancreas?); as well as the extraordinary viscera: the brain, marrow, bone, vessels, and uterus. The *yin* viscera function for the storage of essence and spirit of the body, while the *yang* viscera are responsible for the digestion, transformation, and transportation of residual materials. It is claimed that there exist mutually dependent inhibition relations among the *yin–yin*, *yin–yang*, and *yang–yang* viscera. Visceral manifestations also involve other body substances, including blood, saliva, mucus, sputum, body fluid, as well as body functions such as *qi*, spiritual forces, and genetic functions. The totality of the above-mentioned contents forms the visceral manifestations (Guangdong College, 1972).

Visceral manifestations are closely tied to the theory of channels. Channels, the passages and tracts for the circulation of blood and *qi*, connect the outer with the inner part of the body and branch repeatedly to form a network spread over the whole body. Thus, through its connection, the whole body forms an organic whole. There are altogether twelve main or orthodox channels, each with its own underlying viscera, and eight extraordinary channels and collaterals and capillary networks. When channels are affected, their functions change accordingly, manifesting signs and symptoms by which a correct diagnosis can be made. Regulation of their functions through various stimulations, such as acupuncture, moxibustion, massage, electricity, and percussing, yields therapeutic results (Guangdong College, 1972).

TCM stresses the importance of recognition of etiological factors, which have a direct bearing on the treatment and prognosis of disease. Harmonious relationships among the *yin–yang* viscera themselves, and between the body and its environment, are crucial to the health of the body. All diseases occur on the basis of the disturbance or breaking down of this harmony. Diseases used to occur when the orthodox *qi* (body resistance) was defeated by the heteropathy (pathogenic evil). Orthodox *qi* is responsible for the body's resistance, preventing it from contracting a disease. Pathogenic evils include exogenous (climatic), endogenous (emotional), and others (trauma, accidental insect or snake bites, injuries, dietetic, behavior, etc.). The relative force between body resistance and pathogenic factors determines the result of their struggle, either keeping healthy or falling ill. The aim of treatment is to support the body's resistance and remove pathogenic evils so as to keep one in good health.

There are four diagnostic methods. Inspection includes the spirit, complexion, form, and status of the patient. A tongue picture is also essential, including the texture of the tongue and its coating, the sense organs, and the condition of excreta. These provide much information about the condition of the internal viscera. Auscultation refers to hearing the patient's voice, including speaking, respiration, and smelling the odor from the patient's body and excreta. Interrogation refers to questioning the patient and other respondents about his present illness, past history, and family history. Palpation includes feeling the pulse and other parts of the body. It is sometimes said that TCM puts its main stress on pulse taking, or even relies solely on pulse taking. This is not true. TCM emphasizes that an overall diagnosis should have all four diagnostic methods interpreted comprehensively with equal importance, instead of relying on any single method (Guangdong College, 1972).

The determination of syndrome manifestation (*bian zheng*) is the kernel of TCM clinical science. It is the process of analyzing the information and materials obtained from the four diagnostic methods, differentiating the causes, nature, location, stage of disease, and the reciprocal condition between the body and the pathogens. The result of this process is the identification of the type of syndrome manifestation, which is crucial to therapy. Long experience enables Chinese physicians to form an ensemble of methods, or determination of syndrome manifestations. There are many methods. The important ones are the *ba gang* (Eight Rubrics), applied for all kinds of diseases; the Triple *jiao* Method for warm infectious diseases, and the Six Channel method for diseases due to cold evil.

Among them, the Eight Rubrics method is the most important and universally applied one. Eight Rubrics denotes outer and inner (location of illness), cold and hot (nature of illness), depletion and repletion (reciprocal condition between the body resistance and pathogens), and *yin* and *yang*. Within the Eight Rubrics, the *yin–yang* is the key couple Rubric that dominates the other three. Furthermore, a timely, correct determination of syndrome manifestations, especially the Eight Rubrics, is the key to a reasonable and satisfactory therapy. The conception of Eight Rubrics has taken shape since the Han Dynasty (Cai 2000).

The basic principle for treatment is the exploration of the root of disease, on which various therapeutic methods are based. The uniqueness of this is its flexibility, which varies with the analysis of the condition. Different treating measures may be given to the same disease because of different conditions manifested. Conversely, the same therapeutic measures may be administered for different diseases because of their common manifestations. The major principles include the regulation of *yin–yang*, supporting the body's resistance, and removing pathogenic factors. During the treatment, differentiation of the true nature and superficial manifestation, emergency and steadiness, severeness and mildness are of paramount importance (Guangdong College, 1972).

Moreover, therapy and medication in TCM should be adjusted to the season, the place, and the different individual. First, changes of climate in different seasons exert definite effects on the body. During summer, the pores in the skin and neighboring tissues are open; in winter, they are contracted and closed. Hence, while treating cold disease due to wind and cold evils, therapy in the summer should not apply too many drugs of a pungent and warm nature, in order to avoid profuse sweating, or outer depletion would result. In winter, for the same cold disorders, pungent and warm drugs can be applied in substantial amounts, in order to expel the pathogens through perspiration without the risk of outer depletion. Since cold is very common in the north, for cases of external, pathogenic disorders, one can use a heavy dose of pungent and warm drugs for dispersion of pathogens through perspiration. Applying the same principle to the southern part where weather is generally hot, only a light dose of pungent and warm drugs can be used, to avoid profuse perspiration. Thirdly, all patients vary in sex, age, and body constitution. Moreover, women have the added complications of childbearing, menstruation, and vaginal discharge, while children have tender and delicate visceral systems. These conditions should be taken into account and carefully considered when prescribing. For instance, with a patient who is sensitive to cold with a constitution of cold tendency, cool or cold drugs should be used with caution, and vice versa for those of hot tendency.

As to concrete treating measures, basically there are eight therapeutic methods: diaphoresis, emesis, catharsis, mediation, warming, clearing, removing, and benefiting. All these methods are applied not only for drug therapy, but also for non-drug therapies such as acupuncture, moxibustion, massage, and others (Guangdong College, 1972).

In terms of Chinese materia medica, all the drugs applied are natural products, including those from the plant and animal kingdoms as well as minerals. Most of the pharmacological knowledge is derived from practice. Pharmacological theory is summarized, again on the basis of experience. The theory is also unique. It claims that the potential of the drug comes from its "nature," composed of four *qi* and five flavors. The four *qi* are cool, cold, warm, and hot, while the five flavors refer to sour, salty, sweet, bitter, and pungent. The theory also includes channel tropisms, the functions of ascending, descending, floating, and sinking, as well as the toxicity of drugs. The nature of drugs is relevant to the condition of the disease as determined by diagnosis through differentiation of syndrome manifestations within the Eight Rubrics. Antagonistic therapy such as cool or cold drugs for heat disease, and warm or heat drugs for cold disease, is commonly used. Drugs with ascending nature are applied for heat disease of "collapsed" nature, such as gastroptosis and the like, whereas drugs with descending nature are applied for disease of uprushing or adverse ascending flow of normal *qi*, such as hiccough, belching, vertigo, dizziness, and rushing up of liver fire. The channel tropism of drugs is directly related to the channel attribution of disease. For instance, the primordial stage of influenza falls under the category of Taiyang Channel disorders; hence, drugs of Taiyang Channel tropism are to be applied. Compatibility of drug compounding and toxicity of drugs are all highly stressed in Chinese pharmacy. Precautions when administering drugs are also unique. The breaking of necessary precautions would lead to failure of even a correct treatment. All the drugs are prepared in various forms, including decoction, powder, paste, pills, bolus, ointment, patent drug, and also modern drug forms like injection and aerosol. TCM also pays attention to the time of taking drugs, claiming that this has a direct bearing on the chronophysiology of the body and on its therapeutic efficacy.

The ingredients for compounds of Chinese medical recipes are differentiated into the "king," "ministers," "assistants," and "servants." The aim of this compounding is to focus on the mutual synergic and detoxifying action among the ingredients. As a result, the effect is much more satisfactory than single drug administration, and the toxicity is much ameliorated or even eliminated.

Acupuncture and moxibustion are special treating techniques as well as health care measures in TCM. Acupuncture refers to the needling of specific loci, the acupoints for stimulation, to regulate the disharmonious state and arouse the resistance potential of the body. Moxibustion refers to the application of heat stimulation with a moxa roll or cone on the point or affected site instead of using a needle. As soon as the body is stimulated by these means, the afflicted *qi* and blood inside the channels and viscera are improved, activated, and regulated. Pathogens are expelled or eliminated, and normal physiological function is restored. The basic idea of acupuncture–moxibustion is also established on the same principles as TCM, i.e., treatment based on the differentiation of syndrome manifestations, although it also has its own special demand such as manipulation techniques.

Massage and *qigong* exercise are also integral parts of TCM. The former is performed by specific manipulation techniques on acupoints or specific locations, while the latter is a self-care method in which the patient consciously controls his/her own mind, body, and the circulation of *qi* through controlling one's breathing movement. It is said that a proficient exerciser may even direct the flowing of *qi* in his/her own body at will.

TCM pays attention to disease prevention, or so-called "treating pre-illness" in the Chinese term. Various measures are proposed for this purpose, among them self-care massage, Daoyin, Taiji boxing, hygienic measures, and breathing exercises.

Since the basic conception of traditional Chinese medicine took its shape several thousand years ago, it applied concepts which are rather abstract and vague, not tangible or perceptible, let alone quantitatively estimated. To meet the needs of modern investigation and understanding, over the decades TCM workers have been encouraged to integrate and interpret their knowledge by modern scientific concepts, means, and techniques. A new school, the School of Integrated Traditional and Western Medicine, has thus emerged. This has become one of the modem trends in the development of China's medical science (Cai 2000).

Medicine in China: Forensic Medicine

Cai Jingfeng

Forensic medicine refers to that part of medical science pertaining to legal and political affairs. In order to provide materials and evidence for trying and investigating cases, the discipline of forensic medicine deals with the issues of reconnoitering the scene, surveying the cadaver, and studying the material evidence, poisonous substances, and other relevant items.

Chinese medico-jurisprudence makes its appearance in the Warring States period (475–221 BCE). *Li Ji* (Record of Rituals) and *Lüshi Chun Qiu* (Master Lü's Spring and Autumn Annals) both mention "investigating the wounds and trauma, inspecting and analyzing cases, reconnoitering and judging, and making decisions on lawsuits with justice." In 1975, some bamboo slips, later entitled "Qin Slips from Yunmeng," were unearthed from Yunmeng, Hubei Province in China. Within the slips, legal articles of the Qin Dynasty (221–207 BCE) and criminal cases were recorded. About 7 of the 22 cases involved forensic medical jurisprudence, in which killing, hanging to death, chopped-off heads, abortion due to trauma, and leprosy are included with records from the scene. Foot, hand, and knee prints, as well as blood and stools are mentioned. Circumstantial descriptions are given on the differentiation between homicide and suicide by hanging. All these demonstrate that achievements in legal medicine appeared as early as two to three thousand years ago (Jia, 1980).

The earliest extant Chinese feudal code, *Tang Lü* (Law of the Tang Dynasty) was promulgated in 653 AD. This stipulates that when investigating fake illness, feigned death and injuries, false or incorrect reports will result in punishment in a grade next to that given to the swindler. For victims of illness, death, or injuries, a fake report would be given punishment equal to that of the sufferers themselves. Issues pertaining to autopsies of legal medical cases, including the severity of injury, fake illness, self-mutilation, administering abortion, disability, age, and critical diseases are also mentioned (Jia, 1984).

Medical jurisprudence developed a step forward in the Song Dynasty (960–1279). First, the officials responsible for the investigation of cases are stipulated in writing, saying "for examining cadavers *Canjun* (Adjuvant) at the provincial level and *Xian Wei* (district defendant) at the county level are responsible. In case *Xianwei* is absent, officials of *Bu* (*appointee*), *Cheng* (aide), and *Jian* (directorate) will be responsible in that order. The county governor himself should be responsible when all these staff members are absent." Regulations for responsibility and dereliction of duty, such as when those officials in charge are inaccessible, when there is a delayed presence at the scene, or when the wrong decision for the cause of death is made are also stipulated. *Gemu* (Pattern Catalog), a compulsory regulation for the examiner, is mandated to avoid malpractice; this is claimed to be an important achievement in this field. This rigorous system for examination offers a firm basis for the advent of the prominent monograph on legal medicine, *Xi yuan ji lu* (*Collected Records of Washing Away the Wrong Cases*) and other similar works. Prior to these monographs, other works on legal medicine made their appearance, including *Nei shu lu* (*Record of Forgiveness*) and *Jian yan fa* (*Method for Examination*), which were unfortunately all lost. *Xi yuan ji lu* is an epitome of the achievement in the discipline of Chinese medical jurisprudence. Its merits include records on (Song, 1936 Rpi).

- The occurrence and distribution of cadaver speckle
- Conditions influencing the advent of putrefaction
- The relationship between the cadaver manifestations and the duration after its death
- Types of rope used for hanging
- The features of strangulation and how to differentiate those from self-hanging for suicide
- The difference between drowning and suffocation by compressing someone's nose and mouth
- The difference between fractures before and after death
- The determination of fatal wounds and
- Various methods for determining different causes of death

During the Yuan Dynasty (1271–1368), a formal pattern for examination of Confucian officials was announced. This is entitled *Jie an shi* (*Pattern for Winding Up a Case*). It deals with issues relating to medical jurisprudence, including examination of the cadaver, biopsies for wounds and illnesses, and material evidence. This monograph is the first to combine the three integral portions of medical jurisprudence into a whole.

The Chinese made a significant contribution to legal medicine. Important Chinese monographs on legal medicine including *Xi yuan ji lu ping yuan lu* (*Reassuring the Wrong Cases*) and *Wu yuan lu* (*Free of Wrong Cases*) were translated into many foreign languages, including Korean, Japanese, French, German, Dutch, and English (Jia, 1984).

After 1911, performing autopsies became legal. When procurators and police officers are unable to ascertain the causes of death with a cadaver, an autopsy is performed by a medical practitioner rather than by the old-style *Wu Zuo* (cadaver examiner). This procedure is rigorously regulated.

The first Department of Forensic Medicine was established in the Medical College of Peiping University in 1930, while the First Institute of Forensic Medicine was established in Shanghai in 1932, and a *Medical Jurisprudence Monthly* was first published in China in 1934. A wealth of forensic medicine professionals has been cultivated, in order to increase public security and justice (Jia, 1984).

Medicine in India: *Āyurveda*

Guy Mazars

Āyurveda or 'the knowledge (*veda*) for longevity (*āyus*)' is an ancient medical system whose main theories were already fixed more than 2,000 years ago. It has roots in the *Veda*, especially the *Atharvaveda* (Mazars 1991; Zysk 1996), and the conceptions of the ancient ayurvedic physicians have played a great role in the general culture of India and have spread everywhere in Asian countries. With Buddhism, Āyurveda travelled to Sri Lanka, Nepal, Tibet, Central Asia and as far as Japan, and it reached Indonesia with the Hindu culture and civilization (Filliozat 1934).

The legends related by the ancient Sanskrit medical texts make of this system a revealed 'science', annexed to the *Veda* sometimes as an 'annexed member' (*upāṅga*) of the *Atharvaveda*, sometimes as a 'subveda' (*upaveda*) of the *Ṛgveda*. Created by Brahman and transmitted to men by the successive interventions of Prajāpati, the Aśvins and Indra, this science is theoretically divided into eight branches:

1. General surgery (*śalya*)
2. Surgery of the head and the neck (*śālākya*)
3. Internal medicine (*kāyacikitsā*)
4. Toxicology (*agadatantra*)
5. Demonology (*bhūtavidyā*)
6. Obstetrics and paediatrics (*kaumārabhṛtya*)
7. Tonic medicine (*rasāyana*)
8. Aphrodisiacs (*vājīkaraṇa*)

In fact, very few ancient texts follow this division which has been particularly in vogue among more recent authors. As regards their content, it represents in reality the fruit of the activity of medical observation and speculation in the course of the seven or eight centuries which preceded the Christian era. Unfortunately the documents going back to this period that are properly medical have disappeared, and they have been supplanted by more recent texts.

M

Source Texts

The classical doctrine of Āyurveda is already expounded in two famous treatises dating from the beginning of the Christian era, the *Carakasaṃhitā* or 'Caraka's Compendium' (Sharma 1981–1994) and the *Suśrutasaṃhitā* or 'Suśruta's Compendium' (Bhisagratna 1963), which are the oldest Sanskrit medical texts that have come down to us (Wujastyk 1998). Although these two works agree remarkably in their general teachings, they are too different for us to suppose that one may be an imitation of the other. But they manifestly rely on the same older doctrinal heritage. These two texts were the object, from a period even earlier than the tenth century, of very elaborate commentaries whose purpose was to clarify and add precision to their contents (Filliozat 1964).

Later texts of great importance include the *Aṣṭāṅgahṛdayasaṃhitā* of Vāgbhaṭa (ca. AD 600), the *Mādhavanidāna* of Mādhavakara (ca. AD 700), the *Śārṅgadharasaṃhitā* of Śārṅgadhara (thirteenth or fourteenth century) (Murthy 1984) and the *Bhāvaprakāśa* of Bhāvamiśra (sixteenth century). Vāgbhaṭa is the most celebrated author after Caraka and Suśruta (Hilgenberg and Kirfel 1941). His identity has been the subject of unending discussion, and Indian critics hold that there was an 'elder Vāgbhaṭa' in addition to 'Vāgbhaṭa', grandson of the former and son of Siṃhagupta. In the *Mādhavanidāna* or 'Aetiology According to Mādhava', the author treats causes and symptoms of different diseases, by taking up in a systematic manner the data of Caraka, Suśruta and Vāgbhaṭa (Meulenbeld 1974; Murthy 1993). The *Mādhavanidāna* was the object of numerous commentaries, which proves that the treatise achieved considerable fame. Of considerable interest is the *Śārṅgadharasaṃhitā*. Śārṅgadhara is the first author to discuss several new elements, including diagnosis by pulse (Murthy 1984). He also gives for the first time detailed information on many previously undocumented medical procedures, especially regarding the preparation of remedies. In fact, the main subject of the work is pharmaceutics (Sharma 1979). A whole section deals with pharmaceutical forms, giving exemplary formulations under each category, and adding new drugs and new techniques. Many recipes from Śārṅgadhara's *Compendium* are still in use. There are also divergences between the nosological system of the *Mādhavanidāna* and the nosology described in the *Śārṅgadharasaṃhitā*. New names of diseases are mentioned in the texts. Syphilis is described for the first time, under the name of *phiraṅgaroga*, in the *Bhāvaprakāśa* of Bhāvamiśra (sixteenth century). Alongside the great classical treatises and their commentaries there exists an abundant medical literature that comprises other general texts, specialised manuals and repertories of *materia medica* (Mazars 1995b).

Philosophical Foundations of Āyurveda

The conceptual edifice of Āyurveda rests on ideas which are those of the *Sāṃkhya* philosophy, a system of thought having as its basis the analysis and classification of the constituents (*tattva*) of the world. It is not known in fact which of the two systems influenced the other. Some authors consider that ayurvedic doctrines are older than *Sāṃkhya* whose basic text is the *Sāṃkhyakārikā* or 'Stanzas of *Sāṃkhya*' (fourth century?). However that may be, according to ayurvedic treatises as well as according to *Sāṃkhya*, the human body is composed of the same basic elements (*bhūta*) that constitute the universe: earth (*pṛthivī*), water (*ap*), fire (*tejas*), air (*vāyu*) and void (*ākāśa*), represented, respectively, by the solid parts, the liquids, the body heat, the breath and the emptiness of the hollow organs (Filliozat 1964). The combinations of the five basic elements form the differentiated substances of the body, the *dhātu*, seven in number: chyle or nutrient fluid (*rasa*), blood (*rakta*), flesh (*māṃsa*), fat (*medas*), bone (*asthi*), marrow (*majja*) and semen (*śukra*).

As it is described in the great treatises of Caraka and Suśruta, ayurvedic medicine distinguishes itself explicitly from empiricism, magic and religion. For, the conditions for the validity of the observations and reasoning which are at the root of diagnosis, prognosis and treatment interested the ayurvedic circles very early. Thus, the *Carakasaṃhitā* contains a teaching of logic intended to guide the future physician in his reasoning. Long passages and allusions appearing in various parts of the treatise constitute the exposition of this logic. The most systematic passages are found in Chaps. IV and VIII of the section of the *Carakasaṃhitā* entitled *Vimānasthāna*. This logic, allied to the classical Indian logic, the *Nyāya*, acknowledges three methods of judgement (*pramāṇa*): the teaching of those who are accepted to be an authority (*āptopadeśa*), observation (*pratyakṣa*) and inference (*anumāna*) (Mazars 1995b). There has been much discussion concerning the relationship between Āyurveda and the philosophical system of *Vaiśeṣika*, which has as its object the study of the special characteristics of things, their *viśeṣa*. The *Vaiśeṣikasūtra*, which constitutes the reference text of this school, dates from the early centuries of the Christian era, but its contents seem to show older interpolations.

Ayurvedic View of the Body

The anatomical nomenclature of Āyurveda is rich, but the notions covered by them are fairly rudimentary, especially as regards visceral anatomy. However, the value of opening corpses was known and the *Suśrutasaṃhitā* (Śārīrasthāna, V, 49–56) even describes a procedure of dissection closely resembling the procedure of *hydrotomy* suggested by Lacauchie in the nineteenth century (Lacauchie 1853). As the conceptions of the brahmanical moral code were opposed to true methodical dissections of well-preserved cadavers (Zysk 1983), anatomical knowledge remained scanty. Hence, errors and lacunae are numerous in the lists of organs furnished by the ancient medical texts. Osteology is fairly important in Indian anatomy (Hoernle 1907), but it holds out little interest as regards the constitution of the medical doctrines.

The hollow organs or 'receptacles' were better known. The stomach is called the 'receptacle of the uncooked' while the intestines are the 'receptacle of the cooked'. The gall bladder is the 'receptacle of the bile', the bladder that of the urine and the uterus that of the embryo. In fact, among the organs, the best described are those on which surgical operations were performed: the rectum, the uterus and the bladder. Today limited to minor operations, such as bone setting and to reductions of dislocations and fractures, ayurvedic surgery was once probably the most remarkable in Euro-Asiatic antiquity. The *Suśrutasaṃhitā* mention various operating techniques (incision, excision, scarification, puncturing, catheterisation, extraction, draining and stitching of wounds) as well as instruments and accessories. The *Suśrutasaṃhitā* also describes surgical operations which reveal the great daring of the surgeons of that period: the lowering of cataracts with a needle, grafts for repairing the nose and the earlobe, perineal lithotomy for extracting vesical calculi, resection of scrotal elephantiasis, Caesarean section, surgical removal of a dead foetus from the womb.

The *Carakasaṃhitā* and the *Suśrutasaṃhitā* even teach a very daring procedure for intestinal sutures which avoids the use of non-absorbable threads whose intolerance by the tissues had been recognised. This procedure consists in bringing the edges of the wound together and having them bitten by black ants. The bodies of the ants are then cut off from the head, whose mandibles serve as staples. It only remains thereafter to close up the abdomen by ordinary suture. This was the procedure in case of laparotomy for penetrating wounds of the abdomen and for intestinal occlusion. But instances of success must surely have been rare. One of the commentators on the passage quoted above observes moreover that the outcome of the operation was very uncertain. That was no doubt why the method is no longer taught in the later treatises.

The Indian surgeon had above all to know the 'vulnerable regions' (*marman*), injury to which is either fatal or particularly serious. The notion of *marman* goes back to a Vedic conception. The word is derived from the root *MṚ*, which means 'to die', and denotes above all a lethal point. The classical treatises, which carefully catalogue these bodily zones, describe them as seats of vital energy. They list 107 of them divided into five categories according to their location (flesh, pipes, ligaments, bones and joints) and into five categories according to the seriousness of the harm resulting from injuries to them. The details given by the texts enable us to locate them fairly easily. They are anatomical reference points corresponding most often to big vessel-nerve bundles, tendons or important nerve ganglia, injuries to which are serious because of haemorrhage, paralyses or disabilities that they cause.

Representations of the Vital Functions

In the ayurvedic system, the totality of the transformations undergone by the seven organic substances (*dhātu*) is governed by the combined play and balance of wind, fire and water, present and active in the body in the form of three vital principles. Indeed, wind, the essential motive force of the Universe, is also that of the body in which it is represented by the 'vital breath' or *prāṇa*, which is localized mainly below the navel. 'Fire' is represented by a principle which collects in the form of 'bile' or *pitta*, which is localized between the heart and the navel. As regards water, it is found in the form of *kapha* or *śleṣman*, 'phlegm', a substance common to all the bodily serous fluids and secretions, which is localized in the chest. Each of these three principles acts by assuming five secondary forms which correspond to the different vital functions. Their action works towards a complex and autonomous process of balancing which maintains the organism alive (by the constant renewal of its constituents) and in good health. These Indian ideas are very close to the notion of *homeostasis*, already anticipated by Claude Bernard during the nineteenth century and which Walter Cannon (1871–1945) described as the totality of organic processes which act to maintain the stationary state of the organism, in its morphology and in its internal conditions, despite external disturbances.

Of the three principles, it is the organic wind, under its different forms, which is considered the most important vital element. According to the *Carakasaṃhitā* (Sūtrasthāna, XII, 8), it ensures by its action the ingestion, digestion and assimilation of food, the differentiation of the organic substances and their distribution, as well as the internal circulation of the fluids, respiration and movements, covering in this way a number of aspects of functioning attributed today to the nervous systems. The seven *dhātu* contain a liquid principle which makes them alive and which is named *ojas*, i.e. to say 'strength'.

Psychological Conceptions

Psychological conceptions play a fundamental role in the teachings of Āyurveda (Rosu 1978). The connection between the body and the mind is asserted in the most direct manner by the Sanskrit medical texts: 'The body is governed by the psyche and the psyche by the body' (*Carakasaṃhitā*, Śārīrasthāna, IV, 36).

It is interesting to note that, according to Āyurveda, the psyche represents the contribution of the previous existences of the incorporated soul. This is entirely in conformity with the Indian theory of *karman* (karma) which has become the central dogma of Hinduism. The word *karman*, derived from the root *KṚ*, 'to do', means 'action', but denotes also the results of the good and bad actions in the form of merit or demerit, the inexorable consequence of acts accomplished in previous lives. By affecting the *sūkṣmaśarīra* or 'subtle body', or in other words the psychic individual, the 'Self' (*ātman*), the permanent and unconscious substratum of the human being, *karman* obliges him indefinitely to undergo a new birth in a human or other form, determined by the quality of his past acts.

The observation of the relationship between the body and the mind has led Indian physicians to notions of personal temperament and physiognomony. Ayurvedic biotypology is based on two criteria, one constitutive and the other psychological. The first typology describes three kinds of temperaments based on the predominance of one of the three vital principles: the 'windy', the 'bilious', the 'phlegmatic'. The second typological system of Āyurveda categorises the individuals according to the properties (*guṇa*) of the mind. The ideal standard of behaviour is that which corresponds to a predominance of *sattva*, 'purity', according to the *Sāṃkhya* philosophy.

Diseases and Pathology

According to Āyurveda, diseases (*roga*, *vyādhi*) are of two kinds, exogenous and endogenous (Sharma 1992). The former are caused by damage from outside (blows, injuries, bites, falls, burns, etc.). All the others represent an

> imbalance of the *dhātu*' (*dhātuvaiṣamya*), or in other words disturbances in the normal balance of the elements which constitute the substance of the body and which animate it. 'Wind, bile and phlegm, in the normal state, enable a man to have a long life, with his faculties intact, endowed with vigour, good appearance, and health… But, if they become abnormal, they lead him to great adversity…' (*Carakasaṃhitā*, Sūtrasthāna, XII, 14).

That is why this triad of vital elements has been given the name of *tridoṣa*, the 'three vitiating factors'.

The conditions of perturbation of their functions are complex in most cases. The alteration of just one of these elements or just one of its secondary forms can unleash a disease by virtue of the disturbances resulting in the functioning of the others. Often two among them or even all three of them are simultaneously involved, in varying degrees, in the production of different ailments. Hence there are a very large number of pathogenic combinations. The perturbations of 'wind', 'bile' and 'phlegm' can in their turn affect the *dhātu*, the joints or the vascular system. The elements, the tissues and the organs interact, and imbalance of the ones leads to imbalance of the others. Some parallels have often been drawn between ayurvedic ideas and some of the data from Greek medicine. The text *Airs* of the Hippocratic Collection describes a pathology by the association of blood and 'wind', which brings to mind the theory of the *Suśrutasaṃhitā* relating to the pathogenic role of 'wind–blood'. Furthermore, there is a remarkable analogy between the doctrine of the *tridoṣa* and a theory described by Plato at the end of his *Timaeus* (Filliozat 1964).

The perturbations in the functions of wind, bile and phlegm are themselves related to multiple causes called *nidāna* which are looked for mainly in the behaviour of the patient and his food, having regard to external circumstances. Dietary deviations are often criticised.

Nosology is highly developed. It categorises the diseases sometimes according to their supposed origin and sometimes according to the nature of their symptoms. We also find them divided in another way, according to whether they affect the chyle, the blood, the flesh, the fat, the bones, the marrow or the semen.

Diagnosis and Prognosis

To identify an ailment, to know its stage of development as well as the part which should be ascribed to each *doṣa* in its production, the ayurvedic practitioner must undertake a minute examination not only of the body of the patient, but also of his mental state. The methods of examination must bring into play all five senses.

The practice of the examination of the pulse, common today in ayurvedic medicine, does not seem to have appeared before the twelfth century. The idea of examining the pulse might have been borrowed from China, but the technique attested in India is different and what one expects to learn out of this examination is not what the Chinese physicians look for. Indeed, by taking the pulse the Indian physician claims to recognise the disturbances in the equilibrium of the three vital principles, 'wind', 'bile' and 'phlegm' and in this way he diagnoses all the ailments. The interpretation of the various pulses is connected therefore to the ayurvedic theory of the *tridoṣa* (Kutumbiah 1967).

The palpation is done by bringing the tips of the index finger, the middle finger and the ring finger close to each other and applying them on the radial artery of the right wrist for men, and the left wrist for women. The texts distinguish several types of pulse according to the amplitude of the pulsation (strong, weak or very weak pulse), the frequency (regular, rapid or slow pulse) and the temperature (hot or cold pulse), whose variations are presumed to reflect the activities of the three *doṣa*.

Questioning the patient and his family circle complements the various examinations. The purpose of this questioning is not only for the physician to gain information about the circumstances in which the first symptoms appeared and the development of the ailment, but also about the personality of the patient, his activities, his food and his appetite, having regard to the season, the climate and, of course, the psychological context in which the sickness began, for Āyurveda cares for the whole human being, both his soul and body. According to these ideas, each patient should be treated holistically. Today, however, it is rare to find ayurvedic practitioners who will prepare remedies specific to particular patients. The *Carakasaṃhitā* indicates that the patient should also be questioned about his dreams.

In ancient times, the establishment of the prognosis concerning the curability or the incurability of a disease depended more often on the divining art than on medical science. Thus, one claimed to foretell the outcome of a disease according to the language, the clothes and the attitude of the messenger who came to fetch the doctor, or else according to the direction of the wind blowing at his arrival, or else according to the dreams of the patient. The anomalies that may be noticed in the sensations of the patient were generally regarded as bad signs. Other fatal indications could be drawn from the change in his complexion.

Preventive Medicine

Of all the ancient medicines, it is probably ayurvedic medicine which, from its origins, has accorded the greatest importance to hygiene, to diet, to physical exercises and to massage, both as means of prevention and as curative methods. The rules of hygiene and of diet were already extremely numerous and elaborate in the treatises of Caraka and Suśruta who devote several chapters to them. These rules take into account not only the climate, the season and the circumstances, but also the temperament of each individual.

In the chapters relating to prevention, the *Carakasaṃhitā* (Sūtrasthāna, VII, 31–34) emphasizes the benefits of physical exercise (*dehavyāyāma*). It is said there that gymnastics makes the body light, increases its capacity for work, diminishes the *doṣa* and stimulates the 'digestive fire'. But it must be practised with moderation.

The oldest Sanskrit texts lay stress on the importance of a well-balanced diet, both from the quantitative and the qualitative points of view. According to the *Carakasaṃhitā*, the quantity of food depends on the capacity of digestion (*agnibala*, literally 'strength of the fire'), so much so that even foods considered as very easy to digest must not be consumed in excessive quantities. The medical texts systematically enumerate all varieties of edible products indicating their different properties, according to the temperament, behaviour and state of health of each individual, having regard also to the season, the time of the day, the quality and the quantity of the food taken. Thus, some foods recommended for cold and rainy weathers are strongly inadvisable during summer; a drink that is safe for a healthy individual carries the risk of complicating an already morbid condition, etc.

Āyurveda emphasizes also the benefits of tonics and stimulants, the *rasāyana*, and of aphrodisiacs, the *vājīkaraṇa*. The *vājīkaraṇa* are believed to increase the strength of those who are weakened and whose virility is low. These are most often preparations based on sesame, broad beans (*Phaseolus radiatus* L.), sweet potatoes (*Ipomea digitata* L.), sugarcane juice, long pepper (*Piper longum* L.), emblic myrobalan and milk, in combination with the testicles of goats, buffaloes or donkeys. The roots, bark, buds and fruits of the *aśvatha* tree (*Ficus religiosa* L.) are also used. As regards the *rasāyana*, they are elixirs which are expected to confer long life, health and youth. The *Carakasaṃhitā* gives very detailed instructions for their preparation. One of the most famous is the *Cyavana Prāśa* in the compounding of which more than 30 ingredients figure.

The choice of a therapy depends not only on the disease diagnosed, but also on the causes which are attributed to it in relation to the excessive activity or improper functioning of the three vital principles (wind, bile and phlegm), the temperament and the environment of the patient. Ayurvedic treatments are therefore individualised and they give great importance to prescriptions of diet and hygiene.

'Pañcakarma' Therapy

Pañcakarma therapy is considered the method of treatment *par excellence* for restoring the normal balance of the three vital principles. Under this name are grouped 'five procedures' (*pañcakarman*): the administration of emetics (*vamana*), purgatives (*virecana*), enemas (*basti*), errhines (*nasya*) and bloodletting (*raktamokṣana*).

Vamana consists in orally evacuating the *doṣa* in excess by prescribing emetics in cases of ailments attributed to disorders of the 'phlegm'. They are contraindicated in the case of consumptive disease, in case of weakness and for children, the aged and pregnant women.

Purgatives are administered for eliminating by the lower tract the impurities accumulated in the intestines. Purging is indicated in the case of diseases that result from an imbalance of the 'bile': fever, skin disease, digestive disorders, urinary disorders, eye diseases, etc. It is contraindicated for children and old people, as well as for pregnant women. Enemas are intended to purify the organism. The process owes its name to the bladder (*basti*) used for introducing various medicinal preparations into the body. Rectal injections are especially indicated in case of fever, diarrhoea, constipation, colic and flatulence.

Āyurveda recommends taking medicinal preparations through the nose (*nasya*) to rid the head and the neck of the problems which are located there. The prescriptions are powders and nasal drops whose choice, time of administration and dosage depend both on the condition diagnosed and the vital principle (wind, bile or phlegm) involved in its production.

Bloodletting is for ridding the organism of 'polluted' blood and for combating in this way various diseases for which blood is thought to be the seat, or the source, in particular diseases of the skin. Anaemia, pregnancy, fatigue and old age constitute the major contraindications. Bloodletting can be carried out by means of lancets or by the application of leeches.

Besides these five 'principal measures' (*pradhānakarman*), *pañcakarma* therapy also includes preliminary measures (*pūrvakarman*). Patients are prepared by being oiled and sweated.

Drugs of Natural Origin

Most of the drugs recommended by Āyurveda are plant-based. In the course of the centuries, ayurvedic medicine has used more than 3,000 plant species of which a good thousand still enter, in various forms, into the composition of the remedies prescribed today. One notes also the use of a certain number of substances of animal or mineral origin. Among the animal products figure foods of animal origin, meats, fats, milks and derivatives, as well as blood, bones, nails and horns. The medical texts speak highly also of the beneficial effects of human urine and that of different animals. Goat's urine, for example, is particularly recommended in cases of cough, breathlessness, icterus, anaemia or haemorrhoids. Horse's urine, pungent, caustic and warm, is especially indicated in cases of perturbations of wind or phlegm. As regards human urine, it has been used in salves for treating certain eye affections. The mineral products of the ayurvedic pharmacopoeia comprise notably bitumen, arsenic, copper sulphate, gold, silver, lead and iron. The last mentioned was used very early, in the form of powder, in the treatment of anaemias.

All these natural substances have contributed to the manufacture of thousands of remedies often involving very complex formulas. This complexity of the compositions is explained simultaneously by ayurvedic pathology, by the complexity of the cases to be treated and by the concern for combining the different ingredients in such a way as to counterbalance, increase or prolong the effects of some by the properties of the others.

The forms of drug delivery are varied: powders, infusions, decoctions, macerations, electuaries, pills, liniments or ointments. Apart from aqueous preparations, the usual vehicle is oil or clarified butter (*ghṛta* or ghee), but milk and honey are also used. As regards the methods of administration of these remedies, they depend on the nature of the medicine and/or the location of the disease. A certain number of preparations are administrated orally, through the nose or through the rectum (enemas, suppositories). Others are reserved for external use.

In order to explain the properties of the different substances and their effects on the organism, Indian physicians of antiquity developed theories which apply as much to food as to plants and to the substances of animal or mineral origin in the pharmacopoeia. For that reason they were very early led to establish correspondences between the vital principles and the simplest perceptible properties of these substances such as their consistency, their odour, their colour and above all their savour (Meulenbeld 1987; Mazars 1995a).

According to Āyurveda, there are six basic savours: sweet, sour, salt, pungent, bitter and astringent. For a long time modern physiology only recognised four of them (sweet, sour, salt and bitter), but no one ever thought of verifying their primary character experimentally. In fact we know today that there is no basic savour. Ayurvedic medicine teaches that substances with a sweet, sour or salt savour calm the wind but irritate the phlegm. On the contrary, those which are pungent, bitter or astringent combat the harmful effects of the phlegm but excite the wind. As regards the activity of the bile, it is reduced by sweet, bitter or astringent substances and increased by sour, salt or pungent substances.

Of the six savours distinguished by Āyurveda, the sweet savour appears to be most important, for it has been thought to contribute to long life. But an excess of remedies or foods with sweet savour, by perturbing the 'phlegm', provokes obesity, promotes laziness, weakens the power of digestion and leads to all kinds of diseases.

Observing that some foods and remedies do not provoke the effects proclaimed by the theory of savours, the theoreticians of Āyurveda sought other explanations to account for the properties of all the substances. They were thus led to establish for each substance:

1. Its 'post-digestive' [*vipāka*, literally 'after cooking' (by the 'digestive fire')] effect, which flows from its savour.
2. Its 'quality' (*guṇa*). There are 20 *guṇa*, one opposing the other, as follows: heavy or light, dull or sharp, cold or hot, unctuous or not unctuous, smooth or rough, solid or liquid, soft or hard, stable or fluid, subtle or gross and non-slimy or slimy.
3. Its 'potency' (*vīrya*). Drugs are divided into two categories depending upon their potency: heating or cooling. Substances having 'hot' potency produce heat in the body. On the contrary, the substances having 'cold' potency have a cooling effect.

Finally, to explain the exceptions to these rules, the notion of *prabhāva* or 'specific action' was developed. These different conceptions conditioned the methods of choice, recommendation and preparation of foods and the medicines.

Āyurveda is the result of long medical observation, speculation and practice, and has exerted a great influence far beyond the frontiers of the Indian world. The underlying concepts of this system relating to health and disease are not devoid of interest. The examination of the data collected in the earliest Sanskrit medical texts shows that the physicians of ancient India visualised living beings in a way that we might qualify today as *systemic*. Humans (as well as animals) are considered an open system according to a concept fairly close to that developed by Ludwig von

Bertalanffy (1901–1972), a system exchanging matter, energy and information continually with its environment (von Bertalanffy 1968). Ayurvedic medical practice is also marked by systemic thought. Its overall objective is to maintain the normal balance of the vital principles responsible for the proper functioning of the organism or to re-establish this balance when it is disrupted. Thus, Āyurveda appears as a system which gives greater weight to prevention than to treatment, giving great importance to hygiene, food and environment whose decisive role in triggering certain diseases is being discovered today.

Medicine in Islam

M

Husain F. Nagamia

Preservation of life is mandated by the following verse of the Qurʾān: "The saving of one life is as if one has saved humanity."

From the earliest times in the history of Islam, medicine has played a vital role. The importance of seeking treatment was emphasized by the Prophet himself in his sayings, which are known as the Ḥadīth: "Allah never created a disease for which he did not create a cure. So seek treatment." "There is a cure for every malady (except old age). If the right treatment is administered, Allah willing the malady is cured."

All the religious scholars agree that a medical doctor is ordained to find a cure for a disease and if one is not found, he should continue to do research until it is found. Thus in Islam disease is not looked upon as a curse from God to be endured and suffered but as an affliction for which a cure has to be sought and administered, with patience and perseverance.

Ethics of Medicine in Islam: The Physician and the Patient

Very early in the history of Islamic civilization (second century after Hijra or the beginning of the Islamic calendar[1]), Islamic medical ethical standards of practice were established set, and the relationship between a physician and patient was defined.

The physician was always held to the highest professional standards and ethics in treating his patient. One of the earliest treatises written on medical ethics was *Adab al-ṭabīb* (Practical Ethics of the Physician) by Isḥāq Ibn Ali al-Ruhāwī, a ninth century physician practicing under the Islamic Caliphate. In this philosophical treatise Ruhāwī examines not only the relationships between a patient and a physician, but also a physician's personal standards of behaviour, conduct of daily activities, morality and even his relationship with God. A physician was expected not only to perform to the best of his capacity in treating his patient, but also to be a model citizen in his society.

In Islam certain rules have to be observed when administering treatment (Mohammed 1980). With advances in medical sciences the ethics of a particular treatment have to be examined in light of Islamic tenets and beliefs *the Shariah*.

History of Medicine in Islam

Medicine as a science and art was cultivated during the development of the Islamic civilization (Hamarneh 1983). The advancements made were limited only by the development in the associated fields of physics, mathematics, chemistry, pharmacology, pharmacy, and philosophy. The Muslims gathered material together from extant sources added their own observations and compiled it into encyclopaedic works (Savage-Smith 1994). Medical knowledge disseminated to all corners of the expanding Islamic empire.

The Early Era of Islamic Medicine and the School of Medicine at Jundishapur

Jundishapur or "Gondeshapur" was a city in Khuzistan founded by Shāpūr I (241–272 CE). In present day western Iran the site is marked by the ruins of Shahbad near the city of Ahwaz (Seyyed 1976). The town was taken by Muslims during the caliphate of Hadrat Umar. At this time it already had a well-established hospital and medical school.

Many Syrians took refuge in the city when Antioch was captured by Shāpūr I. The closing of the Nestorian School of Edessa by Emperor Zeno in 489 CE led to the Nestorians' fleeing and seeking refuge in Jundishapur under the patronage of Shāpūr II. The Greek influence was already predominant in Jundishapur when the closing of the Athenian school in 529 CE by order of the Byzantine emperor Justinian drove many learned Greek physicians to this town. A university with a medical school and a hospital was established where Greco-Syriac medicine blossomed. To this was added medical knowledge from India brought by the physician vizier of Anushirwan called Burzuyah. On his return the latter brought back from India the "Fables of Bidpai", several Indian physicians and details of Indian medical texts. Thus at the time of the Islamic invasion the school of Jundishapur was well established and had become renowned as a medical centre of Greek, Syriac and Indian learning. After the advent of Islamic rule the university continued to thrive.

It is likely that the medical teaching at Jundishapur was modeled after the teaching at Alexandria with some influence from Antioch. This hospital was to become the model on which all later Islamic medical schools and hospitals were to be built. The School thrived during the Ummayid caliphate and medical and philosophical works of both Hippocrates and Galen were translated into Syriac. These were later to be translated into Arabic.

It was during the Abbasid Caliphate that Caliph al-Manṣūr, the founder of the city of Baghdad, invited the head of the Jundishapur School to treat him. This physician was Jurjis Bukhtīshūʿ, a Christian. He treated the Caliph successfully and was appointed to the court. He did not stay permanently in Baghdad, returning to Jundishapur before his death, but the migration to Baghdad had begun. His son, Jibrīl Bukhtīshūʿ, established a practice in the city and became a prominent physician. By the second half of the second century after Hijra (eighth century CE) the fame of Baghdad began to rise. Many hospitals and medical centers were established and tremendous intellectual activity was recorded.

Resources for the Development of Islamic Medicine: The Bayt Al-Hikmah or "The House of Wisdom"

Al-Maʾmūn is usually credited with having made the translation of the Greek sciences systematic and institutionalized in the form of the Bayt al-Hikmah. This institution has been variously referred to as an academy, translation centre and library. Its principal activity was the translation of philosophical and scientific works from Greek/Syriac into Arabic.

Scholars have recently begun to doubt some of the assumptions and the interpretations that have been made about the nature and function of this institution. To start with, no date can be established for its foundation, so although the earliest reference to it is in the time of Hārūn al-Rashīd, it may have existed with the caliphs al-Manṣūr or al-Mahdī (r. 775–785). Regarding its function, there are references in the sources to

[1] The Islamic calendar began 16th July 622 marking the migration of the Prophet of Islam from Mecca to Medina.

translation activity, but these are about work from Persian to Arabic, and there is nothing to suggest that there was any translation at the *Bayt al-Ḥikmah* from Greek into Arabic. Perhaps this can explain some of the confusion over its function. The main reason may be that by the time Ibn al-Nadīm was writing his biographical history the institution had assumed legendary qualities, which have continued to impress subsequent commentators (Attewell 2002).

The most celebrated translator of Greek learning into Arabic is Ḥunain ibn Iṣḥāq (d. 873 or 877). Born in Hira, Ḥunain was the son of an apothecary. He soon translated the entire collection of Greek medical works, including Galen and Hippocrates. He was more scientific and interpreted the original text by cross-reference, annotation and citing glossaries. His original contributions included 10 works on ophthalmology. He rose to the highest honor by being appointed the director of the House of Wisdom by Caliph al-Mutawakkil.

Yuḥannā ibn Masawayh (Mesuse senior) was an early director of the House of Wisdom. He wrote about gynecological problems.

The House of Wisdom had enormous effects on Islamic science, philosophy, art, architecture, agriculture and government. Some of the Islamic physicians had available to them much of the knowledge of ancient Greece, Syria, India and Persia and in turn they contributed their observations and originality.

Hospitals During the Islamic Era

The idea of a hospital as an institutional place for the caring of the sick has not been recorded in antiquity. There were sanatoria and "travel lodges" that were attached to temples where priests attended to the sick. Most of the therapy in these sanatoria consisted of prayers and sacrifices to the gods of healing.

A large number of hospitals were developed during the Islamic era. They were called *bīmāristān*. The early Caliphs adopted the idea of a hospital as a place where the sick could get attention. The first hospital is credited to Caliph al-Walid I (86–96 AH 705–715 CE). At first it was considered no more than a leprosarium because it allowed the segregation of lepers from others. It did have on staff "salaried doctors" to attend the sick.

The first true Islamic hospital was built during the reign of Caliph Hārūn al-Rashīd (170–193 AH 786–809 CE). Having heard of the famous medical institution at Jundishapur the Caliph invited the son of the chief physician, Jibrīl Bukhtīshūᶜ to come to Baghdad and head the new *bīmāristān*. It rapidly achieved fame and led to the development of other hospitals in Baghdad. It is claimed but not established that one of these, the "Audidi" hospital was built under the instructions of the Islamic physician al-Rāzī. At its inception it had 24 physicians on staff, including specialists such as physiologists, oculists, surgeons and bonesetters. When Djubair visited Baghdad in 580 AH/1184 CE he recorded that this hospital was "like a great castle" with water supplied from the river Tigris and all the appurtenances of royal palaces.

One of the largest hospitals ever built in the Islamic Empire was the Mansūri Hospital in Cairo. It was completed in 1248 CE. It had a total capacity of 8,000 people. The annual income from endowments alone was one million dirhams. Irrespective of race, religion and creed or citizenship (as specifically stated in the *waqf* documents, see below) nobody was ever turned away. There was no limit to the time the patient was treated as an inpatient. There were separate wards for men and women, and medicine, surgery. Fevers and eye diseases also had separate wards. It had its own pharmacy, library and lecture halls. It had a mosque for Muslim patients as well as a chapel for Christian patients.

The waqf (an inalienable religious endowment in Islam) specifically stated:

> The hospital shall keep all patients, men and women until they are completely recovered. All costs are to be borne by the hospital whether the people come from afar or near, whether they are residents or foreigners, strong or weak, low or high, rich or poor, employed or unemployed, blind or sighted, physically or mentally ill, learned or illiterate. There are no conditions of consideration and payment; none is objected to or even indirectly hinted at for non-payment… (Ahmad 1939).

Some of the hospitals, especially those established by princes, rulers and viziers, were luxurious; some were actual palaces that had been converted to hospitals. The annual income of Jibrīl Bukhtīshūᶜ was 4.9 million dirhams (Rahman 1989). His son, also a doctor, lived in a house in Baghdad that was air-conditioned by ice in summer and heated by charcoal in winter. For comparison, a resident, who was supposed to be on duty for two days and two nights a week, was paid 300 dirhams a month.

The Great Physicians of Islamic Medicine

The era of Islamic medicine produced some very famous and notable physicians. These physicians were not only responsible for getting all the existing information on medicine together, but also for adding to this knowledge by their own observations, experimentation and skills. Many of them were skilled in medical writing and produced encyclopaedic works which became standard texts and reference works for centuries. Some of these tenets form the basis of instruction of students of *ṭibb* and *ḥikmah*, traditional

Islamic medicine still practised in India and Pakistan today, under the name 'Unani or Tibbi' medicine. For the sake of classification, the historic periods of the Islamic physicians can be divided into three parts (1) *the period of Islamic Renaissance*: This started from the beginning of Islamic era and ended with the end of the Abbasid dynasty; (2) the period of Islamic Epoch: when all sciences including medicine reached the pinnacle of development; and (3) *the period of decline*: during which the knowledge of Islamic medicine declined in the Islamic state but was translated into European languages and became the basis of further development and discoveries.

The Bukhtishu Family of Physicians

The oldest in this family was Jurjis Bukhtīshūᶜ who was the Chief Physician at the Hospital in Jundishapur. He came from a Christian family and was summoned to the court of Caliph Maʾmūn (148 AH/765 CE) when the latter fell ill. It was his son Jibrīl Bukhtīshūᶜ who was later invited by Caliph Hārūn al-Rashīd to come to Baghdad to treat him (171 AH/787 CE). He was Chief until he died in 185 AH/801 CE.

Masawayh

Another family that migrated from Jundishapur to Baghdad was the family of Masawayh who went at the invitation of Caliph Hārūn al-Rashīd. One became a famous ophthalmologist. Most famous amongst his three sons who were physicians was Yuḥannā ibn Masawayh (Mesue Senior). He wrote prolifically; 42 works are attributed to him. He is known for having a sarcastic temperament but commanded great respect because of his medical expertise.

Ḥunayn ibn Isḥāq

Ḥunayn ibn Isḥāq, who was a student of Ibn Masawayh, became the greatest translator of Greek and Syriac medical texts during the third century AH/ninth century CE. He was responsible for masterly translations of Galen, Hippocrates and Aristotle into Arabic. He also improved the Arabic medical lexicon giving it a rich technical medical language to express medical terminology. He was himself a physician and wrote two original works on ophthalmology.

Al-Rāzī

The most famous physician of this time and perhaps of the entire early Islamic era is Muḥammad ibn Zakariyya al-Rāzī (born 251 AH/865 CE; died 312 AH/925 CE), called Rhazes by his Latinized name. He was born in Rayy in northern Persia not far from modern Tehran. Although not much is known about his early life or his medical education, his fame started with the establishment of a hospital in Baghdad of which he was the chief. The story of how he picked the site of the hospital when asked to select one has become one of the classical legends of Islamic medicine. He had pieces of meat hung in various quarters of the city and had them examined for putrefaction and recommended the site where the meat had decayed the least as the most suitable site. This made him one of the first physicians to infer indirectly that there was an element of bacterial putrefaction in the degradation of meat, and suggested the environmental role that contaminated air plays in the spread of infection.

Al-Rāzī is known for numerous other original contributions to the art and science of medicine. He described the differences between smallpox and chickenpox and gave an in depth description of measles. He described allergy to roses in one of his classical cases. The Islamic historian and scientist al-Bīrūnī listed 56 medical works of al-Rāzī, the most famous being *al-Ḥāwī*, an encyclopaedia of medical knowledge based on his personal observations and experiences. A Copy preserved in the National Library of Medicine in Bethesda Maryland is described as the third oldest medical manuscript preserved in the world today.

Besides these and other original contributions of which many have been published, al-Rāzi devoted a lot of his time to teaching, bedside medicine and attending to the royalty and court. The impact of these publications on Islamic medicine was tremendous. His books became an invaluable addition to the armamentarium of a medical student of the time and remained standard texts until the appearance much later of texts by al-Majūsī (d. 994) and Ibn Sīnā, who authored such monumental works as *al-Qānūn fī l-ṭibb* (The Canon of Medicine).

Al Majusi

In the fourth century of Hijra, tenth century CE another Islamic physician gained prominence in Baghdad. His name was 'Alī ibn al-'Abbās al-Majūsī (d. 384 AH/994 CE). (Latinized Haly Abbas). He became the director of the Adud-dawlah Hospital. Al-Majūsī dedicated his medical work *Kitāb al-Malakī* (The Royal Book) to its founder. This book is very well systematized and organized. It is divided into two volumes, one covering theory and the other practical aspects. Each of these has ten chapters. The first volume deals with historical sources, anatomy, faculties, six primeval functions, classification and causation of disease, symptoms and diagnosis, urine, sputum, saliva and pulse as an aid to diagnosis, external or visible manifestations of disease and internal diseases like fever, headache, epilepsy and warning signs of death or recovery. The second volume deals with hygiene, diet, cosmetics, therapy with simple drugs, therapy for fevers and diseases of organs. There is a chapter on surgery, orthopaedics, and finally treatment by compound medicaments.

About the second century AH/eight century CE a great centre of knowledge learning and culture had been developing in the western part of the Islamic empire. This was in Spain or "Andalusia" as the Arabs called it. Spain was invaded and conquered by the Muslims in 93 AH/714 CE. When the Ummayad dynasty ended in Baghdad the last of Ummayad princes escaped to Spain where they established the Western Caliphate. The rulers of this dynasty laid the foundation for the Muslim rule of Spain that was to last for seven centuries. During this time Cordoba, also called "Qurtuba", became a great centre of international learning. A great library containing more than a million volumes was established.

Al-Zahrawi

Perhaps the most famous physician and surgeon of the era was Abū l-Qāsim al-Zahrāwī, known to the west as Albucasis (318 AH/930 CE to 403 AH/1013 CE). He gained great fame as a physician. He wrote a 30-volume compendium called *al-Taṣrīf*. The initial volumes dealt with general principles, elements and physiology of humours and the rest dealt with systematic treatment of diseases from head to foot. The last volume deals with all aspects of surgery. It was the first textbook of surgery with illustrations of instruments. He emphasized that knowledge of anatomy and physiology was essential prior to undertaking any surgery:

> Before practicing surgery one should gain knowledge of anatomy and the function of organs so that he will understand their shape, connections and borders. He should become thoroughly familiar with nerves, muscles, bones arteries and veins. If one does not comprehend the anatomy and physiology one can commit a mistake which will result in the death of the patient. I have seen someone incise into a swelling in the neck thinking it was an abscess, when it was an aneurysm and the patient died on the spot.

He described operations on varicose veins, reduction of skull fractures, dental extractions, forceps delivery for a dead foetus to mention just a few. His work raised surgery to a high level.

Ibn Sina

However the greatest physician of the Islamic era was *Abū ͨAlī al-Ḥusain ibn ͨAbdallāh ibn Sīnā*, Avicenna or Ibn Sīnā. Some historians of medicine call him one of the greatest physicians that ever lived. That is because Ibn Sīnā was not only a physician, but also his knowledge and wisdom extended to many other branches of science and culture including philosophy, metaphysics, logic and religion.

Ibn Sīnā was indeed a prodigy. At the age of 10 he had memorized the whole Qurʾān. By age of 16 he had mastered all extant sciences that appealed to him including mathematics, geometry, Islamic law, logic, philosophy and metaphysics. By age 18 he taught himself all there was to learn at that time in medicine. Born in the city of *Būkhārā* in what is now central Asia in the year 370 AH/980 CE, he rapidly rose in ranks and became the vizier (prime minister) and court physician of the Samanid ruler Prince Nuh ibn-Mansūr. The Royal Library was opened to him and this enlarged his knowledge. He began writing his first book at age 21. In the short span of 30 years of writing he wrote over a 100 books of which 16 were on medicine. His magnum opus is *Qānūn fī l-ṭibb* (The Canon of Medicine). This voluminous compendium of medical knowledge rivaled one written earlier by al-Rāzi and al-Majūsī and indeed surpassed both of these in content and originality. It was composed of five volumes: general principles, simple drugs, systematic description of diseases from head to foot, general maladies and compound drugs. The Canon was translated into Latin by Gerard of Cremora and Andrea Alpago and remained the standard textbook of medicine in Louvain and Montpellier until the seventeenth century.

Ibn Nafis

Islamic physicians not only possessed excellent knowledge of anatomy, but also they added some challenging new concepts that were revolutionary to the then understanding of anatomical concepts laid down by the "ancients". The example that has now become well known is that of the discovery of the lesser or pulmonary circulation by Ibn Nafīs (d. 687 AH/1288 CE). The description he gave of pulmonary circulation challenged the fundamental concept held by Galen. In fact it suggested that there existed a pulmonary capillary bed where the blood was "purified" before being brought back to the heart by the pulmonary artery, thus predating the discovery of pulmonary capillaries long afterwards, made possible by the discovery of the microscope by Antony van Leeuwenhoek. Al-Zahrāwī emphasized that the knowledge of anatomy was a prerequisite for the surgeon.

> Now this is the reason why there is no skillful operator in our day: the art of medicine is long and it is necessary for its exponent, before he exercises it, to be trained in anatomy as Galen has described it, so that he may be fully acquainted with the uses, forms, temperament of the limbs; also how they are jointed, and how they may be separated, that he should understand fully also the bones, tendons and muscles, their numbers and their attachments; and also the blood vessels both the arteries and the veins, with their relations.

The physiological concepts embodied in Islamic medicine were based on the Hippocratic and Galenic concepts of elements, natures and humours. In this theory harmony in the body prevails when all the humours are in proper balance and it is their imbalance that creates disease. Under this principle, disease is a state of imbalance of humours and needs the restoration of balance to bring the organism back to its normal healthy state. Islamic medicine also expounds the concept of elements and temperaments. The basic elements are earth, fire, air and water, and each of these is given a temperament: earth is dry and cold; water is humid and cold; fire is hot and dry; air is humid and hot. Each of the four essential body fluids – blood, phlegm, yellow bile and black bile – is assigned a respective temperament. Each dietary food, medicine or climatic environment can thus then modify or temper the humours of the body and it is an interplay of these that can restore health from sickness or cause the sickness to worsen.

It was the fundamental belief of a Muslim physician that the organic body alone cannot manifest life, being innate and devoid of a life force. It was the instillation of a life force, *Ruh*, which gave it vibrancy and vitality of spirit. Thus without the Ruh, no function of the body is possible. It is the Ruh which descends from God to mix with the anatomic and physiologic body to make a complete human being. It is thus essential when treating a diseased state to take the Soul or 'Ruh' into consideration. Laying the foundation of Holistic Medicine.

Pharmacy, Pharmacognosy, Materia Medica and Therapeutics

One of the sciences that had an impetus on Islamic medicine was the development of pharmacy and pharmacognosy. Most Islamic physicians and scholars studied chemistry or alchemy. This study was furthered by the concomitant development of techniques to refine drugs, medications and extracts by processes of distillation, sublimation and crystallization. Pharmacists became commonplace in Islamic lands, and their proliferation ultimately required the institution of licensing.

Pharmacological drugs were classified into simple and compound drugs. The effects of these were detailed and documented. The earliest Islamic works on pharmacognosy, such as "Treatise on the Power of Drugs, Their Beneficial and Ill Effects" and "The Power of Simple Drugs" were written in the third and fourth century AH/ninth century CE. Most medical texts contained chapters on the use of both these types of remedies. Rāzi's *al-Ḥāwī* mentions 829 drugs.

Materia medica and texts containing compendia of drugs and their effects appear frequently during the era of Islamic medicine. Notable amongst these is the contribution of Abu Bakr ibn Samghun of Cordoba, *The Comprehensive Book on Views of the Ancients as Well as the Moderns on Simple Drugs*. Ibn Juljul made a commentary on drugs and plants described by Dioscordes and added a number of newer ones. Al-Zahrāwī's *al-Taṣrīf* mentioned earlier in reference to its surgical volume also had a section on plants and drugs. The second book of the *Canon* is devoted to the discussion of simple drugs and their powers and qualities. One of the most authoritative books on drugs was written by al-Bīrūnī, entitled *The Book on Drugs*, which contains a huge compendium of drugs, their actions and their equivalent names in several languages.

Medicine in Japan

William D. Johnston

When considering the Japanese history of medicine, it is important not to project our ideas about medicine today onto the past. Whereas modern medicine worldwide is based on the language and methods of natural science, the medicine of premodern Japan consisted of many different languages and practices. Moreover, the historical development of medicine in premodern Japan must not be thought of as following a linear development that inevitably ended in the adoption of Western medicine. It is, rather, the story of theories and practices that unfolded according to their own historical logic, often in competition with each other and without theoretical or practical consistency. The fact that the Japanese did adopt Western medical ideas and practices during the premodern period simply reflects the ways in which some Japanese medical ideas and practices developed.

Throughout the premodern period, which in the case of Japan spans all of history until the mid-nineteenth century, numerous medical theories and practices, many of which were mutually contradictory, coexisted. Until modern times, most people depended primarily on folk remedies to treat their ailments. These consisted mostly of shamanistic rituals whose remnants can be found today in a small number of Shinto shrines and Buddhist temples. Physicians with a textually based theoretical training were rare in rural areas, where most Japanese people lived as peasants or fishers. However because few documentary sources exist on which a history of folk medicine could be based, historians have made the textual tradition the focus of their research. Hence it is also necessary to focus on this textual tradition here, but this is, of necessity, only a partial history.

Within these limits, the history of Japanese medicine can be divided into four periods: ancient, medieval, early modern, and modern. The ancient period spans from prehistory to the late twelfth century; the medieval period reaches from the beginning of the thirteenth century to the late sixteenth; and the early modern period encompasses the years from the late sixteenth until the mid nineteenth century. Because in many respects the history of Japanese medicine during the modern period parallels that of the Western world, this article deals primarily with the premodern period.

Prehistoric and Ancient Medicine

Based on skeletal remains, it is clear that the prehistoric inhabitants of the Japanese islands developed rudimentary medical practices. Some bone fractures, at least, were treated so that they healed cleanly. The earliest written records, which date from the early eighth century, recount the use of herbal remedies for some illnesses. However the same records also reflect the belief that most diseases were divine retribution for offending a deity or spirit; they were treated through exorcism, ritual ablution, and purification rituals. Some diseases, such as leprosy and tuberculosis, were also associated with ritual pollution, a belief which has found currency into modern times. Because this pollution was thought to be hereditary, these diseases often made it difficult for the persons who had them and members of their families to find marriage partners. When a disease reached epidemic proportion, it was thought to be caused by the more powerful deities that controlled forces of nature throughout the land, deities that the emperor or empress attempted to assuage with national purification rituals.

It is unclear when Chinese writing first reached Japan, but by the late fourth or early fifth century scholars from the Korean peninsula were tutoring members of the imperial family in the Chinese classics. The real rise of literacy came with the Japanese adoption of Buddhism from the sixth century; it can be surmised that the advent of textually based medicine in Japan also dates from this time. By the seventh century, Buddhist monks from the continent were both practicing medicine and training Japanese monks to become practitioners themselves. Until the seventeenth century most trained medical practitioners retained the trappings, if not always the formal status, of Buddhist priests.

