The most important and spectacular textiles of the Zhou period (1045–221 BCE) discovered so far are from central and southern China, especially from Jingzhou in Hubei and from the region of Changsha in Hunan. In Western Zhou times (1045–771 BCE) the *jin* brocade appeared, an outstanding weave which on the one hand was produced on a rather complicated loom and on the other hand asked for expert craftsmanship. This so-called brocade was a new type of warp-faced compound weave with the warp divided into at least two series, normally of different colors. Even picks of weft interlace with the warp either in tabby or twill. Although this weaving method produced polychrome silk fabrics with a colorful shiny and mostly geometric pattern on the surface, its repertoire was still limited by the weaving technology at the time. Weavers exhausted the technical possibilities of their looms and composed scenes and figures which were evidently intended to be pictorial descriptions, but they are still symmetric with straight lines and cornered outlines. Embroidery helped to make the patterns of tigers, phoenix, dragons, birds, and blossoms appear more lively. The patterns were arranged in various ways adorning the silk robes of the fourth and third centuries BCE.

In 1972 outstanding textile fabrics and garments totalling more than 100 objects were unearthed at tomb no. 1 at Mawangdui in Changsha. The tomb belonged most probably to the Lady Dai (d. 168 BCE). Among the well preserved fabrics and garments there were more than a dozen robes of various make, such as 11 floss-wadded robes, one lined robe, three unlined robes, several blouses and skirts, two pairs of socks, four pairs of shoes, three pairs of gloves, pillow covers, 46 rolls of single-width silk fabrics, and many more items of daily life. The textiles exhibit an unrivaled excellence in weaving skills, the mastering of pattern design, and imagination in applying all sorts of patterning techniques. Favorite weaves were thin and loosely structered gauzes (*sha*) and lozenge-patterned leno (*luo*), a fabric of open structure which is made by crossing warp yarns.

The most sophisticated weaving techniques and looms were used to produce brocade with small geometric patterns. A new technical dimension of weaving becomes obvious with the pile-loop brocade, a velvet-like fabric with geometric patterns of different sizes. Forty silk garments are embroidered with the colorful and curvilinear designs of *xin qi* (abiding faith), *changshou* (longevity), *cheng yun* (riding on the clouds), and various plants and cloud patterns. Embroidery as a patterning technique lost some of its importance when by Eastern Han times (AD 25–220) the variety of weaving patterns was finally extended to include mythological beasts, birds, fishes, flowers, all sorts of four-legged creatures, and Chinese characters.

The brocade manufactured from Han to early Tang times (seventh century) was woven with warp-faced patterns. The colors of the previously dyed warp threads mounted on the looms dominated the patterns. The patterns could be as wide as the width of the fabric (ca. 50 cm) but their length was rather limited. Probably during the eighth century of the Tang dynasty a dramatic innovation took place. The weft-faced patterning method as it had already been practiced in a few woollen textiles from Han times was now widely applied to silk weaving. The advantage of weft-patterning was that the colors of the pattern produced by the weft could easily be changed, which resulted in larger and more vivid pattern units. Furthermore the dressing of the loom was facilitated. After the Tang dynasty, the weft-faced patterning method gained predominance in brocades and in other weaves. At the same time the cultural influence of Central Asia became evident in textile patterns. Apart from several hundred fragments of silks unearthed in 1987 from the underground palace of Famen Temple near Xi'an, most textile finds from the Tang period were discovered in the dry desert region of Turfan (Xinjiang province) and in the cave temples of Dunhuang.

If satin weave (*duanwen*) is classified as an irregular twill (*xiewen*), then satin could have been created as early as Tang times. Whereas the interlacing points of warp and weft in twill weaves are arranged in a continuous oblique line, those points in satin do not form a line but are evenly distributed, thus allowing long floats of the threads which give the fabric a glittering and at the same time smooth appearance. The French name *satin* was derived from the word *zaituni* which was used by Persian merchants to name the city of Citong at the coast of Fujian, another name for the famous commercial center of Quanzhou in the Song period (AD 960–1279). Several well preserved complete sets of official robes, garments of various types, underwear, and other textile items were found in three Song tombs. The tomb of Huang Sheng (1226–1243) in Fuzhou in Fujian province, who was the daughter of an official and married to an imperial clansman, contained 354 textile items, of which 201 were articles of clothing. The textiles are of top quality. The weavers and textile printers made use of the most advanced techniques of their time in producing figured leno (*hualuo*), gauze (*sha*), crêpe (*zhou*), and figured twill silks (*ling*). Even a few satin weaves (*duan*) are described. More than 30 textile items were discovered in the tomb of the student of the Imperial College Zhou Yu (1222–1261) in Jiangsu province, and the recently excavated tomb of Mme. Zhou (1240–1274) in Jiangxi province yielded 329 items of textiles. Among the many regional brocades produced, the pure red brocade from Sichuan (*Shu jin*), with a formidable array of realistically depicted designs, was most famous.

In northern China, where the Liao dynasty reigned from AD 916 until 1125, and in the Song empire, the use of various types of tapestry (*kesi*) became highly fashionable. Among the textiles recovered from the Liao tomb of Yemaotai, dated between 959 and 986, there was a shroud made of silk tapestry in gold threads with a powerful design of dragons. The forerunners of this *kesi* tapestry technique can be traced back to the *zhicheng* technique of Han times, an intricate inlaid pattern produced by the weft yarn employing the swivel weaving method. During the Yuan and the Ming dynasties the use of various types of weaves with gold threads (*jinjin*) increased. The weavers of Ming times, especially the craftsmen of the cloud pattern brocade (*yunjin*) from Nanjing mastered a swivel weaving method (*zhuanghua*) making use of colored wefts to form a pattern on a fabric of various weaves. In many cases a glossy satin served as ground for the colorful swivel weave.

Three types of pile fabrics were produced on a large scale in Ming and Qing dynasties. The *Zhang* satin, originally from Zhangzhou in Fujian, was a figured warp pile fabric. From early Qing times until the end of the eighteenth century its main centers of production were Nanjing and Suzhou. The *Zhang rong* was a velvet where in order to produce a pattern the loops in the pattern area were cut. Thus the velvet pattern stood out on a ground of loops. The *Jian rong* was a cut pile fabric made of black silk threads produced on looms in Nanjing.

For the dragon robes (*longpao*) of the imperial Ming and Qing courts, the formal Manchu court robes (*chaofu*), and the semiformal coats (*qifu*) all patterning techniques known at the time were employed. This applies especially to the robes manufactured during the reign of the Qianlong emperor after 1759. Many of the old weaving techniques were handed down from generation to generation and can still be found in China.

Textiles in Egypt

Gregg De Young

Egyptian textiles during the Dynastic Era (3100 BCE–300 BCE) were almost exclusively linen, although wool was not unknown. (Cotton and silk were introduced only later.) Linen was produced in three basic grades: royal linen, thin cloth, and smooth cloth. Production of royal linen, the highest grade, was a palace monopoly. Its manufacture took place both in the royal palace and in workshops associated with state temples. These workshops were supervised from the royal harem and were obligated to provide specific amounts of linen annually for use of the royal household and in temple rituals.

The Egyptians did not ordinarily color their linen because most of the dyes known to them were not colorfast. When one desired to dye either a piece of linen cloth or the thread used in embroidery, it was generally necessary to treat the fabric first with a mordant (one of several substances, such as alum, that would adhere to the fibers of the linen and allow the chemical bonding of the dyestuff) then with the dye itself. Thus, the typical color of Egyptian linen ranged from near white (from young, immature, flax plants) to golden brown (from fully mature flax).

Tomb paintings show that when Egyptians harvested flax, they pulled it up by the roots, rather than cut the stalks. Presumably this was to obtain the longest fibers possible. The stalks were first drawn through a comb-like devise to remove the seeds. The stalks were soaked, then beaten and sometimes scraped in order to separate the woody parts from the long, flexible fibers. A final combing prepared the fibers to be spun into thread.

Once dried, the flax fibers were rolled together, usually between the palm and the left thigh, forming a loosely twisted strand. These were wound into loose balls on a pottery reel, then stored in clay or basketry containers until ready for spinning. Based on artistic representations, the Egyptians used three different techniques to rotate the spindles while twisting the thread together. The supported spindle was rotated by being rolled between the palm and the thigh of the spinner. The grasped spindle was rotated between the palms. The suspended spindle was set spinning and allowed to drop and swing freely, its rotary motion being maintained by the weight of the whorl, the drum-shaped or dome-shaped stone or ceramic attachment near the top of the thin shaft of the spindle, which acted as a kind of miniature fly-wheel. The dropped spindle produced the most constant tension on the thread, permitting a finer and more homogeneous thread to be produced.

The earliest looms were simple ground looms in which the two beams supporting the warp threads were placed on the ground and held firmly in place with pegs. At about the beginning of the New Kingdom (ca. 1550–1085 BCE) we also begin to find examples of the vertical-framed loom in which the two beams were incorporated into a less portable rectangular wooden frame. Some have speculated that this innovation may have been introduced when Egypt was dominated by the "Sea People" or Hyksos (ca. 1700–1550 BCE).

When thread was ready for weaving, the warp threads were attached parallel to one another between the two main beams of the loom. In the simplest weaving, the weft thread was passed over and under alternate warp threads. On its return, the path of the weft thread was reversed, so that it passed on the opposite side of each warp thread. A stick or comb was often used to beat down and press the weft threads together. There are, of course, many variations on this basic tabby weave, some of them of considerable complexity. Various weaving patterns were used to provide some form of decoration in the fabric.

Based on artistic evidence, it appears that men were most frequently involved in the cultivation and harvesting of flax and in the preparation of the fibers for spinning. Both men and women (and even children) are shown involved in the spinning of the fibers into linen threads. Women, however, seem to be the ones who work at ground looms, while men more often are shown working at vertical looms. Whether this represents a true division of labor or only an artistic convention is unclear.

Woven cloth was cut either with a metal shears or a knife when the ancient Egyptian wished to fashion a piece of clothing. The pieces were sewn together using a fine linen thread and a needle of polished wood, bone, or metal (usually copper or bronze, but occasionally gold or silver). The pieces were held together during sewing with pins of the same composition. Both needles and pins tended to have larger dimensions than modern examples. Pins were frequently capped with a looped head, which may have served a decorative purpose. Seams and hems were frequently rolled and secured by a rather crude whipping stitch. Garments that might experience greater stress or wear might be joined instead with flat seams. There were, as today, many experiments with decorative sewing in order to produce an aesthetic effect.

Fine linen was apparently quite valuable. Considerable effort was often expended to repair damaged garments. Usually repairs were in the form of darning (reweaving), rather than patching. The more ordinary grades of linen, however, were repaired with considerably less effort. A frayed edge might be bound carefully with a whipping stitch, but more serious damage often led to the object being discarded and replaced. Sometimes outworn garments were torn into strips to use in wrapping mummies.

From as early as the Old Kingdom (ca. 3000–2700 BCE), there are indications that laundering was done for wealthy households and temples. Washermen often formed a kind of guild. In the New Kingdom, the Superintendent of the Washermen seems to have enjoyed nearly as much prestige as the Sandal Bearer within the royal household. (Of course, in most households, the task would have fallen to the women or slaves.) Clothing was picked up regularly from subscribing households, identified with specific markings and listed on *ostraca* (pottery shards or flakes of limestone), and taken to the riverside laundry. There it would be treated with natron or other types of surfactants, beaten with sticks or stones, rinsed, wrung out, and spread to dry and bleach in the hot Egyptian sun. When fully dry, it would be folded, bundled, and returned to its owners.

As is often the case, much of our knowledge of the processes for textile production, use, and care is derived from scenes portrayed in the funerary art of the social elite, coupled with study of surviving examples (and Egypt's dry climate has helped to preserve many pieces of textile). These reveal a remarkably sophisticated industry for production of cloth and clothing. Modern archaeology increasingly realizes the importance of textile evidence in dating artifacts, as well as in offering invaluable evidence of the daily life of all classes of ancient Egypt society.

Textiles in India

Vijaya Ramaswamy

India may be described as one of the ancient centers of the cotton textile industry, since early evidence of cloth has been found in prehistoric archaeological sites. The spinning and weaving of cloth was very much a part of everyday life in ancient India. The loom is used as poetic imagery in several ancient texts. The *Atharvaveda* says that day and night spread light and darkness over the earth as the weavers throw a shuttle over the loom. The Hindu God Vishnu is called *tantuvardhan* or "weaver" because he is said to have woven the rays of the sun into a garment for himself.

It is interesting to note that in the third or second century BCE, when the cotton industry in India was in a flourishing state, in Europe cotton was still virtually unknown. The Greek scholar Herodotus thought that cotton was a kind of animal hair like sheep's hair. At the beginning of the Christian era, Indian textiles figure prominently in the trade with Rome. Arrian, the Roman historian, testifies to the export of dyed cloth from Masulia (Masulipatnam on the Coromandel coast), Poduca (Pondicherry), Argaru (Uraiyūr in Tanjavūr district, Tamil Nāḍu) and other places in south India. Legend has it that Indian cloth was purchased in Rome for its weight in gold. The quality of Indian dyeing too was proverbial in the ancient world, and in St Jerome's bible, Job says that wisdom is more enduring than the dyed colors of India. Indian textiles even passed into Roman vocabulary as is seen by the use as early as 200 BCE of a Latin word for cotton, Carbasina, derived from the Sanskrit *kārpasa*.

The history of Indian textiles constitutes one of the most fascinating and at the same time tragic chapters in Indian history. In the sixteenth century the Portuguese first set foot on Indian shores and were followed in quick succession by the Dutch, English, and French. For the next hundred years "Indian cotton was king" and Europe was in the grip of what economic historians describe as "the calico craze." Indian textiles were used in the Middle East, Africa, and Europe not merely as dress material but also as coverlets, bed spreads, and wall hangings. The joint English sovereigns William and Mary are described as having landed in England in 1689, resplendent in Indian calico. Daniel Defoe, the author of *Robinson Crusoe*, commented that Indian calico, which at one time was thought fit to be used only as doormats, was now being used to adorn royalty.

However, there was a dramatic reversal of fortune in the eighteenth century. The cotton revolution in England rendered redundant the products of Indian handlooms. The first ban on Indian textiles was imposed by the British crown in 1700 and repeatedly after that. By the end of the century, instead of Indian cloth being exported abroad, the Indian market was flooded by the machine-made cloth of Manchester and Lancashire. Around the same period, India was hit by one of the worst famines beginning in the late seventeenth century and continuing through the eighteenth century. The words attributed to Lord Bentinck, the Governor of India in the 1830s, that "the bones of the weavers are bleaching the plains of India" are a dramatic but apt description of the fate of the Indian weavers.

The eclipse suffered by the Indian textile industry lasted until the early twentieth century until its grand revival under Gandhi, who initiated the *khādi* movement. The *charkhā*, or Indian spinning wheel, and *khādi*, or homespun cloth, became symbolic of the Indian struggle for independence. Foreign cloth was burnt in the public squares and the Indian spinning wheel became a part of the home of every Indian patriot.

Since Independence, a sea change has occurred in the traditional Indian textile industry. The changeover to power looms and jet looms and the introduction of computer designs is setting new traditions in Indian textiles. In the course of its historical vicissitudes, the Indian textile industry has gone through a process of change as well as cultural assimilation.

Indian Textile Technology

The first process in the weaving of a cloth is warping and sizing, and in India this is done in the open. Bamboo sticks, about one hundred and twenty in number, are fixed upright in the street or what is called the warping grove, at a distance of a cubit from one another. Rows of women walk up and down the line, each carrying a wooden spindle in the left hand and a bamboo wand in the right. As they walk, they intertwine the threads between the split bamboos. These threads are then stretched horizontally from tree to tree, evenly washed with rice starch and carefully brushed. The right amount of tension in the warp in required to prevent the yarn from breaking while on the loom.

In India spinning was and still is almost exclusively the occupation of women. More specifically, this was the sole occupation of destitute women and widows. It is interesting that this corresponds to the English notion of the ‘spinster’ as one who has to spin for her livelihood since she has no one to support her.

The earliest looms in use in India were either the pit loom or the vertical loom. The *Atharvaveda*, probably compiled in the early pre-Christian era, says, “A man weaves it, ties it up; a man hath borne it upon the firmament. These pegs propped up the sky; the chants, they made shuttles for weaving… (sic).” However, the most common type of loom in use was the horizontal pit loom in which the loom is placed inside an earthen pit and is operated with foot treadles. By depressing the pedal with one foot and raising the other, one set of threads get depressed and the weaving shed is formed through which the throw shuttle is shot across by hand. References to such looms are scattered throughout ancient and medieval inscriptions. Around the fifteenth century one begins to get reference to the draw loom. This would consist of several levers and so enable the weaving of complex patterns. The introduction of the fly shuttle in the 1930s toward the end of British rule in India resulted in the partial mechanization of loom technology and in another three decades this was followed by the introduction of the jacquard. Nowadays, partially mechanized looms, power looms, and jet looms are displacing the traditional Indian handloom.

Traditional Indian Costumes

Different types of cloth are worn and woven in the different parts of India, since this is a vast land with varying climates. Generally, men tend to wear a longish lower cloth of about one and a half yards in length, called *dhōti* or *lungi* in the north and *veshti* in south India, while the traditional upper cloth consists of a single piece of cloth called *aṅgavastra*. However, in hot weather, men generally go without the upper cloth. In many parts of northern India, men also wear a head gear against the dust and heat. This is especially true of desert regions like Rajasthān. The Indian women wear large skirts or loose trousers called *salwār* and longish or short jackets. Alternately, they wear a six-yard piece called a *sāri* and a blouse for the upper part. In the colder parts of India, such as the Himalayan mountain ranges and Kushmir, the garments are thicker and more elaborate, including warm woolen shawls and heavy jackets. It is noteworthy that in antiquity, stitched garments such as shirts, trousers, and blouses were hardly ever worn in India. In the ancient sculptures and paintings such as the ones at Amarāvati or Brahadīśvaram, it is only the menials, palace attendants, common soldiers, and dancing girls, all of them belonging to the lower echelons of society, who are depicted wearing stitched garments. Such garments are never depicted on the upper classes or royalty nor on the images of gods and goddesses. A plausible reason may be the association of impurity and pollution with stitched cloth.

Colors and Designs in Textiles

Traditional Indian textiles reflect the Indian ethos. There is an aura of religion and romance around Indian weaving. Everything is significant – the colors chosen, the motifs, and the wearing occasion. Crimson or shades of red are very auspicious and worn by women on the occasion of their marriage as well as by ceremonial priests in certain parts of India, such as the Madhvā Brāhmins of Karnātaka. White represents purity and ochre, renunciation, and these are the colors worn by Hindu widows as well as ascetics. Yellow and green denote fertility and prosperity and are worn in the spring. Black is considered inauspicious, although pregnant women in south India wear black, perhaps to ward off the evil eye. As late as the eighteenth century, coloring was done entirely through vegetable dyes such as madder and indigo, although now dyers have almost entirely switched over to chemical dyes except in the case of highly specialized textiles like the *kalamkāris*.

The earliest designs on Indian textiles seem to have been geometrical. A twelfth century Sanskrit text called the *Mānasōllāsa* described textiles designed with dots, circles, squares, and triangles. The depiction of flora and fauna was related to religion and popular beliefs. The lotus, which has great spiritual significance in Hinduism, and the mango design are among the most popular Indian motifs. Swan, peacock, parrot, and elephant are also commonly depicted. The tree of life, which symbolizes fertility and prosperity, is another auspicious motif. All these designs are patterned on the loom itself and it may take a handloom weaver working on an ordinary frame loom as long as 30 days to weave an elaborate six-yard *sāri* with designs and gold lace. As the weaver weaves, he also sings the special loom songs, a tradition which has now almost entirely died out except perhaps in some interior weaving villages in Uttar Pradesh or the remote south. These loom songs tell of the glory of particular weaving castes or they are full of esoteric religious metaphors describing god as the eternal weaver, weaving the web of life, and the human body as the cloth he has woven.

Textile Varieties

Traditional Indian textiles are unique and unparalleled for their beauty. The *jāmdāni* is an elaborate textile which is woven with multiple shuttles and resembles tapestry work. Floral motifs called *bootis* in gold or silver lace are scattered over the body with heavy gold lace on the borders. The most striking of these designs is the *pannā hazāra*, literally a thousand emeralds, in which the flowers shimmer and gleam all over the sari. The Benarsi sāris called *Kiṁkhābs* woven in Uttar Pradesh are legendary for their loveliness, although Benaras in the north and Kāñchipuram in the south were traditionally associated with pure cotton rather than silk. It was the British who introduced sericulture in Kanchipuram in the nineteenth century. Gadhwāl and Venkaṭagiri saris of Andhra and the Īrkal saris of Karnataka specialize in rich gold borders and heavy panel-like *pallūs* (that portion of the sāri which is draped over the shoulder). Another variety is the tie and dye (called variously *bandini, ikāt,* or *chungdi*) produced in Rajasthān, Orissa, Andhra Pradesh, and Madurai where the fiber is tie-dyed before weaving. A unique Andhra textile is the *telia*, which was soaked in oil before weaving and catered exclusively to the West Asian market because it was woven to suit desert conditions. This textile appeared in the sixteenth century with Muslim rule and died out with the collapse of the Islamic empires. Another textile which became popular in the mughal period was the *mashroo* (also the *himroo*) in which cotton was used in the warp and silk in the weft. Initially these were used as Islamic prayer mats by the Mughal nobility who were forbidden by Islamic tenets to use any animal product. They therefore contrived the mashroo which enabled them to have their comfort without violating the religious tenet against the use of pure silk.

Textiles also form an important part of temple ceremonials such as the flag cloth hoisted in temples, the garments put on the deity, the cloth covering the chariots in which the deities are taken out on a procession and the ritual dance costumes. The *kalamkāri* cloth of Andhra, in which mythological stories are sketched minutely on cloth with a fine pen as well as the *Nādhadwāra pichwāis* of Rajasthan, are of this genre. In India it is also the practice among wandering groups of minstrels to render dramatic narrations of mythological stories, and the elaborately painted screens used on these occasions form an important aspect of traditional Indian textiles.

Textiles in Mesoamerica

Carolyn Jones and Tom Jones

Because textiles are rare among the artifacts of cultures known to us only archaeologically, any analysis of them, or of the technology of their production, must be pieced together from indirect sources. In Mesoamerica, while archeological finds attest to the existence of various textile technologies at specific dates, much of our understanding of the subject comes from ancient Maya, Mixtec, and Aztec books, stone sculpture, painted pottery, murals, clay figurines, European documents from the time of the Conquest, and modern textile traditions.

Though the physical environment of Mesoamerica generally precludes the survival of perishable artifacts, textiles have none the less survived from certain areas. The majority, mostly small fragments, have been found in dry caves in the arid regions of Mexico. In the humid southern lowlands very little has survived, some 2,500 carbonized fragments dredged from protecting mud at the bottom of the Sacred Well at Chichen Itza are the most important single find.

The oldest textiles to survive in Mesoamerica are cordage, netting, and basketry, worked in vegetal fibers other than cotton, with early examples dating to at least 7000 BCE in Oaxaca and to 5000 BCE in central and northern Mexico. Such textiles are fashioned from the leaves and stems of various plants worked without the benefit of a loom. In instances where fibers were extracted from their plant sources, they were probably spun by rolling them together between the hand and thigh, as no tools for spinning have been found. Spindle whorls and evidence of loom woven textiles appear much later.

The earliest evidence for loom weaving in Mesoamerica consists of fabric-impressed ceramics datable to 1500 BCE, at which time spindle whorls also begin to appear. Woven cotton fragments follow soon after. These early woven textiles are worked in plain weave and almost certainly were created on a backstrap loom. From these simple beginnings, a sophisticated textile industry developed.

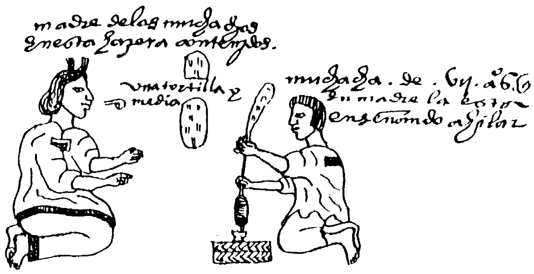
The weaving process begins with the selection and preparation of suitable materials. The predominant fiber of woven Mesoamerican textiles was cotton, *Gossypium* spp., with both annual and perennial varieties reported at the time of the Conquest. Cotton was cultivated in at least two colors, white and brown, and traded throughout ancient Mesoamerica. Other fibers, generically termed istle (from the Nahuatl *ixtli*), were drawn from the leaves and stems of many plants of more local distribution, including *Agave* spp. and *Apocynum* spp. Both cotton and istle required much preparation prior to spinning and weaving. Cotton was carefully picked over, its numerous small seeds and other vegetal debris removed by hand and the mass of fiber then fluffed or beaten to produce a uniform, smooth mass. Istle, on the other hand, was toasted, split, and scraped to remove the plant flesh from fibers which were then washed, dried, and combed. No animal fibers are known to have been used in ancient Mesoamerica. Textile headdresses incorporating human hair, however, have been found.

Both cotton and istle were spun on the spindle, a simple device consisting of a "whorl" wedged onto the end of a straight-tapered shaft. A mass of fiber was attached to the shaft, which was then twirled, imparting twist. The whorl helped the device to spin easily and for an extended time, and provided weight against which the fiber could be drawn out and twisted into thread. Different fibers required different types of spindles and sizes of whorls. Cotton, because of its very short fibers, was spun on a small spindle, the lower end of which was supported in a bowl or on the ground. The longer istle fibers required a larger, heavier spindle. Yarns of any size could be created and some as fine as 0.005 mm in diameter have been recovered. Yarns could be used singly, or two or more individually spun strands could be retwisted ("plied") together. A mixture of cornmeal and water was likely applied to some yarn to smooth and strengthen it for weaving.

While there is little archeological evidence for the use of dyes, Post-Classic pictorial codices and reports of the *conquistadores* both attest to the vivid colors of Mesoamerican textiles. Plant dyes probably included indigo (*Indigofera anil*) for blue, brazilwood (*Caesalpinia* spp.) for red, logwood (*Haematoxylon campechianum*) for black or blue, annatto (*Bixa orellana*) for orange, and many other leaves, seeds, roots, barks, and fruits. Two animal dyes were important: on the Pacific coast, purple was extracted from small mollusks of the genera *Thais*, *Murex*, and especially *Purpura*, while in arid regions, cochineal (*Coccus cacti*, a scale insect of the order Hemiptera) was cultivated on the prickly pear cacti (*Opuntia* spp.). The beautiful red produced by cochineal was much admired by the Spanish, and the dyestuff became a major export to Europe following the Conquest. Mineral pigments, such as ochre, iron pyrite, cinnabar, carbon, copper sulfate, and "Maya blue" clay were known, and there is some evidence for the use of mordants which make dyes more permanent. Dyes and pigments were applied by painting, by stamping or rolling with figured clay implements, and by immersion dyeing. Patterns were produced during dyeing through the application of resists and through tying-off of sections to create undyed areas of yarn or fabric. Fabric incorporating tie-dyed warp, called *jaspe*, is still produced in Guatemala today.

Once suitable yarns were spun and dyed, the process of setting up the loom began. The *Florentine Codex*, a documentary of Aztec life and custom written by the Spanish friar Sahagún just after the Conquest, illustrates the weaver's equipment, including spindle, warpboard, loom sticks, backstrap, and batten. It also describes the training of weavers, from the presentation of the newborn girl with miniature weaving equipment, to the day of a woman's death when her loom and spindle were burned in the funeral pyre awaiting her in the afterworld. In the *Mendoza Codex*, created by Aztec scribes at the order of the first Viceroy of New Spain, there is a section devoted to a mother's training of her daughter in domestic chores. It portrays the child's instruction in spinning (Fig. 1) and weaving, from ages 3 to 14, her food rations, and punishments for unacceptable work.

Information about weaving is also contained in Maya books, whose almanacs provide endlessly repeating prognostications for the timing of certain quotidian activities. One almanac in the *Madrid Codex* depicts the process of preparing the warp for the loom (Fig. 2). The weaving goddess, named *Sak Na* in the accompanying hieroglyphic text, is shown seated cross-legged with her left hand against a horizontal frame supported by at least two vertical posts and with lines stretched between their projecting upper parts. Her raised right hand holds an inverted spindle from which thread reaches to the frame before her. While there have been varying interpretations of the activity portrayed in this illustration, the overhead texts clearly read: *Sinah u chuch Sak Na*, or "She strings her warpboard, *Sak Na*," describing in ancient Mayan the process depicted. This manner of preparing the warp yarn, by measuring and stretching it

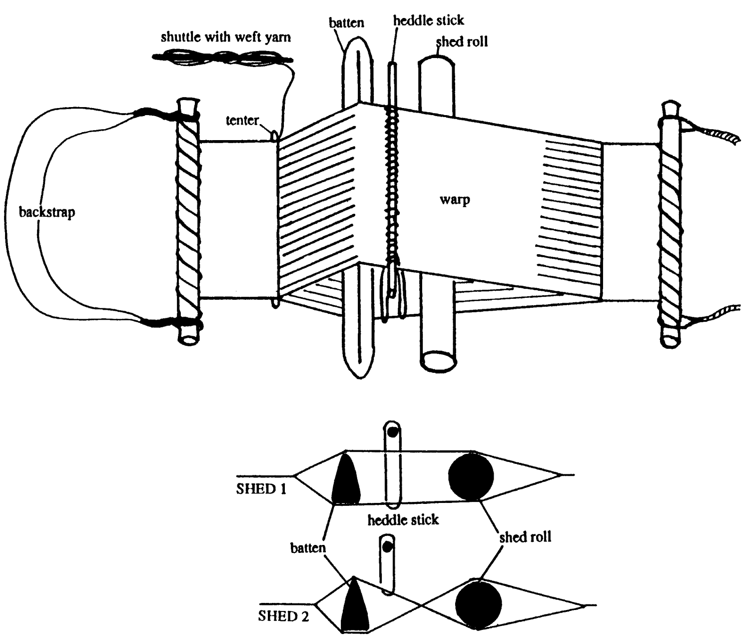


Textiles in Mesoamerica. Fig. 1 An Aztec woman instructs her 7-year-old daughter in the art of spinning cotton on a supported spindle. The child's ration of one-and-a-half tortillas is shown between them (from *Mendoza Codex*, page 59; from a photo of the codex).

Textiles in Mesoamerica. Fig. 2 A Maya almanac illustrating the goddess *Sak Na* preparing her warp (from *Madrid Codex*, page 102; drawing after Villacorta).

between vertical posts on a warping frame, was in use at the time of the Conquest and survives to this day. It is the initial phase of preparing a backstrap loom (Fig. 3) for weaving.

As the warp yarns are measured, they are wound alternately to one side and the other of a pair of vertical posts, thus creating a lease which maintains their order and allows the easy selection of alternate threads. Once wound, the opposite ends of the warp are secured to bars which form the ends of the loom, and a large, smooth, rounded stick (the shed roll) is placed through one side of the lease. The shed roll allows for the lifting of those threads which travel over it, one half of the



Textiles in Mesoamerica. Fig. 3 The structure of a backstrap loom, showing component parts and how they are used to create two sheds for weaving (drawing by Carolyn Jones).

total warp threads in alternating order, creating the first opening or shed. The remaining threads, which travel under the shed roll, are individually secured to a second stick (the heddle). By pushing the shed roll back and lifting the heddle, the other half of the warp threads are raised, creating the second shed. This is the mechanism by which Mesoamerican weavers created plain woven fabric.

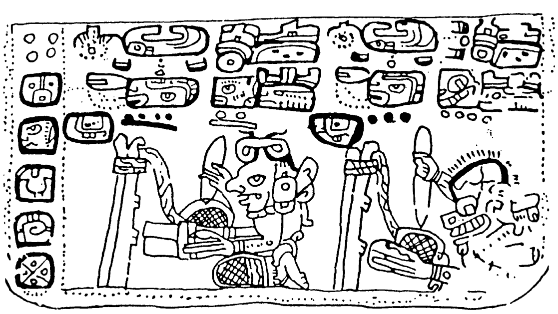
Before the loom is ready for weaving, additional implements are required. A long, heavy, straight-sided wooden stick (the batten) which can be turned on its side to enlarge the shed through which yarn (the weft, carried on a shuttle) will pass, and which is used to beat that weft into place, is employed continuously during weaving. A thin stick (the tenter) is usually attached to the fore-edge of the weaving to regulate the fabric width. Finally, the far end of the loom is tied to a tree or post, while the close end is attached to a strap which travels around the weaver's hips as she sits on the ground. By adjusting the position of her body, the weaver controls the tension of the warp of her loom.

This action is illustrated in the *Florentine*, *Mendoza*, *Matritense*, *Dresden*, and *Madrid Codices*, and in clay figurines from Maya burials on the island of Jaina. The *Madrid Codex* contains an almanac comprised of two episodes (Fig. 4). The first is illustrated with a crude drawing of a skirted female on her knees, her left hand supporting a backstrap loom, her raised right hand inserting the batten. Over the scene is an explanatory text that reads: *Och-i ti te' Ch'ul Na Che'el*, or "Divine *Na Che'el* (another name for the Maya weaving goddess) weaves at the post."

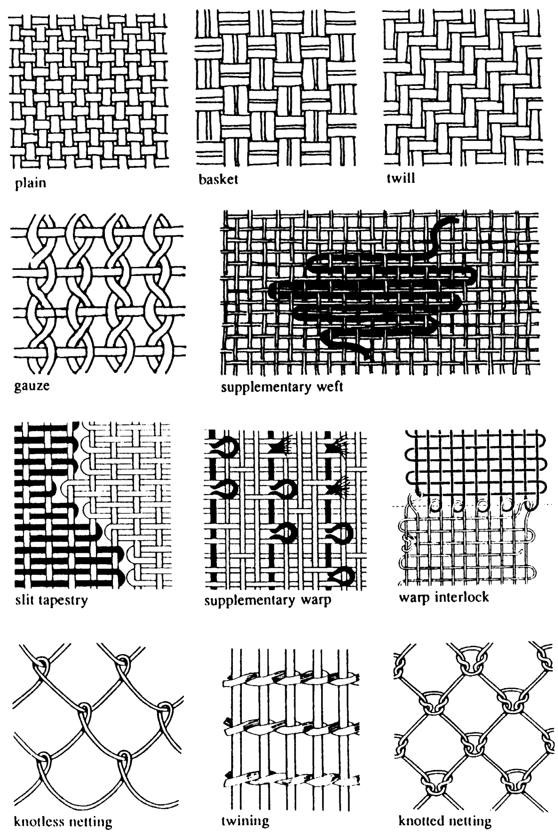
Simple in construction, the backstrap loom was well suited to the Mesoamerican woman's environment. Spinning and weaving were but two of her many daily chores, and the easy portability of the backstrap loom allowed its being rolled up for safekeeping when not in use, or set up when and where convenient. The simplicity of the equipment, however, did not preclude complex weaving. Extant fabric fragments display a wide variety of techniques. Among the simple weaves are plain, semibasket, basket, twill, and gauze. More complex weaves include supplementary weft brocade, tapestry, inlay, supplementary warp patterning and pile, warp interlock, and layer exchange double cloth (Fig. 5).

The structure of the backstrap loom determined several qualities of the fabric to be woven. The size of the finished cloth was determined when the loom was set up, and was limited in both width (by the weaver's armspan and her need to position herself at the center of the loom for proper tensioning), and length (the longer the warp, the more cumbersome and difficult it was to weave). When a large fabric was required, it was woven in small rectangles and pieced together, usually without cutting. Mesoamerican fabrics could include four finished edges and tended to show more warp than weft, with warp counts as high as 78 threads to the inch recorded.

In addition to weaving, ancient Mesoamericans were familiar with twining, braiding, plaiting, knotted and knotless netting, sewing, and embroidery. Methods for making leather, felt, bark cloth, and paper were known.



Textiles in Mesoamerica. Fig. 4 A Maya almanac illustrating the goddess *Na Che'el* weaving at her backstrap loom (from *Madrid Codex*, page 102; drawing after Villacorta).



Textiles in Mesoamerica. Fig. 5 Some structures known from ancient Mesoamerican textiles. The bottom row provides nonwoven techniques for comparison with the loom-woven structures shown above (drawing by Carolyn Jones).

At the time of the Conquest, new materials and techniques were introduced, including needle knitting and the use of sheep wool and silk. In some areas, the treadle loom came into use, and men entered the field of textile production. These different technologies survive side-by-side with backstrap weaving today.