From the late seventh century the Japanese state adopted the legal codes of Tang China. These included provisions for government posts that specified the employment of various medical specialists, including internists, surgeons, acupuncturists, masseuses, exorcists, obstetricians, dentists, and pharmacologists. Although in China these posts were filled with scholars who passed required examinations, in Japan they soon became hereditary and remained so until the nineteenth century. This did not, however, preclude the adoption of new developments in medicine from the continent. Constant interaction with both Korea and China, where numerous Japanese Buddhist priests went to study, kept them informed of changing theories and practices, although the process of change was far slower than during more recent times.

Medicine during the Nara (710–794) and Heian (794–1185) periods remained the domain of court physicians and Buddhist priests. As in premodern Europe, internal medicine and surgery remained distinct practices. Internists had a high level of education and relatively high social status; surgeons, who mostly treated skin lesions, wounds, and fractures, had comparatively little theoretical training and low social status. These remained distinct until the late eighteenth century.

Internal medicine was based entirely on Chinese texts; the first Japanese medical text did not appear until the year 984. This was the *Ishimpō* (literally, Methods at the Heart of Medicine), which was written by the court physician Tanba Yasuyori (912–995) and remained an important text among some schools of medicine until the nineteenth century. This 30-volume work contained information on internal medicine, pharmaceuticals, preventive practices, and other topics, and was based on over eighty Chinese texts written during the Sui (581–617) and Tang (618–907) dynasties.

Until the eighteenth century, anatomy envisioned the human body as containing five organs and six viscera, and physiology focused on their relationships with each other and the meridians found on the surface of the body. Visual observation of the internal organs played little role in the classical Chinese model of the human body, and organs including the brain, pancreas, thyroid, and adrenal glands played no role in the treatment of disease. Indeed, there was no word for the latter three organs, and visual depictions of human anatomy did not appear in the Japanese medical literature until the fourteenth century. Rather this model was conceptual, based on the Chinese notion of the five elements of fire, metal, water, wood, and earth. These were, respectively, associated with the heart, lungs, kidneys, liver, and spleen, and each organ was in turn associated with five colors, tastes, and seasons, the spleen being associated with the time of changes between seasons. Physicians interpreted diseases as resulting from imbalances within this system and treated them with herbal medicines, acupuncture, moxibustion, massage, and restrictions on diet and behavior. Yet this model did not completely replace ideas of disease as being caused by spirit possession, and the literature of the Heian period abounds in examples of Buddhist priests attempting to cure maladies through exorcism, a common practice until modem times.

Because the diagnostic criteria and disease categories of premodern Japan were so different from those used today it is difficult to establish with any accuracy in modern terms the diseases from which people suffered at the time. Yet it is certain that the most common epidemic diseases of premodern Japan, beginning with the Nara and Heian periods and continuing through the nineteenth century, were smallpox, measles, influenza, and enteric infections. Tuberculosis, malaria, and parasitic infections remained endemic during the premodern period. Despite a myth of cleanliness attributed to the Japanese, bathing and the regular washing of clothes were not common practices, making skin diseases common until modern times. In addition, kitchen areas frequently were far less than sanitary, and latrines and even graves were sometimes located close to water sources, contaminating them.

Although most medical folk beliefs are poorly documented, much is known concerning some popular beliefs related to what probably was tuberculosis. During the twelfth century, Chinese Daoist priests thought that a disease they called *zhuan shi* (*denshi* in Japanese), literally "transmission of the consumption bug," was caused by minute worms. According to Daoist texts, this disease passed through a cycle of six phases with turning points on certain calendar days, when the worms metamorphosed from one phase to the next; in the sixth phase they were thought to be highly contagious. A popular belief in these worms took root in Japan from the Heian period as part of the Kōshin folk religion. They were considered a deity's agents that reported a person's sins on the days of *kōshin*, which occurred once every 60 days in the calendar cycle. If a person abstained from sleep on those nights, the worms would remain dormant; otherwise they would divulge their host's sins to the deity, who punished people by causing consumption (*denshi*). At first, only the Heian-period aristocracy abstained from sleep on those nights, but the ritual spread throughout the country and was practiced in rural villages until the twentieth century.

Medieval Japanese Medicine

During the Kamakura period (1185–1333) warrior culture eclipsed the culture of the imperial court, but changes in medical theory and practice remained slow. The hereditary posts of court physicians remained in place, and the physicians who filled them were sometimes dispatched to treat the leaders of the military government in Kamakura. However these physicians had little opportunity to keep abreast of the changes in medicine that occurred in China, and in most of Japan Buddhist priests dominated medical practice.

The most important medical text of the Kamakura period was the *Don'isho* (which is untranslatable), written by Fu-jiwara Shōzen (1266–1337) in 1302. This work was significant for its visual representation of human anatomy, the first in Japan. Like previous Japanese medical texts, the *Don 'isho* was also a compilation of Chinese sources, except for the section on leprosy, which was based entirely on Buddhist thought. This reflected current Japanese ideas concerning this disease. From the Heian period, leprosy was called a karmic disease (*gōbyō*), the result of sins committed in past lives. As in medieval Europe, leprosy was common during the middle ages in Japan and had much the same stigma; persons who developed leprosy became outcasts, shunned by their families and communities alike, finding succor only in the care of Buddhist monasteries. The stigma attached to leprosy did not change even into modern times. (The plague, another representative disease of medieval Europe, did not reach Japan until the late nineteenth century and was never a significant cause of mortality.)

The Muromachi (1333–1468) and Warring States (1468–1600) periods witnessed considerable changes in the theory and practice of medicine. During the Muromachi period Buddhist monks became increasingly knowledgeable in Confucian thought, and were influenced by the rise of Neo-Confucianism during the Song dynasty (960–1279) in China. This new current in Confucian thought emphasized the role of *qi* (vital force; *ki* in Japanese) and *li* (principle; *ri* in Japanese) in the order of nature, states, and individuals alike. The ideas of Neo-Confucianism entered the mainstream of Chinese medicine in the theories of Li Dongyuan and Zhu Danxi, who were active during the Yuan dynasty (1279–1368). Li and Zhu understood disease according to interrelationships between an individual's vital energy, environment, and behavior. In therapeutics they placed a new emphasis on emetics, purgatives, and medicines that caused a person to sweat. The ideas of Li and Zhu became influential in Japan from the early sixteenth century, primarily through the works of Tashiro Sanki (1465–1537), who studied medicine for 12 years in China. They then became established in the mainstream of Japanese medicine through the works of Manase Dōsan (1507–1574), who had studied under Sanki. Dōsan's descendants and followers remained highly influential, treating the warlords and hegemons of the Warring States period. Following the establishment of the Tokugawa *bakufu* in 1603 Dōsan's medical theories and practices became government-sanctioned medical orthodoxy (*hondō*). As such they remained at the core of some schools of medicine until the end of the premodern period, and had virtually no competitors until the beginning of the eighteenth century.

Dōsan and his followers had a powerful influence on diagnostics, which they standardized. Later and competing schools of medical thought only supplemented the diagnostic procedures delineated by Dōsan, which remained standard until the advent of Western diagnostics during the nineteenth century. He based diagnosis on a four-step method. Visual observation focused on the patient's skin color, weight, strength, condition of the hair, and inspections of sputum, feces, and urine. Aural observation included listening for responses indicating pain when the patient was examined, for the type of cough, and for sounds in the chest. The physician questioned the patient concerning appetite, waste elimination, emotional disposition, and the circumstances preceding the illness. Finally there came pulse diagnosis, a technique without parallel in Western medicine, which analyzed the strength, speed, location, and other aspects of the pulse.

Endemic warfare during the Warring States period stimulated new approaches to surgery, with a widespread need for specialists who could treat battle wounds. The arrival of the Westerners in East Asia during the sixteenth century was soon followed by the spread of firearms, whose wounds called for new forms of treatment. This led to the adoption of Portuguese surgical practices during the second half of the century in what was called the *Nanbanryū* (Southern Barbarian School). At this time, however, the Japanese adoption of Western medicine remained limited to practical measures for treating wounds, skin lesions, bone fractures, and dislocated joints, and contemporary European medical theory made little headway into Japanese medicine.

Early Modern Japanese Medicine

The defeat of the last major opponents to the hegemony of the warlord Tokugawa Ieyasu in 1600 marked the end of the Warring States period and the beginning of the Edo period (1600–1868), a time of peace and gradually increasing prosperity. The seventeenth century was a period of political, economic, and cultural stabilization and consolidation during which medical theories and practice changed little, dominated by the orthodoxy of Manase Dōsan and other established schools. A century of peace, however, ushered in a period of intellectual and cultural ferment that began during the last decade of the seventeenth century and continued into the nineteenth.

During the last half of the seventeenth century, Confucian scholars started to reject Neo-Confucian interpretations of the Chinese classics and focused instead on direct textual analysis. This trend appeared at the same time in medicine, with a number of physicians rejecting Song and Yuan dynasty interpretations of medical texts, emphasizing instead the direct reading of ancient Chinese medical works. Most of the leaders of this movement, which came to be called the School of Ancient Medicine (*Koihō*), lived in Kyoto, and included Gotō Konzan (1659–1733), Kagawa Shūan (1683–1755), Yoshimasu Tōdō (1702–1773), and Yamawaki Tōyō (1705–1762). Practitioners of the School of Ancient Medicine were by no means unified in their interpretations of either texts or phenomena, but most did emphasize practical methods to establish the validity of their ideas and methods. This was of momentous importance to the changes in Japanese medicine that followed during the rest of the premodern period.

Yamawaki Tōyō, a physician at the imperial court, was central to those changes. Tōyō questioned traditional Chinese interpretations of human anatomy and attempted to replace them with a view based on a passage in the *Zhou li* (Rites of Zhou), one of the early Chinese classics, which described the body as containing nine organs. To verify his view, Tōyō conducted the first public dissection of a human body in Japan in 1754, and published the results in the *Zōshi* (Anatomical Record) in 1759. Although Tōyō's nine-organ theory did not gain currency, his method of examining the body through dissections did. Thereafter, physicians in various parts of the country performed dissections and advanced other anatomical theories, none of which, however, replaced the Chinese theory of five organs and six viscera.

In 1771 three physicians, Sugita Genpaku (1733–1817), Maeno Ryōtaku (1723–1803), and Nakagawa Jun'an (1739–1786), witnessed the dissection of an executed criminal's corpse in Edo (Tokyo). Discussing the results afterward, they concurred that they could not consider themselves medically qualified without a true understanding of the structure of human anatomy, and that such an understanding could be gained only by translating the Dutch anatomy text which Genpaku and Ryōtaku had brought to this dissection. In 1774 they published the *Kaitai shinsho* (New Book of Anatomy), their translation of the *Ontleedkundige Tafelen*, or "Illustrated Anatomy," by the German physician Johann Adam Kulmus (1689–1745). This both started the study of Dutch medicine (*Ranpō*) in Japan and opened the door to European ideas by making the Dutch language widely accessible; after finishing this translation Ryōtaku then compiled a Dutch–Japanese dictionary.

During the first half of the nineteenth century, growing numbers of Japanese physicians studied Dutch medicine under Dutch and German physicians who offered instruction in Nagasaki. Until after the Meiji Restoration in 1868, when Western medicine became mandated as the sole basis for medical practice, various schools of Chinese medicine coexisted with Western medicine in Japan, but the door to Western medicine and science had been opened because of indigenous Japanese developments that had taken place during the eighteenth century, and in this respect the history of premodern medicine in Japan is unique in the world.

The spread of vaccination from the mid-nineteenth century the marks the beginning of modem medical practice in Japan. By the 1850s, vaccination had become common in many parts of the country. However it was not until after the Meiji Restoration in 1868 that modern medical education became instituted. Tokyo University was established in 1877, with its Medical School one of the initial departments. Thereafter, numerous Japanese students traveled to Europe, and particularly to Germany, to study medicine. Some continued to work in Europe as researchers and several, including Kitasato Shibasaburō (1852–1931), who codiscovered the tetanus antitoxin and plague bacillus, became internationally renowned; he was nominated for the first Nobel Prize in medicine. By the late nineteenth century modern medical schools had been established throughout the country and medical practitioners were required to hold state licenses.

During the twentieth century Japanese physicians have remained on the cutting edge of medical research in many fields. Since World War II, national health insurance has made medical care available to the entire population, helping to make the average life span the longest in the world.

Medicine in Korea

Don Baker

"Oriental Medicine" is the English name Koreans prefer for what is known in most of the rest of the world as Chinese Medicine. Among themselves, Koreans call it "Korean medicine." They believe their traditional medicine is as much Korean as it is Chinese, since for around 2,000 years they have adapted medical theories, practices, and even prescriptions from China to fit Korean needs (Fig. 1).

Koreans probably acquired elements of Chinese medical theory and practices for the first time a little over two millennia ago, after China's Han dynasty established four outposts in and around the peninsula late in the second century BCE. Not long after the last of those outposts disappeared early in the fourth century, Buddhist monks from China and farther West began arriving and teaching not only their religion but also the more advanced civilization of China, including its medical theory and practice.

Exactly how much Koreans learned about Chinese medicine from those outposts and from those monks is not clear, since we have few written records from that period. The oldest extant history written by Koreans, the *Samguk sagi* (History of the Three Kingdoms), dates back only to the twelfth century. However, statements in that book, as well as scattered references in Chinese and Japanese records from centuries earlier, indicate that Koreans were reading Chinese medical manuals and applying what they read in them during the Three Kingdoms period (300–668) as well as during the Silla period (668–936).

The Kingdom of Goryeo (918–1392)

Substantially more information is available on medical theory and practice under the Goryeo, which followed Silla and ruled over the Korean peninsula for four and a half centuries. We know, for example, that Goryeo used Chinese-style civil service examinations to identify qualified candidates for government medical posts. Applicants for Goryeo medical posts were tested on their knowledge of the basic principles of internal medicine and pharmacology, as found in the same Chinese medical classics studied in China. They were also tested on their knowledge of external medicine (as defined in Oriental medicine), primarily acupuncture, moxibustion, and the treatment of wounds. That section included questions on material introduced in more recent medical texts, including at least two books from China's Sui (581–618) dynasty.

Medicine in Korea. Fig. 1 A Chinese herb market in Seoul. Photo copyright Korea National Tourism organization.

Although China was the primary source of medical concepts and practices, Koreans had to adapt Chinese prescriptions to fit what was available on the Korean peninsula. For most of the Goryeo dynasty, Korea was blocked from direct land contact with China by hostile non-Chinese states in southern Manchuria. This forced Goryeo to develop *hyangyak*, Koreanized versions of Chinese prescriptions in which herbs, animal parts and minerals found on the Korean peninsula replaced ingredients from China. The oldest Korean medical text still extant, published in 1245, is called *Hyangyak gugeupbang* (First Aid Prescriptions Using Native Ingredients). Not only did the prescriptions in this medical manual use ingredients available locally, but some of them were drawn from local folk medicine and therefore called for only one or two ingredients, in contrast to the multitude of ingredients in prescriptions which originated in China. This was just one of several medical manuals produced in the latter part of the Goryeo era which emphasized locally available ingredients as well as prescriptions of local origin (Kim 1981: 137–141)

The Joseon Dynasty (1392–1910)

The Joseon dynasty which followed Goryeo, influenced by recent developments in Chinese thought, embarked on a restructuring of Korean government and society along Neo-Confucian lines. That restructuring embraced medical institutions as well as medical practice.

The Neo-Confucian influence on medicine during the Joseon dynasty was seen in two areas: the creation of a national network of medical facilities and the certification of physicians through civil service examinations. The greatest concentration of physicians was in

M

and around the capital city. The government established clinics inside Seoul to provide medical care for the royal family and top officials. It also opened medical clinics for commoners just outside the city walls so that those with infectious diseases would not have to enter the capital itself (Kim 1981: 196–199; 408–416).

In addition, the Joseon government established medical facilities in various regional centers, primarily to deal with outbreaks of epidemics among the general population as well as to collect materia medica from local areas. A Confucian scholar normally led the higher-level medical offices. Under him would be physicians who had passed the civil service medical examination.

Joseon Korea was a highly stratified society and privileged a distinguished ancestry and knowledge of Confucian philosophy and literature ahead of technical expertise. Only those with a good family background and a passing grade on the Neo-Confucian civil service exams could be appointed to the highest posts, such as director of a major medical clinic. Consequently, the heads of central government medical agencies were usually Confucian scholars with more expertise in Chinese poetry and ancient Chinese history than in the details of medical practice.

Professional physicians ranked one step below Confucian scholars on the social ladder. There was a separate civil service examination for those who aspired to such a post. Though there was no legal requirement that those sitting for that examination be descended from a previous exam passer, the emphasis in the Joseon dynasty on hereditary status meant that a few families dominated the list of medical exam passers. For example, ten families produced almost 30% of all officially certified physicians between 1498 and 1894 (we lack reliable records on medical officials for the first century of the Joseon dynasty) (Yi 1997; Kim 1999).

Only physicians who sought an appointment to a civil service position were required to pass the medical examination. Until 1900, medical practitioners among the general population did not need any official certification of their medical expertise. Nor were they subject to government oversight. However, even among those with informal credentials, family background was still important. A popular saying during the Joseon dynasty warned villagers, “Do not accept medicine from a doctor who is not at least a third-generation physician.”

Joseon Korea was a patriarchy and restricted most government appointments, including medical appointments, to men. However, some women were employed as medical technicians because of the constraints of Confucian ethics. Uncomfortable with the idea of a male physician examining the body of a female patient, which would violate the Confucian directive calling for a rigid separation of the sexes among upper-class adults, King Taejong (r. 1400–1418) ordered that a few women be selected for training in acupuncture, moxibustion, and pulse measurement (an important diagnostic tool). Male pharmaceutical specialists could prepare medicines for an upper-class woman who was ill, but they were not allowed to place the acupuncture needle or moxa on her skin nor could they place their male fingers on her veins to feel her pulse. After 1406, such tasks therefore were assigned to a small core of women medical practitioners at court (Heo 1992: 214–217).

Localized Chinese Medicine

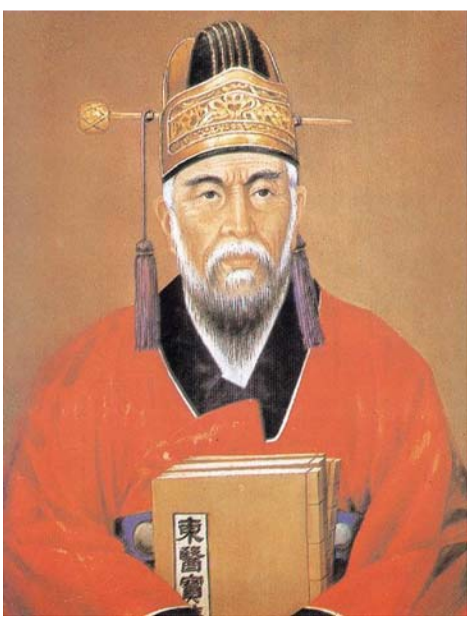
Official medicine in Joseon Korea was based primarily on the canonical texts of Chinese medicine. Koreans supplemented the medical theory and clinical advice in those classical works with more recent Chinese publications as well as with Korean texts that provided local counterparts for the Chinese ingredients in Chinese prescriptions. Both trends are particularly evident during the reign of Joseon’s fourth and greatest King, King Sejong (r. 1418–1450). Among the many volumes compiled and published under King Sejong’s direction, two are particularly important for the history of Oriental medicine in Korea.

The first is the 85-volume *Hyangyak jipseongbang* (Great Collection of Native Korean Prescriptions). Completed in 1433, this encyclopedic pharmaceutical guidebook identified 959 different diseases, arranged under 57 different categories. It described 703 different mineral, vegetable, or animal medicinal products available on the peninsula, told how to identify them, when to collect them, and what diseases they were effective against. Many of its prescriptions were extracted from Chinese medical manuals. However, whenever possible, it substituted native ingredients for expensive or rare Chinese ingredients (Kim 1976: 70–73). In addition, this work listed almost 1,500 ways acupuncture and moxibustion could be used, some based on local experience.

To ensure that his physicians had access to the best advice Chinese medicine had to offer, even if all the prescribed ingredients were not readily available, in 1445 King Sejong also had his officials compile the *Uibang yuchwi* (Classified Collection of Medical Prescriptions). Totaling 365 volumes, this massive reference work listed over 50,000 separate prescriptions, drawn from Chinese sources and arranged according to the symptoms they were believed to alleviate. It also included separate sections on treating childhood illnesses and mental disorders, on childbirth, on first-aid remedies, and on treating fractures (Kim 1976: 80–83).

Both the *Great Collection of Native Korean Prescriptions* and the *Classified Collection of Medical Prescriptions* were compiled for the use of physicians at court and were too large to be made available to the general public. However, in 1613, a more concise guide to medical theory and practice appeared. Koreans consider the 25-volume *Dongui bogam* (A Treasury of Eastern Medicine) their greatest original contribution to the development of Oriental medicine. Compiled by royal decree under the direction of Korea's most revered physician, Heo Jun (1539–1615) (Fig. 2). *A Treasury of Eastern Medicine* provided an encyclopedic overview of Oriental medicine from a Korean perspective. At only 25 volumes, it was more compact than either of King Sejong's two massive medical encyclopedias and therefore could be more easily distributed to government offices throughout the peninsula. Read by Confucian scholars as well as physicians, it shaped medical thought and practice in Korea for the rest of the Joseon dynasty and remains influential today.

A Treasury of Eastern Medicine opens with explanations of the basic concepts of Oriental medicine. Heo placed particular emphasis on *jeong* (Chinese *jing*), *ki* (C. *qi*), and *shin* (C. *shen*). Those three Sino-Korean terms are used in such a wide variety of contexts with such a wide range of meanings that it is difficult to find English equivalents for them. As Heo uses them, they refer roughly to essential bodily fluids, bodily energy, and refined bodily energy, respectively. All three terms refer to the fundamental cosmic energy that animates the universe. Within the human body that vital energy takes three different forms, distinguished according to differences in visibility, tangibility, and density. Jeong is visible vitalizing energy, such as semen or blood. Ki is invisible but palpable vitalizing energy, discerned when a doctor feels the pulse of a patient to determine the state of his or her internal energy. Shin is ethereal vitalizing energy, so rarefied that it provides the physiological basis for consciousness. Heo places fostering and reinforcing that vitalizing energy at the core of his approach to Oriental medicine.



Medicine in Korea. Fig. 2 Heo Jun, the chief author of *A Treasury of Eastern Medicine*. Reprinted courtesy of the Association of Korean Oriental Medicine.

After introducing *jeong*, *ki*, and *shin*, Heo discusses various external windows into the state of vital energy within, including blood, phlegm, saliva, dreams, and the sound of the patient's voice. Only in his third chapter does he turn to the coagulation of vital energy into the five major governing organs (liver, heart, spleen, lungs, and kidneys) and the six supportive organs (gallbladder, stomach, large intestine, small intestine, bladder, and triple burner). He follows that discussion of the inside of the human body with a discussion of the outside, from head to foot. He complements this analysis of the basic components and processes of the body with a detailed analysis of the various ways those components can become dysfunctional and as a result damage the body's other components, preventing them from functioning the way they should. He also included a catalogue of the medicinal substances available in China and Korea, where they could be found, how to prepare them for human consumption, and when to prescribe them. His final chapters are a detailed description of when and how to use acupuncture and moxibustion.

The basic principles of both Heo's medical theory and his practical suggestions for health and healing were derived from the Oriental medicine of China. What made Heo's book different, and so influential, was the way he presented those theories and techniques. Earlier medical handbooks were primarily compilations of medical texts which did not evaluate the relative effectiveness of the various prescriptions and other medical strategies those texts recommended. Heo provided an interpretative framework for understanding which healing and health-enhancing techniques were likely to work better than others. He also provided evaluations of which medicines or procedures were likely to be the most effective in specific situations.

Despite the contributions of *The Treasury of Eastern Medicine*, medical problems increased rather than decreased over the next three centuries. The first serious new threat to Korean health was syphilis. Introduced onto the peninsula early in the sixteenth century, it became a major medical problem during the Japanese invasions at the end of that century. That deadly sexually transmitted disease was joined soon afterwards by one even more deadly because it spread from victim to victim through more casual contact. Sometime in the seventeenth century a new virulent strain of measles appeared in Korea, taking the lives of thousands in periodic epidemics from the late seventeenth through the nineteenth centuries. The nineteenth century brought one more new biological brake on population growth. Cholera reached Korean shores in 1822, returning again several more times that century, each time killing tens of thousands.

The impact on population growth was striking. Instead of growing rapidly, as it had in the first part of the Joseon dynasty, the Korean population first stagnated and then began shrinking. The Korean government counted almost a million fewer Koreans in 1850 than it had found a half a century earlier. That 1800 figure itself was only a slight advance, of less than 100,000, over the census figures for 1750. Both epidemics and famines were taking their toll (Baker 1990).

The response of Korea to this demographic decline was a popularization of Oriental medicine. *The Treasury of Eastern Medicine* was too large for distribution among the general population, so much smaller pamphlets dealing with prescriptions for specific diseases were printed and distributed to meet the growing popular demand for medical information. Such publications designed for the masses were not the only evidence of the popularization of Oriental medicine in the second half of the Joseon dynasty. The opening of Oriental medicine markets in four Korean cities, starting in the mid-seventeenth century, indicates that more and more Koreans were beginning to trust prescriptions more than the shamans and monks they had relied on in the past. By the middle of the eighteenth century there was enough demand for Oriental medicine that a new occupation appeared in Korea-pharmacists. Koreans began to frequent private shops run by men skilled in diagnosing disease according to the categories of Oriental medicine who would then prepare prescriptions in accordance with their diagnosis (Kim 1998: 190–92).

This growing popularity of Oriental medicine among the general population stimulated not only the greater use of indigenous materia medica but also the indigenization of medical theory. Near the end of the nineteenth century, an amateur physician supplemented the medical theory imported from China with some additional reflections on the relationship between differences in individual physical constitutions and differences in responses to medical treatment. Lee Je-ma (1838–1900) suggested that every human being could be assigned to one of four separate and distinct physiological categories, depending on which of four emotions (sorrow, anger, joy, and pleasure) dominated that individual's personality. He recommended that physicians determine which of those four constitutional types best described a patient before they treated him or her, since he believed that the same outward symptoms were manifestations of different internal malfunctions in different physiological types. The physiological category applied to a patient was determined by the emotion that patient tended to display to excess. Someone prone to sudden outbursts of anger, for example, would damage his liver and would therefore have a physiology different from someone who was too quick to indulge in sensual pleasure and would therefore have damaged lungs (Lee Je-ma).

Lee's unique "Four Constitutions" approach to diagnosis and treatment has become increasingly popular in Korea in recent decades. However, before Koreans could create a Koreanized Oriental medicine based in part on Lee Je-ma's hypotheses, they first had to overcome a drastic fall in status for Oriental medicine in Korea at the end of the nineteenth century and the first half of the twentieth (Fig. 3).

In 1884, Christian missionaries from North America entered Korea carrying both Bibles and doctor's satchels. Within a decade, government legitimation of Oriental medicine through state civil service examinations had ended and a hospital practicing the new biomedicine from the West had opened in Seoul with support from the Korean government. Korea's rush to modernization threatened to leave behind Korea's traditional medicine.

Practitioners of Oriental medicine did not vanish from Seoul. There were so few physicians trained in biomedicine on the Korean peninsula that the government found that it had to assign Oriental medicine doctors as medical officers for the modern army it began trying to build in 1896. Moreover, Oriental medicine physicians remained on the staff on the Royal

Medicine in Korea. Fig. 3 Yi Jema. Reprinted courtesy of the Association of Korean Oriental Medicine.

Clinic and the Directorate of Medicine, since the royal family was still more comfortable with traditional medicine than with the new medicine from abroad. In addition, since most of the general population was also more comfortable with Oriental medicine than with biomedicine, and also because there were very few Koreans trained in biomedicine, the Joseon government decided to include Oriental medicine in its plans for the modernization of its public health system. In 1899 it opened the Gwangjewon (Seoul Public Hospital) which it staffed primarily with specialists in Oriental medicine. The next year, the government inaugurated a licensing system for all practitioners of Oriental medicine on the peninsula. This was the first time in Korean history that medical specialists who operated outside of the civil service had received any official certification of their expertise (Heo: 293–301; Shin 1999).

Oriental Medicine in Twentieth-Century Korea

In 1905, however, the Joseon dynasty lost most of its power to make its own decisions when the rising imperial power of Japan imposed Japanese advisors on the Korean government. Five years later, in 1910, the last vestiges of Korean autonomy ended when Japan turned Korea into a colony under direct Japanese control. The Japanese immediately embarked on a campaign to change Korea into a society more closely resembling modernizing Japan. That included changing traditional Korean medicine into the form of medicine Japan considered more compatible with the modern world, the biomedicine imported from the West. Oriental medicine had to wait until the Americans defeated the Japanese in 1945 and Korea recovered its autonomy before it could regain anything close to the respectability it had enjoyed prior to Japanese colonial rule.

The end of Japanese colonial rule created two competing governments on the peninsula, with different policies toward Oriental medicine. The Communist government of North Korea redefined Oriental medicine as the traditional medicine of the Korean people and therefore worthy of government support. An Institute for the Study of Eastern Medicine was established within North Korea's National Medical Science Center in the 1950s, decades before a similar research center received government funding in South Korea. North Korea also incorporated Oriental medicine into the national public health system long before South Korea assigned Oriental Medicine doctors to its rural health centers (Fig. 4).

In pro-Western South Korea, Oriental medicine had to overcome the assumption among South Korea's Westernized elite that Oriental medicine represented a past Korea needed to leave behind to win respect as a modern nation. A shortage of medical practitioners during the Korean War forced the government in 1952

Medicine in Korea. Fig. 4 Medicine Cabinets used by Korean Oriental Medicine Specialists. Copyright: Korea National Tourism Organization.

to formally recognize Oriental medicine doctors as physicians. This paved the way for official recognition of Oriental medicine clinics, as well as a state licensing examination for new Oriental Medicine Doctors (Yi 1977: 316). Formal recognition, however, did not win Oriental medicine doctors the high status and high incomes biomedical physicians enjoyed. Given the traditional Korean respect for educational credentials, parity with biomedicine had to wait until there were respected medical schools for Oriental medicine in Korea.

The first college in independent South Korea dedicated to preparing doctors of Oriental medicine opened its doors in 1953. Four years later it opened an attached Oriental Medicine Hospital. However, it ran into financial difficulties and was absorbed by Kyunghee University in 1965, which created an Oriental Medicine College within the Kyunghee University medical school. Kyunghee University quickly inaugurated a graduate program in Oriental medicine and in 1971 opened South Korea's first large Oriental medicine hospital as part of a newly opened Kyunghee University Medical Center. A year later Won'gwang University, also privately run, opened South Korea's second medical school for Oriental medicine. Won'gwang University added its own affiliated Oriental medicine hospital in 1975 (Yi: 317–319).

There are now 11 medical schools for Oriental medicine in South Korea, all established by private universities. There are also 147 Oriental medicine hospitals, all privately run, and over 8,000 Oriental medicine clinics. As yet, there are no schools of Oriental medicine at public universities, nor are there any government-run Oriental medicine hospitals. However, the growing respectability for Oriental medicine led the South Korean government to open the Korea Institute of Oriental Medicine in 1994 to coordinate research on the theory and practice of Oriental medicine.

That growing respectability has also been reflected in changes in the 1990s in South Korea's laws regulating providers of medical care. Graduates of colleges of Oriental medicine are now allowed to fulfill their obligatory term of military service as medical officers in the South Korean military, just as graduates of colleges of other medical colleges have done since the establishment of the Republic of Korea in 1948. They may also be assigned to responsible positions in public health centers, something not permitted before the 1990s. In addition, in 1996 the law regulating pharmacists was changed to recognize those who had graduated from a pharmacology department of a college of Oriental medicine as certified specialists in Oriental pharmacology. In 1992 South Korea's national medical insurance system recognized this increased respectability of Oriental medicine by adding coverage for a few basic prescriptions to the coverage established in 1987 for acupuncture, moxibustion, and vacuum cupping.

One way Oriental medicine has regained respectability in the last decade of the twentieth century is through modernization. Korean Oriental medicine has become more compatible with modern urban life by adopting such markers of modernization as standardization and mechanization.

Traditionally, an Oriental medicine physician or pharmacist would modify prescriptions to meet the particular needs of a particular patient. It is still possible to obtain individually tailored prescriptions in South Korea today, but it is also possible to walk into a drug store and purchase packages of Oriental medicine prescriptions in mass-produced pill, granular, or liquid form, no different in appearance from many medicines produced in the factories of Western pharmaceutical companies.

Similarly, patients who visit an Oriental medicine hospital for a physical examination might find that their blood pressure is checked the same way it would be checked in a biomedical clinic, although they may also have their pulse checked by a machine which will produce a result framed in terms of the traditional 27 measures of the pulse in Oriental medicine. In addition to an electrocardiogram evaluating how well their heart is functioning, they may encounter another mechanical device that will evaluate the flow of vital energy through their hands and feet.

Not only diagnosis but also treatment, particularly acupuncture, has been modernized as well. The traditional insertion of needles into specific points along the vital energy channels is still practiced, but now those needles sometimes are electrified to provide additional stimulus to vital energy. Lasers are also used to enhance the effectiveness of acupuncture needles. For the treatment of pain, sometimes bee venom is injected into an acupuncture point in a treatment called "medicinal acupuncture." Tapping is another variant on traditional acupuncture. Tape is pasted over an acupuncture point, stretching the muscles and stimulating the vital energy flowing through that point.

Whether Oriental medicine in Korea is a unique Korean approach to health and healing or whether it is a Korean variant of traditional Chinese medicine, it is nonetheless seen by Koreans today as a legacy of their traditional culture worth preserving. Oriental medicine has not been supplanted by biomedicine in twentieth-century Korea. On the contrary, Oriental medicine flourishes alongside biomedicine, in a complementary rather than an antagonistic relationship. That complementary relationship is revealed in the presence of family practice biomedical physicians staffing the emergency rooms of Oriental medicine hospitals. It also appears in the advice of a biomedical physician to a patient recovering from a stroke to visit an acupuncturist, or in the advice of an Oriental medicine physician to a patient suffering from appendicitis to hurry to the emergency room of a biomedicine hospital. For most Koreans today, biomedicine remains the medicine of choice for acute medical problems or for problems requiring surgery. However, Oriental medicine remains the medicine of choice for chronic pain, fatigue, or the ravages of old age. If recent past history is any guide, it is likely that Oriental medicine will remain a viable and vital partner of biomedicine in Korea for decades, if not centuries, to come.

Extra 1

Some nationalists claim that needle-shaped bits of stone found in excavations of Neolithic villages on the Korean peninsula prove that Koreans rather than the Chinese invented acupuncture. Other nationalists cite references to mugwort and garlic in the ancient myth of Dan'gun as "proof" that what non-Koreans call Chinese medicine arose independently in Korea over four millennia ago. Few scholars outside Korea accept such claims. (Kim. *Han'guk uihaksa* [A History of Medicine in Korea] Seoul: Tamgudang 1981: 14–28.)

Extra 2

Recently, one Korean claims to have greatly simplified acupuncture. Yu Tae-u, the founder of hand acupuncture, claims that he discovered in the 1970s that all the acupuncture points on the body have counterparts on the hand and that stimulation of those points on the hand is just as effective as stimulation of the corresponding points on the other parts of the body. Few mainstream doctors of Oriental medicine in Korea accept Yu's restriction of acupuncture to the hand, though hand acupuncture had become popular among the general population as a form of self-medication. It has also gained adherents in Japan and North America (Yu Tae-u 1988).

Medicine in Meso and South America

Ruben G. Mendoza

Ancient America provides a unique case study for examining the independent development of medicinal practices and technologies in non-Western societal contexts (Majno 1975). Initial European contacts with New World cultures of the early sixteenth century made clear that aboriginal medical systems and technologies embodied principles of a holistic – mental, somatic, spiritual, and supernatural – approach to healing (Classen 1993; Guerra 1971; Lopez Austin 1971; Huber and Sandstorm 2001). While the great centers of New World civilization provide our most complete record of medical practices and technologies, many localized native populations contributed to the extensive body of technical knowledge and expertise associated with herbal, chemical, surgical, extrasomatic, or ritual approaches to healing and public hygiene (Ankl 2002; Gall 1997; Kunow 2003). From South American gold and other metal-based dental fillings, cranial trephination, postcranial surgery, and coca-based anesthetics, to Mesoamerican intramedullar nails, medicinal enemas, surgical sutures and cauterization, caesarean sections, topical anesthetics, poultices, and birth control, the list of ancient American medical practices and technologies is as impressive as it is extensive (Mendoza 2003).

Because of the breadth and diversity of these practices in the Americas, we can only examine a narrow sampling specific to ancient Mesoamerica and Peru. The following discussion will move from a consideration of basic Native American concepts pertaining to the causes of disease to the examination of specific case studies concerning the development and sophistication of Native American practices. The perspectives in question are drawn from contact era sixteenth-century accounts of the Aztec and Inca civilizations. One should bear in mind that the New World Inquisition inhibited and condemned the exercise of Native American medical practices. Through the entire duration of the colonial era (ca. AD 1521–1824) these practices were thought to be the work of sorcerers and other native practitioners in league with the Devil (Cobo 1990). European colonials actively sought to destroy ancient medical works, along with pagan practices and practitioners, throughout the contact era. While early chroniclers attempted to document such practices, they openly disparaged them, and every effort was made to minimize their significance by comparison with European practices of the time by way of blatantly ethnocentric and racist assumptions about the mental life and intellectual contributions and potential of America's aboriginal inhabitants. In those few instances where a concerted scientific effort was made to collect information on the medical practices of such groups as the Aztec (Sahagun 1932), the distribution or publication of such works was prohibited for centuries (Cruz, Bylan and Gates 2000).

Much of our knowledge of contact era medical practices is derived from the detailed chronicles compiled to document the cultural history of the Aztec

M

and Inca civilizations. For example, medical anthropologist Bernard Ortiz de Montellano (1990) has subdivided Aztec concepts pertaining to the causes and treatment of disease into three categories: supernatural or religious, magical, and natural or physical. He indicates that the Aztec held a holistic world view pertaining to the causes and cures of disease, and refers us to the work of Mexican ethnohistorian, Lopez Austin: "the origin of illness is complex, including and often intertwining two types of causes: those that we would call natural – excesses, accidents, deficiencies, exposure to sudden temperature changes, contagions and the like – and those caused by the intervention of nonhuman beings or of human beings with more than normal powers. For example, a native could think that his rheumatic problems came from the supreme will of Titlacahuan, from the punishment sent by the tlaloque for not having performed a certain rite, from direct attack by a being who inhabited a certain spring, and from prolonged chilling in cold water; the native would not consider it all as a confluence of diverse causes but as a complex" (Lopez Austin 1974: 216–217). This complex view required that the physician reconcile a variety of conceptual, spiritual, and physical dimensions in the course of diagnosis and treatment. Aztec doctors were required to balance herbal and other chemical treatments with interpretive models of causation ranging from the supernatural and magical to the natural, or a complex mix of both (Cichewicz and Thorpe 1996). The supernatural and magical, encompassing astrological interpretations such as those prevalent in sixteenth-century Europe, were of the greatest interest to early contact-era European chroniclers (Majna 1986).

Botanical Knowledge

While the botanical repertoire of New World peoples is discussed elsewhere within this encyclopedia, the relative significance of botanical specimens and knowledge to New World medical traditions necessitates brief consideration. It should be noted that recent research in this area makes clear the great contributions made by Native Americans (Schultes 1994; Lux 2001; Lopez Austin 1974). The surviving Aztec herbal known as the *Codex Badianus* provides one of the most extensive listings of botanical specimens identified with the medication and treatment of a variety of ailments (Cruz Byland, and Gates 2000). However, in his efforts to make the herbal, authored by the Aztec doctor Martin de la Cruz, palatable to a European audience, Juan Badiano, the chronicler who prepared the document for submission to King Charles, modified it to incorporate European medical beliefs regarding the role played by temperature in illness, diagnosis, and treatment.

The large body of medicinal knowledge identified with the Americas, and subsequently adopted by European-based medical systems, included such ancient Native American medicinal and hallucinogenic substances as coca (*Erythroxylon coca*), mescaline (*Lophophora williamsii*), nicotine (*Nicotiana tabacum*), quinine (*Quina cinchona*), psilocyben (*Psilocybe mexicana*), dopamine (*Carnegiea gigantea*), anodyne analgesics (*Solandra guerrerensis*), the ergot alkoloid D-lysergic acid (*Ipomoea violacea*), and genipen-based antibacterial agents (*Chlorophora tinctoria*). To this list may be added medications and related chemicals and supplements ranging from *N*-dimethylhistamine to atropine, seratonin, tryptamine, kaempferol, prosopine, pectin, and camphor – to name but a few. These served Aztec physicians in a variety of capacities. Ortiz de Montellano (1990) has documented the medicinal properties of many of the herbal and chemical treatments administered by Aztec physicians. Included in that listing are diuretics, laxatives, sedatives, soporifics, purgatives, astringents, hemostats, hallucinogens, anesthetics, emetics, oxytocics, diaphoretics, and anthelmintics. Furthermore, there were a variety of antibiotic or antiseptic treatments for treating wounds, medicating infections and fractures, and performing surgery. These included the herbal vasoconstrictor *comelina pallida,* maguey or agave sap, for its hemolytic, osmotic, and detergent effects, hot urine in lieu of other available sources of sterile water, and mixtures of salt and honey which have been determined to provide enhanced antiseptic functions.

Recent studies of the "hidden chemical wealth of plants" used by the Native American tribes of the Amazon rain forest provide but one more point of departure for gauging the range and extent of pre-Columbian medical traditions (Schultes 1994). In his summary of the pharmacology of the Kofan and Witoto tribes of the Amazon Basin, ethnobotanist Richard Evans Schultes has observed that "the forest peoples' acquaintance with plants is subtle as well as extensive. The Indians often distinguish "kinds" of a plant that appear indistinguishable, even to the experienced taxonomic botanist." This taxonomic acuteness extends to the level of being able to distinguish chemovars, or the basic chemical constitution of a specific subvariety, by visual inspection alone. Despite an estimated 80,000 species of higher plants in the Amazon, fewer than 10% have been "subjected to even superficial chemical analysis (Schultes 1994)." Such a store of indigenous botanical knowledge recently prompted Schultes to ask "why not regard the Indians of the Amazon Basin as a kind of phytochemical rapid-assessment team already on the ground?"

Medical Specialists and Personnel

While it is clear from all accounts that herbal specialists existed in all regions of pre-Columbian America, the existence of a broader corps of trained medical specialists and personnel is less evenly documented. So intent were early contact-era European chroniclers on disparaging and discouraging pagan forms of medicine that much was done to reduce the role of medical specialists from Native American communities. In most instances, medical specialists ranging from herbalists to physicians were simply characterized as sorcerers or charlatans. Given the relatively impoverished state of European medicinal practices of the early sixteenth century, it is no wonder that most European chroniclers of Native American medical traditions expressed outright contempt for Native American physicians and their medical practices and traditions. Despite deliberate errors of omission and commission, surviving documents provide indications of the broad sophistication in Native American medicinal practices.

As for the documented existence of a scientific tradition with trained practitioners specialized in specific forms of surgical treatment, we are informed by archaeologist Burland (1967) that, in a region above Lima, Peru, there existed an ethnic enclave known as the Yauyos with whom the Inca collaborated in the training of specialists in the art of cranial trephination or skull surgery. The patient was drugged, and pain was alleviated by way of the application of direct pressure to nerve endings in the affected area. In such instances, trephination was used only as a last resort, whereby the diseased or smashed bone was cut away from the skull. Other forms of surgery included the "removal of a torn spleen, cleaning out of ulcers, and the cleaning and after-care of wounds" (Burland 1967). Professional alliances between the Inca and Yauyo allowed for the exchange of technical knowledge and technicians. Accounts of the work of Yauyo physicians indicate that they were highly trained and had developed a formal discipline based on a corp of specialists. Apparently, herbal specialists of highland Peru were organized into "local confraternities," while medical specialists and physicians – *camasca* or *soncoyoc* – were sponsored by the Inca state and "highly trained within their own kind of collegiate discipline." This latter point is of paramount significance in establishing the existence of a specialized corps of medical personnel, and as such, the makings of a formally constituted and state-sponsored scientific tradition specialized in the treatment and trephination of the human cranium.

According to medical historian Gordon Schendel (1968), technical distinctions were made between "old" and "new" school physicians. At European contact, old school physicians were thought of as more traditional and more adept at conveying medical and spiritual beliefs pertaining to the art of healing, whereas the physicians of the new school engaged specialized methods and medical procedures. Among the Aztec, medical specialists included the *tlana-tepat-ticitl* or healer who "cured with medicines which were digested or applied on the skin" (Guzman Peredo 1985), the *texoxotlaticitl* or surgeon whose skills included bloodletting, and the *papiani-papamacani* or herbalist. Other terms utilized to identify Aztec medical specialists included *texoxtl*, or surgeons, and the *tlamatepatli* or medical interns of the *texoxtl* surgeons. The *tecoani* were the bloodletters; the *temixiuitiani* were the midwives. The *papiani* were the pharmacologists or herbal pharmacists. The *panamacani* are identified with pharmacognosists, or those individuals specialized in the identification; collection, and dispensing of herbal remedies, a specialty not unlike that of the plant pharmacologists of the Amazon Basin. Schendel has also documented the existence of a variety of specialists and areas of medical specialization, including internists, psychiatrists or psychotherapists, anesthesiologists, dermatologists, dentists, obstetricians, gynecologists, orthopediatricians, ophthamologists, urinogenital surgeons, and other practitioners specialized in the administration of tonsillectomy and embryotomy. In all areas of medical endeavor, specialists were held accountable for their actions and practices by their peers, as well as by the community at large.

Other specialists included those who used chiropractic methods, whereby "these doctors, in the case of falls, usually strip the patient and rub his flesh; they make him lie face downwards and step on his back. I have seen this myself, and I have heard patients say that they felt better… the pity of it is that there are even Spanish men and women who believe them (Aztec physicians) and are manipulated to serve their needs and evil" (Cervantes de Salazar 1936, as cited in Guzman Peredo 1985). Spanish Friar Bernardino de Sahagun commended the technical expertise of Aztec physicians and noted that they "had great knowledge of vegetables; moreover, they knew how to perform bloodletting and to reduce dislocated bones and fractures. They made incisions. They healed sores and the gout. They cut the fleshy excrescence in cases of ophthalmia (inflammation of the eyes)."

M

Surgical Practices

As our discussion of medical specializations makes clear, pre-Columbian medical practices, particularly those pertaining to surgical methods, were comprehensive and sophisticated in scope. According to conquest period chronicles, "Aztec battle surgeons tended their wounded skillfully and healed them faster than did the Spanish surgeons … [and] … one area of clear Aztec superiority over the Spanish was the treatment of wounds. European wound treatment at that time consisted of cauterization with boiling oil and reciting of prayers while waiting for infection to develop the 'laudable pus' that was seen as a good sign" (as cited in Ortiz de Montellano 1990). Medical historian Miguel Guzman Peredo (1985) cites Fray Bernardino de Sahagun: "Cuts and wounds on the nose after an accident had to be treated by suturing with hair from the head and by applying to the stitches and the wound white honey and salt. After this, if the nose fell off or if the treatment was a failure, an artificial nose took the place of the real one. Wounds on the lips had to be sutured with hair from the head, and afterwards melted juice from the maguey plant, called meulli, was poured on the wound; if, however, after the cure, an ugly blemish remained, an incision had to be made and the wound had to be burned and sutured again with hair and treated with melted meulli." This citation makes clear the availability of prosthetic or cosmetic devices, the use of sutures, and the application of maguey or agave sap as an antibiotic ointment.

The Aztec also maintained a complex typology for mapping human anatomy and physiology. They identified specific body parts, organs, and their respective biological functions, and employed anatomical terms for the articular surfaces and attachments of limbs, as for instance in the use of the terms *acolli, moliztli, maquechtli,* and *tlanquaitl*, for the articulation of the shoulder, elbow, wrist, and knee, respectively. According to Guzman Peredo, "those physicians had more than elementary concepts of the different organic functions. They knew, for example, of the circulation of the blood. They even became aware of the throbbing at the tip of the heart; this they called tetecuicaliztli. The radial pulse was called tlahuatl." Armed with such knowledge, the Aztec "used traction and counter traction to reduce fractures and sprains and splints to immobilize fractures" (Ortiz de Montellano 1990). Perhaps one of the most significant medical innovations concerns the use of the intramedullar nail. Bernardino de Sahagun (1932) noted that in instances where bone fractures failed to heal, "the bone is exposed; a very resinous stick is cut; it is inserted within the bone, bound within the incision, covered over with the medicine mentioned." The intramedullar nail was not rediscovered by Western medicine until well into the twentieth century.

The most outstanding example of the empirical reliability and effectiveness of a pre-Columbian medical tradition centering on surgical applications was the use of cranial trephination or skull surgery (Mendoza 2003). Examples of the practice have been documented from throughout South, Middle, and North America. An extensive review of this practice can be found elsewhere in the encyclopedia.

Our review of pre-Columbian medicinal practices raises many more questions than can be addressed in this essay. Clearly, the European predilection for accommodating only that which suited prevailing eurocentric modes of thought contributed to the uneven documentation of significant Native American medical innovations and practices. A selected recounting of significant innovations should take into account practices centered on (a) holistic concepts of health, (b) state-sponsored public health programs, (c) an extensive body of anatomical terminology, (d) the existence of confraternal medical associations and state-sponsored medical corps, and specific practices centered on medical innovations such as those pertaining to (e) cranial trephination, (f) prosthetic and cosmetic devices, (g) antibiotic and antiseptic ointments and medications, (h) intramedullar nails, (i) formal procedures for the maintenance of dental health and hygiene, (j) psycho- and logo-therapeutic, or image-based, psychological approaches, and not surprisingly, (k) the largest pharmacological repertoire of effective and affective herbal and chemical remedies ever documented in the ancient world. Ultimately, any assessment of pre-Columbian medical traditions and innovations will need to contend with the fact that scholars have only just begun to scratch the surface of this New World of lost science and tradition.

Medicine of Native North Americans

CLIFFORD E. TRAFZER

American Indian men and women practiced the first medicine in the Americas, and Native North American medicine took many forms. Some of the Native medicine ways worked much like modern biomedicine, but other forms of traditional Indian medicine differed greatly. The Indian medicine practiced in various communities was different among the thousands of tribes, bands, and groups of American Indian people. Thus, no "generic" Indian medicine ever existed, but most Native American medicine was holistic and practiced by men and women who drew on medicinal plants, prayers, power songs, and experience to heal people. Indian doctors varied in their approaches to curing, but most addressed the physical, mental, and spiritual relationship of humans to the larger world. The differences between Native American and Western medicine are important considerations for health care providers working with First Nations people who often think differently from non-Natives about disease, power, spirits, prayers, and the meaning of medicines.

Native North American Indians believe that medicine emerged with the creation of Indian people, and creative forces gave Native people the first medicine. Indian medicine took many forms, including spiritual medicine that entered the world in the form of positive and negative powers, forces, thoughts, and actions. For example, among some Indians, such as Navajos and Apaches, lightning is a positive force that can bring healing, but it is also a negative, harmful force. One Navajo woman once explained that she had suffered from a large sore on her thigh, which affected her entire body and brought her to the brink of death. A "hand trembler" diagnosed the young woman, explaining that she had become ill because a few days before her own birth, her mother had witnessed the awesome power of lightning that struck and killed an entire herd of sheep. The ill effects of the lightning manifested themselves in the girl and nearly killed her. A medicine man among the Diné (Navajos) performed a Lightning Way ceremony on the girl, and she lived to tell this story. Her sore disappeared, and she became *hozho* or whole, healthy once more.

Indian people brought medicine power with them from other places or "worlds" where they had once lived. In the creation stories of many tribes, the people moved about from one place to another, bringing with them both positive and negative power that they placed in the present world where it is still extant. Sometimes, they used this medicine power to recreate mountains, valleys, rivers, and lakes. As a result, the medicine power of former worlds can be found at certain places in the Americas. Members of some tribes still make pilgrimages to sacred places to pray and sing, make offerings, and hold ceremonies. Sometimes tribal members or medicine people go to these places to gather plants or collect soil for their medicine bundles, taking home with them a portion of the sacred earth that once had been brought here from former lands. Indian people know about these places, their histories, and their uses through ancient stories and songs. Sometimes, medicine people repeat these stores and songs as part of contemporary ceremonies that link the people of today to the ancient ones. In a sense, medicine ceremonies link people with the ancient times, rituals, and medicine, all of which is part of the healing ways of Indian people.

Thus, creation in American Indian medicine is critical to an understanding about the way Native Americans perceive of and use medicine. In addition to bringing soil from other lands and creating sacred space, many Native people believe that at the beginning of time, creative forces set aside certain places on earth and put healing power at the site. Many believe the power is still there in caves, rivers, mountains, stone formations, and other natural occurring places. In the past medicine men and women – or Indian doctors – harnessed this power and usually used it to help and heal their people, although some people could use the power to harm or kill. This concept of power usage is common among American Indians today, and it can be compared to medical doctors and other health officials using their medical knowledge to heal patients or harm them, depending on how they use their talents, skills, and knowledge. The "laws" governing the use of medicine power among American Indian peoples vary considerably from tribe to tribe and region to region.

But in general, Indian doctors, like Western doctors, are expected to use their power for the benefit of others, not to enhance themselves and their place in society.

No discussion of Indian medicine can discuss adequately the many aspects and ramifications of Indian medicine, because they vary considerably among tribes. However, a few shared concepts of Indian medicine exist in North America. First, people living within Native American communities – past and present – believe in unseen forces, powers, or strengths. The people believe that medicine power exists everywhere and within everything, animate, and inanimate. Thus, given the ability to access power, Indian doctors and others may draw medicine strength from rock formations, rivers, valleys, mountaintops, caves, trees, clouds, animals, oceans, fire, and wind. Indian people believe in such power and doctors harness the power to cure disease and prevent illness. The general belief in unseen forces helped Native American people bridge the gap between Indian beliefs about disease causation and Western medicine when Native people first learned about microorganisms that caused disease. American Indians understood bacteria and viruses in terms of unseen enemies, like the ones they had learned about in oral traditions. During the 1940s and 1950s, Navajo nurse Annie Wauneka used traditional beliefs about invisible power to inform her people about the tuberculosis bacterium, a new unseen enemy that had entered their communities.

Second, Native Americans generally believe that all things in the universe are connected and influenced by all other things. Just as the moon influences the tides and the slant of the sun effects the changing seasons, so does the cosmos influence Indian medicine. Destruction of a river by a man-made dam can influence the health of Indian people, and the treatment of one person by another can also affect wellness within an entire community. Third, Indian people believe that their heath and wellness depend on the continuance of prayers, songs, ceremonies, sacrifices, ritual acts, offerings, daily actions, and humor. Tribes often direct prayers for the benefit of the entire universe, not just their own people, because they are part of an enormous system. Every tribe has songs intended for the good of communities and individuals, and medicine people enjoy medicine songs given to them by unseen powers. Fourth, Indian doctors are respected within their own communities and among other Indian groups who know of the person's powers and use of medicine. In English, we refer to these men and women as priests, medicine people, Indian doctors, chiefs, shamans, and caciques. Fifth, all of these Indian doctors possess special medical knowledge and they can communicate with healing powers, summoning them for help during curing sessions and ceremonies. They often employ prayers, songs, stories, and material items such as feathers, tobacco, sage, sweet grass, pipes, and prayer sticks during their curing sessions. They have knowledge about these items or instruments of health, and they know when and how to use them. Sixth, medicine people have a deep understanding of the "laws" governing their communities, and they often interact with patients in discussions to discover the root cause of physical and psychological afflictions. When shaman cannot engage in such discussions because of the patient's condition or inability to communicate the problem, then the medicine people use their special ability to "see" deep within the person's mind and body to find the cause of the health problem. Scholars and contemporary Indians often refer to these laws as rules, customs, and taboos. Seventh, most Indian people commonly believe that everything in heaven and earth has a soul or spirit, because everything is part of the creation and thus related to everything else. The Great Mystery, Great Spirit, Creative Force, or God made all things, and so all things are interrelated and have power, including medicinal power.

Most American Indian communities would agree that medicine is interdisciplinary and woven into their specific cultures in unique ways. The medicine ways of one tribe or group may not be the same as another group. For Indian cultures, medicine is integrated into many aspects of culture, including religion, psychology, economics, and government. Traditionally, Native people lived their medicine every day because they believed it to be alive. Some Native Americans still think this way. Harmony and balance became the objective of Indian medicine in most communities in order to prevent and cure disease. Indians tied Indian medicine closely with seen and unseen forces that existed inside humans and throughout the universe, so that medicine involved the relationship of people to plants, people, places, animals, celestial bodies, and other elements of the natural world. For Indian people "medicine" could bring order and structure to the cosmos and control the forces, powers, and strengths that could influence the health of individuals and communities. In other words, outward forces – beyond humans – influence sickness and death, but so did activities of the individual and community. For example, among the Ajumawe of northern California, the people believe that only holy people or Indian doctors can ascend the heights of Akoyet or Mount Shasta, a sacred mountain that contains within its peak a basket holding all of the goodness of creation. If members of the tribe break this "law,", they place themselves, their families, unborn children, and communities in jeopardy of earthquakes, avalanches, fires, diseases, and death. Among the several tribes composing the Houdenosaunee, commonly called the

Six Nations of the Iroquois, men desiring to cut a false facemask from a live tree must complete prescribed rituals before harming the tree. Otherwise, the health of the carver and others could be compromised. According to an Iglulik woman named Nanoraq from Baffin Bay, "The sickness is due to my own fault. I have not performed my duties well. My thoughts have been bad and my actions evil." And Navajo people could become ill if they shook a tree imitating a bear or by stabbing a knife into a piece of meat. Both of these actions by Navajo people could bring on violent behavior and cause illness among their people. Pima shaman Juan Gregorio once explained that his people could become ill if they did not pray properly before killing an animal, did not handle eagle feathers correctly, or failed to be respectful to desert tortoises. Every American Indian community had "laws" given to them at the time of creation, and they had to obey these laws or suffer disease, natural calamities, or death. Bringing individuals and communities back into balance with the laws occupied some of the duties of medicine people.

Indian medicine helped control forces that could harm the people, and it invited the good strengths to provide the people with abundant harvests, favorable weather, game animals, long lives, and freedom from diseases. The medicine offered Indian people social order, healthy directions, and prevention from illness in an uncertain world. As a result, Native Americans elevated the place of medicine into the realm of the holy and sacred, and those who successfully practiced medicine earned a special place within every community. Different levels of Indian medicine developed with various names, depending on the group, tribe, and region. Some medicine people danced, while others sang, created sacred art, diagnosed, offered herbal remedies, prayed, or helped conduct ceremonies. Indian people knew two larger forms of disease. Communal disease was caused by the transgressions of community members who did not obey the laws functioning within the tribes. Traveling disease included communicable diseases like measles, mumps, smallpox, chickenpox, influenza, and others, and was brought by newcomers. Indian doctors effectively controlled community disease, but they had a more difficult time addressing the new diseases that traveled from tribe to tribe, killing millions of Indian people after 1492.

Among the Indian tribes of North America, two larger categories or levels of Indian medicine existed and still exist today: common medicine and shamanistic medicine – both of which Indian doctors used to address community based diseases and traveling diseases. Within most Indian communities, family elders – particularly women – had a detailed grasp of herbal medicines. Among most Indian communities of the Eastern Woodlands, elders understood the medicinal qualities of sassafras root, which they used to make a tea and prevent and cure colds. The Eastern people along the Atlantic seaboard also used the fronds of the white cedar to make a tea that cured scurvy and relieved some of the painful symptoms of syphilis. Indian people across the West used creosote branches to create a tea to relieve sore throats, and they used the same remedy in larger doses to relieve constipation. Paiute–Shoshoni elder Dorothy Joseph once stated that as a child she never suffered from poison oak because each spring, her mother picked the new leaves of poison oak and had all her family consume a small number of the leaves, creating a temporary immunity. Indian families everywhere knew some of the uses of plants and how to prepare them properly. However, some of the elders knew botanical science far better than others, and they used their in-depth knowledge to help the people.

Very special individuals among all American Indian groups practiced another form of Indian medicine labeled "shamanistic" medicine. Shaman is a term derived from the Tungus people of Siberia, and in the twentieth century, scholars have applied the term to Native Americans. All American Indian languages had words for different kinds of shamans, medicine people, or Indian doctors. Several different types of shamans exist today, just as they did in the past, although their numbers have been reduced over time. Shamans know herbal medicines as well as anyone within their communities, but they also know how to diagnose and cure their patients through spirit medicine. The people expect shamans to work for the good of the community and to help restore the balance within individuals, families, and communities. Most often, Native people pay for the services of a shaman, and sometimes a fee is negotiated before the healing takes place. In the past, families paid for the skills of shaman with trade items, food, furs, wampum belts, and other items. Today, this practice continues in some parts of North America, but more often, people pay Indian doctors in currency.

While most Indian people learned to appreciate and understand some aspects of medicine, Indian doctors had special knowledge of the Native medical field. Indian doctors became familiar with the unexplainable light and knowledge of unseen forces, and opened their minds to receive healing power. They usually gained such knowledge through prayers, songs, dreams, visions, and experiences that brought them into a new realm of understanding and power to heal the sick, control the weather, find lost objects, prophesize, interpret future events, and see into the minds and bodies of their people. Shaman received their power at sacred places away from human habitations, deep in the forests, within the depth of hot springs, in caves, and on mountains. They received power at these sites and converted the powers into energy to heal others. Each medicine person had his own power or powers. In the late nineteenth century, a spring and water bugs gave Wenatchi elder Texanap her power and song, which became so uncontrollable that as a young woman, Texanap could not walk. Her father, a powerful shaman, built five fires, set a post in the middle of the village, and sang. In a community ceremony, Texanap controlled her spirit power, used the pole to stand, and threw her hair into each fire without it burning. In this way, she gained control of her medicine power, which she used to heal others.

The first shaman among the Iglulik came forward to help his people when they were starving because of the lack of game animals. According to oral tradition, he traveled to the bottom of the ocean to visit Arnaluk takanaluk, "the woman down there,", the controller of the animals. He spoke with her, pleaded his case, and asked for animals to visit his people again to save them from certain death. The mother of marine animals responded kindly to his request. The animals came to the people and gave of themselves so that the Iglulik could survive, and they did. This shaman used his power to bring the animals back to the people so they would not die. Indian doctors from other tribes also helped their people in other unique ways, including an Indian doctor among the Mojave of western Arizona and eastern California. He helped his people who were suffering from a tuberculosis epidemic in the late nineteenth century. He reported that even before his birth, he knew he was destined to be a shaman because he had traveled in dreams to the sacred mountain of Avekwame to meet the creator and power source, Kumastahmo. After tuberculosis arrived in the Mojave villages along the Colorado River, the Indian doctor dream-traveled to the mountain where he found Kumastahmo spitting up blood. The creator told the shaman to suck his chest, and so the Indian doctor did so, learning directly from the god how to become a "consumption doctor.". This technique of sucking out poison, foreign objects, and negative power found within a patient's body is a common technique among many shamans. The Mojave doctor reportedly could suck out the disease and destroy it in Mojave patients, and his story is a unique adaptation of a traditional medicine technique used on "traveling" or infectious disease.

Less well known are the smoke doctors who use tobacco smoke to find illnesses, and breath doctors who use their breath and labored breathing technique to open up air and blood blockages in the mind and body. Without surgery, the breath doctors enter the body, find blockages, and use their breath to penetrate the body and remove the objects obstructing the flow of oxygen and blood. Some doctors also rely on dreams and trances that take them inside the body where they locate and destroy disease through thought energy. Such techniques of Indian doctoring may seem fanciful to people accustomed to or trained in Western medicine, and shortly after the arrival of non-Natives, some newcomers described Indian shamans as fakes, frauds, and "witchdoctors,", a representation that tied Indian medicine to Satan and the occult. For Indian people, however, many mysteries surrounded the methods used by their shaman who enjoyed sacred spiritual medical knowledge. However, most Native North Americans believed in the medical techniques of shamans and many still do today.