The importance of textiles, and particularly of weaving, to the ancient cultures of Mesoamerica must not be underestimated. Weaving was not simply a means of producing necessities of daily life, but was an expression of the Mesoamerican world view. The act of weaving was seen as a basic creative force, analogous to the original creation of the world in Mesoamerican myth. The symbolic significance of the act of weaving lives on in the complex patterns of the modern Maya woman's *huipil* (or traditional poncho-like garment), each of which is a cosmogram that places the weaver at the center of the universe. Many designs used today are notably similar to symbols depicted in carved stone representations of textiles from the ninth century, thus displaying remarkable continuity with a lengthy and rich Mesoamerican textile tradition.

Textiles in South America

Amy Oakland Rodman

Unlike most parts of the world where discoveries of ancient textiles are unusual, the Pacific desert coast and dry western Andean slopes have preserved enormous quantities of textiles, wood, feathers, plant material, and other usually perishable artifacts. Most of the best preserved textiles were originally part of burial furnishings left in ancient cemeteries stretching from central Peru to northern Chile. The far north Andean coast (modern Colombia, Ecuador, and northern Peru) encounters periodic torrential showers which have destroyed most ancient remains. Few textiles have survived from the highland wet and dry climate or the rainforest regions of the eastern Andean slopes stretching to the Atlantic ocean.

It is apparent that desert conditions and the careful preparation of tombs are the two elements most responsible for the preservation of ancient Andean textiles. Beginning around 3200 BCE and continuing until the conquest of the Andes in AD 1532, it is possible to reconstruct textile technology in coastal regions and occasionally to witness highland development through textiles preserved in coastal sites.

Archaeologists have designated the Cotton Preceramic (3200–1800 BCE) as a period when a variety of coastal cultures developed cotton twining, looping, and other nonloomed textiles before the use of the heddle loom or ceramics. Major discoveries at Huaca Prieta, La Galgada (a highland site with remarkable preservation), and in Asia have determined that not only were large quantities of cotton textiles used, but that some were elaborately patterned. Images on Preceramic cotton textiles include condors with outstretched wings, two-headed snakes, and humans or deities with splayed feet, all subjects with similar presentation to images which continue in the art of many subsequent Andean cultures. Designs are created through transposing twined elements, often combining a change in regular yarn movement with alternating colored yarns. Cotton dyes include indigo for blue and unidentified, red, yellow, and brown colors. Thicker plant fibers were twisted into sturdy twined mats, while cotton was used for looped caps and twined mantles.

Beginning in the Initial Period (1800–800 BCE) and the following Early Horizon (800–0 BCE), Peruvian textiles developed through the use of the heddle loom. Hundreds of painted Early Horizon cotton plain-weave textiles discovered near Karwa on the Peruvian south coast identified fabrics with designs very similar to stone carvings from the north highland pilgrimage site of Chavin de Huantar. This important and well-preserved painted ritual cloth provided evidence of the ways in which textiles were used to transport religious imagery throughout the Andes beginning in very early periods.

Camelid fibers, sometimes termed "wool" yarn, from the hair of the nondomesticated guanaco and vicuna or the domesticated llama and alpaca, were introduced into coastal weaving during the Early Horizon. Camelid hair is more easily dyed than cotton and its introduction into coastal technology is usually based in its application in brilliant colors for weft-patterned structures. The first all-wool tapestry textiles appear in coastal cemeteries during this period and it is likely that these identify an ancient highland wool technology rarely preserved in the highland regions of natural camelid habitat.

The famous Paracas textiles were woven and embroidered on the southern Peruvian coast during the Early Horizon. On the Paracas Peninsula, elite individuals were buried with hundreds of embroidered shirts, skirts, mantles, feather fans, and golden objects all wrapped inside enormous plain woven cotton winding cloth. The multicolored wool embroideries depicted repeating human, deity, and animal images and were executed in stem stitch on plain-woven fabric. Paracas textiles also included a unique type of three-dimensional embroidery using the crossknit loop stitch to embellish borders with polychrome images. The technique was created with a single cactus spine needle as a continuous form of crossed looping.

The Nazca culture, which followed the Paracas on the south coast in the following Early Intermediate Period (AD 0–500), continued one of the most elaborate weaving technologies ever known, with textiles in double and triple cloth, warp and weft patterning, oblique interlacing, and fine garments woven with both discontinuous warp and weft. Andean loomed textiles are characterized in their tradition of four finished selvedges. Individual finished cloth webs were sewn together to complete a garment and were rarely cut.

Very little is known of north coast weaving during the Early Intermediate Period, the time of Moche cultural development. The few surviving Moche textiles identify a technology principally based in the use of cotton and a narrow backstrap loom like that employed on the south coast. But structurally, Moche textiles are distinguished through the use of fine un-plied cotton yarns in twilled and weft-brocaded structures. Moche tapestry is woven with both cotton and dyed camelid fiber weft over a cotton warp using a noninterlocking weft which creates vertical slits between different color areas. Apparently slit-tapestry was common to coastal cultures both north and south.

Although known for only a handful of large weft-interlocked tapestries or tapestry fragments and triple-cloth narrow bands, the Early Intermediate Recuay culture of the Peruvian north highlands developed a distinctive textile tradition. Recuay tapestries were woven on a wide loom of more than seven feet with a short warp of no more than two feet. Brilliantly dyed red and yellow wool yarns are characteristic of Recuay textiles, and tapestries use the highland weft-interlocked structure which leaves no openings between areas of different color. In the south central Andes, weft-interlocked tapestries uncovered on the Chilean north coast have been attributed to the Alto Ramirez culture of the southern highlands. Alto Ramirez textiles exhibit a decided preference for the use of blue and red dyed yarns almost certainly identifying an ancient source and knowledge of indigo dyeing in the southern highlands.

The following Middle Horizon (AD 500–1000) marks a break with previous cultural development. The Peruvian Huari culture located near the modern city of Ayacucho appears to have controlled the central Andean highlands and coast, while the south central Andes was allied to the site of Tiwanaku. Tapestry was the distinctive Middle Horizon medium woven in slit techniques with cotton on the coast and with interlocking camelid fiber wefts in the highlands. Local, coastal tapestry continued to be woven on the narrow backstrap loom. Highland Tiwanaku and Huari tapestries preserved in coastal desert burials identify the use of the wide loom with narrow warp like that used in Recuay tapestry. Huari shirts were woven in two parts and seamed down the center leaving an opening for the head and neck. The few Tiwanaku shirts discovered in northern Chilean desert cemeteries were patterned with similar images but were woven in a single panel with a neck opening woven through discontinuous wefts. Headgear was always used as an important Andean badge of identity. Huari and Tiwanaku officials wore a knotted hat with four peaks or points on the top. Tiwanaku four pointed or cornered hats created polychrome designs in lark's head knots while similar Huari hats were patterned with knots with tufts of wool pile in each knot.

By AD 1000 the highland centers of Huari and Tiwanaku had collapsed and individual cultures began clearly to establish local identities noted in regional textile styles. Warp-patterned structures such as complementary and supplementary-warp weaves were commonly woven in the following Late Intermediate Period (AD 1000–1450). Textiles are often characterized as having repetitive, small-scale imagery in gauze, painted cotton, weft-brocades, and double-woven fabrics. South coast weavers shaped bags and shirts through the selective addition of warp yarns during the construction process. North coast weavers often wove exotic bird feathers into the cloth, creating shirts and other garments with one face completely covered with feather patterns. During this period coastal weaving especially exploited the full potential of natural native colored cottons which were woven in contrasts of white and natural red-brown, beige, and grey.

The highland Aymara weaving tradition was consolidated in the south central Andes during the Late Intermediate Period after the fall of Tiwanaku. Aymara textiles are characterized by elegantly striped warp-faced shirts, woman's dresses, head cloths, and mantles in natural colored camelid fiber yarns often dyed blue, green, and red.

The Late Horizon (AD 1450–1534) again marks the period when local cultures were brought under highland control, this time that of the monolithic Inca state with its capital at Cuzco in the southern Andes. Inca textile patterns are strictly geometric and nonfigurative and the most valued cloth was weft-interlocked tapestry woven on the wide tapestry loom with a short warp. Some of the best preserved Inca textiles have been discovered as miniature offerings covering gold and silver male and female figurines and left on the tops of Andean mountain peaks from Ecuador to Argentina. Male garments include a tapestry tunic, a mantle, a bag with a carrying strap, and a large feather headdress. Female garments include a large wrap-around dress and a narrow, highly patterned belt. Most of these garments are woven entirely in camelid fiber and are colored with red and yellow dyes.

Following the conquest of the Inca state by European conquerors, European methods of textile manufacture were introduced throughout the Andes. The spinning wheel was adopted for workshop production, and the treadle loom was constructed for the manufacture of yardage to be sewn into non-Andean style tailored clothing. Needle knitting was introduced and is now regularly used for sweaters and knitted caps in local communities. Felting was introduced for wide-brimmed hats which have now become part of indigenous community dress in many regions.

While foreign clothing styles and techniques replaced local garment manufacture in coastal regions, European methods never replaced highland traditions in many indigenous communities in Colombia, Ecuador, Peru, and Bolivia. Today, some areas have maintained camelid-fiber spinning practices using the drop spindle and the backstrap loom or the staked ground loom to produce native four-selvedge garments. Men are the principal weavers in indigenous communities in Colombia and Ecuador, and women weave in Peru and Bolivia. In the southern Andes men weave on the European treadle loom. All community members spin, but spinning is generally considered women's work. Many communities continue to express local identities through handwoven patterns and specific color combinations which are worn daily or for community rituals. Traditional four-selvedged handwoven garments are also worn with European-style vests, pants, sweaters, or skirts in many areas. Some communities have specialized in the decoration of textiles with sewing machine embroidery.

Outside of the Andean region, a few Brazilian tribes and groups living in the Amazonian areas of Ecuador, Peru, and Bolivia, have continued lowland traditions using barkcloth, elaborate feather headdresses, and oblique-interlaced bags and narrow bands, textile traditions which may reflect ancient lowland origins never preserved in these wet regions.

South America continues as the native home to herds of guanaco, vicuna, llamas, and alpacas with an export industry in camelid fiber and manufactured textiles. Peruvian cotton is valued for its luster and is enjoying a revival in interest in native natural-colored cotton yarns.

Thābit ibn Qurra

Boris Rosenfeld

Abū'l-Ḥasan Thābit ibn Qurra ibn Marwān al-Ḥarrānī al-Ṣābi᾽ (836–901) was a Syrian mathematician, astronomer, physicist, physician, geographer, philosopher, historian, and translator from Greek and Syriac into Arabic. His scientific treatises were written primarily in Arabic and partly in Syriac. He was born in Kafartūtha near Ḥarrān (now Altinbaşak in Southern Turkey) and was a student in Ḥarrān. Ḥarrānians, the descendants of the ancient nation Mitanni in the Hellenistic age, were hellenized, and their ancient religion of star-worship was deeply connected to Greek philosophy. In the Arab caliphate Ḥarrānians called themselves Ṣābians since the Ṣābians religion was one permitted by the *Qur᾽ān*. Ḥarrān University was founded in the fifth century in Alexandria as a school of philosophy and medicine. After the Arab conquest it was moved to Antiochia and later to Ḥarrān where, under the influence of Ḥarrānian traditions, astronomy and mathematics were taught, and it became a university.

At first Thābit ibn Qurra worked in Kafartūtha as a money-changer. Here the Baghdad mathematician Muḥammad ibn Mūsā ibn Shākir met him and invited him to Baghdad, where Muḥammad and his brothers Aḥmad and al-Ḥasan, the Banū Mūsā, became his teachers. Later he worked at the court of the caliphs in Baghdad and in Surra man ra'a (Samarra) as a physician and astronomer. His position as caliph's physician allowed him to keep his heathen religion. His son Sinān ibn Thābit and grandson Ibrāhīm ibn Sinān also were mathematicians, astronomers, and physicians in Baghdad.

Thābit ibn Qurra's contributions to science covered many different disciplines, from mathematics to philosophy. In mathematics, he was a translator or editor of translations of many works of Euclid, Archimedes, Apollonius, Theodosius, and Menelaus. Many of these are extant only in these translations. These translations, together with the geometric treatise of Thābit's teachers, the brothers Banū Mūsa, and his *Kitāb al-mafrūḍāt* (Book of Assumptions) constituted the so-called "middle books" which were studied between Euclid's *Elements* and Ptolemy's *Almagest*.

Two of Thābit's treatises on parallel lines were first written in Syriac, the first under the title *Ktovo al-hay da-tren surte trishe kad mettapkin al bshir men tarten gonowoto dagᶜin bahdode* (Book [in which is proved] that Two Lines Produced Under Angles Which are Less Than Two Right Angles Will Meet). The second is called "the second book on the same topic." Both these treatises are extant only in the Arabic translations made by Thābit himself. The ideas of these treatises were further developed by Ibn al-Haytham (965–ca. 1050), ᶜUmar al-Khayyām (1048–1131), and Naṣīr al-Dīn al-Ṭūsī (1201–1274) and later led to the discovery of non-Euclidean geometry.

Thābit's *Kitāb fī taᶜlīf al-nusub* (Book on Composition of Ratios) was devoted to the theory of compound ratios. This theory later led to the notion of real numbers and to the discovery of differential calculus.

Other work covered such subjects as a simple proof of the Menelaus theorem (the first theorem of spherical trigonometry), mensuration of plane and solid figures, and solutions of different problems of integral calculus. His books contained some proofs of the Pythagorean theorem and its generalization, and dealt with the subject of amicable numbers, in which each number is equal to the sum of the divisors of the other.

In the field of astronomy, Thābit was the editor of the translation of Ptolemy's *Almagest* and the author of many treatises on the movement of the sun and moon, sundials, visibility of the new moon, and celestial spheres. In his treatise "On the Motion of the Eighth Sphere," extant only in Latin translation (*De motu octave sphere*), he added the ninth to Ptolemy's eight spheres and proposed the theory of "trepidation" to explain the precession of equinoxes. The fragments of Thābit's Syriac *Ktovo d'pulog d'yumoto d'shoboᶜo al koukbe shabᶜe* (Book on the Subdivision of Seven Days of the Week According to Seven Planets) are extant in Bar Hebraeus' *Chronography*. In this book the planets are designated by their Babylonian and Greek names; this subdivision was known to Romans and Indians and is the source of the names of the days of the week in many European and Asian languages.

Thābit also wrote books on mechanics and physics. His *Kitāb al-qarasṭūn* (Book on Lever Balance) discusses the conditions for equilibrium of different kinds of levers. In his *Kitāb fī masā'il al-mushawwiqa* (Book on Interesting Questions) Thābit tries to explain the phenomenon of the camera obscura. This attempt was erroneous, but it led Ibn al-Haytham in the *Book on Forms of Eclipses* and al-Bīrūnī (973–1048) in *The Exhaustive Treatise on Shadows* to the solution of this problem. He also studied the problems of acoustics in *Mas'ala fī'l-mūsīqā* (Question on Music) which is an extant fragment of his great *Book on Music*.

In geography and medicine, Thābit revised works of Ptolemy (*Kitāb ṣūra al-arḍ*, Book of the Picture of Earth) and Galen. He was the author of the fundamental *Kitāb al-dhakhīra fī ᶜilm al-ṭibb* (Book of Treasure in the Science of Medicine).

In philosophy, Thābit emphasized that integer numbers were abstractions of objects of counting and criticized Aristotle who rejected actual infinity. In his commentaries to Aristotle's *Metaphysics* he considered the problem of the "first motor" and argued with Aristotle's opinion that the essence is immobile. Many of Thābit's treatises are devoted to problems of religion, in which he is critical of both Christianity and Islam.

Timber-Handling Technology in Japan

Conrad Totman

Japan has long been known for the ability of its artisans to construct gigantic, durable wooden structures, lesser wooden buildings of graceful design, and small objects of meticulous craftsmanship. One wonders how they were able to use the trees of their archipelago for these purposes when its topography made logging and timber transport so exceedingly difficult.

Preindustrial Timber Handling

Japan's earliest wood-handling technology was predictably simple. Stone – and later metal – hand axes, adzes, and chisels were used to fell and process tree trunks and bamboo to create rafts, dugout canoes, and plank-walled boats; diverse hand tools, weapons, and other small objects; and post-and-beam buildings lashed together with vine and enclosed with thatch or wattle.

During the seventh century, however, major new architectural forms – grand wooden palaces and Buddhist temples that utilized stone foundations, mortis-and-tenon framing, board walls, and tile roofs – arrived from the adjacent continent. These new forms vastly increased the demand for timber and, as a consequence, produced changes in all stages of wood handling, from felling and transporting to final fashioning into the devices of daily life. In following centuries that technology was elaborated and refined, and its usage spread across the islands.

In the first stage, loggers used slender-hafted, narrow-bladed axes to fell and limb trees and cut them to length. By the sixteenth century blacksmiths were producing large saws with sufficient temper and consistency of thickness for use as crosscut saws, and for several decades woodsmen employed them in felling trees. During the seventeenth century, however, their use for felling was outlawed, evidently to prevent timber theft: the sound of an axe thwack carries much farther than does the swish of a saw, helping guide warden to miscreant. From then until the late nineteenth century felling was handled by professional axmen. To facilitate the felling of especially large trees, choppers gouged holes around the base, stuffed the wood chips back into them, and set them to burning, guiding the burn through the base so as to fell the tree in the desired direction.

Turning to transportation, in early centuries, when adequate timber was available within reasonable proximity of a construction site, logs could be carried to it on two-wheeled oxcarts. Or they could be floated downriver (or hauled upstream by man or animal power), snared and pulled ashore at a landing, and then loaded onto carts for overland transport.

Later, as lowlands were cleared and more and more timber came from steeply mountainous regions, the transport system became more complex. Skidding crews at the felling site used long-handled hooking tools, vine or woven rope, and, where the situation required them, winches and sleds to role, skid, and sled pieces down to a log-assembly point. There (or sometimes at the felling site) axmen hewed the logs to form roughly rectangular pieces. This hewing reduced log weight, rendering sticks more manageable, and it made them more stable for the journey to town. In particular, when used to form rafts, hewn pieces were far less likely to twist and tear apart as raftsmen were negotiating rapids and turns in the river.

Depending on the terrain, workmen might use some of their squared sticks to form log trestles or trough-shaped chutes down which they could slide pieces to streamside. Or in the case of assembly beside a small mountain stream, they could construct splash dams and elevated chutes as needed to propel sticks on the flood down to where normal stream flow would float them freely.

Where felled trees were being converted to shingling or other small pieces, they commonly were split to portable size at the felling or assembly site or at a river landing. And material for conversion to charcoal was processed in kilns and the cooled charcoal bagged for transport. Both split pieces and charcoal were then carried overland to market by packhorse or floated out of the forest aboard log rafts.

The trip by water could be complicated. Most of Japan's rivers rush from mountains down to the sea, and given the frequency and unpredictability of downpours, freely floating logs risked doing damage to riverbanks or facilities, being stranded by high water at inaccessible sites, or even of floating out to sea and being lost. At convenient locations, therefore, river transporters constructed floating booms by lashing bamboo or logs together with vine and anchoring them to rock outcroppings, trees, or huge posts as the site allowed. These booms captured floating sticks, enabling workmen to beach them for temporary storage or processing or to assemble and bind them into rafts for the remainder of their journey.

On the largest rivers, the short initial rafts were beached at a midway point and several then joined end-to-end for the journey's final leg to a landing near the coast. At seaside, especially large logs could be lashed to shipside or hauled astern to a port of destination. But most pieces were taken aboard for the trip.

At the lumberyard or work site, squared logs were left floating in the water until needed, or they were stacked on land for curing and sale or processing and use. To convert a log to boards or planking, sawyers positioned one end on a high A-frame and used wide-bladed saws to rip it to the specified dimensions. The saw teeth were shaped to cut on the draw stroke rather than the push stroke, which reduced the risk of kinking the blade. That design lowered the required level of temper and hence the cost of the saw, but it increased the frequency of sharpening.

Other workmen used regular axes or broadaxes to split sticks into staves, shingles, or fuel wood. And carpenters and craftsmen employed a handsome array of hammers, small saws, adzes, planes, chisels, rasps, and drills to shape pieces for final use, whether as building parts, cabinetry, tools, weapons, *objets d'art*, or whatever.

By the nineteenth century, then, Japan had a well-developed and complex system of wood provisioning. It was operated by an array of professionals – axmen, skidders, raftsmen, other rivermen, sawyers, and carpenters – most of whom were organized in guilds that protected their fields of expertise and employment. And timber merchants, who arranged and financed many of the logging and transport operations, also managed the lumberyards and handled most of the wholesaling, jobbing, and venture capitalization that the timber business entailed (Figs. 1–3).

Timber-Handling Technology in Japan. Fig. 1 Stacking wood at a lumberyard on Tatekawa Canal in a harbor side section of Edo (today's Tokyo). Men on the left stack split pieces of fuel wood; bales of charcoal are stored under thatch cover at their feet; sawyer on right rips a timber to form planks; poles are stacked vertically to his right, partially obscuring Mt Fuji; planking, boards, squared timbers, and long green bamboo poles are below him. (Katsushika Hokusai, *Thirty Six Views of Mt. Fuji* (ca. 1820), in the author's possession.)

Timber-Handling Technology in Japan. Fig. 2 Sawyers rip a squared timber at Yamanaka in Tōtōmi Province, southwest of Mt Fuji, while another workman, seated before their temporary mountain hut, sharpens his saw, as family members look on. (Katsushika Hokusai, *Thirty Six Views of Mt Fuji* (ca. 1820), in the author's possession).

Industrial-Age Timber Handling

The world of preindustrial timber provisioning was thrown into turmoil during the 1860s when the established political order collapsed in the face of foreign encroachments. The new rulers set out to achieve rapid national self-strengthening, and that project entailed, among other things, sharply intensified exploitation of domestic resources, woodland included. Those developments altered radically the techniques of felling, transporting, and milling timber.

Until around 1900 the organized guilds of axmen, raftsmen, and others were able to slow appreciably the inflow of new technology. But by then the use of crosscut saws – no longer forbidden after 1868 – had become common, and they prevailed into the 1950s, until being displaced by chain saws. And in those areas, mainly in Hokkaido, where tractor-mounted mechanical saws are able to function, they and other similarly "high tech" devices – feller-bunchers, skidders, processors, harvesters, forwarders, and tower yarders – have been introduced during recent decades in unsuccessful attempts to reduce labor costs enough so that the domestic timber harvest can compete with imports.

Timber-Handling Technology in Japan.
Fig. 3 Surrounded by his mallets and bamboo for hooping, a barrel maker smoothes the inner surface of his staves at Fujimigahara in Owari Province, west of Mt Fuji. (Katsushika Hokusai, *Thirty Six Views of Mt. Fuji* (ca. 1820), in the author's possession).

Rather similarly, raftsmen and rivermen retained their roles until around 1900, when timber began leaving the forest by tramway and railroad. By the 1930s nearly all flotation and rafting had ceased. But starting then, and especially after 1950, rails in turn gave way to roads as trucks and "Caterpillar" type tractors and sleds took over. In some interior valleys, moreover, highlines have come into use for carrying logs airborne from felling site down to assembly point, where they are yarded and loaded onto trucks or otherwise moved along for processing.

Sawmills had appeared in Japan by the 1870s, initially sash saws (vertically mounted, mechanically powered crosscut saws), subsequently circular saws, and eventually band saws (continuous ribbons of teethed steel driven at high speed by sheaves mounted above and below the saw carriage). The earliest were water and steam powered, but electric power, whether purchased or produced on site, came to prevail during the early 1900s. And internal-combustion engines later powered some portable mills. (Pulp, plywood, and chip mills, technologies that are not discussed here, were introduced to Japan, respectively, in 1886, 1907, and 1957.)

The scale of Japan's sawmill technology has differed greatly from that found elsewhere. During the years ca. 1860–1920 the productivity of mills in Euro-America rose dramatically, tenfold or more. That rise was made possible by myriad technical improvements in saw types, power sources, and other aspects of mill equipment. But it also was premised on two conditions not found in Japan.

First, it presumed the existence of sprawling, richly stocked, flatland forests cut by leisurely flowing rivers that could float vast quantities of large, same-species logs to a sprawling sawmill site, flatland that would, a few decades later, provide easy terrain for the construction and use of roads and railways. Second, it presumed a system of woodland ownership that would allow a mill to obtain vast quantities of logs from large, more-or-less contiguous areas. In Japan, however, nearly all forests were on steep mountainsides, and possession was highly fragmented, about half being owned by smallholders with a few acres apiece, the other widely scattered half by government. Almost nowhere could a mill operator expect to obtain substantial quantities of large-scale timber from his immediate environs for any extended period. In consequence, before World War II the most efficient technology did not fit Japan's circumstances, and the newest devices, band saws most importantly, were used in only a small portion of the country's sawmills.

During the first two decades after that war, great effort was made to introduce and refine the most up-to-date mill technology. However, from about 1970 onward, imported wood undermined the profitability of domestic milling, and the enthusiasm for technological change largely evaporated. Instead, sawmills gradually developed in two directions. Today large, highly integrated mills, which are set up at coastal sites near major markets expressly to handle imported logs, use elaborate, efficient, high-speed equipment to produce great volumes of lumber. Domestic timber, meanwhile, is mostly sawn at small mills set up in major timber-producing areas, where they use much simpler equipment to turn out high-grade, specialty lumber, but at rates comparable to those of American sawmills of the 1860s.

So today the timber-processing technology of Japan is used primarily to handle imported wood. And that situation seems likely to prevail for a few more decades, until destruction of the world's woodland drives global timber prices up enough to make Japan's mountain forests again competitive in the marketplace.

Time

Henry J. Rutz

The dual classification of cultural systems of time as Western or non-Western is an oversimplification that limits our understanding of how time is created, represented, measured, and practiced in different cultures. The premises underlying dualistic thinking about time reveal its limitations.

First, dualistic thinking adopts the premise that Western time is linear (irreversible), abstract, quantitative, and homogeneous. In contrast, non-Western time is cyclical (reversible), concrete, qualitative, and heterogeneous. There is a tendency to draw too sharp distinctions based on characteristics presumed to be in opposition. Underlying these are further distinctions between *them* (Oriental, primitive, oral, preindustrial) and *us* (Occidental, modern, literate, industrial). Embedded in these implicit distinctions is the assumption that non-Western time is to be thought about within a conceptual frame that implicitly adopts Western time as a standard for perception and evaluation of non-Western time. In a word, dualistic thinking about time has been Eurocentric.

Second, dualistic thinking rests on the premise that Western and non-Western cultures are different and unrelated totalities, and that time is unitary within each. The Unitarian premise leads to generalizations such as believing that non-Western cultures have a cyclical as opposed to a linear concept of time. The result is that diversity is underreported and undertheorized.

Third, dual systems of culture and time suffer from an ahistorical and overly formal foundation to knowledge. Western societies have "history" and a consciousness of being in time, in contrast to non-Western societies which have "myth" and a sense only of relational time that renders events mere epiphenomena of structure. Myth is not about the causation of before and after but about a formal means for making all the elements and characters ever-present.

Fourth, the ahistoricist premise also leads to the view that non-Western societies have an awareness of themselves in time only to the extent that westerners bring such awareness to them, either in the form of historical consciousness or as a practical matter of the efficient and productive use of time as a resource.

Fifth, dualistic thinking rests on the premise that time is a thing that is either present or absent in a culture. A dichotomy between western *linear* time and non-Western *cyclical* time appears as real and coerces people to behave and think in a particular way. But the terms of this dualism are highly abstract and refer to no particular period, bounded space, social organization, or real people. The dichotomy bears little relation to the cultural construction of time in the everyday lives of people in a specific region, a particular period, or known conditions of migration, diffusion, and contact.

The situation is complex. While no cultural constructions of time have remained unaffected by European expansion, it is presumptuous to think that we know what aspects of European time (which varied in different periods and places) influenced a bewildering variety of religious communities, empires, and kin-ordered societies, each with its own historically constituted temporal rhythms. Indeed, examining the real complexities of culture and history raises important issues about temporal dynamics only to the extent that we abandon dualistic thinking.

An alternative perspective, one that anthropologists, historians, and archaeologists increasingly embrace, pays attention to multiple constructions of time in single social formations, the extent to which different times are articulated, and the temporal dynamics of development and change in the rhythms of everyday life.

While some languages lack a generic word for time, there is abundant evidence for the universality of concepts of duration and succession in the linguistic and cultural practices of every person. The French sociologist Émile Durkheim expressed the opinion that it is hardly possible to think about time "... without the processes by which we divide it, measure it or express it with objective signs." These processes, he concluded, are social in origin. The anthropologist Edmund Leach, following Durkheim's lead, noted that "We talk of measuring time, as if it were a concrete thing waiting to be measured; but in fact we create time by creating intervals in social life. Until we have done this there is no time to be measured." To these ideas about time we need to add those of another French sociologist, Georges Gurvitch, who pointed out that every social formation has a multiplicity of times. Not only are there different collective representations of time among different cultures, but different time systems coexist within a single social formation.

These ideas, that time is culturally constructed, socially embedded, and multiple, have become guiding principles in cultural studies of time. The other articles on time in this encyclopedia illustrate the complexity and diversity of time systems from the multiplicity of time perspective. A brief comment on a number of issues will clarify the present direction in cultural studies of time systems.

1. Acceptance of the multiplicity of time within single social formations has led to the rejection of attempts to classify whole societies, not to mention a whole class of societies such as "Western" or "non-Western" by any single subsystem of time. Comparison remains important, but comparativists now

recognize that they must seek out similar subsystems in different cultures. Leopold Howe, for example, disputes Clifford Geertz's conclusion that the Balinese calendrical system does not represent a flow by which the passage of time can be measured, that the calendar represents a concept of time that is nondurational, and that Balinese experience of time is of "islands" or points that are unconnected (an extreme form of discontinuity, imprecision, and noncountability). Geertz asserts that the particulate nature of days implies a nondurational concept of time. Such a description of Balinese time carries an implicit comparison with our own, based on dualistic assumptions that go unexamined in both. Howe provides evidence that Balinese count days and are forever referring to past and future in terms of such counts. Geertz confused an attribute of members of a class with the class itself—each day is qualitatively different from others, but days fit into a succession that is endlessly repeated. Each name day partakes of being a day that *qua* day has the attribute of countability. The Maya had no such confusion. They viewed time as a flow that could be measured and also endowed days with qualities dependent upon the work of gods and men.

2. Recognition of the multiplicity of time shifts attention away from gross comparisons of presumed-to-be-different systems of time toward contextualized descriptions and similarities of subsystems in apparently different cultures. There has been a concomitant shift from classification to process, raising questions about temporal dynamics. How *does* time get constructed? What *are* the processes of development and change that account for the multiplicity of time and the degree of articulation among subsystems? Cultural studies of time have taken several directions, none of which is mutually exclusive. Nancy Munn challenges, from a phenomenological perspective, Evans-Pritchard's conclusion that Nuer time amounts to a creation of a static and nondevelopmental experience of time. His structural models of Nuer time overlook Nuer accounts of their bodily activity of procreation, their own subjective experience of time in terms of layers of ash on the fires, their ability to plan for events in the future, and other evidence of developmental constructs of time in their projects and practices. Peter Rigby, who has researched the age-set system of the pastoral Ilparakuyo Maasai in Kenya, challenges, from a historical materialist perspective, Evans-Pritchard's failure to address the degree of articulation of Nuer multiplicity of time. Had Evans-Pritchard taken into account the historical consciousness of Nuer, he would have found that all the elements of time-reckoning can be placed in a single conceptual frame arising from the historical development of Nuer within a specific social formation. Rigby, drawing on his own work and that of others, attempts such a synthesis for the Ilaparakuyo Maasai.
3. Cultural studies of time that explore the underlying temporal dynamics of how a multiplicity of time is constructed have paid increasing attention to the politics of time. Cultural constructions of time are part of the political economy of development. The creation of time requires agents and agencies temporalizing their respective projects in struggles for power and legitimacy. Farriss' attempt to reconcile cyclical and linear concepts within the same calendrical system in Maya culture rests on an interpretation of Maya political transformation from city-states to rule by dynastic lineages. With the demise of Maya elites, subsystems of time wither and die.
4. The attention paid to the politics of time has raised anew issues about the reflexive study of time in different cultures. Johannes Fabian has criticized anthropologists for failing to recognize that theories which distance "other" cultures by placing them in an-other time unwittingly use time as an instrument of political domination. Apparently disinterested studies of difference are revealed to be interested studies of "the other", a form of cultural politics. The solution is to recognize that people of different cultures are contemporaries and use that as a point of departure for all conceptual frames concerning the politics of time. A reflexive approach to cultural construction of time would overcome Rigby's concern that most descriptions of time in "different" cultures are really implicit comparisons using hegemonic bourgeois time as a standard. Most of us reckon time in our daily lives by systems other than the formal-mathematical or chronological ones deployed by an army of scientists, historians, and anthropologists. Such reflexivity, or self-awareness, of our own multiple concepts of time would be salutary for advancing our understanding of the cultural construction of time in different cultures.

Time in Africa

Henry J. Rutz

In every society, one source by which time is divided, measured, and expressed by objective signs is the mutual obligations and principles that structure social relations between persons and groups. Among the most important is kinship. In those societies in which kin communities encompass the widest range of social relations, time is expressed as duration and succession of kin-ordered activity. Perhaps the best-known case is that of the Nuer, a Nilotic pastoral people who live in villages of the upper reaches of the Nile in Sudan.

E.E. Evans-Pritchard has given us a rich account of ways in which village kin communities conceptualize and reckon time as an aspect of social structure. Among the multiplicity of times apprehended by Nuer, three of the most important subsystems are (1) a series of social activities articulated with a series of ecological events by which one is used to measure the duration and succession of the other; (2) a series of age-sets that measures intervals and succession in the life cycle; and (3) a hierarchy of segmented kin groups that measures lapsed time, i.e. a form of collective memory of the "past" that constitutes the conceptual frame of Nuer history.

Nuer livelihood is based primarily on cattle herding and the cultivation of millet, a dual adaptation to vast stretches of marsh and savannah in a climate that necessitates a transhumant existence between village settlements on knolls during the rainy season and dry season cattle camps near rivers. A change of season is the objective sign for a change in settlement pattern, accompanied by changes in ceremonial and social activities. Most collective rituals, such as marriage and male initiation, take place in wet season villages, but the dry season cattle camps, when youth disperse to small camps in search of pasturage near sources of water, are viewed as a time of freedom and courting. In a rare comment on the experience of seasonal rhythms, Evans-Pritchard states that the pace of time speeded up during the wet season and slowed down during the dry season, an effect of the density of social activities and the significance the Nuer attributed to them.

Although the Nuer have no word for a generic "year", they reckon cycles of wet and dry seasons, giving names to each, and divide the cycle into twelve named "moons" of unequal duration that mark the succession from wet to dry season and back again. The duration of months depends less upon lunar observance (though they are familiar with phases of the moon) than the agricultural and pastoral activities associated with ecological phases within seasons. Nuer adjust the series of ecological activities to fit social contingencies. If the Nuer were still in their dry camps, waiting for rain, then they would say that they were still in the named "moon" prior to the onset of rains. If they were still engaged in rituals associated with the wet season villages, then they would reckon the name of the moon by the social activities appropriate to it. The result is an annual calendar embedded in a coordinated parallel series of ecological and social rhythms, the durations of which vary within and between cycles. Working one series against the other, Nuer rename months, skip months altogether, or even omit "years" in their recounting of socially significant events over a number of seasonal cycles.

Nuer can count seasonal cycles, months, and days (there is no "week"), but they tend not to. Chronology or a sense of lapsed time with respect to livelihood is culturally suppressed, giving the illusion of endless recurrence. Days, months, and seasons remain socially embedded and unarticulated as an abstract and numerical system independent of the concrete activities that lend the system meaning. The Nuer have no generic word for time.

Biological facts of individual maturation and aging, like ecological and physical facts, are given social significance in every society. But their division, measurement, and expression in objective signs are contingent and vary from one society to another.

Among Nuer, the reproduction of cattle, or cattle genealogies, is the basis of a concept of male personhood. Individual Nuer men are fiercely egalitarian and quick to defend themselves against perceived affronts to their manhood. The natural reproduction of cattle, combined with a culturally constituted series in the life cycle of male individuals—for example the transition from boyhood to manhood marked by the gift of a first cow, the transition to husband marked by a gift of cattle at marriage (a transfer from the groom's to the wife's kin), and a further transfer of cattle marking the transition to "fatherhood" with the birth of each successive child — regulate the rhythms of interpersonal kinship, articulating the pedigree of specific cows with the genealogy and life history of individuals.

Cattle genealogies mark the passage of time in the lives of individual male Nuer, a process that in its very nature is directional and irreversible. But Nuer also have organized individual male maturation as a collective problem of social significance. Village boys of comparable age (between 14–16 years) are initiated into a named age-set during an open period. A "Man of the Cattle" is responsible for closing a period, "thereby dividing the sets." The initiation consists of a painful ritual whereby each boy is cut to the bone across the forehead six times, producing deep scars called *gar*. His reward is a gift of his first cow and a taboo on milking. The only point of articulation between the seasonal and age-set time systems is the timing of the initiation, which occurs at the end of the wet season when food is plentiful. Proximate villages tend to coordinate periods despite independent declarations in each. Regions tend to share at least some age-set names (but vary the sequence), which differ from one part of Nuerland to another.

In pastoral Kenya and parts of Bantu East Africa, the age-set/generation-set system consists of age-sets organized into three distinct generation-sets of boys, warriors, and elders, with a pronounced taboo on warriors marrying. It is hard to avoid the conclusion that Nuer age-sets have something to do with the collective control of elders over young men. The military and administrative functions of Nuer age-sets, however, are attenuated and appear to have more to do with regulating the domestic obligations of manhood.

Nuer conceive of the age-set system as fixed at six living sets. Using a kinship idiom, they break the sets down into "brothers" who are equals, "fathers" who are elders in authority, and "sons" over whom they have authority. But age-set names are not repeated and Nuer do not perceive the age-set system as cyclical (some Bantu groups do). Age-sets whose members have died are not remembered or recounted. Even when a few old men of the most senior age-sets are still alive, junior age-sets are merging them with members of adjacent age-sets. The system is designed for the living, intended to mark lapsed time by the intervals between open and closed periods that define the age of one group of males relative to another in a weak form of gerontocracy. Like individual biography inscribed in cattle gifts and their genealogies, a sense of an irreversible flow of time is given in the fact that a named age-set "changes its position in relation to the whole system, passing through points of relative juniority and seniority."

All human communities develop collective representations of a past that embody a historical consciousness of the community *qua* community. Nuer have embedded their sense of historical consciousness in a model of a lineage system that creates the illusion of a fixed temporal horizon to events such as migration, tribal war, and territorial expansion that might otherwise be perceived as a succession of unique events in an irreversible "before and after" construction of past and future. The correct view of Nuer history is that it is ever-present and performative in the reciprocal rituals of lineage segments.

The segmentary principle of membership in a Nuer lineage is common descent through males from a recognized ancestor. The way Nuer think about tribal history is structured by how they think about the hierarchical relations between lineages, which also form the basis for claims to a division of territory. Reckoning political relations by lineages is relative because it depends on the particular person who is selected as the point of departure in tracing descent. The largest lineages, those which incorporate the widest latitude of members connected by descent from a common ancestor, are termed clans, and they in turn are comprised of lineages with several lines, each of which is a smaller lineage tracing descent through less distant ancestors to incorporate a narrower range of members.

The lineage system is employed by living Nuer to reckon their common past. Although every man is a potential founding ancestor, the social fiction is that the living are organized into segments in such a way that there are only ten to twelve ancestors at the maximum social distance, and three to four at the minimum. This fixed system of reckoning is in contrast to the real events of Nuer history, which is one of human propagation inscribed in Nuer genealogical reckoning, expansion and contraction of territory, and the actual bifurcation and amalgamation of lineage segments. But the Nuer fit such events into a structure of lineages with a time depth of 10–12 generations when there is no reason to presume that they have existed for so short a time. The Nuer express their political history as a fixed structure of relations between lineage segments. They prefer a stylization of history to a record of the endless march of unique events in an irreversible flow of time. The absence of writing and the strength of oral culture no doubt have something to do with it. The content of relations changes and is irreversible, no matter who the ancestors are or where a particular named unit fits into the hierarchy, but the structure remains constant. Eternal returns, with their prophecies of foretelling and fulfilment, or dynastic genealogies that record the unfolding succession of heroic deeds from some fixed starting point into a receding time horizon, are not the stuff of Nuer social history.

The Nuer are a tribal state without centralized authority. Their kin-ordering and genealogical reckoning are the key to their construction of time, which contrasts greatly with that of empires. In those states where imperial elites (military and religious) ruled over vast areas and innumerable village communities from imperial centres, there developed an awareness of time itself as an objective instrument of power and legitimation.

Time in China

Jean DeBernardi

Chinese methods of calculating time are of great antiquity. According to the *Shi Ji* (Book of Records), as early as 2254 BCE Emperor Yao employed astronomers to calculate solstices and equinoxes and predict seasonal change so that farmers would know when to plant crops. Oracle bones dating to ca. 1200–1181 BCE attest to the fact that Shang Dynasty Chinese calculated time using a 60-day divinatory calendar that still is in widespread use. The early development of methods of measuring time was not entirely endogenous to China; cultures throughout the ancient world exchanged astronomical ideas and data.

Striking similarities exist between calendrical systems in widely separated regions, including parallels between the form and names of the Chinese and Maya divinatory calendars. At least as early as the first century BCE the Chinese used a luni-solar calendar resembling the standardized Babylonian calendar developed in the fourth century BCE. The similarities suggest borrowing, and it is possible that the Babylonians were the original inspiration for the Chinese soli-lunar calendar. In the Sui and Tang dynasties (589–960), Indian astronomers resided in China, and during the Yuan dynasty (1280–1368) Chinese collaborated with Persian and Arab astronomers. The technology of observation and measurement included an observatory built in Beijing during the Yuan dynasty. Contrasting with the astronomical system developed in Greek and medieval European astronomy, Chinese astronomy was polar and equatorial rather than ecliptic.

Although at times the Chinese borrowed astronomical ideas and technologies, these became incorporated into a system of time reckoning rooted in Chinese society. Sociologists have observed that time is a symbolic structure that represents a society's collective rhythms. In the Chinese calendar, some elements are based on astronomical cycles, while others have been shaped by the temporal rhythms of social life.

Chinese notions of the seasonal cycle are integrated into a system of classification based on the dualism of *yang* and *yin*. While *yang* and *yin* are often defined in terms of the complementary dualism of male and female, in Chinese they originally referred to sun and shadow, the very elements used to measure the changing seasons. For Chinese metaphysicians, *yang* and *yin* came to denote primal cosmic forces that interacted to generate a cycle of five phases (*wuxing*) which were identified with five primary elements (wood, fire, metal, water, and earth). These phases and their associated elements were in turn identified with the seasons. Thus Chinese classified spring with wood, summer with fire, autumn with metal, and winter with water, while earth was associated with the midpoint of the year.

This model of cyclical process associated the five phases with five colors (green, red, yellow, white, and black), directions (east, south, the center, west, and north), organs of the body, tastes, planets, virtues, passions, etc. Chinese elaborated rituals designed to control this cyclical process. Throughout the yearly cycle, the Emperor performed rites to inaugurate the seasons, and his performance gave concrete expression to the association of season, direction, color, and ritual. Chinese thought that by means of these ritual performances, the emperor could ensure harmony in the universe, and interpreted natural calamities as evidence of his loss of the "mandate of heaven" (Granet 1934). The cosmological framework of *yin* and *yang* and the five phases also informed Daoist alchemy, and still is fundamental to the Daoist rituals of popular religious culture.

Chinese philosophers and scientists appreciated the importance of natural cycles, and also linked the cycles of time with the cycles of human life. Not only they did link cyclic ideas of time to the liturgical calendar that regulated rites performed in the imperial court and its temples, but also they linked it to the microcosm of the body. In contrast with the taxonomic thinking that informs much Western science, Chinese explored patterns of function *through* time to make sense of various experiences, including ones related to health and illness. The associations of the five phases applied not only to the yearly cycle, but also to the cycle of the month and the day. For example, Chinese medical practitioners thought that the "seasons of the day" could predict crisis periods for physical disorders affecting different parts of the body.

While cyclical time had key significance, Chinese also had a well-developed concept of continuous time.

This concept found expression in “continuity history-writing,” in which historians sought to chronicle causal sequences of events in history. While official historians recorded the objective facts of history, they also critiqued the past in a form of “praise and blame” historiography that sought to discern the logic of a *Dao* (path or way) that had its origins in Heaven. Thus the rulers of China employed history, like divination, as a means to gain insight into the logic of events, and as a guide to appropriate action.

In an agricultural society, charting seasonal change was crucial, and one responsibility of the emperor was promulgation of the luni-solar calendar. Since promulgation of a calendar was a political responsibility and privilege, astronomy was an orthodox Confucian science. Every year a Board of Mathematicians led by an Imperial Astronomer (who was a Minister of State) prepared the calendar. After the Emperor approved the new almanac, high-ranking officials received it with great ceremony. The Emperor, who had exclusive rights to promulgate the calendar, also bestowed the almanac upon China’s vassal states as a mark of favor. During the Qing Dynasty (1644–1911) over two million almanacs were officially printed each year, and excess copies were available for sale. Despite this imperial monopoly, pirated editions circulated widely. Rebellious feudal lords sometimes expressed their withdrawal of allegiance by issuing a new calendar.

The Chinese used the calendar as an instrument to predict not only the best time for planting, but also the best time to initiate action. As a consequence, astronomy was interwoven with astrology and divination. Details of the zodiac are still published in the almanac, and the Chinese may consult this source to predict dates that are propitious or unpropitious for human undertakings such as weddings.

The most ancient method of timekeeping is the 60-day divinatory calendar, evidence for which appears on oracle bones in the late Shang dynasty (ca. 2300–1181 BCE). The cycle is composed of two interlocking sets of cyclical characters that are combined to form 60 unique two-syllable names. The “Ten Heavenly Stems” (*tian gan*) revolve in concert with the “Twelve Earthly Branches” (*di zhi*), and their combination generated 60 cyclical names. These 60 combinations were arranged in six 10-day groupings called *xun*. Since the first century BCE, years have been named after the consecutive days of the divinatory calendar, producing a repeating 60-year cycle. In the late Shang dynasty, the *xun* of the dyadic divinatory cycle was the basis for ordering sacrifices to royal ancestors. A full ritual cycle was completed in 360 days, increased to 370 by the addition of an intercalary *xun* every second cycle. This arrangement created a calendar that approximated the length of a solar year.

The Twelve Earthly Branches correspond to the 12 signs of the Chinese Solar Zodiac, which also name 12 constellations used to calculate the position of the sun every month. The zodiac animals (six wild or mythical and six domestic) are the rat, ox, tiger, rabbit, dragon, snake, horse, sheep, monkey, cock, dog, and pig. They are divided between passive *yin* and active *yang* symbols, and name the years in a repeating 12-year cycle. Chinese popular wisdom has it that persons who are born in a particular year have personalities shaped by the associated zodiac animal. Individuals should avoid marriage with persons born in the zodiac years of antagonistic animals, and also seek to avoid having children during such years.

The task facing early astronomers who sought to invent a calendar for use in predicting the seasons involved reconciling lunar and solar cycles. The regular cycle of the moon provided a readily observed celestial clock, but the lunar year does not correspond with the seasons, since 12 lunar months produces a cycle of only 354 days. The yearly cycle of the sun produces a cycle of 365 1/4 days, but it does not predict the full moon. The 365-day Gregorian calendar follows the solar year alone, with an extra day added every leap year to adjust for the fraction. The Chinese, however, sought to reconcile solar and lunar calendars.

By the eighth century BCE, Chinese could calculate and record eclipses, and they knew of the Metonic Cycle. This was a 19-year cycle at whose beginning and end the sun and moon are in the same relative position to each other. Discovery of this cycle led to a system of coordination of lunar and solar cycles that resembles the Babylonian standardized calendar, and some authors have suggested that this system was perhaps borrowed rather than invented (for details of debates, see Needham 1959: 171–177).

During 19 solar years, there were 235 lunar months, and Chinese astronomers divided these into 12 years that were 12 lunar months long, and 7 years that were 13 lunar months long. The 13-month years were produced by duplicating 1 month. The inventor of this calendar introduced that intercalary month in such a way as to ensure that the winter solstice always occurred in the eleventh lunar month, the summer solstice in the fifth, the spring equinox in the second, and the autumn equinox in the eighth. In addition, the introduction of an intercalary month ensured that the Chinese New Year always fell on the second new moon after the winter solstice, between January 20th and February 19th.

Before the adoption of the luni-solar calendar, Chinese dynasties inaugurated their reign by adopting a different month as the beginning of the civil year. The Manchus are said to have followed this tradition when Emperor Kang Xi in 1669 adopted the revised calendar proposed to him by the Jesuit Father Verbiest. The Republican Government expressed its break with imperial rule by adopting the Gregorian calendar, which was favored because of its universality. Its adoption also eliminated a powerful source of imperial authority, since monopolistic control of the calendar contributed to a mystification of Manchu power. None the less, the traditional luni-solar almanac still regulates the cycle of community festivals and the rituals of ancestor worship.

Time in Islam

M. S. Stern

Islam is now a major global religion. It has its roots, however, in the Arabian Peninsula of the early seventh century. Its core elements were implanted in the early years and all later developments relate, one way or another, to that core.

In pre-Islamic Arabia some elements seem to have related to time (*dahr*) as fate, an underlying force directing human and natural destiny. It was conceived as a power existing eternally and responsible for the happiness or agony of humanity. Thus the *Qurʾān* refers to those who "say… 'nothing but time can destroy us'." [45:24/23]

While time was generally seen as an impersonal force, some people sought to identify God with time or, worse still by Islamic standards, to use this concept to deny God's existence. The Apostolic Tradition (*ḥadīth*) records Muḥammad's saying that Allah commanded men not to blame *dahr* "for I [God] am *dahr*." Later there were various groups of radical thinkers, often only vaguely defined and known primarily from polemic references, who asserted "the eternity of the course of time." Accordingly, because they denied both Creation and Judgment, the beginning and end of time, they were considered atheists. The term *dahrīya*, therefore, came to encompass a broad spectrum of dissenters advocating some form of atheism and/or hedonistic materialism.

Islam universally views time as created. It is God's handiwork which, like all Creation, is under God's command. God acts in and through history but, being eternal, time does not encompass him. Nature is also his Creation but, while it manifests his greatness, it in no way encompasses Allah.

According to al-Bayḍāwī (d. 1282) in the *Anwār at-tanzil wa-asrār at-taʾwīl* (The Lights of the Revelation and the Secrets of the Interpretation), time consists of *mudda*, the period of revolution of the sphere from beginning to end (i.e., the totality of time); *az-Zamān*, a gross subdivision of *mudda* into long periods of time (e.g., specific historical eras such as dynastic reigns); and *al-Waqt*, a fine subdivision of *zamān* into definite points of time or short intervals (e.g., precise times of the five obligatory prayers).

There are some within the Islamic tradition who assert that time, begun at Creation, has no necessary end. Al-Ghazālī (1058–1111), speaking in the *Tahāfut al-falāsifah* (Inconsistency of the Philosophers) for the mainstream tradition, teaches that religious dogma, for example the Day of Judgment, points to a finite end to time.

Measurement of Time

The two most significant historical eras, in the consciousness of Muslims, are the Age of Ignorance (*al-Jāhilīya*), the Dark Age in Arabia before the revelation of the *Qurʾān*, and the Islamic age stretching from the formation of the Islamic community in AD 622 until the end of history at Judgment.

There is evidence which suggests that most ancient Arabs followed a pure lunar calendar. About two centuries before the Prophet, apparently under the influence of Jewish civilization, many in Arabia adopted a lunisolar calendar. After Muḥammad's transfer to Medina (the *hijra*), an absolute lunar calculation was mandated.

The *hijrī* year consists, in theory, of 12 months of 29 days, 12 h, 44 min, and 3 s. In fact, for various practical reasons, the lunar months are computed variously as having either 29 or 30 days. The *hijrī* year is about 11 days shorter than the solar year. There is no intercalation to the solar. Any particular *hijrī* date, over a period of approximately 33 years, will move through all four solar seasons.

A number of Islamic societies have introduced a solar or lunisolar calendar (e.g., pre-revolutionary Iran, Kemalist Turkey). None of these has achieved any universal acceptance among the world's Muslims. It is accepted, further, that such a calendar has no support in the *Qurʾān* or the prophetic *Sunnah*.

Specific points in the yearly cycle are sanctified and celebrated in various ways. There are many local holidays and celebrations, and certain times are acknowledged as primary Muslim holy times. The first is the month of Ramaḍān during which the Muḥammad's prophetic career was begun. For the entire month Muslims abstain from food, drink, smoking, and sexual contact. The fast begins each day at the moment that there is sufficient light to distinguish white from black threads. It ends each night after the sun has completely set. Islam's "lesser feast," *ʿId al-Fiṭr* (breakfast), brings release from the month-long abstention.

The "greater feast" is the *ʿId al-Aḍḥā* (Feast of Sacrifice) on the tenth of Dhū 'l-Hijjah. It celebrates the end of the Holy Pilgrimage (*Hajj*) and reenacts Abraham's sacrifice of a ram in place of his son (*Qurʾān* 37:102). The primary sacrifice is made by the pilgrims in the valley of Minā, near Mecca. Muslims all over the world also offer such a sacrifice.

In Muḥammad's time the Arabs counted a 7-day week. There is evidence that this is a relatively late practice imported from Babylonia (or, perhaps, by way of resident Jewish communities who observed the weekly Sabbath). Earlier time flow was divided according to weather and similar seasonal changes. Under Islam the week was given significance by assigning a special status to Friday. It is not a day of rest but rather a day of communal prayer.

Time as a Moral Dimension

> By [the token of] Time [through the Ages].
> Verily Man is in loss.
> Except such as have faith and do righteous deeds and
> [join together]
> in the mutual teaching of truth and of patience and constancy. (*Qurʾān* 103: 1–3)

There are numerous Quranic references to man's time and God's time. "He rules [all] affairs from the heavens to the earth: in the end will [all affairs] go up to Him, on a Day, the space whereof will be [as] a thousand years of your reckoning [32:5]." Creation, as well, is said to have been effected in 6 days [32:4]. Exegetes often emphasize that the days of Creation, before the placement of the sun, refer to God's days reckoned as a thousand man years (and, in 70:4, to 50,000 years). Muslim scholars reiterate that Allah is in no way bound by time; he is totally transcendent.

The point is that throughout the course of human history God maintains full control over his Creation. In his mercy Allah provided man with a window to his will and commanded him in the straight path. When time ends, at Judgment, man will face his time compacted to God's scale. "… In the immense future all affairs will go up to Him, for He will be the Judge, and His restoration of all values will be as a day or an hour or the twinkling of an eye; and yet to our idea it will be a thousand years" (Yūsuf Alī).

There is an implicit ambivalence as regards the pursuit of scientific and technological knowledge. In so far as the Muslim centers his consciousness on God, his greatness and omnipotence, he can easily succumb to a fatalistic acceptance of what comes to him. He then asserts God's absolute will and denies causality in nature. Without cause and effect there is no necessary natural order. In so far as man sees time as his sphere of action, he can hear the Quranic command to perceive God in his Creation. Exploration of the world becomes an act of moral compliance.

Time's purpose is to serve as an arena of moral action. It is the place which God has established for the exercise of will. Judgment and consequent assignment to paradise or hellfire will mean the end of time, its sole purpose being the setting for man's surrender.

Time in Korea

Nam Moon-Hyon

Timekeeping was both a royal duty and a royal prerogative in Korea since the period of the Three Kingdoms (三國時代, ca. 37 BCE to 668 AD) of Silla, Baekje, and Goguryeo. Although sundials and clepsydras (water clocks) were the main timekeepers, there were also fire clocks such as incense sticks at temples. Chinese calendrical systems, instruments for astronomy, and timekeeping systems were introduced to the Korean peninsula in antiquity, while from 554 AD Baekje sent calendrical scientists to Japan to supervise calendar- and clock-making there. Among the achievements of such missions was the water clock of the Japanese emperor Tenji (r. 661–671) which was made in 671. In Gyeongju, the capital of Silla, a royal observatory known as the Cheomseongdae (瞻星臺) was built in 647 and a water clock was constructed at the temple Hwangryongsa in 718; the latter was used to announce time by striking large bells in the bell tower, as was the case also with the bell shown in Fig. 1.

Time in Korea. Fig. 1 King Seongdeok’s God Bell at Bongdeok Temple, cast in 771. It announced dawn and dusk in Gyeongju, the capital city of the unified Kingdom of Silla (Korean National Treasure Number 29, restored at the National Museum in Gyeongju).

Late in the fourteenth century, the rulers of the Goryeo dynasty (918–1392) adopted Guo Shoujing’s *Shoushili* (授時曆, Time-Giving Calendar) that was compiled during the 1270s in Yuan China. They also introduced Su Sung’s astronomical clock tower powered by water and described in the *Xinyixiangfayao* (新儀象法要, The Appearance, Methods, and Importance of New Instruments, 1092), the Daming Hall lantern clock and Emperor Shunji’s elaborate clock with jacks (figurines) to announce the time automatically as described in the *Yuan Shi* (元史, History of the Yuan [Dynasty], 1369–1370), and various books from the Sino-Islamic tradition of striking clepsydras. Toward the end of the Goryeo dynasty and throughout the Joseon dynasty (1392–1910) astronomical, calendrical, meteorological, and clepsydral affairs were entrusted to the royal observatory known first as the Seoungwan (書雲觀) and then the Gwansanggam (觀象□). King Taejo (r. 1392–1398), the founder of the Joseon dynasty, built in central Seoul a Bell Tower (鐘樓, *Jongnu*) which announced the time provided by a newly cast night-watch[1] clepsydra (更漏, *gyeongnu*) in 1398. The third Joseon king, Taejong (r. 1400–1418), was a scientifically inclined ruler who worked with his son, the future King Sejong (r. 1418–1450), to improve printing Palace Guard technology and clock-making. Assisting them was the Chief Court Engineer Jang Yeong-Shil who cast a new night-watch clepsydra (更點之□, *gyeongjeomgi*, instrument with night-watches and [their] points) in 1424. Sejong became particularly interested in astronomy and, in 1432, initiated a project to reequip the royal observatory Ganeuidae (簡儀臺) using calendrical corrections in the *Shoushili* and the *Datongli* (大統曆, Calendar of the Great System) from Ming China. While the project was underway, 15 kinds of astronomical instruments and clocks were made, including two monumental water clocks by Jang and four kinds of sundials (see “Astronomical Instruments in Korea”). How the clocks were made is recorded in the *Sejong*

[1] “Night-watch” and “night-watch point” are technical terms from ancient Chinese timekeeping. The expression “night-watch” is used for the Korean word *gyeong* (更, *geng* in Chinese), about a 2-h period in the nighttime. There were five *gyeong* each night, corresponding with the 2-h blocks or “double-hours” from around 6 p.m. to 6 a.m., and each *gyeong* was divided into five *jeom* (點, *dian* in Chinese), an expression translated as (night-watch) “point.”

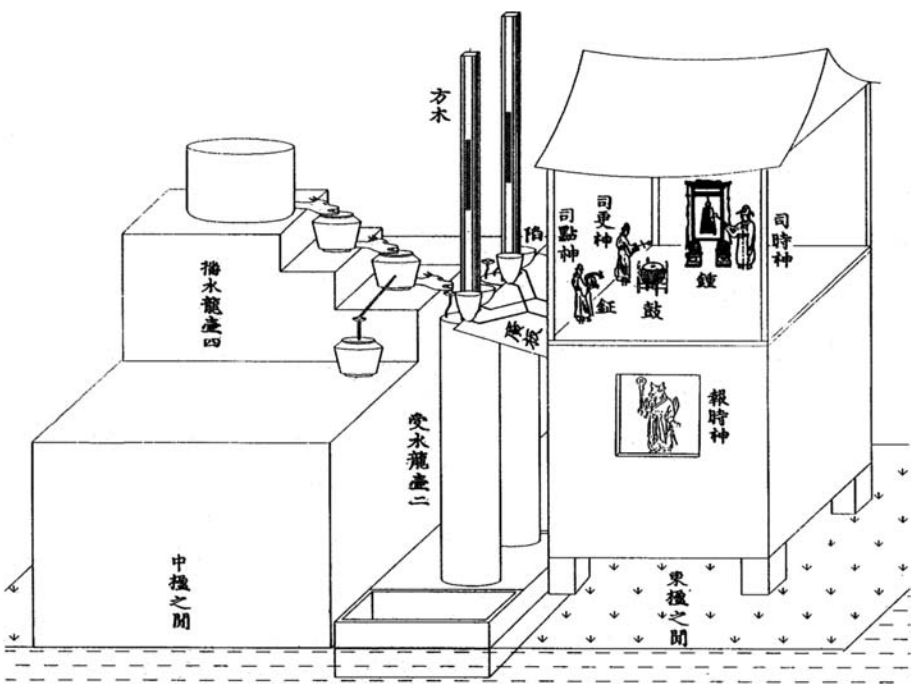
Sillok (世宗實錄, Factual Record of Sejong), which is supplemented in the *Cheungbo Munheon Bigo* (□□□□□□, Enlarged [Edition of] Documents and Notes, 1903–1908), a comprehensive study of civilization.

After the Japanese invasion of Korea late in the sixteenth century and during the emergence of the Qing dynasty in China during the middle of the seventeenth century, a Western-style calendrical system called the *Shixianli* (時憲曆, Calendar of the Constitution of Time) was adopted and several mechanical clocks were introduced through China and Japan in the 1630s and 1660s. In 1669 the horologist Lee Min-Chul and the Professor of Astronomy Song I-Yeong respectively made a traditional water-operated clock and a Western-style armillary clock driven by weights.

The *Jagyeongnu* (Self-Striking Water Clock)

The *Jagyeongnu* (自擊漏) is an elaborate timekeeper which announced the 12 "double-hours" (2-h blocks) that corresponded to the animals of the Chinese zodiac – the rat (which straddled midnight), ox, tiger, rabbit, dragon, snake, horse, sheep, monkey, rooster, dog, and pig – as well as the five night-watches (*gyeong*) that covered the hours from around 6 p.m. to 6 a.m. (and corresponded with the rooster, dog, pig, rat, ox, rabbit, and tiger) and their five "points" (*jeom*). Details about the *Jagyeongnu* are recorded in the *Sejong Sillok*, under the first day of the 7 month of the 16th year of Sejong's reign (1434), in the memoir *Borugakki* (報漏閣記, Description of the Announcement of the Clepsydra Pavilion) that was written by the court official Kim Don. Having been completed in 1434 under the commission of Sejong, it was an improvement on the clepsydra of 1424 and is divided into three parts (Fig. 2).

The inflow part of the clepsydra has four water-supplying vessels and two measuring vessels for everyday changeover. A floating indicator rod, graduated for the 12 double-hours and the points of the five night-watches, was in the measuring vessels, while above these vessels were wooden vertical ball racks with 12 (for the double-hours) and 25 (for the five points of the five night-watches) small bronze balls. The rod would rise and release horizontal latches that let the bronze balls out; the balls then fell and ran along an inclined channel to cause a set of 12 and 25 iron balls about as big as a hen's egg to trigger the time-announcing mechanisms. These mechanisms consisted of two ball-relays and an audible time signal for the double-hours and the night-watches, a visible time-indicator for the double-hours, three wooden jacks which sounded a bell for the double-hours, a drum for



Time in Korea. Fig. 2 The *Jagyeongnu*, "Self-Striking Water Clock." *Left*: The inflow part of the clepsydra consists of a reservoir, compensator, regulator, and overflow receptacle; two measuring vessels are on the floor bed. *Middle*: Two ball racks are implanted on the measuring vessels, which release small bronze balls through the holes that correspond to the 12 double-hours and the five night-watches. *Right*: Devices to announce the time are in the box, and the three jacks on the box strike a bell, drum, or gong; the jack in the middle of the box displays the time by showing the double-hour through the window as the bell is stricken.

the night-watches, and a gong for the night-watch points.

The ball-relaying mechanisms were separated by two large channels for the balls to move along. One channel allowed the balls to cause a jack in the form of a god to ring its bell for the double-hours; it also caused a horizontal wheel with 12 small gods to turn so that the appropriate god would display its double-hour tablet, an example having the character 午 for the hours of the horse (11 a.m. to 1 p.m.). The second channel caused another jack in the form of a god to announce the night-watches by striking a drum the appropriate number of times (e.g., three for the third night-watch), while a third god sounded a gong once for the beginning of a night-watch as well as the appropriate number for each night-watch point (e.g., five strikes of the gong for a fifth *jeom*).

During the Japanese invasion of Korea in 1592, this clepsydra was destroyed, but details about how this ingenious combination of balls and levers operated the mechanisms for announcing time are in the above-mentioned literature and in Joseph Needham's monograph *The Hall of Heavenly Records* (1986: 27–30). Figure 3 is a reconstruction of the *Jagyeongnu* made by the present author and his associates at the National Palace Museum of Korea, and details are in the author's monograph *Jang Yeong-Shil and Jagyeongnu*: *Reconstruction of Time Measuring History of Choseon Period* (2002).

In 1536, by order of King Jungjong (r. 1506–1544), the horologist Park Se-Ryong made a new striking clepsydra for the Changgyeong Palace in Seoul. Similar to the water clock made at the time of King Sejong, the new clepsydra had however an independent time calibrator. Although it had broken down at the time of the Japanese invasion, parts of it that included the major vessels for supplying water survived and were restored, and under King Gwanghae the time-announcing mechanisms were back to work in 1608 in the rebuilt clock house near the former place. After the Jesuit-designed *Shixianli* was adopted late in the seventeenth century, the clock operated on a system of 12 double-hours and 96 intervals; this new system also replaced that of the 12 double-hours and 100 intervals (each interval corresponding to 14 min, 24 s), both of which comprised one full day according to the *Datongli*, with the 24 h and 15-m quarter hours of the Western tradition. The clepsydra operated automatic sounding devices to announce the time, but this came to be done by manually striking a bell, drum, and gong after the building with the clock fell into disrepair in the early nineteenth century. Until the end of the traditional curfew system late in the nineteenth century, this clepsydra had operated as a timekeeper for roughly 350 years. In 1938, what remained of it was moved to the Deoksu Palace in Seoul, and in 1985 the parts were collectively entered as "National Treasure Number 229" (Fig. 4).

The *Heumgyeonggaknu* (Water Clock with the Pavilion of Prudence and Respect)

In 1438, Jang Yeong-Shil made the *Heumgyeonggaknu* (欽敬閣漏), another striking clepsydra. Besides announcing hours automatically by mechanisms known as jade-clepsydra mechanical wheels that were rotated by trickling water, it also displayed celestial movements. The armillary part of this machine had a golden

Time in Korea. Fig. 3 The *Jagyeongnu* made by the present author (NAM M-H) and his associates in 2005 restored at the National Palace Museum of Korea.

Time in Korea. Fig. 4 Relics of the self-striking clepsydra made in 1536 after that commissioned under King Sejong in the 1430s (Fig. 2). Shown here, from the *upper left*, are the reservoir for supplying water, compensator, and regulator vessels, and the two measuring vessels on the floor bed stand two meters high. The parts which announced time have been dismantled. (Korean National Treasure Number 229, the *Jagyeongnu* of the *Borugak*, preserved at the Deoksu Palace since 1938).

model of the sun which moved daily along the peaks of a mountain that was surrounded by five-colored clouds. The clepsydra part had three mechanisms for announcing time: (1) a set of four female jacks in the form of goddesses standing at the four cardinal directions on the mountain peaks and holding wooden mallets to strike at the double-hours, (2) similar to the clepsydra in the previous section, a bell was struck by a jack at the beginning and middle of the double-hours, a drum for the night-watches, and a gong for the night-watch points; and (3) at the base of the mountain, 12 gods represented the animals for the double-hours (rat, ox, tiger, etc.), and each would descend into a hole during its time period as a jack came out of a slot with a tablet bearing the double-hour time. Besides these mechanisms for announcing time, an inclined vessel on another platform automatically was filled by and emptied water which overflowed from the clepsydra. Because the mountain was surrounded by rural scenes from the four seasons and wooden carvings of men, birds, and plants that express labor and difficulties in agriculture, this timekeeper emphasizes the importance of measuring time and making calendars in Neo-Confucian ideology. Ideas from traditional Chinese armillary clocks, such as that of Su Sung in the *Xinyixiangfayao*, and Arabian water clocks were combined to make this automatic armillary clock, which Korean kings had reproduced several times as a symbol of the political ideology of the state. Fig. 5 is an artist's rendition of what this interesting clock looked like.

The *Honcheoneui* (Instrument About the Entire Heavens) and *Jamyeongjong* (Self-Ringing Bell)

In 1669 King Hyeonjong ordered the jade clepsydra system of the *Heumgyeonggaknu* from the time of King Sejong to be rebuilt, and this led to two new armillary clocks being made. One was a relatively traditional water-operated instrument by Lee Min-Chul, which had driving and time-announcing mechanisms like those in the striking clepsydra, jade clepsydra, and King Sejong's armillary sphere from the 1430s. It was a late survivor of the ancient Sino-Korean tradition of water-operated clocks that represented the universe and were operated in completely traditional ways (Needham et al. 1986: 110). Except for not having a compact weight drive, Lee's armillary clock was quite similar to the other made at this time.

Based on a Chinese clock which had been presented to King Injo in the 1630s by a Western missionary stationed in Beijing, Song I-Yeong produced a Western-style, weight-driven apparatus called the *Honcheoneui* (渾天儀) and a self-sounding clock known as, after the Chinese name, the *Jamyeongjong* (自鳴鐘). Song's clock combined Sino-Arabian wheels with jacks, a traditional armillary sphere that represented a rotating-earth system, and a weight-driven clockwork mechanism that had reached Korea via Japan. While making repairs in 1687, Lee Jin replaced a telescopic mechanism with a terrestrial globe and a clockwork mechanism, which was converted into state-of-the-art technology that Christian Huygens had developed in 1672 in Paris. Although it is not known for sure, Huygens' clock probably had been imported from Japan during the reign of King Sukjong (1674–1720). Lee's clock came to be known in the West through studies by Carl Rufus in the 1930s, and in the 1970s Joseph Needham and others did a detailed study on Lee's clock and armillary sphere (Needham et al. 1986: 115–152). From the eighteenth century onwards, royal clock-makers in Korea made weight drives of the sort used by Song in his clock, and parts of Song's clock itself have survived (Fig. 6). They were donated by Kim Seong-Su (a former Vice President of the Republic of Korea) in the 1950s to the Korea University Museum, where they have been restored and, in 1985, became "National Treasure Number 230."

Time in Korea. Fig. 5 Artist's impression of the *Heumgyeonggaknu*, showing the model of the golden sun revolving around the mountain. Standing on the multicolored cloud and facing each of the cardinal directions are four jade girls who strike golden bells with wooden mallets to announce the double-hours; as they do this, the four tutelary spirits (Black Warrior, Blue Dragon, Red Bird, and White Tiger) also face in their respective cardinal directions. At the southern foot of the mountain a jack and three warriors strike the double-hours, night-watches, and night-watch points with their instruments in a similar fashion as that for the *Jagyeongnu* (Fig. 3). At ground level are the 12 animals of the Chinese zodiac which correspond to the double-hours. At midnight (11 p.m. to 1 a.m.), for example, the hole behind the Rat opens, an hour god with a tablet announcing the time comes out, and the Rat stands still. South of the mountain, a man with a vase pours water into an inclined vessel which lies on its side when empty, stands upright when half full with water, and falls over when it has been completely filled. The rural scenery, from the four seasons, depicts various types of labor performed around the mountain by peasants. The design for this impression was made by Prof. Hahn Young-Ho, the author of "Astronomical Instruments in Korea."

Time in Korea. Fig. 6 What remains of Song I-Yeong's armillary clock. At the left is the armillary sphere, in the center a striking train and weights to strike the clock and bell, and at the right a time-announcer, gong train, and striking-release mechanism. The measurements are 120 (length) × 98 (height) × 52 (breadth) cm; courtesy of the Korea University Museum.

Time in Maya Culture

Henry J. Rutz

Classic Maya culture developed from the second to the tenth centuries AD and expanded to encompass all of the Yucatan peninsula including the modern countries of Guatemala, Belize, and portions of El Salvador and Honduras. Unlike the Aztec and Inca states, which developed highly centralized imperial cities, the Maya developed city-states. Elites intermarried, formed alliances, and shared a complex calendar.

While all empires have created multiple times to connect village community to imperial center, and earthly city to heavenly city, the historian Nancy Farriss has noted that "from their earliest recorded history, the Maya displayed an intense interest, bordering on obsession, in measuring and recording the passage of time." Anthony Aveni (1989) observes, "The first bits of information in any Maya inscription are about time. What sets the Maya apart is not the number of time units they devised, or even their complexity; rather, it is their preoccupation with 'commensurateness' – perfecting the way time cycles interlock or fit together." Over a millennium since the climax of classic Maya culture and five centuries after the Spanish conquest, Maya continue to practice their own time, albeit in modified form.

The Maya had a military state with a literate elite. Our information about their multiplicity of time comes from their own writings. Although Maya hieroglyphic writing died out, Maya elites were able to maintain an unbroken continuity from their system of writing to that of Spanish script. The language survived in many colonial documents from the sixteenth century on. Today two million people still speak more than a dozen dialects of the Mayan language.