Wintu shaman Flora Jones of northern California died recently, but her work is well recorded by Indians and scholars alike. She earned a positive reputation as an Indian healer. She used many powerful spirits in her healing ceremonies, including star spirits, moon spirits, and mountain spirits. Other powers also came to her, but she had to order and structure them in order to travel to the site of the sickness and remove them. Like some other Indian doctors, Flora fell into a trance or altered state of consciousness, and spirits spoke through her to diagnose and establish a plan of curing. In severe cases, Flora conducted a Soul Dance, bringing greater power to and through her to help heal her patient. She had her own healing songs, procedures, and material items, which she used in her healing.

In their healing ceremonies, shamans often use a variety of material items to further their healing rituals, including feathers, plant pollens, pipes, tobacco, and other leaves, sand paintings, fans, prayer sticks, soils, crystals, and other items, depending on their power and instructions received from helping spirits. The power vested in these sacred objects also may speak to the shaman instructing the doctor to use particular herbal remedies or specific techniques, such as "roasting" the patient. In this form of treatment, doctors dug holes into the ground, built fires to heat the area, then covered the fire with soil and blankets so that the patients could be buried in the warm pit with their heads above ground. The patient sat or lay down in the ground while the doctor sang and prayed, allowing the warmth of the earth to help the person with blood flow and reproductive problems. In addition to the warmth of the earth, the patient received the spiritual security of the earth wrapped around his body, and some patients felt a rebirth as they stepped out of the pit.

Some shamans worked their medicine in secular sites, while other took their patients to sacred places. In the early twentieth century, Serrano Martha Manuel stepped on spirit power set out by Cahuilla shaman Ignacio Ormego who had warned Martha and her cousin, Vincent Morongo, not to play in the area. Martha became violently ill and could not speak or walk; she ran a high temperature. Her family first took her to Dr. John Evans who placed Martha in a hospital in San Bernardino, California, but after a few days of not being able to diagnose her sickness, Martha's family took her by wagon to Palm Springs, California, where *pul amnahwet* or the highest-ranking Cahuilla shaman, Pedro Chino, doctored Martha. He lay the girl in the sun to help expose her illness. Chino used the power of the hot springs to diagnose Martha's problem, which took him considerable time. He found her sickness in her leg, which he sucked, drawing out a white worm that he showed to his family before destroying it. Martha's fever declined and she gained her ability to walk. She recovered fully, telling Chino and her family of Ormego's warning, and she also said that during her ordeal, she saw several tiny men dressed in black suits, all the same person, running about her leg. The family believes that Martha had seen her relative Pakuma or Santos Manuel, another powerful shaman who had died years before.

Among many Indian people of Southern California, Indian doctoring took place in the Big House or Ceremonial House, and this is still true in central and northern California where tribes have active Dance or Ceremonial Houses. Indian people throughout North America build special lodges for healing ceremonies, including the Medicine Lodge for the Sun or Thirst Dances, tipis for the peyote church, and pole and mat longhouses for the Nez Perce, Yakama, Umatilla, and other tribes of the inland Northwest. Navajos use female hogans for their healing ceremonies, and the people of the Northwest Coast use cedar plank houses for healing ceremonies. Other tribes construct wickiups, log longhouses, kivas, earthen lodges, wigwams, brush shelters, and other dwellings, creating a man-made environment or sacred spaces for their medicine ceremonies and rituals. Nearly all tribes in North America also used sweat lodges to purify minds and bodies, a place to invite the spirits to visit, inform, and heal. Shamans used the lodges and special places as part of their medicine, drawing on various means to follow, find, and eliminate the sources of illness.

Generally, Indian doctors learned from others and pragmatically employed new plants, techniques, and ideas in dealing with the sick. When they found that new ways improved the health of their people, they often adapted and adopted the new medicine. After the Columbian encounter of 1492, Indian people throughout the Americas suffered high death rates because of the lack of natural immunities to contagious or "traveling" disease brought to the Native universe. Since Europeans could barely control diseases, American Indian shamans could not benefit greatly from the medical knowledge of the newcomers. However, contact with the newcomers helped medicine men and women understand more about infectious diseases and to fear the spread of epidemics. Indians in some parts of North America became more familiar with Western medicine after the United States and Canada established forts in Indian country where medical doctors first interacted with some Indian patients. Varying numbers of Indian people sought relief of their ailments from medical doctors. Some doctors, like Washington Matthews among the Navajo and James Walker among the Lakota, learned well from Indian people and their Indian doctors. Others denigrated Indian doctors, referring to them as quacks and charlatans. Still, by the late nineteenth century, Indian and non-Indian medicine began to converge, most often with Indians listening and learning about infectious disease causation and spread.

In 1879, the United States created its first off-reservation boarding school at Carlisle, Pennsylvania, where children became ill and died of infectious diseases, especially measles and tuberculosis.[1] As part of the curriculum at Carlisle and other Indian schools, students learned the cause and prevention of tuberculosis, particularly about the importance of isolating people known to have the disease. Through lectures, slide presentations, and pamphlets, students learned about diseases, and they took their knowledge home to share with their people. During the late nineteenth century and early twentieth century, Indians living on the reservations of Canada and the United States suffered greatly from tuberculosis, measles, influenza, smallpox, chickenpox, mumps, trachoma, accidental deaths, and a host of gastro-intestinal diseases. These diseases also ravaged the Native populations of Mexico and the other countries of Latin America. In the United States, the Office of Indian affairs had a medical division that relied on a few medical doctors often contracted to conduct part time work with Indians. In Southern California during the 1880s and 1890s, for example, the Indian office hired one medical doctor to serve thousands of Indians from the Chumash villages surrounding the Santa Barbara region east to the Colorado River and south to the Mexican border. Neither the Congress nor the Indian Office funded Indian health, and in Canada, the federal government often contracted missionary doctors to serve Native

M

[1] The horror of the Carlisle and other Indian schools is not dealt with in this article, but we urge the reader to read more. See Jessica Enoch, "Resisting the Script of Indian Education: Zitkala Ša and the Carlisle Indian School." *College English* 65.2 (2002): 117–142. See also Clifford E. Trafzer, Jean Keller, and Lorene Sisquoc, eds. *Boarding School Blues*. Lincoln: University of Nebraska Press, forthcoming 2006.

populations. Thousands of Indians died as a result, in spite of the heroic efforts of traditional medicine men and women as well as some medical doctors.

National reforms focusing on Indians during the 1920s and 1930s led the United States and Canada to direct more money to Indian health and the high mortality – including high infant mortality – caused by tuberculosis. Medical personnel also tackled trachoma, often resorting to radical grattage (scraping the eyes with a stuff brush) on Indian patients. Both countries hired more doctors, established more hospitals, and built sanatoria for Indian patients. Both countries also hired public health nurses who became the front line forces of Western medicine, treating Indian people on reservations, reserves, and remote regions of the Arctic. From the 1920s to the 1970s, field nurses traveled thousands of miles each year in automobiles, hydroplanes, dog sleds, wagons, horseback, and on foot to visit reservation populations. Like the teachers in boarding schools, they taught people to identify signs of tuberculosis. Nurses isolated Indian patients, drove Indians to hospitals, conducted clinics, informed mothers at "well baby clinics,", directed Indians to X-ray screenings, and visited families on nearly all the reservations. Their efforts may have influenced the decline of Indian deaths caused by tuberculosis in the late 1930s and early 1940s, before the Indian offices began to use antibiotics in its treatment of tuberculosis.

The Office of Indian Affairs did not provide Indians in the United States with high quality medical care as stipulated by treaties and the laws of Congress. In 1954, the Public Health Service took over the duties of providing Indian medical care through the Indian Health Service. The change proved significant to Indians in the United States, as the Public Health Service provided far better care than the Indian Bureau. Still, Indian health lagged behind that provided to most Americans, Canadians, and Mexicans. In both rural and urban areas, Indian people continue to suffer high infant mortality rates and deaths caused by infectious diseases. However, after World War II, a new trend emerged within Indian communities as more Indians began dying of man-made degenerative diseases such as heart disease, cancer, kidney problems, and complications due to type 2 diabetes, alcoholism, and suicides. Although health services for Indians improved during the late twentieth century, few Indians received first-rate medical care, and most still do not. However, the emergence of high stakes gaming among some tribes has made it possible for some Native Americans to buy their own health insurance and for tribes to partner with highly skilled physicians and the top medical institutions to offer tribal members better medical care. In 2003, Loma Linda University Medical Center, one of the nation's leading medical research institutions, launch a new American Indian health and wellness center and is currently working closely with the Chinook of Shoalwater Bay in Washington state, Shoshoni–Paiute of Fallon, Nevada, and Chemehuevis of the Twenty-Nine Palms Band. Although the Indian Health Service continues to play the significant role in Indian health today, the new partnerships of Indian nations with medical institutions and physicians shows great promise to improve the health of Native Americans throughout North America.

Today medicine among most Native Americans is a combination of traditional Indian medicine and Western medicine. While most Indians consult Western doctors and nurses and use hospitals, they continue to view disease, health, and medicine much like their ancestors. Shamans still perform healing ceremonies in many parts of Indian country and Indians still use common medicine taught to them by elders. Some Indians believe that the combination of Indian and Western medicine will lead to "new medicine" that relies on medical sciences and spirit medicine, particularly the power of prayer and material items taken from the earth.

Medicine in Native North and South America

Åke Hultkrantz

"Medicine" is an ambiguous word in American Indian connections. The first European missionaries and settlers learned that in the aboriginal languages the word corresponding to medicine could also be translated as supernatural power. A "medicine man" could be a man who healed a human being, but also a kind of a miracle man who through his connections with the supernatural world of gods and spirits was able to prophesy the future, locate lost articles or persons, bring on rain, attract game animals, call on the spirits, escort the newly dead to the other world, and many other things. In short, he was, and still is, a mediator between humankind and the spiritual world. It is through his equipment of supernatural power that he can cure the sick. In this article medicine will be understood as the way of curing and as a medicament, except in the compound medicine man, which will retain its old composite meaning. The role of the medicine man in curing will be further elucidated below.

All medical measures depend upon the ideas of the character of the disease. Slight injuries and mild diseases are not interpreted so much in terms of supernatural agencies at work, but dangerous diseases – or diseases considered to be dangerous – are mostly referred to supernatural intervention. Ghosts, unknown spirits, disease demons, witches, or taboo infringements are supposed to be responsible for cases of illness. The supernatural causation is a consequence of the fact that the basic harmony between humankind (or parts of humankind) and the sacred Universe has become upset. Prayers and propitiatory rituals may enclose all kinds of healing procedures but are more common where more grave diseases are concerned.

Whereas the supernatural element in curing is clearly present in the serious cases of disease and damage, natural knowledge plays a dominant role in the curing of ordinary wounds and diseases. Medicine men and women could relieve the pain and remove the diseases of this latter kind, but it was also common for old men and women to take care of them, at least in North America. These old people who had learned their medical arts during a long life and furthermore had particularly observed the traditional healing systems of the tribe, to a large extent used herbal medicines. They could, therefore, be called herbalists. It is not too much to say that herbs, for external or internal usage, were the most common medical cures in aboriginal America.

There were many different kinds of treatments. In Algonquian New England the colonists found that people who had been scalded had their sore skin washed with a strong decoction of tobacco, and thereafter a powder made from dried tobacco was sprinkled on to the wound. More to the south, in North Carolina, seeds of *Datura* were used for the same purpose. Bleeding was arrested with spiderwebs in large parts of North America. James Adair, who was a well-known trader among the Southeastern North American Indians in the latter part of the eighteenth century, reports that every Cherokee carried a variety of herbs and roots such as snake-root and wild plantain in his shot pouch as a remedy for the bites of poisonous snakes (Adair 1775). The Indian chewed the root, swallowed a part of it, and applied another part to the wound. After some pain and contortions the man was relieved of the poison. Here we see how everybody was his/her own doctor.

From the same area the well-informed anthropologist Swanton (1928) reports that the Creek drank a cold decoction of "Devil's shoe-string," or catgut (*Tephrosia virginiana*), to relieve themselves of bladder trouble. They also boiled the roots of sassafras (*Sassafras officinalis*) into a hot drink to get rid of bowel and stomach ache. Sassafras seems to have been a health medicament wherever it occurred. Venereal diseases were also cured with herbal decoctions.

Herbalism was a subject in Aztec schools, and some herbalists were even examined in the priest schools, the *Calmecac*. They were known for their empirical approach to health. Ortiz de Montellano (1989) writes that "the efficacy of Aztec wound treatments has been validated, as well as their accurate knowledge of the physiological activities of plants. Their extensive ethnobotanical knowledge and accurate taxonomy indicates that herbals may have existed and were taught in school, although no genuine pre-Columbian herbal has survived." As the same author points out, it would, however, be wrong to postulate a distinction between empirical and supernatural knowledge among the Aztecs, for "good doctors also included those who used mixed therapies and psycho-religious techniques." In this respect the old Mexican doctors remind us of North American medicine men.

In South America herbalism is mainly thought of as a medical subfield of the medicine man. Herbalist specialists among the Araucanians might know up to 250 medicinal plants. Ackerknecht (1949), an authority on South American Indian medicine, has next to nothing to say about herbalism there. He points out, however, that such measures as massages, drugs, baths, bloodletting, diet and enemas do occur, and are "objectively effective." At the same time, the causation of such diseases, indeed, all diseases, is supernatural, he claims. Another expert, Métraux (1949), insists that "light and common ailments and the sicknesses introduced by the Whites often were regarded as natural and were treated with drugs rather than by

M

shamanistic means." He admits, however, that most diseases were attributed to supernatural causes. It is obvious that these questions have not been satisfactorily investigated. Several works indicate that herbalism was very widespread in South America, but whether there were – and are – herbalists who could be classed as inspirationally initiated medicine men is not clear.

A herbalist is, as seen in this article, a person who primarily deals with herbal medicine for internal or external usage. Secondarily he or she also handles stimulant drugs, emetics, and, in some cases, surgical operations. In North America the *peyote* (*Lophophora williamsii*), a cactus growing in the vicinity of the Rio Grande, is supposed to cure all kinds of diseases when eaten, drunk, or smoked. Peyote is hallucinogenic but not narcotic; it is not habit-forming. A particular Peyote religion was formed at the end of the nineteenth century and spread over large areas of North America. The taking of peyote against disease occurs frequently in individual cases. In the cultic connections peyote is consumed because it gives supernatural blessings, including a medical cure. Peyote is powerful for many purposes, not just for medicine, although the medical reasons have been strongly supportive in the diffusion of the Peyote religion. It is very possible that other "herbs" have also had such a general effect because of their supernatural qualities. In South America narcotic beverages such as the *ayahuasca* prepared from the plant genus *Banisteriopsis* and the decoctions of *Datura arborea* are used in or after shamanic curing séances. Also here the drugs are active because of their spiritual force, and not because they have a specific medicinal content.

Some drugs have been favored since they have emetic qualities. In both North and South America poisonous or impure substances in the body are expelled from the mouth via emetics (and from the rectum via cathartics). The most well-known emetic is prepared from a particular holly, *Ilex vomitoria*, that grows in the southeastern part of North America. This drink, called "black drink" by the Whites because of its color, but "white drink" because of its supposed purifying qualities among the Indians of the Southeast, contains caffeine. Drunk in large quantities it provokes violent vomiting. This emetic was taken as a brew to produce purity before social and religious ceremonies – as ritual sweat baths in other areas – and in connection with diseases. The disease belonged to the impurities that were removed through the black drink.

There are some reputed cases of surgery in the old days; however, amputation seems to have been scarce. Scarification occurred in many places in North America. Thus, according to Frank Speck, the northeastern Algonquians tried to relieve pain by creating an exit for it. Skull surgery, or trepanation, is mentioned from both Americas. Some scholars have tried to find rational reasons behind such operations – head injuries, unconsciousness, and so on. Since they were performed in pre-Columbian times it is impossible to get a definite answer. However, it seems more in conformity with American Indian thinking to presuppose an animistic model of explanation: the surgeons wanted to relieve the sick person from the spirit that plagued him. The most common method was, however, to put some herb or bark on the wound or over the aching area.

If there is much uncertainty concerning the ideas of etiology and the nature of the healers in herbalism, there is more certainty of the medicine men and their disease ideology. As stated above, the medicine men and women, or those medicine men and women who are doctors, function as such when through their own or other healers' inspiration it can be stated that the disease is of supernatural origin. The medicine person was chosen by his/her guardian spirit to conquer the malign spiritual influence behind the disease. His or her healing is dependent upon the power with which he/she was entrusted in the course of his/her calling.

The supernatural aspect of religious causation can mean many things, for instance, that witches on account of their supernatural powers, or sorcerers because of their magical manipulations, upset the normal health of individuals. Or it can mean that transgression of tabooed places or actions, displeasing of the powers, or imbalance in the cosmic harmony cause the same result. Sometimes spirits and divinities introduce disease and wounds without any apparent reason. The immediate outcome of this supernatural line of action may be intrusion into a person's body of objects or spirits (which could be the same thing since objects may be inanimate manifestations of spirits, or instruments of spirits), and the loss of the soul which may be wandering around, or has been stolen by some witch or some spirit(s), usually the spirits of the dead. In the latter case the lost soul may be taken to the realm of the dead from which it is difficult for the medicine man to retrieve it and take it home. The soul entity that has been lost is usually a separable soul, mostly the free-soul, or the soul that sometimes distances itself from the body in dreams and trances. As long as the soul of vitality or, where it exists, the ego-soul remains with the body, the individual is alive; where all the souls (usually two souls, the free- and the body-soul) remain with the body the person is also alive. This is the general program, but many exceptions from this rule have been found among North and South American tribes.

There is a particular tendency among Native Americans to distinguish two definite systems of diseases behind the two causation theories. When the "intrusion" diagnosis is resorted to attention is directed to the body and its diseases. We can say that the patient's physical pain conducts the doctor. In "soul loss," however, it is the sick person's mental state that stands in focus. His intellectual power fades away, fever or absent-mindedness rule, he languishes away, loses his consciousness, and so on. Scholars have until fairly recently tried to show that intrusion was more common in America, and therefore is an older diagnosis, whereas soul loss has had a more spot-like distribution and is therefore a younger diagnosis. As will soon be seen, the latter diagnosis corresponds to more difficult healing procedures. However, the more field research has proceeded the more cases of soul loss have been discovered. The present distribution of diagnoses confirms the generalization made here. Of course, in some regions we find intrusion as the dominating complex, in others, soul loss. But the presence of both diagnoses – for different types of disease – seems to be the original pattern. In our days soul loss is missing in many places, but the memory of its application by capable medicine men some decades ago is living.

In some places, for instance among the Navajo, the decision of the nature of the disease is left to particular diagnosticians who, in an inspirational state, are capable of finding out the roots of the disease. A serious disease to them is always referred to as being a break with the invisible world and its spirits; the diagnosis is never concentrated on the biological state of the individual, but on the acting spiritual forces. Among the Navajo the disease means that the afflicted person has fallen out with the balance and harmony of the Universe, so he has to be reintroduced by being identified with the supernatural powers in nocturnal rituals of up to nine nights. The officiant is a sacerdotal singer, not the diagnostician. The former could be termed a priest, the latter a shaman.

Shaman is a Tungusian word denoting those medicine men who perform their services in a trance or ecstasy. The word has since the eighteenth century become a technical term for medicine men who communicate with supernatural beings in states of trance. The Natives in America rarely have a term for differentiating shamans from ordinary medicine men; usually a shaman is said to be a stronger healer than others. Shamans occur, or have occurred, over most areas in America. The large majority of them, but far from all of them, handle diseases. When the recovery demands contacts with or intervention from supernatural powers, the shaman appears on the scene in order to meet these powers in a trance situation.

All medicine men, shamans included, receive their doctor's powers through inheritance, spiritual calling, or vision quest. In the question of inheritance it is often possible to see who is going to become a doctor; he or she has a nervous psychic constitution or is reminiscent of a deceased medicine man. In South America it is not uncommon for a doctor to transfer his profession to his own sons or nephews. The calling of the spirits is more or less attached to the inheritance idea since the guardian spirits of a shaman try to find his successor in the same family. In The American Great Basin, California, and Gran Chaco are areas where shamans are called by the spirits. Sometimes this calling follows very aggressive lines, for instance, among the Mapuche of Southern Chile. Vision quests are used in the areas in eastern North America where ordinary individuals also seek guardian spirits in order to procure their powers and their protection. Shamanic spirits are stronger and more specialized in healing than other visionary spirits. The acquisition of spirits is connected with fasting and several days' staying out in the wilderness with the dangers of climate and wild animals. In South America the candidate smokes strong cigars and consumes *ayahuasca* wine in order to attain shamanic ecstasy. The novice also joins a medicine man school, or an experienced older shaman, in order to learn shamanic procedures and tricks.

The medicine man heals the patient partly through herbalism and partly through suction, blowing, massage, and wafting with feathers, to remove the disease object or disease spirit. In South America the medicine man may attain some degree of ecstasy by drinking *ayahuasca*, whereupon he blows thick clouds of tobacco into the patient's mouth. The disease object – an arrow, a dart – is sucked out by the medicine man and then regurgitated by him. In both Americas the medicine man often produces a little thing that he claims to have sucked out of the patient and that is supposed to have caused the disease.

In cases of soul loss the healing procedure is often more difficult and more dramatic. Let us, however, first of all state that the usual background of soul loss, the serious change of consciousness, in some places can be healed without too much difficulty on the part of the acting medicine man. Thus, sometimes the soul may be called back by the medicine man, or sought by him and his associates in the neighborhood of the camp or village. According to Karsten (1955), the Jivaro Indians at the sources of the Amazon River know no remedy for fever diseases but destroy their own villages and leave them, apparently in the belief that not soul loss, but attacks of disease demons have hit the patients. In North America, for instance among the Yuma, it happens that soul loss is cured through blowing and suction, a proof that the intrusion model of disease diagnosis has formed a general curing pattern here.

The most common cure of soul loss is that the medicine man – who in this case operates as shaman – sinks into a trance to transgress the boundary between this and the other world. In North America this entrance into ecstasy is mostly brought about through autosuggestion and drumming, and in South America narcotics such as tobacco and ayahuasca effect the same state. The shaman's soul, and in some cultures his guardian spirit (it also happens that he is transformed into his guardian spirit) then departs on the long road to the land of the dead. Sometimes he manages to catch up with the fleeing soul and can then return it to its owner. If however the soul of the sick patient has reached the land of the dead, the shaman has to risk his own life by seeking the fugitive soul in that realm and trying to persuade it to come back with him. In such cases the shaman has to fight violently with the mass of the departed who want to retain their newly arrived visitor. Usually the shaman wins the struggle and brings the patient's soul back home. He presses the soul against the patient's head or some other place, and after a short while the patient wakes up again. The shaman, who in most cases has been lying down as if he were dead during the soul journey, now also comes back to life.

Sometimes many shamans cooperate in a ritual drama in a so-called imitative shamanistic séance. An example of the latter is the voyage of shamans in a symbolical canoe to the land of the dead among the Puget Sound Coast Salish. The medicine men are equipped with boards which represent a canoe and paddles and act out the events of the voyage: the hardships on the journey, the battle with the dead, the release of the imprisoned soul, and its transporting home. Here it is not the question of a deep trance, but a dramatic performance in the inspired state of an actor.

Collective medical contributions are also given in some agricultural societies, such as the Pueblo societies in New Mexico and Arizona. They have curing organizations constituted of people who have once been ill and healed by the same organizations. Animal spirits, so-called Beast gods, are the patrons of the medical societies among the Zuni Pueblo Indians. The societies are specialized in curing particular diseases, and use the methods adopted by medicine men healing patients suffering from "intrusion" diseases.

Medicine in Oceania

Cluny Macpherson

Accounts often portray 'indigenous' or traditional medicine as a culture-bound set of knowledge and practice, rooted in superstition and indigenous religion, which will eventually be displaced by a more powerful scientific biomedicine (Strathern and Strathern 1999). A study of traditional medicine in Oceania (and probably anywhere else) reveals that it is, in fact, a dynamic body which routinely incorporates new forms of medical knowledge, material and practice which have been shown to be effective, and which, in the process, becomes progressively more useful. The extent of this incorporation is often missed because its practitioners soon come to regard innovations as part of tradition, and because users often assume that since a traditional healer dispenses the medicine it derives from some indigenous medical repertoire. This makes it difficult to reconstruct traditional medical knowledge. It is, however, possible to reconstruct the trajectory of the incorporation and to identify the sources of new knowledge and the circumstances in which it occurred. In the Oceanic case, the late introduction of Western illnesses and medical knowledge, and the circumstances of their arrival, have meant that scientific biomedicine is considered a useful adjunct to, rather than a replacement for, traditional medicine and the two systems sit alongside one another as complementary elements of a healing system.

Some 5,500 years ago, people moved out of South China and, along two routes, into Oceania. Descendants of the original settlers moved steadily eastward, pausing only briefly while they developed the naval architecture and navigational knowledge to make the steadily longer voyages between ever more scattered easterly islands possible (Goetzfridt 1992). They eventually settled the furthest reaches of the last uninhabited region on earth with voyages to Aotearoa (New Zealand), Rapanui (Easter Island) and Hawaii some 900 years ago.

The path, progress and timing of the settlement of the Pacific have been confirmed by oral history, and by steadily growing volumes of linguistic, archaeological (Kirch 2002), anthropological (Kirch and Green 2001) and, more recently, DNA evidence. Studies of voyaging and navigation techniques and, more recently, a series of voyages in replica sailing vessels (Finney 1988) have confirmed that the required journeys could have been made with available nautical knowledge and technology, and have dispelled the earlier view (Sharp 1957) that these were accidental or drift voyages. Findings of ongoing research in each of these fields confirm this theory of easterly settlement and typically refine dates or clarify processes. There are now accepted explanations for the presence of the few elements which led to consideration of the possibility that Oceania had been settled from South America.

On the surface at least, it should be possible to trace continuities in the knowledge and practices of the settlers. There was little which would have been expected to transform established knowledge and practice as the explorers moved from west to east. The settlers, who were agriculturalists, carried a limited range of cultigens and technologies necessary to farm these. Beyond what is now New Guinea, they encountered no other peoples on their way eastward, and settlement occurred within a restricted range of terrestrial (Muller-Dombois and Rapaport 1999) and marine ecosystems within a relatively limited range of latitudes. Once settled, the Oceanic settler societies were only infrequently visited and then, typically, by Oceanic neighbours. This situation persisted until European explorers reached the region some 2,500 years later and limited the external influences on these Oceanic cultures. Despite thousands of years of separation, similarities are evident in the lexica of the Oceanic languages, and these have been recognized in the designation of an Austronesian language family (Pawley 1999). There is also evidence of the passage of some cultural traits from west to east, and explanations of why these might have taken various forms in different places (Kirch 1989; Kirch and Green 2001).

M

Yet despite that, there is little evidence of the passage of a body of medical knowledge and practice from west to east.

That does not, however, mean that there was not a body of Oceanic medical knowledge and practice, but rather that it was not documented at contact, which had more to do with the worldviews of those who were in a position to record it. The earliest traders and missionaries typically dismissed the knowledge of indigenes as insignificant, and as artefacts of a worldview which they sought to modify or replace. By the time better educated missionaries and settlers became interested in documenting indigenous knowledge, much of what had existed had been either lost, transformed by, or fused with the introduced worldviews with which it had collided. Introduced material and beliefs had found their way into traditional medicine and, in some cases, even the practitioners were unaware of the extent of these incursions.

It has, as a consequence, become difficult to reconstruct the autochthonous medical knowledges of Oceania. There are numerous studies of traditional practices in contemporary Pacific societies (Feinberg 1979; Connell 1980; Parsons 1985; Whistler 1985, 1992, 1996), but few comprehensive reconstructions of pre-contact Pacific medical knowledge and practice. One exception is Samoa (Macpherson 1985; Macpherson and Macpherson 1990) which lies near the geographical centre of Oceania. This case is significant because of Samoa's place in the settlement of Oceania, and because it provides some insights into the dynamic nature of traditional knowledge.

Samoa was settled some 3,500 years ago, and a distinctive society developed over some 1,000 years before the bearers of this culture set out to settle the eastern reaches of Oceania. This case is culturally significant because Samoa lies at the boundary of Eastern and Western Polynesia, contains elements of western Polynesian culture, and is widely acknowledged as the birthplace of eastern Polynesian cultures. From the point of view of cultural reconstruction, Samoa is also significant. By the time European contact and settlement occurred in Samoa, there was more systematic interest in indigenous knowledge and practices, and a more comprehensive record, from authors with diverse personal and professional interests. These provided a more reliable basis for historical reconstruction. This study is used here as the basis of an account of what might have existed in Oceanic societies.

Samoans referred to health as *soifua mālōlōina* which means "life rested" and refers to a form of biosocial equilibrium.[1] It embodies the idea of balance in relations between individuals, the social entities to which they belonged, the physical environment in which they lived, and the supernatural realm within which all humanity existed. An individual exists at the intersection of a number of related realms. These linkages were called *va* and had to be consciously maintained, *teu,* by individuals who wished to maintain good health. Such relationships were ideally balanced and reciprocal, or *fealoa'i*, which implied mutual respect of rights and obligations which attached to related roles. This balance existed when norms of conduct for people in related roles were observed. Health was attained, and maintained, when a person attended to his or her relations with others and with the spiritual agencies, *atua* and *aitu,* which controlled human activity. An ordered society is one in which relations between the realms were in a form of equilibrium and is known as one in which relationships are balanced, *va fealoaloa'i*.

Conversely, ill health occurred where people violated the norms and rules of social and spiritual relations. Ill health was the consequence of offences against either social or supernatural agencies and the causes of everything from physical trauma to mental illnesses were sought in these areas of social and supernatural relationships (Turner 1983). These gods' influence was so pervasive, and their powers so extensive, that they were held to be the principal authors of all human illness. Gods generally created illnesses to punish people under their protection for a lack of appropriate respect or for acts of meanness to them. Various people, known as *taulāaitu* or *taula ole aitu,* or anchors of the spirits, acted as mediums and identified social and supernatural sources of an illness (Moyle 1974). In the case of supernatural causation, the medium sought to identify the offended spirit or god, to clarify the cause and offer the appropriate form of conciliation.

In other cases, offended living persons could call on another class of gods, known as *taula-aitu-vavalo-ma-fai-tu'i,* to make the offender ill. The resulting illness could take several forms, and the form gave some clues to the nature of the offence which, in turn, focused enquiries on people who might have committed it. Where social offence was suspected, a process of systematic enquiry led eventually to the offended person who had engaged in the sorcery which had created the illness, and to the form of social activity which would lead to its removal. This consisted of incantations directed at the identified spiritual agencies (Moyle 1974). Only when these causes were identified could the process of intervention commence, and only when this was completed and accepted, could relationships be restored.

The focus of activity in each case involved the identification of the relationships which had been

[1] It was also referred to as *la'oifua*, or "to be recovered from sickness", and in the language of chiefs, as *laumālie*.

disturbed, and the activity necessary to *teu le va* or heal the relationship. In most illnesses, the human body was simply the site in which the offended party had sought to demonstrate their displeasure. To complicate matters, the person who became ill was not always the one who had caused the offence, and so diagnostic inquiries had to extend to the conduct of those around the victim in case this person was a surrogate.

The level of agreement on an essentially social intervention process in the writings of a range of early observers of Samoan society was unexpected: traditional models of physiology, aetiology and epidemiology, an extensive, and apparently thriving, body of plant-based medicines and forms of massage are in use in contemporary Samoa (Macpherson and Macpherson 1990). This paradox led to consideration of the possibility that those who documented it were led by their religious and social agenda to focus on these elements of practice,[2] and to overlook either accidentally, or deliberately, other elements of Samoan medical practice. However, an examination of both religious and a number of secular authors' works suggested that there were only very rudimentary indigenous models of human anatomy and physiology and little in the way of biomedicine. Early missionary authors, such as Dr. George Turner, who sought information on medicinal uses for Samoan plants, reported that relatively little medicinal use was made of the local flora and fauna (Turner 1983). This was confirmed by other missionaries, and surprised them as they were themselves regular users of herbs and simples. Comprehensive and well-regarded dictionaries compiled by early missionary linguists (Pratt 1862) contained extensive lists of flora and fauna but few terms for medical implements or procedures, and few annotations of medicinal plant uses. Relatively few indigenous terms or concepts relating to human physiology or biology were discovered by these linguists. Early plant collections contained extensive notes on various practical uses of plants, but little evidence of medicinal uses (Powell 1868). Comprehensive studies of Samoan material culture located no implements used in medicine (Hiroa 1930).

This finding was remarkable, given that there is an extensive traditional knowledge and thriving traditional practice, and that Samoans make regular use of both traditional knowledge and practitioners, and flora and fauna in their search for health (Macpherson 1985; Macpherson and Macpherson 1990; Whistler 1996, 2000). The finding raised the issue of how missionaries and other settlers, who had so assiduously documented other areas of Samoan life, could have missed a body of traditional medicine.

One possibility canvassed was that the medicinal material and knowledge was, for various reasons, not revealed to early missionaries. Other forms of sacred knowledge, such as navigation, had been hidden from visitors to Oceania (Lewis 1972). In this case, the missions had sought to undermine belief in Samoans' traditional gods, and had ostracized those who had expressed continued support for them. The close association between the family and village gods and health and illness might then have been systematically hidden from missionary eyes by those who sought to retain their affiliation with the mission. This does not appear to be the case. Missionaries, who lived on mission stations with numbers of Samoans, were well placed to obtain this information but did not, and secular settlers who lived close to the Samoans (Pritchard 1863–1864; Pritchard 1866) also found little evidence of an extensive indigenous medical knowledge and practice. They were able to obtain information on and document a range of other sacred practices, and did so in the belief that their activity would be more successful where missionaries understood Samoan culture. Nor is it clear that Samoans were as completely dominated by missionary power as this explanation requires. At the turn of the nineteenth century, Samoans were reluctant to share medicinal knowledge, not out of fear of the missionaries, but out of suspicion that others might use it. The German naval physician, and pioneer ethnographer, Dr. Augustin Krämer, reported that Samoan healers would not share their knowledge with him because they believed he might expropriate it and incorporate it in his own medicine (Kramer 1994: 134).

Another, and more likely, possibility is that Samoans, living in relative isolation in the middle of the Pacific Ocean with few disease vectors, suffered a relatively limited range of recurrent illnesses (Kramer 1994). Those could be adequately explained by a paradigm which placed more emphasis on the social and supernatural causes of illness, and rather less on the biological and physiological ones. This seems probable: Samoans lived in that archipelago for some 2,800 years until European contact occurred in the late eighteenth century. During that time, and after an epidemic which followed a visit by an Oceanic neighbour, Samoans prayed daily to deities to prevent 'sailing gods' from landing, and physically repulsed those who sought to land to prevent further epidemics (Turner 1983; Stair 1983). The presence and absence of illness could be explained by reference to humans' relationships within social, natural and supernatural realms. In the circumstances, there was no need for a

M

[2] These missionaries were dependent on their supporters in Britain for the resources for the mission. Their records and tracts tended often to focus on areas of activity which showed the enormity of their task of conversion and which generated the most interest and most generous support on the part of British congregations.

paradigm which systematically linked illness to biological vectors and or physiological processes.

This would also explain why in a relatively short period, between the early nineteenth century and the present, Samoans incorporated new medical ideas and practices which are now widely regarded as traditional. If this is indeed so, the Samoan case demonstrates that traditional Oceanic medicine is not static but dynamic, and is constantly expanding as new materials and ideas become available and are incorporated. The problem then becomes one of explaining the conditions under which an indigenous medical paradigm might expand and of identifying the factors which might influence the shape of the neo-traditional paradigm.

The commencement of contact between Samoans and people from beyond the archipelago provided a motive to rethink the pre-existing paradigm. Contact resulted in the immediate introduction of new diseases which struck indiscriminately at a population with little resistance or immunity to them (Macpherson and Macpherson 1990: 54–58). Ironically, the isolation which had produced the relative epidemiological stability before contact (Kramer 1994) had prevented the Samoans from developing immunity and ensured that each of the illnesses introduced between 1830 and 1918[3] would have significant impacts on Samoan society. Traditional aetiological and epidemiological models could not explain the new forms and patterns of illness. This inadequacy led Samoans to seek new explanations for the new experiences.

The growing frequency of contact with visitors and settlers from beyond Samoa also provided opportunity to expand their models of illness. Settlers from Britain, Germany, the United States, Australia, New Zealand, visitors from elsewhere in the Pacific, indentured labour from Melanesia, and later, from China took up residence in increasing numbers just as the Samoans' new health problems were emerging. Bearers of new models provided the knowledge necessary to augment the Samoan explanations and, in some cases, new material and practices to expand their medical repertoire.

Some of this knowledge transfer was deliberate. The missions sought to undermine polytheistic Samoan religion by providing alternative explanations for illnesses. This involved, ironically, persuading Samoans to replace many gods who caused and healed their illnesses with a single one with similar powers. But not all missionary effort was driven by a religious agenda. The London Missionary Society, in an attempt to provide comprehensive theological education for Samoan missionaries, translated and published works on zoology and biology including, in 1886, a 330 page tome entitled, *O le Tala i Tino o Tagata ma Mea Ola eseese: e iai fo'i o tala i manu ua ta'ua I le Tusi Pa'ia* which is, literally, an account of the bodies of people and various animals and of animals mentioned the Bible (Powell 1886). The manual was provided to pastors who were encouraged to use the information to improve the quality of their teaching. The missions may not have fully appreciated the ways in which Samoans would use the explanations in these to supplement, rather than supplant, their own earlier ones. Some other manuals found even wider readerships.

But their efforts were duplicated by those concerned with public health. In 1912, Cottle, the Health Officer at the US Naval Station at Tutuila, translated a health care manual for school children in American Samoa entitled, *O le Tusi e a'oa'oina ai i le Tausiga o le Soifuaga o Tagata Samoa,* sub-titled *Health Care for Samoans* (Cottle 1912). A final, and influential, example was the comprehensive 1937 work by Downs and Turbott entitled, *Health for Samoans* (Downs and Turbott 1937). It was subsequently translated by Drs Ielu I'iga and Atimalala Mama as *Maloloina Mo Samoa* or *Health for Samoans*, in a text which contained side-by-side translations of the original material. The Samoan language version was widely distributed to upper school students, teachers, native medical practitioners (NMPs), nurses, and women's health committees in villages and copies are still found often in the possession of healers and others. From the time that new health problems confronted the Samoans they had access to a series of texts which opened up new ways of thinking about the human condition and managing illness.

Not all health knowledge transfer was deliberate. Some transfer was incidental and occurred as Samoans observed and availed themselves of the health practices of those who increasingly lived among them. Missionaries and others noted that Samoans were very interested in the visitors', often experimental, use of herbs and simples, particularly since they had access to the power of an omniscient and omnipotent god, to whom Samoans expected them to turn for remedies for their illnesses.

Some transfer was deliberate. Early in the twentieth century, the German administration and the US Naval Administration sought to reduce the costs of administering their Samoan possessions by training Samoan paramedics to minister to Samoans. Similar programs were later extended by the New Zealand Administration in Western Samoa. The training programs were based at hospitals and graduates were given medical kits, texts and basic equipment. The Samoans embraced the programs and villages often sent for training people who had shown a disposition for healing. These were often traditional healers, known as *fofo* or *foma'i samoa,* who on graduation returned to their former practice with an expanded medical repertoire.

[3] The 1918 influenza pandemic resulted in the death of some 23% of the population of Western Samoa.

The availability of new knowledge led to the expansion of both explanations and treatments. For instance, the highly influential teachings of Christian missionaries taught that an omniscient and omnipotent God could and would bestow on faithful followers the ability to heal. The gift of healing, given to Jesus and later to his apostles, and demonstrated in a series of acts in a sacred text, which rapidly became central to the Samoan worldview, was also available to the faithful and was, arguably, more powerful than other forms of human intervention. This led to the early incorporation of the belief that the most devout Christians might receive god-given healing powers, and of such practices as prayer, singing and fasting into Samoan healing.

From the mid-1800s, Samoan pastors became central in the missionary activity as the mission sought to convert the peoples of western Oceania. Samoan pastors trained in Samoa and served with distinction in Western Polynesia and Melanesia. In the mission fields, they were often left to their own devices, and became in many cases dependent on their congregations for food, shelter and medicine. There, and particularly on high islands with abundant flora and fauna and often separated from support, they became familiar with a range of local medicinal plants and learned local uses for plants. The Samoan pastors, duty bound to eradicate heathen practices, tended to ignore forms of intervention which invoked supernatural agency and to focus instead on plant-based medicine.

These practices and the associated plants were often repatriated at the end of their mission service, and are now found so widely in Samoa that they are supposed to be indigenous. It is not unusual to come across gardens of introduced plants from Melanesia in Samoan villages, and to find that their medicinal value and uses were originally acquired by missionary relatives who had served in those regions as much as a century earlier. This may explain why some Samoans assume that the plants and their medicinal uses are indigenous. This trend is evident in the steadily growing range of medicinal plants documented in Samoa. The ethnobotanist, Whistler, for instance noted that of 59 plants used in Samoan medicine, about 53% were native, 30% were Polynesian introductions and 17% were recent or European introductions (Whistler 1992: 64), and that similar mixes were found in the Tongan islands to the south.

Despite white colonial administrators' attempts to prevent it, fraternization between the Samoan, Chinese and Melanesian populations occurred during the first half of the twentieth century (Shankman 2001; Field 1984). Intermarriage and cohabitation made the medical knowledge and practices of these groups available to Samoans with whom they lived. Melanesians, who also came from high islands with similar flora and fauna, extended the Samoans' appreciation of medicinal indigenous flora, and there are cases where the Melanesian origins of contemporary Samoan uses are marked linguistically and or acknowledged by those who use them. However, it is also true that the use of certain Melanesian practices connected with sorcery, and known as *fa'alauatau,* was banned by missions. Medical concepts and practices also undoubtedly derive from Chinese medical models used by the 2000 plus Chinese labourers who worked in Samoa, some of whom later married into and lived in Samoan society. Again, the Chinese origins of some contemporary medicinal ideas and practices are marked linguistically and or acknowledged by practitioners who use them. It is, however, impossible to establish the exact extent of these influences since only systematic questioning of those who know of the origins of their practices could determine this. In some cases, information on origins, which is not usually central to competent healing, has simply been lost in transmission.

The practice of incorporation continues. As Samoans have become more mobile, and despite increasing biosecurity measures at Samoa's borders, new plants are regularly introduced, established and soon incorporated into traditional medicine. The dynamic nature of Samoan medicine is not always apparent to Samoans since most patients seek relief and do not routinely ask their healers about the origins of either the plants or practices in use. Contemporary practitioners do not always know the origins of knowledge and practices which were incorporated into traditional medicine two or more generations earlier. Occasionally, the source of plants is marked linguistically, as in *'ava fiti, 'ava toga* and *'ava niukini* which distinguish varieties of *Piper methysticum* from Fiji, Tonga and New Guinea, respectively, but this is often not so. However, systematic inquiry about exotic plants can yield interesting material on sources of exotic plants and ideas in use in traditional Samoan medicine where these are known. A Samoan rigger who had worked in Papua New Guinea in the 1970s and had hunted pigs with local tribesmen, had brought to Samoa a plant used by hunters to relax cramped muscles. He had given the plant and instructions for its use to his mother's sister who had incorporated it in her repertoire. A Samoan Mormon missionary had brought back to Samoa a plant from New Mexico used as a nasal decongestant by native Americans which is now in use in her mother's sister's practice in Samoa.

Nor is the incorporation confined to plant materials. A number of traditional medicines are prepared in different strengths for babies, children, adolescents and older adults, respectively. This practice, a healer explained, derived from the filariasis eradication program carried out in Samoa in the 1960s on which she had served as a liaison person. She explained that the connection between body mass and dosage was obviously effective and she had subsequently adopted a variant in her own practice.

The Samoan case offers evidence of two other forms of medical dynamism. Several studies have pointed to the declining use[4] of certain plants where either the plants become scarce, or other more efficacious materials and treatments have become available (Macpherson and Macpherson 1990; Whistler 2000). Whistler, for instance, reports that of the 130 plants which have had medical usages reported for them, only some 84 are currently in use, and that of the latter group some are now used by only small numbers of healers. Other plants, however, have been found in an extended range of medicines. Significant numbers of the plants recorded by Kramer at the turn of the twentieth century are now used in a wider range of medicines. In these cases, new uses are sometimes the consequence of experimentation and, more commonly, of a growing awareness of alternative uses as a consequence of contact. Unusual uses of particular plants in some healer's repertoires were usually tracked to the presence of migrants from either Asia or the elsewhere in the Pacific, and occasionally, to the practice of western-trained medical professionals who recommended readily available local plants as effective alternatives to more expensive imported medicines.

This search for new ideas and practices has not, however, led to the abandoning of pre-existing models, which have, after all, served Samoans well over some 3,000 years of residence, but rather to their augmentation. The new illnesses, which were determined to be a distinct category of illnesses, and the property of the visitors, became known as *ma'i mai fafo,* sicknesses from outside, and included *ma'i papālagi,* the illnesses of Europeans, *ma'i saina,* the illnesses of Chinese, *ma'i meauli,* the illnesses of Solomon Islanders. Their diagnosis and treatment required additional medicinal knowledge which was supposed to be possessed by those who had brought them. Just as Samoans were supposed to be familiar with the causes and management of *ma'i Samoa* or 'Samoan illnesses', the visitors were supposed to be familiar with the nature and management of these new illnesses. The people who brought the diseases were supposed, by the Samoans, to be well-versed in their management, and versions of visitors' explanations and management became incorporated into augmented Samoan models of illness and management. This meant that there was no obvious reason to establish empirically which, if any, of the available medical paradigms was more effective than another. This way of thinking about illness and its management opened the way for the co-existence of a set of complementary medical paradigms which continues today.

In these circumstances, there is no obvious reason why healers would not continue to expand traditional medicine or for patients to discontinue the use of traditional medicine since its use does not prevent them from using other forms of treatment where this may appear appropriate.

This case, outlined in greater detail elsewhere (Macpherson and Macpherson 1990), shows that Pacific indigenous medical systems need not be unchanging, culture-bound paradigms which depend solely on cultural and religious logics for their power. They can be dynamic systems in which both knowledge and practice are routinely augmented as observation and experience of new models and practices suggests additional and more effective ways of approaching health. It also suggests that attempts to reconstruct truly indigenous medical knowledge and practice in such circumstances confront real problems. Because of the ways in which the sources of these ideas, materials and practices are constantly expanding, and because these are incorporated into traditional medicine without drama it becomes difficult to tell which part of today's traditional medicine was yesterday's introduction.

[4] The empirical evidence must be considered carefully, because of the difficulties of accurate sampling of the usage of plants in healers' repertoires which is compounded by the difficulties of doing longitudinal comparisons where plant names change over time. However, anthropological studies routinely reveal the dynamic nature of the process and Whistler's ethnobotanical work is the very best available for Samoa.

Medicine in Sri Lanka: Traditional Medical Knowledge, Its History and Philosophy

Arjuna de Zoysa, C. D. Palitharathne

A Framework for Medical Histories

The study of Sri Lankan history recognizes four distinct periods (Bandaranayake 1990) from prehistoric times (ca. 125000 BCE) to a proto-historic era, when settled agriculture and Iron Age technology began. The historical period begins with the growth of advanced irrigation systems for food production and the surplus created by this results in the emergence of a flourishing civilization centered on cities such as Anuradhapura, Sigiriya, and Pollonnaruwa in the north central province. These city-centered civilizations spanned a period of one and a half millennia, from around 300 BCE to 1250 AD (De Zoysa and Palitharatne 1992). From 1250 AD onwards one sees a number of "centrifugal" tendencies, with fragmentation of centralized power to the periphery. With the arrival of the Portuguese (sixteenth century), a period of colonization by European powers followed and ended only after the Second World War. Modern Sri Lanka was heavily influenced by this colonial period (ed. note: see the article on Colonialism and Medicine in Sri Lanka).

M

From Proto-Histories to Civilizational Periods

Living evidence of conditions in the pre- and proto-historic periods exists among the Veddha community, an indigenous people who retain most of their hunter–gatherer past even today (Spittel). The Veddhas possessed sufficient medical knowledge for their survival needs. They had knowledge of medicinal plants to treat wounds and used python fat for fractures. They practiced exorcism, which is still practiced today and reputed to have great value in an appropriate socio-cultural context. There is however no evidence of any attempts to build a connected knowledge system out of these curative practices, and their life spans were short (Sagara 1995).

With the coming of the city-centered civilizations (ca. 300 BCE), there was rapid development in all fields of knowledge. Historical information of this period is derived from several sources (Bandaranayake 1990; Uragoda 1987):

1. Written material, which was recorded on Ola leaves. The *Mahavamsa* a collection of historical information, is such an example (Guruge 1989);
2. Rock inscriptions at religious and archaeological sites;
3. Artifacts and buildings from archaeological sites.

A reasonable picture of what constituted medical knowledge in Sri Lanka during this time can be derived from these sources (De Zoysa and Palitharatne 1992). By the end of the proto-historic period, curative medicines and practices were locally found and available, but it was probably not until the early historic period that Āyurveda and Siddhi (Classical Indian) and Unani (Classical Middle Eastern) systems were extensively used and integrated with local regional (*Deshiya Chikitsa*) practices or folk practices. Āyurveda forms the major practice of traditional medicine in Sri Lanka. The well-known texts on Āyurveda such as the *Carakasaṃhitā* and the *Suśrutasaṃhitā* were known and read in Sri Lanka from before the historical period. The *Arkaprakāśa* an early book on Āyurveda, supposedly written by a king, Ravana, is still available (Buddhadasa 1960). The *Carakasaṃhitā* refers to a legendary conference on medicine held in the Himalayas (ca. 6000 BCE), where a number of *Rishis* (meditating recluses), worked out the fundamentals of Āyurveda in consultation with divine beings. The Rishis are named, and one of them, Pulasthi, was from Sri Lanka, an emissary of Ravana who was supposed to have returned with the principles of medical knowledge to Lanka (Buddhadasa 1960: 1–2). Āyurveda was probably first introduced to Sri Lanka during the time of king Ravana.

Āyurveda had the character of a well-connected knowledge system (De Zoysa and Palitharatne 1992). There were for instance sections describing fields similar to surgery, toxicology and ear, nose and throat diseases. The *Suśrutasaṃhitā,* a book on surgery from India, describes 121 surgical instruments (Pilapitiya 1982), many surgical practices using them, and dissections on dead bodies for surgical practice. Surgical procedures show knowledge of the infective power of microorganisms too small to be seen by the human eye. The underlying paradigms of Āyurveda were very different from biomedicine and form a powerful alternative to such a system.

During the city-centered historic period, extensive state sponsorship was given for medical practice and science. Some kings, such as Buddhadasa (fourth century), Aggabodhi (eighth century) and Parakrama Bahu (twelfth century), were actual practitioners and scholars of Āyurveda. The *Mahavamsa* records the existence of hospitals (Guruge 1989), dispensaries and medical halls during this period, and archaeological excavations are supportive of these claims. Medical practice at this time was in line with Ayurvedic practices; as such it would have been comprehensive, covering both preventive and curative measures which extended even to the care of animals.

With the decline of the city-centered civilizations one sees the emergence of a number of regional centers of administration around the sea port cities such as Kotte, Jaffna and in the hill country Kandy. Although a large body of medical knowledge was preserved and passed down through generations, no notable achievements were recorded during this period (De Zoysa and Palitharatne 1992).

The Colonial Period to Modern Times

Colonial conquests started with the Portuguese in 1505 and continued for nearly four and a half centuries. This period saw also the rapid growth of modern science in Western Europe and its introduction to Sri Lanka by the conquering colonial powers, in particular the British.

Both the Portuguese and Dutch had a great respect for local medical knowledge and used it at times to treat even their own sick and wounded (Uragoda 1987). The Portuguese are reputed to have used local knowledge to cure dysentery and snake poisoning among soldiers. They did however reject culture-bound practices such as exorcisms on religious grounds. The Dutch, who captured the coastal towns from the Portuguese in the seventeenth century, are credited with building many hospitals in Sri Lanka (Uragoda 1987), where herbal medicines were used alongside drugs imported from Europe. Towards the latter part of the eighteenth century they even appointed "native" physicians proficient in Āyurveda in all their hospitals. During the Dutch period there was a brief renaissance in the study of traditional medicine. King Narendrasinghe (1707) translated a thirteenth century palm-leaf manuscript, the *Bhesajja Manjusa,* on medicine and was also responsible for compiling a *Vattoru Vedapotha,* a book of traditional medicinal prescriptions. Paul Hermann, a surgeon attached to the Colombo hospital, was interested in botany; he was at that time in contact with Linneaus and sent collections of local plants to him. It is said that Linneaus used these as part of his famous plant classification (Goonatilake 1985).

The British colonial period in Sri Lanka started from 1796 and lasted 150 years. During this period the rapid industrialization of Europe and North America and its domination of the rest of the world took place. Not surprisingly, Western medical science was introduced and it established a dominant position in Sri Lanka. Āyurveda and traditional medicines were generally discouraged under British rule and the colonials learnt little from it. There were however notable exceptions. Sir Henry Blake, a British Governor in Sri Lanka, translated parts of the *Suśrutasaṃhitā* using Buddhist scholars; he claimed in a lecture delivered to the Royal Asiatic Society in 1905 that malaria was recognized as a vector borne disease (Uragoda 1987). This was never accepted in Europe, but it is difficult to envisage how an irrigation-based civilization flourished if it did not understand even the causative mechanisms of such a devastating disease like malaria. Another notable exception was the establishment of a College of Indigenous Medicines in 1929 with state sponsorship. These instances of support were however, very much the exception.

In spite of heavy state support for Western allopathic medicines and the marginalization of traditional practices, the latter survived and were used by a majority of people; even the urbanized middle classes, who were heavily "westernized" in outlook, continued to use them. What were the reasons which made these traditional systems of medical knowledge so resilient? We will in the following text investigate the world-views behind the two knowledge systems of Āyurveda and allopathy (biomedicine). To do so, we will first touch on some developments in the philosophy of modern science.

A Philosophical Note

The term *incommensurable* first introduced by Kuhn (1970) and later developed by Feyerabend (1978) refers to the impossibility of comprehending a theory "A," based on a paradigm "A," by using concepts and terminology of a theory "B" based on a different paradigm "B." By paradigm we mean,

> On the one hand it stands for entire constellation of beliefs, values, techniques, and so on shared by the members of a given community. *On the other, it denotes one sort of element in that constellation, the concrete puzzle – solutions which, employed as models as models or examples, can replace explicit rules as a basis for the solution of the remaining puzzles of normal science.*

Numerous examples can be taken from the history of science itself as evidence for incommensurability between theories. Relativistic and Newtonian physics form two of the best-known examples. In Newtonian physics, mass, time, and energy are observer-independent entities, existing in absolute space. In relativistic physics, they depend on the relationship between the observer and the observed, have no fixed value and lose all absolute meaning. In fact the concepts are so radically different that the use of the same words – "mass," "time," etc. – leads to confusion. A student used to years of reference to "Newtonian mass" finds it difficult to comprehend and adjust to "relativistic mass." Perhaps it would be easier to make the gestalt switch if different terminology were used.

Werner Heisenberg (1952) provides a rather striking, but less well-known example of incommensurability. Heisenberg shows the almost total incommensurability between Newton's and Goethe's theories on color. Newton's theory of color was mechanistic, precise and with later modifications proved to be useful for all kinds of practical purposes. Goethe's theory of color was based on symmetry and complimentarity. Its purpose was very different from Newton's; it described a sensory world of color which was relevant and proved useful for aesthetic purposes.

Differing Worldviews

The worldviews or broad paradigms on which the two medical knowledge systems are based are different and incommensurable. The ontology of classical Western science takes for granted the existence of subatomic particles which form atoms, and these arrange themselves into chemical compounds growing in complexity to form organic molecules and hence life. In Vedantic philosophy, material form is described by five fundamental attributes, the Pañcamahābhūta. These attributes can be understood metaphorically by use of commonly encountered substances, such as Air (motion), Water (fluidity), Earthiness (solidity), Agni (fire), or energy in thermal form and Voidness (or emptiness). The above list of metaphors exhausts the discourse on materiality, and there can be no further additions to this particular classification. One can only go for an alternative form of classification which may contain as many as 12 properties. The substance-based element theories in modern science are different. They refer to "elements" which exist "out-there" in material form. The discovery of additional elements to the original 92 is therefore expected. It is important to realize this difference; as the foundational base of Āyurveda is unchanging, its pharmacopoeia and curative techniques are dynamic. Health in the human body in turn is described as a balance between three metaphoric properties, known as the *tridoṣa*: *Vata, Pitta and Kapha*. The substance metaphors for these are often given as Air, Bile, and Phlegm. These metaphors should not be mistaken to mean the same as these actual substances. However, a *Kapha* imbalance would lead to a preponderance of phlegm in the body. These properties in turn are connected to conditions in the natural environment, age and disease. The knowledge system is thereby connected as a whole. A superficial understanding of this could lead to "fuzziness." With the modern focus on quantitative exactness and reductionism many prejudicial viewpoints could result, if one views these ancient sciences with a simplistic lens. In understanding these concepts, language itself is an impediment, as they are difficult to translate. A proper understanding can only be derived by an appropriate gestalt switch from knowledge system "A" to knowledge system "B" (De Zoysa and Palitharatne 1992).

Let us examine the paradigms underlying the theory of disease causation in the two systems.

In Āyurveda, there are four reasons for disease: *Aganthuka* (external factors such as injuries), *Sharirika* (Physical), *Manasika* (mental), and *Swabhavika* (natural, such as old age, hunger, thirst). Disease itself is defined as contact with *dukkha* (Pilapitiya 1982). The meaning of *dukkha* is very comprehensive and includes unsatisfactory physical as well as mental states, both temporary and permanent. Negative emotions such as anger and jealousy are considered to be disease states. We can at once see why such a system has to deal with both physical and spiritual treatments. *Āyurveda* recognizes the existence of microorganisms, however, the main causative factor lies in an imbalance within the human body. Using such a theory, it would be easy to explain the occurrence of influenza and to adopt preventive measures against it. Cold temperatures, moisture, food described as cooling, all enhance *Kapha*, leading to an imbalance, which makes the body susceptible to a viral invasion. Person "A" may contract it in autumn and not in summer and so forth. The virus after all presents itself constantly, but it is only sometimes and only some people who are affected. The *tridoṣa–vada* of balance and imbalance can be thought of as a comprehensive theory of resistance and susceptibility to disease. Its real benefits lie in disease prevention. There is also the recognition of *Kamma* (karma; ethical acts), either done in this life or in a previous life, which impact on disease. In fact if negative *Kammic* effects are dominant (*Kamma Roga),* special acts are specified to nullify these before or during medical treatment (Buddhadasa 1960: 63–64). In the *Carakasaṃhitā* there are diseases mentioned which cannot be cured by clinical means alone. It is said that people who think that one is born purely by the coming together of man and woman are supposed to have limited vision (Buddhadasa 1960: 337). The worldviews between allopathy and Āyurveda are thereby fundamentally different.

In South Asian traditional systems, the emphasis is on health, not disease; the re-establishment of a diseased body to health is extensively dealt with. The cure in biomedicine might sometimes be worse than the disease. For example some chemotherapies and radiation treatments for cancers could be worse than the cancer itself and might lead to a disabled existence or death for the treated person. In South Asian medical processes such "cures" are no "cures" as they do not lead the patient's body to health. Much could be learnt from the practice of Āyurveda, and a reasonable cross fertilization of knowledge systems could be beneficial to all.

Ayurvedic medical treatment is considered to be both a science (*Shashtra*) and a craft (*Shilpa*). The practitioner takes a personal interest in the patient and ethical norms are built into the very development of the *Shashtra.* For instance, animal experimentation is not allowed in Ayurvedic research.

On Validation

I will here use a particular example which brings the problem of validation into sharp relief. The double-blind test for the efficacy of drugs is a special case of a control widely used to determine the solely physical effects of drugs. In Āyurveda we find a category of herbal medicine known as *Khema,* in which a "wanted" physical component interacts with the "unwanted" psychological action. A *Khema* is always accompanied by an intricate story of its origin, and ritualistic preparations are used before administration. The patient is made to believe in these, and although the herbal medicine has a physical effect, its value is substantially enhanced by psychosomatic interactions. The two effects may not be separated out and studied, because in general their interaction is nonlinear, affecting the whole human body rather than the merely diseased parts of it. A double-blind test would be irrelevant in such a case (De Zoysa and Palitharatne 1992). Validation of Ayurvedic efficacy should be taken as a whole treatment regime, and validation is a process, not a single medicine, which in any event is a *Sanyojanaya* (compound mixture) and not a chemically extracted active ingredient.

Quantification in classical systems is personalized. For instance Āyurveda gives three major measures – *Anguli, Anjali, and Matra* – with reference to the patient's body size (Balasubramaniam 2005). In the Western medical system measurement is with reference to abstract quantities. This difference means that any validation of classical medicines should be quantified accordingly.

The Future

Both Ayurvedic and Western medical practice claim to rest on a firm "scientific" basis. These claims are only partly true. The practice in a number of cases does not flow naturally from a theory based within a broad paradigm. In a Kuhnian sense, we cannot say that both are fully "mature sciences" flowing from broad generally accepted paradigms of theory to practice. There are many practices and medicines, in both

Western and Ayurvedic systems, which are used simply because they work. Some times ad hoc practices which do not deeply penetrate the respective knowledge systems are used. Vaccinations were used in Europe for smallpox long before any theory of immunity had been accepted as a specialist discipline. Smallpox inoculation is mentioned in the ancient Indian text, *Atharvaveda,* and was practiced in Ancient India by introducing "inoculated pustules of the previous year" to healthy persons (Pilapitiya 1982). Again it is unlikely that Ayuvedic theory prompted such treatments. Treatment of many common ailments, such as back pain, is treated on a "try and see" basis in biomedicine, and often the patient knows what course of action would be best for him. Many other examples can be taken to show this disjointedness between theory and practice in both systems (De Zoysa and Palitharatne 1992).

Western medical scientists interested in creative work have a fertile field in traditional systems of medical knowledge. They can learn much from the history of Western science itself, in particular from its major creative periods, to develop an openness and methodology for fruitful cross-fertilization of knowledge with traditional knowledge systems. A healthy respect for alternative knowledge systems would be a liberating force for science.

Medicine in the Talmud

Samuel S. Kottek

Although whole books have been devoted to the study of talmudic medicine and quite a number of studies to specific related topics, only a small number of scholars in the field of medical history are aware of this rich corpus of knowledge. The core of the Talmud (the authoritative body of Jewish law and tradition), called *Mishnah* (divided into six tractates), was compiled between the second century BCE and the second century AD. Two extensive commentaries and glosses were added to the basic text. One is the so-called Jerusalem Talmud, which was completed in the fifth century AD. The Babylonian Talmud, which was much larger, was sealed in the sixth century. No medical texts from the ancient Hebrew–Jewish period have reached us, so the wealth of medical knowledge that is interspersed in the Talmud is the sole source of documentation in these matters. It should be made clear that these medical data are recorded by talmudic scholars in the midst and for the sake of legalistic discussions. In most cases few details are provided and only those that are relevant to the specific point under consideration.

The spectrum of medical knowledge covered in the Talmud is very wide. The field of anatomy (mainly of animals) is impressively represented, particularly in the tractate *Ḥullin* which deals with dietary laws. The inspection of slaughtered animals is one of the remarkable institutions of Jewish law, as it related to public health. In order to decide whether an animal was acceptable for consumption (*kasher*) or not (*taref*), anatomy and pathology had to be mastered to a considerable degree. Two examples will be given here.

The number of bones is considered in the context of uncleanliness: it is ruled that everything contained in a tent (or room) in which there is a number of bones amounting to more than half of a corpse becomes unclean. The body is comprised of 248 bones (it says "members," *evarim*), corresponding to the number of days of the lunar year, and 365 "sinews" (*gidim*) corresponding to the solar year [bab. Makkot 23b]. The Talmud mentions that once research was done on the corpse of a young female prostitute who had been executed by the (Roman?) authorities, and it was found that there were 251 bones. The Sages opined that the discrepancy was due to the fact that this was a young woman [bab. Bekhorot 45a]. Another opinion was that the number of bones may vary from 200 to 280 [Tosefta, Oholot 1: 7]. Osteology was not very exact, even in "academic" medicine. Galen speaks of "more than 200 bones" [De Form. Foet., Bk. 6]. Interestingly enough, Ibn Sīnā (Avicenna) and al-Zahrāwī (Abulcasis) both accepted the number 248, most probably in accordance with the lunar analogy and the macrocosmos/microcosmos similarity.

The second example is related to neuroanatomy. The case history featured a lamb which dragged its hind legs along, and the question was, "What kind of lesion does it have?" One sage said, "This is a case of sciatica" (Hebr. *shigrona*). Another replied, "Possibly this is a lesion of the spinal cord" (Hebr. *ḥut ha-shedrah*). The text then says, "They examined it (i.e., they performed an autopsy), and the second diagnosis was authenticated." This shows a remarkable experimental approach. The sages decided that if an animal dragged its legs it would be said to have sciatica, and such an animal would be permitted for consumption [bab. Ḥullin 51a]. This is a very typical example of talmudic casuistry. The sages not only allow, they even advocate thorough examination of the case, but the decision is based on the opinion of the majority and on the most frequent occurrences.

The Talmud, in both versions, is full of observations of medical and historical interest pertaining to internal medicine, gynecology and obstetrics, dermatology, neuropsychiatry, surgery, traumatology, and most other specialties (including otology, ophthalmology, and dentistry). Other fields such as dietetics, preventive medicine, forensic medicine, public health, and materia medica are also widely represented. Instead of listing a catalog of items, we shall give a number of examples that stand out for their detailed description and/or for their originality.

Commenting on the scriptural verse [Deut. 7: 15] which reads, "And the Lord will take away from thee all sickness…," the Talmud asks the question, "What is sickness?" A number of answers are provided by the Sages in both versions of the Talmud [bab. Baba Mezia 107b; jer. Shabbat 14: 3]. In both versions we find three cardinal causes of diseases. One pertains to scientific medicine: the bile; one is related to popular medicine: the cold (or cold-and-warm); and one belongs to magic lore: the evil eye. Other agents that appear only in one version include: air (or wind); fever; abnormal or superfluous secretions; climatic factors (the *sharav* wind); obsession (one who is persuaded that he is sick), and carelessness (which is particularly stressed, thus enhancing the preventive aspects of medicine). Two other factors are mentioned elsewhere in the Talmud. One is blood (i.e., plethora): "At the head of all (causes of) diseases am I, the blood" [bab. Baba Bathra 58b]. The other is changes in one's habitual way of life [ibid. 126a]. Another version mentions changes in one's usual diet [bab. Kethubot 110b]. This particularly developed topic is characteristic of talmudic lore, as it includes popular beliefs, empirical notions, and scientific aspects. Humors (blood, bile), specific symptoms (fever), environmental causes (winds, cold), magical aspects (evil eye), psychic factors (obsession), and a heedless way of life (carelessness): these are part of a broad spectrum of the agents of sickness.

Gynecology and obstetrics are well represented in the talmudic corpus, particularly in the tractate *Niddah*. Menstruation (during, and 7 days after which a woman cannot be approached by her husband), vaginal bleeding, recognition and duration of pregnancy, as well as a wealth of details related to embryology, sterility, and abortion, are only examples of the topics considered by the Sages. We shall again select two items: cesarean section and embryotomy. Regarding cesarean section, it is stated [bab. Arakhin 7a], "If a woman dies during labor, the operation is performed even on the Sabbath day and the child is ripped out of the womb." A decree of this kind was already extant in the early Roman *Lex Regia* of Numa Pompilius. More challenging is the question of whether cesarian section was performed on a *living* mother in talmudic times, a procedure that has not been documented in adjoining contemporaneous cultures. We read [Mishnah, Bekhorot 8: 3]: "A child born through the (abdominal) wall (Hebr. *yoze dofen*), and the one who comes (i.e., is born) after him, none of them are considered (legally) as being first-born." It seems that it was acceptable in the times of the *Mishnah* (second century AD) that a woman gives birth by cesarean section, recover, and gives birth later to another child in the normal way. Such a possibility seemed quite strange to Maimonides [see his commentary ad loc.], who tried painstakingly to devise a case that would make sense. There has been a lively and prolonged discussion among historians of medicine and talmudic scholars regarding the definition of *yoze dofen*. Some think it could mean extrauterine pregnancy; others advocate abnormal birth through a perineal tear, or even through the anus. I am among those who think that this was a theoretical case based maybe on animal pathology [see ibid. Bekhorot 2: 8], but the question is still open to discussion.

Embryotomy is mentioned in the *Mishnah* as well: "In case a woman experiences difficulty in labor (her life being in danger), her fetus should be cut to pieces inside her womb and extracted limb by limb" [Mishnah, Oholot 7: 6]. It is clearly stated that the life of the mother has preference over that of the fetus. However, once his head, or the majority of his body, is out of his mother's body, the fetus may no longer be harmed, for one life cannot be put aside for the sake of another.

Circumcision was, according to the biblical narrative, first performed by Abraham, and was henceforward to be performed on every male child at the age of 8 days [Gen. 17: 10–14], The technical details of the surgical procedure are nowhere mentioned in the Bible; they are, however, discussed in the Talmud. What interests us here are some of the complications of the operation. It is stated that if two children of the same mother have died (from hemorrhage) as a result of circumcision, the third child should not be circumcised. It says further that if two children of one mother or one child each of two sisters dies, the third should not be circumcised.

The sages remark that there are families in which the blood is "loose," whereas in others it is "tied up". This is most probably the first historical description of hemophilia and of its genetic transmission [bab. Shabbat 134a and Yebamot 64b].

The operation that should be performed on a newborn baby which presents an imperforated anus is described in detail [Shabbat, ibid.]. It says that the membrane should be opened crosswise. This is noteworthy because a circular incision would indeed have been ineffective.

In accordance with Hippocratic medicine, the Talmudic sages considered that an eight-month baby could not be viable [bab. Shabbat 135a]. A baby was usually breast fed for 2 years. Therefore if a nursing mother lost her husband, she was not allowed to marry again until 2 years (at least 18 months) had elapsed, for fear that she might become pregnant again and her milk production could be stopped [bab. Yebamot 42ab]. In order to prevent a nursing mother from becoming pregnant (which could stop lactation), some sages advocated the use of a pessary (*mokh*) during intercourse. Others promoted withholding intercourse altogether during lactation, which was repeatedly urged in ancient medical lore. Wet nurses were hired in case the mother could not nurse her child. The wet nurse was supposed to tend this nursling exclusively; she could not even nurse her own child [bab. Kethubot 60b]. The use of non-Jewish nurses was permitted. Some sources granted this permission without any condition [Tosefta, Niddah 2: 5]; others asked that the nurse be under the parents' close supervision [Mishnah, Avodah Zarah 2: 1]. Moreover the use of milk from animals, even from unclean beasts, was permitted, as the child was considered in deadly danger if he got no milk whatsoever.

Even a brief abstract of talmudic medicine cannot disregard the topic of public and personal hygiene. Dietetics is not exclusively centered on dietary laws. Several axiomatic statements, based on empiric and popular lore, are recorded. One should eat simply [bab. Shabbat 140b], slowly (carefully chewing food) [bab. Berakhot 54b], moderately [Shabbat 33a], and regularly. "Any change in one's usual diet is the beginning of bowel disease" [bab. Sanhedrin 10la]. Wine and meat are characteristic of a festive meal [bab. Pesahim 109a]. Excess of meat is considered harmful; the priests in the Temple suffered from bowel diseases, as they consumed too much meat (from the offerings). There was even a "specialist" for these diseases; his name was Ben Ahijah [Mishnah Shekalim 5: 1–2].

Fasts were instituted by the sages to commemorate great calamities such as the destruction of the Temple. The only fast that is of biblical foundation is the Day of Atonement (*Yom Kippur*). Fasts were also initiated in case of oncoming epidemics, wars, floods, or drought. Such fasts did not usually exceed 24 h [Mishnah, Ta'anit 3: 3–5].

Personal hygiene included cleanliness as reflected in the laws of purity. Women took a ritual bath after menstruation and observed an additional 7 days purification period. General hygiene is featured in a number of regulations on water supply, lavatories, bathing, care for the dying and burial, and the Sabbath rest.

Even after all this explanation, we can still ask the question: Is there actually a specifically talmudic medicine? I prefer the view that there is definitely a fascinating topic labeled "Medicine in the Talmud." These rich and multifaceted data should take their legitimate rank in the history of both medicine and culture.

Medicine in Thailand

VIGGO BRUN

There exists in Thailand a medical tradition based on local disease concepts, the use of natural products and certain magical rituals which have been practiced by local doctors for centuries. This local wisdom has been passed on both orally and through manuscripts from teacher to pupil for generations. Traditional Thai medicine exists in two versions: a village variant, containing many regional and personal variations, and a court variant influenced by Indian (Ayurvedic) medicine, which has been standardized to a certain extent.

Since around 1900 the official medical system in Thailand has however been solely based on biomedicine, and biomedicine is now widely accepted by the Thai public. But even without any official support, traditional Thai medicine has survived quite well in the rural areas, and in present-day Thailand, the public makes use of both traditions – predominantly the official cosmopolitan medicine, and, to a lesser extent, traditional medicine. Since the beginning of the 1990s the attitude of the state towards traditional medicine has changed, and the official policy is now to integrate traditional medicine into the public health system.

The Village Tradition

In villages all over Thailand one finds people referred to as traditional doctors (*moo phaen booraan*) who mainly use medicinal herbs (*samunphraj*) and other natural substances to cure diseases. The sum of knowledge and practices of these experts is labelled "traditional Thai medicine". There is no traditional doctor who knows the entire body of traditional medical knowledge, and there are many local and individual variations of traditional Thai medicine within Thailand, both in the way plants and diseases are labelled, in the way disease terms are understood, in the way concrete cases of illness are diagnosed, and in the way plants and other materia medica are used in the curing process.

Traditional Thai medicine includes knowledge about the identification of plants (and minerals and animal components) and their curing properties, about diagnosis, cause and development of diseases, about prescriptions and about relevant incantations and ceremonies. The prescriptions, which exhibit the concrete relationship between diseases and the plant world, are – together with the incantations – considered to be the essential and most valuable part of the tradition and are surrounded with a certain amount of secrecy. The prescriptions contain any number of ingredients, normally from five to ten, but sometimes less and often more, even comprising as many as 50 different ingredients. For each ingredient the prescription will ideally specify which part of the plant should be used – root, leaf, bark, fruit, etc. – and normally in what quantity. While much of the medical knowledge is transmitted orally, the prescriptions are written down. There are a vast number of medical manuscripts in Thailand, both in temple libraries and in the care of the herbalists, and almost all of these manuscripts are merely collections of prescriptions.

In order to access the information in the manuscripts as well as to copy them and write down the prescriptions, it was necessary to be able to read and write. In former times these skills were taught only in temples to boys, so the traditional doctors were exclusively male. Monks and former monks were central in the transmission of all written traditional knowledge, including medicine, and Buddhism has – as we shall see below – left a deep imprint on the way traditional medicine has been organized.

To a certain extent, the general public also possesses medical experience and knowledge which people use to talk about diseases, to chose between available curative alternatives, and for self-medication. There are a number of simple traditional remedies known to villagers, commonly referred to as "household remedies" (*jaaklaangbaan*).

The traditional doctors are often called to a career in medicine after they themselves have been sick. They will seek out a traditional doctor, get cured, and thereafter ask to be accepted as a student of that doctor and learn the prescription that cured them. After that they start treating people with this particular disease. If the treatment is successful, and if the new doctor feels he has a knack for traditional medicine, he seeks out more knowledge from other teachers, and thus gradually expands his curing range. Another path is to learn the trade from a practicing relative. Few traditional doctors become true generalists, though, and few become full-timers. For most of them, curing provides them with supplementary income, although a successful traditional doctor will be respected and obtain higher social status.

Traditional Thai doctors neither perform surgery, except for lancing abscesses, nor do they undertake dissection. Thus they do not have a very precise or systematic knowledge of the human's interior organs and how they function. A certain amount of anatomical knowledge is gathered from partitioning animals, and Buddhist scriptures do enumerate body components.

Some traditional doctors perform bone setting. The broken bones are pulled back into place – no painkiller! – and the area around the fracture stabilized with sticks of wood tied together, after which incantations are blown onto the fracture. Traditional bone setting may result in the bones growing together at unusual angles, so most people prefer to go to Western-style hospitals to be treated for fractures.

Massage and midwifery are separate branches of the local medical tradition. Traditional midwifery is fast disappearing, while Thai massage has become tremendously popular – also outside Thailand. A number of drawings of the human body in Wat Pho, the largest and oldest temple in Bangkok, pertain to Thai massage, indicating points on the exterior of the body on which applications of pressure have a therapeutic effect for specific ailments. Other drawings of the human body show lines (*sen*) connecting various points on the body. The meaning and practical application of these lines and how they connect up with the rest of traditional medical theory and practice are not clear. One homepage, ►http://www.bomi.info/books/thai_massage.htm, lists 12 books on Thai massage which have been published within the last decade – some accompanied by videos – mostly practical introduction written by people who operate clinics for Thai massage in various countries.

Traditional saunas, where steam from herb-steeped water is directed into a small, closed room, are also used. These steam baths are regarded as generally healthful but are also used specifically to cure certain skin or respiratory diseases.

In the countryside people used to rinse their mouths with water after eating, and they used toothpicks and sometimes rubbed their gums with salt. Now most people use toothbrushes and toothpaste. Previously toothache was simply considered to be bad luck. When the pain became intolerable, the tooth was pulled out. Until recently there were peddlers appearing in the villages trying to convince people that their toothache was caused by small worms eating the teeth – they could miraculously produce such worms from the mouth of any bystander with toothache – and that their bottles of medicine would kill these worms. This medicine was very popular. The bottles they sold merely contained a simple plain painkiller.

Transmission

The medical tradition in Thailand is said to have been transmitted through a chain of teacher–pupil relationships which goes back to the tradition's original teacher, Jivaka Komarabhacca, the legendary physician of the Lord Buddha, and each practitioner pays respect to his teacher at annual rituals. On every occasion in which he uses the knowledge from the tradition, he should ceremonially invoke the whole chain of teachers – living and dead – to be present and thus infuse his actions with their sacred power. Medical knowledge is in principle restricted to those who have been ritually initiated into the tradition, and thus every potential doctor has to find a teacher who will accept him as a pupil and share his knowledge with the student. The teacher is important because the tradition consists of both oral and written information. The written manuals contain the essence of the tradition – the prescriptions – but the manuals contain almost no information about each particular disease or plant, beyond their names. All the background knowledge and detailed information which the manuals presuppose are transmitted orally. The student needs a teacher to give him this oral information and from whom he can observe the finer points of medical practice.

The ideal would be if the complete primordial knowledge was passed on verbatim through faithful repetition and copying. Still, time involves change and decay, and it is recognized by everyone that losses, fragmentation, external additions and copying mistakes have occurred all along the transmission chain. Medical manuals are no longer complete and homogeneous, but fragmented and heterogeneous. The actual transmission of knowledge is no longer only faithful copying but also a continual process of selection and reorganization, and new knowledge may even be added to the tradition. The standard way of justifying additions is to present them as revelations, often referred to as *tamraa phii book* (manual told by the spirits). In other words, additions and innovations are permitted as long as they are received directly from the "other world", i.e. as long as they are disguised as restoration, rediscovery or reestablishment of something original.

Traditional Pharmacy

There are probably several thousand plants (and ingredients from the mineral and animal kingdoms) in traditional Thai medical prescriptions, and these should – alone or in combinations – have a curing property of one kind or another. There are a number of herb stores in the larger towns where the traditional doctor can buy the ingredients he needs. Still it is convenient if he has the plants he uses most frequently ready at hand. Many traditional doctors therefore grow medicinal plants in their gardens and possess some botanical knowledge.

A number of monks also practice as traditional pharmacists or doctors. In Buddhist temples one can sometimes find extensive gardening of medicinal plants.

There are also a number of traditional pharmacists who produce homemade traditional medicines for sale at markets and fairs or through local stores. With the increasing popularity and growing demand, the traditional medicines – and herbal-based cosmetics – are now also being produced industrially by a number of firms. Thus people have easy access to ready-made traditional medicines, which are cheaper than the available biomedical medicines, and although it is widely viewed that they may take a longer time to produce results, it is also claimed that they have fewer side effects than cosmopolitan medicines.

The Ministry of Public Health stipulates that traditional drugs should be approved before public sale, but this law is not strictly enforced.

Botanists and pharmacists in Thailand have published a large number of books on Thai plants and their claimed curative properties. There is also a "pharmdatabase", ►http://www.medplant.mahidol.ac.th/index.asp, where one can search by plant name (English or Thai), genus, or biological activity.

Etiology

Many of the disease causes recognized by traditional Thai doctors are also causative factors in modern medicine. Some diseases are, for example, regarded as contagious and some as inherited; some as caused by changes in the climate and others by contact with external agents such as metal chains or washing powder, resulting in skin eruptions. Some are caused by insect or animal bites and others by spoiled food, or bad smells. There are natural causes for fracture, dislocation, contusion, burns, or wounds.

The close relationship between food and disease can be seen in the monastic rules (*Vinaya pitaka*) where medicines are classified as "non-substantial food". Many of the most common medicinal plants are also ingredients in food. Food prohibitions are, moreover, integral to the treatment of many diseases. Such prohibitions might be against meat, frogs and fish with skin, seafood, pickled food, certain vegetables, eggs, liquor, or foods with certain tastes – all depending on the disease in question. There are also specific dietary rules for the post-natal period. Adding and withdrawing certain foods from the diet can also function as preventive measures.

A causative factor specific to the medical tradition of the court is "imbalance in the elements (*thaat*)", i.e. imbalance between wind, water, earth, and fire. These are the elements of which our body (and indeed all matter) is composed.

In addition, traditional Thai medicine operates with other types of causes, which modern science summarily dismisses as superstition. These can be classified as spirits, black magic, and *karma* (past actions). If the diagnosis is that a patient in some way has offended and angered a spirit, who in retaliation has caused the offender to fall sick, then the curing process may consist of ritual offerings only.

There are cases characterized by sudden violent and abusive behaviour, which may be attributed to possession by an inferior, evil spirit. A specialist is then called upon who will talk to the spirit and ask it who it is, where it lives and what it wants. If the spirit does not want to leave the body after offerings have been given, it is mercilessly beaten out – the spirit apparently feeling all the pain, while the possessed person feels nothing.

Another type of mental disturbance may, after all other treatments have proved fruitless, be attributed to a superior, good spirit who wilfully has inflicted this kind of suffering on the patient to force her to become its medium. When the person accepts mediumship, the spirit immediately withdraws the ailment, and the person recovers.

Piercing or lancing pains in the joints, abdomen, or chest may, if unresponsive to treatment, be attributed to black magic. This means that an object – like a nail or a lump of skin – has been inserted into the patient's body by a doctor using special incantations and acting on the instructions of an enemy of the patient. The only solution for the victim is to find a doctor who has even stronger incantations to counteract the original ones and can thus remove the object or even send it back to attack its owner. The Northern Thais say that the Karen and the Khamu hill tribes harbour powerful incantations, in Northeastern Thailand they may blame the Khmer for the black magic, and in Southern Thailand the Malays.

The Buddhist concept of karma may also be used as an ultimate causative factor, but normally only after all other explanations have failed. Using karma as the cause implies that the disease is a deserved and inescapable result of a previous action by the patient. People do not favour this explanation, because it means that a cure is impossible and that a person simply must endure his or her fate. However, people confronted with the inevitable deterioration and malfunctioning of their bodies, such as the elderly and those with incurable diseases, use karma to indicate that they have accepted the inevitable. This resignation can also be a relief for relatives, who no longer need to feel obliged to search for new remedies and pay even more bills.

The recitation of holy words plays an important role in many contexts in Thailand, and there is a strong belief that recitation of holy stanzas (*weedmon khaathaa-aakhom*), if performed by the right persons, produces power and that this power is transferable. Incantations are an integral part of traditional medicine and are in many cases recited over or blown on to the medicines and the patients by the traditional doctor.

Magical practices are a central part of Thai culture and thus also of traditional Thai medicine. Still this must not overshadow the fact that traditional Thai medicine is basically a rational tradition based on experience. The traditional doctor will first seek a natural and rational explanation to a disease. Only if this does not work will he resort to other types of explanations and treatments. And if one accepts the premises of magic, such as the existence of spirits and other levels of existence, it too possesses its own rational logic.

Heterogeneity

A central feature of the Thai medical tradition is its heterogeneity: it generates many different answers to the same question. This is true at all levels of the tradition.

The names for one and the same plant may vary from locality to locality, and one and the same name may be used for different plants in different places (which is nothing peculiar to Thailand, of course).

The claimed medical properties of plants in isolation vary from informant to informant, and do not necessarily conform with the prescriptions in which the plant actually occurs. When one, for example, asks, "What are the curative property/properties of plant P?" the first informant says, "It cures disease A", the second informant says, "It cures disease B", and when we check the prescriptions we have collected, we find that plant P does not occur in prescriptions against diseases A and B, but in prescriptions against diseases C and D.

The content of the local disease names varies according to the informant. Furthermore, disease names known by one expert may not be known by another even if they live in the same area. And finally actual diagnosis varies a lot.

One could speculate that a likely reason for this heterogeneity is a slow and erratic process of crystallizing experience, which again could be due to the lack of communication (i.e. competition) between the herbalists and the lack of records of the experiences of the individual herbalist. Furthermore, the lack of standardization of disease concepts and the lack of an explicit epistemological framework could well be factors which have hampered the crystallization process of the popular medical tradition and contributed to its continued heterogenic character.

But there exists another branch of the medical tradition in Thailand emanating from the royal court with an explicit and rather elaborate theoretical framework.

The Court Medical Tradition

At the Thai court royal physicians (*moo luang*), who held official positions within the Medical Department (*krom phaet*), were responsible for the well-being of the king and his court. The knowledge of the court medical tradition was kept within the court, and transferred in many cases through certain families. Rama III decided to make public parts of the traditional knowledge harboured within the court when he restored the Wat Pho (Wat Chetuphon) temple in central Bangkok from 1834 onwards – including medical knowledge, especially related to massage (stone inscriptions) and physical exercise (stone statues).

In 1870, during the reign of King Chulalongkorn (=Rama V, 1867–1910), a committee of royal physicians was appointed to collect and edit old medical manuals. The result of their work became known as *tamra luang*, the Royal (Medical) Treatise, and was kept in the library of the palace, available to court physicians only. When Siriraj Hospital was established in 1887, the patients could choose between cosmopolitan and traditional treatment, and likewise the curriculum at the Siriraj Medical School (1889) included instruction in both cosmopolitan and traditional Thai medicine. To standardize the teaching of traditional medicine, a printed version of the *tamra luang* was introduced as textbook at Siriraj Medical School with the title *tamraa phaetsaat songkhro*. Thus the court medical tradition went public, and became the official medical tradition until the teaching of traditional medicine was discontinued around 1906 (some say in 1913). Some 50 years later, in 1957, the Association of the School of Traditional Medicine was established at Wat Pho (Bangkok), and both the teaching and the officially supervised examinations there were based on reprints of the *tamra phaetsaat songkhro*. The Wat Pho school later established schools at a number of temples in major towns. Since 1957, in order to practice traditional medicine legally one has had to pass examinations from these schools, where courses in traditional pharmacy, midwifery, and general medical practice are offered. As an innovation women have been allowed to participate on equal footing with men.

In the court medical tradition we find a theoretical framework which is based on the four elements (earth, water, wind, and fire), the three humours (bile, wind, and mucus), and the ten tastes (hot, cool, mild, astringent, sweet, poisonous, bitter, oily, salt, and sour). The fact is, though, that the theoretical framework lacks internal coherence and consistency, and that its relationship to actual medical practice is weak: it is not readily applicable to diagnosis and treatment of concrete cases of diseases. One could say that the theoretical framework we find in the court tradition is divorced from practice and functions only as a frame of reference, a model. This framework legitimates practice, but does not dictate it.

During the Aythaya period, the capital was a lively international trading port with many foreign communities from various Asian as well as European countries. A number of these foreigners were employed in the King's service. It is quite likely that these foreigners left an imprint on the court medical tradition, although it is not clear how and to what extent this actually happened. It is quite obvious, on the other hand, that there is an element of Sanskrit influence in the court tradition. A number of court medical manuscripts on which the *tamra luang* is based have Sanskrit names – although no one has yet been able to identify these names with titles of Sanskrit medical manuals in India – and many of the concepts and the disease names are borrowed from Sanskrit. Still, no comprehensive comparative studies on this matter have, to my knowledge, been undertaken, so it is difficult to ascertain the extent and exact nature of Ayurvedic influence on the court medical tradition in Thailand. Even now, there are separate institutions for Ayurvedic medicine, such as the Ayurvedic Society of Thailand (*samaakhom ajuraweed haeng pratheedthai*).

Many Thais regard the court medical tradition as more advanced than the village tradition, and thus accord it the status of *the* Thai medical tradition, considering the village tradition but a crude simplification with many local variations (cf. Somchintana 1989: 280). This attitude is unfortunate because it glosses over the fact that even if the royal tradition has an explicit theoretical framework which the village tradition lacks, the medical practices of the two are still very similar.

Furthermore, there have not been any court physicians proper practicing traditional medicine for the last 100 years, so that the oral tradition that goes with the court medical tradition has been broken. Today there are therefore hardly any people who can explain the theories, concepts, organization, and the quite numerous unintelligible passages in the court medical manuals with authority.

Buddhism and Traditional Medicine

Buddhism is a crucial factor in Thai culture, but still there is no study of the influence of Buddhism and Buddhist medical lore on the Thai medical tradition.

In his study of the development of Buddhist medical knowledge within a broader Indian medical tradition, Kenneth Zysk points out that Buddhist monks at the time of the Buddha already acted as healers for their fellow *bhikkhus* (monks), and that "from around the mid-third century BCE monk-healers and the monasteries extended medical care to the population at large" (Zysk 1991: 41). Portions of the medical knowledge and experience of the Buddhist bhikkhus were recorded in a chapter on medicines (*Bhesajjakhandhaka*) in the *Mahavagga* of the *Vinaya Pitaka*, the monastic rules, thereby giving rise to a Buddhist monastic medical tradition.

Medicines were part of the five requisites a monk could possess, and originally the monks were allowed only a very limited number of basic medicines. As time went by the list of medicines allowed was increased and became in principle open ended. Furthermore,

> Medicines of the Buddhist monastic materia medica were considered to be foods but classified as nonsubstantial nourishment, allowing them to be consumed at any time (Zysk 1991: 73).

The medical knowledge in the *Vinaya* is organized in the form of case histories, where Buddha tells about the disease of a certain person and the remedies used to cure that person:

> The section on medicines in the *Mahavagga* (of the Vinaya Pitaka)… is characterized by reference to actual cases, and functioned as a handbook and guide for the treatment of common afflictions… The medical importance of these Buddhist records, however, is their recounting of patients' medical problems and the corresponding treatments. The academic medical treatises of classical *ayurveda* offered no such case-by-case medical instruction… Between those two traditions [i.e. the Buddhist Pali records and the classical Indian medical treatises] many similarities, but also numerous differences, exist – significantly, the Buddhist emphasis on practical application *devoid of the theoretical considerations of disease etiology* (italics added) that dominate the [non-Buddhist] medical books. This difference supports the view that codified Buddhist monastic medicine, with its emphasis on materia medica and case-based therapies, represents an early attempt to provide a manual of medical practice and in some sense legitimated the formalized collections of prescriptions… (Zysk 1991: 71–72).

As for knowledge of anatomy we find that:

> In the *Mahasatipatthanasuttanta* of the Dighanikaya (in Sutta Pitaka), the four intents of contemplation (*cattaro satipatthana*) are detailed. The first

of these was the human body (*kaya*) in all its parts, aspects, and impurities. The monk was to endeavor, through persistent contemplation, to realize the fundamental impermanence of his physical and mental constitution by meditating on the body:

> And in addition, O monks, a monk contemplates this very body, up from the soles of the feet (and) down from the crown of the head, bound by skin (and) full of manifold impurities. "There is in this body (the following): hair of the head, hair of the body, nails, teeth, skin, flesh, sinews, bones, bone marrow, kidney, heart, liver, pleura, spleen, lungs, bowels, intestines, stomach, excrement, bile, phlegm, pus, blood, sweat, fat, tears, grease, saliva, mucus, serous fluid, and urine..." There is in this body "earth element, water element, fire element, and wind element" (Zysk 1991: 34).

This list includes anatomical parts, but does not give any further descriptive details, neither how they function and relate to each other nor how they relate to diseases. The four elements are mentioned, but only to underline that the body, like all other matter, is ultimately composed of these elements.

Buddhist medical knowledge encompasses concepts such as the four elements, the three humours, and the 32 constituents of the body, and shows a very practical attitude to the curing process, but it does not attempt to construct specifically medical theoretical frameworks. Thus when Zysk concludes that, "The medical doctrines codified in the monastic rules probably provided the literary model for the subsequent enchiridions of medical practice" (Zysk 1991: 118), it is not difficult to agree that this has indeed also been the case for traditional Thai medicine.

Traditional and Cosmopolitan Medicine

If we look at patients' choices of curing methods in the countryside nowadays, we find, according to some statistics, that 95% prefer cosmopolitan medicine as a first choice, while only a small minority chooses traditional medicine. Furthermore, traditional medicine is in many cases resorted to only after treatment with biomedicine has failed. This means that patients who no longer can afford modern treatment or people with terminal, incurable, or chronic diseases will resort to traditional medicine. But there are also certain illnesses where traditional medicine has a reputation of being more efficient than biomedicine. These include haemorrhoids, kidney stones, and diseases with "wind" as the prominent symptom. In addition, the simple fact that traditional doctors are local people who know their patients' social situation, speak the local dialect, talk in a way the patients understand, and have more time to listen may give them an advantage over the more sterile and impersonal relationships the patients have with the Western-trained physicians and hospitals.

From the patient's side, it is not an either–or situation. Many patients will choose both traditions. People who are sick often go to several doctors and several pharmacies at the same time, both biomedical and traditional, and thus follow parallel treatments. This may have the consequence that they stuff themselves with too many drugs, thus rendering it impossible to decide which medicine actually cured the disease.

While cosmopolitan-trained doctors are quite sceptical of the efficacy of traditional medicine, the reverse is not true. Traditional doctors recognize quite readily the qualities of cosmopolitan medicine, such as the surgical skills and the value of vaccination and antibiotics for example. They also in some cases refer patients to modern doctors and they may (re)sell certain Western drugs they find useful. Ideologically they also feel akin to biomedicine in that, as one traditional doctor put it,

> Diseases are a terribly complicated business, so traditional doctors must use the same method as the Western trained ones, namely the trial-and-error approach: If one prescription does not work, I will try another, and yet another, until I have found one that works, just like the pharmacists and the modern doctors.

But cosmopolitan medicine does indeed also take an interest in traditional pharmacopoeia, trying to identify and extract medically active chemical components from traditional medical herbs in the hopes of being able to design new drugs. Transnational – and Thai – pharmaceutical firms are involved in this search, and the Government Pharmaceutical Organization has in fact for years been producing herbal remedies for sale based on their own research.

Cosmopolitan medicine in Thailand is also adopting traditional Thai disease terms for modern diseases, thus eroding the traditional concepts and causing some confusion. Modern medicine has, for example, adopted the traditional term *mareng* for cancer, while the term originally was a vague disease term covering various skin diseases with itching eruptions. So it seems rather far-fetched to claim – as some traditional doctors do – that traditional prescriptions against certain skin diseases (*mareng*) also cure cancer (*mareng*) in general, simply because the names for the two diseases coincide. Also, some traditional doctors are claiming to have found or invented herbal medicines which can cure other "new" diseases, such as diabetes and AIDS, and herbal mixtures have also been used to cure heroin addicts.

Current Developments

Over the last decade or so, the Thai government has radically changed its policy towards traditional medicine.

The general context for this change has been the new WHO policy to encourage governments to incorporate traditional medicine into their official medical systems. Furthermore, public expenses for medical care have continued to increase at an accelerating rate, and so has the bill for imported medicines and medical supplies. Thai politicians and bureaucrats also see the possibility for export of traditional Thai drugs, and that Thai medicine can play an important role in transforming Thailand into Asia's health service centre.

There has also been a growing awareness of and pride in one's national heritage and local wisdom and knowledge, and "nature", "ecology", and "holistic approaches" have become very popular concepts and part of the current discourse on health. Some even feel that there is an incongruity between modern technology and the Thai way of life and indigenous culture. All these factors have contributed to strengthening the hand of traditional medicine and also in changing the attitude of the bureaucracy. One of the first official steps in this direction was the Seventh National Economic and Social Development Plan for 1992–1996, which stated that:

> The promotion of people's health entails the efforts to develop traditional wisdom in health care, including Thai traditional medicine, herbal medicine and traditional massage, so as to integrate it into the modern health service system.

The Thai government has followed up on this plan, by adopting the goals of the plan in its official health policy and by establishing in 1993 the National Institute of Thai Traditional Medicine (NITTM) under the Ministry of Public Health. Its first director was the energetic and knowledgeable Dr. Phennapa Subcaroen. The basic aim of the NITTM is to integrate Thai Traditional Medicine (TTM) effectively into the National Health Service system. To achieve this aim, NITTM must, according to a brochure it has published, "systematize and standardize the body of TTM knowledge" and thus "gather knowledge, revise, verify, classify, and explain TTM knowledge" as well as "compare and explain the philosophies and basic theories of TTM and to produce textbooks on TTM".

Thus in order to revitalize traditional medicine and make it acceptable to the official medical system, the NITTM has deemed it necessary to create a new traditional medicine with a coherent medical theory, a consistent diagnosis and a consistent use of medical herbs, as well as a safe and efficient medical practice, or in other words, to replace heterogeneity with homogeneity. The result is no longer called "traditional Thai medicine" but simply "Thai medicine", "traditional" having been dropped because it sounded too outdated.

This recreation of tradition is supposed to be done in cooperation with traditional doctors, NGOs, and other interested parties. But, according to Rancarati:

> Not all health care workers, academics and traditional healers are content with official views of TTM… since they (particularly those in peripheral regions) feel that it is just another form of homogenization and domination of Central Thai culture within national boundaries… Standardized Ministry of Public Health TTM exams favour the Central Thai model, particularly by adopting Central Thai names and concepts related to medicinal herbs (Roncarati 2003: 209).

Another important step taken by the NITTM has been to protect Thai traditional medicine from being appropriated and exploited by foreigners. Thus the NITTM drafted the Traditional Thai Medicinal Wisdom Protection Bill which, after several years of discussion, was approved and came into effect in May 2000. This bill makes Thailand one of the first third world countries to regulate foreigners' access to all aspects of traditional medical knowledge. The law drew quite irate comments from the US embassy in Bangkok but was lauded by the local media. In a commentary in the *Bangkok Post* of 18 June 1997 for example, the editor Sanitsuda Ekachai praised this initiative to "defend our indigenous plants and age-old knowledge of their use from being hijacked by richer countries". She deplored the fact that rich countries with advanced biotechnology and sophisticated laboratories can use the genetic resources of developing countries free of charge, extract the effective chemicals, patent them and sell them back as expensive Western medicines. She also referred to the unfair global trade laws, and concluded, "The Traditional Medicine Bill is a small effort by Thailand to defend itself against such injustice. No one can rob us of this right".

The increased awareness about the value and potentials of traditional medicine in Thailand and the attempts to revitalize this tradition will hopefully contribute to a better and more self-reliant public health system, but it has also made traditional medicine a highly political issue.

Chinese Medicine

Chinese medicine is quite visible in Thailand, especially in the towns, where drugstores sell Chinese herbs and where acupuncture treatment is offered. Still, Chinese medicine remains quite a distinct tradition used mainly by the Sino-Thai population. Although the use of certain Chinese herbs and prescriptions – as well as massage theories – may have entered the Thai medical tradition over the centuries, no systematic study has been made to verify the extent of such influence. The popularity among the Chinese – be it in the Mainland, Taiwan, or parts of Southeast Asia – of using the horns, bones, or bile of certain animals as aphrodisiacs has contributed to the endangering of mammals like the rhinoceros, tiger, wild boar, bears, and certain snakes, among others.

References

This bibliography includes works on Thai traditional medicine defined narrowly, thus works on botany, pharmacy, medical practice in general as well as contemporary health problems and policy issues have not been included. I have also left out numerous studies on rituals and religion, many of which have a bearing on traditional medicine. Furthermore, the bibliography confines itself to Thailand and does not include relevant works from neighbouring countries, and it contains only works in Western languages, thus omitting a number of studies in the Thai language. For further bibliographic references to works on traditional medicine in Thailand, including works in Thai, see Shigeharu Tanabe, ed., *Religious Traditions Among Tai Ethnic Groups: A Selected Bibliography.* Ayutthaya (Thailand): Ayutthaya Historical Study Centre, 1991 (which contains special sections on Traditional Medicine).

The bibliography below reveals that most studies in Western languages on traditional Thai medicine are articles on specific aspects of traditional medicine. There exist only a few more comprehensive studies: Golomb (1985) gives a broad anthropological view of medical practices in Southern Thailand; Bamber (1987) studies disease classification from a linguistic point of view; Brun and Schumacher (1987) concentrate on medical practice in Northern Thailand using the traditional doctors as informants; Mulholland (1987) studies traditional paediatrics based on manuscripts from the court tradition; and Somchintana (1989) studies the concepts and system of traditional court medicine in Bangkok from a cognitive anthropological point of view.

There are but few works on the historical development of traditional medicine in Thailand for the simple reason that there is very little material in Thai which has survived from before around 1800. Scattered evidence can be found, but thorough and critical studies are extremely time-consuming and would not necessarily yield substantial results. Furthermore, detailed and critical comparative studies, both historical and contemporary, between the Thai medical tradition(s) and similar traditions in India, Sri Lanka, Burma, Cambodia, Laos, and China have yet to be undertaken. Thus how and to what degree these traditions have influenced each other is still an open question. What role Buddhism and the Buddhist *sangha* have played in the development of Thai traditional medicine awaits further studies. There is also a huge number of medical manuscripts which are in need of critical study which would also deepen our understanding of regional variations – just to mention some obvious areas of study which are needed to give us a better understanding of traditional Thai medicine.

Today Thai scholars conduct most of the research on traditional medicine, with basically two aims: to preserve tradition and to make it applicable to the health needs of contemporary Thailand.

Medicine in Turkey

CHRISTOPHER DOLE

Turkey comprises a territory that has long been a crossroads for numerous empires, religions, and cultures. The medical and healing techniques that are practiced and utilized in contemporary Turkey reflect this diverse history. While cosmopolitan medicine has been practiced in Turkey for centuries and patients overwhelmingly prefer it when available, there exists a rich set of health care options for problems not defined as treatable within medical settings, in instances where one has no access to or cannot afford medical treatment, or, most commonly, alongside biomedical treatments. Despite a history of opposition toward nonbiomedical forms of healing (Dole 2004, 2006), traditional healing practices are still widely practiced and used within both urban and rural settings. As with any social practice, these healing practices change in relation to ongoing political, economic, historical, and social transformations.

The majority of traditional healing practices are closely related to Turkey's dominant religious orientation, Islam. Of these religious forms of healing, four general categories or types of healing can be identified. While there is a significant degree of regional, local, and individual variation, these categories reflect the most widespread practices and can be distinguished based upon their respective conceptualizations of therapeutic efficacy, of how each form of healing is understood as affecting a cure.

The first form of healing, *kurşun dökme*, roughly translates as "the pouring of lead" and consists of a lead pouring specialist (*kurşuncu*) who treats patients who have been struck by the *nazar*, or evil eye. The evil eye can manifest itself in a variety of forms – fever, sweating, "fright," bad luck, pimples, skin rashes, and nightmares, to mention but a few (Maloney 1976; Çelik 1974). Although practiced exclusively by women, both men and women go to this specialist for treatment. Women and children (both male and female) are, however, the most frequent visitors. The primary ritual feature of the *kurşuncu* is the pouring of molten lead into a basin filled with water over which the patient, with a scarf or covering of some sort over her or his head, leans. While the lead is being poured, the *kurşuncu* recites prayers and commonly says, “It is not my hand, it is the hand of our mother Ayse Fatma.” After the lead has been poured – which creates a cloud of steam that passes over the patient’s face – the *kurşuncu* removes the solidified piece of lead and reads it to divine the source of the evil eye. This is typically repeated three times.

Outside of this basic ritual formulation, there is remarkable variation, particularly in the many additional items that accompany the lead pouring and what the *kurşuncu* instructs the patient to do with them. For instance, items such as onions, bread, salt, oil, coal, keys, soap, strainers, brooms, forks, and gold rings can be utilized within *kurşun dökme* rituals. After finishing the lead pouring, the patient can be given specific instruction about what should be done at home and what should be done with each item. Instructions can include such things as not talking with or kissing anyone, not telling anyone that their condition has improved, throwing the water where no one will walk, tossing the onion behind oneself without looking, feeding the bread to a dog or cat, burying the bread at a crossroads, and so forth.

Women who specialize in the pouring of lead commonly learn the practice from older female relatives. As children, they assist their elder relatives with the ritual, thus learning the ritual variations of each healer. In this regard, the relationship between female elder and daughter or granddaughter is central to the succession of healers. In addition to passing on the specifics of ritual practice, this relationship is significant in that the ability to heal is passed through the female line of a family. The actual passing on of the ability to heal is described as *el vermek* – to give one’s hand. As compared to other forms of healing, this has perhaps shown relatively little historical change (Dole 2002).

A second category of religious or ritual healing widely practiced is that of the *ocaklı*. The practices of the *ocaklı* are incredibly broad and overlap with *kurşun dökme*. This form of healing, however, is not defined so much by the ritual style of its healing, but its association with holy or sacred ancestors. The term *ocak*, the root of *ocaklı*, while having many connotations (furnace, hearth, fireplace, mine, political body, guild, fraternity), is associated here with the notion of “family line.” To be *ocaklı* – literally, “with the *ocak*” – connotes someone having special powers to heal based upon their relationship to an ancestor. The *ocaklı* is thus usually linked to a particular tomb, that of his or her dead ancestor, which is generally located near his or her home village.

While different *ocaklı* may perform very different rituals, they all tend to be marked by a considerable specialization in regard to the problems treated. There are respective *ocaklı* who, for instance, treat specifically warts, rashes, arthritis, shingles, and jaundice. In addition to these more localized ailments, some *ocaklı* were known for their ability to cure alcoholism, to miraculously induce fertility for those who were unable to conceive, and provide good fortune in general.

Although the ritual techniques of the *ocaklı* vary considerably, the recitation of Quranic verses appears to be consistently present. Many, as well, utilize particular verses from the Qurʾān known as *şifa ayetler* (curative Quranic verses) that are recognized as being particularly effective in treating specific problems. While these verses are supposed to be effective no matter who reads them, the *ocaklı* is regarded popularly as having special powers in the realization of the verse’s intent. Beyond this, there are some common but less ubiquitous ritual components to the practice of the *ocaklı*. Drawing or scratching (*çizmek*) on the skin is one such practice, particularly for skin related ailments.

As with the *kurşuncu*, the efficacy of the *ocaklı* is attributed to their inheritance of a special gift or power to heal from an ancestor to whom miraculous or extraordinary powers are accredited. Similar to the *kurşuncu* as well, the training of the *ocaklı* typically occurs through assisting an elder *ocaklı* as a child. Although like the *kurşuncu* the *ocaklı* is customarily elderly, unlike the *kurşuncu* both men and women can be *ocaklı*. Likewise, both men and women go to *ocaklı*. Similar to the *kurşuncu*, the practices of the *ocaklı* seem to have changed little over the years and there appears to be little difference between *ocaklı* practicing in rural and urban settings.

While the *ocaklı* may be popularly ascribed titles like *ana* (lit. “mother”) or *dede* (lit. “grandfather”), mention should be made here of the distinct category of *dede* among Turkey’s Alevi Muslim minority (comprising approximately 20–25% of the total population). For the Alevi, *dede* is a title used to describe someone whose lineage can be traced back to Muḥāmmad through one of the Twelve Imams. While a given village, or group of villages, may be headed by a *dede* recognized as having spiritual and moral authority, there are commonly many more *dede* who do not perform the customary judiciary, ritual, and religious functions of the *dede* who heads a village or group of villages. These individuals are *dede*s principally in name only. On occasion, however, particular *dede*s – in their association with their lineage, or *ocak* – are considered to have the ability to cure illness or fulfill wishes. While at times referred to as an *ocaklı*, they may also be described as a *dede*. The Alevi *dede*, however, is distinct from the *ocaklı* discussed earlier, although the latter may also be referred to as a *dede*. Among Turkey’s Sunni Muslim majority, there is no figure that precisely resembles the *dede*, as it is understood among the Alevi. In terms of the more general category of *ocaklı*, however, there were few discernable differences in how the Alevi *ocaklı* and the Sunni *ocaklı* practiced.

The third form of healing, that of the *cinci hoca* or *üfürükçü*, treats a range of illnesses and problems which typically involve people being struck, harassed, or possessed by spirits (*cin*) or fairies (*peri*). Hence the title *cinci* (exorcist) *hoca* (teacher, or more specifically Muslim teacher or cleric). The *cinci hoca*, however, does not only treat those who have already been affected by *cin*. They may also work to control *cin*, and thus bring harm upon others. In this regard, such cinci hoca are considered practitioners of magic (*büyü*). Furthermore, their characteristic ritual blowing over either the patient while being prayed for or over the object being made serves as the basis for the title *üfürükçü*, itself a derivative of the verb *üfürmek*, to blow on someone or something. Although they address an incredible range of problems, the most common ones are epilepsy, nightmares/fright (*korku*), adultery, and a host of relationship problems.

Rather than an emphasis upon the inheritance of a sacred gift, such as with the *ocaklı* and the *kurşuncu*, the capacity of the *cinci hoca* to heal centers upon training and the learning of specific ritual formulas. Correspondingly, many *hoca*s base their practice on such texts as *Gizli İlimler* (Secret Sciences), *Havasu'l-Havas*, and *Kenzü'l-Havas*. These books, which are readily available at many religious bookstores, contain extensive lists of ritual prescriptions that are said to have been passed down from the distant past. A given treatment is typically the result of computations based on the Arabic equivalent of the letters of a patient's and that patient's mother's name, the patient's birth date, and the presenting illness, problem, or intention (*niyet*). Based upon these, the book then provides the appropriate ritual formula. This ritual formula can include not only the appropriate prayers to be recited a specific number of times and at specific times, but also instructions for the production of different ritual objects or talismans (*tılsım*).

The *muska* is by far the most recognizable object produced by the *hoca*. A *cinci hoca* may also be referred to as a *muskacı* – a writer of *muska*. The *muska* is a sheet of paper over which a Quranic verse, a ritual prescription, the patient's name, the patient's mother's name, and/or the object of the spell's intent has been written in Arabic. The paper is then folded, frequently into a triangle, and put into a pouch. This pouch can either be worn or placed on the body of the patient (e.g., around the neck, in one's pocket), or can be placed in prescribed locations to realize the desired effect. For example, there are numerous accounts of *muska* being placed under a bed so as to block the sexual drive of a person. Alternatively, the *muska* can be burned or soaked in water, after which the water is consumed (Eyuboğlu 1987, 1998). Although there are instances of female *cinci hoca*, male *cinci hoca* are far more prevalent. Both women and men, however, visit the *cinci hoca*. The *cinci hoca* is a highly controversial figure and the target of considerable animosity (Dole 2006).

In many a neighborhood mosque, or *cami*, the local imam may treat members of the community for various problems using some of the same practices as the *üfürükçü*. While any imam, or *cami hoca* as they are sometimes distinguished from the *cinci hoca*, would fervently disagree with being compared to the *cinci hoca*, many imams utilize similar rituals treatments for the ill, assign enormous importance to the *şifa ayetler*, and incorporate the ritualized blowing over the patient while reciting prayers. There are however drastic differences. The imam does not utilize the astrological and numerological aspects of the *üfürükçü*'s practice. Outside of perhaps writing out the *şifa ayet* for the patient, the imam also does not utilize talismans such as the *muska*. Finally, the *cami hoca* tends to treat minor ailments and does not venture into the realm of magic and witchcraft. On theological grounds, imams categorically denounce the work of the *üfürükçü* as not part of Islam. The *cami hoca* is relatively rarely utilized and not typically conceived of as representing a specific tradition of healing.

The fourth, and far less prevalent tradition of healing, is that of the *evliya*. Although the meaning of the term is most closely approximated with the English concept "saint," one should be careful not to assume a homogeny between Christian and Islamic notions of sainthood. Nonetheless, an *evliya*, as with a saint, is broadly definable as a person acknowledged as possessing extraordinary spiritual powers, which in turn connotes exceptional status. An *evliya* is commonly defined as a possessor of *keramet*, the God-given power to perform miracles. Unlike the *ocaklı*, the saint's power does not necessarily have to be the result of being a descendant of a holy person; they are the holy person from whom the *ocaklı* will be descended and to whom a *türbe*, or tomb, will most likely be dedicated. *Türbe* visitation is an extremely popular tradition in Turkey and commonly coincides with requests for cures (Olson 1991, 1994). It could possibly be viewed as its own form of traditional medicine, although no designated healing practitioner is commonly associated with tomb visitation.

Although there are no specific passages in the Qurʾān that authorize the recognition or veneration of saints, saint worship is nevertheless extremely popular. The existence of those recognized as living saints is however still rare. It should be noted that unlike Christian sainthood, particularly in Catholicism, there is no formal system of canonization when discussing the *evliya*. *Evliya* are, in many regards, "self made" (Faroqhi 1979:658). As with the Christian saint, though, the principal task or duty of the *evliya* is to intercede with God on behalf of petitioners or supplicants. While being able to heal is one of the commonly ascribed God-given powers of the *evliya*, they are not solely healers. Because the centrality of their efficacy revolves around an ability to perform miracles and speak directly with God, training is of little significance for the *evliya*'s authority. Though there is supposed to be only one *evliya* on earth at any given time, scattered throughout Turkey are nonetheless rumors of numerous saints appearing and disappearing.

Other than the principally religious based forms of healing discussed earlier, there are also prominent forms of healing for which there is limited scholarship. For instance, the use of herbal remedies is widespread in Turkey. In addition to frequently being self-prescribed, one can find individuals in both urban and rural areas who have received special training in mixing medicinal herbs. Additional healing specialists that were in the past particularly widespread in rural areas of Turkey are the *kemikçi* (bone-setter) and the traditional midwife (Önder 2005).

The traditional healing practitioners described earlier constitute significant aspects of local health care systems, and people (from all backgrounds) seek their assistance for a variety of reasons. Most commonly, they are utilized alongside biomedical treatments. With the exception of perhaps the *evliya*, such practitioners are not leaders of religious groups or organizations. They are individuals who, like others, assume a variety of social positions – neighbor, greengrocer, butcher, relative – but have acquired a body of specialized knowledge that bestows upon them a certain degree of reverence.

Medicine Wheels

LAWRENCE TYLER

The Indians of the North American Plains, because of their nomadic ways, were not dependent upon permanent settlements and structures. Aside from rings of stone left after *tipis* were moved there is little evidence of construction left by these tribes. The noted exceptions to this generalization are the formations known as "Medicine Wheels". More than one hundred of these formations have been found in North America ranging through Saskatchewan, Alberta, Montana, North Dakota, Wyoming, and Northern Colorado. These sites are all located north to south, within a few hundred miles of the eastern boundary of the Rocky Mountains, suggesting the migratory patterns of the Native American culture of this area. They are distinguished from *tipi* rings and camp sites by their size and by the spokes or arms which radiate from a central cairn. These formations are found in isolated locations, inappropriate to community dwelling. Always of native stone, these "wheels" usually consist of a central hub of stone, and/or an inner circle, from which other stone lines radiate out toward the horizon. They are not meticulously constructed but rather seem like a design that a few workers could put together in a matter of days. However, the dimensions are sometimes substantial. The Bighorn Wheel in Wyoming, for example, has a central hub about 12 ft across; with radiating spokes 90 ft in length.

The existence of many of these stone formations has been known for at least a century. The Bighorn Medicine Wheel was reported in the 1880s by explorers and prospectors; by radio carbon analysis it has been dated AD 1600–1700. The first archaeologists to investigate the Bighorn site asked local Native Americans about its use or origin but initially none of the tribes claimed responsibility for its existence or knowledge of its use. Gradually stories emerged, but there is always the question of whether the informants were creating the sort of responses that they thought anthropologists wanted to hear. In point of fact, none of the indigenous groups, such as Sioux, Cheyenne, and

M

Arapaho, have folk legends and traditions which either explain or validate the role of Medicine Wheels in their traditional cultures.

Until the 1970s, the generic explanation for Medicine Wheels was that they must have been of "ceremonial" use, though no one was forthcoming with any detailed account of just what ceremony. The Sioux and Cheyenne are known for their Sundance ceremonies, for which special circular medicine lodges were built. Some observers have been tempted to point out the spatial similarities between the circular medicine lodges built around a living tree used as the center pole with roof and walls radiating from that center and the medicine wheels with central cairn and radiating spokes. The symbolic similarity may be clear, but real intent and purpose remain unknown. So until the 1970s, Medicine Wheels were at most a curiosity of Plains Indian culture neither well known nor well explained. Then an integrative approach called archaeoastronomy, linking the previously separate disciplines of archaeology and astronomy, emerged as a new way of examining ancient phenomena. Basically its unifying theme is to examine megalithic and prehistoric formations for astronomical significance. One example of this is Gerald Hawkins' work documenting the astronomical alignments of Stonehenge in Salisbury, England. Soon practitioners of both astronomy and archeology were looking with renewed interest at ancient megaliths around the world, including Medicine Wheels.

The astronomer John Eddy is most closely associated with an archeoastronomical interpretation of North American medicine wheels. He, in collaboration with an archeological team, studied several medicine wheels, including the Bighorn Wheel in Wyoming and the Moose Mountain Wheel (radio carbon dating, AD 100–500) in Saskatchewan. His findings suggested that many such formations could have been used as landmarks in the rolling plains of an otherwise undistinguished terrain. The simplest of these seem only to point to other stone formations, in the same way guideposts mark long trails across isolated lands.

However, for both the Bighorn and Moose Mountain wheels, Eddy notes solar and stellar alignments that could have been used for solstice calculation. Normally solstice observation is associated with agricultural societies, but nomadic groups such as Plains Indians also needed techniques for anticipating the severe weather changes of the northern plains. While such an interpretation is not conclusive, various studies are now suggesting that the Plains Indians were very careful observers of the evening sky as well as the land. The Medicine Wheels may be indicators of their ability to use markings on the earth to note celestial changes in the sky and the corresponding journey of the seasons; all useful information for high plains travelers. In any case Medicine Wheels could have been of both ceremonial and astronomical utility since the world view of the plains tribes would have made no significant distinction between spiritual and stellar forms.

Metallurgy in Africa

S. Terry Childs

A condensed discussion of African metallurgy is difficult because of the large size of the continent and the 3,000 years over which it developed south of the Sahara desert. Furthermore, several metals were produced and used in Africa, and metal production involved many technological steps which were not necessarily used for each metal type (i.e., iron, copper, gold, and tin). Iron production, for example, involved mining iron ore and smelting it to a bloom, a nonmolten mass of metal intermixed with a waste product called slag. The bloom was then forged into objects by hammering, welding, and other processes. Some preindustrial societies made cast iron, a molten form of iron, but there is little evidence for this technology in Africa. Copper and copper alloys, on the other hand, were often made by reducing ore into molten metal and pouring it into molds, or by hammer forging solid copper. Gold was hammered out from its original nugget form, or melted and cast. Pellets of tin were removed from the slag output of tin smelting and were then melted into ingots. Moreover, not all societies used the same metals or mastered the same manufacturing steps for any given metal. Some cultures specialized in iron smelting, while others forged iron blooms into objects. In copper producing areas, some societies had craftsmen who cast molten copper into molds, others hammered out unrefined copper, and still others specialized in drawing out copper wire.

Much of the current knowledge about African metallurgy concerns iron production. There are several reasons for this. Iron has the clearest presence in the archaeological record, iron ore is virtually ubiquitous across Africa, and, for centuries, it was a subject of interest to Greek and Arab travelers and, later, European explorers, missionaries, and scholars. Copper smelting and casting, as well as the production and use of bronze (an alloy of copper and tin), brass (an alloy of copper and zinc), and gold, have also received considerable attention. The more isolated occurrences of these technologies across Africa in the archaeological and ethnographic record, however, have resulted in less detailed reconstructions of their diverse histories and their significance to African cultures. Some tin production occurred in southern and western Africa, but this is the least studied indigenous metal and may have a relatively short history as compared to iron, copper, and gold.

The prehistory and history of African metallurgy come from several sources. Archaeological excavations often yield metal objects, and/or the physical remains of production centers (i.e., smelting furnaces containing slag, tuyères or blow pipes, and charcoal fuel; forging pits; casting crucibles; molds). Increasingly, archaeologists submit these remains to laboratory analysis to determine how an object was made, or the chemical and physical dynamics of an ancient metallurgical process, its environmental context, and its age by radiocarbon dating. Some scholars conduct collaborative research with village elders who still remember how to smelt and forge iron, or cast copper. Several projects have resulted in important films which underscore the complexity of many metallurgical operations, provide critical insights into poorly understood ancient practices in Africa and worldwide, and highlight the nontechnical aspects of production. Some researchers also perform experimental reconstructions of metallurgical processes to understand further the thermodynamics involved. A final source of information is the archival record of numerous visitors to Africa over the centuries. The reports from the early twentieth century first featured the nontechnical characteristics of African metallurgy, including esoteric knowledge, decorated furnaces, ritual, music, and taboos.

The following discussion begins with a brief overview of the prehistory of African metallurgy, then examines the technical diversity of metallurgical practices across Africa, and concludes with a look at its social and ideological components.

Although this review principally concerns Africa south of the Sahara desert, the earliest evidence of metal production and use was in Egypt. Copper was first used there around 5000–4000 BCE and was being smelted by 3000 BCE. Iron objects were rare through the Middle Bronze Age, but became more frequent during the New Kingdom after about 1570 BCE. Iron smelting was practiced by the eighth century BCE.

Ancient Egyptian metallurgy had no influence on the rest of the continent except to the immediate south in Nubia and the later kingdom of Kush, both in modern Sudan. An Egyptian outpost was established in Nubia to smelt local copper ores in 2600 BCE, and Egyptians exploited Nubian gold from an early time. By the next millennium, Nubian craftsmen worked copper, bronze, silver, and gold. At Meroë (ca. 500 BCE to AD 300), the capital of the Kushite state, there were craftsmen of copper, bronze, gold, and iron. The earliest iron slag from the site dates to the fifth century BCE; domed, brick smelting furnaces, possibly of Roman influence, were used after about 200 BCE.

There is controversy over two interrelated aspects of the origins of metallurgy in sub-Saharan Africa (1) whether it was invented indigenously or introduced from elsewhere and (2) which metal – copper or iron – was smelted first. Researchers looking for a "natural" progression of pyrotechnological knowledge (i.e., simpler copper smelting to more complex iron smelting) to prove indigenous origins have been thwarted to date. Copper smelting only seems to have preceded iron smelting in Nubia and, during the early to mid first millennium BCE, along the southern Sahara in Niger and Mauritania. Current evidence shows that iron appeared first or at the same time as copper in the rest of sub-Saharan Africa. Other than at Meroë, the earliest indications of iron smelting are in Nigeria (ca. 900–800 BCE), Niger (ca. 500 BCE), Rwanda/Burundi (ca. 700–500 BCE), and Tanzania (ca. 300 BCE).

Many archaeologists believe that knowledge of iron smelting was brought from abroad, but they cannot agree on the route of introduction. Several routes have been proposed (1) Egypt to Meroë, then west and south, (2) from the Phoenician or Roman coast of North Africa across the Sahara desert, and (3) via the Indian Ocean. The first has been ruled out because of the early evidence of iron smelting in West Africa. Little else can be resolved until issues over radiocarbon dating are settled, excavations are conducted in poorly explored regions, including the North African coast and Ethiopia, extensive historic linguistics are done, and the possibility that more than one route existed is carefully investigated. It is now recognized, however, that iron and copper were introduced to different regions of Africa at different times.

Iron working spread from the regions of early introduction in West Africa, Sudan, and East Africa to Southern Africa in 500–700 years. This rapid expansion was once thought to be linked to the movement of Bantu-speaking agriculturalists as they traveled south and east from their homeland in present-day Cameroon, over 3,000 years ago. Recent archaeological and historic linguistic evidence discredits this theory. Traces of early iron smelting have been found in modern Gabon and Congo, but not in northeastern Zaïre. Historic linguistics suggest that iron working in East Africa probably had northeastern, not western, origins. The earliest evidence of copper smelting to the south of Cameroon, on the other hand, occurs by the fourth century AD in copper-rich areas on the Congo coast and in northern Zambia/southeastern Zaïre at about the same time as iron working.

Intensified use of iron, copper, bronze, gold, and brass during the first and second millennia AD was connected to, but not the cause of, the rise of African states, urbanization, and the development of long distance trade routes in some regions. For example, the city of Jenne-Jeno in present-day Mali was well-developed by the third century AD. It did not begin to receive gold from across the Sahara desert until around the eighth–ninth centuries AD or brass (a known import based on the nonindigenous zinc present in the alloy) until the ninth–tenth centuries AD. Jenne-Jeno then became a major trade center in metals. In southern Africa, a long distance trade in gold developed between people living in modern Zimbabwe and those in coastal towns on the Indian Ocean by the tenth century, on the back of an earlier trade in ivory and skins. A powerful state with its capital at Great Zimbabwe (AD 1275–1550) prospered, in large part, by taxing the gold mined and traded from this region. Bronze, a golden alloy of copper and tin, also was developed in the area around this time, but little is presently known about the technology and its local significance.

In many other parts of Africa at this time, relatively small quantities of iron and/or copper were produced, used, and traded locally. The diversity of mining, smelting, and forging techniques that developed over the last two millennia is extensive.

Metal ores, such as specular hematite, malachite, and galena, may have been mined many millennia ago in sub-Saharan Africa, but they were ground to powders for cosmetics. Once ores were mined for smelting, several techniques were developed depending on the type of ore exploited and the physical and technical constraints encountered.

A similar array of mining techniques was developed for copper, iron, gold, and tin across Africa. Some copper and gold ores differed from iron and tin ores in one critical way, however: they could be found in their native metallic state. Mining for native metals involved picking up workable nuggets, panning for and concentrating metal flakes in watery contexts, or digging shafts along seams of metal. This was often labor intensive, such as in ancient Zimbabwe where gold mining involved considerable digging, crushing the matrix rock, and then amassing the gold by panning.

African miners exploited the oxide minerals of copper, iron, and tin at or near the earth's surface for smelting. They dug narrow shafts until the ore was exhausted, the shaft was unsafe, or they reached water. Large open ditches were also excavated. Both techniques required metal tools and, in the latter case, fire-setting was also used to break up the rock. Often, the matrix rock had to be crushed to concentrate the ore. Cases also existed of panning to concentrate rich iron ores dispersed in sandy matrices. While many aspects of African metallurgy were performed and controlled by men, the labor of carrying the ore, panning, and working in the narrow shafts was often done by women and, probably, children.

A facet of African metallurgy that has long intrigued scholars is the bewildering diversity of iron smelting furnaces over lime and across space. At a very general level, three types of furnaces were built: pit or bowl furnaces lacking walls and operated by bellows and tuyères; shaft or walled furnaces with a pit beneath, also operated by bellows and tuyères; and tall furnaces (ca. 2.5–4 m), often without a pit, that used natural draft to stimulate combustion. Within each general type, there was enormous variation based on whether or not slag was tapped from the furnace during smelting, numbers of tuyères, bellows type, pit depth and diameter, height and shape of the furnace walls, building materials, decoration on the furnace walls, and presence/absence of interior furnace features.

Some scholars have theorized a chronological sequence for these general furnace types, from "primitive" pit furnaces in which wrought iron was made to shaft furnaces in which low grade steel was produced to natural draft furnaces. Regional and local variations would have then developed over time. Recent findings reveal that the earliest furnaces all had walled shafts, and that a heterogeneous bloom, varying from soft wrought iron to high grade steels, could be produced in each furnace type. It is now generally thought that furnace variation was a response to certain local constraints, such as ore types, but primarily to the different sociocultural contexts into which iron smelting was brought or developed.