The Maya calendar is the centerpiece of Maya concepts of time and its measurement. It consists of the conjunction of cycles upon cycles of time of long duration. Like the Gregorian calendar we use today, the Maya calendrical system was the culmination of many different cultural influences over millennia. The conception of time underlying the calendar is one of movement. Maya referred to time as a flow and perceived a need for both human and divine intervention in maintaining it. In Maya culture, people actively construct their sense of time, a point to which I return below with reference to daykeepers and their role in the regulation of everyday life.

The flow of time is incorporated into an all-encompassing cyclical pattern. Conjunction of complex forces mark cycles of different duration. The Body Count of twenty is the basic unit of Mesoamerican counting (ten fingers plus ten toes). The classic Maya week consists of twenty named days, each propitious or unpropitious for particular activities. The twenty-day week was combined with a separate series of thirteen numbered days to create the Sacred Round of 260 days. Later, a Solar Year was calculated consisting of eighteen twenty-day months plus five days. The solar year was articulated with the sacred round to create the Calendar Round of 52 years. The Maya also developed a Katun Round consisting of thirteen twenty-year periods for a duration of 260 years. Despite an obsession with commensurability that led Maya priests into astronomy and cosmology, not all the cycles were articulated with each other. Late in the political development of pre-Conquest Maya culture a Long Count of five millennia appeared. Today, Maya daykeepers reckon the rhythms of everyday life by interpreting the solar and divinatory calendars.

Although Maya viewed time as a flow, it is also time with a content. Each day was named after a god and was qualitatively different from every other. Furthermore, the content of time was regulated by a conjunction of forces. Those days that were at the conjunction of different cycles had a greater force than other days. The larger the cycle, the greater the number of forces intermeshing from different subcycles. The Maya depicted time on stone carvings or drawings as weighty numbers carried by gods.

Intermeshing cycles produce a succession of days whose events are linear, unique, and irreversible. But this apparent linearity is an illusion because "no matter how unique a pattern of events may seem, no matter how long the sequence, it will eventually be repeated, when the governing forces of all the cycles of different dimensions coincide in one huge cycle" (Farriss 1987).

Why these cycles? Maya observers were not disinterested observers of the heavens. Cosmic time links common people to rulers through the latters' association with the cosmos. The construction of cycles appears to be associated with the problems of legitimacy and political order. Returning to the same point, at least logically, is the ultimate form of reassurance against the reality of present conflict, chaos, and events that seem to be getting out of hand. As Farris says, "Accounts of the famine in the books of Chilam Balam show less concern with starvation than with the fact that people flee into the forest to eat roots and other wild food… In other words, people cease to live in their customary fashion... Political conflicts are condemned because they disrupt the established hierarchy, and upstarts and invaders are vilified for breaking the rules." Encompassing cycles provide a cosmic charter of legitimacy of a magnitude rarely conceived in the history of cultures.

The predictable order of cosmic time reckoning, unfortunately, depended upon human agency for execution. "It is unlikely that the Maya priests claimed to comprehend all the possible combinations of divine forces governing the subordinate movements of so immense a projection." Past, present, and future are written in a single bound book, but one that admits of many interpretations.

How did the dual conception of cyclical and linear time work out in practice? Both serve as charters for sociopolitical arrangements, but each in its own way. It appears that classic Maya elites confined linear concepts to relatively short term duration out of choice (they possessed the literary or numeracy skills to create historical memory). Among the most important were the katun round and the chronicles written by members of Maya royal lineages during the colonial period.

The katun round, consisting of a recurring wheel (time is often depicted as a wheel in Maya stone carvings) of thirteen twenty-year counts for a total of 260 years, recorded the important events of royal lineages. The interesting aspect of the katun round is its duality of both history and prophecy. Each year has its own name together with characteristic and appropriate events. The future is contained in the past, and therefore Maya could look to a record of the past as a guide to the future. The same pattern of events for a given year recurs every 260 years. In Chilam Balam texts, logically associated events always occur in the same katun regardless of their inner chronology. It is as if all invasions were taken out of their chronological sequence and placed in their cosmological reckoning. Even references to the most recent "descent" – the Spanish conquest – are woven into the pre-Hispanic mix.

In addition to general reference to recurrent patterns of events there is also remarkable specificity to katun accounts, which name specific people and places, details of real famines, invasions, migrations, exiles, and rivalries. The specific content is about unique and irreversible events. The chronicles appeal to secular principles as the basis for claims to legitimacy, for example descent from previous rulers. The twenty-year katun cycle may have served as a calendar for rotation and succession of ruling families in post-Classic Maya. In contrast, books of Chilam Balam that record cycles stress quality of time – joy, misery, abundance, and the place of cosmic and divine forces in their production. The sacred personages of the calendar rounds merge with their worldly actors.

There is some evidence that the Maya calendar evolved toward a dominance of linear over cyclical concepts of time during the post-Classic period as a consequence of the emergence of dynastic rule and its dominance over the more autonomous city-states of the Classic period. Unlike the calendrical system of cycles and their conjunction, which have no particular starting date, the Long Count system measured elapsed time from a starting point that would extend to a time horizon of 5,200 years before its repetition. This new calendar represented a radical shift from the dominance of cyclical time over linear time because its duration was long enough to encompass the ancient Calendar Round of 52 years and more recent katun round of 260 years. Specific details of human affairs accompany the Long Count and a new emphasis on written genealogies supports the hypothesis of a shift to dynastic rule.

If it is unlikely that ancient Maya priests could comprehend all the divine forces converging on particular days or years, how much less likely is it that ordinary people could use the Maya calendar to take control of their own lives? A partial answer appears in the guise of Maya daykeepers. Barbara Tedlock (1982) has given us an account of time among Quiche Maya in the town of Momostenango, highland Guatemala. There daykeepers use an integrated solar year and the sacred round to divine whether a day is good or bad for particular activities. The appropriate determination of qualities to a day are specific to a particular client and require active participation on the part of both daykeeper and client.

Daykeepers use a set of practices referred to as "the speaking of the day" and "the speaking of the blood." The qualities of the twenty name days are based on stipulated but vague mnemonic phrases that require interpretation by the daykeeper. Other factors specific to a client enter the picture, including the client's character, part of which is determined by the particular day on which a child is born.

The daykeeper achieves understanding by sortilege or divination by lots. She or he mixes, grabs, and arranges piles of seeds and crystals into a pattern, all the while counting and interpreting the 260 days of the divinatory calendar. The blood is considered to be an active substance that sends signals or "speaks" to the daykeeper. The rapport between daykeeper and client is also thought to affect the divining of a day as good or bad for a particular activity. Clients come to a chosen daykeeper with a specific question about such probable occurrences as illness, accident, land disputes, building houses, inheritance, business transactions, travel, marriage, adultery, quarrels, dreams, births, deaths, and interpretation of omens. The divination is performed for the specific question posed by a particular client.

Time in Native North America

Michael Zeilik

The Pueblo people of the United States Southwest believe in a cosmos in which nature functions with the active cooperation of humankind. The proper ceremonies must be carried out at the proper time so that the cosmic order is sustained. Traditional doctrines held that there were correct times for planting, harvesting, hunting, ceremonies, and many other activities – all embedded in a sense of sacred time. The right times for these crucial undertakings are established by astronomical observations to regulate the ritual calendar. The cycles of the sun and moon set the rhythm of Pueblo time.

Sacred time is ordered with different levels of periodicities. The longest appears to be the seasonal year. We have very little evidence – almost all ambiguous – that the Pueblos kept long counts or tallies greater than a year. Until the twentieth century, with the intrusion of European concepts of time, no indigenous interest appears in tracking cycles over many years. The yearly cycle is all important; after its end, a new, equally unique one begins. Within the seasonal span, ceremonies occur in a fixed sequence, in which the completion of one sets the stage for the next. The observation of the phases of the moon marked the subdivision of the year. Within a night, the start and end of some ceremonies are flagged by observations of the positions of certain stars, especially the Pleiades as seen from the smokehole of a *kiva*, a structure used as a ceremonial room.

The shortest unit of time reckoned by the Pueblos is the day, which begins with sunrise. The day has vague subdivisions into loose "hours," most of which are noted near sunrise and sunset by the color of the sky. About the only time of day noticed with any care is that of noon, which is typically observed by the length and directions of shadows cast by the edges of walls, buildings, trees, or sticks embedded in the ground.

A religious official has the responsibility and the authority to set the ceremonial dates within the ritual cycle. The crucial task entrusted to this official is the forecasting of the correct date by making anticipatory astronomical observations. The dates are announced ahead of time so that the people of the pueblo can enter into proper preparations (abstinence, practicing songs and dances, preparing costumes and special foods) so that the ceremony may be carried out with "good heart" and be effective.

Typically, one official – the Sun Priest – performs the sun-watching for the seasonal cycle, which includes the planting schedule. He does so from a sun-watching station that is usually located within or close to the pueblo. From this fixed spot, the Sun Priest keeps a horizon calendar (usually at sunrise using an observation of the first gleam) against the horizon profile. He knows from experience that when the sun rises (or sets) against a certain horizon feature, so many days will elapse until, say, the winter solstice. Then he uses tally markers (such as a knotted cord) to count down to that day, with an announcement made to the pueblo a few days ahead of the celebratory date. This anticipatory technique allows the Sun Priests to forecast the dates of the solstices to within 1 day of the astronomically correct date when the sun appears to “stand still” at its sunrise point. The observations made about two weeks in advance catch the sun when the angular speed of its sunrise position is large enough to be discerned by the naked eye on a day-to-day basis. Hence, this practice neatly solves both a cultural and astronomical problem.

Moon watching regulates timings between the seasonal and daily ones. The official responsible for tracking the phases of the moon generally is not the one who watches the sun. A Pueblo month begins with the observation of the first visible crescent and ends with the last. The days of invisibility are not typically counted. Calendar sticks were used to tally the observed months.

The months of the year are counted starting with the first before the winter solstice ceremony. The first five (or six) are named (usually after seasonal characteristics); then these names are repeated for the next five or six. The lunar calendar needs to be synchronized with the solar one, which is accomplished by adding an intercalary month (which can be as short as four days!) at the end of the regular count or after the winter solstice.

Although Pueblo people feared eclipses of the sun and the moon, they had no way to forecast them. In part, this lack was related to their disinterest in keeping counts longer than a year. We also find no evidence for knowledge of the 18.6-year lunar standstill cycle, even though the moon certainly was observed rising and setting. The historic Pueblo culture did not seem to attach any importance to this astronomical cycle so it was ignored.

The ancestors of the Pueblo people were the Anasazi, who inhabited what is now the greater Four Corners area of the US Southwest as a settled agricultural people. During the height of the classic Anasazi culture some thousand years ago, two major sites developed: Mesa Verde and Chaco Canyon. A regional center developed in the San Juan basin around Chaco by AD 1110; as many as 70 communities dispersed among 50,000 km^2 were integrated into a socioeconomic and ritual network connected by a road system.

How did the Anasazi regulate and track time? By using ethnographic analogy, we can generate hypotheses about Anasazi astronomy that can be checked against the archaeological record. The most important cycle of time for the Pueblos is the seasonal year, which is typically tracked by horizon calendars. Anticipatory observations are made about two weeks prior to the solstices. Of the Anasazi sites field-tested so far, about one-third have reasonable horizon calendars.

A secondary strategy employed in the historic Pueblos used a special opening or window to cast sunlight on an opposing wall. The best Anasazi analogs to this type of interior observational technique occur in Hovenweep National Monument at Hovenweep Castle, Unit Type House, and the Cajon Group ruins with small portals. Hovenweep Castle and Cajon ruins work at sunset, Unit Type House just after sunrise. In all three locations, the horizon profiles lack the relief for tracking horizon calendars. For all, the throw from the shadow-casting edges is large enough so that the linear motion on the receiving wall is typically a few centimeters per day from the sun’s angular positional change at sunrise or sunset. The evidence so far hints that interior light and shadow casting played an important role in Anasazi seasonal time keeping.

Exterior light and shadow casting was not an important time keeping technique in historic times. It may have been used more extensively by the Anasazi though perhaps more for ritual than calendric purposes. The three-slab site atop Fajada Butte in Chaco Canyon has been much investigated; so has the Holly site at Hovenweep. In both these cases, light and shadow cast by rock edges fall onto panels of rock art at important seasonal times of the year. These exterior sites generally suffer from a lack of resolving power for reliable calendric forecasting, if we apply the standard achieved by the historic Pueblo Sun Priests – within a day of the astronomical date of the solstices. Hence, these sites may have served as sun shrines for offerings to the sun with a light and shadow display that served a commemorative rather than a calendric function.

We have no firm evidence so far of prehistoric monthly lunar calendars, though such a count of days would have a unique sequence tied to the phases of the moon. No rock art in the Anasazi region has been demonstrated to display the measure of a lunar tally.

Occasional claims have been made that the Anasazi noted the 18.6-year standstill cycle of the moon. The hypothesis of attention to this interval has been put forth for the Fajada three-slab site and for Chimney Rock Archaeological Area in Colorado (among a few others). The most convincing case is made for Chimney Rock, where the natural rock pillars (after which the site is named) act as a natural foresight when viewed from the site of Chimney Rock Pueblo, a Chacoan outlier, which was occupied from about 1075 to 1175.

The orientation allows a spectacular anticipation and forecasting of the major lunar standstills. For about two and a half years prior to the standstill, the moon rises between the pillars for 1 or 2 days per month. Starting after the summer solstice, the moon appears as a waxing crescent. Finally, near the winter solstice, the full moon stands between the pillars at around sunset. Hence, the priest in charge of the moon watching could forecast the date of the standstill and also the full moon nearest the winter solstice – an important conjunction among the historic Pueblos.

Time: Non-Western Views

C. K. Raju

Time is a difficult notion, since time beliefs underlie a variety of seemingly unrelated areas like (1) scientific theory, (2) philosophy of science, (3) religious beliefs about the nature of life after death, and consequently about the soul (4) human values and the (5) nature of language and logic, etc. These various time beliefs may or may not cohere with each other.

The structure of the English language, unlike that of the Hopi (American Indian) language, presupposes that time and space are entirely separate entities, and this makes it hard to understand the intermingling of time and space in relativity theory. As another example, the Buddhist Dhamma (ethics, way of life) is closely connected to the Buddha's concept of *paticca samuppāda*, or conditioned coorigination, the proper understanding of which requires the concept of a structured time, in which the instants of time are not featureless geometrical points. This notion of a structured time is incompatible with the two-valued logic assumed in Western philosophical discourse. In Buddhist thought, seemingly contradictory properties may coexist, as in the quantum-mechanical Schrödinger's cat who is both alive and dead at a single instant of time. Thus, the attempt to understand one aspect of a non-Western view of time, such as the Buddhist notion of *paticca samuppāda*, can force us to reconsider fundamental issues like the logic underlying Western thought.

Any attempt to provide an account of non-Western views of time is a very difficult enterprise, involving complex relationships across widely different areas of knowledge, and potential conflicts at a deep level with stock metaphysical assumptions underlying even the language and logic of Western discourse. This entire gamut of relationships between different pictures of time has been covered in the books *Time: Towards a Consistent Theory*, and *The Eleven Pictures of Time*, by this author, but it is too complex to be covered in the span of this one article, which will focus on only a single aspect related to the Western stereotype of non-Western beliefs about time.

The Western stereotype: "linear" time versus "cyclic" time

Non-Western views of time have typically been represented in Western literature and scholarship by contrasting Western "linear" time with non-Western "cyclic" time. Linear time is endowed with a variety of positive properties: rationality, progress, free will, etc. while cyclic time is attached to a variety of negative properties: spirituality, stasis, fatalism.

The first step needed to understand non-Western views of time is to get rid of this stereotype.

For example, the time beliefs underlying scientific theory are not the same as those underlying the philosophy of science, and the two do not cohere, but both can be classified as linear time. Thus, scientific theory is today presented in the form of differential equations, such as Newton's laws of motion, or the Hilbert-Einstein equations, or Schrödinger's equation. These equations fix the state of the cosmos at any time, once its initial state is known. However, all these equations involve the mathematical notion of a derivative with respect to time – for example, velocity, or the rate of change of position, is the time derivative of position, and acceleration is the rate of change of velocity or the time derivative of velocity. On the existing Western mathematical understanding of the calculus, these derivatives with respect to time force us to suppose that time is a continuum, which can be represented using real numbers. That is, current scientific theory necessarily presupposes that time is like the real line, or that time is "superlinear".

On the other hand, our reasons for believing in this or that scientific theory are (or ought to be) based on experiments, and this presupposes the belief that one can perform various experiments, the outcomes of which were not all determined beforehand, by the state of the cosmos at some moment in the remote past. That is, the philosophy of science presupposes a different belief about time: that the future of the cosmos is a consequence of human choices and actions, and not merely of its past state. One does not normally stop to think about such presuppositions because everyday human actions are premised on the same belief that human actions are powerless to change the past ("no use crying over spilt milk") but that they do bring about the future in some small way ("if I don't watch the milk it will boil over"). Thus, the philosophy of science subscribes to the belief in "mundane time".

These two types of time, superlinear and mundane, are both linear, but they are nevertheless incompatible and in conflict with each other. This conflict is a serious matter, for it pits scientific theory against the reasons for regarding it as valid. How is this conflict to be resolved? This would naturally seem to require a correction in one or the other picture of time.

However, the slightest alteration in one's time beliefs can have profound consequences. Changing the picture of time in scientific theory fundamentally changes the type of equations used to formulate the models of physics. On the other hand, if one were to believe that the future of the cosmos has already been rigidly determined by its past, there would be little point to human action, and life itself would become meaningless, as in the theory of the Stoics, or in Nietzsche's thought.

Since there are different notions of linear time, such as superlinear time and mundane time, which do not cohere with each other, so the very category of linear time is not meaningful. The category of cyclic time is not meaningful for similar reasons.

On the other hand, there need not be any particular conflict between a locally superlinear time and a globally recurrent cosmos. If the cosmos is restricted to a finite region, like a gas in a box, and evolves deterministically – according to Newtonian mechanics, say – then the Poincaré recurrence theorem tells us that, with probability one every state of the cosmos must repeat to an arbitrary degree of precision, infinitely often. Recurrence would similarly take place even if the cosmos evolves probabilistically rather than deterministically, so long as the future state of the cosmos depends only on its present state, an assumption more precisely formulated in current mathematics as the Markovian assumption for the evolution of a stochastic process. These recurrence theorems assure us that a recurrent cosmos, instead of being in conflict with superlinear time, is a logical consequence of it, under some rather general conditions, such as finiteness. In the above situations of cosmic recurrence, it could be argued that time only seems superlinear because the time scale of cyclicity – the recurrence time – may be very large, just as the earth seems flat, although it is round, since it is very large. Thus, a linear picture of time, need not be in conflict with a cyclic picture of time.

This meaningless dichotomy of linear versus cyclic time has nevertheless been persistently used in the West to characterize non-Western thought about time. A non-Western historical perspective on the development of Western time beliefs is helpful in understanding the origins of this incorrect (but widespread) stereotype about time and its linkage to religious ideology.

Quasi-Cyclic Time and the Soul

Early notions of the soul (in India, for example) were based on the belief that the cosmos went through recurrent cycles, or, equivalently, that time was quasi-cyclic. It was believed that each cycle of the cosmos lasted for an enormous duration of time – billions of years – and that each cycle of the cosmos was approximately like the preceding one. Events repeated in approximately similar ways in successive cycles of the cosmos. Roughly the same people were reborn in successive cycles of the cosmos, and lived roughly the same lives, and died roughly the same death repeatedly, across cosmic cycles. This perceived state of affairs was described by saying that each individual has a soul, which persisted beyond death, and was repeatedly reborn (in successive cycles of the cosmos), until such time as it achieved deliverance.

The duration of a cycle of the cosmos is reckoned in the *Viṣṇu Purāṇa* as a day and night of Brahma, and amounted to 8.64 billion years. (An ordinary day and night amount to 86400 seconds.)

This notion of a soul which persists across vast cosmic cycles is not a metaphysical notion, since it presupposes a cosmic state of affairs, which may or may not be the case. That is, this notion of the soul is a physical notion, since it involves a refutable or falsifiable picture of the cosmos.

It is a common error to confound quasi-cyclic time with eternal recurrence. It was not generally believed that these cosmic cycles were exact or eternal. The whole possibility of deliverance – *mokṣa*, *nirvāṇa* – was premised on the idea that these cycles were neither exact nor eternal. (However, the category of cyclic time encourages such an error by suggesting that various types of cyclic time are the same.)

In India, this was the traditional view of time and life after death held from before the time of the Buddha. The Lokāyata denied the belief in life after death as a fraud. An interesting feature of this denial is how Pāyāsi sought to establish the non-existence of the soul by performing some 37 experiments with dying men, and condemned felons. It is unlikely that such experiments were ever performed anywhere else.

The Buddhists did not deny this cosmic state of affairs. Indeed, popular stories like the *Jātaka* tales clearly accepted what was then the prevalent common belief about the world. What Buddhists denied was only the significance of cosmic recurrence, for they denied the existence of a soul or any continuity between two similar individuals across two cycles of the cosmos. In fact, they also denied that anything essential persisted between two similar individuals across even two instants of time: they maintained that the seed in the granary is a distinct entity from the seed in the ground, which is bloated. The seed in the granary cannot be the cause of a plant, because the seed in the granary remains a seed at the next instant. There is a similarity between the two seeds, and hence, due to the paucity of names, one gives the same name to both seeds. Therefore, in the Buddhist view it would not be proper to say that there is some essential sameness in an individual which persists from birth to death: in the Buddhist view, an individual exists (unchanged) only for a single instant.

This notion of quasi-cyclic time is incorporated in artistic or mythical representations, like the Wheel of Time, the Phoenix, or the Plumed Serpent of Central America, that are found from across the world, and certainly existed in Egypt. And, as Herodotus informs us, numerous ideas, customs, and religious beliefs were transmitted from the Egyptians to the early Greeks. Therefore, it is not surprising that a similar notion of the soul is found in the works of Plato, and was subsequently developed by the Alexandrian Neoplatonic philosophers.

Indeed, it is little known that this belief in quasi-cyclic time was the anchor of early Christianity, as enunciated by one of its greatest real (as opposed to mythical) teachers, Origen of Alexandria (3rd–4th century CE). This early Christian notion of cyclic time was remarkably similar to what is today known as the Hindu doctrine of *karma-samskāra*. According to this doctrine, the actions (*karma*) in one cycle determine the dispositions (*samskāra*) in the next cycle, and the objective of life is taken to be deliverance (*mokṣa*) from these repeated births and deaths.

Quasi-Cyclic Time, Immanence and Equity

Curiously, while cyclic time and *karma-samskāra* are today associated with casteism and inequity, in early Christianity, Origen argued in his *De Principis* that this notion demonstrated both equity and justice: equity, since God had created all souls equal, and justice, since souls were rewarded and punished in each cycle of the cosmos according to the merits or demerits they had earned from their good or bad actions in the preceding cycle. Origen's argument was not an isolated curiosity.

Thus, the notion of equity was related to immanence or the idea of divinity with in man, and hence the importance of deep introspection. The discipline of Yoga (union) is not a physical exercise, but a technique of meditation or introspection to bring about the union of ātman with Brahman, inside man, and thence lead to deliverance. Mathematics (geometry) was perceived by early Greeks to be a technique, exactly like Yoga, to achieve the same goal. Thus, in Plato's *Meno*, Socrates demonstrated the slave boy's prior knowledge of mathematics, in support of his theory that all learning was but reminiscence of the prior knowledge of the soul. Likewise, Proclus explained the etymology of mathematics (from *mathesiz* or learning) as the science of learning, or the science of the soul, since he thought mathematics related to eternal truths, and forced one into an introspective state, which then aroused the immortal soul and induced it to recollect its past knowledge, which it had forgotten since birth.

Immanence related to equity, since all souls were regarded as being part of one God. This relation is well brought out by the following story. Śankara was the founder of Advaita Vedanta, a philosophical system which asserts that ātman and Brahman are "not two" (but one). Śankara was returning from his bath in the river, when he was accosted by a *candāla* (outcaste). By force of habit, Sankara shrank back. After this the *candāla* taunted him, asking how Śankara could maintain this distinction when both had an ātman one with Brahman, hence equal to each other. Realizing his mistake, Śankara prostrated himself before the *candāla*. Almost every theorem of Euclid's *Elements* is about equality (not congruence), and this was unambiguously related to political equality as in the mystery story that there is "no royal road to geometry". The connection to political equality was made quite explicit in subsequent Islamic rational theology (*aql-i-kalam*). The lasting impact this had on Islam is obvious from the fact that religious-minded emperors like Aurangazeb, even though they ruled vast empires, worked to earn their livelihood – something observed with great astonishment by Europeans who had never known any ruler of this sort. In the early Christian version, Origen argued that not only were all souls created equal, but they would again become equal at the end of time, since all would ultimately achieve deliverance, as in *karma-samskāra*, and there would be a time when God would be all *in* all.

This notion of an immanent God was also essentially a celebration of the creativity of life. Man creates the future cosmos (at least a tiny part of it), just because God is in Man (and also other living creatures). All people are equal, just because all people are equally parts of one God. Since these notions involved a celebration of creativity, they were associated with what have been called "fertility cults", such as the worship of Bacchus or Dionysius. In India, various Tantric schools have many similar practices. The relation of equity to creativity is well brought out by the Lokayata festival, today known as Holi. On the one hand it is related to the harvest and is thus a celebration of creativity. The custom of throwing color on people was intended to erase the social distinctions that are displayed by means of clothes, and in fact to erase all individuality. The custom of taking bhang (marijuana) was intended to further creativity by heightening sexual passion.

Inequity as the Basis of Linear Time

After Constantine, this belief in the equity of all souls stood in the way of the political goals of the church, which now viewed the world from the imperial perspective of the Roman state: if all souls would be saved anyway what was the advantage to be gained by turning Christian? If God was within man, where was the need to fear God, and be obedient to the priest? Hence, theologians like Augustine proposed to erase equity and erect a transcendent God who would judge people and establish a simplistic moral division between good (Christians) and bad (non-Christians). In the revised picture proposed by state Christianity, all souls were NOT equal, so not all souls were eventually saved. Instead God established a permanent inequity in the world, sending some souls (those of good Christians) to heaven (forever), and other souls (non-Christians) to hell, as described in gory detail by Dante, for example. Reincarnation was accordingly changed to resurrection – life after death, just once.

Because the earlier notion of soul depended upon a view of life after death deriving from the belief in quasi-cyclic time, time beliefs were also compelled to change with this changed notion of the soul and of life after death. Time beliefs changed from qausi-cyclic time to linear apocalyptic time: the world, as conceived by Augustine, began a few thousand years ago, and would soon come to an end. The notion of the soul became metaphysical.

Thus, the question of linear versus cyclic time is an issue that lies at the very foundation of Christianity (and the related historical notion of the West, as in Toynbee's classification, used more recently by Huntington). Rejection of that view of (apocalyptic) linear time would amount to a denial of the entire religious ideology of state Christianity, as it is understood today. This explains the significance and importance to the West of the competitive stereotype of linear time versus cyclic, directed as much against early Christianity as it is directed against non-Western views of time.

The Western Misrepresentation of Quasi-Cyclic Time as Supercyclic

Augustine argued against Origen's view, by misrepresenting "cyclic" time as eternal recurrence or a state of affairs where deliverance was available to none. He asserted that the cosmos would recur exactly, so that even Jesus Christ would be repeatedly reborn and repeatedly crucified, so that no one could be saved. "Heaven forbid that we believe this, for Christ having died once for our sins, rising again, dies no more". Augustine then rejected this state of affairs on the grounds of "fatalism" (which, he quibbled, was different from "determinism").

This was certainly a misrepresentation of non-Western views, where deliverance from the cycle of birth-death-rebirth was not only held to be possible, it was regarded as the ultimate aim of life. This was also a misrepresentation of Origen who explicitly stated:

> And now I do not understand by what proofs they can maintain their position, who assert that worlds sometimes come into existence which are…in all respects equal. For…then it will come to pass that Adam and Eve will do the same things which they did before: there will be a second time the same deluge…. So therefore it seems to me…that a diversity of worlds may exist with changes of no unimportant kind…in that age [world] which preceded this, Christ did not suffer…. (*De Principis*, Book II, chapter III.4-5)

Augustine's misrepresentation of "cyclic" time may be presented thus: time was thought to be quasi-cyclic, whether in *karma-samskāra* or in Origen's teachings; however, Augustine misrepresented quasi-cyclic time as supercyclic time – a situation (of "eternal and exact recurrence") where no change is possible in the cosmos, which repeats mindlessly like a stuck record (this "repetition" being in some implicitly assumed notion of increasing time, external to the cosmos, perhaps in the mind of God). Most Western thinkers have fallen into the same Augustinian trap of confounding "cyclic" time with "eternal recurrence" because they lacked even the words required to make a distinction between different varieties of cyclic time.

Therefore, Augustine's misrepresentation of Origen's notion of "cyclic" time has confused a long line of Western thinkers like Nietzsche, who founded an entire philosophy on this misunderstanding of "cyclic" time as supercyclic time or "eternal recurrence of the same". The same confusion between quasi-cyclic time and eternal recurrence can be found in T. S. Eliot, or in Mircea Eliade's *The Myth of the Eternal Return*.

Starting from Newton, the same confusion about "cyclic" time persists in scientific theory to this day. For example, Stephen Hawking and G. F. R. Ellis, in their *Large Scale Structure of Spacetime,* argue against closed time loops (a third variety of partially cyclic time, distinct from quasi-cyclic time and super-cyclic time) repeating exactly Augustine's mistaken arguments. The first step of the argument confounds any sort of cyclicity with eternal recurrence, and the second step rejects eternal recurrence on grounds of fatalism. More recently, arguments in the scientific literature related to the Grandfather paradox of time travel, which involves a loop in time, have again endlessly repeated Augustine's wrong arguments. The confusion between quasi-cyclic time and eternal recurrence seems to reverberate eternally in Western thought: "cyclic" time represents "eternal recurrence" hence fatalism, and should be rejected. On the contrary, as this author has pointed out, such closed loops in time, being causally inexplicable from the past, are the way to have spontaneity, or creativity, within the frame of current physical theory.

Thus, the Western stereotype of non-Western views of time involves involves a very deep-seated and long-standing confusion about the nature of time within Western thought, starting from Augustine and stretching down to people like Newton, Einstein, and Hawking.

There are a few other aspects of non-Western views of time that deserve at least a brief mention.

Discrete Versus Continuous Time

First, consider the issue of discrete versus continuous time. The belief that time is a continuum is forced in present-day physics, as we have seen, only by the Western understanding of the calculus, based on an idealistic understanding of mathematics. However, the calculus that developed in India incorporated a different understanding of mathematics, that could be called a realistic understanding. The difference between the two may be explained with reference to the Buddhist denial of the existence of the soul. The Buddhists (especially followers of Nāgārjuna's *śūnyavāda*) maintain that between two instants of time, an individual changes, and there is nothing "essential" in the individual that remains the same. In common parlance, and for practical purposes, we neglect or zero the differences as inconsequential, or non-representable, due to a paucity of names.

Let us now apply this understanding to a number like π, which denotes the ratio of the circumference of a circle to its diameter. No matter how we try to express this number, it cannot be specified – that would require a supertask. In idealistic (formal) mathematics, it is asserted that there really is such a number, although any actual representation of it will always only be approximate or erroneous. In realistic mathematics it would be asserted that calculations can only be done with an actual representation and not an idealized one. There is a paucity of names, and therefore we use a representation appropriate for a given practical purpose, zeroing certain things treated as non-representable. The subtle difference between the two positions is brought out very clearly in the representation of such numbers on a computer; the actual numbers (floating point numbers) do not follow the same rules or "laws", such as the associative law for addition that the ideal "real" numbers are supposed to obey.

This leads to a fundamentally different understanding of "infinitesimals" (as non-representable quantities discarded in a calculation), which presented such a problem for Newton and Leibniz. However, all practical conclusions drawn from the calculus use realistic mathematics and computation, rather than idealistic mathematics. Therefore, the idealistic point of view, which forces time to be a continuum in physics, involves the superposition of "extra baggage" from Western metaphysics, and there is no real need to believe that: time may well be regarded as discrete or atomic, provided one does the calculus with a different philosophy of mathematics. The point here is not to argue that time is, in fact, discrete, but rather that the discreteness or continuity of time should not be fixed purely from mathematical and metaphysical considerations, since these metaphysical considerations could be fundamentally different in the non-West.

Atomically Structured Time and Quasi Truth-Functional Logic

The second question concerns the link between time beliefs and logic. Time may be related to logic through Wittgenstein's notion of logical worlds: the state of the physical world at an instant of time can be specified by specifying all the statements that are true at that instant of time. In the West it has been believed that if A is true at an instant of time, then its negation $\sim$A cannot be true at that very instant. Certainly there are schools of thought in the non-West which also subscribe to this belief, but it is not universal. Buddhist and Jaina logics permit both A and $\sim$A to be true at an instant of time. This involves the concept of an atomically structured time. The classical way to explain this would be to think of an instant of time as a microcosm. A modern explanation for this state of affairs can be provided using microphysical loops in time.

Imagine that one has a time machine, and that one puts Schrödinger's cat (now dead) on board the time machine and sends it back to the time of Schrödinger. The events here described from a future perspective would actually have been observed by Schrödinger somewhat differently: for Schrödinger, the "observed" sequence of events would have been that time spontaneously and inexplicably split into two streams (both part of this world), in one of which the cat is alive, and in the other it is dead. (At the microphysical level, one can actually "see" a somewhat analogous phenomenon of a photon or a particle of light splitting into an electron-positron pair, which may later recombine to produce back a photon. The positron has exactly the properties of an electron travelling back in time, so the process can also be described as an electron executing a closed circuit in time.) These two streams of time, witnessed (or rather inferred) by Schrödinger, are NOT "parallel" worlds, for the two worlds do meet, and the two cats would coalesce back into a single cat at the time we put the cat into the time machine.

In place of imaginary time machines, one can construct a more realistic desktop model involving parallel computing, although understanding this requires a little more technical knowledge. In parallel computing, a single process executing on parallel processors may be in multiple states at a "single instant" of time. Needless to say, "parallel" is a bit of a misnomer, since it is an essential feature of parallel computing that the processors (logical worlds, in the Wittgensteinian sense) and processes communicate with each other, and that they branch and collapse. Time, so to say, acquires a structure, and it is necessary to take into account this structure to understand the semantics of formal parallel computing languages.

Microphysical closed time loops enable us to understand how an atom of time can nevertheless have a structure, in the sense that multiple logical worlds are attached to a single instant of time. This structure is manifested not by further subdivision of the atomic instant, but by a change of logic. In such a situation of an atomically structured time, it is perfectly possible to have both A and not-A valid at a single instant of time that cannot be further decomposed.

This notion of an atomically structured time or a structured instant is the basic unit of reality in Buddhism. It leads to the alternative notion of "causality" in Buddhism, called *paticca samuppāda*, or "conditioned co-origination". The present is not the cause of the future, but the future cooriginates, conditioned by the past. *Paticca samuppāda* is identified by the Buddha as the key to his Dhamma. Thus, the use of a logic of four alternatives in Buddhism is not incidental to Buddhism but is integrally linked to its worldview, for it is only through an understanding of the causes of *dukha* that one can remove it.

Ontically Broken Time

The common terminology of the laws of physics – for example, Newton's laws of motion – is related to the theological idea that creation was a one-time process and that subsequent states of the cosmos were controlled by God using laws. This idea of a clockwork cosmos is denied in many non-Western systems of thought. Al-Ghazālī, argued from a different perspective, where the world is continuously created by God. In this situation, any causal connection becomes a restraint on the powers of God; al-Ghazālī denied the existence of causal connections. He conceded that there are observed regularities in the cosmos, but he explained them as arising from force of habit. God habitually creates smoke with fire; he is not obliged to do so. Of course, one does not know on what time scale God changes habits, but it could be imagined that the cosmos is such that not only would physical theories change, but physics itself would change, over a time scale of, say, a thousand years.

More to the point, this helps us to see the historical evolution of the idea of the laws of God. Thus, al-Ghazālī was speaking about an immanent God, the apparent restrictions on whose powers were all too obvious. When this was taken over in the West, as by John Scotus Duns, it created a problem, because it was supposed (at least by the opponents of this point of view) that this description concerned a transcendent God. Under those circumstances, God would become a terrible tyrant, since one would never know what to expect next. Accordingly, God's intervention was toned down, and his role limited to instituting laws. This led eventually to superlinear time.