Less is known about African copper smelting because it was practiced less widely and has been the subject of less research and ethnographic observation. Most copper smelting furnaces were the shaft type, but considerable variation existed based on whether the molten copper was tapped directly from the furnace into molds or was melted in crucibles within a furnace. Pit size, building materials, wall height and shape, number of tuyères, bellows type, mold sizes and shapes, and wall decoration also varied.

Gold was not smelted, but melted in crucibles over an open fire. There is little evidence of gold extraction technologies in Africa except for occasional pieces of gold-encrusted crucibles from Zimbabwe and South Africa. Tin ore, like iron ore, had to be smelted or reduced in a furnace, but little is known about the processes used or when they were developed. An ethnographic account from Nigeria indicates that tin and iron ores were cosmelted and tin was removed from the slag. In South Africa, tin ore was smelted in tiny furnaces, pellets of tin were extracted from crushed slag, melted in crucibles, and cast in molds.

The fabrication techniques used to transform raw metal into objects were also diverse and varied by type of metal and region. Iron and steel, for instance, were always hammered into shape, but many types of hammers and anvils were used over the continent. Skill at welding together pieces of iron and/or steel and other joining techniques varied widely. Evidence that iron was drawn out into wire comes from East Africa and to the west in modern Angola, but the history of this technique is vague. Interestingly, no evidence of pre-colonial heat treatment of steel (i.e., quenching it in water) to harden and strengthen an object has been found.

Copper was manipulated in several ways: hammer forging solid metal into various forms; drawing out wire; casting molten copper into molds; and alloying copper with another metal, like tin to make bronze, and then casting the alloy (the ability to cast copper is improved by adding tin). Evidence to date suggests that a sophisticated lost-wax casting technology (intricate forms are made of wax and encased in clay; molten metal is poured into the mold which replaces the wax) was developed in West Africa by the ninth–tenth century AD. The site of Igbo Ukwu in Nigeria has yielded remarkable castings that were followed by later traditions at nearby Ife and Benin.

Igbo Ukwu also provides the earliest evidence of bronze which was used to make many lost-wax castings. Investigations into whether bronze alloying was an indigenous discovery in West Africa is ongoing. The only other region where bronze alloying developed was around present-day Zimbabwe, although little is known about the stimulus and dating of this technology. It probably arose after the beginning of the maritime trade along the Indian Ocean, perhaps in the eleventh–twelfth centuries AD, and was used to make wire, beads, and simple two-sided mold castings. Brass, the alloy of copper and zinc, on the other hand, was used extensively for lost-wax casting in West Africa beginning around AD 1000, although the metal itself was imported into Africa from across the Sahara Desert and along the West and East African coasts.

There is no evidence of lost-wax casting outside West Africa, although casting traditions did exist. Open-faced or one-sided molds seem to have been used to cast copper into bar shapes as early as the seventh century AD in present-day Zambia. In the Zaïre–Zambia copper belt region, cross-shaped molds were made by the ninth–eleventh centuries AD in northern Zambia, but not until the fourteenth century in southeastern Zaïre. These ingots were then traded. Objects were made as the ingots or raw metal were hammer forged into sheet, rods, ribbon, and other shapes. Drawing copper into wire, a fabrication technique found in Central, Eastern, and Southern Africa, was used by the mid-second millennium. The history of its development and spread is unknown, although iron/steel draw plates for wire were found at Ingombe Ilede, Zambia, dating to the fourteenth–fifteenth centuries AD.

Gold objects tended to be produced by the same techniques as copper in a given region. Lost-wax casting of gold in West Africa, such as among the Asante of present-day Ghana, is particularly exquisite. Wire drawing of gold was also practiced in West Africa. At ancient Zimbabwe, gold was usually hammered to shape beads, wire, and sheet. Finally, there is no evidence that any objects were made of pure tin in Africa. Occasional ingots cast of tin are found in South Africa, presumably for used trade.

A critical part of African metallurgy that has not been discussed is the nontechnical – the social organization of labor, the use of space, and the esoteric knowledge, rituals, taboos, special clothing, and music involved. The innumerable processes of African iron and copper smelting, in particular, were complicated mixtures of technique, special knowledge, and ritual controlled and designed by men to ensure success and circumvent danger and malevolence. This involved not only pleasing the ancestors, but countering the acts of sorcery that were perceived to be a threat to the process.

Central to this examination is the recognition that all social activity, including technology, must be explained and done so within a framework meaningful to the people involved. Questions concerning the sources of ore, how rocks become shiny metal, why some smelts are unsuccessful, and what slag is are answered in modern, Western societies by scientific principles of geology and engineering. In pre-colonial Africa, these questions were resolved through principles based largely on human physiology and social structure.

A compelling framework was offered recently to consider how many pre-colonial African societies explained metallurgical activities. This is based on two fundamental aspects of human experience – gender and age. Gender concerns the interaction of males and females through a life cycle, but focuses on one critical stage of life that is not shared. Women are capable of transformation and creation through their ability to give birth, a process that is interrupted by monthly periods of sterility and ends at menopause. The links between women, production, and reproduction are poignant. Male metal workers could only generate similar creative forces with which to transform rock into metal and then into objects by controlling and appropriating women's natural abilities through symbol, metaphor, and ritual.

The axis of age encompasses the relationships between youth and elders, as well as between the living and the dead. In many African cultures, the human life cycle involves the accumulation of wisdom and power through adulthood. Greatest power is acquired as an ancestor. Thus, elders have the expertise and knowledge to demand and exploit the labor of youth in most activities, including metallurgy; the ancestors have ultimate power over all significant activities of the living, particularly its reproduction. Integral to mining, smelting, and fabricating metal objects, therefore, was gaining and maintaining ancestral approval.

The cultural influences of gender and age were most obvious during iron and copper smelting – technologies of transformation and creation with many opportunities for failure. These influences were manifested in highly diverse ways. Often, smelting involved rituals and song that simulated significant times in the life of a productive woman, such as marriage, pregnancy, and birth. The Fipa of Tanzania, for example, adorned and treated a newly built iron smelting furnace as a bride who would have many children. The furnace was perceived as a "wife" to the iron smelters in many African cultures, such as the Phoka of Malawi. Furthermore, various parts of furnaces were often given the same names as female body parts, particularly those related to sexuality and birth. The Shona of Zimbabwe, the Chokwe of Angola, and others were more explicit and built their furnaces as women. They decorated the walls with breasts and scarification, denoting fertility, and the bloom sometimes came out between leg-like projections. Rituals also were used to consecrate new iron forges or tools which drew analogies between the anvil/hammer (the most important tool of a smith) and a second wife, such as among the Nyoro of Uganda, or a child, such as among the Ondulu of Angola.

Both age and gender strongly affected the roles played and choices made during metal working, including the significant influence of ancestral spirits, the technical and ritual expertise of elders, the work load of the youth, and the exclusion of women. Although women were often miners in cultures with labor shortages, all women, particularly pregnant or menstruating ones, were excluded from smelting operations. Prepubescent girls and postmenopausal women, however, sometimes participated in presmelting rituals or cooked and transported food to the smelters. Furthermore, strong taboos existed to prevent men from having sexual relations prior to a smelt. Such behavior represented infidelity to the furnace, and adultery was often thought to cause miscarriages in pregnant women. Furnaces were usually placed far away from villages to minimize this potential threat.

These rules of participation were designed to please the ancestors by preventing the presence of forces – uncontrolled fertility and temporary sterility – that might jeopardize a productive metallurgical operation. Young girls and postmenopausal women were not threatening because of their lack of fertility and active sexuality. The rules also served to separate metalworkers from the general public as people with special knowledge and capabilities. Many accomplished metal workers became wealthy members of their societies, as well as important political figures.

Other forces influenced how a smelt proceeded and how failure was explained, including visible problems with the materials or technical steps used. In less obvious circumstances, however, a common explanation for failure was sorcery by jealous villagers or by competing metalworkers. Since iron, copper, bronze, brass, and gold workers were often relatively rich and powerful men, they sometimes became foci of envy. Actions to avert evil spells, therefore, involved meticulous attention to the preparation and placement of medicines in and around a furnace and, sometimes, a forge. Ethnographic and archaeological evidence reveal that the placement of medicines inside furnace pits has been practiced for two millennia. As a result of this integral part of the metallurgical process, metalworkers were often believed to be sorcerers and/or people with special powers. Particularly skilled metalworkers were regularly in demand by the general public for their abilities to heal and divine.

Two significant lessons – actually two sides of the same coin – may be learned from the study of African metallurgy (1) a technology can exhibit tremendous variation through time and across a continent and (2) a technology is a system that is at the same time technical, economic, social, ideological, and political. A technological system affects and is affected by the culture and society in which it operates such that a great diversity of associated behavior and knowledge may result over time and space. Unfortunately, all the complexity and variation of African metallurgy will never be fully appreciated and known, particularly as the elderly experts die with much of their precious knowledge untapped.

Metallurgy in Ancient Eastern Eurasia

Katheryn M. Linduff

Background

The development of metallurgy is considered fundamental to the emergence of complex societies in many regions of the ancient world. Until recently, little evidence could be obtained to explain the emergence and spread of metal technology in the third and second millennia BCE in the Eurasian Steppe where life was centered in kin-based, relatively independent pastoral or agropastoral communities. Archaeologists in central and eastern Eurasia have recently uncovered information about early metal use and production by residents of the steppe and the significance of this development in the area east of the Urals and west of the Yellow River. This is the area addressed in this essay.

Eurasia is a term given to the combined areas of Europe and Asia. Eurasia forms the largest landmass on the globe, or about 20,816,400 square miles. Many geographers claim that this is one continent and therefore that Europe is merely a peninsula of Asia. But whatever one's conception of continent, the area extends from the Balkans to the Yellow Sea and links Europe and Asia. Lying between the 40th and 50th latitude of this enormous land belt is a steppe land with a fairly uniform terrain with an average altitude of between 500 and 1,000 m. Like the prairie across much of the mid-section of the United States, this terrain is covered either by coarse grass or low woods. Only one mountain barrier with high forests, the Urals, crosses Eurasia in a north–south direction, giving rise to the nineteenth century conception of two continents of Europe and Asia divided at the mountains. The Urals are, however, merely an interval, rather than an interruption, in the vast sweep of the Eurasian steppes.

Decades ago studies on the beginnings of metallurgy envisioned the setting in the centers of early civilizations. Mesopotamia and Egypt in the west and China in the east, and early centers of production could be documented in West and East Asia, but not in between (Tylecote 1992; Moorey 1985; Knauth 1974). Both the intellectual climate and the evidence available conceptualized the advent of metal use as a spontaneous occurrence in a single ancient society. But, given the discrepancy in start dates and distance between the Near East (beginning as early as the fifth millennium BCE) and the Far East (beginning at the earliest about 3000 BCE), there has been much speculation about what role, if any, Eurasia had in the process of transmission. Researchers asked whether such a complex technology could be transmitted across the vast steppe to East Asia by the peoples of Eurasia or whether it was spontaneously generated in the Far East.

Sites excavated in Eurasia, that is in the border provinces of present-day northern and western China, the Republic of the Altai, Kazakhstan, Mongolia, and Russia east of the Urals, in the past two decades document the production and use of metals as early as the late fourth and third millennia BCE (Chernykh 1992: 190–234, 2000; Linduff et al. 2000; Linduff 2003). Based on a synthesis of the current Russian and Chinese chronological and metallurgical information from the area, it is possible that the entire area, including north China, might be better understood as part of a larger sphere of interaction that produced metallurgical traditions that emerged during the late fourth to the second millennium BCE. Technological as well as typological differences found across the area may be explained by noting the availability of ores, use of artifacts, and social complexity and even the environment of the generative societies. It is clear that many regional traditions abound, but that movement of ideas as well as artifacts, and people, perhaps technicians more than whole groups, was likely and was a stimulus for the transfer and invention of the variety of technologies now known to have been employed in this vast area.

The Problem

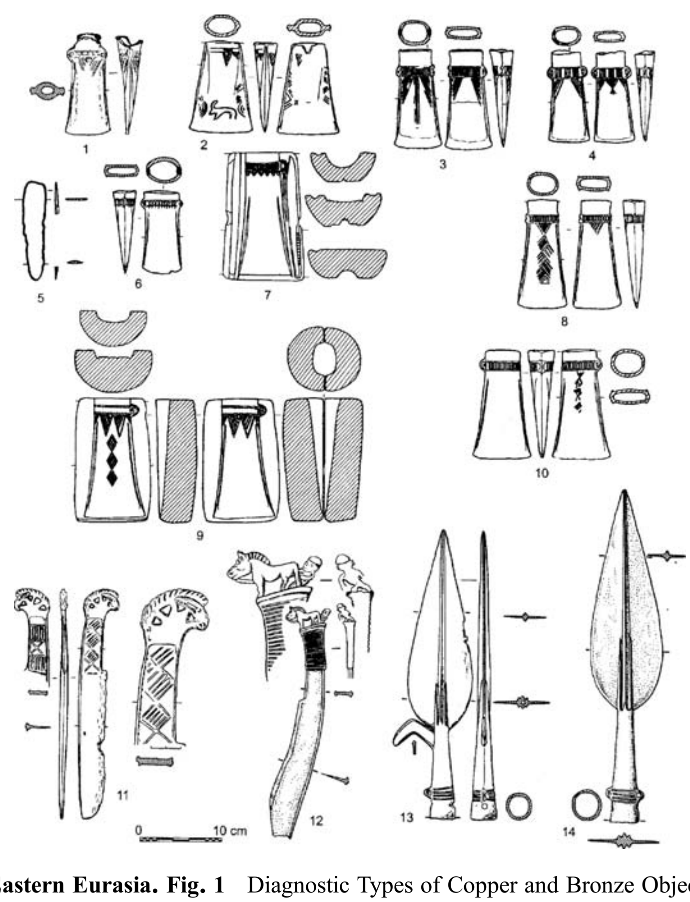
At the eastern edge of the Asian continent, analysis of metallurgy has figured centrally, for its development was thought to signal the advent of "historic Chinese civilization." In establishing ownership of the earliest bronze, priority was conventionally given to central China largely because it was where a high Bronze Age civilization eventually arose. The areas adjacent to ancient dynastic Chinese lands where early metallurgy was documented, even as distant as southern Siberia and Mongolia, were seen as peripheral to it as independent centers of invention. The direction of

M

exchange of people, ideas, artifacts and/or technology in the area, was a topic hotly debated in the past, and is no better exemplified than by the dispute between Bernhard Karlgren (1945) and Max Loehr (1949a,b) over bronze daggers and knives. They described the differences in the weapon and tool inventories of each area and agreed that there were two distinct traditions represented by diagnostic artifacts known from a limited number of excavations and from museum holdings. China was represented by straight-edged bronze knives; outward curving, hafted knives; single-edged daggers with tangs decorated with conventional Chinese motifs, particularly *taotie* (animal mask) and dragon designs. The Eurasian (or Siberian) typology included socketed axes; curved knives with naturalistic images of animals on the pommels; and double-edged short swords, also often with recognizable animal designs on the handles (Fig. 1). The discussion was focused on issues of cultural primacy and the dating of the Siberian against the Chinese Bronze Age. Since no carbon dates were available then, the discussion rested on reasoning about typological sequencing. This debate has persisted in the literature for many decades.

Based on her own fieldwork and that of others in Russia and Kazakhstan, Legrand has recently reviewed the discussion, but not with an eye toward solving the debate over initial invention (2003). We now know that the "Karasuk" and "Andronovo" material does not represent the earliest use of bronze in either area and that the broadly defined dichotomous model developed by Karlgren and Loehr is far too simple to address the question of the emergence and spread of metallurgical technology, even in eastern Eurasia between the Altai mountains and the Yellow River.

Among Chinese and Russian scholars, study of the metal industry and proposals about who initiated the technology have been affected by mutual lack of information because of language barriers, and especially by modern political borders and nationalistic sentiments. The Chinese and Russian studies, as well as the now-dated debate between Profs. Karlgren and Loehr, presented judgments about the direction of



Metallurgy in Ancient Eastern Eurasia. Fig. 1 Diagnostic Types of Copper and Bronze Object Categories from the Seima-Turbino Complexes (Asian Centers). From: *Metallurgy in Ancient Eastern Eurasia from the Urals to the Yellow River*. Ed. Katheryn M. Linduff. Chinese Studies Vol. 31, Lewiston, Queenston, Lampeter: The Edwin Mellen Press, 2003. Fig. 1.10.

transmission for the technology that were based on comparisons of style of artifacts and on relative dating of each "host" culture. Their arguments, Karlgren as the champion of Chinese and Loehr of Siberian prototypes for certain artifacts and ultimately for the technology itself, were mounted at times when excavated, tested, and dated materials earlier than about 1250 BCE were lacking, so that only the fully developed phases of the second millennium BCE were studied. And, although archaeologists and metallurgists still debate the diffusionist and spontaneous generation models, new archaeological data, C14 dates and metallographic studies from both Russia and China (Chernykh 2000; Linduff 2003) permit a different way of thinking about the issue. After the break-up of the Soviet Union, both Kazakh and Mongolian Institutes of Archaeology have conducted their own investigations and some of those results have been reported as well (Goriachev 2003; Erdenebataar 2003). These studies are the first in English to document carefully the earliest known use of bronze in each area.

In the current literature, there is another problem worth mentioning. Field archaeologists, whether trained in the Russian or Chinese intellectual tradition, for the most part have defined cultures according to pottery types and styles and discussed the transmission of technology accordingly by these "archaeological cultures." The metallurgical scientists have looked at metallurgical traditions first, and then connected them with cultures. The application of a single term to identify a "culture" such as the "Andronovo" in much of Eurasia generalizes to the point where its descriptive meaning is useless since it often ignores regional cultures and perhaps even very different traditions altogether (Korochkova and Stefanov 2003).

For instance, bronze artifacts that follow the shape and style of ones called Andronovo or Seima-Turbino, such as trumpet-shaped earrings and socketed axes, have been excavated at a site called Huoshaogou, in Gansu Province in western China and date from between 1900 and 1600 BCE (Linduff et al. 2000: 15–19). Russian archaeologists might, on the basis of those objects, identify Huoshaogou as an Andronovo or Seima-Turbino culture site. One the other hand, no Chinese archaeologist has labeled it thus, but rather consider it as part of a western extension of the "Yangshao" culture because the painted pottery found at Huoshaogou, they say, is a variant of the Yangshao diagnostic type known from the central Chinese heartland. Not only is the terminology of archaeological cultures true to neither "type" in this case, the application of these labels obscures the nature of the local setting. The site, its organization and use, shows that this community both produced metal artifacts, and also imported metal items for burial. The issue here is not about to what "culture" they might belong, but how the local community was constituted and connected to traders, metal workers, and each other. Clearly the site and its regional neighbors absorbed peoples and information from both their west and east, but are quite self-sufficient and distinct.

Or, similarly, there is no doubt that the Semireiche region in Kazakhstan is an important one for the development and transmission of metallurgical materials and technology throughout its immediate region as well as to its east, especially into what is now western China. Although the several pottery traditions have been identified there have been variously labeled Andronovo or Fedorovo, the distinctiveness of these sub-areas is argued for by Goriachev while recognizing how important large regional networks might have been to them (2003). Such a network has been determined with the excavation of a site where a massive mining effort was recently identified and dated in the late fourth or third Millennium BCE at Kargaly (Chernykh 2003). Kargaly is now known, for example, to have supplied large numbers of artifacts and raw materials to peoples living to the west of the Urals. Another such network probably connected patrons and metal manufacturers living in areas to the west and east of the great tin loads in the Altai Mountains (Chernykh 1992). The territorial extent of these Eurasian trade networks are only beginning to be understood, but the amount of data now available allows us both to examine carefully local operations as well as to speculate on how individual societies might be connected others.

M

The Data from Southern Siberia, Kazakhstan, and the Altai

Debates and assessments of incipient metallurgy and its consequences in the ancient world now consider several crucial factors:

1. Knowledge of the presence of ores and the corollary existence or creation of trade networks
2. The presence of knowledgeable local and/or itinerant artisans who knew metals and their properties
3. A community able to support such workers, with a degree of social and/or ritual complexity to create a demand for metal products
4. The ability to create high temperature furnaces for smelting and refinement of ores and final castings

The most sophisticated and earliest known metal-producing industries were located in or near the more complex societies in the Near East where these products were used for many purposes ranging from utilitarian to luxury items for use in everyday activities to solemn rituals. The Eurasian metal period is on the whole later than that in western Asia.

The publication of Evgenii Chernykh's texts and bibliographies on the early metallurgy in the USSR

(Chernykh et al. 2003; Chernykh 1992, 2000, 2003) and many reports on individual sites have provided data on excavated materials from the territories between the Near East and the current Chinese borders. In addition, more complete reports on copper- and bronze-using sites in Russia, especially those near the Ural Mountains, such as Arkaim and Sintashta-Petrovka (Gening 1992; Zdanovich 1997), have been published. Chernykh and his colleagues in Moscow have collected almost 2500 C14 dates from metal using sites across Eurasia (Chernykh et al. 2000). The map of the earliest known metal production from Chernykh's essay (2003) shows quite clearly that metals were part of village life in Eurasia no later than the late fourth millennium BCE (Fig. 2).

Chernykh defined "Metallurgical Provinces" as large contiguous regions linked through shared utilization of morphologically defined ornaments, tools, weapons; a common technology of metallurgical production; availability of or access to the same metallurgical resources often emerging into large trade networks; and comparable dating (Chernykh 1992: 7–16). These provinces cover distinct areas at different times and include discrete sub-areas of metallurgical knowledge and metalworking. What he calls the Eurasian Metallurgical Province (EMP) and its sub-category, called the Seima-Turbino chronological horizon, date from the late fourth and third millennia BCE, or Late Bronze Age, are the most relevant here (Chernykh 1992: 7) (Fig. 3). Some artifacts, such as fishhooks, awls, rings, and bracelets, are ubiquitous in the Seima-Turbino contexts.

Although Kuz'mina challenges the method and details of dating this complex against the Andronovo (2003: 37–84), there seems to be little argument about the importance of this metallurgical development. The disagreements over the dating of each sub-area complex depend at least in part on the methodology used to establish a chronology. Chernykh depends largely on C14 testing with calibration (Chernykh et al. 2000). Since carbon dates are never precise, Kuz'mina, for instance, proposes that the most reasonable dating can be derived from classification method using evolutionary-typological analysis (2003). Her system finds the Andronovo (and possibly the Fedorovo in Kazakhstan) and the Seima-Turbino synchronous in the seventeenth century BCE (2003). Many authors use a combination of both methods (Korochkova 2003; Legrand 2003; Goriachev 2003).

More recently, however, regions called foci, or distinct centers of production, were also identified within the EMP (Chernykh 1992). For example, the

M

eastern region includes the Andronovo historico-cultural community and other archaeological cultures recognized previously by archaeologists in the southern Urals and central and northern and eastern Kazakhstan to the Altai and Tianshan mountains (Kuz'mina 2003: Fig. 2.5). The significance of these regional centers is very evident in the study of sub-areas just east of the Ural Mountains (Korochkovo 2003) and in eastern Kazakhstan (Goriachev 2003) where small Andronovo/Fedorovo type metal objects have been excavated recently; and in western China where similar metal items have also been uncovered (Han and Sun 2003; Mei 2000, 2003). Although separated in many cases by large distances, analogies in the shapes and décor of these metal objects can and have been noted. In each case, however, regional peculiarities such as pottery types or décor and/or metallurgical traditions clearly mark important distinctions which Chernykh claims constitute sub-areas of a larger complex. For instance, unique types such as socketed axes with hatched triangles and rhombuses, forked-shank spearheads, and curved knives with animal (sheep and horses) and human subjects on the pommel were made only in the eastern region in the Altai and Tianshan. Because these items were used sparingly in burial and were unique in décor, they have been labeled "princely" artifacts (Chernykh 1992: 218–219). Currently available materials make clear these differences, while recognizing that there is interchange throughout this region no later than the third and early second millennia BCE (Linduff 2003).

Spectrographic analysis was carried out on all dated metal items from the Seima-Turbino area and Chernykh attributes fundamental innovations in metallurgy and metalworking to this region at this time; his conclusions are based on analysis of the 422 metal objects and 30 casting moulds excavated from burials. In the "eastern focus" area (that is, up to the borders of present-day China), only two examples of arsenic–copper were found; all other examples were tin–bronze (all from Rudny Altai, Rostovka). The curved knives with horse figures on the hilts, for instance, are all high quality tin–bronze and were found by him only in the Altai. The vast quantity of tin ore in the Altai is given as the reason for such a concentration of tin–copper alloys in eastern and southern Siberia (Chernykh 1992: 224–226). By contrast, products typical of the western sub-area were made from "pure" and arsenical copper and billon found in abundance in the Urals. And, although tin–copper and tin–arsenic–copper products were found throughout the EMP defined by Chernykh, only certain shapes such as ornately decorated Seima-Turbino socket axes were excavated in the western region, suggesting that the axes were supplied in a finished state (Chernykh 1992: 224, 2003). Finally, Chernykh proposed that the Altai was the source of particular tool types and chemical compositions of tin–bronze and depictions of animals (Chernykh 2000). In addition, jade and flint, bone tools and protective armor are also exclusive to this area. The notion of an EMP can be extended to include Xinjiang, and even probably Gansu and various of the northern provinces in present-day China, given the materials found and analyzed there in the past couple of decades (Han and Sun 2000, 2003; Mei 2000, 2003; Linduff 1997; Linduff et al. 2000: 1–29).

The Data from the Northern Zone of China

Syntheses that investigate China usually view the archaeological landscape during the fourth millennium BCE as a mosaic of regional groups that interacted with each other (Chang 1986). When dealing with the period of early metal use however, most Chinese archaeologists have accepted a traditional model which regards the Central Plain of northern China as the dynamic center of social, political and technological change and proposes that complex societies emerged in Asia through a process of political expansion and cultural diffusion from the Yellow River Basin (An 1982). The elevated position of metal artifacts as well as the highly specialized and sophisticated multipiece mould technology developed to produce them in early Chinese society has led to the assumption/conclusion that the commencement of metallurgy in East Asia was to be found inside the early Chinese cultural, and/or even the political sphere. Now this conclusion must be reexamined because there is adequate information to show that metal artifacts were locally produced in enough volume to confirm their regular use all across the Northern Zone. Moreover, the types of objects found in this region as well as the component percentages of metals in the alloy corresponds to metal types and alloying formulae found in the EMP, including both arsenic- and tin–bronzes (Sun and Han 1997) and suggest that the advent of metallurgy in this region was not a separate occurrence.

Over the past two decades, articles about more than seventy sites that can be dated either by C_{14} and/or by archaeological context earlier than 1500 BCE have been published. These sites yielded metal artifacts and/or metal production materials such as crucibles or slag, and so forth. These sites date to the late fourth and third millennia BCE (Linduff 1997: 306–418; Mei 2000). The earliest metal-using communities are in Qijia/Siba sites in Gansu, with comparable sites in Xinjiang in the west, and others in Shandong, Liaoning and Inner Mongolia in the east and north, and in the Central Plain in the lowest levels at Erlitou. Because several levels of excavations are C_{14} dated and those dates have been matched up to ceramic types and styles, chronologies are more secure. An approximate chronological correspondence between the sites in the earlier eastern Eurasian steppe and China is now clear, and suggests that the emergence of metallurgy was supra regional (Linduff 2000 et al.).

Analysis of both the Chinese and Russian data, including metallic composition, casting technology, as well as types and uses in the period from about 3000 to 1500 BCE has led to some surprising observations about the advent of metallurgy in eastern Asia. (Barnard 1993: 3–48; Barnard 1987: 3–37; Linduff 1997, 1998: 619–643). First, we can see that one of the most striking, as well as usual, additions to late Neolithic village life in northeastern Asia as far east as the Russian Far East was the use of metals. Sites where metals (including copper as well as alloyed metals) were first used and manufactured are located across a large area, showing that the growth of the industry did not solely, or even primarily, occur in the Central Plain. Moreover, preliminary observations on the process and patterns of use of the technology are both shared and diverse (Siba versus Erlitou) (Sun et al. 2000).

Areas in China where metallurgical knowledge was in use emerged near ore sources of metals, especially copper in several combinations. For instance, arsenical bronzes produced in Gansu at Siba sites must have been manufactured by exploiting local arsenical copper resources still available in present-day Gansu. All areas developed a taste for items made from "pure" copper and copper alloys, and gold items have been found in the northeast and northwest China. Trumpet-shaped earrings, for instance, have been found all over eastern Eurasia and northern China and were made from copper, tin–bronze as well as gold and sliver according to the local preference. The lack of consistency in formulae suggests that that knowledge was gained from several sources and not through local invention (Han/Sun 2000; 2003; Mei 2003).

In contexts where manufactured metal artifacts have been found in China, excavated villages have yielded evidence of both cultivated crops and domesticated animals, as well as the continued practice of hunting with improved arrowheads made of bronze, especially in the northeast. Chernykh's fanciful speculation that the Seima-Turbino was formed though a fusion of metallurgists and warrior horse-riders of the forest zones of the Altai and eastern Siberian taiga mobile hunters (1992) is supported in the recent excavations of the village at Gorny (Chernykh 1998), Kargaly (Chernykh 1997, 2003), and many others including Arkaim and related sites (Zdanovich 1997). Located close to vast resources of ores in the Urals, these excavations reveal that isolated groups of miners and metallurgists worked in specialized communities for many generations supplying patrons across western, and possibly eastern, Eurasia.

General Observations

The many shared traits discussed above suggest that there was a "metallurgical network" of some type, however loosely connected. The region is linked through comparable artifact types, by closeness to ores, and by shared metallurgical technologies not easily transmitted without movement of craft workers or even groups of travelers. The consistently local character of pottery types and styles in sub-areas, as well as the appearance of metal items with affinities to cultural debris from Bronze Age southern Siberia, has suggested that there was movement into the area of western China, likely bronze producing peoples of Andronovo background from eastern Kazakhstan and/or Transbaikalia (Ke 1998; Linduff 1998; Mei 2000; Kuz'mina 2000). Although animal sacrifice signified status and/or leadership in burial and metal items included tools, weapons and personal ornaments associated with individuating societies in the region of Gansu (Linduff 1997), metal items ultimately were used to identify only elite members of a centralized political unit at Erlitou in the center of early dynastic China (Linduff 2000). As Kuz'mina suggests (2003) the appearance of wheeled transport, metallurgy and use and/or breeding of horses signal not only movement of ideas, technology, and perhaps peoples, but also significant societal change, often to a more complex social order.

This change evidenced and discussed for the earlier to middle second millennium BCE was not a one-time affair. That was not the only period of interchange between the peoples of western China and points west. Continued stimulation, moving in both directions, can be witnessed in the later second and early first millennia BCE (Legrand 2003). Nor are the border regions of present-day western China the limit of that exchange system. Both local pottery and early metal artifacts suggest that knowledge of metallurgical traditions and artifact types extended into northeastern China (Linduff et al. 2000) and into what is now the Russian Far East (Konkova 2002).

Nevertheless, when considering the advent of metallurgy in the late fourth and third millennia BCE, all the criteria of the EMP defined by Chernykh are found in the "Chinese" contexts. If separated from modern nationalistic and centric views of ancient culture and considered as part of a larger metallurgical context, even the multipiece-mould casting method developed in the late second millennium BCE at Erlitou, seen as a hallmark invention of early dynastic China, may be seen as a local technological variation within the easternmost Eurasian territory made for specialized ritual use.

Metallurgy of Ancient Indian Iron and Steel

R. Balasubramaniam

Early ideas about the Aryan migration theory and the introduction of iron into India from the West have now been proved to be incorrect. For example, Pleiner (1971) proposed that so-called Aryans had no iron production until the second half of the first millennium BCE, and that there was no iron export to the West from the area of the Aryans, whom he assumed to be "the Sanskrit speaking people." However, there are firm dates for the advent of iron in the Indian subcontinent before this period. The independent origin of iron has been convincingly argued by Chakrabarti (1992). Agrawal and Kharakwal (2002) have compiled radiocarbon dates of excavated iron manufacturing sites in the Indian subcontinent. The earliest available date, 3050–90 BP, is from Raja-Nala-Ka-Tila in Uttar Pradesh (Tiwari 2003).

The primacy of iron technology in the Indian subcontinent is well established and there are several published books on the state of ancient Indian iron technology (Neogi 1914; Chakrabarti 1992; Biswas 1996; Tripathi 2001; Balasubramaniam 2002). The metallurgy of iron and steel in ancient India is the topic of this article, which includes the working of iron, the extraction of iron and salient features of ancient Indian iron. Some objects illustrating the skill of the Indian blacksmiths are provided. The Delhi Iron Pillar (Fig. 1) illustrates the pride of Indian blacksmithy skills.

Metal Extraction

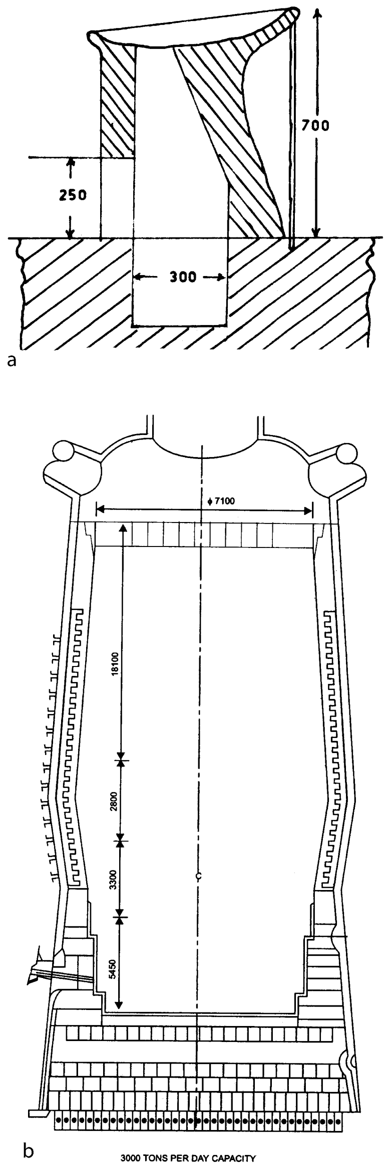
The direct reduction method of iron extraction was used for a fairly long period in India's history. Iron lumps were the starting material for the fabrication of most objects.

Iron melts at 1,540°C and the ancient Indian furnaces were incapable of attaining this high a temperature. The various aspects of construction and operation of ancient Indian iron furnaces (called bloomery furnaces because

Metallurgy of Ancient Indian Iron and Steel. Fig. 1 Delhi Iron Pillar located in the Quwwat-ul-Islam mosque in the Qutub Complex at New Delhi.

the end product was an iron bloom) have been discussed in the literature (see Tripathi 2001). The ore for extracting iron was carefully collected by the ironsmiths. Interestingly, specific ore was collected depending on the end application. Preheating facilitated breaking of the ores, and the fine dust was separated by washing or by wind. The preheated iron ore and charcoal were charged in alternating layers, the furnace ignited and slowly heated to the reduction temperature (1,000–1,200°C). Different designs of iron extraction furnaces have been described in the literature. Their heights ranged between 5 and 20 ft. A typical ancient Indian bloomery furnace is schematically compared with a modern blast furnace in Fig. 2.

Bellows placed at the bottom of the furnaces were operated at a controlled rate. The iron ore had to be reduced in order to obtain the iron. Iron ore is essentially oxide of iron and it is reduced by the carbon monoxide (CO) that is produced by the burning of charcoal in the bloomery furnace (or coking coal in a modern blast furnace). The other unwanted oxides, like silicon dioxide (SiO_2), which is commonly found in iron ores, have to be removed and this was possible by the creation of a liquid slag called iron silicate or fayalite $FeSiO_4$ or $2FeO{\cdot}SiO_2$. While some of the liquid slag flowed out of the bloomery furnace during the reduction of iron ore to iron, some of the liquid slag still remained when the hot iron lumps were taken out of the furnace. Therefore, the hot lumps that were extracted from the bloomery furnace at the end of the heat (typically lasting for about 6 to 8 h) were immediately hammered. In this process, most of the entrapped liquid fayalitic slag flowed out of the solid reduced iron mass. However, it was not possible to remove all the entrapped liquid slags and ancient irons produced by the direct reduction process will always contain entrapped inclusions. The inclusions are essentially composed of fayalite, some iron



Metallurgy of Ancient Indian Iron and Steel. Fig. 2 Comparison of (a) modern and (b) ancient furnaces for extracting iron from ore.

oxides (for example, wüstite FeO) and glassy phases (due to calcium silicon phosphates). As a result of entrapped slag particles and iron oxides in the structure, the specific gravity of ancient irons is lower than that for the purest form of iron (Fe).

The slag present in ancient irons is generally microscopic in nature with a few in larger sizes. As the solid-state reduction resulted in a fine distribution of slag particles, it was difficult to completely hammer the slag out of the metallic matrix. The resulting sponge iron always contained some amount of entrapped slag inclusions and unreduced FeO. These are not of uniform size and also not strictly uniform in composition.

M

Viewing the production of iron lumps from a powder metallurgical viewpoint, the ancient Indians produced iron "pre-forms" directly from iron ore which implied that the powder production, powder consolidation, and sintering[1] processes were combined into one operation (Dube 1990).

The end product of the extraction process was a lump of iron that was subsequently used for a wide variety of applications, either directly or after further heat treatments. One important heat treatment that was successfully conducted was controlled carburization of iron in specially designed crucibles. The carbon content of steel (i.e., an alloy of iron and carbon) was carefully controlled by subsequent decarburization treatments. It is important to control the carbon content in steel because the mechanical properties of steel are critically dependent on the carbon content. As a rule of thumb, the higher the carbon content, the higher the strength of steel.

The relatively small iron lumps produced in the bloomery furnace were the starting materials for the manufacture of large iron objects. The lumps were also used, after suitable heat treatments, for manufacturing agricultural (hoes, spades, sickles, and weeding forks), household (knives, ladles, spoons, sieves, saucepans, cauldrons, bowls, dishes, saucers, and tripods), building (nails, clamps, staples, sheets, door handles, and spikes), tools (anvils, hammers, scissors, saws, chains, and smithy tools), and warfare (swords, javelins, armor, helmets, and shield bases) items. A marvelous example of a forge-welded object is the gilded Buddha head from the Gupta period (320–600 AD) (Fig. 3).

With the advent of the carburization of iron, a special type of high carbon steel was produced in India from as early as the fourth century BCE. This steel was known as *wootz steel* and it was much prized by warriors because tough swords could be wrought from wootz steel (Srinivasan and Ranganathan 2004). There were several applications for wootz steel, like the manufacture of tough swords (see Fig. 4), helmets (see Fig. 5), and armor (see Fig. 6).

Classification

Ancient Indians were masters in the production of iron and steel. The method of production of wrought iron directly from the ore by the process of direct reduction continued for a fairly long time, up to the end of the eighteenth century AD. The Indians knew fairly early about the beneficial aspect of carburizing iron to increase its strength. The earliest evidence for

[1] Sintering is a process in which fine solids are combined into a porous mass that can then be added to the blast furnace. These include iron ore fines, pollution control dust, coke breeze, water treatment plant sludge, and flux.

Metallurgy of Ancient Indian Iron and Steel. Fig. 3 Gilded wrought iron Buddha image of the sixth Century AD, now in Lucknow State Museum.

Metallurgy of Ancient Indian Iron and Steel. Fig. 4 Typical watered blade manufactured from wootz steel.

carburization of iron dates to about 800 BCE (Ghosh and Chattopadhaya 1982). The second urbanization of India (i.e., settlements along the Ganga) was strongly influenced by the steeling of iron.

Three principal varieties of iron were recognized based on the carbon content. Each of these was further subdivided into other varieties depending on the composition and properties (Prakash 1991). Sanskrit literary sources (for example, *Rasa Ratna Samuchchaya* dated to the eighth to twelfth century AD) classify iron into three basic categories: wrought iron (*Kanta Loha*), carbon steel (*Tikshna Loha*), and cast iron (*Munda Loha*). *Rasendrashār Samgraha* also mentions these three classifications and states that "*munda* is ten times better than iron rust, *tikshna* hundred times better than *munda*, and *kanta* million times better than *tikshna* iron." These three basic categories were further classified according to the carbon content, heat treatment, and end use. *Munda* was again subdivided into three varieties: *mridu*, which easily melts and does not break and is glossy; *kuntha*, which expands with difficulty when struck with a hammer; and *kadāra*, which breaks when struck with a hammer and has a black fracture surface. Six varieties of *tikshna* were provided: *khara*, *sāra*, *hrinnāla*, *tārābatta*, *bājira*, and *kālaauha* (black metal). One variety is rough and free from hair-like lines and has a quicksilver-like fracture surface, while another variety breaks with difficulty and presents a sharp edge. Five different varieties of *kanta* were recognized: *bhrāmaka*, *chumbaka*, *karshaka*, *drāvaka*, and *romakāntā*. The variety of iron which makes all kinds of iron move about was called *bhrāmaka*; that which kisses iron was called *chumbaka*; that which attracts iron was called *karshaka*; that which at once melts iron was called *drāvaka* and *romakāntā* was the kind which, when broken, shoots forth hair-like filaments.

Metallurgy of Ancient Indian Iron and Steel. Fig. 5 A typical medieval Indian helmet fabricated out of wootz steel.

The ancient Indian iron furnaces were capable of producing iron of consistent (low) carbon content-containing entrapped slag inclusions (Tripathi 2001). Iron meant for corrosion-resistant applications contained higher phosphorous (P) contents. Therefore, it is reasonable to conclude that the ancient Indian metallurgists possessed the art of manufacturing iron and steel according to the desired application and corrosion-resistant steel was one among them. The excellent corrosion resistance of ancient Indian iron can be attributed to its relatively high phosphorus contents. This is due to the absence of CaO (calcium oxide, i.e., limestone) in the charge of the bloomery furnace.

Microstructures

In materials engineering, the close correlation between structure and properties is well known. Structure indicates arrangement of the material. When one views the arrangement of electrons, neutrons, and protons, we call it atomic structure. On a microscopic scale, in the order of micrometers, the grain structure of engineering

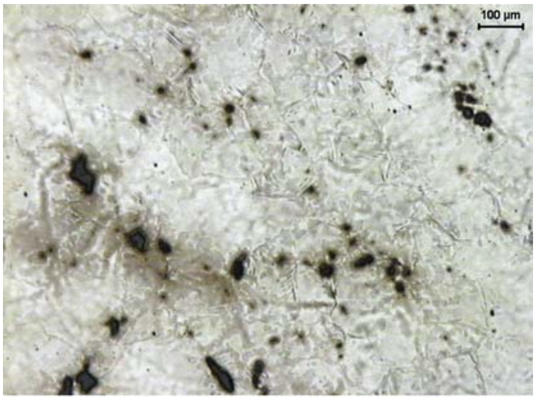
Metallurgy of Ancient Indian Iron and Steel. Fig. 6 Typical medieval Indian body protection gear wrought out of wootz steel.

materials is understood. Finally, the macrostructure refers to observations made in the range millimeters. Structure affects the properties of engineering materials.

The microstructures of ancient irons are highly heterogeneous; the iron normally possesses nonuniform grain structures.

In the unetched condition, the specimens generally reveal slag inclusions irregularly distributed in the microstructure. The end product of the bloomery furnace was a lump of direct reduced iron, which contained phosphorous as the major alloying element. The end product of the ancient Indian direct process of extracting iron can be called phosphoric iron. The end product of modern blast furnaces is pig iron, in which carbon is the major alloying element. In contrast to macrosegregation of P in pig iron, microsegregation of P is realized in ancient phosphoric irons. Fig. 7 shows an optical metallograph obtained after polishing an ancient Indian iron sample to a mirror-like finish and etching it with Oberhoffer etchant. The particular etchant reveals the distribution of P in the microstructure. The dark areas in Fig. 7 are the regions where the P content is less, while the bright areas are indicative of higher P contents. Notice that P is depleted from the grain boundaries and from the regions surrounding the entrapped slag particles. There are several fascinating insights that can be obtained from the study of microstructures but this is beyond the scope of this article.

The forge-welding method of manufacturing iron objects continued for a long time. Indians did not quickly adopt the cast iron technology that was becoming popular in Europe from the beginning of the sixteenth century. They continued with their traditional method of forge welding to manufacture large objects like cannons. One typical example of a massive cannon manufactured by forge welding is seen in Fig. 8. This cannon was fabricated in the early part o the seventeenth century and is located at Thanjavur. There are several other massive forge-welded cannons from the medieval period (Balasubramaniam 2007).



Metallurgy of Ancient Indian Iron and Steel. Fig. 7 Microstructure of Gupta period (320–600 AD) iron revealed using Oberhoffer etchant. The regions depleted in P appear darker in contrast. The dark structures are entrapped slag inclusions.

Death of Indian Iron

Indian metal crafts flourished until the end of the Mughal period (1526–1705). After the establishment of the British Empire, restrictions were imposed by them in the form of production taxes and bans on export. It was natural that this industry should die. This disappearance of the ancient technology during the eighteenth to nineteenth centuries was aggravated by the discovery of new scientific principles and development of new industrial process of metal production in Europe.

The direct reduction process of iron making declined after the advent of the processes for making liquid steel in large-scale in the middle of the nineteenth century. The iron and steel trade from India declined and the ancient method of extraction and processing became extinct by the beginning of the twentieth century.

The British in India made attempts to work on iron ores on a large-scale by modern methods. Several iron and steel works were set up in the country. For example, the Bengal Iron Company was established at Barakar in 1874. It employed 821 people in 1891 and produced 12,000 ton of pig iron (Jaggi 1989). However, these iron works depended on the availability of charcoal and this necessarily meant the destruction of forests and depletion of charcoal supplies. Another factor was also at play. By the end of the century, indigenous iron ceased to be produced because of the import of iron.

Another factor in iron's decline is the fact that certain essential steps were not shared by the master smiths with anybody except their favored apprentices. Traditional artisan communities in India never reveal full

Metallurgy of Ancient Indian Iron and Steel. Fig. 8 The massive forge-welded iron cannon called *Rajagopala* located at Thanjavur.

details to outsiders and when the communities disappeared, so did the methods. Other factors include the use of the same age-old furnaces, processes, and blowers (*bhathi*) by many tribes. This shows that these process secrets were well guarded and any change in the process or equipment was considered a bad omen. Probably this is one of the reasons for the loss of metal technology like wootz steel manufacture.

In the twentieth century, the condition had become so bad that the memory of ancient glory remained only in the form of stories narrated by old men. After independence in 1947 India had to borrow the modern technology from western countries to set up steel plants. The situation is now changing with India again rising to the challenge and hoping to be one of the largest producers of iron and steel in the twenty-first century.

The wishful thinking of Neogi in 1914 is worth recollecting.

> We hope we have been able to give a trustworthy account of the process of the manufacture of Indian steel, which was an object of envy of all nations but successfully imitated by none and which supplied the materials of many a true blade of warriors both in the East and the West. It is sad to reflect that an ancient indigenous industry which attracted merchants from Persia, as narrated by Dr Voysey, barely a hundred years ago, is on the point of extinction; but as even the darkest cloud is not without a silver lining, a distinct ray of hope is visible in the not very distant horizon presaging that India will yet regain her lost iron industry under modern scientific conditions together with other attendant industries depending upon iron.

Metallurgy in Arabia

Gerd Weisgerber

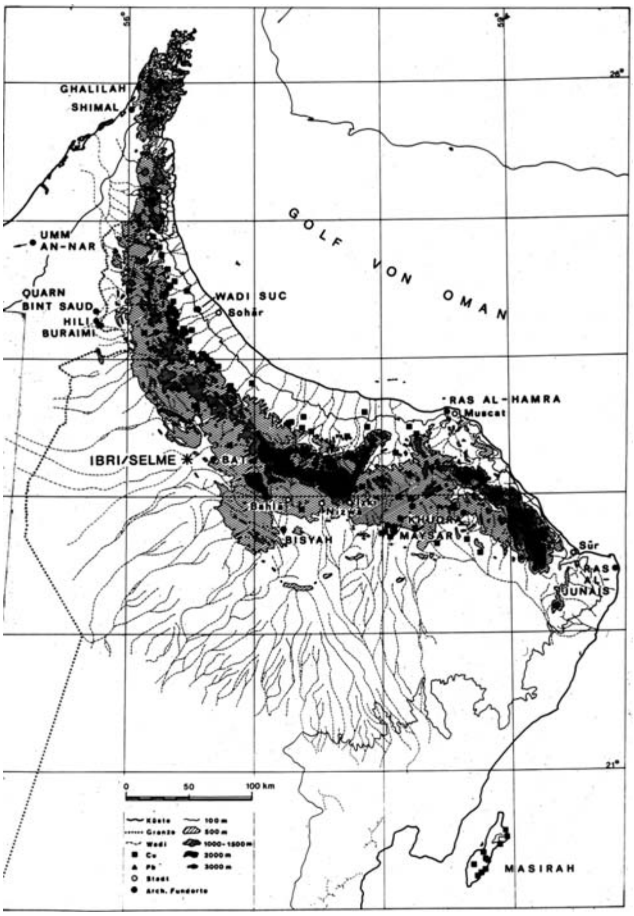
Geology

The Arabian Peninsula as a whole is rich in metalliferous ores and minerals, especially in gold, lead and silver, and copper. In the North there are the copper deposits of Feinan and Timna (Hauptmann 2000; Weisgerber 2006); the Yemen also has many. There are many ore bodies in the Hedjaz Mountain range in the west of Saudi Arabia that are nearly archaeologically unexplored. In the early 1980s three visits to ancient mining and smelting sites were undertaken (Hester et al. 1984).

So far only the copper deposits of Oman and their exploitation during the last 5,000 years have been studied (Fig. 1). There is not only the Early Bronze Age production of the third millennium connected with the Sumerian copper country of Magan, but also the Iron Age and the Early Islamic productions represent real industrial scale production.

Copper ores occur in two occurrences of ophiolite in the Oman mountains: in the Semail Nappe formation and on Masirah Island (Peters 2000). Copper deposits are formed by irregular mineralization at the transition zone of peridotite to gabbro. Of the 44 locations studied until 1975 more than the half comprise shear zones with secondary copper minerals in gabbro and peridotite (Goettler et al. 1976: 47; Hauptmann et al. 1988). Other copper deposits occur in ophiolitic pillow lavas. These stratified deposits sometimes are indicated by gossans, a rusty-red mineralization originating from the weathering of massive cupriferous sulphides (Coleman et al. 1979, 1981; Hauptmann 1985). In total the entire mountain chains of Oman and those in the Masirah Island have more than 150 copper ore deposits (Goettler et al. 1976; Hauptmann et al. 1988; Peters 2000). They were newly discovered

M



Metallurgy in Arabia. Fig. 1 Copper deposits (squares) and important Bronze Age (third to second millennium BCE) find spots (dots) in Oman (scale 100 km).

Metallurgy in Arabia. Fig. 2 ʻArja. The red gossan on top of the copper deposit results from the weathering and oxidizing of mainly chalcopyrite. This ore body recently has been completely removed by modern opencast mining.

either by copper slags or by the red colour of their gossan (Fig. 2).

Except for a few big ones, most of the deposits in Oman are small. Small green showings indicate veins of the copper ore, e.g. malachite. They were mainly exploited during the Chalcolithic and the Bronze Age, between 3000 and 1300 BCE. During the Iron Age and probably during medieval times, the large deposits under the gossans were preferred, perhaps mainly in the enrichment zones.

Therefore most copper production sites show more than one period of production. But today no site shows the whole spectrum of ruins – from mine to cemetery.

The Chalcolithic

There are some rare metal finds in the shell middens of the Neolithic found of Oman. But in the following Hafit period more metal occurs in the tombs. During this time copper production started. The oldest slags come from Batin in the Wadi Nam near Ibra (Fig. 3). They indicate local metal production (Yule and Weisgerber 1996). In the new burial cairns all over the country metal finds are standard but beside the new metal finds flint tools still occur. In a not plundered tomb under the Umm un Nar fortress at Maysar-25

Metallurgy in Arabia. Fig. 3 Batin in Wadi Nam near Ibra has the oldest slag. As is typical for the third millennium, the slag had to be crushed to expose and collect the copper drops and prills (scale 10 cm).

Metallurgy in Arabia. Fig. 4 Maysar-25, grave 1. Beside a typical Hafit vessel the grave contained two caramel coloured flint flakes, two copper needles, and beads.

Metallurgy in Arabia. Fig. 5 Nujum near Bidbid. These Bronze Age stone tools were lying around a trench mine.

Metallurgy in Arabia. Fig. 6 Wadi Miadin. A most impressive several hundred metres long trench mine in the Wadi Ma'aidin is a good example of shallow mining in the Bronze Age.

(Weisgerber 1981: 198) there was an untouched burial with two metal needles (Fig. 4).

The Early Bronze Age

Sumer in Mesopotamia from 2500 to 1800 BCE received a large portion of its copper from a country called Magan. Business transactions were written on cuneiform clay tablets. Ships from Dilmun/Bahrain, Magan/Oman, and Meluhha/India at the time of king Sargon (about 2400 BCE) docked at Akkad were unloaded, reloaded, and prepared to start for the next several months' journey. For their exports the merchants intended to exchange, in addition to copper, Afghani lapis lazuli, gold, cornelian, and exotic kinds of wood from India (Heimpel 1987). From Magan came copper and black diorite. Usually the ships would make a stopover in the trade emporium at Dilmun/Bahrain, a well-known source of fresh water, which probably had full control over the seafaring in the Gulf (Bibby 1970; Cleuziou 2003; Potts et al. 1986, 1992, 2003; Weisgerber 1983, 1986).

From Dilmun ships connected Magan for the first time probably at the small Island of Umm an-Nar off the coast of today's Abu Dhabi. Here the inhabitants of a small village had become extremely rich by transit trade, at least if one regards their large tombs with collective burials. They probably controlled the export of Magan's copper. But the ships may have had stopovers also at other islands in the south (Carter 2003). Bands of porters and caravans of donkeys brought the copper from the Oman mountain range to the island.

During the Early Bronze Age oxidic and carbonate ores were exploited. The Magan miners used stone hammers but had also metal chisels to break the rock. Good examples for mines of this time are the trench mines at Wadi Miadin and Nujum near Bidbid (Figs. 5 and 6). In addition to the local metal it seems that foreign copper was also in use (Prange 2001; Weeks 2003a).

M

Metallurgy in Arabia. Fig. 7 Maysar-1. Furnace fragments with fragmentary holes indicate the use of bellows to increase the heat for smelting.

Metallurgy in Arabia. Fig. 8 Maysar-1. The mass of furnace fragments (left) in comparison with the few pottery sherds, both are the content of the same excavation square.

The ores had to be reduced by charcoal with heat above 1,100°C. Smelting happened in small free-standing pear-shaped and knee-high furnaces built of clay. In the walls these furnaces had holes for artificial ventilation probably by bellows. The copper ores became reduced in the heat by the charcoal to metal (Figs. 7–9). All remains such as fist-sized crushing stones, slag, ash- and fireplaces, holes beside them, fragments of furnaces and of crucibles, metal scrap, and an ingot hoard were excavated in the 4,000-year-old al Maysar-1 in the Wadi Samad south of the oasis village al-Maysar (Weisgerber 1981; Hauptmann 1985). The copper finds were made of local metal but not the ingots (Prange 2001). Inside of one house stood a large anvil stone surrounded by several fireplaces (Fig. 10). Finally the fluid metal had to be poured in a flat hole in the ground, and after cooling the ingots got their typical planoconvex shape (Fig. 11).

The site of Maysar-1 produced more than copper. There were also a pottery kiln, manufactories for soft stone vessels (steatite, chlorite), and evidence of agriculture. The oasis garden of Maysar-1 is the oldest preserved oasis in all Arabia. The dams to improve irrigation must also be mentioned (Hastings et al. 1975; Weisgerber and Yule 2003).

Building towers, organizing mining, smelting, and trading of copper depend on competent leaders and led finally to an elite which used seals (Fig. 12). Tower tombs are the monuments they built to house themselves after death.

In trade with Mesopotamia and the Indian subcontinent copper from Oman played a key role. But, Magan also became dependent on these contacts. When it lost the market both because of a competitor with higher technology resulting in a much cheaper copper production at Alashia/Cyprus and when the Indian partner ceased to arrive because of their own internal political, social and cultural decline, then the end of the Magan civilization arrived.

Metallurgy in Arabia. Fig. 9 Based on many fragments a pear-shaped smelting furnace could be reconstructed for the third millennium BCE. But in contrast to this artist's view the bellows most probably were simple skin bellows.

The Middle and Late Bronze Age

Traces of second millennium smelting are rare. But they show that the same types of ore and smelting furnaces were used as before. The best information comes indirectly from the rich metal finds. Villages are nearly unknown (Cleuziou 1981; Velde 2003). But

Metallurgy in Arabia. Fig. 10 Maysar-1, House 6. Fireplaces and an anvil stone indicate a workshop.

Metallurgy in Arabia. Fig. 11 Maysar-1, House 4, Locus 31. Between two fireplaces in a small depression a hoard of 6 kg of copper ingots was found in 1981. Only one ingot was complete.

Wadi Suq tombs among Late Iron Age cemeteries indicate some kind of occupation of the same oasis areas also during that period.

The rich community grave of Al Wasit (Wadi Jizzi) had 50 soft stone vessels and 16 swords and daggers and 42 spearheads. They probably are of local production as proved by the many tons of slag between the houses of today's village. But as most of the weapons are of pure Omani copper it is obvious that in those days tin for bronze was hardly available even for elites (Fig. 13) (al-Shanfari and Weisgerber 1989: pl. 5; Weisgerber 1991; Prange 2001).

Some hundred years later the evidence had changed. In a thirteenth century warrior tomb at Nizwa the types of weapons correspond to those of that time elsewhere in the Near East, but now they are of bronze (al-Shanfari and Weisgerber 1989). Tin had become

Metallurgy in Arabia. Fig. 12 Impressions of a three-sided 4,000-years-old prism seal from the debris of house 4 of Maysar-1. The impressions show sheep, goat, dog, ibex, and scorpion, but most interesting is the humped bull in the middle (Indian zebu).

Metallurgy in Arabia. Fig. 13 Al Wasit in the Wadi Jizzi. This collection of swords and daggers of copper were found in an extremely rich community tomb.

available again as demonstrated by some hundred bronze bangles of the Ibri/Selme hoard (Yule and Weisgerber 2001).

The Iron Age

Beginning during the twelfth century BCE, large copper production restarts most probably with new kinds of ores possibly from the enrichment zone of the massive ore bodies (Weisgerber 1988; Prange 2001; Weeks 2003b). The Cyprus multiple step chalcopyrite smelting technique which made Cyprus what amounted to a 'global copper player' in those days arrived in Oman (as it did also in the Alps). Cyprus lost its predominance and in Oman copper production continued or restarted on a large-scale. There is no large medieval smelting site without a predecessor of that period because both partly used the same ore bodies. The smelters are situated near the ore body but never as close as the later medieval ones. The smelting debris results in large tapped slag cakes of up to 10 kg. Only furnace fragments were found in Wadi Qatof (Fig. 14). We know no details about the Iron Age smelting processes.

The largest and highest slag heap of that period is at Raki 2 near Yankul (Fig. 15). The site is located near the gossans of two large copper deposits, but they mainly used another ore location at Loch Bab. The large settlement site Raki 2 specialized in the production of copper from around 1200 until 800 BCE (Table 1).

Metallurgy in Arabia. Fig. 14 Wadi Qatof. On the rather low Iron Age slag heaps well-fired fragments of furnaces could be collected.

Metallurgy in Arabia. Fig. 15 Raki 2 near Yankul. Here a more than 4-m high slag heap represents the highest Iron Age dump of smelting waste.

Slag cakes were used like stone slabs for constructing house walls. These often were built on top of slag piles (Yule and Weisgerber 1996; Weisgerber and Yule 1999) (Fig. 16). At Semdah or Lasail the Iron Age slag heaps cover areas near the entrance to the sites. At Wadi Miadin a fortification building of that period controls the mining and smelting activities as does the fort of Qarn al Muallaq at 'Arja. Fortresses all over Oman controlled the new villages which had been created after the installation of a new subterranean system of water supply – the qanat or falaj system. The typical stone built hut tombs often survived near smelting sites, e.g. the largest cemeteries known with more than 100 hut tombs lay at the copper sites near Gebel Saleli and Bilad al Maaidin, but they also occur at Mullaq. The tombs give a strong indication for a long lasting Iron Age copper production, although scanty habitation remains.

After the first half of the first millennium BCE copper production in Oman seems to have been interrupted for a while. For the Samad period only weak hints exist. But at ʿArja there are indications of possible Sasanian occupation.

The Early Islamic Period

On first view nearly all smelting sites checked in Oman date to the Early Islamic period, because this was the latest metallurgically active period, and the ruins are therefore rather undisturbed (Weisgerber 1993). This provides a great opportunity because in other parts of the world, like Central Europe and in the Mediterranean, hardly anything is known about mining and smelting techniques of that period.

When the new mines at Lasail and 'Arja in the Wadi Jizzi were reopened at the beginning of the 1980s insights into the old mines became possible (Fig. 17). At a depth of 65 m a gallery supported by wooden props was detected. Fragments of windlasses in that depth showed that the medieval mines were entered and ores were hauled up through vertical shafts; this was also true at 'Arja.

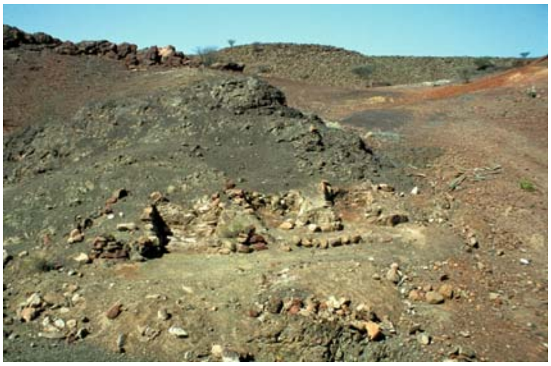
Excavations in 'Arja and Bayda yielded an interesting infrastructure (Costa and Wilkinson 1987) – a relatively well-preserved battery of three roasting pits to burn the sulphur out of the ores and two smelting furnaces. The roasting pits consist of three or more chambers which apparently were used in turn (Weisgerber 1987) (Figs. 18 and 19). Parallels can be found in the book by Georgius Agricola from 1556 (Agricola 1950). The backs of furnaces stood up to 1.40 m in height and had an interior diameter of 0.60 m. They were operated probably with natural wind draught by means of clay nozzles (tuyères). At their front metal and slag were tapped into pits (Figs. 20 and 21). In front of many furnaces, which show traces of several repairs or

Metallurgy in Arabia. Table 1 Generalized chronology

Chalcolithic	(Hafit Period)	3200–2500 BCE
Early Bronze Age	(Umm an-Nar Period)	2500–1800 BCE
Middle Bronze Age	(Wadi Suq Period)	1800–1300 BCE
Late Bronze Age/Early Iron Age	(Nizwa Period)	1300–1200 BCE
Iron Age	(Lizq/Rumeilah Period)	1200–300 BCE
Late Iron Age	(Samad Period)	300 BCE–AD 600
Early Islamic Period	AD 600–1100	
Middle Islamic Period	AD 1100–1500	
Late Islamic Period	Since AD 1500	

Metallurgy in Arabia. Fig. 16 Raki 2, near Yankul. Ruins of a house on top of a stratified heap of crushed slag.

Metallurgy in Arabia. Fig. 17 ʿ the small gossan of Bayda became exploited by a large opencast mine. In the walls several medieval galleries can be seen.



Metallurgy in Arabia. Fig. 18 ʿArja-Bayda. Battery of roasting installations. Three chambers are cut in the rock and framed by local stones.

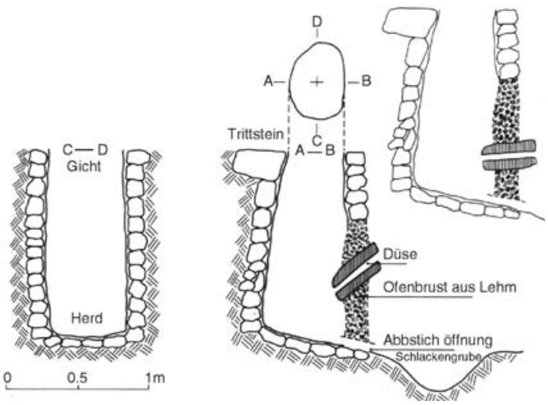
Metallurgy in Arabia. Fig. 19 Artist's view of a three-chambered early medieval roasting installation.

reconstructions, up to 6,000 tons of slag may occur (Fig. 22), giving an idea of the thousands of tons of copper produced in medieval Oman (Weisgerber 1978a, 1980a, b, 1981; Hauptmann 1985).