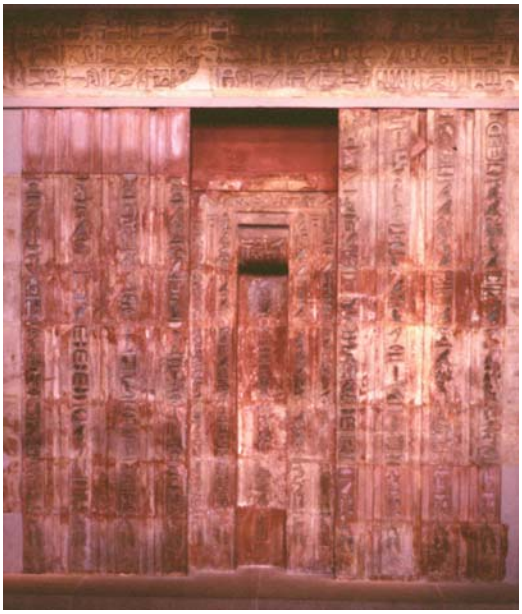
Tombs in Ancient Egypt

Aidan Dodson

An Egyptian tomb ideally comprised two basic parts. One was intended to house the body for eternity; the other was to act as the interface between this world and the next. These two elements could lie close to one another or could be separated by some considerable distance; they could also be of various constructional types and materials. However, the fundamental distinction remained between the mortuary chapel, or offering place, open to the public, and the burial chamber, intended to be sealed for eternity.

The public element usually focused on a stela, an inscribed slab that provided a point at which the two worlds met. It might be of simple form, bearing a depiction of the deceased (and perhaps his or her spouse) receiving offerings of food and drink, together with a ritual formula that guaranteed their eternal provision. On the other hand it might be an elaborately panelled 'false door' (Fig. 1), making explicit the stela's role as a portal between the worlds. In certain cases a statue of the dead person might replace or supplement the stela.

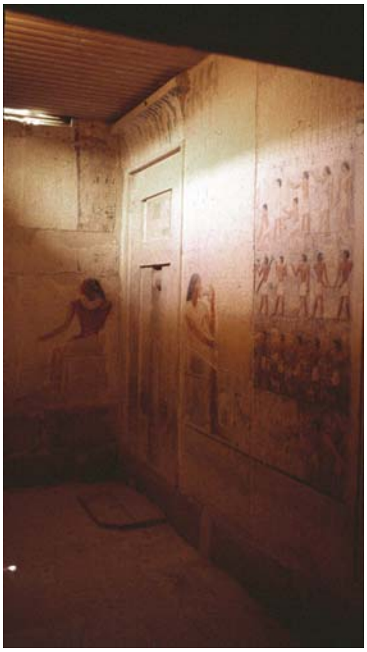


Tombs in Ancient Egypt. Fig. 1 A typical false door stela of the Old Kingdom (British Museum EA682) belonging to Ptahshepses (ca. 2425 BCE) Photo by author.

In many tombs the offering place comprised simply the stela, standing exposed, or with a very basic shelter carved out of the rock or built in brick or stone. However, in other cases the offering place was housed in a far larger structure, which could in turn be extensively decorated (Fig. 2). This structure may be referred to as a mortuary chapel or a mortuary temple, the latter term being generally used for royal examples.

For much of Egypt's history, the decoration of such structures was concerned with food production, other motifs taken from the agrarian world and the experiences of the deceased. In royal cases, this could include scenes of the gods and events of the reign. Tableaux in private chapels are often referred to as 'daily life' scenes and provide an important source for our understanding of life in ancient Egypt. Their primary role was clearly to recreate magically the world the deceased had once enjoyed, as well as providing a further source of eternal sustenance. It seems likely, however, that they had other more esoteric significance, linked with concepts of regeneration and rebirth in the next world. From around 1250 BCE, these 'daily life' scenes tend to be replaced by others of purely ritual type, with images of the gods and extracts from the various Egyptian funerary 'books' that aided the dead person in his or her posthumous destiny.

As already noted, the form of the offering place varied. At one extreme, those of kings could be huge temples, either freestanding or, prior to the middle of the second millennium BCE, attached to a pyramid. Prior to the appearance of the pyramid, royal tombs seem to have had a simple offering place adjacent to the burial chamber, and a large rectangular enclosure up to 1.5 km away. A mound of rubble or some other structure may have topped the burial place itself. At the beginning of the Old Kingdom (ca. 2650 BCE), these separate elements were united in a single location, in the Step Pyramid complex of King Djoser at Saqqara. For perhaps the first time, all parts were built of stone, and a low square structure over the burial place was soon extended to form the basis of a six-stepped pyramid, the first of its kind (Fig. 3).



Tombs in Ancient Egypt. Fig. 2 The false door of Ptahhotep at Saqqara (ca. 2350 BCE) lies within a highly decorated chapel. Photo by author.

Only the very earliest pyramids were stepped, perhaps to provide a stairway to heaven for the dead king. They were soon replaced by smooth-sided structures ('true pyramids'), apparently intended as a recreation of the sun's rays, along which the monarch might make his way to join with the sun god (Fig. 4). The very first step pyramids were surrounded by large rectangular enclosures holding ritual buildings (Fig. 5). However, these were soon superseded by a smaller enclosure with a mortuary temple on the east side of the pyramid. From this a causeway led to a 'valley temple' on the edge of the desert (Figs. 6 and 7).

The free-standing temples that were adopted by the kings of the New Kingdom (1550–1070 BCE) after the royal abandonment of pyramids were all but indistinguishable from contemporary temples of the gods, the differences being in detail only (Figs. 8 and 9). Unlike earlier mortuary temples, the king's spirit now shared the temple with Amun, the King of the Gods, and the sun god, Re, each of whom had his own separate sanctuary within the temple.

Private individuals' mortuary chapels fall broadly under three headings. One type is built against or within *mastabas*, stone or brick structures shaped like low benches ('mastaba' means 'bench' in Arabic). They are used throughout Egyptian history at sites with a flat basic topography, although the best-known date to the Early Dynastic Period and Old and Middle Kingdoms (ca. 3000–1700 BCE).

Mastabas of the earliest times usually had a panelled exterior, but from the Old Kingdom onwards they tended to have flat, slightly sloping, sides, although panelling is occasionally found down into the Middle Kingdom (2100–1700 BCE). Chapels range from a simple niche at the southern end of the eastern face, holding the stela, to a complex of a dozen or more decorated rooms occupying much of the interior of the mastaba. Most usual is an offering place with one or two rooms (Figs. 10–12, 15).

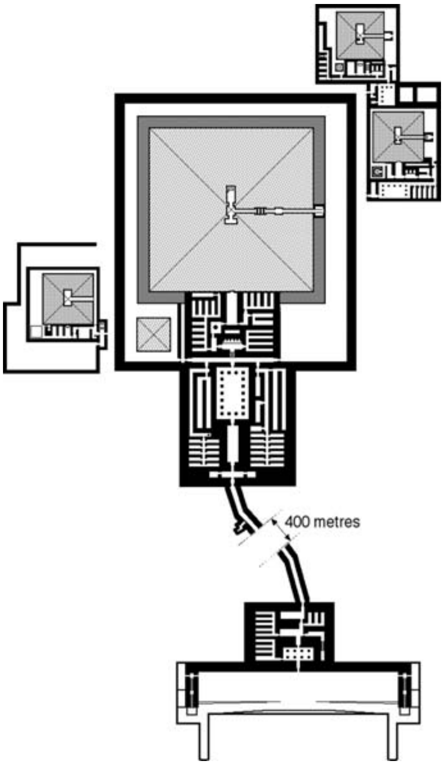
Tombs in Ancient Egypt. Fig. 6 Typical of later pyramids is that of Sahure (ca. 2465–2450 BCE), with a mortuary temple on the east side. Photo by author.

The next type of mortuary chapel is also employed on flat sites, but comprises a freestanding building without an associated mastaba. Once again, these can vary considerably in size and elaboration, from little more than a shed around the stela to a miniature temple. The latter seem to appear first late in the Eighteenth Dynasty and are referred to as 'temple-tombs' (Fig. 13).

The final form of mortuary chapel is that which is cut into a rock face (Fig. 14). Such offering places first appear around 2500 BCE at Giza, and are found throughout the rest of Egyptian history. Plans are almost infinitely variable, although a number of fairly standardised plans are to be seen at Thebes during the New Kingdom (1550–1070 BCE). In particular there is the T-shaped tomb, with a broad but shallow hall running across the axis, and a long corridor running from the middle of its back wall to the offering place, deep in the rock. This basic form could be greatly elaborated by the addition of columns and further chambers – one had no fewer than 70 columns.



Tombs in Ancient Egypt. Fig. 7 This shows the layout of the whole complex of Pepy II (ca. 2290–2180 BCE); the small pyramids belonged to his wives. Plan by author.

Of course, this division is purely for convenience, and many tombs exist that are a combination of more than one category. In particular, rock-cut mortuary chapels could have freestanding courtyards built in front of them (Figs 17 and 18). Particularly elaborate examples date to the Saite Period (663–525 BCE). In addition, after the abandonment of pyramids by kings, miniature examples often appeared above private sepulchres, of both built and rock-cut designs.

The burial chamber and its associated elements are collectively known as the 'substructure'. The two key types are those approached via a vertical shaft and those accessed by sloping passage or stairway. A further consideration is whether the substructure has been tunnelled out of the living rock, or whether it has been constructed out of stone or brick in a cutting in the desert surface and subsequently covered over. There are, however, tombs that use more than one approach to various elements of their substructures.

In the vast majority of Egyptian tombs the substructure lay close to, or directly under, the offering place. Many Old Kingdom mastabas had shafts descending from their roofs to burial chambers in the rock below (Fig. 15), while royal pyramids usually had their burial chamber under the centre of the monument, approached via a sloping corridor from the centre of the north face of the pyramid. In rock-cut mortuary chapels, sloping passages are found in the earliest examples, but later shafts are used as well.

Tombs in Ancient Egypt. Fig. 8 The earliest surviving New Kingdom royal mortuary temple is that of Queen Hatshepsut (ca. 1472–1457) at Deir el-Bahari. Photo by author.

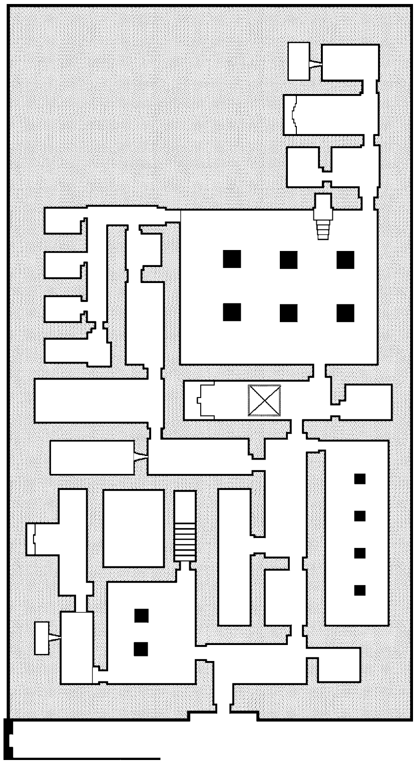
Tombs in Ancient Egypt. Fig. 11 A group of stone mastabas at Giza (ca. 2430 BCE). Photo by author.

Occasionally, the substructure lies some way from the offering place. The best examples of this are the royal tombs of the New Kingdom at Thebes, where the mortuary temples lay on the edge of the desert, but the tomb chambers were up to 2 km away in a desert valley. This is now known as the Valley of the Kings, and also held the burial chambers of a handful of highly placed nobles, whose rock-cut mortuary chapels lay a similar distance away.

Substructures took a variety of forms, ranging from a single chamber and approach shaft/corridor, to a long sequence of corridors, pits and halls. Some included special security features, with sliding trap doors, hidden entrances, and/or burial chambers cut from single blocks of stone, closed with the aid of a 'hydraulic' system using sand. Such features were first employed during the late Twelfth Dynasty (ca. 1800 BCE), and then revived over a millennium later, during the Saite Period.



Tombs in Ancient Egypt. Fig. 12 The most elaborate chapel within a mastaba is that of Mereruka (ca. 2340 BCE) at Saqqara. Plan by author.

Royal tombs were not surprisingly amongst the sepulchres with the most elaborate substructures, although certain private examples, particularly of the Saite Period, exceeded even them. Many earlier pyramids had a standardised substructure, built of stone in a shallow cutting, with a group of three chambers reached by a long corridor. This was blocked by three vertical portcullis slabs of granite (Fig. 7). From the middle of the Middle Kingdom, however, changes were brought in to increase security. Entrance locations became random, and the aforementioned security arrangements introduced.

The security imperative probably also lay behind the separation of the royal burial chamber from the mortuary chapel early in the New Kingdom. The Valley of the Kings tombs generally take the form of a set of

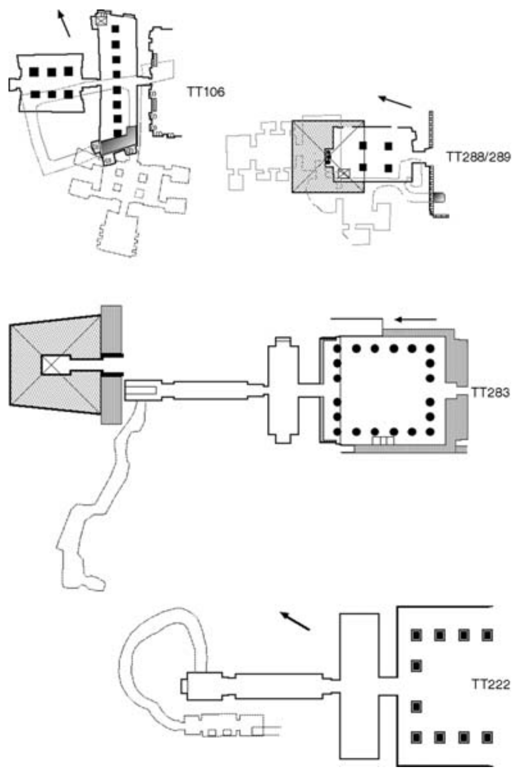
Tombs in Ancient Egypt. Fig. 16 Plans of the tombs of Kings Thutmose III, Amenhotep III and Horemheb in the Valley of the Kings, showing the evolution from a 'bent' to a straight plan between ca. 1450 and 1300 BCE. Plans by author.



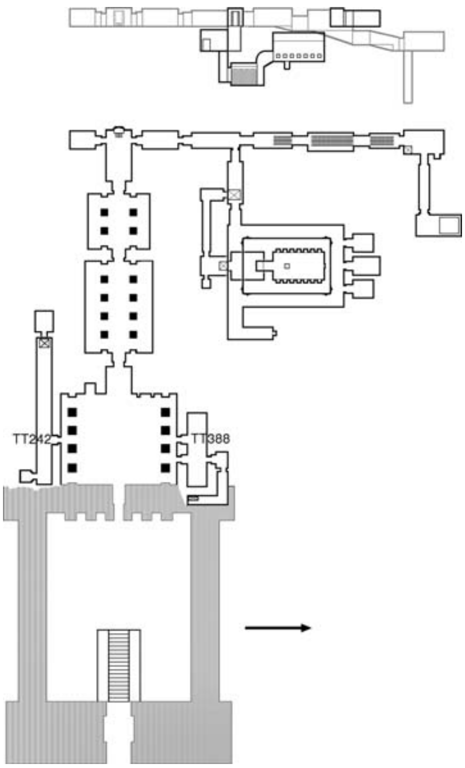
Tombs in Ancient Egypt. Fig. 17 Plans of the private tombs of Paser, Setau, Roma-Roy and Heqamaatrenakhte at Thebes during the middle of New Kingdom (ca. 1300–1150 BCE), showing the relationship between the mortuary chapel, in some cases pyramid, and the substructure. Plans by author.

passages and stairways, leading to a pillared antechamber, and finally to a pillared burial chamber. A shaft in the floor interrupted progress down the tomb, probably with a dual role of hindering thieves and preventing storm water's penetrating the inner rooms (Fig. 16).

In contrast to the mortuary chapel or temple, which almost always had some form of decoration, the substructure was usually completely plain. The principal exceptions were the royal tombs of the late Old Kingdom and the New Kingdom onwards, and a handful of private sepulchres of the Sixth Dynasty, Middle Kingdom, New Kingdom and Saite Period. In the late Old Kingdom, royal burial apartments were adorned with the *Pyramid Texts*, magic formulae intended to aid the king in the next world. They are the ancestors of a whole series of 'books' that formed the basis for all later substructure decorations.

Royal tombs of the New Kingdom and later were principally adorned with various heavily illustrated compositions relating to the sun god's nocturnal journey through the underworld, in which the dead king would participate (Fig. 19). At first these works were a royal prerogative, but by Saite times they could also be found in private tombs as well, which also revived the ancient *Pyramid Texts*.

The rare Old Kingdom decorated private burial chambers generally had illustrated lists of offerings on their walls. This was also the case in the Middle Kingdom, but in the New Kingdom the main decorative composition was the *Book of Coming Forth by Day* – better known as the *Book of the Dead*. This was essentially a guidebook to the next world, and was more usually found on a papyrus placed alongside the mummy. Extracts are also found in mortuary chapels of the Nineteenth Dynasty and later.



Tombs in Ancient Egypt. Fig. 18 One of the largest and most elaborate tombs in Egypt belonged to the priest Pedamenopet (ca. 600 BCE). It was partly built of brick and partly rock-cut, with an extremely elaborate substructure. The burial chamber was carefully concealed, and was approached from below. Plan by author.

Following the Macedonian and Roman takeovers of the country, Egyptian-form tombs were supplemented by those in the Classical tradition, in particular at Alexandria and in other areas with high levels of European settlement. However, even these sepulchres often included Egyptian features, especially in their decoration, where the native gods often appeared. A key difference between the two mortuary traditions was the blurring of the previous rigid distinctions between the chapel and the burial place. In Classical tombs the body was placed in a sealed loculus in the wall of a generally accessible catacomb that might include both a chapel and a room for funerary feasts.

Tongren Zhenjiu Shuxue Tujing

Richard Bertschinger

The *Tongren Zhenjiu Shuxue Tujing* (Illustrated Canon of Acupuncture Points based upon the Bronze Figure) was written by Wang Weiji, and published in AD 1026. It has been a baseline in the identification of acupuncture points ever since. It is used not only in Chinese medicine, but also in acupressure as developed recently in the West, in *shiatsu* (pressure point massage) in Japan during this century, and in all acupuncture-related disciplines.

By the Song Dynasty (AD 960–1126), after much copying and recopying, the locations of the points and channels had become confused. Because of this and the greater stability brought about by the Song reunification of the empire, the medical scholar Wang Weiji reorganized and collated all the then available material in order to locate and define the points precisely.

He produced a book which very quickly became the authoritative text throughout the country. It gave very detailed and accurate information concerning the points, the channels, the depths and effects of needling. The total number of points named in the *Huangdi Neijing* (Yellow Emperor's Canon of Medicine) had been 160; in the *Zhenjiu Jiayi Jing* (A–Z of Acupuncture and Moxibustion) it was 349. But now it was raised to 354. Not long afterwards, the full text of this

T

book was cut onto two stone tablets, each some 2 m high and 7 m in length, which were erected in the Song capital, Kaifeng, where they could be read by everyone, or where ink-impressions could be made from them.

At the same time Wang Weiji directed the casting of two life-size bronze figures – hence the title of his book – which were completed in 1027.

These bronze figures are the very earliest of their kind. They were hollow and had the exact locations and names of the acupuncture points marked on their surface. It is noted in the Song histories that the purpose of the figures was for them to be covered in beeswax and then filled with water. When a student palpated and punctured a point correctly, a stream of water would flow out, reminiscent of the energy stream (or *qi*) tapped by that particular point.

The later history of these figures and tablets is also revealing. After two hundred years, when the Yuan Dynasty moved the capital to what is now Beijing, the bronze figures and tablets were also moved, to take pride of place in the temple at the new Imperial Medical College. However, much use had been made of the figures, and the tablets were so worn that they were indecipherable. Reproductions were therefore made again. During excavations from 1965 to 1971 in Beijing, fragments of the original Song tablets were discovered, and their texts shows that the tradition has been faithfully and accurately preserved to the present day. This book is used as the foundation text for the listing of points in the *Essentials of Chinese Acupuncture* (Beijing 1980) and other texts which have all been recently produced in China and which are aimed at the interested acupuncture audience in the West.

Tools Used in Ancient Egyptian Construction

James A. Harrell

Building Materials

Most ancient Egyptian buildings were constructed of either mud bricks with wood elements or waddle-and-daub walls of intertwined poles packed with mud. These include all the houses and even the royal palaces. In the better-built structures, mud bricks were used for the foundations and walls with wood planks and poles employed for most everything else, including door and window frames, doors, window shutters, vertical supports (pillars) for roofs and upper floors, and horizontal supports for the mud-brick walls. Stone was also sometimes used in these buildings wherever extra strength and durability were required, such as for door thresholds and pillar bases. The only buildings constructed largely or entirely of stone were the temples and freestanding tombs (pyramids and mastabas [tombs]), although some of these were also built of mud brick, and many stone temples were surrounded by massive mud-brick walls.

The construction tools considered here were in use during Egypt's Dynastic period (Dynasties 1–30), which ranged from about 3000 to 332 BCE (Table 1). The subsequent Greco-Roman period is excluded because many of the tool designs (and construction practices) were imported from the Greeks and Romans. Although there are no ancient Egyptian texts describing the use of construction tools, many of the tools themselves have survived, and there are also numerous carved reliefs and painted scenes on the walls of tombs showing the tools in use (Petrie 1917; Clarke and Engelbach 1930; Arnold 1991; Gale et al. 2000; Kemp 2000). Two such tombs are especially noteworthy in this regard, those of (1) Ti, an overseer of pyramids and temples under three 5th Dynasty kings (late Old Kingdom) at Saqqara near Cairo (Epron 1939; Wild 1966) and (2) Rekhmira, a vizier under two 18th Dynasty kings (early New Kingdom) at Qurna near Luxor (Davies 1943). It is the art in these tombs that supplied the representations of tool use in Figs. 1–17. Another source of information

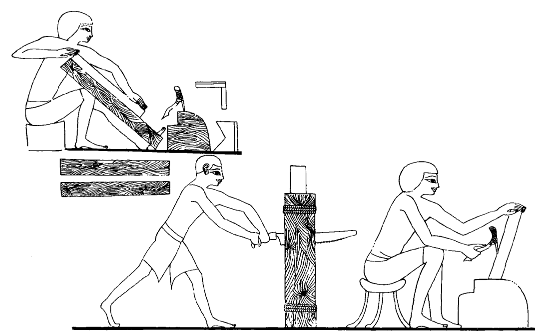
comes from experimental archaeology, where facsimiles of ancient tools are made and then used to test their efficacy in various applications and materials (Stocks 2003; Solenhofen website).

Measuring Tools

Construction, especially of the more elaborate stone structures, required the use of a variety of measuring tools, including ones for determining distance, slope, and flatness. For distance, the Egyptians had "cubit rods" and "measuring cords." The "cubit" was a standard unit of distance that varied slightly during the Dynastic period but averaged 52.5 cm. It was divided into seven "palms," each of which was further subdivided into four "fingers." The working cubit rods were carved from wood, and some could even be folded along hinges. Measuring cords were used to mark off both short and especially longer distances, and these were subdivided by knots tied at fixed multiples of cubits (Fig. 1).



Tools Used in Ancient Egyptian Construction. Fig. 2 Woodworkers using a saw (center), adzes (lower right and upper left), and a straightedge (or perhaps a cubit rod; upper left). Note the builder's square just to the right of the adze (upper left). Redrawn from a painting in the tomb of Rekhmira (18th Dynasty). From Davies (1943: pl. 55).

Squared edges and corners were achieved through the use of a "builder's square," which consisted of two straight lengths of wood joined at their ends to form a right (90°) angle (Figs. 2 and 7). The "square level" combined a builder's square with a "plumb bob." It had two perpendicular sides of equal length that were joined by a crosspiece. At the apex, where the two joined sides met, there was an attached cord with a plumb bob suspended from the other end. The conical plumb bob was typically carved from stone. In use, the square level was placed upright on (vertical and perpendicular to) a surface, resting on the free ends of its two sides. By noting where the cord with the plumb bob lay on the crosspiece, the slope of the surface could be ascertained. Plumb bobs suspended from long cords were used to mark straight lines on vertical surfaces, check the verticality of walls, and measure vertical distances. A tool called a "plumb rule" was also employed to determine verticality. This consisted of a flat wood plank with two short shelves of equal depth at one end. A cord was attached to the end of the plank, just above the shelves, and this was threaded through a hole in the top shelf, exiting at its outer edge. A plumb bob was suspended from the cord's other end. To use the plumb rule, the back of the plank was pressed against a surface with the end bearing the attached cord and shelves oriented upward. The cord with the plumb bob was draped over the bottom shelf, and if the surface was vertical then the cord would just touch the shelf's outer edge.

"Marking cords" were employed to draw straight lines on a surface. The cord was first dipped in a colored paint or powder (usually made from red ochre) and then pulled taunt across the surface. By flicking the cord against the surface, a straight line was marked off.

A set of "leveling (or boning) rods" was used to ascertain the flatness of a stone surface (Fig. 1). The set's three or four short wood rods were of identical length, and two of these were joined at their tops by a cord with the others left unattached. Two workers, each holding one of the joined rods, would place their rods upright (perpendicular to) the surface and then pull the cord taunt. With their free hands, or with the assistance of a third worker, the loose rods were placed upright on the surface and moved along the stretched cord. Wherever one of these rods fell below or rose above the cord, a departure from flatness was indicated. Areas that were too high were probably marked with colored paint or powder to show where additional dressing of the surface was needed. The degree of flatness of a small surface could also be determined with a "straightedge," which was a long piece of wood with a straight edge (Fig. 2).

Cutting Tools

Stone vs. Metal

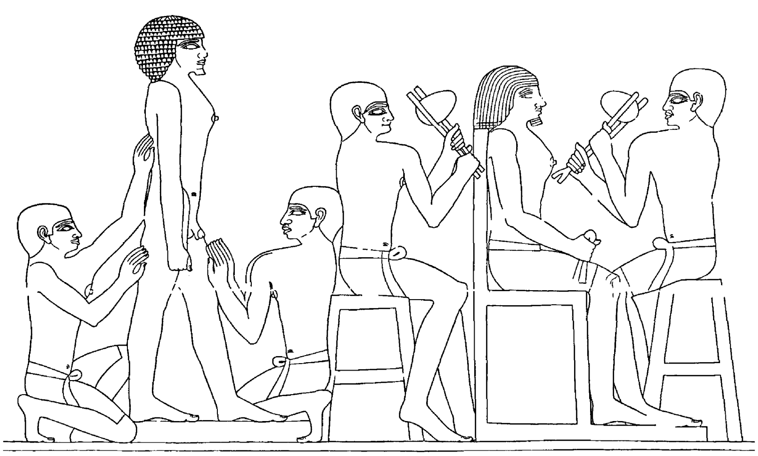
The first tools used in ancient Egypt, and volumetrically the most common ones employed throughout the Dynastic period, were made of stone. Tools requiring a hard, sharp edge or point were fashioned from chert (also known as flint), a rock consisting of microcrystalline quartz. These were used to cut soft stones (limestone, sandstone, travertine, and rock gypsum) as well as wood. Hard stones with good impact-fracture resistance (notably anorthosite gneiss, dolerite, and siliceous [quartz-cemented] sandstone or "quartzite") were employed for pulverizing and grinding the hard stones, including anorthosite gneiss, basalt, granite, granodiorite, metagraywacke, and siliceous sandstone among a few others.

Copper tools, like those of stone, predated the Dynastic period. Because copper is a very soft metal, it could only be used to cut wood and soft stones, and being much costlier than stone, it was used sparingly for tools and then just for the more important projects. The much harder bronze metal (copper alloyed with tin) was first introduced during the Middle Kingdom and became the predominant material for metal tools beginning in the New Kingdom. Even though much harder than copper, bronze was still too soft to use on hard stones. Iron-bearing tools first appeared toward the end of the New Kingdom and came into common use during the Late period. Although usually described as consisting of "iron," these tools were actually made from either a primitive kind of steel (iron alloyed with carbon) or case-carburized wrought iron. Iron tools were strong enough to work the hardest materials and quickly replaced the stone tools formerly employed.

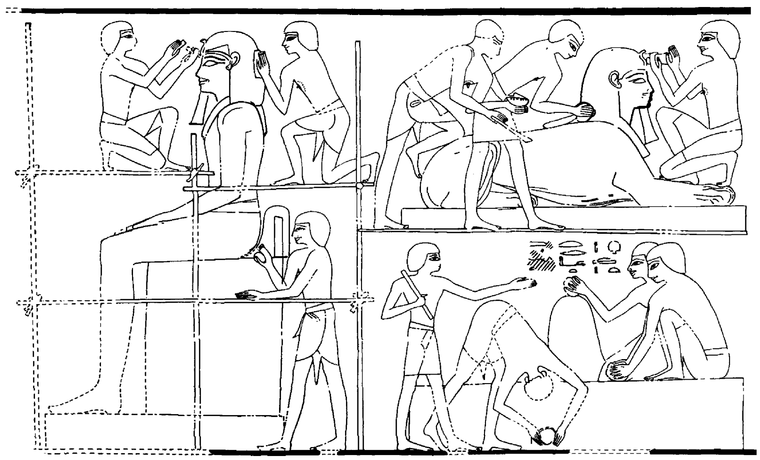
Stone Tools

"Stone mauls" were elongated, generally roughly shaped pieces of hard stone with a blunt tip and a pinched waist where a wood handle was attached (Fig. 3). In contrast to this hammer-like tool, "stone pounders" were compact, generally well rounded and often nearly spherical, pieces of hard stone that were handheld (Fig. 4). Both tools cut stone by pulverizing it. They were used to work soft as well as hard stones, but saw their greatest application with the latter.

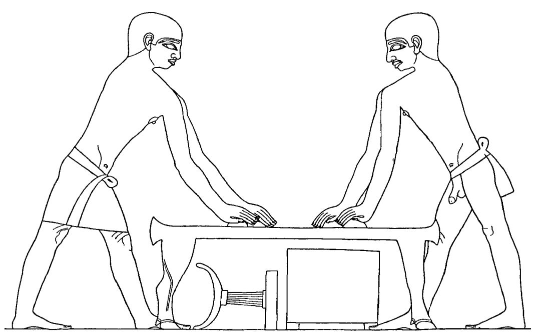
"Grinding stones" were employed for smoothing both stone and wood surfaces (Figs. 4–7). The same hard stones used for mauls and pounders were utilized



Tools Used in Ancient Egyptian Construction. Fig. 3 Stoneworkers using stone mauls (right) and possibly abrasive sand for polishing (left). Redrawn from a relief carving in the tomb of Ti (5th Dynasty). From Wild (1966: pl. 173).



Tools Used in Ancient Egyptian Construction. Fig. 4 Stoneworkers using grinding stones (left and upper right), a chisel struck with perhaps a small piece of wood or stone (upper left corner), stone pounders (lower right), and possibly abrasive sand for polishing (upper right – man with cup and ladle). Redrawn from a painting in the tomb of Rekhmira (18th Dynasty). From Davies (1943: pl. 60).



Tools Used in Ancient Egyptian Construction. Fig. 5 Woodworkers using grinding stones. Redrawn from a relief carving in the tomb of Ti (5th Dynasty). From Wild (1966: pl. 174).

for grinders, but siliceous sandstone was especially favored for this application. Only the harder stones can take a polish, and smoothing with grinders was the first step. Producing a good, reflective polished surface required rubbing with an abrasive paste. Quartz sand was almost certainly the abrasive used, and this would have been applied with either a piece of leather or cloth (Figs. 3 and 4). Using progressively finer-grained sands would produce an increasing degree of polish.

"Hand-cranked stone drills" were used to hollow out the interiors of stone vessels, and may have had some construction applications as well (Figs. 8 and 9). The drill consisted of a wood shaft with a forked end into which was lashed either a siliceous sandstone or, more often, a chert bit. The other end of the shaft was bent to form a handle, and suspended just below this were stone weights that served to increase the downward cutting force of the bit. By cranking the handle back and forth, a worker could drill a cylindrical hole.

Chert is the only native Egyptian stone that can be shaped into a tool with hard, sharp points and edges. It was consequently widely utilized for a wide variety of nonconstruction applications, such as arrow and spear points, and knife and sickle blades. In woodworking, chert was used for axe and adze blades, but it is unclear whether this stone was also used in stoneworking. It has been shown experimentally that chert pick heads, adze blades and chisels can easily cut the softer stones (limestone and sandstone), and chert gravers (sharp-pointed inscribing tools) can be used to incise both soft and hard stones. Although there is no direct archaeological evidence for such applications, it seems likely that chert was employed for stoneworking tools.

Metal Tools

The principal metal tool used for stoneworking during the Dynastic period was the "chisel" (Figs. 1 and 4). Copper and bronze chisels were formed from stout cylindrical bars with either a pointed or flat-edged tip, and were struck with a wood mallet. Some, especially for woodworking, were fitted with a wood handle (Figs. 7 and 10). The chisels were used to dress soft stones, and to cut holes and grooves in wood. Even for such soft materials, the tips needed frequent sharpening. It was not until the advent of iron chisels (and the first metal hammers) during the Late period that the hard stones were worked with metal tools. Copper and bronze "gads" resemble chisels but were not used for cutting. They were instead hammered into existing cracks and fractures within wood or stone in order to split these materials. The woodworkers also used a

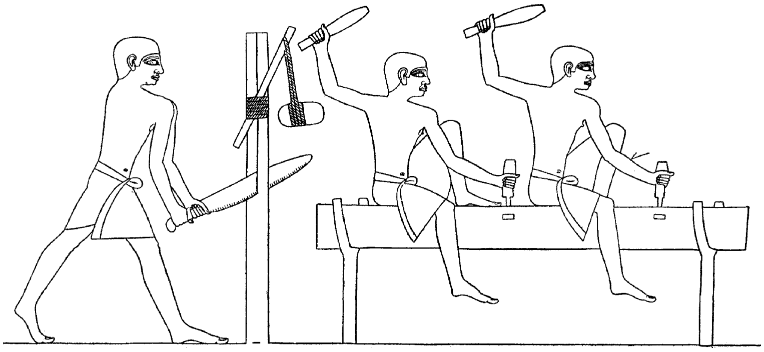
Tools Used in Ancient Egyptian Construction. Fig. 9 Stoneworker using a hand-cranked drill with a stone weight just below the handle. Redrawn from a painting in the tomb of Rekhmira (18th Dynasty). From Davies (1943: pl. 54).

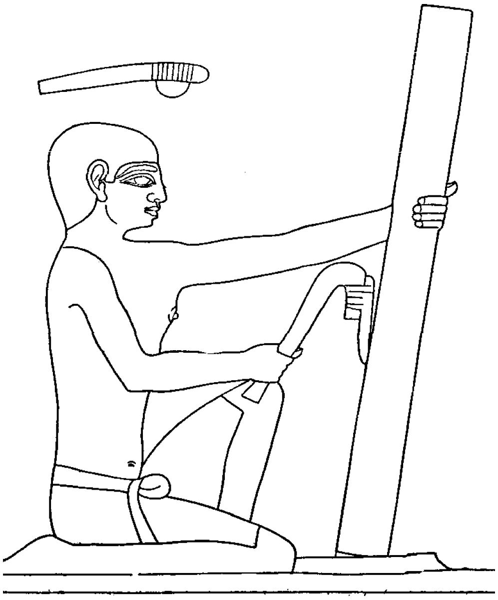
"gouge," which was a small hand-held, chisel-like tool for cutting grooves (Fig. 6).

"Adzes" are essentially flat chisels with a broad, straight cutting edge that were mounted on the end of a hooked wood handle (Figs. 2, 6, 7, 11, and 12). Blades of both metal and chert were employed. Adzes were used for trimming and smoothing soft stone surfaces, and were especially effective for stripping wood.

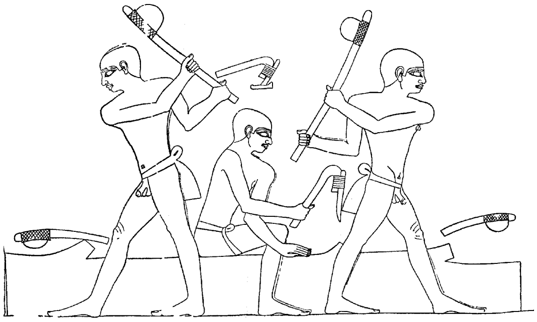
Copper and bronze "saws" were employed for cutting wood and stone (Figs. 2, 6, 7, 10, and 13). Those with a serrated blade cut both wood and soft



Tools Used in Ancient Egyptian Construction. Fig. 10 Woodworkers using a saw (left; note the stone weight keeping the saw cut open) and mallet-struck, wood-hafted chisels (right). Redrawn from a relief carving in the tomb of Ti (5th Dynasty). From Wild (1966: pl. 129).

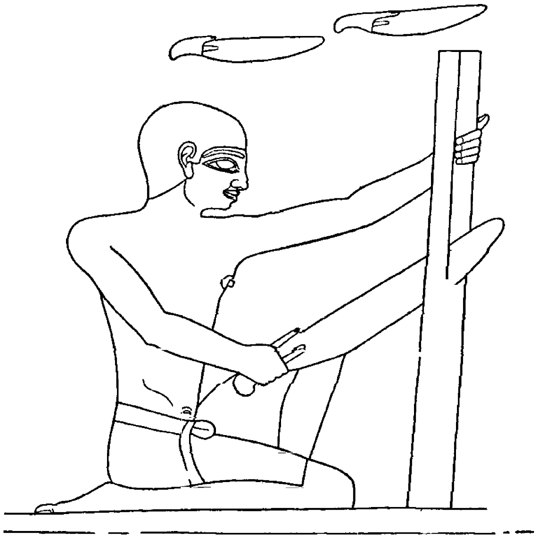


Tools Used in Ancient Egyptian Construction. Fig. 11 Woodworker using an adze. Redrawn from a relief carving in the tomb of Ti (5th Dynasty). Note the axe at top. From Wild (1966: pl. 174).



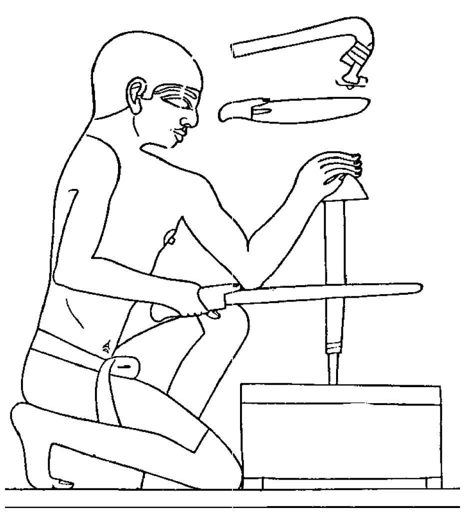
Tools Used in Ancient Egyptian Construction. Fig. 12 Woodworkers using axes (left and right) and an adze (center). Redrawn from a relief carving in the tomb of Ti (5th Dynasty). From Wild (1966: pl. 129).

stone, whereas saws with smooth, nonserrated blades were used to cut the hard stones. In the latter case, the cutting was not done by the metal blade itself (unlike the serrated blades used for softer materials) but rather by a quartz sand abrasive that was fed into the saw cut and over which the metal blade moved. Weights were normally attached to the ends of the longer saws of both types in order to increase the downward cutting force. Although iron saws eventually replaced those of copper and bronze, the basic designs did not change: serrated blades for soft materials, and nonserrated blades for hard stones.



Tools Used in Ancient Egyptian Construction. Fig. 13 Woodworker using a saw. Redrawn from a relief carving in the tomb of Ti (5th Dynasty). From Wild (1966: pl. 174).

"Bow drills" with a metal bit ("bit drills") were used to cut holes through wood and soft stones (Figs. 6, 7, and 14). The drill consisted of a wood shaft into one end of which was fitted a solid metal bit. A bow strung with cord (similar to those wielded by archers) was used to rotate the drill shaft. This was accomplished by tightly looping the bow cord around the shaft and then moving the bow back and forth. While operating the bow with one hand, the worker used his other hand to hold onto a loosely fitting, hemispherical wood or stone cap on top of the drill shaft. In place of the solid metal bit, other bow drills were fitted with a hollow metal tube ("tube drills"). Unlike the bit drill, where the bit itself does the cutting, the tube drill used a quartz sand abrasive fed into the bottom of the hole. As with the nonserrated saw, it was the quartz sand that did the actual cutting, thus making the tube drill suitable for hard stones. As a by-product of the use of this kind of drilling, a cylindrical core was extracted from the hole. Both types of drills originally had copper or bronze fittings; later ones were made of iron. Both were also much used in woodworking to produce the holes for doweled joints and lashings.



Tools Used in Ancient Egyptian Construction.
Fig. 14 Woodworker using a bow drill. Redrawn from a relief carving in the tomb of Ti (5th Dynasty). Note the adze and saw at top. From Wild (1966: pl. 174).

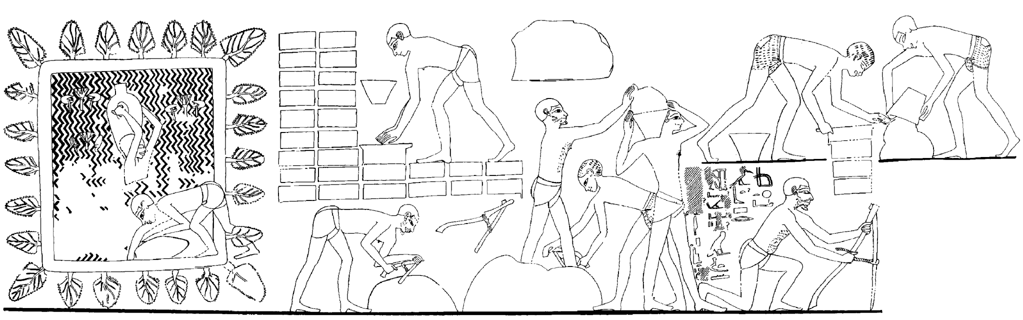
An especially important tool for woodworking was the "axe," which was used to chop and cleave wood (Figs. 7 and 12). Axes had either a subcircular or subrectangular metal blade that flared out into lugs on the dull side and were used in lashing the blade onto a wood handle.

Tools for Mud Brick Manufacturing

Mud bricks were made from a mixture of fine-grained sediment (especially clay-rich mud), sand, chopped straw or other plant chaff, and perhaps also, as in modern-day Egyptian mud bricks, animal manure (Fig. 15). Excavation of the sediment and mixing the ingredients was done with the same "hoe" used by the ancient farmers. The wood blade of this tool had a narrow extension or "tang" on one side and this was fitted into a hole cut through one end of a short wood handle, with the two parts lashed together. The mud mixture was typically packed into wood "moulds" to produce bricks of uniform size. After drying and hardening in the sun, the bricks were ready for use.

Moving Tools

The construction of stone buildings required the lateral movement and lifting of stone blocks weighing anywhere from a few tons to tens (and exceptionally hundreds) of tons. Nearly all of this work was done with ropes, levers, and sledges combined with a large measure of human muscle. The ancient Egyptians had ropes made from a variety of materials, including palm fibers, grasses, and papyrus and other reeds. Ropes up to several centimeters thick have been found and would have been strong enough for the heaviest loads. These

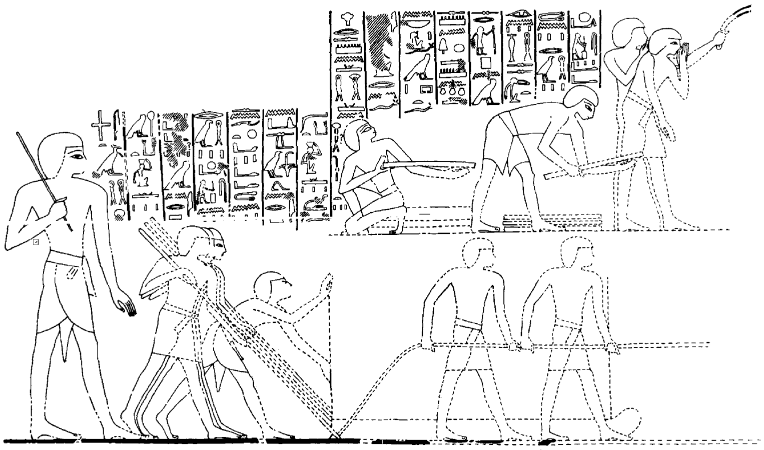


Tools Used in Ancient Egyptian Construction. Fig. 15 Workers making mud bricks: obtaining water from a pond (far left), mixing the wet mud with hoes (lower center), placing the mud in brick moulds (upper center and upper right). Redrawn from a painting in the tomb of Rekhmira (18th Dynasty). From Davies (1943: pl. 58).

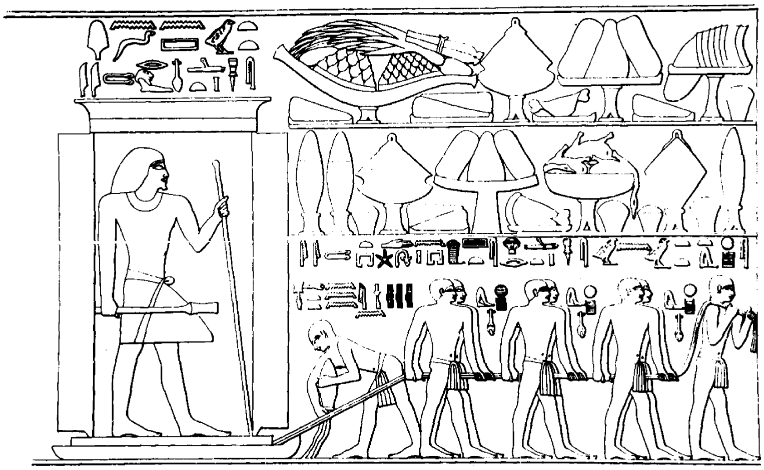
were sometimes used in conjunction with grooved "bearing blocks," which were carved from wood or stone and served as rope guides. By draping a rope around this device, the workers were able to pull from an angle.

Stout wood poles or beams were employed as "levers" for shifting stone blocks (Fig. 16). The largest were operated by teams of workers who would pull down on the elevated end with attached ropes. Stone blocks sometimes had small recesses ("lever sockets or holes") cut along their sides where the lower ends of levers could be inserted. Wood or stone "fulcrums" were placed under the lower end of these levers, and wedge-shaped pieces of wood were pushed under the levered-up edge of a block to allow deeper insertion of the lever.

"Sledges" made from wood were employed for moving heavy loads around the construction site (Figs. 16 and 17). This conveyance consisted of two parallel runners joined by a series of crossbeams. Along the sides, on top of the runners, wood stakes or other attachments would have been present to restrain the load or anchor tie-down ropes. The front ends of the runners were rounded and angled upward to allow the sledge to ride up and over irregularities in the ground. The back ends of the runners were often



Tools Used in Ancient Egyptian Construction. Fig. 16 Workers with a sledge using levers behind it (lower left), pulling on a rope (lower right), and handling sleepers (or rollers?; upper right). Redrawn from a painting in the tomb of Rekhmira (18th Dynasty). From Davies (1943: pl. 58).



Tools Used in Ancient Egyptian Construction. Fig. 17 Workers pulling a sledge with ropes while another worker pours water on the ground in front of the sledge. Note the rounded front and chamfered rear of the sledge runner. Redrawn from a relief carving in the tomb of Ti (5th Dynasty). From Epron (1939: pl. 52).

T

chamfered (beveled) with a cut angling downward toward the front of the sledge (as in Fig. 17), and these allowed the insertion of levers to help move the sledge forward or adjust its direction. Using attached ropes, the sledges were pulled by teams of men or, less often, draft animals.

In order to reduce ground friction, the sledges were pulled over either wetted ground or wood beams ("sleepers") laid crosswise along the sledge's path (Fig. 16). It has been suggested that the sledges were also sometimes pulled over wood "rollers," but this is unlikely as rollers would only be effective on ground that was hard, smooth, and relatively flat. Even though the Egyptians knew about the wheel from earliest Dynastic times, they had no wheeled wagons until the early New Kingdom. From this time onward, wagons may have been used for hauling stone blocks, especially the smaller ones, but sledges almost certainly remained the main conveyance for moving blocks around the construction site.

Wood "rollers" were apparently sometimes placed directly under stone blocks when these were being moved across hard, flat pavements. Another tool thought to also assist in moving stone blocks is the so-called "rocker." Made from wood, this device had two parallel, vertical sides that were joined by cross-beams as in the sledges. The tops of the sides were flat and level, and their bottoms were rounded into a half circle or ellipse. There is much speculation on how the rockers were used, but it is generally agreed that a block of stone was placed on top of the sides, and then by rocking it back and forth, the block could be "walked" across a hard surface or pivoted to assist in its placement.

Extra: Wood or Iron Wedges?

In hard stone quarries dating to the Late period and especially the subsequent Greco-Roman periods, one sees lines of wedge-shaped holes on quarry faces and extracted blocks. It is a common misconception that these holes were cut to hold wedges of wood, which when wetted would swell and so split the rock along the line of wedge holes. In actuality, however, these holes were cut to hold iron wedges, which were struck with an iron sledgehammer to split the stone. This same method of splitting stone was also used in stone construction work toward the end of the Dynastic period.

Trephination

Ruben G. Mendoza

Perhaps one of the least understood surgical practices performed in ancient America concerns cranial trephination (also spelled "trepanation"), or the surgical modification of the skull. While much of the prevailing literature is largely dated, an older generation of theories tended to ascribe the practice to primitive wonderment and notions of spirit release and possession. This is despite a substantial body of technical evidence available from trephined specimens and a large and specialized body of surgical instruments and procedures documented in archaeological and contact-period historical contexts. According to medical historian Guido Majno, trephination was used as a cure for a number of ailments including skull fractures and related trauma, epileptic seizures, and insanity. In fact, many of those skulls examined to date bear evidence of blunt trauma or pathology that may provide a more direct indicator of why the practice was carried out in the first place.

While ancient Peru provides the largest body of trephined specimens available for study, and the clearest evidence of an established medical tradition in skull surgery, other important specimens have been reported from throughout the Americas. Documented examples, with evidence of osteitis, have been reported from the Mexican states of Chihuahua and Oaxaca, and archaeological sites in Lamy, New Mexico, and Accokeek, Maryland, in the United States, where trephined surgical openings are often no more than 2 cm in diameter. Reported trephined specimens from Columbia County, Georgia, archaeological zones along the Skeena River, and in the sites of Eburne and Lytton, British Columbia and Kodiak Island, Alaska, range between 3.8 and 6.0 cm in diameter. If all the putative cases of trephination reported in these examples are a reliable indication of areas in which the practice was known, then cranial trephination was quite widespread.

Majno has identified five primary techniques of trephination in specimens from both Peru and Mesoamerica. These include the most ancient method on record – the scraping-away of that bone just underlying the scalp – as well as other techniques such as grooving, boring, cutting, sawing, and rectangular intersection incision, the most predominant method employed, in which cut, sawed, or abraded grooves were used to perforate the skull in a rectangular pattern. Once the intersection incisions were connected to each other, a rectangular or octagonally shaped plate of bone remaining within the intersection was removed with a spatula-like device. Schendel (1968) notes that "the trepanning technique used in Mexico was to punch a series of small holes in the skull outlining the fracture, or the area to be removed, then to cut between those holes and lift off the depressed section of cranial bone." After this initial procedure, the exposed brain was protected with a thin plate of hardwood and cotton pads. When trephination was not deemed suitable because of the extent of skull trauma, the damaged portion of skull was encased in a protective plaster cast. There were two types of plaster cast. The first was a mixture of feathers, egg whites, and resin, and the second was prepared from a mixture of animal ash, blood, and egg whites.

Specialized tools and instruments employed by Inca physicians in the trephination of the skull included *tumi* knives crafted from alloyed and annealed, or metalurgically hardened, copper and bronze metals. The *tumi* knife consisted of a crescent-shaped blade, at the midpoint of which was attached a cylindrical metal handle or other appendage. *Tumi* knives used in trephination included razor sharp, serrated, or other sawtooth-edged crescent-shaped scalpels. Additional instruments included bronze perforators, drills, and chisels. The basic surgical instrumentation utilized in cranial trephination long predated the rise of the Inca state, whose government came to sponsor and control this specialized field of medical endeavor (Burland 1967). Cranial trephination, and both *tumi* knives and bronze perforators, are frequently depicted on the carved and painted surfaces of vessels of the Mochica civilization of the north coast of Peru (ca. AD 500).

In one collection of 273 skulls from Peru, 47 bore evidence of having been trephined between one and five times. According to Majno, the skulls studied thus far suggest that the survival rate was near 100%. Only a few cases of osteomyelitis, or bone deterioration, were documented in the cranial collection he examined. Those cases appear to have been associated primarily with the size of the original injury, and whether or not the trauma was located at the base of the skull. Apparently, patients suffering blunt trauma over the cerebral cortex or brain stem were least likely to benefit from treatment by trephination. In other recent studies, projected survival rates, based on the examination of the presence of osteitis, range from 62.5% in one study that found healing or evidence of osteitis in 250 of 400 skulls examined, to between 23.4% and 55.3% in other studies (Froeschner 1992). These latter figures are questionable in that the studies cited by Froeschner do not distinguish postmortem trephination from that performed on severely traumatized patients. Froeschner's review also fails to acknowledge the existence of even the most basic metal instruments and surgical kits documented for the practice of trephination in ancient Peru, claiming instead that "primitive tools" were the mainstay of the art of Inca trephining.

It is clear that specialized techniques and treatments contributed to the diversity and variation in surgical localities known from trephined specimens alone. In one analysis of a trephined skull collection consisting of 112 specimens (the Tello collection housed at the Peabody Museum of Harvard), 53.6% of the skulls, or 60 specimens, bore trephined areas in the frontal area of the skull (26 of which were situated in the frontal bone, 12 in the region of the bregma, and another 12 crossing over the left coronal suture); 33%, or 37 specimens, were trephined in the parietal area (18 of which bore surgical openings over the left parietal, while 15 crossed the sagital suture), and 13.4%, or 15 specimens, were trephined over the occipital area (with seven in the region of the lambda, and four in the occipital bone). Most trephined specimens from the Harvard collection bear surgical openings within the frontal areas of the cranium, and again, trephined openings are most highly correlated with blunt trauma and other pathologies. The incidence of epileptic seizures among Inca era peoples was documented by both European-contact chroniclers and contact-era Inca scribes. This fact may provide directions for future inquiry into the origins of specific types of trephination among Inca and related peoples.

Based on a worldwide survey of ancient skull surgery, Majno has concluded that the Inca were the "Masters of the Art of Trepanning." He also noted that the survival rate for patients in Inca times was better than for such rates in modern times. He says that modern survival rates are the inverse of what they had been in earlier Inca times, and concludes that modern humans complicated the task of skull surgery by introducing new sources of infection and disease. In turn, modern physicians were trained to perpetuate otherwise antiquated traditions of skull surgery based on flawed nineteenth century assumptions and beliefs.

European medical belief systems regarding infection, surgical procedure, anesthetics, and basic hygiene necessitated a constantly expanding and contracting repertoire of experimental procedures which further complicated survival rates. As a result, the fledgling early twentieth century version of modern skull surgery suffered many casualties.

Tribology

Lu Jing-Yan

Tribology, the study of the phenomena and mechanisms of friction, lubrication, and wear of surfaces in relative motion, can be traced back to remote antiquity in China, where it developed significantly.

Sliding bearings were discovered in ancient mechanisms, especially in carts which operated at high speeds and carried great loads. In order to reduce friction and damage, Chinese mechanics lubricated bearings on their carts. This was recorded in the earliest poetry collection entitled *Bei Fen Quan Shu* (The Bei Wind and Spring Water) as follows:

The grease used is sufficient to lubricate the axle shaft.
On the shaft end, we carefully check the pin bolt.
Quickly, send me home driving the cart.
Quickly, send me back to my Wei country town.

It proves that before the book *Shi Jing* (Poems and Odes) appeared – before 1100–600 BCE – lubricant was widely applied in China. Owing to their rhythmic quality, the verses were repeatedly quoted and talked about, and often appeared in later books as well.

By the time of the Chun Qui (Spring–Autumn) period (500 BCE) in the Lu and Qi states, there was a group of special officers called *Jinche*, whose duty was to check the pin bolts on the shaft ends. They were probably the earliest tribology supervisors. This demonstrates that the ancient Chinese already knew well that the better the lubrication, the faster and easier ran the cart.

Early lubricant was called *zhi* or *gao*. According to research on ancient characters, *zhi* was the fat of horned animals, and that of hornless animals was called *gao*. The lubricant used might be sheep oil, which was easier to get. Since *zhi* or *gao* is in a solid state at normal temperature, it had to be heated and melted before it was used. In 300 BCE petroleum began to be used.

Metal bushes appeared in China quite early. There were relevant records about their use in *Wuzi Yebing* (Wuzi casting), which shows that they appeared not later than 400 BCE. The metal bush was made of two layers: outside and inside. The outer one was called *gong*, which turned together with the wheel, and the inside one was *jian*, which turned together with the shaft. Between them a kind of lubricant was provided, and the cart ran quickly and easily. In addition to carts, the metal bushes were applied in other mechanisms of antiquity, and they appeared in a variety of forms. In the Han Dynasty, they were already used quite widely. This is illustrated by the discovery of hundreds of mold sets of metal bushes in county Wen in Henan province.

Most of them were still undamaged. They reflect the level of manufacturing as well as the scale of their production and application in the Han Dynasty.

The ancients took other measures to reduce friction and damage. Most mechanisms were made of wood. In the *Kao Gongji* (The Artificer's Record), three principles of wood selection were listed (1) the wood must be smooth, without joints; (2) it must be tough and wear-resistant; and (3) it must be thick enough and easy to revolve. In the sixteenth century a book entitled *Tian Gong Kaiwu* (Exploitation of the Works of Nature) was written, in which a further summary on the basis of experience was made. It analyzed the advantages and shortcomings of various woods, and provided an example: if wood works for too long, it gives out heat. In the field of structural design, the *Kao Gongji* and other books analyzed the relationship between the axis path and the length of the shaft, and pointed out that when the cart and load were different, the interior axis of the wheel must keep a fixed proportion to the length of the shaft.

There was one other achievement of note in this field. In the Yuan Dynasty (thirteenth century) a ball bearing, which was circle-formed and consisted of four balls, was successfully applied to an astronomical instrument made by Guo Shoujing.

Trigonometry in Indian Mathematics

Michio Yano

Trigonometry offers one of the most remarkable examples of transmission of the exact sciences in antiquity and the Middle Ages. Originating in Greece, it was transmitted to India and, with several modifications, passed into the Islamic world. After further development it found its way to medieval Europe.

The very term "sine" illustrates the process of transmission. The Greek word for "chord" (εὐθεῖα, literally "a straight line [subtending an arc]") was translated into Sanskrit as *jīva* or *jyā* ("string of a bow") from the similarity of its appearance. The former word was phonetically translated into Arabic as *jyb*, which was vocalized as *jayb* (meaning "fold" in Arabic), and this was again translated into Latin as *sinus*, an equivalent to the English sine.

It was by tracking back along this stream of transmission that the first chord table ascribed to Hipparchus (fl. 150 BCE) was recovered by Toomer (1973) from an Indian sine table (compare Tables 1 and 2). Toomer showed that some numerical values ascribed to Hipparchus in the *Almagest* of Ptolemy (fl. AD 150) could be explained by hypothesizing the use of this reconstructed table.

According to this reconstruction, Hipparchus used 6,875′ as the length of the diameter (1) of the base circle, in other words, as the greatest chord subtending the half circle($= R\,\mathrm{crd}\,180^{\circ} = 6{,}875$). This number is the result of rounding after dividing 21,600′ (360°) by the value of π = 3; 8, 30. (In this article we follow the convention: integer and fraction are separated by a semicolon, the former is in decimal form and the latter is in sexagesimal form with commas to separate the places.) In India 3,438′, namely, the rounded half of D, was used as the length of the radius (R), which is the largest "half chord" (*jyārdha* or *ardhajyā*).

Thus the relation between the Greek chord and the Indian sine can be expressed as:

$$AB = 2AH, \quad R\,\mathrm{crd}\,2\alpha = 2\mathrm{R}\sin\alpha. \tag{1}$$

Plane trigonometry was the essential tool for mathematical astronomy in India. All the astronomical texts in Sanskrit either give a kind of sine table or presuppose one. On the other hand, trigonometry was studied only as a part of astronomy and it was never an independent subject of mathematics. Furthermore since they were not aware of spherical trigonometry, Indian astronomers developed the method called *chedyaka* in which the sphere was projected on to a plane.

24	90	3,438	7

Sine Table with R = 3,438

The earliest Indian sine table with R = 3,438 is found in Āryabhaṭa's book on astronomy, *Āryabhaṭīya* (AD 499). It should be remembered that "table" here does not mean that the numbers are actually arranged in a tabular form, i.e., in lines and columns. As is usually the case with Sanskrit scientific texts, all the numbers are expressed verbally in verse. For brevity's sake, Āryabhaṭa gives only the tabular differences (Δ, the fourth column of Table 2). This is the standard sine table in ancient India. Exactly the same table is found in the *jiuzhili*, a Chinese text on the Indian calendar written in AD 718 by an astronomer of Indian descent, but it did not have any influence on Chinese mathematics.

The values of sines were geometrically derived from R sin 90° (=R) and R sin 30° (=R) by two formulas:

$$R\ \sin(90^{\circ} - \alpha) = \sqrt{R^2 - (R\ \sin\ \alpha)^2}, \qquad (2)$$

$$R\sin\frac{\alpha}{2} = \sqrt{\left\{\frac{R - R\sin(90^{\circ} - \alpha)}{2}\right\}^2 + \left(\frac{R\sin\alpha}{2}\right)^2}. \qquad (3)$$

It is worth noting here that the first tabular sine was equated with the arc (3; 45° = 225′) which it subtends. This means that, when α' is small enough, the approximationsin $\alpha' \approx \alpha'$ can be applied.

What is more remarkable in Āryabhaṭa is that he gives an alternative method for computing tabular differences by means of the formula:

$$\Delta_{n+1} = \Delta_n - (\Delta_1 - \Delta_2)\frac{J_n}{J_1},$$

where $J_n = R\ \sin\ n(3;45^{\circ})$. The formula, after several centuries of misunderstanding, was correctly interpreted by a South Indian astronomer Nīlakaṇṭha (born in 1444), one of the most distinguished scholars belonging to the Mādhava school (see below). When suitable values of $(\Delta_1 - \Delta_2)$ and J_1 are used, this formula produces very good values for the rest of R sins. It seems that Āryabhaṭa's sine values were computed by this second method rather than by the geometrical method. This means that the table with R = 3,438 is not a mere copy of the Hipparchan table, if ever existed.

Sine Table with R = 120

There is another kind of Indian sine table which uses R = 120. The table is found in the *Pañcasiddhāntikā* of Varāhamihira, a younger contemporary of Āryabhaṭa. This table is closely related to the Greek chord table with R = 60 which is offered in Ptolemy's *Almagest*. Because of the relation (1) given above, all the numerical values in the chord table with R = 60 can be transferred directly to the sine table with R = 120. Table 3 compares the first four and the last four values in the *Pañcasiddhāntikā* with Ptolemy's corresponding ones. The fractional parts after the semicolon in both tables are expressed sexagesimally. It seems that Varāhamihira's values were the results of rounding the numbers in the second fractional place of a chord table similar to that of Ptolemy.

In these earlier Indian sine tables, only the 24 values in the first quadrant are given, with the interval of 3°45′. Although Indians knew and used cosines (*koṭijyā*), they had no need of tabulating them because they knew that cosines could be derived from sines by the relation (2) above. On the other hand they were interested in the versed sine (*śara* in Sanskrit, meaning "arrow" or *utkramajyā*, "sine of the reversed order," CH in Fig. 1) which is defined as:

$$R\,\text{vers}\,\alpha' = R - R\ \sin(90^{\circ} - \alpha).$$

Using this relation, Brahmagupta (seventh century) simplified some formulas. For instance, formula (3) was rewritten as:

$$R\ \sin\frac{\alpha}{2} = \sqrt{\frac{D \times R\,\text{vers}\,\alpha}{4}}. \qquad (3')$$

A table of versed sines can be easily obtained by adding Δs in Table 2 successively from the bottom upward (namely, in the "reversed order").

Trigonometry in Indian Mathematics. Table 3 Comparison of the first four and last four values in the *Pañcasiddhāntikā* with those of Ptolemy

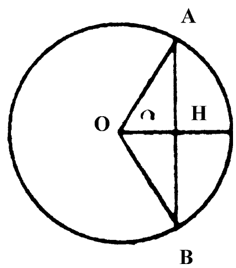
23	86; 15	119; 44	119; 44, 36
24	90	120	120



Trigonometry in Indian Mathematics. Fig. 1 Sine of the reversed order.

Brahmagupta computed anew 24 sines with R = 3,270 in the *Brāhmasphuṭasiddhānta*. Elsewhere in this book and in the *Khaṇḍakhādyaka*, he offers a sine table with R = 150 and with the interval of 15°. This small table generates remarkably correct sine values when his ingenious method of second order interpolation is applied.

Bhāskara II

An improved version of the traditional sine table was prepared by Bhāskara II (b. 1114). In the chapter "Derivation of Sines" (*Jyotpatti*) of his *Siddhāntaśiromaṇi* he introduces two new values:

$$R \sin 36^{\circ} = \sqrt{\frac{5-\sqrt{5}}{8}}R,$$

$$R \sin 18^{\circ} = \sqrt{\frac{\sqrt{5}-1}{4}}R.$$

With these two values and formulas (2) and (3) above, he obtains $R \sin 3n°$ (where n = 1, 2, 3,…, 30). Further he combines them with the approximate value

$$R \sin 1^{\circ} \approx 60'$$

using the new formula

$$R\sin(\alpha \pm \beta) = \frac{R\sin\alpha R\cos\beta \pm R\cos\alpha R\sin\beta}{R}, \quad (4)$$

which is equivalent to the modern formula:

$$\sin(\alpha \pm \beta) = \sin\alpha \cos\beta \pm \cos\alpha \sin\beta.$$

Thus he could obtain sines for all the integer degrees of a quadrant. Formula (4) was unknown to Indians before Bhāskara II, while a chord version of the same formula was known to Ptolemy.

Trigonometry underwent a remarkable development in the early fifteenth century on the western coast of South India (the modern state of Kerala). The person who initiated this development was Mādhava (fl. ca. 1380/1420) of Saṅgamagrāma (near modern Cochin). His important works on astronomy and mathematics are now lost, but we know his achievements from the books of his successors. A sine table ascribed to him is quoted in Nīlakaṇṭha's commentary on the *Āryabhaṭīya* (Table 4).

A couple of verses, which are often quoted by the students of the Mādhava school and which are ascribed to Mādhava himself by Nīlakaṇṭha, give the method of computing sines. The method can be expressed as

$$R \sin\theta = \theta - \frac{\theta^3}{3!R^2} + \frac{\theta^5}{5!R^4} - \frac{\theta^7}{7!R^6} + \frac{\theta^9}{9!R^8} - \cdots$$

with R = 1 this is equivalent to Newton's

$$\sin\theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \frac{\theta^7}{7!} + \frac{\theta^9}{9!} - \cdots.$$

Similar power series for cosine and versed sine are ascribed to Mādhava.

Trigonometry in Islamic Mathematics

Sami Chalhoub, Boris A. Rosenfeld

Trigonometry is the connecting link between mathematics and astronomy, between the way calendars are calculated, the gnomon, and the sundial. In the Islamic world, the calculation of spherical triangles was necessary to carry out ritual customs. The *qibla*, the direction to Mecca, was indicated next to the hour lines on all public sundials.

The first trigonometric problems appeared in the field of spherical astronomy. Around the year 773 one of the Indian *siddhāntas* (astronomy books) was made known in Baghdad. The Indian astronomers Varāhamihira (fifth century) and Brahmagupta (sixth century) solved different problems in spherical astronomy by means of rules equivalent to a general sine theorem for a spherical triangle ABC with sides a, b, c and angles A, B, C (where angle A is opposite to side a, etc.), namely $(\sin A/\sin a) = (\sin B/\sin b) = (\sin C/\sin c)$ and to the cosine theorem for the same triangle $\cos a = \cos b \cos c + \sin b \sin c \cos A$.

In the ninth century Ptolemy's *Almagest* and Menelaus' *Spherics* were also translated, and commentaries were written to these works. Many trigonometrical problems were solved in Ptolemy's *Almagest*, in which Menelaus' theorem on the spherical complete quadrilateral was used. The cases of this theorem used by Ptolemy are equivalent to the sine and tangent theorems for a right-angled spherical triangle. The *Almagest*, the *Spherics*, and the Indian *siddhāntas* formed the basis on which Arab mathematicians built their trigonometry.

The ancient Greek astronomers only used one trigonometric function, the chord of an arc. The "theorem of Ptolemy," which is equivalent to the formula for the sine of the sum of the angles, forms, together with the formula for the chord of the half arc, the basis for the chord table in the *Almagest*. The Indian people replaced the chord with the sine, introduced the cosine and the versed sine, and compiled a small table of sine values. The Arabic mathematicians progressively made trigonometry into a science independent of its (astronomical) context.

Applications of trigonometry analogous to those in the Indian *siddhāntas* are found in the astronomical works of al-Khwārizmī. An analogous geometric construction for finding the azimuth according to the rule formulated in al-Khwārizmī's third treatise was provided by al-Māhānī (ca. 825–888) in his *Treatise on the Determination of the Azimuth at Any Time and in Any Place*. The rules equivalent to the spherical sine and cosine theorems were also used by Thābit ibn Qurra in his *Book on Horary Instruments Called Sundials*. With Ḥabash the applications of the tangent and cotangent functions went beyond the usual applications in the theory of sundials. The introduction of the tangent and cotangent and their application in astronomy was a novelty. The names *zill* (shadow) and *zill maʿqus* (reversed shadow) apparently are translations from Sanskrit. In the case of a vertical gnomon, al-Ḥabas expressed the cosecant as the "diameter of the shadow" for a given height of the sun, i.e., as a hypotenuse. He computed a table for the cosecant with steps of 1°.

For a long time, the chord was used along with the sine. A theory of these magnitudes is found in the work of al-Battānī (ca. 858–929). In his astronomical work *Islaḥ al-Majisṭī* (The Perfection of the Almagest), he systematically employed the trigonometric functions sine and versed sine with arguments between 0° and 180°. Since the cosine is defined as the sine of the complement of the angle, and since no negative numbers are used, the versed sine is defined in the second quadrant as a sum of two quantities. The elements of trigonometry are set forth in an even more systematic way in the *Kitāb al-Kāmil* (Perfect Book) of Abū'l-Wafāʾ (940–997/998). He defined several trigonometric functions in the circle with radius 1. The trigonometrical tangent function is defined as a line on a tangent to the circle.

The proof of the general spherical sine theorem was given by Abū'l-Wafāʾ in his *al-Majisṭī* (Almagest), by his pupil Abū Naṣr ibn ʿIrāq (d. 1036) in the *Risāla fī maʿrifa al-qisī al-falakiyya* (Treatise on the Determination of Celestial Arcs), and by al-Khujandī (d. ca. 1000) in the *Kitāb fī al-sāʿāt al-māḍiyya fī al-layl* (Book on Past Hours in the Night). The history of the discovery of this theorem was described by al-Bīrūnī, the pupil of Ibn ʿIrāq and al-Khujandī, in the *Kitāb maqālīd ʿilm al-hay'a* (Book on the Keys of Astronomy).

The use of trigonometry was expanded through al-Bīrūnī (973–1048). He is the author of the *Masʿūdic Canon*, which is a summary of the results from the works of many predecessors and of personal observations and calculations. It comprises 11 books. Book 3 is dedicated to trigonometry. It has calculations equivalent to the formulas for the sine of the sum of two angles, the sine of the differences between two angles, and the sine of the double angle. It also includes the solution of cubic equations and the division of angles into three parts, and the sine rule of plane trigonometry: $(\sin A/a) = (\sin B/b) = (\sin C/c)$. (The plane cosine theorem $a^2 = b^2 + c^2 - 2bc \cos A$ is equivalent to two of Euclid's theorems.)

Another important scholar in the area of trigonometry was Naṣīr al-Dīn al-Ṭūsī (1201–1274). His principal work was *Kitāb al-shakl al-qaṭṭāʿ* (Book on the Secant Figure, also known as Treatise on the Complete Quadrilateral). It was written in Persian and translated by the author into Arabic in 1260, possibly for the needs of the observatory of Maragha. In five books, it contains a full system of trigonometrical formulas for plane and spherical triangles. If any three elements of such a triangle are given, the other three elements can be found by the theory explained in this work, which also contains the notion of the polar triangle $A'B'C'$ of a spherical triangle $ABC(A' = 180° - a,\ B' = 180° - b,\ C' = 180° - c)$. This work played an important role in the development of mathematics in Europe.