One may imagine that the long mining and smelting activities of the Early Islamic period over centuries led to a complete devastation of Oman's vegetation because millions and millions of trees were needed both in underground mining and in the roasting and smelting work on the ground (Eckstein et al. 1987).

M

Metallurgy in Arabia. Fig. 20 ‘Arja. Early medieval smelting furnace ‘Arja 103 after excavation. Note the closed forefront above the opening which probably had to be opened and re-closed for each smelting process and the ramp to the right for going to the top of the furnace to fill in charcoal and ores.



Metallurgy in Arabia. Fig. 21 Scheme of an early medieval smelting furnace.

Metallurgy in Arabia. Fig. 22 Tawi Raki. More than 60,000 tons of smelting remains at many production units prove that here an extremely successful mining venture had taken place. The slag heaps are clearly separated from each other. Individual smelting firms have their own smelting furnace and roaster. Between them a lot of houses can be seen.

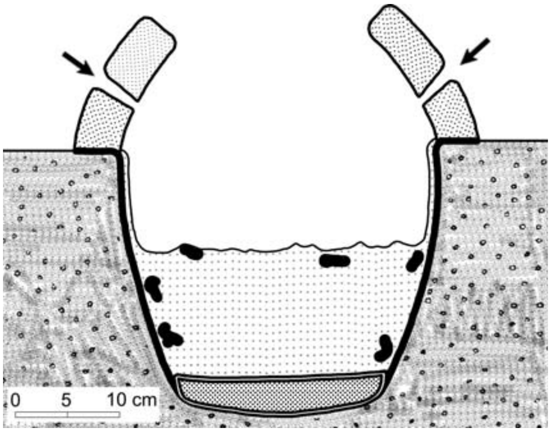
Metallurgy in Arabia. Fig. 23 ‘Arja. In the plain around Tawi ‘Arja flat fields of bowl slag indicate the late and post-medieval production of copper.

Metallurgy in Arabia. Fig. 24 ‘Arja. At Tawi ʿArja some complete slag cakes helped to reconstruct the bowl furnace. To remove the copper ingot the lower edge of the slag had to be smashed away.

The Middle and Late Islamic Period

In the area around the old well of ʿArja fields of slag cover the plain. There are no heaps or dumps but flat covers (Fig. 23). The complete slag pieces have a diameter of about 25–30 cm. The bottom is concave, the sides curved. This slag of 13–16 kg was produced in a bowl furnace dug into the ground (Figs. 24 and 25). Copper smelting in bowl furnaces took place from the Middle Islamic times to the nineteenth century (Weisgerber 1978b).

There is no mining activity which could be attributed to these periods. But all the Early Islamic slag heaps are marked by more or less circular depressions irregularly scattered in the dumps. Slag analyses confirm that they are high in copper (1–4%; Goettler et al. 1976: 47). Remains of copper and copper–matte in the Early Islamic slags were the target of this secondary digging work. And these were reduced in the bowl furnaces.



Metallurgy in Arabia. Fig. 25 Scheme of a late medieval bowl furnace. The upper part is still unclear. The 4–5 cm wide holes for the air of skin bellows were found in specially formed wall fragments. Charcoal occurs in most bowl slag cakes. Only the copper ingot below has been reconstructed.

Recent Copper Production in the Sultanate of Oman

From 1983 to 2003 Oman is once again exporting copper to the world market. Modern mines have been opened at Lasail, ‘Arja, and ‘Arja–Bayda in the Wadi Jizzi west of the old town of Sohar; a copper smelter has been constructed nearby. The mining and smelting work is connected with a new modern town, named ‘Magan’. And it is this name which gives a hint to the 5,000-years long history of copper production in the Sultanate of Oman (Mobbs 2003).

Metallurgy in China

HUA JUEMING

The earliest metal relics ever found in China are two brass artifacts from the Yangshao Culture Ruins in Jiangzai Village, Lingtong County, Shaanxi Province. They date as far back as 6,000 years ago, providing strong evidence that metallurgy germinated in China during that period. Considering that studies of possibly earlier metal relics are not done thoroughly enough, the problem of the origin of metallurgy in China has yet to be further explored.

By the latter part of the third millennium BCE, metallurgy had come into being in a number of regions, and many kinds of metal materials – red copper, primitive brass, tin bronze, and lead–tin bronze – were already used for small implements and ornaments.

The Xia Dynasty (twenty-first century to sixteenth century BCE) had evolved into the Bronze Age. In Erlitou Cultural Ruins, Yanshi County, Henan Providence, remains of foundry workshops have been discovered where bronze sacrificial vessels, weapons, implements, and casting moulds have been excavated. Apparently, the making of articles was done with casting as the main means.

The earliest copper mining and smelting ruins known in China are located in Tongling (meaning copper ridge), Ruichang County, Jiangxi Providence. Its mining can be traced back to the fourteenth century BCE. The shafts and drifts were supported by timber frames. Also excavated were ore-dressing troughs and wood winches for hoisting. Further study reveals that during Shang-Zhou Periods (Shang Dynasty: sixteenth century to eleventh century BCE; Western Zhou: eleventh century to 771 BCE; Eastern Zhou: 771–221 BCE) the mining of copper minerals had progressed to a rather large scale in the Liao River Valley and Yellow River Valley, especially in the middle and lower reaches of the Yangtze River. The smelting of copper was done in semicontinuous operation in shaft furnaces. By the late Western Zhou at the latest, copper sulfide minerals had been used to smelt copper.

The smelting technologies of lead and tin were mastered from the Shang Dynasty on. The lead vessels unearthed in Anyang have a purity of over 95%. Tin ore deposits were scattered in the Northeast, Northwest, and South China regions, especially in Jiangxi, Guangxi, and Yunnan, where tin reserves were very abundant. The early tin material must have come from these regions.

Alloying techniques improved greatly during the Shang Dynasty. The sacrificial vessels of imperial courts unearthed in Yin Ruins have a tin content of 18% or more. The book *Kao Gong Ji* of the Warring

States (475–221 BCE) recorded something about the alloy proportioning of *liu qi* (seven kinds of bronzes): *zhong* (bell), *ding* (cauldron), *fu* (hatchet), *ji* (halberd), *jian* (sword), *zu* (arrowhead), and *jing* (mirror). This indicates the craftsmen's clear understanding at that time that the mechanical performance of tin bronze varies with different contents of tin.

Shang-Zhou bronze culture was characterized by sacrificial vessels, complex in shape and delicate in design, which were mass-produced by casting. The key in achieving this characteristic without applying techniques such as the lost-wax process lays in the skillful use of composite pottery molds and various cast-joint technologies.

Beginning with the Spring and Autumn periods (771–475 BCE), it became in vogue to apply synthetically various shaping processes and decorating techniques: cast-joint, soldering, lost-wax process, forging, gilding, gold-plating, red-copper inlay, gold and silver inlay, engraving, etc. This significant change brought the manufacture of bronzes to a still higher level; the implements produced looked brighter and more colorful. As early as the late Neolithic Age, small-sized gold had already appeared. By the Warring States periods, there were more and more articles made from gold, and coins were first minted of silver. These may have been obtained by cupellation, a refining process in which metals are oxidized at high temperatures, and base metals are separated by absorption into the walls of a cupal, or porous cup made of bone ash. The production of mercury also reached a certain scale. It is recorded that a great amount of mercury used to preserve bodies from decay was found in the imperial grave of Emperor Qin.

It was far back in late Shang Dynasty that iron meteorites were used to be forged into blades and cast with bronze into weapons. This process was passed down all along to the end of Western Zhou, perhaps providing impetus to the origin of certain iron smelting technologies.

Archaeological excavations have shown that artificial ironmaking may have begun in the late Western Zhou in China. It is worth noting that the smelting and casting of pig iron began only about 200 years later, i.e., the late Spring and Autumn periods. Only another 100 years had passed before pig iron was in wide use for casting production tools, especially for farming implements, thus marking the beginning of the Iron Ages in China.

Correspondingly, a series of outstanding inventions related to pig iron came springing up one after another. Two of the most important were the iron mold casting and cast iron toughening techniques. In these, pig iron castings were changed into white-heart malleable cast iron or black-heart malleable iron through decarbonizing heat treatment or graphitizing heat treatment, respectively. Others were the later ones of puddling iron (Western Han 206 BCE–AD 8) and Guan-steel (made by smelting pig iron and puddling iron together, about the end of Eastern Han AD 25–220). These revealed a technological course of development, which, though markedly different from that in ancient Europe, led to the same goal. This unique instance in the history of technology is interesting and thought provoking.

In China, many of the most important inventions in ancient metallurgy were made before the sixth century BCE. After the fruits in the preceding times were digested and imbibed in the Tang Dynasty (AD 618–907) and Song Dynasty (AD 960–1279), metallurgical technologies in China took shape, leading to further prosperity and greater achievements. For example, in the southern regions there was full scale mining and smelting of iron minerals and others such as copper, tin, lead, gold, silver, and mercury. There were also large and extra-large castings and bronze or iron structures, etc.

It must be mentioned that the making of white copper (copper nickel alloy) was already mastered as early as the fifth century, and that during the Han and Tang Dynasties and later, metallurgy in China had exchanges with and mutual impact on the surrounding regions. Some examples are the westward spreading of iron-casting skills and the influences of Persian artistry on gold or silver wares in the Tang Dynasty.

In the Song Dynasty, wet metallurgy was put into large-scale practice to extract pure copper, annually yielding about 500 tons, which amounted to about one-third of the total copper produced in the whole country.

About 1620 in the Ming Dynasty, it was possible to smelt zinc, which was used in great amounts for minting coins. Antimony was smelted in the Ming Dynasty (AD 1368–1644), but it was not recognized at the time as a new kind of metal and thus was mistaken for tin.

Recently, some unexpected archaeological discoveries – such as the bronze culture of the ancient Kingdom Shu and the bronze groups of the late Shang in Xinggan, Jiangxi Province – indicate that there are still many mysteries in the metallurgy of ancient China which remain to be disclosed. Those disclosures would contribute greatly to academic studies.

Metallurgy: Early Metallurgy in Mesopotamia

JEAN-FRANÇOIS de LAPÉROUSE

The development of metallurgy in ancient Mesopotamia and the surrounding regions of the Ancient Near East to the end of the Neo-Babylonian period (ca. 539 BCE) represented a largely unprecedented achievement that strongly influenced the evolution of technology in much of the ancient Old World. Although the alluvial plain of the Tigris and the Euphrates was lacking in the mineral resources and fuel required to extract metals, the rise of urban centers and long-distance trade networks allowed this region to benefit from raw materials and expertise gathered over a wide area from the Aegean Sea to the Indus River valley. This technology required an investment in labor and materials that reached beyond the constraints of earlier industries and enabled advancements in many fields including agriculture, transportation, armament production and the visual arts. Although much has been learned from archaeological exploration, the study of ancient texts and the application of scientific analysis to the study of ancient materials, many aspects remain to be elucidated in a field for which the following can serve only as an introduction.

The Nature of Metals

Cuneiform texts do not reveal any evidence that Mesopotamian craftsmen sought to develop a theoretical understanding of the nature of metals and their alloys. Nevertheless, the artifacts they produced bear witness to a considerable practical knowledge accumulated from centuries of experience manipulating the raw materials at their disposal. A brief consideration of metallic microstructure provides some insight into the medium with which they were working. The atoms of each metal species are arranged in one of fourteen possible crystal lattice configurations that can be visualized as closely packed spheres arrayed within larger crystals known as grains. Metals of the face-centered cubic configuration which include gold, silver, copper, and lead – all of which were used in the ancient world – are malleable at least in part because their compact geometry limits the friction encountered in slippage between atomic planes when stress, such as hammering, is applied. When the planes begin to interlock with continued working, heating the metal in a process known as annealing enables the atoms to reorder themselves thus restoring plasticity.

Impurities introduced naturally or by intentional alloying affect both grain size and composition and may result in the precipitation of immiscible inclusions at the grain boundaries. These discontinuities within the crystalline structure can increase an alloy's hardness and brittleness which are useful for certain utilitarian purposes but may render the metal unfit for forming by hammering. At the same time, alloying lowers the melting point of the more refractory constituent – a useful quality when casting and producing solders with melting points lower than those of the surfaces being joined.

When buried in the seasonally damp and salted soils of the Ancient Near East, metals, with the exception of gold, will begin to return to an oxidized state similar to the ore minerals from which they were extracted. As a result, the structure and appearance of many of the metal artifacts recovered from this region have been altered in some way since their original manufacture. Over time, corrosion as well as the precipitation of alloy components can cause embrittlement. Corrosion usually proceeds inward along the grain boundaries producing metallic salts that deposit on the surface and often cause internal fractures due to the expanded volume of oxidation products relative to that of the original metal. Nevertheless, careful cleaning and x-radiography can reveal surface details preserved within corrosion layers and a considerable amount of evidence about an object's manufacture, and subsequent history can be gleaned by analyzing cross sections prepared from small samples taken from artifacts.

Copper and its Alloys

While valid in broad terms, the tripartite division of human civilization into the Stone (ca. 7000–3000 BCE), Bronze (3000–1200 BCE), and Iron Ages (1200 BCE–present) proposed in the early nineteenth century CE has been extensively refined. It is now known that lithic, metal and even ceramic-based tools and technologies coexisted in the Ancient Near East both earlier and later than it would indicate. The earliest extant metal objects are beads and small tools such as pins, hooks and awls made of relatively soft native copper – i.e., geological deposits of metallic copper discovered near the earth's surface – that have been recovered from eighth millennium BCE contexts at sites in Anatolia, Iran and northern Mesopotamia. While knowledge of smelting during the following millennium is implied by the presence of a lead bracelet in level 1 of Yarim Tepe in Iran, it is not until the first half of the fourth millennium BCE that clear evidence from Levantine sites – such as the impressive hoard of 416 copper alloy objects discovered at Nahal Mishmar (Fig. 1) – indicates that the extraction of metal from ores was occurring on a significant scale.

Experimentation in the annealing and melting of native copper alloys as well as the accidental reduction of copper oxide pigments during the firing of decorated pottery may have prompted initial experimentation into the smelting of metal from copper ores. Early smelting furnaces, such as the late fourth millennium BCE example excavated at Timna in the southern Negev, consisted of a bowl or pit cut into the ground that was packed with dressed ore and charcoal – the latter providing both heat and carbon which combined with and removed oxygen. High temperatures were attained by drafts of forced air supplied by bellows inserted into the fire whose tips were protected from burning by refractory ceramic cones known as *tuyères*. At around 1,083°C – the melting point of pure copper – molten metal would puddle at the bottom of the furnace while the lighter, silicaceous impurities of the ore, known as the *gangue*, would separate out with the aid of a flux forming a layer of slag. Since both slag and *tuyères* were discarded in situ, they provide evidence of metallurgical activity at particular sites even in the absence of metal artifacts which were often hoarded and recycled.

Metallurgy: Early Metallurgy in Mesopotamia. Fig. 1 Objects from the hoard found at Nahal Mishmar. Copper alloy. Levant, first half of the fourth millennium BCE (Israel Museum, Jerusalem). Roaf 1990 (Photo: David Harris).

Much of the initial smelting took place in the mountainous regions surrounding Mesopotamia that possessed mineral resources as well as extensive forests for producing charcoal. After an initial extraction, further refining could be achieved by repeated smelting in crucible furnaces at or near the workshops where artifacts were produced. Copper mines in the highlands of Iran, accessible by overland routes, appear to have been an early source of metal for the urban centers that arose in southern Mesopotamia – the heartland of ancient Sumer – during the period which is named after the important city of Uruk (ca. 3800–3200 BCE). With the expansion of seaborne trade fostered by the city-states of the Early Dynastic period (ca. 3000–2350 BCE), ore sources in Oman, which has been identified with the Magan of ancient texts, as well as the eastern lands of Aratta and Meluhha, both of which most likely received partially refined copper from various sources in Iran and Central Asia, increased in importance. The island of Dilmun – modern Bahrain – was well situated near the southern end of the Persian Gulf to serve as a mediator in this maritime copper trade particularly in the late third and early second millennia BCE. To the west, the copper mines in Anatolia supplied copper to production centers in the Levant and northern Mesopotamia from an early period and provided the raw materials for an indigenous tradition of sophisticated copper metallurgy exemplified by the late third millennium BCE objects found at the central plateau sites of Alaca Höyük and Horoztepe (Fig. 2). With the rise of important trading cities on the Levantine coast in the mid-second millennium BCE, the importation of Cypriote copper to the region also increased.

While bronze, an alloy of copper and tin, is attested in texts and objects dated to the beginning of the Early Dynastic period, modern analysis has indicated that for many centuries the copper used in Mesopotamia actually contained low concentrations of arsenic, nickel

Metallurgy: Early Metallurgy in Mesopotamia. Fig. 2 Bull Standard. Copper alloy and electrum. Height: 48 cm. Alaca Höyük, Anatolia. Late third millennium BCE (Ankara Museum of Anatolian Civilizations, Turkey, 11850) Aruz 2003 (Photo: Bruce White).

and other elements (often referred to as arsenical copper) and that the use of tin only gradually increased toward a standard concentration of around 10% as that of arsenic decreased. Arsenical copper has often been viewed as bronze's inferior precursor – a soft alloy that was unfit for most practical purposes. However, ancient metalworkers appear to have been aware that this alloy could be effectively work hardened by hammering and cast more easily than pure copper, making it a useful alloy.

It has been suggested that the progression from native copper to bronze alloys reflected the nature of the ore deposits being exploited (Tylecote: 7–9). In many copper ore bodies, the layer closest to the surface and most easily exploitable consists of copper carbonates and oxides as well as native copper. Below lie two copper sulfide deposits which must be oxidized by "roasting" in an open fire before smelting. Of these, the uppermost layer, which is enriched by copper washing down with ground water from above, contains the highest concentration of impurities including arsenic, nickel and antimony. As these arsenic-containing deposits gradually became depleted by ancient miners, it is possible that the need for a new alloying metal promoted the use of tin. However, recent archaeological work indicates that the actual situation may have been less straightforward, as complex ores containing different mixes of impurities were cosmelted from an early period. In addition, the possibility that arsenic in some form was intentionally added remains a matter of debate.

Tin is not usually found as a natural impurity in copper ores and tin deposits are relatively rare. While evidence of tin mining in eastern Anatolia indicates that this area may have been a source of this metal at least in the Early Bronze Age, the primary source of this metal appears to have been the Badakhshan region of Afghanistan where oxidized tin is associated with alluvial deposits of weathered granite. Afghanistan is also thought to have been a primary source of the lapis lazuli, gold and semiprecious stones that played an important role in Sumerian art of the mid-third millennium BCE. This is seen most impressively in the finds from the Royal Tombs of Ur (Figs. 15 and 16), when bronze alloys increasingly were used. Like these prized materials, tin may have been traded initially as a precious commodity used in the production of highly valued objects. Early in the succeeding millennium, however, cuneiform texts indicate that large quantities of tin – presumably obtained in the East – were being transported up the Euphrates to the ancient city Mari from where they were distributed to other urban centers. During approximately the same period, merchants from Ashur, the historic and spiritual capital of the land of Assyria in northern Mesopotamia, established a merchant community (*karum*) at Kanesh in central Anatolia where tin and textiles were exchanged for locally obtained precious metals.

Gold and Silver

While gold and silver objects have been recovered from early contexts in northern Mesopotamia and Anatolia, it is not until the third millennium BCE that significant numbers of precious metal objects were being produced across the entire region. Gold, found in many of the lands encircling Mesopotamia, was retrieved from alluvial deposits in nugget form or gleaned from quartz veins by grinding and separation in water. Native gold usually contains some silver and copper or these metals could be intentionally added to achieve desired working properties and/or color. Natural or artificially produced gold alloys with high silver contents, such as the inlays in a copper alloy standard from Alaca Höyük (Fig. 2), as well as the jewelry and ingots found by Schliemann in Early Bronze Age levels at Troy, are known as electrum. Alternately, gold could be refined by the preferential oxidation and removal of the baser elements from the parent metal. This process, known as cementation, is alluded to in textual evidence dated to the first half of the second millennium BCE and may have been practiced even earlier. A recent study of a dagger from Ur suggests that a similar process of surface enrichment known as depletion gilding, which was independently developed in the pre-Columbian

New World, was practiced by Sumerian metalworkers in the mid-third millennium BCE (La Niece 1999).

Although some smelting of silver ores may have occurred, most ancient silver appears to have been obtained by cupellation from argentiferous lead ores mined in mountains of Turkey and Iran – two regions that displayed an early expertise in silversmithing. In this process, the ore was heated in porous bone cups, or cupels, that absorbed oxidized lead, leaving behind silver droplets that were collected and melted together. The earliest archaeological evidence of this technology in the region has been found at the site of the Late Uruk city of Habuba Kabira which was located on the Euphrates River in what is now the country of Syria.

Metalworking Techniques

Forming objects by hammering and annealing, first attested in the earliest copper artifacts, remained an important manufacturing technique throughout the history of the Ancient Near East. Worked sheet was used to make simple tools, vessels (Figs. 3–5) and relief decoration (Fig. 6). Vessels were formed by sinking or raising which involved hammering in concentric circles on the inside or outside surface, respectively, of the container being formed sometimes with the aid of a form. Decorative reliefs and friezes were formed by repoussé in which figures were raised against a flat background plane by light hammering from the reverse. After forming, fine linear details were added by lightly tapping metal tracers with various shaped heads on the surface which displaced the metal forming lines and decorative patterns as seen in the figural decoration on a silver vase dedicated by Enmetena, a ruler of the city-state of Lagash, to the god Ningirsu around 2400 BCE (Fig. 7). A masterful example of all these combined techniques is also provided by in a cylindrical silver container attributed to western Central Asia of the late third–early second millennium whose surfaces virtually erupt with lions, bulls and wolves in extraordinarily high relief (Fig. 8).

Worked metal sections were joined to produce some of the earliest known metal sculptures in the round. The ability of ancient silversmiths to produce sensitively modeled, naturalistic figures on a small scale through the careful combination of separately formed components is demonstrated by an anthropomorphic kneeling bull attributed stylistically to the Proto-Elamite culture

(3000–2800 BCE) of western Iran (Fig. 9). Worked sheet was also used to create large freestanding figures with a minimal use of metal. The bull statues that originally adorned the façade of the Early Dynastic IIIB (2400–2250 BCE) Ninhursaga temple at Tell al Ubaid featured bodies consisting of worked copper alloy plates that were nailed onto carved wooden cores. Before its cladding, the wood was coated with a pliable

bitumen layer in order to support the metal during its final chasing (Fig. 10).

Various casting methods also were employed according to the type of object being produced. Open-faced moulds may have been used to produce flat tools such as the sickles found in a hoard of mid-second millennium farming implements from Tell Sifr in southern Mesopotamia (Fig. 11). Bivalve moulds were used to cast solid objects of simple shape. Reusable moulds – which varied in complexity from the late third millennium BCE stone mold for casting trinkets and jewelry such as the example found at Sippar (Fig. 12), to a Neo-Assyrian multipart metal mould for simultaneously casting several arrowheads – were used to mass produce identical castings. Such easily portable molds, which may have been owned by itinerant craftsmen, enabled the widespread diffusion of cultural forms and metalworking expertise.

Aruz 2003 (Photo: The University of Pennsylvania Museum of Archaeology and Anthropology).

It was the technique of lost-wax casting, however, that provided Mesopotamian craftsmen with their greatest opportunity to display their metallurgical and artistic skills. First attested by the intriguing "standards" and "scepters" of the Nahal Mishmar hoard, this technique was sufficiently advanced by the Akkadian period (ca. 2350–2100 BCE) to facilitate the production of the earliest large scale metal sculptures known from the ancient world including the head of an ruler and the lower half of a male figure on an inscribed base, both dated to the Akkadian period and found in northern Iraq (Figs. 13 and 14) (see Extra). Lost-wax casting begins with the sculpting of a model in wax or other thermoplastic material that is covered – or invested – with clay and fired, causing the wax to melt out through channels provided in the investment. During casting, these channels provide access for the molten metal to enter the mold and egress for gases evolved that could impede its flow. In order to reduce the amount of metal required as well as the risk of casting flaws, the model can be fashioned over a core of refractory clay that is held in place by metal supports inserted through the investment and into the core before the removal of the wax. After casting, the investment is broken away and the core supports are removed down to the surrounding surface.

Bronze – often with the addition of minor amounts of lead – is an excellent casting alloy, as tin can lower the melting point of copper by as much as 200°C and inhibit the oxidation of copper which can lead to casting flaws. Since the use of tin is so advantageous,

its absence in many of the copper alloy sculptures produced before the Iron Age has often been attributed to disruptions in the tin trade. That other factors may have influenced the composition of the metals used, however, is suggested by the sculpture of the Middle Elamite Queen Napir-Asu (ca. fourteenth century BCE) that was excavated in Iran at the site of the ancient city of Susa. The outer shell of this life-sized metal sculpture was cast by the lost wax method over a ceramic core using copper containing only 1% tin (Meyers 1996). For reasons that remain unknown, the ceramic core was subsequently removed and the void was filled with a bronze alloy containing 11% tin (Fig. 15). That the more intractable alloy was used for casting the outer shell even when tin appears to have been on hand may be due to the fact that a considerable amount of work was required to remove and/or patch casting imperfections and to add surface details and inscriptions with tracers after casting. Before the advent of hardened iron alloys that could engrave or cut into copper, this work may have been easier to execute on relatively pure copper rather than on bronze.

Although some casting of precious metals occurred, the rarity of gold and silver dictated that they be used more economically in sheet form to create vessels, jewelry and small figures. The numerous elements of gold sheet used in the elaborate headdress of Queen Puabi found at Ur undoubtedly created a striking visual and aural impression when worn (Fig. 16). Silver and gold also were also beaten into foil or very thin leaf that was used in the embellishment of baser materials in objects destined for elite or sacred use such as the lyres and rearing goat statues also found at Ur

(Figs. 17 and 18). Grooves for mechanically locking metal foils in place found on copper alloy sculptures – including that of Queen Napri-Asu – indicate that metal surfaces could also be partially or fully gilt.

In addition to mechanical joins involving nails, rivets, crimping and casting onto existing metal surfaces, metallurgical joins were made using solders of various compositions. The use of soft (i.e., lead/tin) solders, which melt at low temperatures and are difficult to control, was mainly relegated to joins in copper alloy objects that would not be readily visible. Metallurgical joins on precious metal objects were made either by carefully heating metal surfaces until they fused – a technique known as "sweating" – or by using hard solders containing copper which has a lower melting point than either silver or gold. Ancient metalworkers were very skillful at exploiting minor differences in the melting temperatures of these hard solders when constructing complex objects. For example, the seventeen sections of the Proto Elamite kneeling bull noted above were joined using silver solders containing increasing amounts of copper – and consequently lower melting points – as the figure was assembled, thus ensuring that previously made joins would not fail each time the appropriate amount of heat was applied. Elements in gold jewelry also could be affixed in place

Metallurgy: Early Metallurgy in Mesopotamia.

using a colloidal hard solder consisting of an organic binder such as animal glue mixed with ground copper salts. When heated, the combustion of the glue provided a locally reduced atmosphere that aided the diffusion of copper ions into the adjacent gold to produce a strong and virtually invisible join that was ideal for affixing tiny gold grains in granulation work as well as other joins in complex jewelry constructions (Fig. 19).

The Advent of Iron

While iron oxide minerals and pigments as well as meteoric iron had been used for centuries, the use of iron alloys did not become widespread until the early first millennium BCE, following an early development in the region whose specific origins remain obscure. The late appearance of iron is ascribed to the relatively complicated processes required to obtain and fashion usable iron objects. Due to a melting point – almost 500°C. above that of copper – that exceeded the capability of early Mesopotamian pyrotechnology, iron could not be directly separated from its slag or melted for casting. (In the ancient world, only the Chinese craftsmen appear to have developed the technology for casting iron.) At about 800°C, the mass obtained from the furnace – known as the bloom – required repeated heating, folding, and hammering to squeeze out the slag and provide a metal that could be shaped by forging. While forging largely limited the use of iron to the production of utilitarian objects such as tools and weapons, skillful smiths could fashion complex shapes such seen by a the multipiece sword attributed to the Luristan region of southeastern Iran in the first half of the first millennium BCE (Fig. 20).

Metallurgy: Early Metallurgy in Mesopotamia.
Fig. 20 Multipiece sword. Iron. Length: 50.1 cm. Luristan, Iran. 750–650 BCE (The Metropolitan Museum of Art, New York, H. Dunscombe Colt Gift, 1961 61.62). Muscarella 1988 (Photo: Photo Studio, The Metropolitan Museum of Art).

Initially, wrought iron objects were relatively soft and it was only with the development of techniques such as carburization, in which carbon was introduced at the surface to form low carbon steel, and quenching, which preserved crystalline phases and structures normally found at high temperatures, that useful cutting edges harder than bronze could be produced. Although this technology was not completely mastered in early Mesopotamia, the relative abundance of iron ore deposits allowed for a dramatic increase in the use of this metal in the production of tools, weapons and armor from the Neo-Assyrian period onward (Fig. 21). Unfortunately, the extensive deterioration and loss of many early iron artifacts has often complicated a full reconstruction of early ferrous metallurgy.

As outlined above, almost all of the metalworking techniques used up to modern times were developed in the Ancient Near East. In addition, the long distance trade spurred by the demand for raw materials and metal artifacts resulted in the widespread dissemination of technical knowledge and artistic styles across the entire region. The study of recent archaeological discoveries such as the Early Bronze Age copper manufactory at Khirbat Hamra Ifdan in the southern Levant (Levy et al.), as well as the continued examination and analysis of artifacts, will undoubtedly broaden and revise our understanding of the interaction of culture and technology during this crucial period.

Extra: Head of a Ruler

Based on its style, purported Iranian provenance as well as the perceived ethnicity of its facial features and hair treatment, the *Head of a Ruler* now in The Metropolitan Museum of Art in New York has been attributed most often to the Elamite cultural sphere of the late third millennium BCE (Fig. 22). Whether or not it is a true portrait, this cast copper sculpture possesses a strikingly life-like presence that is enhanced by specific features such as the broad nose, deeply set eyes and prominent ears. The eye sockets, which are now empty, were probably inlaid with shell or stone. A tang projecting from the plate across the bottom of neck indicates that this head was attached to a body or other mount that may have been made of another material.

Long thought to be virtually solid, radiographic cross sections recently obtained by computed tomography revealed that this head contained a core and may be among the earliest examples known of life-sized hollow casting. In addition to locating the position of core supports, this examination found internal porosity associated with the casting flaw on the right side of the beard as well as voids around the ears which may indicate that they were made separately and joined to the wax model of the head before casting (Fig. 23). If such is the case, then this head bears some similarity in technique to an Akkadian period copper head found at Nineveh that is now in the Iraq National Museum in Baghdad (see main text Fig. 12 and Strommenger 1986).

Metallurgy in Egypt

Gregg De Young

Gold, silver, lead, and copper were among the metals exploited by Egyptians since the pre-Dynastic period (prior to ca. 3100 BCE). The main sources of these metals were the deposits in the ancient rocks of the Eastern Egyptian desert near the Red Sea and in the Sinai. Iron implements, although present in Egypt from the 26th Dynasty (ca. 665–525 BCE), did not become common until the Ptolemaic period (305 BCE–30 BCE), for Egypt had no access to major sources of iron ore. The most common metals for daily use were copper and bronze (a copper–tin alloy).

With no written descriptions of the mining or metallurgical operations we rely on vignettes of metalworking that appear in some funerary art for our understanding of the processes involved in procuring metallic resources. Of course, some nuggets of relatively pure metals can be found, but these were certainly used up very quickly, forcing the ancient Egyptians to learn the techniques for exploiting deposits of metal ores. Mines might be either open shallow pits or underground tunnels following promising veins of ore. The remains of ancient mine shafts and miners' stone tools, as well as heaps of waste, still indicate many of these sites. By the time of the New Kingdom (ca. 1550–1085 BCE), Egypt probably was relying more and more heavily on imports of copper, as well as tin and iron to meet its needs for metal implements.

There is some evidence to suggest that an initial extraction of the metal from the ore matrix took place in the vicinity of the mine itself. Extraction of the metal involved either roasting (heating the ore with charcoal in the open air) or smelting in closed furnaces using either the addition of coke and silicate particles to absorb impurities and aid in reducing the oxides to metallic form or a forced air blast through the molten slag to oxidize impurities and so free the metal. These effects require a high temperature that is only achieved though use of blowpipes or bellows to feed oxygen to a charcoal fire. Many ancient peoples knew the technical processes. In the context of ancient Egypt, however, we should not forget the geographical setting in which trees were not plentiful. Large-scale building projects, such as pyramid construction, therefore, which require extensive metallurgical implements, must have placed many strains on the natural economy and demanded complex administrative planning for their completion.

Pure copper is relatively soft, and so nearly useless for many implements. When hammered, it rapidly becomes harder and more brittle. This hardness may be removed by annealing (heating the metal above 500°C and allowing it to cool again). Many early edged implements were apparently shaped through repeated hammering and annealing, ending with a final hammering to harden the cutting edge.

Other metal products might be formed by casting (pouring molten metals into a pre-shaped stone or ceramic mold) and allowing the metal to cool and harden. For metallic objects not requiring solidity, the "lost wax" technique of casting used less of the precious metallic resources. In this process, the object was first modeled in clay or some other heat-resistant medium. This model was then coated with a layer of wax of uniform thickness. The wax, in turn, was completely surrounded by yet another layer of clay or plaster, leaving only a small opening into the wax-filled layer. The mold was then heated, melting the wax, which ran out through the drain provided. Through this opening, molten metal was then carefully poured in order to avoid formation of gas bubbles that might mar the finished product and allowed to cool.

The formation of gas bubbles is difficult to avoid with pure copper, since it absorbs gases which then produce bubbles that weaken the final product. If, however, a bit of tin is added to the copper, the results are significantly improved. Alloying copper with about 10% tin also produces a considerably harder and more durable metal, bronze. Bronze, therefore, was widely used for tools and weapons from the time of the Middle Kingdom (ca. 2150–1780 BCE) until replaced by iron implements late in the New Kingdom period (after ca. 1000 BCE). Since tin is not found in commercial quantities in Egypt, it is not certain whether bronze was imported as a semi-finished product or was internally produced with imported tin.

Metal tools such as chisels, knives, axe heads, and adzes are common in funerary collections and are often portrayed in Egyptian art. Another major use of metal was in the production of weapons: daggers, swords, spears, and battle axes. Defensive armor, such as mail coats (made by riveting small bronze plates onto leather jerkins) first became common during the New Kingdom period. Protective helmets also appear to be a relatively late innovation, although some tomb paintings from the Ramesside period (ca. 1290–1225 BCE) show foreign mercenaries equipped with protective headgear. A third important use of copper (and later, bronze) was in the production of domestic articles such as cauldrons, ewers, basins, and ladles. Mirrors of polished metal were common throughout the dynastic period. Excavators have also found pins, tweezers, and razors.

The gold deposits of the eastern Egyptian desert and Nubia were the largest in the ancient world, so perhaps the techniques for extracting gold and its alloys, as well as methods for working them, were discoveries of the inhabitants of the Nile valley. We cannot be certain, of course, for such knowledge was handed down from father to son and from master to apprentice without being recorded.

Sheets of metal, whether gold, silver, copper, or bronze could be worked by a variety of techniques to produce decorative effects. Repoussé is worked from the back of the metal sheet so that the design stands out on the front in raised relief. Chasing is relief worked from the front of the sheet by hammering down the background while leaving the desired figures raised in the foreground. Engraving, also worked from the front of the piece, means cutting a groove into the metal during which a portion of the metal is actually removed. Tracing, which leaves a similar effect, does not remove any metal from the piece.

Sometimes it is desirable to join together pieces of worked metal to form an object. The ancient Egyptians knew how to use a variety of soldering techniques effectively. In soldering, a metal or alloy with a melting point lower than that of the metal pieces to be joined is allowed to flow along the seam. On cooling, the two metal parts are joined together. Since the ancients rarely worked with pure gold or other metals, the choice of suitable solder was very important. For example, gold and copper melt at very nearly the same temperature (1,083 and 1,063°C, respectively). If 10 parts by weight of copper is added to 90 parts of gold, however, the mixture's melting point is only 940°C. Thus, if one were working with relatively pure gold, a gold–copper alloy might prove a suitable solder to use. A somewhat similar technique, sweating, involved coating the edges of the pieces with the solder, bringing the edges together and heating until the jointing compound melted, without adding further solder. This latter often makes a neater join than does soldering.

There has been considerable debate about whether the ancient Egyptians knew how to draw wires. There exist, both physically and in funerary art, numerous examples of what seem to be beads strung on wires. It is not clear, however, whether these were truly wires or merely thin strips cut from a sheet of metal using a chisel, for example, or whether friction with the beads of the jewelry might be the true cause for such strips to appear round like modern wire. Since Egyptian beads were manufactured by drilling a hole through stone or metal, there would be ample room for frictional forces to enter the manufacturing process.

Jewelry was an important adornment of both gods and humans. In ancient Egypt, people wore jewelry for a variety of purposes. Perhaps the most important was as amulets to protect the wearer from evil forces that seemed to surround human life on every side. Gold itself was considered magical, identified by some with the flesh of the gods since gold, among the metals known to the ancient Egyptians, was least susceptible to tarnishing and change. Precious stones were also used, along with natural objects such as the claws of a ferocious creature (who may have been considered to embody the powers of the god). Jewels could also be used, perhaps as an extension of their magical power, to enhance the sexual attractiveness of the wearer. They could also, as today, serve as symbols of status and wealth. We have reports of Pharaohs giving golden collars or other ornaments to their favorites as a mark of distinction. Jewelry was also essential to the burial customs of the Egyptians. Finally, jewelry could indicate the power to carry out royal prerogatives delegated by the Pharaoh. The man who held the king's signet ring or royal seal, for example, carried enormous responsibilities, both politically and religiously.

Jewelry making seems to have been an important activity in relatively few centers of culture and political power. Since gold was mainly the possession of royalty, it seems probable that jewelers who supplied the royal household with golden ornaments enjoyed considerable social and economic status. Three overseers of goldsmiths had tombs at Thebes, as did two goldsmiths, indicating a fairly high social status. Of course, the workers who actually carried out the designs of the jewelers must have had a lower social status, but they were not of the lowest social class. Skilled workmen in metals would always have been in demand, and this demand would translate into at least a modest level of social prestige and influence.

Metallurgy in Meso and North America

RUBEN G. MENDOZA

Native American metallurgical technologies held great attraction for sixteenth century European empires seeking to stake claims in the American New World. While the technical feats and mastery of Native American metalworks have only recently generated systematic scientific inquiries (Benson 1979; Lechtman 1979, 1984, 1991; Lechtman et al., 1982), the attraction of Mesoamerican and Andean precious metals has resulted in the plundering of massive quantities of these metals – often in the form of jewelry and other materials – from ancient centers where they served both ceremonial and funerary functions. Precious metals craftsmanship was an ongoing enterprise at the time of the Spanish conquest of the Inca state in 1532; heirloom items, ritual caches, and funerary offerings fed the raging smelters of European outposts in the New World for the duration of the colonial period. The crafted booty delivered to Fernando Pizarro by the Inca nobility, as ransom for the Inca Emperor Atahualpa, occupied nine forges for four months in 1533; this, in order to smelt the over 26,000 pounds of silver and 13,420 pounds of gold jewelry and other reliquary collected as tribute at that time. For the Spaniards, gold and silver were the fuel that propelled the expansion of the Holy Roman Empire; while for the Inca, gold, and silver symbolized the sweat of the sun and the tears of the moon, and thereby, the cosmologically ordained male and female principles, respectively.

Much of the precious metal processed by early European colonists in the New World was smelted from intricate works of art crafted into jewelry sewn into elaborate blankets, capes, shawls, and other clothing, as well as worked into ritual and funerary art and furnishings, weapons of war, and medical and agricultural tools (Easby 1974). Ancient and large-scale metallurgical workshops and industrial centers are known from the *patios de Indios* (native workshops) of Colombia, and from such ancient centers as Atzcapotzalco, Mexico, where craft guilds were a significant aspect of the economic and social landscape.

The growing international black market in antiquities has both hastened the looting of ancient sites containing pre-Columbian metal craft, and has, by extension, spurred the collection and preservation of these works as priceless relics of a bygone age. When one takes into account the fact that individual tombs from sites such as Batan Grande, Peru, contained as many as 200 gold objects, much of which consisted of tall – 30 cm – gold beakers, it is no wonder that much of this legacy has already been destroyed. Other funerary chambers, like that of Tomb 107 at Monte Alban, Oaxaca, Mexico, contained a veritable treasure trove of over 500 precious metal and stone objects recovered by Mexican archaeologists in the 1930s. Other archaeologically documented precious metals caches have been recovered from Zaachila, Oaxaca, and Coclé, Panama. Where bronze craftsmanship is concerned, individual tombs have produced upward of 500 kg of such metals worked from alloys of tin and arsenic–bronze. Given the notoriety of such discoveries among grave robbers and the general public, it should be of no surprise that looters persist in destroying ancient sites in search of treasures.

The recent discovery and subsequent excavation of the tomb of the warrior-priest of the ancient ceremonial center of Moche, Peru – which contained a collection of dynastic relics and funerary items of gold, silver, and alloys of copper and tin – was initially brought to the attention of the scientific community as a result of looting. Despite such destruction, archaeologists and other investigators continue to document the technical achievements of Native American metallurgists of Peru, Mesoamerica, Central, and North America (Shimada et al., 1983).

In 1921, Swedish ethnographer, Erland Nordenskiold began research into technical secrets made apparent through metallurgical analysis of ancient metal objects from South America (Linné 1957). Nordenskiold ascertained that pre-Columbian metalworks were far more technically sophisticated than imagined at that time. He made a number of observations concerning metallurgical problems, including those pertaining to the metallurgical composition of *tumbaga* (a complex alloy of copper and gold, or copper, gold, and silver), soldering with silver, and the welding of copper. The technical analyses completed by Nordenskiold were a precursor to the sophisticated analyses now undertaken by archaeologists, and metallurgists, using a variety of techniques ranging from replicative experiments – where the objects themselves are reproduced with known ancient methods and technologies under controlled conditions – to physical and chemical tests to ascertain the composition and construction of the alloys employed in the creation of pre-Columbian metal objects (Shimada 1988; Meeks et al., 2002; Lechtman 1991).

The body of ancient technical secrets relevant to the manufacture of pre-Columbian metal objects has grown considerably since the first European observations of Native American metallurgical techniques in the sixteenth century.

The Old Copper culture, which flourished from 3000 BCE to 1000 BCE along the shores of Lake Superior in North America, is credited with having introduced the earliest known metalworking tradition in the Americas. This tradition was the basis for later developments in the use of copper and related metals by Hopewellian and Mississippian peoples of the first-millennium CE. Old Copper culture sites have produced evidence of significant early metallurgical techniques, including cold hammering, hammer welding, annealing, and the production of socketed metal tools, conical points, knives, axes, chisels, awls, harpoon heads, and a variety of projectile point types derived from prototypes of stone, horn, shell, and bone. To this list we can add sheet metal, intricate sheet metal cut-outs, repoussé decoration, crimping, riveting, the gold sheathing of copper, gold and copper beads, and the hammer-welding of silver and copper, or "copper and meteoric iron to produce bimetallic objects" (Easby 1966, 1974). This demonstrates an early, independent, and regional tradition in the art and science of metal craft.

The lost-wax, or *cire perdue,* casting process was first employed in the region of Colombia by 100 BCE, but quickly spread into Ecuador, and lower Central America (Panama and Costa Rica), and was subsequently adopted in Peru and Mesoamerica by AD 800 (Hosler 1986). Ultimately, according to historian Easby (1966), lost-wax casting achieved "its highest development in the Oaxacan area of Mexico, where during the fifteenth and sixteenth centuries AD Mixtec master craftsmen produced little hollow castings that are unrivaled for delicacy, realism and precision."

Where Mesoamerica is concerned, the North American tradition of cold hammering and annealing, and that of South America, consisting of cold hammering, annealing, and casting, inspired the initial development of three distinct Mesoamerican metallurgical traditions. These traditions include those that emerged in the areas of upper Central America or southern Mesoamerica (including southern Mexico, Guatemala, Honduras, and El Salvador); the Pacific coastal lowlands including the Tarascan culture area, and the Mexican Gulf Coast lowlands and Yucatan Peninsula which encompassed the ancient Huastec, Totonac, and Maya cultures. Archaeologist Hosler (1986) argues that the relatively late adoption of metallurgy in Mesoamerica – after AD 700 – serves to explain the largely elite character of the Mesoamerican metallurgical tradition. While both South and North American metalcraft evolved from a utilitarian foundation centered on the manufacture of agricultural implements and other tools, trade and exchange in precious metals ultimately inspired the Mesoamerican metallurgical tradition. Hence, the wholesale and widespread adoption and exchange of metallic axe monies, tokens, and precious-metal objects.

While recent studies have yet to establish definitively the earliest dates identified with the origins of bronze metallurgy, Lechtman (1986) argues that arsenic bronze was in use in northern Peru by the fourth-century AD. Tin–bronze originated in highland Bolivia by AD 700, and, by the Inca era (ca. AD 1450) spread throughout the areas identified with the modern states of Peru, Bolivia, Chile, and Argentina. Finally, metallic money – in the form of copper axe blades and tokens – appeared in Ecuador by AD 1000 and quickly spread throughout South, Central, and Middle America.

The holistic nature, independent development, and antiquity of Native American metals craftsmanship are only now beginning to be clarified (Meeks et al., 2002). Metallurgical technologies that were developed by pre-Columbian craftsmen are far too numerous to discuss in any detail in this essay. However, a partial listing should provide some idea of the significance of this legacy. Those identified to date include (a) the *cire perdue* or lost wax casting process, (b) surface metallurgy, depletion gilding, acid pickling, and tumbaga, (c) the application of organic reagents and binding emulsions, (d) arsenic, copper–arsenic, and tin–bronze casting, (e) copper–arsenic, tin, and bizmuth alloys, (f) silver chloride coatings, (g) gilt copper sheeting, gold and silver sheathing, sheet metal processing and fabrication, mechanical crimping, gold-leaf treatments, hammer-welding, and the raising of sheet metal vessels, (h) silver/silver–copper/spot solder and soldering, (i) copper soldering, brazing, and spot welding, (j) electrochemical replacement plating, (k) complex annealing, cold-hammer and anvil, binary and ternary alloy processing, and ground and hammered meteoric iron implements, (l) charcoal-fed ore reduction and air-blast smelting/refining furnaces, (m) iron ore or hematite flux, and the reduction of sulfide ores, (n) open cast, multicomponent, and vented casting molds, and powdered carbon casting emulsions such as that of the Aztec *teculatl* (charcoal water), (o) mechanical and metallurgical joins including metal nails, rivets, staples, ribbon clips, strip clips, lacing, long sockets, short tabs, tab-and-slot and other metal fasteners, (p) repoussé and other embossed sheet metal applications, including cinnabar cloisonné, (q) solid-state diffusion bonding, sweat welding, fusion gilding or Sheffield plating, and cladding, (r) slush casting, (s) multicomponent sheet metal miniatures, (t) color surface and powder metallurgy, (u) technologies for the manufacture of thin cast rods, wire coils, strip wire, wire-work surfacing and filigree, metal sequins, quad metal mosaics, architectural cramps, agricultural blades and implements, socketed chisels and related tools; and copper and bronze axe blades, metallic monies and tokens, (v) arsenic and tin–bronze implements including fish hooks, eyed needles, pins, depilatory tweezers, and surgical instruments such as *tumi* knives and blades, (w) the standardization of metal ingots and tools, (x) platinum plating, ore processing, and the sintering of refractory metals such as platinum, and finally, (y) a variety of prospecting methods, including shallow shaft mining, the strip mining of exposed deposits, and the placer mining of alluvial gold and platinum. According to Lechtman, the tumbaga alloys alone "constitute the most significant contribution of the New World to the repertoire of alloy systems developed among ancient societies." It should be noted that the processing of platinum (which has a melting temperature of 3,000° Fahrenheit), was a feat accomplished by ancient Ecuadorian metallurgists by way of the "mixing of grains of platinum with gold dust" through a powder process identified with the "sintering of refractory metals" (Easby 1966; meaks et al., 2002).

Electrochemical replacement plating and depletion gilding, developed by the Moche of Peru nearly 2,000 years ago, allowed ancient Native Americans to plate precious metals on to semiprecious metals to a thickness of less than 1 μm. This electrochemical replacement process was not rediscovered until the twentieth century CE. Recent studies indicate that electrochemical replacement plating and depletion gilding or silvering "both involve sophisticated chemistry, and pre-Columbian surface metallurgy is surely as much chemistry as it is metallurgy" (Lechtman 1986). As Easby says, "the tale persists that the egotistical Benavento Cellini spent months trying to ascertain how an ancient Mexican craftsmen had fashioned a silver fish with gold scales and finally conceded that he was baffled." Unfortunately, as is the case with so many other aboriginal New World technological innovations, the very presence of such metallurgical traditions as that of the lost-wax casting process and tin and arsenic–copper bronze alloys was once taken to indicate that such technologies were introduced or diffused from the Old World.

Recent archaeological investigations underscore the paucity of information pertaining to metallurgy currently at our disposal, as well as the abundance of ancient archaeological materials that have yet to be studied in any systematic fashion (Lechtman 1986). Unfortunately, the relatively recent and highly specialized nature of publications pertaining to pre-Columbian metallurgy have led some scholars to suppose that even the most ingenious ancient Native American technologies were little more than isolated or accidental instances of technical insight and ingenuity. Such scholarly perspectives are clearly artifacts borne of the relative scarcity of and limited access to information. As the body of studies grows, it is becoming clear that innovations in metallurgy, such as depletion gilding and electrochemical replacement plating, were far more ancient and widespread than once thought.

While the wholesale destruction of the pre-Columbian world has closed an important window on the cosmology and beliefs of its metallurgists, we can nevertheless advance interpretations as to the social and ritual significance of metals based on contact-period and ethnographic accounts.

Both Inca and Aztec craftsmen, and Native Americans more generally, identified precious metals – gold and silver – with the male and female principles. The alloying of copper and gold, or, copper, gold, and silver, which produced a red, pink, or golden metal known as *tumbaga*, was in turn identified with the menstrual flow and ambered moon. Among the contemporary metals craftsmen of west Africa, smelters are designed to symbolize the female sexual organs, while the metals themselves are thought symbolic of the male principle embodied in semen and other bodily fluids. The cosmological message inherent in the metal itself, when combined with the supernatural and religious icons and images, must surely have served to enhance the power and prestige of the bearer, while at the same time providing clear indications of that individual's identification with supernatural and cosmic forces. The use of metals in personal adornment and ritual attire served to convey the associations of the bearer with universal principles, within which gender ultimately served as a distinguishing characteristic of the individual, and thereby, the cosmos.

Metallurgy in the Near East

A Zooarchaeological Perspective on the Origins of Metallurgy in the Near East: Analysis of Stone and Metal Cut Marks on Bone from Israel

Haskel J. Greenfield

The Near East represents one of the earliest centers for the development of metallurgical technology and is crucial to the investigation of issues related to the development of metallurgy (Tylecote 1986, 1987, 1992; Muhly 1988; Wertheim and Muhly 1980). Metallurgy appears very early, with the recovery of cold-hammered copper artifacts from the Late Pre-Pottery Neolithic. With the development of smelting techniques, copper metallurgy spreads fairly quickly and widely during the Chalcolithic. Metallurgy spread ever more rapidly when it was discovered that the properties of copper could be improved by alloying copper with other metals such as arsenic, lead, or tin, to produce bronze. Bronze tools begin to be found in the Early Bronze Age (EBA). By the Middle Bronze Age, the use of bronze becomes more frequent (Maddin et al. 1999; Mellaart 1976; Moorey 1998; Redman 1978). However, it is impossible to document the introduction and spread of metallurgy into a region by simply using the frequency of metal finds. Metals, such as bronze and copper, are notoriously unstable. They decompose under most depositional conditions and/or are reused.

The objective of my research has been to investigate this issue from the perspective of Zooarcheology, or the analysis of animal bones from archaeological contexts. Slicing cut or butchering marks on bones can be used to identifying the nature of the raw materials which were used in the butchering of animals (Fig. 1). By distinguishing whether metal or stone tools make cut marks on animal bones, an independent measure of the relative importance of the different raw materials used for butchering or cutting of meat can be generated. The spread of metallurgy, as a result, can then be quantitatively monitored both across time and space within a region, and even within a single settlement.

Method

The method for distinguishing between stone and metal cut marks is based on experimental research conducted by the author and others and is discussed at length elsewhere. It will be only briefly summarized here (Greenfield 1999, 2000a, 2002a, 2002c, 2006; Olsen 1989). In order to identify bones with butchering marks on them, each bone fragment was individually examined. Most of the butchering marks were readily identifiable to the naked eye. A low power magnifying glass was used to survey each bone in order to enhance the potential for discovering butchering marks. Even though microscopic examination of the entire surface of each bone

Metallurgy in the Near East. Fig. 1 Cut mark on bone from site of Atlit Yam, sample 164 (Photo by Haskel J. Greenfield).

may have located a higher number of butchering marks, it was not deemed to be a realistic in terms of sample size, time, and finances.

Butchering marks are often relatively easy to distinguish in this period from tooth and other marks in later prehistoric bone assemblages. The nature of the activity leaves a relatively clear signature for even the naked eye – a relatively short straight incision in the bone. Many bones with potential cut marks were rejected when subjected to microscopic examination since they were deemed to be caused by nonbutchering sources. Once butchering marks were identified, the cut mark was examined under a light optical microscope and a tentative identification of the nature of the raw material of the implement was made – stone or metal.

Subsequently, a silicone mold of the incision was made in order to further study the mark in a scanning electron microscope. Each mold was subjected to further examination by the author and another assistant in the lab at the University of Manitoba. In this way, each mold was separately and repeatedly examined to determine whether a stone or metal blade had been used during butchering. This ensured a level of accuracy and repeatability of results rarely encountered in such analyses.

Several simple diagnostic criteria can be used to distinguish metal from stone tools. Metal tools have the following patterns (Fig. 2):

1. Metal knife blades sharp V-shaped or (Fig. 3) hard cornered |_|-shaped grooves (Fig. 4) that meet at a distinct apex at the bottom of the groove (Fig. 2a,b).
2. Metal tools make more uniform patterns on the bone, often removing material in the groove more effectively. They leave either no striations or striations of a more uniform depth and spacing than when stone tools are used (Fig. 5).

In general, metal knives produce a cleaner and more even slicing cut (except for serrated-edge blades – Fig. 2c).

By contrast, chipped stone tools have different diagnostics, which can be summarized as follows:

1. Chipped tools (blades or flakes) create a groove with one side rising steeply and smoothly and the other side rising more gradually (Figs.6 and 1e), except for scrapers (Fig. 1d).
2. The gradually rising side will have one or more striae that run parallel to the apex of the cut, depending on whether it is retouched or not (Fig. 7).
3. Retouched tools may have lateral striations on both sides of the apex, depending on whether they are unifacially or bifacially retouched (Fig. 1f,g).
4. Stone tools produce a shallower, less even cut mark.

In sum, the type of raw material used in making a butchering implement can be distinguished on the basis

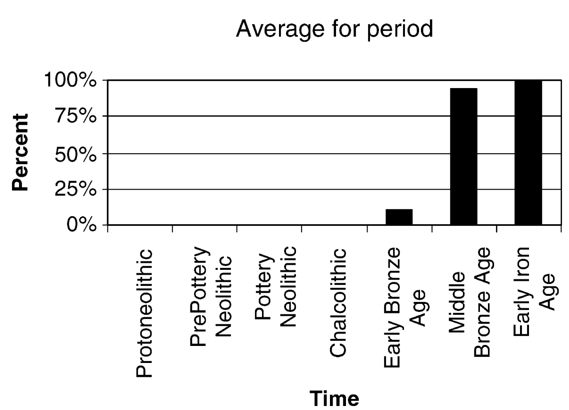
of its profile. In this illustration, typical profiles for different types of metal or stone butchering implements are presented.

Data

In order to investigate the origins of metallurgy in an area, sites from before and after the assumed starting point must be included in the analysis. Data from Israel were chosen since this is an area with early metallurgy (Levy 1998; Levy and Shalev 1989; Mazar 1990; Shalev 1994; Shugar 1999) and is one of the few areas of the Ancient Near East where many animal bone collections are easily accessible for analysis. At this point in time, data from over seventeen zooarchaeological collections have already been analyzed from sites excavated in Israel and the present Palestinian Authority areas (Greenfield 2004a,b; Greenfield et al., 2006; Saidel et al., 2006).

Data from the Proto-Neolithic through the Middle Bronze Age are included in the study. In this way, it is possible to monitor the possible introduction of metallurgy even the Chalcolithic, when the first metallurgy has been proposed to exist. Most of the sites

Metallurgy in the Near East. Fig. 8 Map of sites used in analysis.



Metallurgy in the Near East. Fig. 9 Histogram of percentage of metal cut mark frequency over time (average per period).

fall into the PrePottery Neolithic, Pottery Neolithic, and EBA. The other periods are more poorly represented. Over the next few years, more sites will be added to the database.

Results

A total of 857 bones with useable butchering related cut marks have been identified (to date) from the above sites. The data can mostly be analyzed from the perspective of time, although there are some inferences that can be made with regard to spatial divisions with the data.

Temporal Distribution of Butchered Remains

In the Proto, PrePottery, and Pottery Neolithic assemblages, there is no evidence for metal cut marks on bones (Fig. 9 and Table 1). This is not unexpected, but is important to demonstrate. A few metal cut marks were found at (Jericho in the PPNB sample), but these have been deemed to be from intrusive or improperly labeled specimens.

This pattern of stone tool dominance continues during the Chalcolithic. While the sample size of sites is much smaller than in the previous periods ($n = 1$, Gilat), there are a substantial number of cut marks from the site.

During the EBA, the pattern begins to change. Metal cut marks begin to appear. The data from Jericho indicate that both stone and metal cut marks were found in the assemblage in substantial numbers. During the EBA, metal tool marks are present in 41% of the bones of Jericho.

But the frequencies of metal cut marks in other Early Bronze (EB) sites is different from that seen above for Jericho. At sites, such as Afridar near Ashkelon, 89% of the cut marks belong to stone tools and the remainder are metal tool marks. At the nearby EB site of Ashkelon Marina, the similarly low percentages of metal cut marks are found. Only 1 out of the 7 bones with identifiable cut marks had a metal cut mark on it (14.28%). At Be' erotayüm, all of the bones were butchered with stone tools. The situation is less clear at the EB sites of Dalit and Tel Kinrot. While the data are evenly split, the frequencies of cut marks are so small that they have no statistical reliability and should not be given any weight in the analysis. They are presented here merely to demonstrate that metal appears across a wide range of sites during the Early Bronze Age.

Only one site with a Middle Bronze Age (MBA) sample has been analyzed so far (Jericho). The frequency of metal tool marks rises dramatically in the MBA at Jericho to 94% of the total (85.19% in the tell deposits and to 95.19% in the tomb deposits). This indicates the nature of the dramatic change between the two periods. The pattern for the MBA continues in later periods. Metal tools made almost all of the cut marks.

Raw Material by Geographical Region

Some spatial interpretations of the data can be made, but the data are very incomplete. There is evidence for early use of metal for butchering during the MBA from a variety of sites, ranging from the southern (Afridar and Ashkelon) and central coastal regions (Dalit), through the northern Negev (Arad) to the Jordan Valley (Jericho) see

Metallurgy in the Near East. Table 1 Distribution of cut marks by period and site

below. Other regions of the Country, such as the Central Negev, do not show any use of metal. It is difficult, at present, to discuss spatial trends within any single site since the data are not yet processed from this perspective.

Raw Material by Taxon

While there is no perceived pattern of which taxa were butchered with the various types of raw material, the EB metal cut marks are concentrated on domestic and wild cattle remains. This is visible in the data from Jericho, with its large frequencies (Table 2). In the periods with metallurgy (EBA and MBA), both domestic and wild taxa are butchered with both metal and stone tools. This pattern can also be seen in the data from EB Afridar (Table 3).

Comparison with Other Sources of Data

In Israel and the PA areas, the origins of metallurgy have also been investigated through the analysis of lithics. Steve Rosen (1997) demonstrated that the first stage in the adoption of metallurgy did not involve the wholesale replacement of flint tools (as is commonly assumed). Functional chipped stone tool types gradually disappear between the end of the Chalcolithic and Iron Age. Some types disappear because of changes in subsistence (arrowheads), while others are replaced with metal types that had a corresponding function (axes). Some stone tool types disappear quickly (at or prior to the beginning of the Bronze Age – arrowheads), others disappear gradually through the Bronze Age (axes), and some continue to be used into the Iron Age (sickles). To explain the continued use of stone (in the face of increasingly available metal tools) into later periods, Rosen has suggested that until a clear improvement in efficiency emerges, the economy would perpetuate the use of the traditional material.

While the data from the region is admittedly very small, geographically unrepresented, and was collected for the most part haphazardly archaeologists in the field, they still represent the only available data. Even so, they can be used to represent changes in the region over time. Eventually, more information will be added to the database and process across space may be investigated.

Problems that plague the analysis are that it is hard to obtain a statistically significant pattern from small sample sizes and it is always possible that some material from multiperiod sites (e.g. Jericho) that is found in one or another stratum is either residual or intrusive, especially when the objects are small (such as animal bones). As a result, it is always possible that when you have a very small database, the effect of possible intrusions becomes statistically greater. It will only be from relatively large samples that we can have enough reliable data to draw definitive conclusions. Nonetheless, the data allows us to draw some tentative conclusions.

The evidence indicates the evolution of a butchering technology that changes over time. It was exclusively

reliant upon stone tools from the Pre-Neolithic levels (represented at Jericho), through the various sites represented by PrePottery and Pottery Neolithic, and into the Chalcolithic periods. Most tools were probably unmodified flakes, haphazardly made, or blades. In contrast, the data from the EBA and MBA indicate a gradual, followed by a substantial shift in butchering technology from stone to metal. Stone butching

M

technology continues to play an important role in the EBA, but it is barely present in the MBA. This is not surprising given the differences in the nature of metallurgy between these two periods. Only copper or occasionally natural arsenical alloys (i.e., arsenical bronze) are in use until the very end of EB III, when tin makes its appearance. The evidence from the cut marks provides independent supports such a shift in metal technology. A functional butchering bronze metallurgy is entirely or almost nonexistent in the EB and this is evident by the lower use of metal tools in the butchering process.

It is apparent that there are some spatial differences in the availability of metal. While most sites have little or no metal cut marks during the EBA, major centers such as Jericho have substantial quantities. This may reflect the beginning of differential access to valued resources over time.

The data presented above are important for increasing our understanding of the spread and rate of adoption of a functional metallurgical butchering technology. It would appear to be adopted in spurts, similar to the process described for the abandonment of stone tools (Rosen 1997). These patterns appear to be more common than previously thought. Comparable data from other regions show striking similarities (as in the central Balkans and in southern Turkey; see Greenfield 1999, 2000a,b, 2002b).

Acknowledgments

I would like to thank Liora Horwitz, Elizabeth Arnold, Matthew Singer, Tina Jongsma, the late Eitan Tchernov, and the many excavators for access to and use of the data presented in this report. Any errors are of my own making. Based on a paper originally presented in the session “Organic Approaches to Near Eastern Archaeology,” organized by Ed Maher, at the Annual Meeting of the American School of Oriental Research, November 19–23, Toronto.

Metallurgy in Northern South American Indigenous Societies: Pre-Columbian Goldwork and Social Change

Carl Henrik Langebaek

Goldwork played an important role in the development of northern South American chiefdoms, particularly in Columbia. Thus, the history of goldwork is also the history of social change among indigenous societies. Although relations between social organization and goldwork are little known, new research has provided valuable information especially during the last years. It is now known that just the presence of goldwork is no indication of social complexity. How spectacular and well crafted goldwork is does not help to measure social complexity either. In all northern South American regions, first evidence of social differentiation (*not* political centralization) is reported early in the sequence, sometimes in the absence of evidence of goldwork. In most cases, goldwork was introduced at a relatively late date, long after social differences developed. But there are chronological differences, both in the introduction of goldwork and the development of complex societies. In the San Agustín Region, goldwork is dated around 0 AD in the Upper Magdalena Region. It is somewhat earlier in the Calima region and much later in the Sierra Nevada de Santa Marta and the Eastern Highlands. The range is from around 400 to 1000 AD in the Sierra Nevada de Santa Marta and from 1000 to 1200 AD in the Eastern Highlands. Evidence of social differences, on the other hand, is much earlier in all regions. Nonetheless, despite differences in chronology, and the contrast in some of the most conspicuous evidence of monumentality, early chiefdoms with political centralization are associated in many regions with an important investment of energy in mortuary practices and spectacular goldwork. Late indigenous society's goldwork was much less impressive.

There is evidence regarding the highly individualistic nature of the early elites. Objects that are found in their burials are frequently unlike anything else excavated in the same region. Early burial goods from Sierra Nevada de Santa Marta, Calima and the Upper Magdalena are not only different from materials found in domestic contexts but also from those found at other elite burials. Frequently, elite objects are inspired in foreign iconography. The San Agustín statuary incorporated lowland representations; in Calima, goldwork was similar to Upper Magdalena statuary. Neguanje offerings have been compared to Lower Central American and Quimbaya goods. Early Muisca goldwork was similar to the Quimbaya goldwork. Nonetheless, long distance trade of luxury items during the periods of chiefly development seems to be limited. The Calima goldwork imitated the statuary of San Agustín, but elite objects from San Agustín are yet to be found in the Calima region. Likewise, the La Badea burial in Dosquebradas includes gold ornaments similar to those found in the Calima region during the Yotoco Period, but they are not identical. The Neguanje burial includes goldwork similar to what has been called Classic Quimbaya, as well as pottery that has been compared to that of la Guajira and stone adornments comparable to those of Lower Central America. But these goods are not identical to anything else found in other burials and they seem to have been locally crafted. In the Muisca territory early evidence of goldwork was probably inspired in the so-called Classic Quimbaya style. However, we are not talking about imports, but instead of locally produced goods. This is not to argue against the fact that during the early period of chiefly emergence some objects were traded, sometimes over long distances, for this was certainly the case. It just means that copy and imitation were practiced more often than trade. Whether this means common cultural identity or not is not known. What is clear is that local conditions seem of importance to explain when and how goldwork was adopted and consumed.

The role that imitating crafts from abroad played in early chiefdoms was probably related to the role of leaders as intermediaries with the outsiders. Helms

(1981) has proposed this on numerous occasions. If Reichel-Dolmatoff (1988) is right about the iconography of many Columbian gold objects, it seems reasonable to argue that shamanistic icons played an important role as the basis of leader's legitimacy. The fact that most of the early goldwork in all four regions was locally crafted contradicts the idea that emerging elites concentrated on long distance trade. Instead goldwork would have functioned in highly competitive systems, within the context of basically local changes in demography, settlement patterns and economic conditions. As most elite objects were locally crafted, and undoubtedly are of extraordinary elaborate craftsmanship, it seems reasonable to argue that the production of elite objects was of importance for early chiefs, whether they or attached craftsmen were in charge of such production. Thus far, the direct evidence of such craftsmanship is scant. Besides isolated objects, like an Ilama metallurgy tool kit and the fact that an early workshop for goldworking was found in San Agustín associated to a mound and elite burial, no other workshops have been found. At any rate, production of gold adornments seems to have been very limited precisely because these were elite objects, limited to few individuals. The only way in which such early craftsmen had a "market" was because of the fact that prominent leaders passed away and elite goods went with them.

The contrast with late chiefdoms is evident in all four regions. What were previously materials associated with the elites (i.e., gold or luxurious stones) were later extensively used by the populace. Most frequently, gold adornments did not find their way to burials because they were inherited and accumulated by the living. In the case of the Muisca, the use of gold was not limited to the elite and neither was it among the Tairona. The fact that nose rings are so frequently represented in Sonso pottery suggests that this might have been the case in the Calima region too. This information is consistent with the idea of increasing craft specialization. Despite the fact that certain objects were consumed only by the elite, a characteristic of late chiefdoms in the Sierra Nevada de Santa Marta, Eastern Highlands, Calima, and the Upper Magdalena was that production became specialized and oriented toward the supply of a larger number of consumers. Late Muisca, Tairona, and Calima pottery becomes so standardized that the existence of centers dedicated to their production is suggested. In the Muisca territory, sites dedicated to the production of large quantities of pots, gold offerings, and spindle-whorls have been reported. In the Valle de la Plata region, it is only during the last pre-Columbian period that a distribution network from a single producing center of pottery prevailed. And this was probably not just the case with ceramics. In the Sierra Nevada de Santa Marta ethnohistorical information documents the existence of villages specializing in the production of stone adornments and goldwork.

Another common trait in late chiefdoms is that most of the labor force was not used for the construction of monuments, but rather for the construction of earthworks dedicated to the production of food. Terraces for agriculture, irrigation, and drainage systems become usual traits in the Sierra Nevada. In Calima, the landscape is transformed as never before by agricultural practices. In the Eastern Highlands, mounds and terraces are also related to agriculture for the times prior to the arrival of the Spaniards. Archaeological surveys in the Upper Magdalena and the Muisca territory suggest settlement was not oriented toward the exploitation of the best soils during the period of early chiefdom emergence. Conversely, in the case of the Muisca, it seems that the sixteenth century large villages and seats of chiefly power were located on some of the best soils in the region.

There are few documents where the production of ornaments is described in detail for northern South America. According to one source from the Magdalena Valley the leaders themselves were goldworkers (Martínez 1989). Nonetheless, in the Muisca territory production was in the hands of specialists attached to their service. In this territory it even seems that the position of goldsmith was inherited (Langebaek 1996: 130). In all regions, the production of gold objects in late periods was directed toward supplying a large portion of the population, whether it was a matter of producing adornments, as was the case among the Tairona, or offerings, as it is reported among the Muisca. In all cases, it seems that a larger demand relates to processes of population growth. Available research does not allow comparisons between the production of late chiefdom metal ornaments and that of earlier chiefdoms. The often small, mostly *tumbaga* (an alloy of gold and copper) ornaments that seem to constitute a large proportion of production in late chiefdoms are certainly not very attractive to museums, and they are often disregarded. But given that access to such goods was in most cases open to the populace, there is every reason to believe production was considerable.

Another feature of late Columbian chiefdoms was the increase in external relations that were at least partially controlled by the elites. The traditional view is that early elites depended on long distance exchange networks and that somehow they collapsed before the Spanish conquest. However, early goldwork was not only locally produced in all areas but in many cases it was highly individualistic, and probably made for specific individuals. Thus it is difficult to speculate about extensive trade networks and even less about their demise. In contrast, sixteenth century sources depict active trade routes (Langebaek 1987, 1996; Kurella 1994). Such trade involved the long distance exchange of luxuries (Szaszdi 1983; Boomert 1987; Whitehead 1990), as well as the exchange of raw materials and crafts. In the case of long distance trade, goods such as seashells, stone beads, and even some gold ornaments from the coast found their way to the Eastern Highlands. Crafts such as pottery circulated across ethnic frontiers, but this usually involved short distances within ethnic boundaries.

Goldwork played an important role in the development of northern South American chiefdoms. Gold objects are ideal means of communication. Therefore, its use depends upon a social context that determines the way in which it was used, its value, and, undoubtedly, its meaning too. As archaeologists learn more about pre-Columbian goldwork they have become aware of the complex ways in which ideological and economic factors came into play among goldworking indigenous societies.

Metallurgy in Pre-Columbian South America

Gray Graffam

Numerous pre-Hispanic artifacts of gold and silver craftsmanship testify to the exquisite skill of ancient Andean peoples in their production of metallic art. Prior to European arrival, ancient metallurgists prevailed in working gold, in winning silver and copper metal from a variety of rich ores, and in creating various sophisticated alloys. Ancient artisans triumphed in working these materials in ingenious ways to improve their performance and appearance, and in joining them to form complex composite pieces. A tremendous wealth of exquisitely crafted metal ornaments and metallic art was created through native talent. Today, the skill of pre-Hispanic Andean peoples in winning and working metals is revealed by early historical sources, archeological research, and the remaining portion of metal objects that avoided the Conquistador's torch. Some of the finest examples come from the Moche and Chimu regions of northern Peru; they include funerary masks, breastplates, diadems, and crowns, some of which are inlaid with decorative stones of turquoise and chrysocolla.

Early historical sources are clear in their portrayal of native Andean peoples as skilled metallurgists. Among the first chroniclers, Cieza de Leon described the successful native process of smelting silver, using wind-blown furnaces (*huayras*). Historical records for Potosi are also clear in stating that it was through the work of native metallurgists that the silver wealth was first tapped. For nearly three decades, from 1545 to 1572, all silver production was the result of skilled Andean natives, who used thousands of wind-blown *huayra* furnaces to smelt the rich silver–lead ores. Such furnaces were still employed by Andean natives in the seventeenth century, at which time they were recorded by people familiar with Old World metallurgy, and similar devices have been employed well into the twentieth century.

Archeological research today includes the discovery and study of metallurgical sites. Work at the site of Batan Grande in northern Peru reveals a centuries-long sequence of copper–bronze production, ending with Inca-period efforts just prior to the Spanish Conquest. Detailed research by such scholars as Izumi Shimada and John Merkel reveals the sophisticated nature of the smelting procedure, and reconstructs the various steps used in the metallurgical process. In addition, recent related efforts by Heather Lechtman focus on the source of the ores used in the production of the copper–arsenic alloys, arguing for a highland-coastal exchange. With regard to detailed archeological investigations of sites where metal was crafted, rather than smelted, the research on metal craftsmanship at Chan Chan is an important contribution, which examines the activities carried out by metal smiths within a particular district of that pre-Incaic city. Also of note are investigations into the pre-Hispanic smelting facilities and processes in the South Andes. To date, the earliest metallurgical (copper) slags in this latter region come from the Wankarani site in highland Bolivia; they date between 250 and 1200 BCE. Of particular note, research at the Ramaditas site in northern Chile reveals a highly skilled, natural draft technology operating in the Atacama region by 100–50 BCE, where pre-Hispanic metallurgists were capable of achieving a good separation of copper metal from slag during production. These studies lend weight to the idea of a highly effective metal smelting technology in place in the South Andes during the first millennium BCE.

In general, it is thought that gold working preceded copper smelting, gold being found in a natural metallic state in association with certain minerals. The earliest known gold-working kit and beaten gold work in the Andes date to approximately 1500 BCE from Waywaka, Peru. The first working of native copper would also be theoretically of a similarly early date.

The most extensive body of research on ancient Andean metallurgy deals with analyses of the metal artifacts themselves. Included here are laboratory studies on gilding, joining of metals, alloying, and the other techniques of artistry and design. When the Spanish began melting metal objects shortly after the Conquest, they noted with dismay that not all "golden" objects were in fact pure gold. Many specimens appeared to be gold on the surface, but were actually copper alloy in the core, which meant that they had little of their anticipated content of precious metal. Modern laboratory studies have succeeded in replicating the ancient techniques employed in gilding, as well as the casting, welding, and forming of exceptionally well-crafted objects (Lechtman et al. 1982; Tushingham et al. 1979). Andean craftsmen were adept in altering the appearance of an alloy, sometimes within the same piece, as in the case of Vicus nose ornaments. In some cases, their illusions seemed to accomplish the impossible, where different metals appeared to be welded together. These ancient metal smiths exercised superb control over their artistic medium, in which the color of the metal was as important a factor as the iconography that the piece intended to convey.

As one shifts from the North Andes to the South Andes, there is a shift in the metallic art from complex and fully modeled pieces to artifacts of decorated sheet metal. In Bolivia, northern Chile, and northwestern Argentina, metallic art most often takes the form of objects made from flat metal. Discs, diadems, bracelets, rings, and pendants are common forms, all executed from hammered sheet. Casting is also known, but seems to be used primarily in the manufacture of axes and mace heads, i.e., nondecorative objects that required more substantial weight. The tradition of working sheet metal has a long antiquity, extending back three millennia.

Today, Andean natives remain active in working metal and crafting pieces of native art. Like their counterparts in the American Southwest, they melt coins for metal, rather than smelt ores as formerly done. The end product is most often geared toward tourist consumption, which means that it is generally of a form that is readily marketable. Still, there is a folk practice that persists among the native Andean peoples, one which has an extremely long history.

Metallurgy: Pueblo Indian Adaptations of Spanish Metallurgy

Mark T. Lycett, Noah Thomas

Despite the long pre-Columbian tradition of metallurgical technology in West Mexico, there is no evidence for the development of metallurgy in the US Southwest prior to Spanish colonization. Metal bearing minerals are widespread in the region and were used as pigments and ornamentation prior to Spanish contact (see Extra). Discussions of the largely untapped potential of mineral wealth are ubiquitous in Spanish colonial descriptions of New Mexico from the sixteenth through the nineteenth centuries. Documentary sources suggest that iron, copper, and other metals of every day necessity were relatively scarce in this colony. Small amounts of manufactured metals appear in assemblages from Franciscan missions and other Pueblo settlements occupied during this period. Despite the importance and widespread use of these metals, there is little evidence of mining or processing of local ores, and it has generally been assumed that all metal in colonial period New Mexico was imported from New Spain. While this supposition may be true for much of the material recovered in colonial period assemblages, strong evidence of metal production has been found in a few Hispanic contexts and from the missions of San Pedro and San Marcos. While some of these processes were spectacularly unsuccessful, copper metallurgy appears to have been the predominant focus of this technology. Archaeological and metallurgical analyses suggest a number of important patterns in the organization and development of these processes. Spatial segregation of technological processes and activities is coupled with a diversity of ore bodies, metals, and products, and shifts in the use of facilities and processes. These create a complex mosaic of emergent experimentation in novel and hybrid technologies shaped by the requirements of colonial tribute demands, locally available resources, indigenous knowledge and practices, and frontier exchange relationships.

The colony of New Mexico was established in 1598, at the height of Spanish silver production in the New World. The mines in New Spain had produced unprecedented wealth for the Spanish crown and had begun to influence European economic systems through the easy availability of silver currency allowing for the development of early capitalism. The profitability of the mines in New Spain was in a large part due to the availability of cheap labor, primarily composed of both coerced and paid Native American workers. In addition to mining activities, Native West Mexican smiths were sought after for their traditional metalworking skills. The incorporation of indigenous individuals within the industry also allowed for the development of technologies better suited to the dry, wood scarce environment of northern New Spain than European water powered and charcoal fueled smelting practices, through the incorporation of indigenous traditional materials and technologies. To facilitate production along these lines, Spanish administrators often uprooted whole indigenous communities through forced relocations in order to obtain closer proximities of labor, ore and fuel sources.

In contrast to Western Mexico, the organization of early colonial metallurgy is very poorly documented in New Mexico, with strong evidence of metal production from a very few contexts. Recent excavations on the early to mid-seventeenth century industrial terrace at the Mission of San Pedro, known alternately as Paa-ko Pueblo, have recovered extensive evidence suggesting that the Pueblo occupants of this village experimented with a range of metallurgy technologies including the reduction of copper oxide and lead sulfide ores to produce copper and lead metals, the refining of silver through cupellation,[1] the manufacture of sheet and cast copper artifacts, and the forging of iron artifacts.

Located at the head of the San Pedro Valley, one of three major drainage systems on the eastern slope of the Sandia Mountains, this site lay outside of any of the major settlement clusters or "provinces" identified by Spanish colonists. It was a small scale, intermittently occupied, and partially incorporated community. Although the village was part of the mission system, it never had a resident friar or a permanent Spanish presence. The situation of a metallurgical facility within this remote community may have allowed some colonists to engage in a valued form of production outside of the scrutiny of colonial administration while

[1] Cupellation is the recovery of precious metals in a cupel by exposure to a blast of hot air that oxidizes the unwanted base metals, such as lead, which are partly absorbed. A cupel is a small container in which precious metals are refined, especially in which gold and silver are separated from base metals during assaying.

still maintaining access to mineral sources, fuel, and a subject labor force (Fig. 1). Nevertheless, the evidence at Paa-ko points toward a strong Pueblo involvement in the design as well as the implementation of these technologies.

At this site, a terraced hill slope covering more than 200 m^2 was repeatedly used for metal production with numerous superimposed and interdigitated facilities produced through periodic episodes of use, maintenance, and reconstruction over a number of years (Fig. 2). The specific functions of these facilities may have included copper smelting, copper ore roasting, charcoal preparation, and iron forging. Both Spanish and Puebloan construction techniques were incorporated in the structure of the facilities. Traditional Puebloan adobe and masonry construction techniques are integrated with introduced construction technologies such as mold-made adobe and core and veneer masonry techniques. In addition, ventilation shafts and deflector shields typical of pre-Columbian subterranean structures in the region are incorporated into several different furnace designs (Fig. 3). Such syncretism suggests a process by which Puebloan knowledge as well as labor were incorporated within the introduced technology.

Slag and metal recovered from Mission San Pedro suggests wide variation in the technology producing materials reflecting temperature and atmospheric conditions of the smelt. Though copper appears to be the primary metal produced, in some high temperature smelts, large amounts of iron were cosmelted from the gossan[2] ores producing a copper–iron alloy (Figs. 4, 5a, b, and 6). Lower temperature smelts were conducted as well, producing a copper metal with copper sulfide inclusions (Fig. 7). Both alloys have been found in association with finished copper artifacts and copper sheet scrap suggesting the inclusion of both alloys within the overall production process of the facility (Fig. 8).

The variation in smelting regimes may represent the experimental and improvisational nature of the technology employed at the facility suggesting a process by which practitioners developed techniques appropriate for local materials. The development of extractive metallurgy at Paa-ko employed both the knowledge of

high temperature and high reducing metallurgy technologies, such as those applied to iron smelting, as well as knowledge of lower temperature processes more appropriate for copper extraction.

The focus on copper production apparent from the volume of copper slag and predominance of copper artifacts and scrap recovered from the facility is unusual given that the focus of Spanish colonial metallurgy in the New World was on silver extraction. Copper production as an industry in New Spain was relatively small and was focused in West Mexico, under the technological control of indigenous Tarascan smiths up until the turn of the seventeenth century. Yet, copper played a significant role in the global exchange of metals. The growth of the copper industry in Europe can be directly tied to the development of colonial exchange at the frontier of colonial expansion. Central Europe became a center for production in this system during the fifteenth and early sixteenth centuries, using copper left over from the *Saigerprozess*, the extraction of silver from copper metal with the addition of lead, to produce items for trade such as copper and brass kettles, knives, and ornaments.

A possibility that may explain the predominance of copper metallurgy at Paa-ko may be the adaptation of this global model to local silver ores and colonial exchange relationships in the New Mexico colony. The materials recovered from the facility such as lead slag, galena, and litharge fragments containing copper and lead prills,[3] suggest that one of the technologies present at the facility included a process of silver refining utilizing cupellation, involving both lead and copper metal (Fig. 9).

Photo by Noah Thomas.

The evidence from Mission San Pedro may represent a participation within two colonial systems of value: one centered on the production of silver and the generation of wealth within models of European commerce, and one centered on the colonial trade and exchange relationships of frontier communities. The most common form of manufactured copper in these samples is sheet copper, occurring as both manufacturing debris and finished artifacts (Fig. 10). Sheet copper commonly occurs in other mission assemblages, although there is no evidence of copper production or its by-products from most of these sites. Copper, as distinct from silver, was a metal of relatively little value in the exchange networks of colonial New Spain, but copper ornaments were a novelty in colonial New Mexico, circulating in

partially overlapping systems of value defined by both colonizer and colonized. Metallurgical practices may have been simultaneously understood as forms of commercial production, disciplinary instruments of Spanish church and state, and an idiom of Christian and indigenous identity formation through personal adornment.

Metal has been recovered from the seventeenth century missions at the sites of Abo Mission and Quarai, in the Salinas district, from San Marcos, San Lazaro, and San Cristobal in the Galisteo Basins, and from the Zuni site of Hawikuh and the Hopi site of Awatovi. Much of the metal recovered from these sites is poorly documented or is so sparse that it is impossible to develop an overall sense of how metals were used by the Pueblo population. The excavations at Pecos Pueblo are an exception. Over 344 metal objects were recovered from this excavation, providing for an adequate data set in which to compare the information gleaned from the historical documents.

The metal assemblage from Pecos is dominated by copper sheet scrap both as sheet fragments and as rolls. As Kidder notes, "more than half of the collection consists of small, irregularly shaped scraps of thin sheet metal, varying from the size of a fingernail to that of the palm of one's hand. Their edges are sometimes cut as with a sharp instrument, sometimes roughly torn" (Kidder 1932: 308). The high frequency of this material suggests that copper metal was being worked by the Pueblo inhabitants of this Mission. Kidder suggests that the scrap represented the reduction of copper kettles much like that which occurred in Northeastern Native American historic sites. This may in fact be the case, as the historical documents suggest that a large volume of copper material was coming into the colony as copper alloy vessels (see Note) (Fig. 11).

The frequencies of artifact types listed historically and recovered archaeologically suggest a pattern of Puebloan use of metal artifacts in the seventeenth century that stresses clothing and adornment (Fig. 12). In addition to this, the predominance of copper sheet scrap suggests that European copper goods were eventually highly modified to produce other artifacts that perhaps were perceived to have a higher value. At least eight of the 16 crosses recovered from Pecos were made from sheet copper suggesting a relationship between the working of copper sheet through the reduction of domestic artifacts, and the production of objects of adornment.

The emergence of novel forms of production in colonial settings is an historical process marked by experimentation, adaptation, and variation. Evidence of this process at sites like Paa-ko (San Pedro) and Pecos indicates involvement with European metallurgical technologies included production of a variety of metals through a variety of techniques, recycling of existing materials, and the working or finishing of metals from both sources. The participation of Puebloan communities in Spanish metallurgy suggests that indigenous knowledge, indigenous materials, and indigenous exchange networks may be at least as important as indigenous labor in the implementation of new technologies.

Extra 1: Pre-Colonial Metal Use in the Southwest

Despite the presence and time depth of metallurgical technology in West Mexico, little evidence exists for the transference of techniques of metallurgy to the US Southwest prior to Spanish colonization. Trade in metal objects of West Mexican origin existed by the tenth century, and possibly earlier, based on the presence of copper bells in sites from Chaco Canyon, the Hohokam region of southern Arizona, and the Mogollon mountain region. Trade in bells to the US Southwest follows the chronological patterning of technological style of West Mexican bell types. Based on this chronology, two phases have been recognized by Vargas. Phase I consists of trade in non alloyed copper bells 800–1250 AD, and Phase II consists of trade in stylistic forms associated with alloyed copper bells from 1250–1520 AD. As Vargas (1995) notes, this trade appears to have been highly restricted and/or infrequent. In both phases distribution is centered on the Hohokam region of southern Arizona. As of yet, no solid evidence exists for the smelting of copper or the production of copper objects within the region during the precolonial period.

Despite the fact that metallurgy appears not to have been practiced, metal bearing minerals are prevalent within the region and were extensively used prior to Spanish contact. Both copper and lead bearing minerals were used as pigments, as objects of adornment, and as components in the indigenous pyrotechnology of lead glazed ceramics. The development of lead glaze in the Puebloan world began in the fourteenth century and continued to be practiced through the early colonial period up until the Pueblo revolt of 1680.

Extra 2: Historical Data on the Introduction of Metals and Metallurgy

The historical record suggests that a wide variety of metals came into New Mexico with the initial colonization of the late sixteenth and early seventeenth centuries. Iron, lead, and mercury were brought in as raw materials for the mining industry and the production of tools and lead shot. Other metals and alloys entered the colony as finished

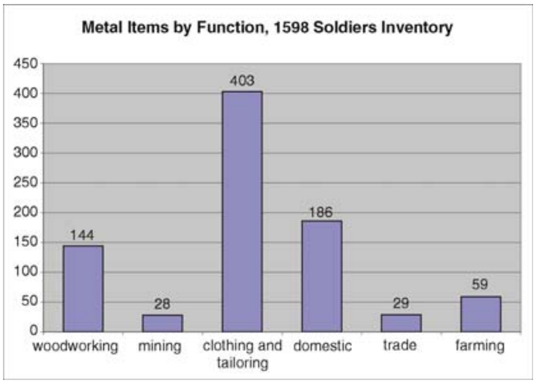
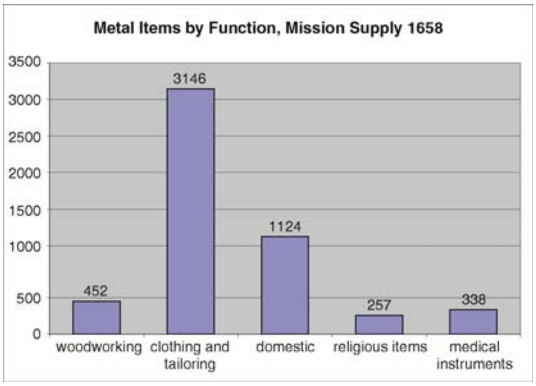
tools, religious articles and ornaments. Though iron was probably the most predominant of metals imported, copper and copper alloys appeared in large quantities primarily in the form of domestic items. Tin, pewter, silver, and gilded items are mentioned both within the inventory of items brought in the initial colonization of 1598 and in the requested items of the mission supply caravan as well.

Excluding iron goods needed for horseshoeing, when comparing the lists of items brought in the initial colonization with the mission supply lists of the 1650s, the most prevalent metal items are tools related to clothing and tailoring activities (Figs. 13 and 14). These include items such as needles, thimbles, awls, pins and scissors. These items were also the predominant trade good brought in the initial colonization. Their high frequencies may be due to their ease of transport, the low cost per quantity as an item of trade, and/or their general perceived utility across ethnic boundaries.

The second most prevalent item by function is domestic implements. This category most likely represents the largest category outside of horseshoeing equipment in terms of volume and weight and is dominated by copper alloy items. Copper kettles, boilers, *ollas* (a pot or jar having a wide mouth), and *comals* (large flat griddles on which tortillas are cooked) are mentioned specifically. In the mission supply list of 1658, 37 and 20 pound bronze *ollas* and 25 pound copper kettles are requested. These probably refer to both European and Mexican manufactured items. Brass and bronze alloys were most likely produced in Europe, while copper vessels may have been produced in traditional copper working communities in West Mexico. Much of the copper produced in New Spain in the sixteenth century was done so within these communities.



Metallurgy: Pueblo Indian Adaptations of Spanish Metallurgy. Fig. 13 Metal items listed in the Salazar inspection of the Oñate colonizing force of 1597. Items grouped by function.



Metallurgy: Pueblo Indian Adaptations of Spanish Metallurgy. Fig. 14 Metal items listed in the mission supply list of 1,658. Items grouped by function.

In the colony of New Mexico, as a remote and isolated enclave, access to European and West Mexican goods and smithing expertise was limited, yet maintenance of metal goods must have been a concern and required individuals with requisite experience. The inventory of tools for the forging and smelting of metals brought in the initial colonization suggests that this knowledge and expertise resided primarily with individuals in the mining industry. Though mission centers were established as institutions for the socialization of Native American individuals, mission supply lists do not carry requests for metallurgical tool kits. Therefore it is more probable that the transference of the technology, at least in the initial colonization of the seventeenth century, occurred through the mining industry among coerced Native American laborers.

Metallurgy in Southern South America

Colin A. Cooke, Mark B. Abbott, Alexander P. Wolfe

The Andes represent the largest source of mineral wealth in the Americas and the birthplace of New World metallurgy. Metallurgical exploitation of these resources occurred for millennia prior to colonial contact, as testified by numerous artifacts of gold, silver, and bronze. Prior to the arrival of Spanish conquistadors in 1532 AD, indigenous South Americans smelted silver ores, hammered gold sheets, and annealed copper alloy sheets, independently of technologies that, by then, were highly developed in the Old World. Despite this extensive history, we know astonishingly little about the development of metallurgical techniques through time.

Today we learn about ancient metallurgy primarily through three sources of information. The first is the collection and analysis of artifacts recovered from archaeological excavations. However, looting of archaeological sites is pervasive and as a result the archaeological record is incomplete (Jones and King 2002). This means that the archaeologist often works with either a small fraction of the original material, or with artifacts that have been removed from their original context. Moreover, looters frequently "restored" looted artifacts, severely limiting what information can be drawn from their appearance (Shimada and Griffin 2005). The second source of information comes from historical and ethnographical data collected at the time of conquest. For recordkeeping purposes, Spanish conquistadors documented the looting of Inca palaces and exploitation of Inca mines (Lechtman 1976). Useful as these archives are, they tell us little about those peoples who preceded the Inca. Moreover, the Spanish were primarily concerned with the acquisition of gold and to a lesser extent silver. They make little mention of copper and copper alloys, even though these represent the foundation of Andean metallurgy. The third method is that of archaeometry. Archaeometry is the application of scientific methods to archaeological sites or artifacts. In the Andes, the most common archaeometric analysis employed is a compositional chemical analysis (Lechtman 1999, 2002). Recently, scientists have also utilized geochemical analysis of lake sediments to track atmospheric pollution from smelting. This method was used to establish the onset of smelting at the town of Potosí in the highlands of southern Bolivia (Abbott and Wolfe 2003). This method provides an independent record of the timing and intensity of smelting for the region. However, as with the previous approaches, it has its limitations. It cannot answer which group specifically was smelting or how it was used or valued by ancient South Americans, and is restricted to regions, which contain continuous sedimentary environments suitable for analysis (i.e., lakes, swamps, bogs, etc.). Despite the limitations of each of these methods, by studying them in concert, it has become apparent that indigenous South Americans possessed extensive knowledge in acquiring metals from various ores and also in combining and working metals into elaborate artifacts. Here, we review the major findings related to the procurement and smelting of nonferrous ore bodies in the southern Andes and the manufacture and use of various alloys as tools and objects of adornment within indigenous South American culture.

Smelting

Nonferrous metal ores have been smelted in South America for approximately 2,500 years. The earliest evidence to date for smelting activity in southern South America comes in the form of copper slag from the Wankarani site in the highlands of Bolivia dating between 900 and 700 BCE (Ponce 1970). Slag, also known in the Andes as *scoria*, is the waste or by-product of smelting. Often this is all that remains for the archaeologist to find as an indication of metallurgical activity (Van Buren 2005). Very little research has been conducted on the metallurgy at Wankarani and to date little is known about what type of metal artifacts were being produced and how the control of metal resources was governed.

To the southwest, additional evidence for early smelting comes from recent research at the Ramaditas site in the Guatacondo Valley of northern Chile (Graffam 1994, 1996). Here, excavations have revealed evidence that copper smelting and sheet metal working (*repoussé*) began near the first century BCE. This finding confirmed that not only does metallurgy date back in excess of 2,000 years in northern Chile, but that this activity was often carried out independent of the presence of a large formalized state or Empire (Graffam 1994, 1996). Northern Chile contains abundant ores of copper and the exceptionally arid environment allows excellent preservation of artifacts. This makes Chile an ideal locality to conduct future metallurgical research.

On the *altiplano* of southern Bolivia, a silver deposit known as Cerro Rico de Potosí was once the world's richest silver mine. Legend attributes the discovery of silver at Potosí to the penultimate Inca ruler, Huayna Capac, in the mid-fifteenth Century AD. However, this date was recently challenged by the discovery of much earlier metal pollution in a nearby lake that can only be explained by local smelting activity (Abbott and Wolfe 2003). During smelting, trace metals are released into the atmosphere and are subsequently deposited into the lake environment through precipitation and dry atmospheric deposition. As soils, algae, and sediments accumulate at the bottom of the lake, they preserve these atmospherically derived metals. Natural archives, i.e., lake sediments, are sensitive enough to pick up even preindustrial emissions (see Renberg et al. 1994). Lake sediment cores (tubes of sediment recovered vertically from the bottom of a lake) were collected from a high alpine lake downwind of Cerro Rico de Potosí. Geochemical analysis of the sediments revealed a long history of smelting activity beginning shortly after 1000 AD, 400 years prior to the supposed discovery of silver! The use of this method to track metallurgical activity has only just begun and research is currently underway to understand the chronology of smelting throughout the Andes.

The final source of information on indigenous smelting at Potosí comes from a combination of historical archives and ethnoarchaeological research. Given its richness, Potosí was the central focus of colonial mining for years after conquest. As a result of this attention, a written chronicle of smelting techniques in use at Potosí exists. For example, between 1545 and 1572 AD, Inca silversmiths under colonial rule using indigenous furnaces conducted all silver production. Three different types of furnaces were recorded by the Spanish during this time as they worked Potosí and the nearby mine of Porco. The first type of furnace was simply a pit dug into the ground that reduced ores rich in silver. The second type was a small, and sometimes portable, reduction furnace called a *huayara*. These charcoal-fired, wind-drafted furnaces were lined with clay and were often placed on mountaintops to take advantage of strong winds. As such, they were prone to destruction by any number of natural forces (e.g. landslides, earthquakes) and to date none have been recognized in the archaeological record. Recently, however, a huayara has been found still in use today in Bolivia (Van Buren 2005). This is an important discovery, which promises to contribute a great deal toward the understanding of ancient smelting techniques and their remains in the archaeological record. The third type of furnace was a *tocochimpu*, which was normally used to refine silver in combination with argentiferous galena or *soroche* (lead sulphide). Cieza de León was one of the first Spanish chroniclers to describe the use of soroche at Potosí and documented its use as a flux to enable extraction of silver from even low-grade ores. Future research combining historical archives, archaeological and ethnoarchaeological research is sure to illuminate lingering questions regarding the spatial and temporal homogeneity of smelting technology in the southern Andes.

Despite these advances in the smelting of ores, direct analysis of the metal artifacts themselves is the most common analytical approach. The most frequent analysis performed is that of a compositional analysis which determines the relative proportions of the metals which make up an artifact. This has shown that the vast majority of Andean artifacts are composed of alloys. Alloys, rather than pure metals, are pervasive in both Old and New World metallurgy for three reasons. First, occurrences of pure copper, silver, and gold do not commonly occur in any large quantity. Second, alloys have the benefit of often being harder than objects made of native metal, as is the case with silver and gold (Lechtman 1996). Third, by combining one or more metals, the melting temperature of those metals is lowered, which facilitates the smelting of ores. This is important as all pre-Columbian metallurgy was done without the use of bellows and had to rely on natural drafts to aerate furnaces.

The most common alloys found in southern South America have been those of arsenic–copper (arsenic bronze), tin–copper (tin bronze) and ternary alloys of copper, arsenic and nickel. There is also evidence that the Inca alloyed bismuth in bronzes recovered from the site of Machu Picchu (Gordon and Rutledge 1984). Alloys composed of copper–gold (a binary alloy sometimes referred to as tumbaga) and copper–silver–gold (a ternary alloy) have also been found, though not in the same quantity as copper alloys (King 2000). The precious metal artifacts that are found normally occur as items of personal adornment (e.g., discs, bracelets, rings, and pendants) associated with individuals of high social status, and as religious or ceremonial items (Olsen Bruhns 1994). Because of the extensive looting which has taken place in Peru, both recently and during colonial times, few precious metals remain and our understanding of them remains comparatively sparse. Here we focus our discussion on the appearance and distribution of copper alloys as they represent the backbone of Andean metallurgy. We then highlight two examples in which indigenous South Americans altered the appearance of copper-gold and copper-silver alloys to give them the appearance of precious metal.

Bronze Alloys

Arsenic bronze was the earliest alloy to be utilized in both northwest Argentina and southern Peru. In northwest Argentina, arsenic bronze was in use by 400 AD and its use continued until colonial conquest. This bronze alloy was used both for tools (axes, chisels, and wedges) and finer domestic items (awls, needles, bracelets, and tweezers) (González 1979; Fester 1962). In southern Peru the earliest evidence for arsenic bronze metallurgy occurs at the site of Pikillacta in the Lucre Valley circa 600 AD (Lechtman 1997). This occurs during the influence of the pre-Inca Empire known as the Wari, which controlled the area from approximately 600 to 1000 AD (McEwan 2005). These arsenic bronze artifacts are normally represented by domestic items or tools (Lechtman 1997). Naturally occurring alloys of copper and arsenic are readily available in the high Andes of central/southern Peru and would have been accessible to native South Americans. Therefore, arsenic bronze metallurgy characterized the time period between 400 and 1000 AD in southern Peru and northwest Argentina.

In contrast, in Bolivia there is a paucity of both natural alloys and artifacts made of arsenic bronze. Rather, tin bronze and copper–arsenic–nickel alloys seem to have been the metals utilized. The earliest occurrence of this alloy in Bolivia is found on the Bolivian *altiplano* around 600 AD (Lechtman 2002). Tin bronze was favored for ornamental rings, while copper–arsenic–nickel appears to have been preferred for needles, nails, and chisels (Lechtman 2002). The tin for tin bronze appears to have been obtained from the rich "tin belt" of the *altiplano*, where it primarily occurs in the mineral cassiterite (tin oxide). No source has yet been found for the copper–arsenic–nickel alloys. Therefore, tin-based bronze metallurgy in northern Bolivia appears to have begun around 600 AD. This is broadly contemporaneous with the widespread use of arsenic bronze metallurgy in nearby southern Peru and northwest Argentina. Future research is needed to understand what, if any, interaction was occurring between Bolivia and southern Peru at this time of florescence of the copper industry.

Traveling north and forward 200 years to 800 AD, the site of Batán Grande represents early arsenic bronze metallurgy along the north coast of Peru. Previously undocumented in the New World, Batán Grande is a prehistoric metallurgical center situated in the La Leche Valley (Shimada et al. 1982, 1983). Smelting here began circa 800 AD and continued until just prior to the Spanish conquest. Though small quantities of copper ore are locally available, arsenic bearing minerals are not. However, the highlands of northern Peru are rich in arsenic bearing minerals; this fact has led Lechtman (1991) to argue that highland miners might have provided coastal smelters with the necessary arsenic.

The mechanism for this highland-coastal exchange, be it social, economic, or otherwise, has yet to be adequately explained.

Batán Grande was also the site of a large-scale cosmelting operation heretofore undocumented (Lechtman 1999). During cosmelting, a mix of both the sulfides (the primary ore minerals) and oxides (the secondary or the weathered alteration product of sulfides) were charged into the furnace. This mixing need not be deliberate and yielded clean, coherent copper–arsenic alloy ingots (Lechtman and Klein 1999). Cosmelting represents a dramatic improvement in smelting operations while eliminating noxious arsenic fumes that might otherwise have been generated.

Moving forward to the mid-fifteenth century AD, the Inca Empire implemented the use of tin bronze for domestic and household metal items throughout Peru, Bolivia, northwest Argentina, and northern Chile. This widespread occurrence of tin bronze associated with the Inca Empire has been dubbed the so-called "Tin Horizon" (Costin 1989; Lechtman 1996; Lechtman and Klein 1999; Owen 1986). The tin would have been prepared as sheet stock and then could be dissipated through the Empire where it was added to local alloys of arsenic bronze or simply added to local copper to form tin bronze (Cositn 1989; Lechtman 1976). Adding tin to existing bronze technology improves the workability of the metal and increases the hardness of the finished product (Costin et al. 1989). The Inca represent the culmination of metallurgical development in native South American history until the conquest of the Spanish in 1532.

In summary, two loci of bronze based metallurgy can be distinguished for the southern Andes. This appears to be a direct result of differences in local resources (arsenic-copper deposits in southern Peru and northwest Argentina versus tin–copper deposits in northern Bolivia). The situation changes with the establishment of the Inca Empire, after which tin bronze becomes the domestic metal of choice throughout the Andes.

Precious Metals

Although artifacts made of bronze alloys are the most commonly found during archaeological excavation, gold and silver remained the most prized metals during Inca and pre-Inca times as well (Costin et al. 1989). For the Inca, gold was endowed with spiritual and symbolic meaning and was believed to be the rain of the sun, while silver was the rain of the moon (Jones and King 2002). However, artifacts composed purely of silver or gold are extremely rare. Considerably more common are alloys containing a mixture of copper and gold or silver. After the Spanish conquistadors took control of Peru, they began to melt down what they believed to be golden objects. To their surprise, they discovered that these "golden objects" were in fact composed of copper alloys and had only very thin surfaces of gold. This was because locally available resources, combined with sophisticated alloying techniques were used to produce golden surfaces on alloys containing small percentages of precious metals (Lechtman et al. 1982).

Experimental archaeology has been especially important here in determining how Andean cultures manipulated alloys to accentuate desired qualities. Two of the best examples of native abilities were the processes of electrochemical replacement plating and depletion gilding. In electrochemical replacement a copper alloy is given an extremely thin and even surface coating of sliver or gold. To accomplish this, silver and gold were dissolved in an acidic or corrosive solution (Lechtman et al. 1982). A copper artifact was dipped into this solution, and a chemical reaction would occur that resulted in a very thin and even "plate" or surface coating of silver or gold. In addition, the specific color of the object could be altered simply by varying the relative amount of silver or gold in solution (Lechtman et al. 1982). Depletion gilding was used on alloys of copper-silver-gold. Here, naturally-occurring chemicals are used to separate the gold from the silver, leaving a surface of the desired precious metal. These are just two of the techniques in which native South Americans manipulated the appearance of metal artifacts in order to achieve a surface of silver or gold. These technologies appear to have been developed by the Moche (100 to 800 AD) on the north coast of Peru and remained a northern phenomenon until the rise of the Inca Empire in the mid-fifteenth century. At this time the Inca Empire relocated the northern metallurgists to Cuzco to serve at the Inca capital. Further research is needed to document fully the full range of both Inca and pre-Inca alloying techniques.

In short, a wide variety of metallurgical techniques were used by Andean cultures, and considerable skill was demonstrated in the manipulation of nonferrous ores. By integrating the fields of archaeology, ethnohistory, and geology a great deal can still be learned about these cultures' use of metals.

Meteorology in China

Li Di

Chinese meteorology, here referring to the traditional meteorology which was used in China, has many unique characteristics. Although China began to adopt Western meteorological knowledge as it was introduced in the seventeenth century, Chinese traditional meteorology lasted 250 years. Chinese meteorology can be described from four aspects.

Knowledge About Meteorological Phenomena

The Chinese recognized some meteorological phenomena 3,000 years ago. In the inscriptions on borns or tortoise shells of the Shang Dynasty (ca. sixteenth to eleventh century BCE), there were some words meaning rain, frost, snow, thunder, lightning, rainbow, etc. The Chinese identified the relationship between the rain and rainbow;

they knew if there was a rainbow in the western sky in the morning, it would rain soon. The Book of Songs declared, “White dew is frost.” In this case, frost must have been frozen dew. Two thousand years ago, the Chinese also recognized the six segments of a snowflake.

Wang Chong (AD 27–97) was one of the first to record meteorological phenomena. He said that the rain came from the ground, not from the sky, meaning that the rain came from the vapor rising from the ground. He also said that clouds and fog are omens of rain, there is dew in the summer but frost in the winter, and rain when it is hot but snow when cold. He understood that rain, dew, frost, and snow were formed of vapor from the ground at different temperatures.

The ancient Chinese had exact knowledge about rainbows, too. Kong Yingda (AD 574–648) who lived in the early time of the Tang Dynasty, pointed out that the rainbow was created by the sun’s shining on the waterdrops. Sun Wanxian and Shen Guo (AD 1030–1094), who lived in the Northern Song Dynasty, studied the rainbow too, and agreed with Kong Yingda. Sun Yanxian said that the rainbow was the reflection of the sun in the rain, created when the sun shines on the rain.

They also had a good deal of knowledge about the wind and the clouds. In the fourth century, it was recognized that the trade wind had 24 fans. Li Chunfeng (seventh century) recorded the wind as having 10 grades according to its strength and 24 types according to its direction. Shen Guo once recorded a land tornado in his book. “There is a tornado coming from the south-east in Enzhou and Wucheng. It looked like a huge sheep horn, and carried all the big trees. Quickly it disappeared in the sky.” Sima Qian (b. 145 BCE) divided clouds into three types according to their height from the ground. Eighteen pictures of clouds were drawn in the fourteenth century according to weather conditions. Later the number reached 32.

Weather Forecasting

Many methods of weather forecasting were used in ancient China. The first is forecasting according to the air humidity. In the second century, the Chinese recognized the relationship between the sound of a musical instrument and the weather. Later, Wang Chong pointed out that it would rain as the strings of a *zheng* (an instrument in some ways similar to the zither) became slack. No later than the eighth century the Chinese recognized that many waterdrops appearing on a solid body with good heat-conductivity, or high temperature and great humidity, were all omens of the rain.

The second method is forecasting the weather according to optical phenomena such as rainbows, rosy clouds, and halos. Some records written in the nineteenth century proved that the natives of Fuzhou could predict a heavy rain and a great wind, even a typhoon on the sea, according to the position and height of the rainbow. In the eleventh century, Kong Pingzhong pointed out that the morning glow is the omen of a rain, while the evening glow is the omen of a sunny day. Lou Yuanli, who lived in the Yuan Dynasty, stated that the solar halo was the omen of a rain, and the lunar halo of a wind. He also pointed out that the direction of a wind was the direction of the gap of the lunar halo.

The third method is forecasting according to the movement and patterns of clouds and fog. Clouds and fog are the bases of some weather phenomena such as rain and snow, so their height, patterns, and direction can be used to forecast the weather. Since the Tang Dynasty, there have been many such forecasts. Huang Zifa, who lived in the Tang Dynasty, once forecasted, “if there is some cloud moving against the wind, it will rain.”

The fourth method is the forecast according to sounds and lightning. There were many weather-related proverbs in ancient China. “If there is lightning in the southern sky, it will rain; if in the northern sky, it will not.” (Lou Yuanli). “If the lightning is irregular, it will rain hard.” “No rain, but thunder, go by boat, come by feet,” meaning it would not rain for some days.

The fifth method is according to the activities of animals. Some animals are sensitive to weather changes. The ancient Chinese could forecast the weather according to their activities. Wang Chong said, “If it is going to rain, ants migrate, earthworms come from their holes.” There was a proverb in the Tang Dynasty that said that if ants blocked up their holes, it would rain. Also ancient Chinese recognized that if birds’ wings moved hard as they fly, it would rain.

Meteorological Survey and Instruments

The ancient Chinese conducted many meteorological surveys and invented many surveying instruments.

Wind and Surveying Instruments

Two thousand years ago, the Chinese used a surveying flag and Xiangfeng bird to judge the direction of the wind. A Xiangfeng bird was made of copper slices fixed on the top of a high pole. It could be revolved by the wind, and its head was always along the direction of the wind. At first, Xiangfeng birds were used in meteorological observatories; later they were used in the government and private houses. Even now, some Xiangfeng birds can be found on the tops of some towers. Li Chunfeng recorded the method to measure the direction and speed of the wind using a chicken feather, i.e., to measure according to the moving direction and dip angle of the feather. In 1716, the Qing Government set up a meteorological network to survey the direction of the wind using surveying flags, which was the primary form of the modern meteorological network. However, the Chinese also began to use western wind surveying instruments at that time.

Precipitation and the Chinese Precipitation Gauge

Because precipitation was very important to agriculture and people's lives, in the Eastern Han Dynasty (AD 25–220) the court ordered that every noble government should report precipitation in the period from the beginning of the spring to the beginning of the autumn. Qin Jiushao recorded a kind of precipitation gauge – Tianchi Basin, which was widely used in 1247. The Western precipitation gauge and distiller were recorded in Chinese books of the eighteenth century.

Humidity and the Surveying Method

In the Western Han Dynasty, the Chinese invented a method to measure the air humidity by hanging a lump of earth and a bar of charcoal (or a feather). When the air was dry, the bar of charcoal (or the feather) was light; when the air was humid, it was heavy, but the earth had little change in its weight. By hanging a lump of earth and a bar of charcoal (or a feather) on the two ends of a staff separately and fixing a lifting string on the middle point, making the staff horizontal in the dry air, a humidometer was made. When the air became humid, the end which had the charcoal fell down. Huang Lüzhuang (AD 1626–?) invented a humidometer to indicate the air humidity by a moving needle. Later, Ferdinand Verbist (AD 1623–1688), a Belgian missionary, invented another one.

Atmospheric Temperature and Pressure

The Chinese paid much attention to atmospheric temperature. Wang Chong once pointed out that the atmospheric temperature changed during a day and affected rain and snow directly. Until recent centuries, the Chinese had not invented a thermograph. In the nineteenth century, Zou Boqi (AD 1819–1869) recorded a barometer for the first time.

Achievements in Phenology

Phenology is the process of discovering meteorological laws by the regular activities of some animals and the regular changes of some plants. The Chinese began their study in phenology a long time ago; some records of phenological phenomena written 3,000 years ago have been found. In Xiaxiaozheng (Lesser Annuary of the Xia Dynasty), there were some records of the turn of the months. The knowledge of the 24 divisions of the solar year in the traditional Chinese calendar was gained in the Spring and Autumn Period (770–476 BCE) and the Warring States Period (475–221 BCE). Every day marking the 24 divisions has relationships with agricultural activities. The Chinese usually arranged their agricultural work and other activities according to the 24 divisions of the solar year.

There are many records of phenological phenomena written during the period of the Western Han Dynasty to the Song and Yuan Dynasties (ca. second century BCE to fourteenth century AD). Lu Zuqian (AD 1137–1181), who lived in Northern Song Dynasty, observed the phenological phenomena in Jinhua, Zhejiang province for 19 months and made many records, including the blossoming of 24 kinds of flowers such as winter sweet, peach, plum, lotus, and chrysanthemum, and the first appearance of the spring warblers and the autumn insects.

No later than the Spring and Autumn Period the Chinese recognized that migrants' activities changed with the seasons. Shen Guo recorded in his book that the natives of Hebei called the frost "information frost," because they knew there would be a frost when the wild white geese came.

There are many Chinese records of meteorological phenomena, and they are still used today.

Meteorology in India

A. S. Ramanathan

From the beginning, people tried to understand their surroundings and make use of their beneficial aspects. Their first action in this direction was to produce food, making use of the available water in the rivers and rainfall in the region. Though initially extreme phenomena like heavy rains, winds, cold and hot spells, droughts, and floods appeared incomprehensible and hostile, early humans gradually sorted out their seasonal character and planned their agricultural operations accordingly. Thus began in a crude way the development of weather science all over the world.

In India, the development of this science commenced in the early Ṛgvedic period. That the heat of the sun lifts the water to the atmosphere which after some time comes down as rain was recognized by the Vedic seers at a very early stage. In order to explain the occurrence of rain during a restricted period of about 2 months in their region in extreme northwest India, they imagined that water was absorbed by the sun's rays in the vast ocean areas in the south during the winter season and the humid air carried northward by the sun's rays. When the sun attains its extreme northward position and starts retracing its path, the humid air gets deflected near the foot of the Himalayas and brings rain from the east to their region. These moist easterlies replace the westerlies that were present in the region before the arrival of the monsoon rains. Whenever there was drought, they performed rituals to invoke the rain god. They believed that in nature there is a feed of a substance called *soma* from above into the atmosphere, which aids the occurrence of rainfall. Therefore they fed into the ritual fire some substances like wild dates and some special types of grass which produced smoke and were believed to be effective in aiding rainfall.

The post-Vedic scholars developed the subject further, mainly working on the pregnancy concept of rainfall. They looked for symptoms in the winter season for the commencement of pregnancy and identified the characteristics of winter disturbances in their region as indicating the same. Working along these lines, they were able to observe weather very carefully during the premonsoon months and were able to define the course of events which go toward the nourishment of rain embryos and the delivery of good summer rainfall at the right time after 195 days. Any departure from the defined meteorological conditions during the growth period, such as too much rainfall or snowfall, unfavorable winds, and temperature, was said to affect the quantity of rainfall delivered during the rainfall period. They also believed that hail would occur if the rain fetuses stayed too long in the atmosphere. The moon's position with respect to the sun and the stars was believed to influence the formation of rain embryos. The moon was conceived as a replica of soma in the heavens, and soma was capable of fertilizing the atmosphere.

Based on such concepts and extensive observations, the post-Vedic scholars developed several rules of long range rainfall forecasting. If they were successful, it was certainly due to their capacity to observe day-to-day weather and individual weather elements, like clouds, temperature conditions, wind, rain, lightning, and thunder. They were extremely clever in mentally working out correlations based on observed data. For short- and medium-range forecasting they framed many rules of thumb based on winds, clouds, temperature, lightning, thunder, moisture in the atmosphere, behavior of people, animals, birds, snakes, worms, insects, trees, and plants, as well as visual impressions of the sun, moon, stars, and sky. They were so thorough with local weather that their capacity to forecast in the short- and medium-range was as high as that of any modern forecaster who does the same with sophisticated equipment and maps.

Measurement of rainfall in India dates back to the fourth century BCE. A standard rain gauge was constructed around the third century BCE, and this system of measurement was prevalent in North India for a very long time (third century BCE to sixth century AD).

Well before the birth of Christ, the Arab dhows sailed across the Indian Ocean for trade purposes. Hippalus, a Greek pilot of the first century, sailed across the Arabian Sea for the first time. A handbook for merchants called *Periplus* was written by a Greek around AD 50. Subsequently, Arab geographers wrote many books giving details of Indian Ocean voyages. Sidi Ali's *Mohit*, written around AD 1554, not only gives a map of the Indian Ocean area, but also mentions the occurrence of monsoons at 50 distinct places.

With the arrival of more voyagers from the west in the Indian Ocean, a steady effort for systematically observing the wind, weather, and weather systems of the Indian Ocean commenced. In his first voyage from Melinda to Calicut in 1499, Vasco da Gama made use of the monsoon winds and reached his destination in just 3 weeks. William Dampier published many observations of Indian Ocean weather and weather systems in his travel accounts. He was a sixteenth-century buccaneer who lived and worked with some of the rowdiest pirates in history. But he was also an astute observer of nature in general and weather in particular. In his *Discourse on Winds and Breezes*, *Storms and Currents*, he deals with general wind systems throughout the world and their seasonal changes, which include the Southeast trades of the South Indian Ocean and Northeast and Southwest monsoons of the North Indian Ocean. During the seventeenth and eighteenth centuries, the military and trade activities of the European powers in the Indian Ocean waters increased.

Matthew Maury in his *Physical Geography of the Seas* (1874) explained the formation of monsoon winds as resulting from the heat of the plains and deserts of the Asian region. The following ideas about the mechanism of the Southwest monsoon and its rainfall were generally agreed upon by the meteorologists of the nineteenth century.

The plains of North India get very hot during the summer, and the air over that region ascends and becomes light. As a result, air over the sea areas, where the pressure is high both in the neighborhood of the equator and south of it, moves toward the region of low pressure of the land. The Southeast tradewinds, while moving northward and crossing the equator, become

Southwest winds, owing to the rotation of the earth. Again, these Southwest winds do not blow directly into the region of low pressure, but go around it in an anticlockwise direction. If one stands with one's back to the wind, the pressure to the left is lower than to the right in the northern hemisphere. In the southern hemisphere, the relation is reversed. The copious precipitation of the west coast is due to the high mountains which run along the coast. The higher the mountains, the heavier the precipitation. The monsoon is sustained by the latent heat released during the precipitation, which adds more heat to the atmosphere, and therefore further rarefaction takes place. Strong winds blow into the region of heavy rainfall, since air from the neighboring regions rushes to occupy the space created by ascending air.

Meanwhile, more knowledge was added to the science of cyclones in the Indian Ocean. Henry Piddington made a monumental contribution to the science of storms. He was the first to coin the term "cyclone", which gained world usage later. In a series of papers he gave detailed accounts of many Indian Ocean cyclones. His bestseller at that time was the *Horn Book of Storms for the India and China Seas*, which was followed by another book called *Horn Book for the Law of Storms*, in which he explained the use of transparent horn cards provided in his book for finding out the center of cyclones.

Many Indian meteorologists, led by Desai, Rao, Koteswaram, and Majumdar, worked on various aspects of the formation of cyclones. They investigated the role of the upper tropospheric flow patterns in the intensification, movement, and dissipation of tropical disturbances in the Indian Ocean. The availability of aircraft winds and satellite pictures enabled the meteorologists, such as Raman and Srinivasan, to study the low-level convergence and associated winds around the calm eye region of the cyclone, upper-level divergence, and the relation of the direction of movement to the upper-level winds. They also studied the influence of sea surface temperature on the formation of the cyclone.

As regards the Southwest monsoon, the upper air observations of wind and temperature and also the newly formulated dynamical concepts enabled the meteorologists to understand many synoptic aspects of the monsoon. Many meteorologists studied the role of the easterly jet stream and the Tibetan high, the northward shift of the westerly jet stream, the advance of the intertropical convergence zone to northern India, and the extension of equatorial westerlies. Koteswaram and Flohn (1960) made important contributions in this field.

Today meteorology in India is a highly developed subject, both from the research and service point of view.

Meteorology in the Islamic World

William J. Mcpeak

Medieval Islamic conceptions of nature and physical phenomena were partially based upon a translated accumulation of Greek thought. Among the Greek philosophers who had conjectured upon the phenomena of the atmosphere, the most famous was Aristotle (384–322 BCE), whose geoscience treatise in four books called *Meteorologica* dealt not only with atmospheric phenomena but also with the general terrestrial aspect (including geological, hydrological, and oceanographical ideas) of his systematic cosmology.

Some of the questions pondered were meteorological: whether the Milky Way and comets were of terrestrial or celestial origin, hail forming theories, the origin of wind, the relation of thunder and lightning, and optical theories of the rainbow and the halo.

With the ninth century came a stabilization of the long political turmoil after the Islamic conquests. Also, with the rise of the Abbasid Caliphate at Persian Baghdad, that civilization and India significantly influenced the seminal culture of the new Islamic empire. With the founding of a translation center within Caliph al-Maʾmūn's (813–833) *Bayt al-Ḥikma* (House of Wisdom) at Baghdad, the next three quarters of a century would be very important for Islamic thought.

The *Meteorologica* would have been included among the Aristotelian translations. Evidently the first translation of the work into Arabic from the original Greek or Syriac of about 820 was that by the Jewish Arabic scholar Yaḥyā ibn-al-Biṭrīq (fl. ca. 820). Abū Naṣr al-Fārābī (ca. 870–950) had, following the Persian mathematician al-Kindī (ca. 801–ca. 866), adopted the Aristotelian classification of knowledge with study of nature under physics. In addition, the general scheme of Islamic knowledge defined philosophical science with seven subdisciplines of natural sciences, with meteorology as one of those. Though virtually lost, al-Fārābī's many large commentaries on Plato and Aristotle included the *Meteorologica* in his *Kitāb Iḥṣāʾ al-ʿulūm*. But he only discussed the traditional conception of the four elements of matter – earth, air, fire, and water – in noting the contents of the work.

Four particularly outstanding Islamic thinkers accentuate the tenth through the twelfth centuries. The great Afghani polymathic scholar Abū Rayḥān al-Bīrūnī (973–1048) wrote copiously, though again many works are known only by name. A rare linguist, who knew not only Arabic and Persian but also Turkish, Sanskrit, Hebrew, and Syriac, he steered clear of formal Aristotelian commentary, showing an observationally rich interest in the geosciences. His *Taḥdīd Nihāyāt al-amākin li-taṣḥīḥ masāfāt al-masākin* (Determination of the Coordinates of Cities) discussed fossils, physical geology, geography, and the ancient geodetic problem of finding the circumference of the earth. His *Kitāb al-tafhīm li-awāʾil ṣināʿat al-tanjīm* (The Book of Instruction in the Art of Astrology) also contained much on the sublunar world, including weather and climate over the known globe. Of the more conventional meteorological fare, he accepted basic ancient atmospheric ideas, including a variant view of the Milky Way as atmospheric smoky vapors screening the stars. The three most recognizable Islamic contributors to meteorology were: the Alexandrian mathematician/astronomer Ibn al-Haytham (Alhazen 965–1039), the Arab-speaking Persian physician Ibn Sīnā (Avicenna 980–1037), and the Spanish Moorish physician/jurist Ibn Rushd (Averröes 1126–1198).

The commentaries of these great philosophers reflected the high end of Arabic evolution toward the dictates of observation based on the logic of both critical deductive and inductive reasoning. Ibn al-Haytham, particularly noted for his seminal experimentally based inductive reasoning, was the first outstanding medieval Arabic theorist of physical optics with important applications to meteorological phenomena. His prolific output included some 20 science treatises, including his great optical treatise *Kitāb al-manāẓir* (Book of Optics).

Among the optical discussions, the treatise contained his extensive experiments and findings on reflection and refraction, and his experiments on the rainbow mechanism, a phenomenon all the vogue as a physical problem in the Middle Ages. His rainbow findings were also reported in his *Qaws quzaḥ wa'l-ḥāla* (On the Rainbow and the Halo), a work not in the *Optics* nor available other than as a manuscript. Ibn al-Haytham's innovative experimental method entailed a laboratory to study the phenomena of the earth, such as chemical compounds, as well as his optical studies. Aristotle had considered the rainbow a reflection phenomenon from clouds of uniform drops acting as a continuum surface like a convex mirror. Ibn al-Haytham, researching reflection of light from plane and curved mirrors, reasoned that the phenomenon was a case of reflection similar to a spherical concave mirror. He simulated the rainbow colors by transmitting sunlight through glass spheres of water, spherical concave mirrors representative of clouds, with the cloud still acting as a continuum. Unfortunately, he also decided that refraction had nothing to do with the phenomenon, considering the same mechanism for the lunar halo and solar corona. He also employed his ideas of reflection in dealing with a terrestrial Milky Way in one of his treatises, *al-Majarra* (On the Milky Way).

Ibn al-Haytham has been considered the first thinker to realize the refractive, i.e., light bending properties, of the atmosphere. The phenomenon had been continually hinted at since ancient times in the discrepancies found in observing celestial objects because of near horizon distortion of position and size. He wrote a short treatise, *Mas'ala fī Ikhtilāf al-naẓar* (A Question Relating to Parallax). And, in his *Fī maʿrifat irtifāʿ al-ashkhāṣ al-qāʾima wa-aʿ midat al-jibāl wa irtifāʿ' al-ghuyūm* (Determination of the Height of Erect Objects and the Altitudes of Mountains and of the Height of Clouds), he was evidently the first medieval thinker to use knowledge of refraction in theorizing by a convoluted geometry that the atmosphere was much lower than the ancients had estimated. His near contemporary Cordoban Ibn Muʿādh (ca. 989–1079) should also be mentioned in regard to atmospheric height for his singular hypothesis in his treatise – mistakenly attributed to Ibn al-Haytham – "On the Dawn" (evidently known only by the Latin translation by Gerard of Cremona *Liber de crepusculis*), also called "On Twilight and the Rising of Clouds." Sunlight before sunrise and after sunset are also phenomena of refraction, and Ibn Muʿādh estimated the angle of depression or the sun at dawn and evening twilights, arriving at the fairly accurate value of 18° by which the height of atmospheric moisture (believed responsible for twilights) and thus atmospheric height could be determined.

Ibn Sīnā a and Ibn Rushd represented concerted Arabic commentary as it moved from the eleventh to the twelfth century. Though more noted for his varied contributions to medicine, Ibn Sīnā contributed to physical science in 20 volumes of general thought, *Kitāb al-ḥāṣil*. He also wrote on the seasons and climate in the *Kitāb al-Anwā*ᵓ (Book of Meteorological Qualities). Ibn Sīnā's meteorological significance centers on the rainbow mechanism and the medieval fascination with the origin of the Milky Way. Departing from Aristotle's cloud continuum and Ibn al-Haytham's spherical mirror analogy, he reasoned that the rainbow was the result of reflection from the total amalgamation of water drops – this being the key discovered later – supposedly released by clouds as they dissolved into rain. His observational prowess is seen in his explanation. The idea came to him by watching the diffraction of sunlight by water drops created by the watering of a garden in a bathhouse. He thought the Milky Way celestial in origin, voicing yet one more assent to a physical concept important to both meteorology and astronomy as an eventual point of redefinition of the ancient boundaries of celestial and terrestrial phenomena. Yet, as with thinkers to follow and into the late eighteenth century, the fact that the Milky Way was an expanse of stars and not a by-product of those stars, escaped him as well. Ibn Rushd also held a celestial opinion of the Milky Way, one more both analytical and worthy of further discussion.