Ulugh Bēg

Boris Rosenfeld

Ulugh Bēg, Mīrzā Muḥammad ibn Shārhrukh ibn Tīmūr Ulugh Bēg Guragān, 1394–1449, was the ruler of Samarqand (now in Uzbekistan) and an astronomer, mathematician, and poet. His nickname, Ulugh Bēg, means "great prince". He was the grandson of the great conqueror Tīmūr. In 1417, as a pupil of Qāḍī Zādeh al-Rūmī of Bursa (Turkey), he opened in Samarqand the *madrasa* (school) where al-Rūmī was the teacher. In 1425 he founded an astronomical observatory and invited Jamshīd al-Kāshī to be its director. After al-Kāshī's death, the head of the observatory became ʿAlī al-Qūshjī. Ulugh Bēg was killed by enemies of enlightenment. After his death his observatory was destroyed, and al-Qūshjī fled to Turkey.

The main work of Ulugh Bēg was a book of astronomical tables known as the *Zīj-i Ulugh Bēg* or *Zīj-i jadīd-i Guragānī* (New Zīj of Guragan) written together with al-Kāshī, al-Rūmī, and al-Qūshjī. The tables are written in Persian and are extant in many manuscripts in Persian and Arabic translations. The work consists of four books of trigonometrical, astronomical, geographical, and astrological tables.

Book I covered the subject of calendars, including the Muslim lunar calendar, the pre-Islamic Persian solar calendar, and the Chinese–Uyghur calendar. Book II dealt with spherical astronomy, covering sine and versed sine, shadows (tangents and cotangents), spherical coordinates on the celestial sphere (equatorial, ecliptical, and horizontal coordinates), geographical coordinates, as well as spherical distances between stars and the direction of *qibla* (to Mecca). In Book III Ulugh Bēg considered planetary and stellar astronomy, such as the motion of the sun, moon, and planets, the distances of the sun and the moon from the center of the world, and the equalization of astrological houses. Finally, Book IV dealt with astronomical calculations.

Ulugh Bēg also was the author of the mathematical *Risāla fī istikhrāj jayb daraja wāḥida* (Treatise on the Determination of Sine of One Degree). Originally the treatise was wrongly ascribed to al-Rūmī; Ulugh Bēg's authorship was established on the basis of the information in al-Birjandī's commentaries to the *Zīj* of Ulugh Bēg.

Umar al-Khayyām

Boris A. Rosenfeld

ʿUmar al-Khayyām (Ghiyāth al-Dīn Abū'1-Fatḥ ʿUmar ibn Ibrāhīm Khayyām (al-Khayyāmmī) al-Naysābūrī (Nīshāpurī), 1048–1131) was a Persian mathematician, astronomer, philosopher, and poet. His scientific treatises were written primarily in Arabic; his poems were mostly written in Persian. The name Khayyām means "the tentmaker" – probably it was the profession of his father or grandfather. He was born and died in Nīshāpūr. Khayyām was a student in Balkh (now in Afghanistan), and worked at first in Bukhārā and Samarqand (now in Uzbekistan). In 1074 he was invited by Saljūq Sultan Mālikshāh Jalāl al-Dīn to the capital Iṣfahān to participate in the reform of the solar Persian calendar and to organize an astronomical observatory. The calendar reform was completed in 1079; the new calendar era was named according to the names of the sultan Māliki or Jalālī. In 1092, after Mālikshāh's death Khayyām fell into disgrace, and his observatory was closed. This was because of suspicions that some of his verses were anti-Islamic. To allay these suspicions, he made a pilgrimage to Mecca. Later he worked in Marw (now Marv in Turkmenistan) which was the new capital of the Saljūq sultans.

Two of Khayyām's treatises are very important for the history of mathematics. One is the *Risāla fī'l-barāhīn ͨala masā'il al-jabr wa'l-muqābala* (Treatise of Demonstrations of Problems of Algebra), written in Samarqand and dedicated to the judge Abū Ṭāhir who had given him the opportunity to devote himself to the science. The topic of this work was the theory of cubic equations. Here the complete classification of cubic equations with positive roots was given, and for every type of equation the solution by means of the intersection of circumferences, equilateral hyperbolas, and parabolas was also given.

The second work is the *Sharḥ mā ashkala min muṣādarāt kitāb Uqlīdis* (Commentaries on Difficulties in Introductions of Euclid's book). It was written in Iṣfahān in 1077 and contains the commentaries to Euclid's *Elements*. The treatise consists of three *maqālas*: (1) on the theory of parallels, (2) on the theory of ratios, and (3) on the theory of compound ratios. The ideas of this work were developed further by Naṣīr al-Dīn al-Ṭūsī (1201–1274), John Wallis (1616–1703), and Girolamo Saccheri (1667–1733) (Khayyām's quadrangle is also called Saccheri's quadrangle).

Before the *Risāla fī'l-barāhīn*, Khayyām wrote the *Risāla fī taqsīm rubͨ al-dāʾira* (Treatise on Division of a Quarter of a Circle) and *Mushkilāt al-ḥisāb* (Problems of Arithmetic). In the first, a geometric problem is considered. It is reduced to a cubic equation whose solution by means of the intersection of the circumference and equilateral hyperbola and an approximate numerical solution are found. Here the problem of classifications of cubic equations is formulated. The second work is not extant, but is mentioned in the former as "the treatise on the demonstration of methods of Indians of extraction of square and cube roots and on generalization of these methods for determination of bases of square-squares, square-cubes, cube-cubes and so on as many as you like, what was not earlier." These words show that this work was devoted to the extraction of roots of *n*th degree, which was explained later in the arithmetic treatise of Naṣīr al-Dīn al-Ṭūsī. Probably in this work, as in al-Ṭūsī's treatise, "Newton's binomial formula" for $(a + b)^n$ for an arbitrary natural n was explained.

Khayyām also made many contributions to the study of astronomy and the calendar. His *al-Zīj Mālikshāhī* (Malikshah Astronomical Tables) is not extant, except for the catalog of fixed stars from this work. In Khayyām's calendar there were 8 intercalary days in 33 years. The error is 1 day in 5,000 years (in the Gregorian calendar the error is 1 day in 3,330 years). After the closing of his observatory Khayyām wrote the Persian historical treatise *Nowrūz-nāmeh* (Book on the New Year) on reforms of the solar Persian calendar and on the Persian New Year holiday Nowrūz in pre-Islamic Iran.

In the field of physics, Khayyām wrote *Fī ikhtiyāl maʾrifa miqdāray al-dhahab wa'l-fiḍḍa fī jism murakkab minhumā* (On the Art of Determination of Quantities of Gold and Silver in a Body Consisting of Them) and *Fī'l-qustāṣ al-mustaqīm* (On the Right Balance). Both of these works are included in the *Kitāb mīzān al-ḥikma* (Book of the Balance of Wisdom) of Khayyām's student ͨAbd al-Raḥmān al-Khāzinī, who worked in Marv. In this he explains a method to determine specific gravity.

Khayyām also made significant contributions to music and philosophy. He wrote a *Qaul ͨalā ajnās allatī bi'l-arbaͨa* (Speech on Genera Which are [formed] by a Quarter) on the division of a quarter into three intervals in accordance with three genera of tonality – diatonic, chromatic, and enharmonic.

In philosophy, Khayyām was a follower of Aristotle and Ibn Sīnā (Avicenna). On the question of universalia he was near to Peter Abelard. Many philosophical questions were considered in Khayyām's poetry, particularly in his well-known *Rubāͨīyāt* (Quatrains).

U

Vāgbhaṭa

Guy Mazars

In the history of medicine in India, Vāgbhaṭa is the most celebrated author after Caraka and Suśruta. It is not known at what period Vāgbhaṭa lived. We usually place him in the sixth century; he is in any case earlier than the tenth century. His identity has been the subject of unending discussion, and Indian critics hold that there was an "elder Vāgbhaṭa" in addition to "Vāgbhaṭa", grandson of the former and son of Siṃhagupta.

Several treatises of Āyurveda (Indian medicine; see article in the encyclopaedia) are ascribed to him. The most interesting are the *Aṣṭāṅgasaṃgraha* and the *Aṣṭāṅgahṛdayasaṃhitā* which are probably two different versions of the same medical text whose teachings agree generally with those of Caraka and Suśruta. However the more commonly used text of Vāgbhaṭa is the *Aṣṭāṅgahṛdayasaṃhitā* or "Compendium on the Heart of Medicine" which is considered the greatest synthesis on Āyurveda ever produced. The Chinese pilgrim Yi Jing, who stayed in India from AD 673 to 688, spoke, without mentioning its name, of a work that was then recent and that summarised the eight branches of medicine. It is thought that he was referring to the work of Vāgbhaṭa, but he may also have been referring to the *Yogaśataka*, "The Hundred Formulas", which fits Yi Jing's description perfectly. This work consists, as its name indicates, of a series of 100 therapeutic formulas distributed according to the eight theoretical divisions of Āyurveda. Its author is a certain Nāgārjuna, perhaps the same author who is reputed to have revised the *Suśrutasaṃhitā* but who is not necessarily the Buddhist patriarch of that name with whom he is nevertheless identified by the tradition.

The *Aṣṭāṅgahṛdayasaṃhitā* gives full expression to the richness and detail of the ancient tradition of Āyurveda. Numerous manuscripts of the work are extant in Indian libraries and the first printed edition appeared in 1874–1878 in Calicut. Since then, countless editions of the whole or of parts of the treatise have been published.

Vāgbhaṭa enjoyed early and widespread recognition. The *Aṣṭāṅgahṛdayasaṃhitā* was the object of numerous commentaries. The work is quoted in the *Firḍaws al-Ḥikma* or "Paradise of Wisdom" composed in AD 850 by the Persian physician 'Alī Ibn Sahl Rabban aṭ-Ṭabarī who gives a very complete summary of the āyurvedic doctrines. The *Aṣṭāṅgahṛdayasaṃhitā* was also translated into Tibetan and incorporated into the immense Buddhist Encyclopaedia of the *Tanjur* between the years 1013 and 1055.

Vākyakaraṇa

K. V. Sarma

Vākyakaraṇa, apocryphally ascribed to Vararuci, is an astronomical manual produced in about AD 1300 which was very popular in South India, especially in Tamil Nadu and the adjoining regions. The work is so called because it was a *karaṇa* (astronomical manual) which used computational tables where the numbers are expressed in mnemonic sentences (*vākyas*), phrases, and words. It is also called *Vākyapañcādhyāyī*, because it contains *pañca adhyāyas* (five chapters). Until recently, when the *Nautical Almanac* came to be used in South India for the computation of the Hindu almanac with its "five limbs" (*pañcaṅga*): the lunar day, weekday, asterism, *yoga* and *karaṇa*, the *Vākyakaraṇa* was widely used for that purpose.

The author of the *Vākyakaraṇa* hailed from Kariśaila or Kānchī in Tamil Nadu, as he himself states in his work. He also states that he based his work on the writings of Bhāskara I (AD 629), the exponent of the school of astronomy promulgated by Āryabhaṭa (b. AD 476), and the works of Haridatta (AD 683), author of *Grahacāranibandhana* and *Mahāmārganibandhana*. The *Vākyakaraṇa* was elaborately expounded by Śundararāja (AD 1500) who had contacts with the Kerala astronomer Nīlakaṇṭha Śomayāji. The date of *Vākyakaraṇa* is determined as ca. AD 1300, on the basis of epochs which the author gives for the computation of the planets.

In five chapters, the *Vākyakaraṇa* deals with all aspects of astronomy required for the preparation of the Hindu almanac. Chapter I is concerned with the computation of the sun, the moon, and the moon's nodes, and Chapter II with that of the planets. Chapter III is devoted to problems involving time, position, and direction, and other preliminaries like the precession of the equinoxes. The computation of the lunar and solar eclipses is the concern of Chapter IV. Chapter V is devoted to the computation of the conjunction of the planets, and of planets and stars.

For the computation of the moon, the *Vākyakaraṇa* employs the 248 moon sentences of the ancient astronomer Vararuci. But for the five planets, Mars, Mercury, Jupiter, Venus, and Saturn, the author himself computed 82 tables devoted to the different planetary cycles, containing, in all, 2,075 mnemonic sentences (*Kujādi-pañca-graha-mahāvākyas*).

The results obtained through the computations enunciated in the *Vākyakaraṇa* are not very accurate, going by modern standards, but they were accurate enough for the determination of auspicious times and other matters required in the routine life of orthodox Hindus. Besides, there was the saving of much time and labor in working with the simple methods advocated in the work.

Values and Science

Ziauddin Sardar

Is science value free? If "science," as Lord Rutherford is reported to have said, "is what scientists do" then scientists would have to be superhuman to keep their values out of what they do in their laboratories. We cannot clinically isolate our cultural and ethical (and through them our historical) baggage from our human activities. Values play an important part in what we select to do or not do and how we actually do it. In as far as science is a human activity, it is subject to the strengths and weaknesses of all human activities.

However, in Western tradition, up to quite recently, scientists were seen as quasireligious supermen, heroically battling against all odds to discover the truth. Also, the truths they wrestled out of nature were said to be absolute, objective, value-free, and universal. The idea of scientists as dedicated hermit-like lone researchers is now obsolete. Nowadays, science is an organized, institutionalized, and industrialized venture. The days when individual scientists, working on their own, and often in their garden sheds, made original discoveries are really history. Virtually all science today is big science requiring huge funding, large, sophisticated, and expensive equipment, and hundreds of scientists working on minute problems. As such, science has become a unified system of research and application, with funding at one end and the end-product of science, often technology, at the other.

Values enter this system in a number of ways. The first point of entry is the selection of the problem to be investigated. The choice of the problem, who makes the choice and on what grounds, is the principle point of influence of society, political realities of power, prejudice, and value systems on even the "purest" science. Often, it is the source of funding that defines what problem is to be investigated. If the funding is coming from government sources then it will reflect the priorities of the government – whether space exploration is more important than health problems of the inner city poor, or nuclear power or solar energy should be developed further. Private sector funding, mainly from multinationals, is naturally geared toward research that would eventually bring dividends in terms of hard cash. Some 80% of research in the United States is funded by what is called the "military–industrial complex" and is geared toward producing both military and industrial applications.

Subjectivity thus enters science in terms of what is selected for research which itself depends on where the funding is coming from. But values also play an important part in what is actually seen as a problem, what questions are asked and how they are answered. For example, cancer rather than diabetes may be seen as a problem even though they may both claim the same number of victims. Here both political and ideological concerns, as well as public pressure, can make one problem invisible while focusing attention on another. Moreover, if, for example, the problem of cancer is defined as finding a cure then the benefits of the scientific research accrue to certain groups, particularly the pharmaceutical companies. But if the function of scientific research is seen as eliminating the problems of cancer from society, then another group benefits from the efforts of research: the emphasis here shifts to investigating diet, smoking, polluting industries, and the like. Similarly, if the problems of the developing countries are seen in terms of population, then research is focused on reproductive systems of Third World women, methods of sterilization, and new methods of contraceptives. However, if poverty is identified as the main cause of the population explosion then research would take a totally different direction: the emphasis would have to shift to investigating ways and means of eliminating poverty, developing low cost housing, basic and cheap health delivery systems, and producing employment generating (rather than profit producing) technologies. The benefits of scientific research would go to the Third World poor rather than Western institutions working on developing new methods of contraceptives and companies selling these contraceptives to developing countries. Thus both the selection of problems and also their framing in a particular way are based on value criteria.

It can be legitimately argued that these factors are external to science, that within science, the scientific method ensures neutrality and objectivity by following a strict logic – observation, experimentation, deduction, and value-free conclusion. But scientists do not make observations in isolation. All observations take place within a well defined theory. The observations, and the data collection that goes with them, are designed either to refute a theory or provide support for it, and theories themselves are not plucked out of the air. Theories exist within paradigms – that is a set of beliefs and dogmas. The paradigms provide a grand framework within which theories are developed and make sense, and observations themselves have validity only within specific theories. Thus, all observations are theory laden, and theories themselves are based on paradigms which in turn are burdened with cultural baggage. All of which raises the question: can there ever be such things as value-neutral "objective facts"? Studies of scientists working in laboratories have shown that the scientific method, by and large, is a myth. Researchers seldom follow it in the linear fashion that exists in the text books. Neither do they ascertain new "facts" suddenly out of the blue. And the same holds true of the laws of nature they are supposed to be discovering. It appears that scientists do not actually "discover" laws of nature; they manufacture them. Scientific knowledge advances by a process of manufacturing which involves thousands and thousands of workers assembling "facts" which through peer review and other procedures end as description or laws of nature.

Value judgments are also at the very heart of a common element of scientific technique: statistical inference. When it comes to measuring risks, scientists can never give a firm answer. Statistical inferences cannot be stated in terms of "true" or "false" statements. When statisticians test a scientific hypothesis they have to go for a level of "confidence". Different problems are conventionally investigated to different confidence-limits. Whether the limit is 95 or 99.9 per cent depends on the values defining the investigations, the costs, and weight placed on social, environmental, or cultural consequences. In most cases, the importance given to social and environmental factors determines the limits of confidence and the risks involved in a hazardous scientific endeavor. For example, when a chemical plant is placed in an area with an aware and politically active citizenry the risks are worked out to a high level of confidence. However, when one is located in an area where the citizens themselves are ignorant of the dangers and do not command political power, the confidence levels are much more relaxed. The people of Bhopal and Chernobyl know this to their cost.

But it is not just in its institutions and method that science is value laden. The very assumptions of science about nature, universe, time, and logic are ethnocentric. In modern science, nature is seen as hostile, something to be dominated. The Western "disenchantment of nature" was a crucial element in the shift from the medieval to the modern mentality, from feudalism to capitalism, from Ptolemaic to Galilean astronomy, and from Aristotelian to Newtonian physics. In this picture, "Men" stand apart from nature, on a higher level, ready to subjugate and "torture" her, as Francis Bacon declared, in order to wrestle out her secrets. This view of nature contrasts sharply with how nature is seen in other cultures and civilizations. In Chinese culture, for example, nature is seen as an autonomous self-organizing entity which includes humanity as an integral part. In Islam, nature is a trust, something to be respected and cultivated and people and environment are a continuum – an integrated whole. The conception of laws of nature in modern science drew on both Judeo-Christian religious beliefs and the increasing familiarity in early modern Europe with centralized royal authority, with royal absolutism. The idea that the universe is a great empire, ruled by a divine logos, is, for example, quite incomprehensible both to the Chinese and the Hindus. In these traditions the universe is a cosmos to which humans relate directly and which echoes their concerns. Similarly, while modern science sees time as linear, other cultures view it as cyclic as in Hinduism or as a tapestry weaving the present with eternal time in the Hereafter as in Islam. While modern science operates on the basis of either/or Aristotelian logic (X is either A or non-A), in Hinduism logic can be fourfold or even sevenfold. The fourfold Hindu logic (X is neither A, nor non-A, nor both A and non-A, nor neither A nor non-A) is both symbolic as well as a logic of cognition and can achieve a precise and unambiguous formulation of universal statements without quantification. Thus the metaphysical assumptions of modern science make it specifically Western in its main characteristics.

The metaphysical assumptions of modern science are also reflected in its contents. For example, certain laws of science, as Indian physicists have began to demonstrate, are formulated in an ethnocentric and racist way. The Second Law of Thermodynamics, so central to classical physics, is a case in point: due to its industrial origins the Second Law presents a definition of efficiency that favors high temperatures and the allocation of resources to big industry. Work done at ordinary temperature is by definition inefficient. Both nature and the non-Western world become losers in this new definition. For example, the monsoon, transporting millions of tons of water across a subcontinent is "inefficient" since it does its work at ordinary temperatures. Similarly, traditional crafts and technologies are designated as inefficient and marginalized. In biology, social Darwinism is a direct product of the laws of evolutionary theories. Genetic research appears to be obsessed with how variations in genes account for differences among people. Although we share between 99.7 (unrelated people) and 100 per cent (monozygotic twins) of our genes, genetic research has been targeted toward the minute percentage of genes that are different in order to discover correlations between genes and skin color, sex, or "troublesome" behavior. Enlightened societal pressures often push the racist elements of science to the sidelines. But the inherent metaphysics of science ensures that they reappear in new disguise. Witness how eugenics keeps reappearing with persistent regularity. The rise of IQ tests, behavioral conditioning, fetal research, and sociobiology are all indications of the racial bias inherent in modern science.

Given the Eurocentric assumptions of modern science, it is not surprising that the way in which its benefits are distributed and its consequences are accounted for are themselves ethnocentric. The benefits are distributed disproportionally to already over-advantaged groups in the West and their allies elsewhere, and the costs disproportional to everyone else. When scientific research improves the military, agriculture, manufacturing, health, or even the environment, the benefits and expanded opportunities science makes possible are distributed predominantly to already privileged people of European descent, while the costs are dumped on the poor, racial and ethnic minorities, women, and people located at the periphery of global economic and political networks. Science in developing countries has persistently reflected the priorities of the West, emphasizing the needs and requirements of middle class western society, rather than the wants and conditions of their own society. In over six decades of science development, most of the Third World countries have nothing to show for it. The benefits of science just refuse to trickle down to the poor.

But modern science is not only culturally biased toward the West: it represents the values of a particular class and gender in Western societies. As feminist scholars have shown, science in the West has systematically marginalized women. Women, on the whole, are not interested in research geared toward military ends, or torturing animals in the name of progress, or working on machines that put one's sisters out of work. But more than that, even the least likely fields and aspects of science bear the fingerprints of androcentric projects. Physics and logic, the prioritizing of mathematics and abstract thought, the so-called standards of objectivity, good method and rationality – feminist critique has revealed androcentric fingerprints in all. This is the case, for example, in the mechanistic model of early modern astronomy and physics, in modern particle physics, and in the coding of reason as part of ideal masculinity. The focus on quantitative measurements, variable analysis, impersonal and excessively abstract conceptual schemes is both a distinctively masculine tendency and one that serves to hide its own gendered character. Science has tried to hide its own masculine nature in other ways, by, for example, making women themselves objects in scientific investigation. It was not entirely accidental that sexology became a major science at the same time as women in the West were fighting for the vote and equal rights in education and employment. A number of studies have shown that scientific work done by women is invisible to men even when it is objectively indistinguishable from men's work. Thus, it appears that neither social status within science nor the results of research are actually meant to be neutral or socially impartial. Instead, the discourse of value-neutrality, objectivity, and social impartiality appears to serve projects of domination and control.

The history of science bears this out. The evolution of Western science can be traced back to the period when Europe began its imperial adventure. Science and empire developed and grew together, each enhancing and sustaining the other. In India, for example, European science served as a handmaiden to colonialism. The British needed better navigation so they built observatories and kept systematic records of their voyages. The first sciences to be established in India were, not surprisingly, geography, and botany. Western science progressed primarily because of the military, economic, and political power of Europe, focusing on describing and explaining those aspects of nature that promoted European power, particularly the power of the upper classes. The disinterested commitment of European scientists to the pursuit of truths had little to do with the development of science. The subordination of the blacks in the ideology of the black "child/savage" and the confinement of the white women in the cult of "true womanhood" emerged in this period and are both by-products of the Empire. While the blacks were assigned animal and brutish qualities the white women were elevated and praised for their morality. While the blacks were segregated and enslaved, the women were placed in narrow circles of domestic life and in conditions of dependency. Racist and androcentric evolutionary theories were developed to explain human behavior and canonized in the history of human evolution. The origins of Western, middle class social life, where men go out to do what men have to do, and women tend the babies and look after the kitchen, are to be found in the bonding of "man-the-hunter"; in the early phases of evolution women were the gatherers and men went out to bring in the beef. Now this theory is based on little more than the discovery of chipped stones that are said to provide evidence for the male invention of tools for use in the hunting and preparation of animals. However, if one looks at the same stones with different cultural perceptions, say one where women are seen as the main providers of the group – and we know that such cultures exist even today – you can argue that these stones were used by women to kill animals, cut corpses, dig up roots, break down seed pods, or hammer and soften tough roots to prepare them for consumption. A totally different hypothesis emerges and the course of the whole evolutionary theory changes.

Thus the cultural, racial, and gender bias of modern science can be easily distinguished when it is seen from the perspective of non-Western cultures, marginalized minorities, and women. The kinds of questions science asks when seeking to explain nature's regularities and underlying causal tendencies, the kinds of data it generates and appeals to as evidence for different types of questions, the hypotheses that it offers as answers to these questions, the distance between evidence and the hypothesis in each category, and how these distances are traversed – all have the values of white middle class men embedded in them. Put simply, this implies a relativism in science as in any other sphere of human knowledge. However, most scientists do not look kindly toward criticism, or sociological, philosophical, historical, and anthropological studies which highlight science's value laden nature. Relativism is anathema to scientists: many believe that they are engaged in revealing nature's absolute truths. Science, they argue, is special and different from any other body of knowledge: it is counter-intuitive and rarely a matter of common sense. Some propagandists for science have even suggested that the entire discipline of the sociology of knowledge is a conspiracy of the academic left against science.

The idolization and mystification of science, the insistence on its value neutrality and objectivity, is an attempt not only to direct our attention away from its subjective nature but also from the social and hierarchical structure of science. Whenever we think of "the scientists" we imagine white men in white coats: the sort of chaps we see in advertisements for washing power and skin care preparations, standing in a busy laboratory behind a Bunsen burner and distillation equipment telling us how the application of science has led to a new and improved soap or cold cream. This view of scientists is not far from reality. True power in science belongs to white, middle-aged men of upper classes. Everyone else working in science – women, minorities, black men, white men of lower classes, and third world researchers – are actually basically rank and file laboratory workers. The social hierarchy within science by and large preserves absolute social status, the social status scientific workers hold in the larger society. The people who make decisions in science, who decide what research is to be done, what questions are going to be asked, and how the research is going to be done are a highly selective, tiny minority. These people have the right background, the contacts to get the necessary appointments, and then further contacts to secure funding for their research projects. The actual execution of scientific research, the grinding and repetitive laboratory work, is rarely done by the same person who conceptualizes that research; even the knowledge of how to conduct research is rarely possessed by those who actually do it. This is why the dominant (Western) social policy agendas and the conception of what is significant among scientific problems are so similar. This is why the values and agendas important to white, middle class men pass through the scientific process to emerge intact in the results of research as implicit and explicit policy recommendations. This is why modern science has become an instrument of control and manipulation of non-Western cultures, marginalized minorities, and women.

Even if we were to ignore all other arguments and evidence, the very claim of modern science to be value-free and neutral would itself mark it as an ethnocentric and a distinctively Western enterprise. Both claiming and maximizing cultural neutrality is itself a specific western cultural value: non-Western cultures do not value neutrality for its own sake but emphasize and encourage the connection between knowledge and values. By deliberately trying to hide its values under the carpet, by pretending to be neutral, by attempting to monopolize the notion of absolute truth, Western science has transformed itself into a dominant and dominating ideology.

Varāhamihira

K. V. Sarma

Varāhamihira, who flourished in Ujjain, in Central India, during the sixth century, was perhaps the greatest exponent of the twin disciplines of astronomy and astrology in India. A master of all three branches of the disciplines astronomy, natural astrology, and horoscopic astrology, he was a prolific writer whose works number more than a dozen, some of which are extensive.

Varāhamihira was born in Kāpitthaka, present-day Kapitha, in Uttar Pradesh, known also as Saṇkāśya and mentioned as a great center of learning by the Chinese pilgrim Yuan Chwang as Kah-pi-t'a. He was the son of Ādityadāsa, and a Śakadvīpī brāhmaṇa of the Maga sect who were sun worshippers. His renown has caused several legends, both Hindu and Jain, being woven round his birth, growth, and predictive propensity. A legend has it that he was one of the nine luminaries of the court of King Chandragupta II Vikramāditya, but the definitively known date of Varāhamihira goes against this identification. Varāhamihira's patron has now been identified as King Mahārājādhirāja Dravyavardhana who ruled over Ujjain during the middle of the sixth century. Varāhamihira also possessed great poetic talents, so that some of the later rhetoricians have extracted verses from his writings to illustrate poetic qualities. Indeed, the fame of Varāhamihira has even induced several places in India to be named after him.

It is a characteristic of Varāhamihira that he produced larger and shorter versions of most of his works. His only work on astronomy is *Pañcasiddhāntikā* (The Five Basic Texts), being a redaction of select topics from the basic texts of five earlier astronomical schools: *Vāsiṣṭha, Paitāmaha, Romaka, Pauliśa*, and *Saura*, in 443 verses, in the form of a work manual.

Varāhamihira wrote several astrological works. In his *Bṛhajjātaka* (Large Horoscopy), also called *Horāśāstra* (Science of Hours), in 25 chapters, containing about 400 verses, he treated all conceivable topics on the subject. This work has been a model for later works and is highly popular even today. In this work, Varāhamihira exhibits his understanding of Greek astrology and employs the Sanskritized forms of a number of Greek terms. His *Laghujātaka* (Shorter Horoscopy) is an abridged form of the previous work. On marriage and the prediction of auspicious times to marry, Varāhamihira composed two works: the *Bṛhadvivāha-paṭala* (Larger Treatise on Marriage), and its abridgement, the *Svalpa-vivāha-paṭala*. Prognostication on military marches and domestic journeys was treated in three works: *Bṛhad-Yoga-Yātrā* (Larger Course on Expedition), in 34 chapters, *Yoga-yātrā* (Course on Expedition), and *Svalpa-yātrā* (Shorter Course on Expedition).

On natural astrology, Varāhamihira's major work is the *Bṛhatsaṃhitā* (Large Compendium), the *Svalpa-saṃhitā* (Shorter Compendium), and *Vaṭakaṇikā* (Short Text), the last two known only through profuse quotations in later works. The *Bṛhatsaṃhitā*, in 106 chapters, is an encyclopedic compendium on numerous subjects relating to life and nature, such as physical astronomy, geography, calendar, meteorology, flora, portents, agriculture, economics, politics, physiognomy, engineering, botany, industry, zoology, erotica, gemology, hygiene, omens, and prognostication on the basis of asterisms, lunar days, etc. A fund of material on applied science, physical observation, and deduction on the basis of statistics and experimentation went into the production of this work which is perhaps unparalleled in the early literature of the world. Varāhamihira's works, set in precise terminology and in graceful language, have been models for writers of later times, not only in astronomy and astrology, but in other disciplines as well.

Vaṭeśvara

K. V. Sarma

Vaṭeśvara (b. AD 880), son of Mahadatta, hailed from Ānandapura or Vaḍanagar, in Gujarat in Western India, a great center of learning of the time. The *Vaṭeśvara-siddhānta*, composed by Vaṭeśvara in AD 904, is one of the largest and most comprehensive works on astronomy, a work which throws much light on the theories, methodologies, and processes of Indian astronomers until the tenth century AD. It was one of the standard works for the study of the discipline, and several of the rules enunciated by Vaṭeśvara were adopted by later astronomers like Śrīpati (eleventh century) and Bhāskara II (b. 1114). It is also noteworthy that the Persian scholar and polymath al-Bīrūnī, who came to India early in the eleventh century, referred to

V

Vaṭeśvara and cited some of his views in his own writings. Vaṭeśvara also wrote a *Karaṇasāra*, known only through references, and a *Gola* (Treatise on Spherics), which is available only in part, the existing portion dealing with a graphical demonstration of planetary motion, construction of the armillary sphere, spherical rationale, and the nature of the terrestrial globe.

The *Vaṭeśvara-siddhānta*, in 1326 verses set out in eight chapters, deals exhaustively with all aspects of Indian astronomy, besides bringing in a number of methodologies, short-cuts, and interpretations. Chapter I, on mean motion, depicts the astronomical parameters, time-measures, calculation of the aeonary days, and computation of the mean planet in three ways: using parameters, using a cut-off date, and by the orbital method. The longitude corrections to be applied to mean longitude are also dealt with here. Chapter II, on true motion, deals with the corrections to be applied to the mean planet by the epicyclic theory, by the eccentric theory, and by the use of the R sine table. Different items relevant to the almanac are also set out here. Chapter III treats in detail the three problems in diurnal motion. Chapters IV and V deal with the computation of lunar and solar eclipses. Chapter VI treats of heliacal rising, chapter VII with elevation of lunar horns, and chapter VIII with the conjunction of celestial bodies.

Again, a unique feature of the work, found in no other work, consists in Vaṭeśvara's dividing each chapter into small sections earmarked for different topics. Unlike other works, rules are formulated for all possible alternatives of a theory or practice. It is interesting that sets of problems are posted at the ends of chapters for the student to solve, as in textbooks of modern days. The work is also characterized by the depiction of novel interpretations and methodologies practised by early Indian astronomers. In fact, the invaluable service done by Vaṭeśvara through his *Siddhānta* lies in his presenting the achievements of the Indian astronomers from the sixth century to the tenth century and methodically documenting the astronomical knowledge of the Hindus during those centuries.

Veterinary Medicine in India

Guy Mazars

A tradition of veterinary therapy developed very early in India. Modelled on Āyurveda,[1] this veterinary medicine is known through a specialised literature which tells us about the ancient methods of prevention and treatment of animal diseases in India before the advent of modern medicine (Mazars 1994, 1999). Some of these treatments, as yet little known outside India, are still practised today.

The surviving texts are concerned mainly with the treatment of horses and elephants. The legends incorporated in these texts present knowledge regarding the medical treatment of horses and elephants as being directly revealed by the gods. This may be explained partly by the need to provide veterinary medicine with an origin similar to that of the Āyurveda, which is also presented as 'divinely inspired' knowledge. In fact, veterinary medicine developed from the ayurvedic model over the seven or eight centuries which preceded the Christian era. It is also known, from the inscriptions of Aśoka in the middle of the third century BCE, that this Buddhist sovereign opened hospitals for animals (Schneider 1978). Unfortunately, no actual veterinary records exist from this period.

The oldest Sanskrit text of veterinary medicine that has come down to us is a treatise entitled *Aśvāyurvedasiddhānta* (Complete System of Āyurveda for Horses) attributed to a certain Śalihotra (Mukhopadhyaya 1926: 356–99). This text is probably dated before the tenth century. There also exists a Tibetan version written at the beginning of the eleventh century, and the text was translated into Persian in the fourteenth century. Subsequently, various treatises on horses and diseases of horses were composed. The principal surviving ancient text dealing with elephant medicine is a treatise which tradition ascribes to Pālakāpya, a legendary person, also known as Dhanvantari, the father of Indian surgery (Mukhopadhyaya 1926: 400–24). The text, entitled *Hastyāyurveda* (The Āyurveda of Elephants), is divided into four parts. The first part is devoted to general diseases, the second to localised and minor ailments, the third to surgery and anatomy, and the last to the feeding of elephants and medicinal preparations. The text cannot be earlier than the Middle Ages, but it contains medical concepts and veterinary practices of long standing.

Specialised treatises are not the only source of existing information. The treatises of the Āyurveda sometimes refer to veterinary treatments. Thus, a passage

[1] Āyurveda is a holistic medical system that is explained in detail in an article in the encyclopaedia.

in *Carakasaṃhitā* (Siddhisthāna, XI, 20–26) contains a list of ingredients for preparing enemas for elephants, camels, cattle, horses, and sheep (Sharma 1983: 665–6). There is also information on animal-borne human diseases. For example, rabies is described under the name *jalatrāsa* (hydrophobia) in the *Suśrutasaṃhitā* (from the beginning of the Christian era) (Bhishagratna 1963: 733–734). A small collection of therapeutic formulae from the eleventh century, the *Rājamārtaṇḍa,* contains a chapter devoted to the treatment of domestic animals (Misra 1966: 108–112). In addition, certain nonmedical texts contain information on the veterinary art. Some information regarding veterinarians is contained in the *Arthaśāstra* (Kangle 1960–1963), a treatise of government traditionally attributed to Kauṭilya, possibly an adviser to Chandra Gupta (313–289 BCE), founder of the Maurya dynasty.

In the field of anatomy the knowledge of the ancient Indian veterinarians seems to have been quite extensive and is more accurate than that concerning the human body. Observations on animal carcasses were favoured by sacrifices, wars and other events. As regards the physiopathological conceptions in the Sanskrit texts of veterinary medicine, they are those of classical Āyurveda. According to these conceptions the health of both animals and human beings depended on the normal balance and proper functioning of the three vital principles: wind (*vāyu*), bile (*pitta*) and phlegm (*kapha* or *śleṣman).* Generalised diseases and localised ailments were linked to imbalance in these principles, or disturbances in the secondary forms of a single principle. Consequently, the name *tri-doṣa* (three troubles) was given to this triad of elements. Disorders in the functions governed by the three principles were themselves the outcome of multiple causes related to behaviour, character, feeding, mode of life, season, habitat, etc. In particular, equestrian texts often invoked a nutritional cause: food poisoning or unbalanced feeding.