Contrary to a later conception of Ibn Rushd as slavishly Aristotelian, we can say that his jurist's logic followed the exact Aristotelian order of nature as a model of systematic formulation. Ibn Rushd wrote both short introductions and extended larger commentaries, such as *Al-aṭār al-ᶜalwiyya,* which included textual discussion, arguments about the opinions of other commentators, and his own analysis.

The Milky Way was a more bothersome challenge. Ibn Rushd decided that Aristotle's theory was untenable since it depended on the reality of hot and dry exhalations which had not been proved. He also reasoned by the phenomenon of parallax (the apparent change in position of relatively close objects with change in position or view of an observer) that if the Milky Way were terrestrial (below the sphere of the moon) and thus relatively close, it would have a backdrop of different stars depending on where it was observed. In proving this, Ibn Rushd spent time observing and recording the positions of the Milky Way with respect to the stars in the constellation of Aquila from different locations. He found no change. He also noted that because the Milky Way was a constant phenomenon, whereas the exhalation was an ever changing one, the Milky Way appeared to be in the celestial sphere. But ultimately he kept the phenomenon terrestrial, calling it an atmospheric refracted image of light from a conglomerate of small stars seen from the perspective of earth.

Among later commentators was Abū'l-Faraj (Aboulfarag d. 1286), the Nestorian bishop, who wrote a theory in 1279 of the Milky Way phenomenon in relation to fixed stars and constellations. He leaned toward considering the Milky Way as wholly consisting of stars and having nothing to do with terrestrial nature.

Islam's commentary also turned to its first generation of philosophers. Optical interests seemed to die with Ibn al-Haytham, until Quṭb al-Dīn al-Shīrāzī (1236–1311) and his student Kamāl al-Dīn (d. 1320) pursued a more critical look at his optics in *Tanqīḥ al-manāẓir* (Revision of Optics), which also delved into rainbow and halo theory. In analyzing Ibn al-Haytham, Kamāl al-Dīn initially looked to Ibn Sīnā's rainbow as a water drop reflection phenomenon, leading him to consider the water drops as analogous to transparent spheres of water. This was the breakthrough conclusion, allowing him to reason that two refractions took place, one on and one in a cloud drop in the rainbow optics. Kamāl al-Dīn used a better conceptual physics and geometry to explain the rainbow than Ibn al-Haytham had used.

The cultural devastation of the Mongol invasion of the thirteenth century punctuated the end of the Islamic golden age. Nonetheless, it left its intellectual legacy in North Africa and passed to Spain, where cosmopolitan Toledo served as a clearinghouse of translation for both Christian and Islamic scholars.

Military Technology

William J. McPeak

The term military technology is broad, and, as a subject restricted to non-Western cultures, potentially laden with analytical complexity. In fact, the constraints of a survey make it necessary to view the more technical innovations of the larger cultures rather than the myriad of variations on pointed weapons fashioned by essentially all peoples. Stimulated by environment and nature, the gamut of world cultures have used artistic and functional inventiveness in weaponry. Non-Western ancient military technology provided significant origins for Western military technology as well.

The first most significant line in the military technology progression was metallurgy of copper in the transitional period between the Neolithic and true Bronze Ages, approximately between 4500 BCE (perhaps 5000 BCE) and 3500 BCE in the Near East arc from Mesopotamia to Egypt. Copper's cold malleability enabled the earliest metalworkers to beat, rather than fire it from the ore as with harder metals. In doing so, they could fashion a metal version of basic wood, bone, and stone pointed weapons: arrow tips, spears, and particularly, swords. This was followed by smelting (melting metal to separate out impurities) and founding (melting the purer metal for casting and molding). By about 3000 BCE the general use of copper and experiment with its alloys (bronze with tin and brass with zinc) ushered in the Bronze Age to southwestern Asia over five centuries before general use. This was an essentially Near Eastern phenomenon, probably disseminated to India, Anatolia, and surrounding areas after this.

As far as we know today, the first great civilization of humanity was that of Sumer in southern Lower Mesopotamia after 4000 BCE. Among so many accomplishments handed down to subsequent Mesopotamian civilizations and the west, one especially important one was worked copper alloys and probably bronze swords. Mesopotamian cast copper mace heads, the first technical use of metal, date from 2500 BCE. About the same time Sumerian smiths were casting socketed axe heads. In the north, Semitic peoples to be called Akkadians, from which the Assyrian and Babylonian cultures developed, assimilated Sumerian technology. Before 2000 BCE non-Semitic, Indo-European invaders from central Asia began various waves of infiltration from Asia through Asia Minor into Mesopotamia and on to India. All would leave their military mark. Among these were the Hittites from the northwest and later the Hurrians from the northeast and the Caucasus – the one moving into Lower, the latter into Upper Mesopotamia.

The Hittites overran most of Asia Minor (Anatolia) after 2000 BCE and about 1500 BCE invaded Babylonia long enough to raze Babylon. Anatolia, a high plateau fringed by mountain ranges, was rich in mineral resources, among these gold and silver, but most importantly iron. The Hittites probably ushered in the early Iron Age by their use of this much harder metal in their weapons. In the general extent of southwestern Asia the Iron Age did not arrive until about 1000 BCE, although a few Mesopotamian objects of perhaps smelted iron have been dated before 2200 BCE, and some Egyptian work has been conjectured as even older. Iron was much superior to bronze in edged and projectile weapons and required higher temperature metallurgical processes of smelting iron ore and founding the crude metal. Although it was thought in some quarters of the last century that Egypt was the cradle of iron work, development of its metallurgy may have been contemporary with that of Asia Minor, considering abundant Egyptian iron resources. The use of iron also brought more effective defensive hardware, i.e., in armor and in horse trappings and the chariot.

The horse and the two-wheeled chariot were Hittite innovations to western Asian warfare. The horse brought mobility to tactical maneuvering on the battlefield for the specialized soldiers called cavalry. The chariot was introduced during the eighteenth century BCE and likely by the Indo-European Aryans (Indo-Iranian, also metalworkers – perhaps early iron weapon users) who invaded Iran from the northeast at that time and influenced the Hittites and evidently held sway over the Hurrians. The chariot provided a further tactical edge, allowing a soldier or two soldiers to act in concert in inflicting multiple casualties at one time. As specialized warriors, the charioteers introduced military class rule to Near Eastern civilizations. With the added innovations of scythe-like blades on its wheels, the chariot also added the mass fear psychological factor to warfare. The Hittites took northern Syria in their clash with Egypt about 1400 BCE, the latter having adopted the horse and chariot after their temporary defeat by the chariot tactics of the Hyksos, Amorite peoples who invaded Palestine about 1700 BCE. These latter also contributed large fortification technology to the general mud wall military architecture pool of the Near East which started with the high curtain walls of ancient

Jericho (8000 BCE), the first example of specialist military architecture.

By the middle of the fourteenth century BCE the Assyrians were able to take the military ascendancy in Upper Mesopotamia and eventually all of Mesopotamia by the late eleventh century BCE, to become a great empire. By the eighth century BCE the Assyrian army had reached an apex of coherency, a blueprint for the Persian army. Made up of both professional and militia soldiers, the Assyrian army equipped all troops with finely tempered iron weapons. They employed cavalry and chariots, archers (using the composite recurved or reinforced bow, found in the Middle East to 3000 BCE), and slingers, who used the simplest, oldest missile weapon. Adding to their siege tactics, sappers (essentially meaning diggers at that time) were used in approaches to mud-walled defenses, as were battering rams and wheeled platforms, equipped with shielding defenses against arrows, for rolling against such walls. By the sixth century BCE the Persians had become heir to the Assyrian Empire and to the diverse military technology of the Near East. It remained dominant for 200 years until the informal transition of east to west finally came face to face with the challenge of Greece under Alexander the Great in the middle of the fourth century BCE.

In the Far East, Chinese civilization as far back at 2000 BCE was characterized by a value placed on functional technology. The integration of the wall into Chinese cultural architecture was given a profound military expression in the Great Wall, which was started in 214 BCE by the first emperor Shi Huangdi as a linking of earlier rampart walls. It was meant to keep out the north/northwestern invaders who would plague China for centuries. The crenellated, brick-faced wall still stands, stretching some 4,000 miles and 30 ft (9 m) high, with regular spaced square watchtowers 40 ft (12 m) high with a 9–12 foot (3–4 m) passageway through them. Along with their own cultural variations on basic weapons, the Chinese designed light hunting crossbows by the fifth century BCE and were using them in combat by the second century BCE.

The use of iron metallurgy continued to be the prime advance in military technology. Iron ore is plentiful all over the world. Variations of alloying iron with carbon in smelting processes, which included the introduction of air blasting to fan the fire (the forge) to high temperatures, meant that steel (iron with a small proportion of carbon) and its hardening were probably fairly contemporaneous with iron working (from 1000 BCE). Although dating is indeterminate, the great deposits of iron in Central Africa and the proximity of the Egyptian influence point to limited iron and steel forging. Indian weapons of iron were prevalent by 500 BCE. In fact, tempered steel was produced fairly early in India. Bars, rods, and plates of raw steel were exported throughout the Near and Middle East. Indian steel was used in the founding of blades of "watered steel" (the process of folding malleable steel over and over then beating it out). These light, high tensile strength curved (Damascus) blades enabled the effective long sweeping offensive draw cut, used by both the infantry and cavalry of western and central Asia down through the last century.

The development of the relatively simple smelting methods of steel and steel weaponry was disseminated eastward to southeast Asia via Indian colonization. Iron weaponry and working began independently in China about 500 BCE and smelting of crude steel was fairly contemporaneous (about 400 BCE). By the Middle Ages the effectiveness of the Mongolian steel saber, influenced by Middle Eastern contacts, was supplanting the straight Chinese sword. Japanese iron weaponry, with Chinese influence, began about 200 BCE, although the earliest relics date between the second and eighth centuries BCE. The best of the distinctive long, slightly curved samurai steel blades date from the twelfth century and progress to the fine temper-lined watered blades of later centuries. All these areas applied iron and steel technology to military accoutrements and armor. The work of the Near and Middle East, China, and Japan was particularly artistic as the Middle Ages progressed.

Although the steel sword would remain the principal weapon of the great non-Western cultures, the destructive potential of gunpowder technology into the High Middle Ages was to affect the larger non-Western cultures as it did the West. The use of incendiaries was already ancient, most noticeably in China. The so-called "Greek fire," the generic term for a variety of mixtures based on naphtha (a petroleum distillate) added to sulfur, pitch, turpentine, tars, and oils (in modern interpretation, probably a suspension of metallic sodium, lithium, or potassium in a petroleum base), was perhaps in crude use by the fifth century BCE. It is noted as being used by the Boeotian Greeks at the siege of Delium in 424 BCE during the Peloponnesian War.

The historiographic origin of gunpowder, that is black powder, is still controversial. The gunpowder recipe itself is of uncertain origin, but its basic constituents are now generally first attributed to ninth century Chinese alchemists. It might also be the independent product of Islamic lands, most like Moorish Spain by the mid-twelfth century. From there it perhaps moved to India where there may have been independent knowledge and use of the chemical ingredients from the late eleventh century. It was known in northern Europe by the early thirteenth century. The argument for an intermediary disseminator, the Eurasian Steppe lands, the European/Asain crossroad, to Islam and Europe, particularly by the thirteenth century Mongols is also plausible.

Explosive application of gunpowder in a weapon has also been controversial. Some theorists of Chinese primacy (Chinese toy rocket experiments for fireworks evolved early) date bamboo-tube hand guns or cannons and rockets for arrows and spears from AD 900–950. Various types of incendiary arrows, slings, and javelins, as well as incendiary and exploding bombs, grenades, and fire-balls are also attributed to the Chinese by the eleventh century. The historical point of military effectiveness of such devices remains uncertain. Widespread military use in China did not appear until the Song-Jin dynastic wars of the twelfth and thirteenth centuries. By the thirteenth century bomb technology with iron casings and large size was used by Chinese and Mongolian antagonists in land siege warfare. There is also evidence of time delay fusing using flintstone abraded against steel wheels to set off multiple mines in fourteenth century China. Rockets were introduced to Europeans during the Mongol western invasions at the Battle of Legnica in 1241. There is also evidence of rockets in India in the 18th century.

Gunpowder weapons applications appeared about the middle of the thirteenth century in Muslim North Africa and Moorish Spain as crude iron and iron-reinforced wooden bucket mortars for flinging stones in fortifications warfare. Also, Moors were using effective rockets on Spanish soil by 1249. Thereafter some evidence shows that the evolution of mortars, cannons, and finally handheld firearms progressed with most tactical efficiency in Europe, although some historians date Chinese cannons of significant size and metal composition from as early as the tenth century. Non-Western applications were innovative in their own right. By the middle of the fourteenth century, cannons mounted on walls or on mobile carriages and cradles had replaced most of the traditional engines of war in both Europe and the Near East. And Eastern projectiles ranged from stone balls to huge arrows with sheet-metal fins.

The growing threat to Eastern Europe, the Adriatic, and the Aegean by the ascendancy of the Ottoman Turks through the fourteenth century was furthered by their pursuing the use of artillery to challenge the weakening Byzantium Empire. A parallel was the thirteenth century Mongol challenge and conquest of China, with cavalry, siege tactics, and gunpowder technology. By the fifteenth century the Turks were casting – sometimes with the guidance of European renegades – huge bronze mortars and cannons, such as those used in the final siege and fall of Constantinople in 1453.

The Turks also turned to the Western matchlock arquebus, the first gunpowder longarm, which was the single most important transitional pivot from medieval to modern warfare. The Ottoman domination over the Arab world influenced firearm dissemination to Arabia and North Africa where, unlike the more angular stock of Turkish and Persian guns, styles reflected Arab and Kabyle preferences.

The influence of the West on the Asian Pacific was initially felt in trade and subsequently in acquaintance with western gunpowder technology. Perhaps the most interesting case involved the Japanese, who quickly adapted the matchlock arquebus which the ubiquitous Portuguese traders, already established in China, brought in 1542. The Japanese matchlock was an austere but highly stylish weapon, smaller in size and caliber than western matchlocks with a spring design firing mechanism, which soon joined the traditional feudal weapon array and went on to change the tactical maneuvering of the civil warfare of the sixteenth century.

The Korean civilization provides an interesting development in Asian and world naval warfare at this point in military technological history. Located on a strategic peninsula, the Korean people endured centuries of piratical incursions from the Japanese islands on one hand and politically complex dynastic invasions' from the Chinese mainland on the other. A sophisticated native culture, including science and technology (particularly, shipbuilding), was able to grow from the tenth century. Until 1592 peace and cultural advances continued. Then the Japanese general Toyotomi Hideyoshi unified Japan, calling for the invasion of China through Korea, which refused his passage. Although they had cannon, the Koreans did not have the matchlock longarms of the 200,000 Japanese invaders. The ensuing incursion was successful until 1593 when the Korean admiral Yisunsin invented what must be the first ironclad ship, evidently thin iron plating over a high, flattened oval-shaped ship of 16 oars with circumference cannon ports. Burn and board-proof, a fleet of these "tortoise boats" was sent against and defeated a Japanese armada in Chinhai Bay. This triumph provided the impetus to drive the Japanese out.

The Chinese perpetuated their own hand cannon, large wall artillery technology, and shipboard cannon well into the nineteenth century. They adapted to the Portuguese style of longarm lock but designed their own pistol grip-like stock. Both features influenced the far away Malaysian peninsula gun style which itself influenced the intermediate region of the Gulf of Tonkin. On the under side of Asia, Indian matchlocks showed significant regional variations from both the Portuguese and Arabic initial introduction. Three basic subcontinent Indian matchlocks were joined by very stylized weapons from Ceylon (Sri Lanka). By the early seventeenth century the Ceylonese exceeded the Portuguese in the manufacture of musket size matchlocks, one type with a unique bifurcated scroll butt. The Burmese side of the Malaysian peninsula essentially used Indian matchlocks with local decorations.

Although more isolated non-Western peoples continued to use the matchlock (indeed, the Japanese did until the early nineteenth century), most succumbed to trade and import and adapted to the progression of firearms manufacturing and, just as significantly, ordinance technology in keeping with the single-minded exigencies of superiority in warfare. These latter factors inevitably and irrevocably set the new course of non-Western military technology as a dependent reflection of the West, a reflection all the more thought provoking in the modem shadows of nuclear and chemical weaponry.

Military Technology in Ancient Egypt

MICHAEL BERGER

Weapons and warfare were a part of ancient Egyptian life from the Prehistoric periods through Dynastic times. While examples of actual weapons, chariots, fortifications, and ships are relatively rare, Ancient Egyptian art and archaeology provide us with many depictions and descriptions of these objects. This information helps us to identify and reconstruct some of the technologies of the Late Prehistoric and Pharaonic periods (3500–332 BCE).

Weapons

The Ancient Egyptians used a large a variety of weapons in the Predynastic and Dynastic periods. Many of the early types continued to be used throughout the Pharaonic period. Generally, weapon innovation in Egypt tended to lag behind neighboring states and groups in Southwest Asia due to social, technological, geographical, and political factors (Spalinger 2005: 15). Whereas individual craftsmen produced weapons until the Late Neolithic period, by the Early Dynastic period specialized royal workshops were producing larger volumes of weapons (Gilbert 2004: 71–72; Gnirs 2001: 405). At the beginning of the New Kingdom, new weapons were introduced into Egypt from Western Asia, and a period of innovative design started, during which Egyptian craftsmen perfected designs for the chariot and composite bow (Shaw 1991: 59, 68–69; Spalinger 2005: 1).

Most scholars categorize Egyptian weapons by their range: short-, medium-, and long-range (Schulman 1995: 290). Weapons can also be grouped according to their function: e.g., specialized weapons, tool-weapons, etc. (Gilbert 2004: 33). Both methods are useful, and they provide different perspectives on the way weapons were used in Egypt.

Short-range or close-combat weapons were the mace, club, ax, stabbing spear/lance, dagger, sword; medium-range weapons were throwing stones, throw-stick/boomerang, throwing spear/javelin. Long-range weapons were the sling and bow and arrow. Specialized weapons were the mace and sword; weapon-tools were the spear, ax, club, boomerang, sling, and bow and arrow. Tool-weapons were knives, hammers, etc. (Gilbert 2004: 33).

The primary materials for the production of weapons were stone, copper or copper alloy, wood, and leather, but bone and ivory were also used (Hoffmeier 2001: 406). Use of chert/flint in tools and weapons dates to the Paleolithic period and continues through the Dynastic period, for specific weapons, like spear and arrow heads, because it was abundant in Egypt and fairly easy to work (Hoffmeier 2001: 406; Gilbert 2004: 33, 71–72; Nicholson and Shaw 2000: 28–29). Copper was used for weapons by the end of the Neolithic period, and continued to be used after bronze became more widely used in the Middle Kingdom. (More copper objects were found in Tutankhamun's tomb than bronze ones; Nicholson and Shaw 2000: 153–154.)

Natural, unworked stones were probably one of the earliest weapons (along with sticks). Stones could be thrown or used as hand-held weapons (Newberry 1893: Pl. 14). Slings were an inexpensive and easily made weapon, and could propel a stone to a greater speed and attain a superior range than a thrown stone (Hoffmeier 2001: 410). While there is no evidence in early Egypt for slings, they are used in later periods (Gilbert 2004: 70).

Military Technology in Ancient Egypt. Table 1 Ancient Egyptian chronology

Late Predynastic period (3200–3032 BCE): Dynasty 0
Dynastic or Pharaonic period (3032–332 BCE): Dynasties 1 to 30
Early Dynastic period (3032–2707 BCE): Dynasties 1 and 2
Old Kingdom (2707–2216 BCE): Dynasties 3 to 8
First Intermediate period (2216–2046 BCE): Dynasties 9 to early 11
Middle Kingdom (2046–1794 BCE): Dynasties late 11 to 14
Second Intermediate period (1794–1550 BCE): Dynasties 15 to 17
New Kingdom (1550–1070 BCE): Dynasties 18 to 20
Third Intermediate period (1070–664 BCE): Dynasties 21 to 25
Late period (664–332 BCE): Dynasties 26 to 30
Greco-Roman period (332 BCE–395 AD)
Ptolemaic period (332–30 BCE)
Roman period (30 BCE–395 AD)

Maces were made from a shaped stone with a hole drilled through its middle for the handle. Many examples of disc-, oval-, and pear-shaped maces have been found in mortuary or temple contexts. Hard stone mace-heads in early Egypt were a status symbol. Maces are represented in the art of all periods, but their numbers decline after the early Dynastic period (Shaw 1991: 31; Gilbert 2004: 35–41; Shaw 1991: 31–32; *MH* 2, Pl. 102).

Although primarily used as hunting weapons in the Predynastic and Dynastic periods, sticks were also used by warriors and soldiers (Capart 1904: Pl. 1; Gilbert 2004: 69–70). Staffs and clubs were probably among the earliest weapons, and they are used throughout the Pharaonic period (Capart 1904: Pl. 1).

Axes were some of the oldest and most common weapons in ancient Egypt (Shaw 1991: 34–37). Stone axes (probably all hand-held) date to the Paleolithic period (Hoffmeier 2001: 407). Flint axes were produced in the Neolithic period, but the earliest evidence of an ax with a handle is perhaps the one on the Hunter's Palette, which dates to the end of the Late Predynastic period (3500–3300 BCE; Gilbert 2004: 63). Starting in the Mid-Predynastic period copper axes appear in Lower Egypt and subsequently appear throughout the country. Early axes are of plain form, some with holes and others with lugs for attaching to a handle, and most examples seem to be from the Early Dynastic period (3032–2707 BCE; Gilbert 2004: 63–68). In the Old and Middle Kingdoms semi-circular and rounded ax blades are shown used by Egyptian troops in siege scenes (Arnold and Settgast 1965: Fig. 2). These ax heads would have been attached to the haft with leather bindings (Shaw 1991: 34–37). A "scalloped" or three-"tanged" ax head was also used in the Middle Kingdom (2046–1794 BCE; Blackman 1914: Pl. 3). At about the same time, in Syria and Palestine axes with "duck-billed" blades and socketed heads were used and show up as copies or imports in Egypt (Hoffmeier 2001: 407; Spalinger 2005: 15; Gnirs 2001: 405). Later, in Western Asia and New Kingdom Egypt, longer, narrower ax blades that were more suitable for piercing shields or helmets appear and were possibly developed as a response to the introduction of armor (Shaw 1991: 34–37) (Table 1).

Examples of large-chipped stone spearheads dating to the Paleolithic period have been found in Egypt (Hoffmeier 2001: 407). One of the earliest representations of a spearman is on the Hunter's Palette (Gilbert 2004: 58). Flint spearheads continued to be used in the Old and Middle Kingdoms, even though copper spearheads appear in the Late Predynastic period (Gilbert 2004: 59). Bronze, socketed spearheads appear in the New Kingdom (Shaw 1991: 37). Spears could be used as an offensive or defensive weapon, but the javelin was primarily an offensive weapon. The lance or long spear was used as a thrusting weapon and was used in the Predynastic and Dynastic periods (Gilbert 2004: 60–61; Hoffmeier 2001: 407).

Bifacially flaked flint daggers and knifes were used in the Neolithic period and Predynastic periods. Copper daggers appear in the Middle Predynastic period and continue in use throughout the Dynastic period. Daggers were provided with wood, bone, or ivory handles (Gilbert 2004: 42; Shaw 1991: 37). As the use of bronze expanded in the New Kingdom, a longer dagger or short-stabbing sword was developed (Hoffmeier 2001: 407). By the Ramesside period (1292–1070 BCE), mercenaries in the Egyptian army employed longer, double-edged, pointed swords. The sickle-sword or *Khepesh* first appeared in Mesopotamia, and the Egyptian varieties that appeared in the New Kingdom were modeled on the West Asian types and may have been used more like an ax than a sword (Spalinger 2005: 15; Hoffmeier 2001: 408).

The bow and arrow were used in all periods, starting as early as the Late Paleolithic period (Gilbert 2004: 44–45). Until the New Kingdom most bows were made from a single piece of indigenous wood, which could be used to construct both the simple and double-curved/convex types of "self"-bows (Western and McLeod 1995: 77–79). These early bows did not have a nock for the bowstring, but instead the string would have been wound around the ends several times (Hoffmeier 2001: 408–409). Self-bows continued to be used in the New Kingdom, and 14 examples were discovered in the tomb of Tutankhamun (McLeod 1982: 1–2).

Influences from Western Asia led to the adoption of the composite bow in Egypt. Because of its construction – a laminated sandwich of wood between horn and sinew – the composite bow was more elastic and therefore had greater range and penetrating power than self-bows (Shaw 1991: 37, 66). There were recurved and triangular types of composite bows (Shaw 1991: 42, 66).

Arrows were composed of three elements: the point or arrowhead, the shaft, and the fletching. Arrow points were made from stone, ivory, bone, and wood in all periods and copper and copper alloys in later periods (Gilbert 2004: 46; Hoffmeier 2001: 409). Arrowheads were made in a variety of shapes, depending on use (Gnirs 2001: 405). Arrows with copper alloy points did not become common until mid- to late Dynasty 12 (ca. 1875–1794 BCE; Spalinger 2005: 15), and it was afterwards that the use of flint points declined (Gilbert 2004: 48–54). However, 20 arrows with flint transverse points were discovered in Tutankhamun's tomb (Gilbert 2004: 48–54). Reeds and wood were used for arrow shafts. The nocks could be cut in the reed or in a nock-piece made from wood, bone, or ivory fitted into posterior end of the shaft (McLeod 1982: 4–5). Fore shafts were attached to the anterior part of the shaft and could be made from the same materials as the nock-piece; the fore shaft was often sharpened to serve as the point. If arrowheads were used they could be attached to the shaft with mastic (Gilbert 2004: 49). Two, or more commonly, three, or four vanes of feathers were added to provide stability to the arrow in flight (Western and McLeod 1995: 77–79). Depictions of quivers were rare until the Middle Kingdom, and prior to that time archers usually carried arrows in their hands (Capart 1904: Pl. 1; Blackman 1915: Pl. 8 – both methods depicted here). (It is possible that the quiver was introduced into Egypt from Western Asia, since the Egyptian word for quiver is derived from a Semitic word; Spalinger 2005: 15.) In the New Kingdom quivers were still carried but were designed to attach to the sides of chariots as well (Shaw 1991: 66–67).

Shields are the only type of defensive equipment depicted in early Egyptian art (except perhaps the parry stick; Gilbert 2004: 43–44). In the New Kingdom new types of shields, helmets, and body armor appear, possibly as a reaction to the introduction of new powerful offensive weapons, like the composite bow and sword, and the increasing use of copper alloy for missile and hand weapons (Davies 1930: Pls. 16, 22, 23, and 24; Gnirs 2001: 405). The shields found in Tutankhamun's tomb were made from wood, leather, and other animal hides. In the New Kingdom copper or copper alloy shields or shield parts may have been used. Leather scale armor was used, as were leather tunics with attached copper alloy scales (Hoffmeier 2001: 410).

Chariots

Whether the Hyksos introduced the chariot into Egypt or if it came from Southwest Asia by some other means, its first mention in an Egyptian context does not occur until the beginning of the New Kingdom (1550 BCE; Spalinger 2005: 8–14, 18–23). The adoption of the chariot was rather rapid, since many of the technologies and conditions required for its construction and use already existed in Egypt in the late third and early second millennium BCE. For example, horses and the wheel are attested prior to Dynasty 18 (Gnirs 2001: 402; Shaw 1991: 65). However, the first steps in the development of the chariot occur elsewhere in the Middle East (Schulman 1980: 117–118; Hoffmeier 2001: 410; Littauer and Crouwel 2000). While the Hyksos may have employed chariots, there is no mention of their using them, nor has any evidence of chariots been discovered at Tell ed-Dab'a (Hoffmeier 2001: 410). There may be a reference to a chariot or chariot team on the Kamose stela, but the first clear text reference is found in the autobiography of Ahmose Son of Ibana, a career sailor who fought under the early kings of Dynasty 18: Ahmose, Amenhotep I, and Thutmose I (Lichtheim 1976: 12–14). Fragmentary battle scenes depicting teams of chariot horses and chariots were discovered in the ruins of King Ahmose's funerary structure at Abydos (Harvey 2001: 52–55).

The expense of chariot building and maintenance meant that its use was limited to the royalty and nobility (Schulman 1995: 295–297; Gnirs 2001: 403), so from the very start, the chariot was a status symbol, which besides being used in a military context was also employed in domestic activities like hunting and inspecting estates (Davies and Gardiner 1936: Pls. 50, 68; Davies 1903: Pl. 17; Davies 1905: Pl. 13).

There are few surviving examples of chariots or parts of chariots, but fortunately the Egyptians often portrayed them in paintings or relief sculptures on tomb or temple walls. Actual vehicles or vehicle fragments include the chariot from Yuya and Tuya's tomb, the Florence chariot, the six examples from Tutankhamun's tomb, the body of a chariot of Thutmose IV, and the Amenhotep III hub fragment (Davis 1907: Pl. 32; Carter and Mace 1927: 54, 60; Carter and Newberry 1904: 24–38; Hansen 1994: 52).

In art, chariots are shown in domestic contexts (e.g., Ahkenaten and Nefertiti visiting a temple), being constructed (e.g., in the tomb of Puimre), or in military contexts (e.g., Ramses II fighting the Hittites at Kadesh). In battle scenes, there is often a two-man crew represented, a driver, who also often holds a shield, and an archer.

The chariot was a mobile platform for archers, usually operating at a distance from the enemy. It also performed some of the duties that were later assigned to cavalry, such as screening infantry and out-flanking and pursuing the enemy. Use was limited by terrain: rivers could be difficult to ford and rough ground presented obstacles. Therefore chariot use was restricted to relatively flat ground, and because they were light and unarmored they could be easily damaged (Davies and Davies 1933: Pl. 7 – bearers easily carry parts of a chariot). Egyptian accounts of the battle of Kadesh relate that the Hittites deployed 2,300 chariots, but Schulman believes this is an exaggeration (Schulman 1980: 132). Nonetheless, the *Annals* of Thutmose III record that 924 chariots were captured at Megiddo (Gnirs 2001: 402).

Chariots were primarily composed of parts made from a variety of woods and leather, although other materials like metal fittings, textiles, glue, bone, and ivory were also used (Shaw 1991: 64). Chariot workshop scenes became a popular subject for New Kingdom tombs; they show workers making wheels, bodies and other components of chariots (Davies and Davies 1933: Pls. 7, 10, 11, and 12). Local and imported woods were used for many parts, some of which, like rails, drive poles, and yokes, required steam bending, a technique the Egyptians possessed prior to the New Kingdom (Nicholson and Shaw 2000: 357; Shaw 2001: 63–64). Leather was also used liberally in chariot construction, for floors, harnesses, and tires (Nicholson and Shaw 2000: 309; Scheel 1989: 47; Hoffmeier 2001: 410; Carter and Mace 1927: 56; Shaw 1991: 63), and for binding and protecting the more vulnerable components of the chariot (Davies and Davies 1933: 12).

The first Egyptian chariots had wheels with four spokes (Davies 1923: Pl. 23, bottom). A larger, stronger wheel was probably required as the chariot became bigger in order to accommodate a two-man crew (driver and warrior). Therefore, an eight-spoke wheel was briefly used, but this was abandoned in favor of the six-spoke wheel, which was found sufficiently strong to bear the weight of the crew (Carter and Newberry 1904: Pls. 10–11; Carter and Mace 1927: 57, 58). The hub or nave was the most complex component of the wheel and was composed of morticed halves, together with the six V-shaped spoke segments, and tenoned wheel flanges (used to extend the hub along the axle to prevent wobbling; Hansen 1994: 52; Carter and Mace 1927: 57).

Fashioned from a single piece of wood, Egyptian chariot axles were long (2–2.3 m) to provide great stability and maneuverability. There were no bearings, but the axle could be fitted with greased leather sleeves to minimize friction and wear from the wheel (Hansen 1994: 54). The placement of the axle at the rear of the vehicle helped to distribute the crew's weight between horses and wheels, and absorb some of the shock of the ride (Carter and Mace 1927: 56) (Fig. 1).

The body of an Egyptian chariot was small and light, being composed of a bent wood support frame and rails, with side panels of linen and leather. Most chariot bodies were open in the back. Portions of the body were attached or stabilized by leather lashings to the floor, pole, and axle (Hansen 1994: 59).

Bow cases, arrow quivers, and javelin cases would have been attached to the sides of the chariot, but only paintings or relief carvings of these survive (Fig. 2).

Chariot warriors are occasionally shown wearing helmets and leather (?) armor, but most commonly, the crew and horses were nearly unprotected. Perhaps its mobility and speed were effective in keeping the chariot crew and team safe. Representations of chariot teams on tomb or temple walls provide much of our information about leather harnesses and bridles. Though metal bits were used, none have been found with surviving chariots (Carter and Mace 1927: 59), but

examples from excavations indicate metal bits were standard equipment (Spalinger 2005: 19).

Horses became an important commodity in Egypt at the same time the chariot was introduced. Most of Egypt's horses were captured in battle, imported, or obtained as tribute (Spalinger 2005: 19; Shaw 1991: 65; Schulman 1995: 295–297).

Fortifications/Siege

Evidence for fortifications, assaults on fortified places, and sieges first appeared in Ancient Egypt during the Predynastic period. Some of the large, decorated cosmetic palettes, or fragments of palettes that were found at Hierakonpolis and elsewhere, are decorated with scenes that occasionally include fortifications. For example, on a fragment of the "Bull Palette" is a relief carving of a fortified enclosure, represented in plan by a wall with buttresses. Similar scenes are found on the Narmer Palette and the so-called "Libyan Palette." From this time forward, depictions and descriptions of defensive architecture and assaults on fortified places became popular subjects in Egyptian art and literature. Monumental mud-brick structures were constructed during the early Dynastic period at Hierakonpolis (Kasekhemwy "Fort") and Abydos (Shunet el-Zebib), and while these buildings had a funerary purpose, they are our earliest archaeological evidence that the Egyptians were capable of building large-scale fortifications at this time (Figs. 3–7).

Scaling ladders and towers start to be represented in some of the tomb decorations of the Old Kingdom, as seen in the Dynasty 5 (2504–2347 BCE) rock cut tomb of Inti at Deshasheh (Petrie 1898: Pl. 4) (Fig. 8).

Beneath the scaling ladder two Egyptian soldiers and their commander are prying blocks or bricks from the wall. In the Dynasty 6 (2347–2216 BCE) tomb of Kaemheset at Saqqara a large ladder with two wheels at the bottom is shown propped against the wall of a city during an Egyptian assault (Quibell and Hayter 1927: Frontispiece). Egyptian soldiers armed with axes and

Military Technology in Ancient Egypt. Fig. 7 "Libyan Palette" (Capart 1904: 229, Fig. 160).

pickaxes are shown, attempting to create a breach or undermine the fortifications.

A number of fragments of a siege survive from the mortuary temple of the Dynasty 11 King Mentuhotep II (2046–1995 BCE) at Deir el Bahri and from the Theban tomb of Intef (TT#386), who commanded the army under Mentuhotep (Arnold and Settgast 1965: 50–51 and Fig. 2). A mobile siege tower is shown in the battle scenes from Intef's tomb, and like the ladder portrayed in Kaemheset's tomb it also has wheels.

From Dynasties 11 and 12 are depictions of assaults on fortifications from the tombs of high officials at Beni Hasan (Newberry 1893: 85, Pl. 14 – tombs of Khnumhotep I (#14) and Amenemhat (#2); Newberry 1893: Pls. 5, 15 – tombs of Baket III (#15) and Khety (#17)) (Fig. 9).

Either the fortified structures depicted in these tombs were constructed on mounds, or the lower portions of their walls were protected by a glacis (a cleared bank sloping down from a castle's walls. It makes a clear line of fire in which attackers have nowhere to hide). The glacis would have reinforced the walls, made it difficult for sappers to undermine them, and prevented siege towers from approaching. The tops of the walls were crenelated and had towers that protruded outward. From the protection of a shelter the attackers used a kind of lance-like weapon to create a breach in the upper parts of the walls or to clear the parapet of defenders.

As Egyptian influence grew in Palestine and Nubia during the Middle Kingdom, Egyptian kings constructed forts along these frontiers to protect trade and communication routes (Shaw 1991: 16–23). In the region of the Second Cataract several forts and fortified

Military Technology in Ancient Egypt. Fig. 9 Assault on a fort from the tomb of Amenemhat (#2) at Beni Hasan (Davies 1903: Pl. 14).

towns were constructed or expanded; the most elaborate ones were at Mirgissa, Buhen, and Aniba. The forts had elaborate defenses, including massive brick walls, buttresses, towers, counterscarps, glacis, and ditches. Their plans were similar to one another, with regularly laid out streets, lined with buildings for government officials and garrison troops (Emery et al. 1979: Pls. 2–4).

The kings of the New Kingdom maintained many of the older frontier forts and built new ones in the region south of the Second Cataract.

Depictions of battles and assaults on fortified towns are displayed on the walls of later New Kingdom temples. Textual references to sieges include the account of Ahmose Son of Ibana about the fall of Avaris, the Hyksos capital in Egypt's eastern Delta, and Sharuhen, a Hyksos stronghold near present-day Gaza City. These cities only fell to the Egyptians after several campaigns and sieges (Lichtheim 1976: 12–14), leading Redford to suggest that Egyptian siegecraft was not very sophisticated at this time (Redford 1992: 138–139). However, it is possible that the Egyptians revisited these cities several times, during several campaigning seasons, rather than conducting a single lengthy siege (Redford 1992: 129).

Thutmose III spent several campaign seasons in Palestine, Syria, and Mitanni. For the first time in Egyptian accounts the *Annals* of Thutmose III describe a siege wall at Megiddo, presumably constructed to prevent any of the populace from escaping and to protect the Egyptians from sorties and from an enemy relief force (Redford 2000: 31–33).

There are several temple relief scenes from the reign of Ramses III that depict assaults on fortified towns in great detail but show no real advances in either fortification or siege technologies (*MH* II, PL.90; *MH* II, PL.87; *MH* II, PL.94 and 95 (photo); *MH* II, PL.88 and 89 (photo)). The fortified "Eastern High Gate" of Ramses III's mortuary temple at Medinet Habu resembles some of the Syrian fortifications that are depicted in some of the relief scenes of sieges from Dynasties 19 and 20 (*MH* VIII, PL.591; *MH* II, PL.87).

Following the New Kingdom, Egyptian control of Nubia and Syria–Palestine began to wane as did royal authority inside Egypt. The unsettled conditions of the Third Intermediate period (1069–664 BCE) were witness to the construction of additional fortified towns and cities throughout Egypt. The Kushite King Piye (r. ca. 746–715 BCE) recorded the events of his campaigns in Egypt on the Gebel Barkal Stele, including descriptions of fortified sites in Middle Egypt and the Delta, some of which were besieged and assaulted by his forces (Lichtheim 1980: 66–84). At the siege of Memphis, one of his commanders suggested building a ramp or causeway across inundated land to bring Piye's troops before the walls of the city. Though there is no previous record of ramps being used in sieges, there are examples that survive in architectural contexts (as on the inside face of the first pylon at Karnak). In addition, in Papyrus Anastasi I, which dates to the late New Kingdom, a military officer is given the task of estimating the volume of materials (brick, reeds, and beams) needed to construct a ramp of specific dimensions (Gardiner 1911: 16–17, 31–33). Rather than construct a causeway or build siege towers, Piye used ships to ferry his troops right up to the walls of the city where they successfully overwhelmed its defenses (Lichtheim 1980: 75–76). Piye's forces also may have used siege engines called "hurler" and "wooden servant" at Hermopolis, but their exact functions remain unknown (Lichtheim 1980: 71–73; Schulman 1995: 298–299). A generation later the Assyrians assaulted Memphis and captured it using siege techniques similar to those used earlier by the Egyptians.

Navy

Although boats have been depicted in Egyptian art since Predynastic times (Berger 1992: 107–120), it is difficult to ascertain their specific military uses until later periods. The earliest boats were reed craft, but local and imported woods were used in boat construction from at least the Old Kingdom (2707–2216 BCE). In a military context it seems that boats were primarily used to transport troops and materials (Lichtheim 1976: 12–14). The earliest surviving representation of a conflict on water is carved into the ivory handle of the Gebel el-Arak knife, which dates to the Naqada II period (ca. 3500–3300 BCE; Shaw 1991: 59–63). Examples of large-wooden boats were discovered in 1991 in 14 boat graves near the Shunet el-Zebib at Abydos (University of Pennsylvania; Pierce and Kosty 2000: ►http://www.upennmuseum.com/pressreleases/forum.pl?msg=43).

Scenes of boat building are often included on the walls of Old Kingdom tombs, such as the Dynasty 6 tomb of Mereruka at Saqqara (Sakkarah Expedition 1938: Pl. 152). Two large, wooden boats dating to Dynasty 4 (2639–2504 BCE) and belonging to the funerary equipment of King Khufu were discovered beside the Great Pyramid at Giza, and the Palermo stone describes a 52-m boat that was built during the reign of Khufu's father Sneferu (r. ca. 2639–2604 BCE; Wilkinson 2000: 141–144). One of the Khufu boats has been restored at Giza. Instead of a keel it has a central shelf and two side shelves that provide stability. The planks of the sides are joined to one another by pegs, ropes that run through a system of holes on the inside of the planks, and by hook scarves (Landström 1970: 28).

Six boats were discovered near the pyramid of Sesostris III at Dashur. One of the boats has planks that are joined only by pegs and by dovetailed fasteners (Landström 1970: 90). Hogging-trusses were also used in lieu of a keel to strengthen river craft and sea going ships alike (Landström 1970: 64, 12–23).

Ships are often shown in the funerary art of the Middle Kingdom, including model wooden boats, and it is in a scene from the early Middle Kingdom tomb of Inyotef at Thebes that archers are depicted firing from boats or barges. Prior to the emergence of the chariotry, it seems that the elite mobile arm was the navy (Spalinger 2005: 5). At the end of Dynasty 17 and the beginning of Dynasty 18 Egyptian naval activities against the Hyksos are described on the Kamose stele, and in Ahmose Son of Ibana's tomb biography (Goedicke 1995: 103–104; Lichtheim 1976: 12–14).

The Sea Peoples attacked Egypt during the reigns of Rameses II (r. ca. 1279–1213 BCE), Merneptah (r. ca. 1213–1203 BCE), and Rameses III (r. ca. 1183–1152 BCE). The sea and land battles that Ramses III fought against these invaders are described and depicted on the walls of his mortuary temple at Medinet Habu. They provide the first glimpse of a pitched sea battle in Egyptian art. Ships seemed to be specifically constructed for warfare; the Egyptian examples have fighting platforms at prow and stern, and lion-headed protrusions at the prow, which have been described as both battering rams and figureheads. Sailors and marines fought ship-to-ship, using swords, slings (?) and bows and arrows, during the melee phase of the battle (*MH* I, PL.40).

As previously described, at the beginning of Dynasty 25 the forces of King Piye used ships as assault craft to overwhelm the defenses of Memphis (Lichtheim 1980: 75–76).

As Egyptian maritime contacts widened during the mid-first millennium BCE Egyptian naval technology was influenced by other powers in the Eastern Mediterranean, and in order to compete, Dynasty 26 kings built Phonecian/Greek type war galleys (Shaw 1991: 59–63).

Mining: Copper Mining in the Great Lakes (USA)

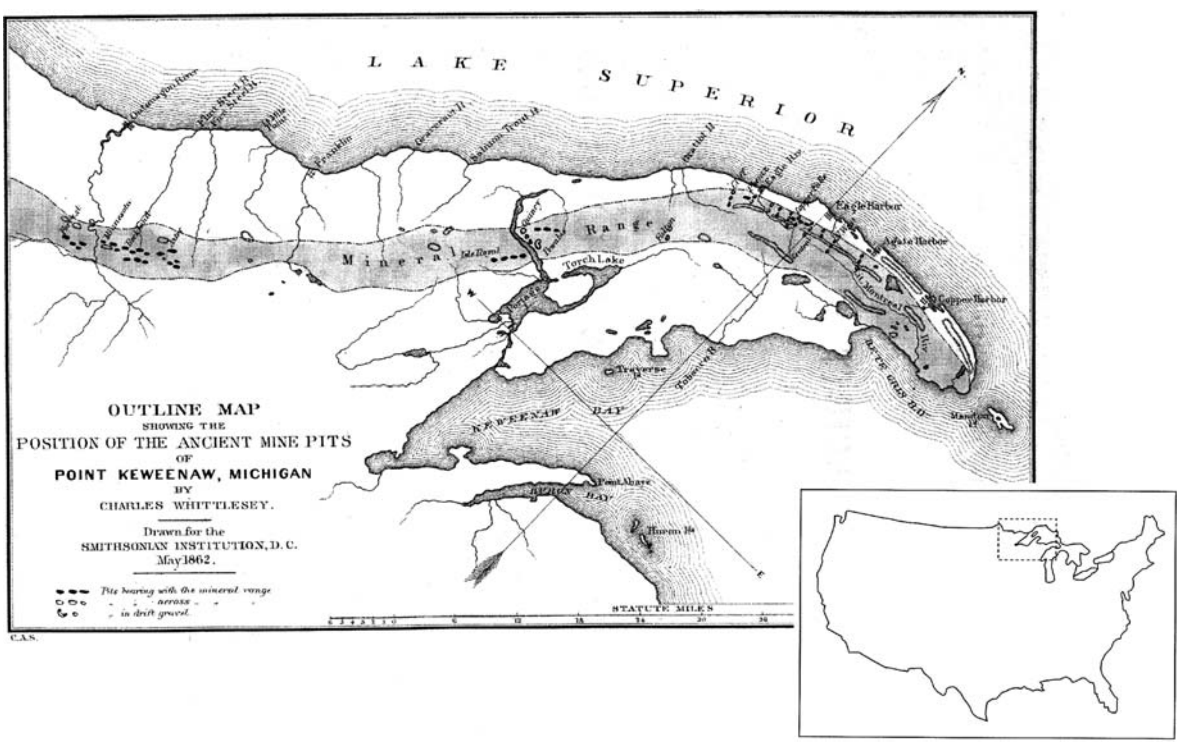
SUSAN R. MARTIN

The roots of indigenous metal mining are ancient in eastern North America. Evidence for early metal mining in North America comes from the copper-bearing regions of the western Lake Superior Basin in the central part of the continent. Here are to be found veins of elemental copper dispersed within sandstone and basalt bedrock, lying relatively close to the surface. In addition, pieces of loose elemental copper lie scattered in the glacial drift that is to be found in many streambeds and riverbanks. These pieces of useable copper and their parent veins were discovered and exploited by Native American people as early as 7,000 years ago. Though the first metalworking technologies of North America derived from the same technologies that people worldwide universally applied to reducing and using stone for tools, this long tradition of using copper for tools and ornaments is the product of native North American ingenuity. Moreover, the traces of this industry of copper mining and working (spoil piles, pits, discarded hammers, and other tools) were visible to the first capitalist American mining entrepreneurs of the Lake Superior basin who established their own mines on the same old ground that had proved itself first via native mining efforts (Foster and Whitney 1850). Archaeological research in the Lake Superior Basin and other copper-bearing areas documents the long-standing importance of copper technologies in the lifeways and practices of the indigenous people of the continent (Fig. 1).

The bedrock geological history of the Lake Superior region is fairly well understood (LaBerge 1994); its basement of pre-Cambrian bedrock, part of the Canadian Shield, is very ancient. The deposition took place around 1,100 million years ago (MYA), initiated by a period of roughly 25 million years during which a series of enormous movements of magma broke through a cross-continental rift and laid down some 200 extensive lava flows. This activity was intermittent, and followed by long periods of erosion and sedimentary deposition. The resulting strata are deformed by faulting and subsidence to a broad syncline that underlies Lake Superior and its drainage basin.

Gases trapped in the cooling lava, especially at the tops of flows, created porous structures in which later precipitation of minerals took place. Fissures in the lava and interspersed sedimentary rocks provided places where deposition of elemental copper occurred. The copper itself "was likely leached from volcanic rocks deep within the rift by hydrothermal solutions and was then deposited in these same rocks at relatively shallow levels closer to the surface. The timing of the widespread deposition of copper postdated the formation of the bedrock strata by about 20–30 million years and occurred from about 1,067 to about 1,047 MYA" (Martin 1999: 27–28). The result of this activity comprises the largest body of elemental copper known on earth, and its relatively shallow and accessible position allowed people to recover it. The copper-bearing strata outcrop in a narrow band about 3–6 km wide lying in a southwest to northeast direction along the Keweenaw Peninsula and Isle Royale on the western shores of Lake Superior; the beds also outcrop at the northern and eastern shores of the lake, and extend, deeply buried, further to the west into Minnesota. In other areas, native (elemental) copper is a common though irregular constituent of copper ore deposits in Tennessee, Georgia, New Jersey, Nova Scotia, and elsewhere (Levine 1999).

The Lake Superior deposits are quite variable in actual copper content and in form. In sedimentary bedrock deposits, the copper is finely dispersed; in the basalt bedrock the copper is more likely to be found in



Mining: Copper Mining in the Great Lakes (USA). Fig. 1 Map of the keweenaw Peninsula, Lake Superior, USA, indicating locations of prehistoric copper mining pits. Source: Whittlesey 1863.

fissures, veins or nodules of varying sizes. Masses of copper weighing several thousand kilograms were occasionally encountered. The most useful deposits for prehistoric people were of two kinds: thin veins that yielded sheets of copper, or fist-sized nodules of copper. Reducing very large pieces to useable sizes was somewhat beyond the reach of native technologies, but smaller pieces of both kinds could be rendered into tools and useful objects relatively easily. Useful nodules were sometimes found as constituents of the local late Pleistocene glacial drift or in redeposited gravel banks along streams and rivers. This copper-bearing drift is also widely dispersed across the central portions of the North American continent, where glacial ice flows carried copper and other detritus far from their points of geological origin.

The simplest and least-effort way to acquire copper in elemental form was to search and dig through the many beds of glacial drift in the rivers and streams surrounding the Lake Superior and adjacent regions. Based upon the many pitted areas observed and mapped by Whittlesey during the mid-nineteenth century (Whittlesey 1863), these beds of glacial drift were systematically explored for copper nodules. The glacial drift with copper as a constituent was/is widespread across the central part of North America (Salisbury 1885), and occurred south and west of Lake Superior as far as Iowa and the Dakotas.

In addition to such areas, the bedrock veins were also systematically visited and mined over many thousands of years. Finding the buried veins was a simple matter of being observant. In the western Lake Superior basin, the veins of metal are visible in some surface basalt bedrock outcrops, particularly those that were scoured by glacial action. In other areas, erosion and water action revealed buried veins and nodules. In still others, companion minerals marked the probable occurrence of copper veins. Mining pits on Isle Royale investigated by the University of Michigan in the early 1960s dated to ca. 2470 BCE ± 150 radiocarbon years (Fitting 1975: 238). The early geologists Foster and Whitney described the pattern of such mining pits on the south shore of Lake Superior; observing that along "a distance of nearly 30 miles, there is almost a continuous line of ancient pits along the middle range of the trap (sic), though they are not exclusively confined to it" (Foster and Whitney 1850: 161). The typical pit was rather shallow and followed the course of a vein of copper in a small-scale simple excavation. Alvinus Wood described one that he observed during his excavations on the Keweenaw Peninsula in the late nineteenth century. "It was shown to be 14 ft. deep, having been filled up by the sliding-in of material composed largely of broken rock, taken out in sinking the ancient shaft, and left near its mouth" (Wood 1907: 288). According to Wood, the pit measured about 7 ft. in diameter. In scale, these pits were most comparable to quarrying a face of exposed rock, similar to the mining of flint that had been done for millennia, as opposed to the burrowing or tunneling more typical of recent hard rock mining.

The ancient mining was done with stone hammers that people used to crush the bedrock surrounding a copper-bearing vein. The hammers were, for the most part, unaltered impromptu tools found in the local glacial gravel. Mining pits are sometimes most readily identified by the appearance of many of these expended (shattered) hammers. The hammers were of various sizes and materials; most were of basalt or gabbro and weighed about 2–4 kg, although larger ones were also used, especially early in the mining sequence. Some of the hammers had minor surface modifications, such as a partial or full groove pecked into the circumference to allow a withe or handle to be attached. Pry bars of wood or copper were probably also used to loosen the copper within the vein, and there is some suggestion, especially borrowed from other primitive mining locations around the world, that fire might have been used to weaken the trap rock so that freeing the copper took less mechanical effort. Experimental work on Lake Superior prehistoric mining methods demonstrated, however, that such methods did not measurably improve the efficiency of removing copper (Bastian 1963). Additional artifacts, including copper tools, wooden bowls, wooden ladders, paddles, and other accoutrements of mining were reported to be found in the mining pits investigated by Whittlesey (1863). The size of the mining pits and their conformation suggests that one or two persons could work comfortably within a pit, and experiments showed that ca. a cubic foot of trap rock per hour could be removed from a pit face simply by stone hammering (Bastian 1963: 24).

The native people of central North America fashioned myriad forms of elemental copper artifacts, using simple techniques of repeated cold-hammering and annealing. Despite a search that has already lasted for more than 150 years, there is no unequivocal evidence for intentional melting, smelting or casting of metal artifacts in the Lake Superior region or elsewhere in the eastern United States. All known artifacts were produced in much the same way: careful repeated hammering and heating to recrystallization temperatures. The finished copper objects ranged from weighty woodworking tools to finely crafted ornaments and decorative objects. It is probable that the basic knowledge of elemental metal-working was more or less common across North America, because many elemental metal deposits were known and exploited: at multiple localities in the eastern United States, in Mexico, in the southwestern US, and along the western rivers of Canada. The region around the Lake Superior basin with its large numbers of copper artifacts from local sites allows the researcher a fairly comprehensive look at how specific artifacts were designed and manufactured. Modern researchers established, via experimental replication as well as microscopic studies, the basic outline of prehistoric metalworking techniques (Clark and Purdy 1982; Leader 1988; Vernon 1990). Using the methods of cold or hot-hammering and annealing, the artifacts were carefully fashioned by repeated cycles of heating, hammering, and cooling, with carefully directed blows from a stone hammer creating the final form. Annealing, or reheating to recrystallization temperatures (in excess of ca. 250–300°C), restores malleability and was an essential part of the process; otherwise the hammered copper quickly became brittle and cracked under additional stress. Metallographic inspection of hammered copper revealed "the hammering technique, although primitive in itself, was carried out with assurance and skill; the sheet metal is often of fairly uniform thickness even though laminations are sometimes present" (Wayman et al. 1992: 133–34). Larger artifacts, such as wood-working tools, were hammered and annealed to render a nodule of copper to a desired form. Or, copper sheets were hammered to an even thickness, rolled and then rehammered to consolidate the copper into a thicker artifact form. Final annealing was frequently done, and annealing temperatures may have exceeded 600°C for some artifacts. Ornaments (such as beads) and sheets of copper were sometimes hammered around wooden forms, or mandrels, to produce a final artifact shape. Other artifacts, such as Hopewellian earrings and decorative ornaments of some Mississippian cultures, were composite artifacts of wooden cores clad with a thin cover of fine sheet copper (Fig. 2 and 3).

Finishing touches sometimes included additional limited cold-hammering to harden work edges of tools such as knives and projectile points. Grinding or beveling of work edges was also fairly common, and some artifacts such as harpoons or projectiles were perforated to enable the securing of a wooden shaft or handle via a copper rivet. Hopewellian and Mississippian cultures used elaborate finishing techniques on their ornaments. Decorative items were embossed, cut out, and perforated in a wide variety of forms depending upon the particular cultural traditions of the artisans producing the artifacts. Some were finished with a high gloss or polish produced by systematic rubbing with ashes and abrasives such as sand. There is some experimental evidence that prehistoric metal workers were able to draw thin strands of copper wire (Cushing 1894).

There is ample evidence derived from the study of the physical distribution of worked and unworked copper to claim that prehistoric people surrounding the Great Lakes communicated with one another, in part, through the exchange of raw and finished copper materials. In addition, overall close similarities in finished copper artifact forms that occur among and

within regions close to bedded sources suggest active contact between people of different areas, and at least the copying of each other's artifact forms, if not direct/indirect exchange of finished materials. This pattern is well documented for areas east and south of the Lake Superior basin (Brose 1994; Goad 1979; Walthall et al. 1982). It is also apparent from research conducted in the northern Plains, where Lake Superior copper may have been exchanged for locally derived lithics such as obsidian and catlinite (Vehik and Baugh 1994). Other raw materials reported from the western Great Lakes region that may have been involved in regional and interregional trade *vis a vis* copper include hornstone (Pleger 1996), Hixton orthoquartzite (Clark 1991), galena (Ritzenthaler 1957), Burlington chert (Pleger 1996), Knife River flint (Salzer 1986), and marine shell (Hruska 1967). Many authors agree that copper was likely widely distributed via trade over vast distances (Brose 1994; Goad 1979; Winters 1968). Other authors add that trade in perishable items, invisible for the most part in the archaeological record, was certainly part of the picture; meat, skins, shells, reed mats and tobacco are suggested as important commodities, especially in the seventeenth century (Smith 1996). Other less tangible commodities and/or motivators to trading activities may have been related to social status, ethnic differentiation, information exchange, and ritual knowledge (Martin 1999). There is, at least by the seventeenth century AD, a solid body of first-hand reporting that documents the connection between native ideologies and copper materials, which were sought after because they were believed to hold the ritual power to bring good fortune, health, wealth and hunting success (Kellogg 1917: 105).

The use of copper was widespread in prehistory and was an important part of the cultural adaptations of the native peoples of eastern North America, beginning by the seventh millennium BP and extending until the advent of European-influenced cultures. The earliest and strongest evidence for the importance of copper mining in native American technologies and lifeways comes from the region adjacent to the bedded copper deposits of the Keweenaw Peninsula, the southwestern shore of Lake Superior, and Isle Royale, Michigan. Here there is material evidence of systematic collecting for copper within surface glacial deposits as well as extensive evidence of the activities of hard rock mining and quarrying by native Americans. The technologies of mining and cold-hammering elemental copper have become well understood through the efforts of experimental (replicative) research and metallurgical studies. Copper was an integral part of the technological, social and ideological experiences of the region's first people, and was equally significant as a material from which to fashion a tool, a social interaction or a ritual transaction. Copper's significance included social reckoning as expressed in burial and in decorative contexts among peoples of many regions and cultures, as well as social interactions as expressed through trade contexts, and finally within religious representation as expressed in elaborate beliefs about its ritual power.

Mining in Ancient Egypt and Nubia

Dietrich Klemm, Rosemarie Klemm

After an early period around 4,000 BCE, during which gold nuggets were collected in some Pleistocene wadi (a valley, ravine or channel that is dry except in the rainy season) grounds and perhaps some native copper was also collected in superficial altered copper sulphide-containing quartz veins, real metal mining started in Egypt from around 3,000 BCE. Until that time tools and weapons in early Egyptian culture were generally based on stone tools such as flint knives, arrow- and spearheads, scrapers and axes and hammers of hard stone. The few predynastic copper artefacts, like small tools and fishing hooks, may have been made from such copper sheets in altered copper sulphide-containing quartz veins but also from scanty imports.

It is not clear whether copper or gold mining started first in Egypt; most probably both started contemporaneously.

Copper Mining in Ancient Egypt

Fig. 1 shows the positions of the various copper production sites mentioned in the text. Pre- to early-dynastic (ca. 3,200–2,600 BCE) gold mining has been reported from only a few sites in the Egyptian Eastern Desert, such as Wadi El-Urf near Ras Gharib, Abu Mureiwat near Safaga, Bokari and Higalig in the Central Eastern Desert (Klemm and Klemm 1994). But only in Higalig do remains of early waste dumps with malachite-stained granitic rocks give some hint to copper mining during those early times.

Convincing arguments for Old Kingdom copper mining were found in Buhen south of Wadi Halfa at the western bank of the river Nile, where copper furnaces of the fourth and fifth dynasty were excavated (Emery 1963). But the nearest copper mine in that region is Um Fahm some 80 km south and 30 km inside the eastern Desert (Figs. 2 and 3). In Quban, at the mouth of Wadi Allaqi, copper slags from the Middle Kingdom were discovered (Emery and Kirwan 1936). The next copper mine is Abu Seyal, again about 80 km away in a tributary of Wadi Allaqi. Unfortunately this site is archaeologically very poorly known, but it seems that copper mining here dates back at least until Middle Kingdom times. Also very poorly archaeologically studied is the copper mine of Umm Semiuky in the Southern Eastern Desert of Egypt. The site was covered up during careless early twentieth century copper mining with modern shafts, which also destroyed possible underground operations. Thus, no clear information concerning ancient exploitation of this site is available.

In the Central Eastern Desert of Egypt, in Umm Soleimat (Fig. 4), Old Kingdom to Middle Kingdom copper mining has been detected (Klemm and Klemm 1994). Middle Kingdom copper mining settlement with small furnaces in Wadi Dara (Northern Eastern Desert of Egypt) was confirmed (Castel and Mathieu 1992).

Mining techniques did not vary significantly during the various ancient periods. They started with open cast trenches, following the direction of the copper-containing quartz veins within which the primary copper ores were chalcopyrite ($CuFeS_2$) occasionally digenite (Cu_2S) and a few others. These copper minerals were leached by water and, whether directly in the quartz vein itself or in the joint systems of the host, rocks re-precipitated as copper carbonates, mainly as malachite ($Cu_2[(OH)_2/CO_3]$) or, very rarely, as azurite $Cu_3[OH/CO_3]_2$. Only these carbonates were usable for the ancient metallurgists.

Mining tools for metal mining were until the New Kingdom exclusively of stone. After that bronze

M

chisels, and from Ptolemaic times on, iron and steel were used in metal mining. They mined not only the copper carbonate containing quartz ore, but also the malachite filled joint systems in close vicinity to the veins within the host rocks.

Because of the necessary superficial alteration of the primary copper sulphide minerals, the depth of the trenches reached a maximum about 20–25 m, but they could be deepened when it turned out that the vein might be even richer, e.g., gold bearing.

Apart from imports from Cyprus, mainly during the New Kingdom, the main sources of copper in ancient Egypt from at least the Old Kingdom but probably also from pre-dynastic times on, was the Sinai (Lucas and Harris 1962). In Magharah (southwest of the Sinai Peninsula about 16 km from the turquoise mining site of Serabit el-Khadim) copper mining dates back at least until the third dynasty. In the nearby Wadi Nasb, various inscriptions give evidence of copper mining from the twelfth until the twentieth dynasties. Predynastic copper production was reported (El Gayar and Rothenberg 1995) from Wadi Ahmar, west of Bir Nasb with slags and remains of ancient smelters. Quite a number of other sites was reported (Lucas and Harris 1962) with heaps of copper slag also close to Serabit el-Khadim. The most important copper mining site is Timna, which today is in Israel, not far north of Eilat. The work of Rothenberg et. al. (1988, 1990) gave intensive insight not only to the special mining techniques of this site but also to smelting procedures. According to Rothenberg (1988), copper

workings at this site probably started during the second part of the fourth millennium BCE. In contrast to the Eastern Desert of Egypt, where the copper mineralizations are from hydrothermal quartz vein systems, the Timna ore occurs exclusively as malachite impregnation pockets in sandstone.

Gold Mining in Ancient Egypt

In addition to copper mining, more than 250 gold production sites in the Eastern Desert of Egypt and the Nubian Desert of Northeast Sudan were located (Klemm and Klemm 1994; Klemm et al. 2001).

Gold Production in Predynastic and Earlydynastic Times

Discoveries of gold artefacts, dating back as far as predynastic times (about 3500 BCE) demonstrate that gold production must have taken place in Ancient Egypt (Kroeper and Wildung 1994). Statistical analysis of the geological environments around pre- and early dynastic mining sites indicate unambiguously that the earliest prospectors concentrated their mining activities on well-selected geological targets of gold-enriched quartz veins, mainly in granodioritic rims of Neoproterozoic granitic intrusions, belonging to the so-called older and younger granites of the Eastern Desert. Furthermore, discoveries of the oldest mining tools are connected to mining sites associated with superficially altered quartz vein systems, which originally contained a variable

copper-sulphide mineralization that is almost completely leached out and which has been re-deposited as typical green malachite within the host rock's joint system. This green staining guided early prospectors not only to copper but also to the auriferous quartz veins.