Classification of diseases was broadly similar to the principles applied to human diseases but differed in detail, except in certain cases such as the diseases common to horses and human beings. The various conditions were classified according to their supposed origin, their apparent seat, or the nature of the symptoms. In the first category were diseases attributed to a disorder of wind, bile, etc. Diseases of wind were the most numerous, totalling 76 in the case of elephants. In the second category were diseases of the skin and the head, chest pains, etc. The last category notably included fevers, which were differentiated into many types according to the involvement of wind, bile or phlegm, and according to the other symptoms which accompany hyperthermia. One of the most detailed classifications is that of the *Hastyāyurveda*, which placed diseases of elephants in two broad groups. The first group was endogenous diseases, including diseases attributable to disturbance of the vital principles. The second group was exogenous diseases, mainly traumatic injuries: accidental wounds and those caused by weapons, bites of wild animals, etc. However, identification of the diseases listed in the texts is often uncertain, and sometimes even impossible, due to a lack of information. The passage in the *Suśrutasaṃhitā* (Kalpasthāna, VII, 43–50) concerning rabies was translated as follows: ‘The bodily Vāyu in conjunction with the (aggravated) Kapha of a jackal, dog, wolf, bear, tiger, or any other such ferocious beast affects the sensory nerves of these animals and overwhelms their instinct and consciousness. The tails, jaw-bones and shoulders of such infuriated animals naturally droop down, attended with a copious flow of saliva from their mouths. The beasts in such a state of frenzy, blinded and deafened by rage, roam about and bite each other’. The text states further: ‘A person bitten by a rabid animal barks and howls like the animal by which he is bitten, imitates it in many other ways and, bereft of the specific functions and faculties of a human subject, ultimately dies…’ (Bhishagratna 1963: 733–734).

As in Ayurvedic medicine, prevention occupies an important place. It is based on general and dietary hygiene. The texts lay stress on the layout and maintenance of cowsheds and stables, the different sorts of foods with their qualities and their drawbacks, as well as on the dietary rules to be observed. They underline the importance of moderation in food for domestic animals and enumerate the undesirable consequences of an excess of food. Furthermore, like Āyurveda, the veterinary tradition of India emphasises methods aimed at strengthening the general state of health, notably by the use of tonics and stimulants (*rasāyana*), and aphrodisiacs (*vājīkaraṇa*). The latter, containing various constituents, which have been the object of little study to date, augmented the strength of enfeebled animals and those of poor virility. Sanskrit texts provide various recipes for potions enabling a stallion to mate repeatedly. The *rasāyana* (elixirs of long life) were prescribed to strengthen animals and were recommended for preventing all sorts of illnesses. For example, a mixture based on aconite and three sorts of peppers was recommended for extending the life span of horses. The following plants were main constituents of such elixirs: *Asparagus racemosus* Willd., *Emblica officinalis* Gaertn., *Terminalia bellerica* Roxb., *Terminalia chebula* Retz., *Tinospora cordifolia* (Willd.) Miers and *Zingiber officinale* Rosc. Buffalo horn was also a valued ingredient.

Veterinary medicine is theoretically divisible into eight branches, corresponding to the eight divisions set out in the Āyurveda. Thus, hippiatry was divided into general surgery, general therapeutics, ophthalmology and otorhinolaryngology, care of foals (corresponding to

Ayurvedic paediatrics), toxicology, fortifying treatments, demonology, and the use of aphrodisiacs. Apart from surgical operations, therapy consists most often in the administration of medicinal preparations by different routes and under different forms: mixtures of powders, decoctions, electuaries, ointments… The texts lay stress quite particularly on the benefits of using medicinal oils and butters in food, in external applications and in enemas. We find also various procedures intended to make horses sweat, techniques of cauterisation, bloodletting and several kind of enemas. Procedures of inducing sweating, eight in number, are indicated for treating the sicknesses due to wind and to phlegm. The texts of hippiatry distinguish between violent and mild sudorifics. They specify the method of use of each by indicating the most favourable periods for this type of treatment. Cauterisations with red-hot irons are reserved for the treatment of diseases which neither dietary regimes, nor errhines, nor enemas have been able to cure. The sites to be cauterised and the form and the number of the cauterisations vary according to the case to be treated. We are well informed also on the post-operative care and the precautions to be taken in the days that follow the operations. We note also the use of caustics. As far as bloodletting is concerned, the treatises on hippiatry tell us also about the contra-indications and indicate the food for 'reconstituting' the blood and the remedies to be administered if the bloodletting is substantial.

Since India gained its independence in 1947, the Indian Government, recognising the services rendered by traditional medicine, has given a new impetus to these practices. The study and practice of traditional medicine has been regulated, and training is provided at present by a large number of schools with associated hospitals and care centres. This movement has also benefited traditional veterinary medicine, which has undergone a revival.

Several Indian laboratories now produce preparations from ancestral recipes, which are packed under modern conditions and sold throughout India for the treatment of domestic animals. Traditional formulations produced on a large scale include tonics, fortifiers and digestives, as well as antiparasitic and antifungal products. Many of these medicaments are polyvalent, due to the multiplicity of ingredients used in their preparation. For example, a company in Bangalore produces a stomachic and tonic containing 59 ingredients. This preparation is recommended for treating digestive disorders (anorexia, dyspepsia, constipation, etc.) in cattle, sheep, goats, horses and dogs, in doses proportional to the size of these animals. The principal ingredients of vegetable origin include the following: *Aegle marmelos* Corr., *Aquilaria agallocha* Roxb., *Butea monosperma* (Lam.) Kuntze, *Centratherum anthelminticum* Kuntze, *Curcuma longa* L., *Ferula narthex* Boiss., *Moringa oleifera* Lam., *Piper longum L.*, *Punica granatum* L., *Terminalia bellerica* Roxb., *Terminalia chebula* Retz., *Tinospora cordifolia* (Willd.) Miers, *Trachyspermum ammi* (L.) Sprague and *Zingiber officinale* Rosc. These ingredients were prescribed in Ayurvedic medicine for their aperitive, digestive, stomachic, carminative or anthelmintic properties. Another example is provided by an ointment against sprains and sores, prepared from the following plants: *Abrus precatorius* L., *Acorus calamus* L., *Celastrus paniculatus* Willd., *Hyoscyamus niger* L., *Moringa oleifera* Lam., *Nardostachys jatamansi* D.C., *Ocimum sanctum* L., *Saussurea lappa* C.B. Clarke and *Vitex negundo* L. To these oils are added extracts of seven other plants: *Anacyclus pyrethrum* D.C., *Colchicum luteum* Baker, *Curcuma amada Roxb*., *Gloriosa superba* L., *Litsea sebifera Pers*., *Myrica nagi* Thunb. and *Nerium odorum* Sol. All these plants have been investigated and their active principles are known. *Nardostachys jatamansi* is often combined with oil of henbane (*Hyoscyamus niger*) as an antineuritic. *Ocimum sanctum* and *Vitex negundo* are used as wound dressing. In traditional medicine, the root of *Curcuma amada* is applied to contusions and sprains. Extract of *Colchicum luteum* is applied externally as an analgesic (Mazars 1994: 449).

Many plants of the Ayurvedic pharmacopoeia have been shown to be effective. Listing and identification of the many plant species used in preparing remedies described in the ancient medical literature was accomplished during the 1970s. Veterinary applications of these medicines were also taken into account. Despite the increase in chemical and pharmacological studies in recent years, there is still much to be done in evaluating the resources of India with regard to medicinal plants, which may be useful in veterinary medicine.

Long before the development of veterinary medicine in the West, the veterinary tradition of India had already originated a large body of theoretical and practical knowledge. Before the advent of modern medicine and the discovery of antibiotics, the knowledge of veterinarians in the West was not much further advanced than that of their Indian predecessors. Certain aspects of ancient veterinary medicine in India, neglected or unknown in the West, merit deeper study. These include the ideas regarding the feeding of animals, preventive methods and cauterisation techniques. Also of interest are the medicines derived from plants which are still in use, as well as those medicines which are no longer used but are fully described (together with indications, and mode of preparation and administration) in ancient texts.

Veterinary Medicine in Iran

H. Tadjbakhsh

Veterinary medicine was known in Iran from the time of the Sassanids (212–652 AD). They treated useful animals with drugs or surgical operations. Veterinarians received wages and each animal had a tariff of its own. General practice was the same in human and veterinary medicine, but the duties of physicians and veterinarians have been separate since the Sassanid reign. Administration of a vast country like Iran with so many poor roads required the transport of army equipment to meet public demands. Domesticated draught animals, such as horses, mules, and camels, received special attention. This called for a disciplined veterinary organization. Veterinarians, especially army veterinarians, were celebrated figures in the country. In ancient Iran there were more veterinary clinics than in other countries of the world at that time (Elgood 1974).

There were almost 70 important offices in the Sassanid government. One of the important offices related to horses and other domesticated animals and was administered by the head equerry (*Akhvarbadh* = *Hwrpt*). This head equerry was one of the key figures responsible for animal husbandry and veterinary organization. Another senior official was *Nhcyrpt* (master of the hunt) who was responsible for hunting affairs, breeding and treating hunter animals and birds or wildlife in modern-day terminology. The head equerry and master of the hunt had other responsibilities that sometimes were nonveterinary, but they were aware of veterinary affairs and sometimes they were veterinarians. There were also second-class equerries who offered veterinary services especially to the horses. Ruminants were not paid equal attention. Experienced shepherds or rustic veterinary technicians treated them.

In the Sassanid reign, Becheshk Sotur (Quadruped Doctor) was the one in charge of treating army horses. He was an important figure. According to *Mafatih al-Olum* (Keys to Sciences) of Kharazmi, there were almost seven forms of writing for registering accounts and provisions. *Dad Dafira* was used for writing justice rules and *Ahur Hamar Dafira* was used for keeping the accounts of stables and horses. These forms of writings belonged to seven secretariats or ministries, and one of them was the Ministry of Stables that dealt with livestock affairs.

During the Sassanid era, veterinary medicine was separated from human medicine as a specialized art and profession, although it shared its roots with medicine. These two fields were unified to some extent in post-Islam Iran and some of the celebrated physicians of the time wrote independent treatises on veterinary medicine or allocated chapters of their medical collections to this field. Meanwhile, some of these people researched animal diseases and treated horses and birds of prey. However, there were certain people who practiced solely in the veterinary field during all the centuries since Islam. They had their own special clinics or offices and did not practice human medicine.

In Iran of the Islamic period and in other Muslim countries, they recognized the similarities between medicine and veterinary medicine, but at the same time they believed in their independence from each other. The most important duty of veterinarians was in treating and preventing equine diseases, because this animal was important to them in war and in performing the Hajj.

The Iranian state-run veterinary system was divided between the head equerry organization and the Investigation Department. The head equerry's organization was a well-organized department that took care of the health of animals in state studs and stables. In addition to these, the investigating departments inspected the affairs of the stables, and cookery inspectors were busy with food hygiene inspection. Documents suggest that veterinarians headed all these practices.

Private veterinarians had their own special veterinary associations and veterinary regulations. They treated horses, mules, asses, and camels in their clinics or in their cottages. When there were disputes between the animal owner and veterinarian, the master of veterinarians or chief of the veterinary association intervened and reported the result to the market inspector for a final ruling. The final arbiter was the market inspector who also administered tests and issued certificates for veterinarians.

In the ancient Iranian and eastern world, people attached special significance to breeding and treating horses and birds of prey but not to ruminants. Perhaps one reason was the abundance of these animals, as there were vast ranges and low population densities. There was little need for treating ruminants, because these animals were religiously permitted meat, and so people slew them at times of probable danger and ate them if they were not rotten. But there was a dire need for horses, for protecting state borders, consolidating the ruler's power, and carrying food and ammunitions. People did not eat the flesh of these animals; they had to cure them.

The places and routes for keeping or trafficking horses, mules, asses, and camels, was chiefly in the cities, suburbs or probably in the studs, but the ruminants were kept in villages and suburban areas. Veterinarians and educated physicians depended on urban life and tended to work in developed areas. This is why, until the early twentieth century, rustic eastern communities had little access to physicians and veterinarians. People had to learn medicine, veterinary medicine, and midwifery through their own experiences.

Iranian Veterinarians and Hippologists

Fakhr Modabber, in his *Adab al-Harb*, alludes to a hippologist and horse master named Muhammad Marzban, who visited Hadjaj, the ruler of Iraq, in the company of Ibn Qerryah (d. 703) a great man-of-letters and horse master in Iraq. He said, "Marzban is the mother and father of this profession." That means that he is a master in hippology (the study of the horse). Ibn Qerryah was himself a student of Marzban. Marzban thought there was a direct link between the color and efficiency and physiological properties of horses. "A dark bay horse is good for war, a gray or white horse is good for plains, a piebald horse is good for hunting, a dun horse is good for visiting friends and walking, a colored horse is suitable for playing polo and a grass-green blond horse is the best for escaping." He then gave anatomical characters of the horse in great detail and in beautiful words. Marzban is a famous Iranian name meaning chief. According to the *Adab al-Harb* the title of horse master was attributed to a veterinarian skilled in raising horses.

The most renowned and best learned of the veterinarians of the first three centuries was Ibn Akhi Hozam, the chief of veterinary medicine and stock-breeding affairs of Motavakkel of Abbasids (d. 861). He was Iranian by birth and his father and uncles were all skilled veterinarians. His magnum opus lists the names of some notable veterinarians such as Abu Qoreh and Muhammad ibn Suleyman ibn Ghaleb, who was apparently a relative of Hozam.

Pre-Mongolian Veterinary Organization of Iran

In the administrative chart of Iran, the grand vizier or prime minister was second in administrative rank to the Sultan. The viziership was for some time hereditary in some families such as Jeyhani, Balami, and Nezam al-Mulk. There were almost ten tribunal courts in the office of the grand vizier, such as the Inspector's Court (*Divan Moshref*), *Mohtasseb*, *Saheb-e Barid* (which was responsible for mounted couriers), and the equerry office. This last was responsible for breeding horses, news dispatches, taking care of the pony express, veterinary medicine and inspecting livestock and food.

Breeding horses and training them for war were the chief responsibilities of the head equerry. The Moshref was in charge of animal health, administering veterinarians' affairs and other affairs related to animals. The inspectors' organizations and a number of other Seljukids administrative systems were in force until the end of the nineteenth century but changes occurred in the course of time in the nature and sometimes in the names and terms.

Any business, including medicine and veterinary medicine, had a chief of its own. These people, in addition to observing professional rules and regulations, were in charge of collecting taxes from the businessmen and industrialists. In some cases they defended the rights of their guild members against the government.

During the Ghaznavid dynasty, the head equerry was a distinguished title in the administrative system and army. It was the same during the Seljukid's reign. Ibn Abi Toba Nassir al-Din Kharazmi (killed 1135), the Shafiite vizier of Sultan Sanjar, was born in Merv and entered the court of the sultan upon learning the sciences of the time. He was skilled in inspecting the stables and food hygiene service and in veterinary medicine and stockbreeding. He served for a short time in the beginning. Twice he was appointed minister of Sultan Sanjar but was jailed following a conspiracy of one of the emirs of the Sultan and died in prison. He was a patron of scientists and authors. Ekhtiar al-Din Kushli was one of the head equerries at the court of Kharazmshah who fought in the Mongolian raid on Bukhara and was killed.

Veterinarians and Their Activities (10–13th Centuries)

Veterinarians carried out their duties in the state veterinary service or as private practitioners. Some had veterinary offices. Veterinarian masters and sometimes master physicians, skilled in both medicine and veterinary medicine, wrote books on horses and their diseases. Abū Rayḥān Bīrūnī in his *Al-Tafhīm*, writing about of astrology from a Persian point of view, cited various professions such as veterinary medicine and its relation with the stars. Fakhr al Din Rāzī in his *Djama al-Olum* in the *Treatise on Al-Baytara* wrote about the activities of the veterinarians.

Physicians Writing About Veterinary Medicine

Many physicians of Iran and the world of Islam have written about veterinary medicine and zoology. Ibn Baytar belonged to a family of veterinarians living in Andalusia. He wrote a book entitled *Kashf al-Vayl fi Marefat al-Amraz al-Khayl* (Detection of Afflictions in Horse Diseases) that showed his thorough knowledge of veterinary.

Veterinary Organization in the Mongolian and Timurid Periods

Veterinary medicine was a common profession during the 13–15th centuries. Many books were written on veterinary medicine and zoology in Persian or in Arabic, either independently or as chapters of general books. Some of these books are extant. They provide solid evidence about the education of veterinarians during this period.

In *Rozat al-Djannat*, falconers' treating birds of prey was explained. It says that Shams al-Din Kart, king of Herat who fell captive to Abaqa Khan, cured his beloved falcon in 1277. According to Shah-Qoli, the head equerry, Tamerlane was so skilled in veterinary medicine that he performed necropsy to find out reasons for the horse's death. Ibn Arabshah (1436) writes that Tamerlane, in his military march to Damascus, sent a number of veterinarians, physicians, industrialists, and scientists to Samarkand. Veterinary medicine was also a profession of high value in other states of the world of Islam. Ibn Monzer wrote the book *Kamel al-Sanaatayn* at the request of Nasser al-Din Qalavoon, King of Egypt (fourteenth century). Al-Malek al-Mujahed, King of Yemen and Arabia, wrote *Al-Aqval al-Kafia* on veterinary medicine.

Veterinary Organization in the Safavid Era (16–18th Centuries)

Like previous periods, veterinary and animal husbandry affairs in the reigns of the Safavids, Afsharids, and Zands were a chief responsibility of the head equerry, hunt master and inspectors' court. A number of veterinarians cured sick animals in clinics or in the field. The head equerry was an army commander and the third most important person in the nation. According to Mirza Sami'a, he had thousands of men working under him, ranging in rank from second-class head equerry, *Baytar* (veterinarian), inspector of technical and financial affairs, horseshoe maker, cattle breeder, horse groom, technicians, and saddle keepers and setters. There were many organizations related to animal husbandry and wildlife organizations such as organizations for grooms (*Mehtarbashi*), head of cattle or horses (*Ramedarbashi*), head of herd of cows and sheep, grooms of mules and camels, grooms of lions, grooms of dogs, snake handlers, etc.

Investigation Department (*Eshraf*) or Veterinary Organization of the Safavids

There was an organization called *Eshraf* that supervised all governmental affairs both before and after the time of the Safavid reign. Part of their responsibility concerned the supervisors of the quadrupeds, camels, kitchens, etc. They also inspected the stables and studs of the horses and other animals producing food and dairy, and checked on taxes levied on animals. According to Chardin and Mirza Sami'a, the inspectors paid attention to the health of the camels and horses. Special officers studied animal corpses to identify causes of death.

There was a ministry called the head equerry organization that administered the affairs and inspected the health of the horses and other animals. Another organization called Eshraf, coequal with a modern-day veterinary organization, was responsible for treating and supervising the technical and financial affairs of the animal breeding sector of the monarchy. The chief of this organization in the time of the Shah Abbas II was Nezam al-Din Ahmad.

The Veterinary Profession in the Time of the Safavids

Medicine and veterinary medicine in the Safavid reign inherited the traditions and knowledge of the Timurid dynasty.

Amin Ahmad Razi in *Haft Eqlim* (Seven Continents), written in 1601, mentions Romia or Constantinople, where there was a bazaar of veterinarians. There were special bazaars or marketplaces of veterinarians in other Muslim nations. Safavid kings, especially Shah Abbas I and II, paid special attention to breeding horses. At the order of Shah Abbas II, many veterinary books were written. Shah Abbas I used to go to the stables and inspect horseshoes; he knew about horse diseases and means of treatment.

Some of the great veterinarians of the period, as mentioned in the available manuscripts, treatises of falconry and hippology, are Hashemi, Saffi, Nezam al-Din Ahmad, Mohebali Khan Khas, Majd al-Din bin Muhammad Shafi, Abdullah Khan Bahador, Arab Najafi and a few others.

Department of Veterinary Medicine in the Time of Qajars

In the time of Qajarids (until almost 1921), the department of veterinary medicine was part of the head equerry organization. The head of this department was the deputy chief of the head equerry organization.

Veterinary medicine was an independent job, and although many people contributed to it, as they did with humans, the veterinarians only were responsible for treating animals, especially horses. Another veterinarian and hippologist of the time of Nasser al-Din Shah was Haji Muhammad Qoli Beyq Turkman.

Since the middle of the Qajarid reign, Iranian veterinary medicine gradually lost prestige compared with Western veterinary science. Unfortunately Iranian ancient veterinary medicine completely fell into oblivion, as did medicine. They could still use bleeding medicine, which is similar to Chinese acupuncture in some of its aspects, and use medicinal herbs observing rules of sanitation.

The political and social instability of Iran in the nineteenth century affected veterinary medicine. "Almost all of the veterinarians and the majority of the peddler physicians are Turkman. Veterinary is confined to a few diseases of horse and mule, and after cauterization and drainage they use purgatives. Since there are no sanitary police, sanitation measures, or veterinary establishments, deadly diseases have killed a greater number of animals making the tribal people poor" (Polak 1865).

Comte de Gobineau, in his trips to Iran in 1855–1856, mentioned peddler veterinarians but did not attach significance to them. The fact that they said Iranian horses and sheep were the best of these animals in the world, shows that Iranian veterinary medicine must have been well developed.

The first faculty of veterinary medicine in Iran was founded in 1933 in Tehran and the German Dr. Damon, the French Le Louet and seven other German and Hungarian professors plus Iranian army veterinarians who had graduated from France, taught in this faculty.

In between the years 1926 and 1931, 15 civil students left Iran for France to study veterinary medicine. They studied at various schools of veterinary medicine and some of them passed specialized courses. On their return they taught at the Tehran Veterinary Faculty and they replaced foreign professors.

Veterinary Practice in Nepal

Krishna Kaphle

Nepal is a landlocked country lying between 80°04′ and 88°12′ East longitude, and 26° 22″ and 30° 22′ North latitude. It extends over an area of 147,181 sq. Km with an average east to west length of about 885 kms. The north–south width is not uniform and it varies from a maximum of 245 kms to a minimum of 145 kms. Politically and geographically Nepal is located between two giant nations, China on the North and India on the South. The country has three patterns of landscape: the mountains, mid hills and the plains. The plains and hills with valleys are the major sites of human settlement and major cities are located here. Nepal has a population of slightly over 23.15 million. Though the political boundary of Nepal was restructured by the British colonial era occupation in the Indian subcontinent, isolation from the world was almost total until the mid twentieth century. This isolation affected Nepal both in positive and negative ways. On the positive side, when ancient cultures and traditions were safeguarded, progress made elsewhere was slow to be. This has happened with veterinary medicine in Nepal. The tradition of ethno-veterinary medicine awaits revival, while the copied concept of western veterinary system has limited use. This short article describes the historical and contemporary situation of organized veterinary services in Nepal.

Agriculture, the only source of livelihood for most of the Nepalese people, is not only an occupation but also a way of life. About 85.80% of the population live in rural areas and earn their living from farming, whereas only 6% live in cities and are involved in non-farming occupations. Livestock is an indispensable part of agriculture, which provides employment to over 80% of the country's population. Livestock is now looked upon with great expectations as playing a great part for the development of the nation, and attempts are made to boost production. The efforts are seeing results, with farmers turning to commercial livestock farming which in the past was just a satellite component of agriculture, basically intended for manure production and domestic consumption (APP 1995). However, in recent years dairy and poultry farming are turning into industries making a large contribution to the national gross domestic product (NGDP). Planners have identified three main ecological components of Nepal to implement various development activities (Carson and Sharma 1992). The three ecological zones of Nepal have different distributions of livestock numbers, as illustrated in Table 1, with higher numbers in the mid

hills. Almost every household in the villages has an animal. The percentage of households keeping livestock and birds by region is shown in Table 2. The status of livestock population by ecological region according to the reports of 1989/99 as in Fig. 1 shows poultry population higher in the hills, but commercial poultry farms are located in plains and valleys. Poultry farming is the one most successful story of Nepal's transition of animal husbandry (Kaphle 2000).

Situation of Animal Health Care Systems in Different Ecological Zones

The mountainous regions, ranging in altitude from 4,877 to 8,850 m above sea level, covers 35% of the country. This area is less developed and has only 6.97% of the country's population. The mountainous topography makes it virtually cut off from other parts of the country; transportation is by foot and on the back of yaks and ponies, although there are some airstrips with irregular schedules. This region has the highest number of sheep, yaks, and chengras (hill goats). The population and economy of the mountain region is based on trade with Tibet and tourism, as well as support from animal husbandry. The demographic distribution is mostly people like the Tamang, Rai, Limbu, Gurung, and Sherpas famous for their mountaineering skills. The pastoral communities have been employing unique ethno-veterinary practices since time memorable. This region has 16 districts and each district headquarters has a government veterinary hospital. A veterinarian supported by junior technicians and some other staff mans these hospitals; their prime duty is to give outdoor health care support, monitor disease outbreaks, and implement and monitor government policy in the related sector. Private practitioners are out of question in these situations where farmers consult veterinarians as a last resort. Traditional veterinary practices like herbal medicines and bloodletting are used for simple cases; however parasites, foot rot, plant poisoning, and microorganism related diseases are commonly encountered and they respond poorly to traditional medication. The region, with its rough topography and difficult communication networks, has a slow economic growth with livestock, tourism, and herb collection as the only path to greater income. Tourists in this area provide markets for local livestock products. Lack of proper technical and financing institutions with difficult communication and marketing opportunities can be viewed as the obstacles for livestock development. However if successfully harnessed, high altitude animal husbandry will flourish well and the standard of living of the people in this region can be raised substantially.

The hilly region comprises 42% of the land area and 43.97% of the total population of the country. This region has some major cities. The livestock health diagnosis aspect of this region is also controlled by the government veterinary hospitals with only a few private organizations and practitioners concentrated in the main cities. The government disease diagnosis mechanism is more concentrated in this region with the location of central veterinary laboratory and major regional laboratories. These laboratories are mainly concerned with large animal diseases and only the central veterinary lab at Tripureshwor, Kathmandu has some facilities for poultry disease diagnosis. This region is making progress, as roads linking to district headquarters make the flow of goods and people easy and convenient. There are some milk collecting, chilling and processing centres in this region that are boosting dairy farming. As the genetic makeup of the livestock is being improved by upgrading with pure breeding males distributed by government or use of artificial insemination, so is the demand for commercial feed and health care attention. There was an early setback when pure Holstein and Jersey breeds of dairy cattle were introduced, as they could not receive optimum management and nutrition, they developed gynecological and metabolic disorders. Thus government policy has been to see that the genetic make up remains at 62.5% so that increased productivity and the thriving ability of the animals are enhanced at the same time. The law forbids cross breeding of some indigenous cattle, buffalo and sheep species to preserve genetic composition. Poultry, goat and swine farming are gaining popularity with the effort of private entrepreneurs, government poverty elimination schemes and support of non-government organizations. Co-operatives and villagers' group formations, mainly for women, are encouraged, and facilities for providing loans are adopted to initiate cottage industry and livestock farming. Similarly leasehold forestry projects are implemented in some parts of the region which aim to provide the community a means to use and protect the forest and to help small unit livestock development and at the same time conserve the forest.

The plain region or the terai is the major centre for buffaloes, cattle and poultry. The terai and inner terai accommodate almost 50% of the nation's population. The plains are densely populated, and migration from the hills and abroad are using up the fertile agricultural land for settlement purposes. There are private practitioners along with the government animal health care system; farmers are educated to a certain extent and like to be in touch with veterinarians for consultation. The supply of western drugs is also bountiful, with many veterinary drug stores located in this region. Farmers sometimes seek the support of the Indian Veterinary Research Institute (IVRI) and other institutions in India as they have advanced technology for disease diagnosis. This region is developing fast and the livestock industry is making rapid progress. The extreme summer temperature, marketing facility and occasional disease outbreaks are hampering the established poultry and dairy industry. Lack of proper regulation in line with consumers health and public health concerns compounding with transportation to markets in cities is a major hurdle too (Joshi and Oleson 1999).

History of Animal Disease Diagnosis Pattern in the Country

The government and the private sector both provide animal disease diagnoses. The history of the animal health care system in Nepal is not old; previously traditional health care practices dominated.

The first recorded establishment of a veterinary dispensary at Kathmandu was in the year 1950 B.S (beginning of the nineteenth century in the Julian calendar). In 1940 the present Central Veterinary Hospital was established at Tripureshwor, Kathmandu. The period from 1943 to 1957 saw the establishment of ten veterinary hospitals in different district headquarters of the country. In the year 1964 AD14 zonal and 19 district veterinary hospitals (DVH), 21 veterinary dispensaries and 18 veterinary check posts were established. With the addition of 25 veterinary hospitals in 1981 and 16 in the year 1984, the country had a government veterinary hospital at all headquarters in the 75 districts. There are five regional laboratories set up to speed up disease diagnosis with special programs for epidemiologically important diseases. There are also regional training centres training farmers on recent techniques of management and primary health care, while selected candidates are given preliminary training to work as auxiliary village animal health workers (LSMP 1993).

The private sector involvement in this regard is mostly concentrated with the poultry and dairy industry as they are commercially practiced. The share of the private sector in poultry health care is around 60%, while the government jointly handles the remaining section. The central veterinary hospital and laboratory at Tripureshwor is the most refereed one in the country. It is equipped with modern laboratory facilities and manned by skilled personnel. The district veterinary hospitals and their sub-centres are limited in providing this service. Pet animal veterinarians are based in Kathmandu having their private clinics, while many government vets also have private practices outside their office hours. The military have five veterinarians in their service to take care of stud farms while in the police a single veterinarian looks after the health of the dog squad.

Most commonly encountered communicable diseases of livestock in Nepal are peste des petits ruminants (PPR), rinderpest, foot and mouth disease (FMD), rabies, brucellosis, haemorrhagic septicaemia, black quarter, anthrax, mastitis and swine fever. Infectious bursal disease, Newcastle disease, Marek's disease, infectious bronchitis, chronic respiratory disease and coccidiosis are common poultry diseases. Fasciolosis and infertility are other common diseases of dairy animals (Mathema and Joshi 2000).

Traditional Animal Health Care Practices in Nepal

Ethnoveterinary medicine describes the traditional practices used by livestock raisers all over the world to keep their animals healthy and productive, and to treat and control diseases (Mathias 1996).

Ethnoveterinary medicine is an effective means to safeguard the health of animals and the interests of the poorer communities around the world. Poverty and remoteness prevent access to conventional animal health care. To counter this, traditional animal health care has been reborn and now plays a greater role in the lives of poor farmers. Traditional animal health care is cheap, readily available and safe for poor livestock keepers, but lack of information on its scientific validity, lack of policy support, and the negative attitude from modern veterinary practitioners has until recently limited its promotion. Ethnoveterinary practice in Nepal is a blend of Tibetan and Indian practices. The medicinal plants in the Himalayan range that stretches across the whole length of the country and the diverse ecological conditions have provided suitable grounds for traditional animal health care practices. Adding to that process was the late exposure of the nation to the outside world (~1950s), the fact of having no history of colonization and snail-paced industrialization of animal farming. All these shielded traditional animal health care knowledge from being overwhelmed by Western medicine. However, in recent times, with poultry and dairy farming using advance rearing practices, ancient ways are frowned upon. The consequences of Western medicine misuse in animal production from elsewhere in the world has yet to be learned by the Nepalese industrialists. However, there is a rising awareness to preserve ancient knowledge in the art of traditional animal health care. Encouraging the use of ethnoveterinary medicine, or preventing misuse of Western practices, is part of an important policy for the non-governmental agencies working with their international counterparts in the field of poverty elimination. Restrained if not total ban in use of chemical pollutants in the communities around the vicinity of wildlife reserves is gaining momentum. Nepal is at a crossroads, deciding whether to subsist in the safe ancient way of animal health treatment or to industrialize animal husbandry to meet the growing food challenge and leave the consequences for generations to come.

Animal husbandry is rapidly changing from the traditional system to an industrial form. There are ample opportunities for its growth, as it is deemed the only option for over 80% of the national population. The small farmers relying on age-old traditional agricultural practices will not be in a position to compete with cheap products from India, China and elsewhere. Tourism, a major source of foreign exchange, is also seeing its worst days with international terrorism. Thus with no other clear options available, livestock enterprise is making progress. The animal health care system is also making progress, but the speed is much slower. With around 400 veterinary doctors and slightly more junior technicians, the country is not able to meet its requirements. The Institute of Agriculture and Animal Science (IAAS), the only agriculture college, has started to produce around 25 veterinarians per year which is partially filling the growing demand. The lack of infrastructure and other factors makes the level of education below the global level. With advanced training to faculties and infrastructure development the future of the veterinary school at IAAS is bright. Research activities with the limited resources available have been a trademark of IAAS, and it will only get better. Some works on buffaloes (Dhakal and Salman 1992) and poultry (Kaphle 2000) have to great extent helped the farmers gain confidence and will to invest and upgrade their animal production activity. Commercialization of animal husbandry and increase in farmer's awareness will make animal health care an important factor, as can be evident from the hustling activities around IAAS, Chitwan. Thus, the nation needs to set up strict guidelines and regulations in implementing the policy of animal health care practices. At the same time, making service available to all the community at an affordable price and in a sustainable way should be the priority of the government (Linet al. 2003). There should be a mandatory flow of information regarding epidemiological reporting from the field level to the concerned authorities and a rapid execution of appropriate steps. The reckless import of vaccines from foreign countries and reckless use of medicines like antibiotics and hormones should be controlled and a governing authority should look into the necessary criteria. Emphasis should be given to the preparation of vaccines from the local strain of pathogens within the country. Basic laboratory facilities should be developed for disease diagnosis in all district veterinary hospitals. The school of veterinary medicine and animal science at Institute of Agriculture and Animal science should be strengthened. The manpower development program as well as faculty and student research activities should be initiated. One research area that has the potency to be of great use not only to Nepal but to the whole world is the research of medicinal herbs for various animal healthcare Hence, in spite of the huge resources in form of traditional ethnoveterinary practice and bountiful medicinal plants, Nepal still needs to pull up its socks to learn from success stories of others, Taiwan being an ideal example (Kaphle et al. 2006).

Wang Chong

Fabrizio Pregadio

The Chinese philosopher Wang Chong was born in Shangyu (modern Zhejiang) in AD 27. According to his biographies, he came from a poor family and devoted most of his life to teaching, but also held minor posts in the state administration. Later he retired to compose the work by which we know him today, the *Lunheng* (Balanced Discussions). This extensive treatise in 85 chapters (one of which is lost) was completed in AD 82 or 83, about 15 years before the author's death.

Wang Chong lived about one century after Confucianism had emerged as imperial ideology. In this process, the "rationalist" and socially minded philosophy taught by Confucius had been integrated with cosmological doctrines extraneous to the letter of his teaching. The school of though: to which Wang Chong belonged propounded, on the contrary, a reading of the classic texts devoid of esoteric interpretations.

In his work, Wang Chong analyzes, with a strongly skeptical and even iconoclastic spirit, ideas expounded by earlier thinkers and beliefs shared by the people of his time (e.g., the recourse to divination, the belief in ghosts, the search for physical immortality, and the idea of an individual spirit that persists after death). Wang's typical procedure is to bring out contradictions in the anecdotes and accounts that he first quotes in full. Through an exemplary logical method, he often does not hesitate to take as true one detail that he has previously refuted, if this may serve to invalidate a different detail.

Philosophically, Wang Chong maintained that all phenomena arise spontaneously, and are not expressions of Heaven's will. Related to this was his opposition to the belief in prophecies and portents, through which Heaven was deemed to legitimate or censure rulers, and assent to or dissent from their policies. While Wang Chong rejected the blend of these forms of esoterism with Confucianism, he fully accepted the metaphysical and cosmogonical doctrines traditionally placed under the egis of Daoism. In this way, he anticipated some of the new developments in post-Han Confucianism.

Wang Xiaotong

Ang Tian Se

There is no record of Wang Xiaotong's early life nor his year of death. We estimate that he flourished from the second half of the sixth century to the first half of the seventh century. The little we know of him is from a memorial he presented to Emperor Gaozu of the early Tang dynasty (AD 618–906) on the occasion of the submission of his mathematical text to the throne. The mathematical text he submitted was known as *Jigu Suanjing* (Continuation of Ancient Mathematics) and was subsequently selected as a prescribed text for imperial examinations in AD 656. In his memorial, which is now attached to his mathematical text, he mentioned that he had studied mathematics from a very young age. He studied the *Jiuzhang Suanshu* (Nine Chapters in Mathematical Art) thoroughly and had great admiration for Liu Hui's in-depth commentary on the text. On account of his mathematical acumen, Wang Xiaotong was appointed as an instructor in the Department of Mathematics, and later as a deputy director in the Astronomical Bureau. In AD 623, together with Zu Xiaosun, an official of the board of Civil Office, he was appointed to re-examine the adequacy of the current calendar.

Composed by Fu Renjun and promulgated for use since AD 619, the calendar had on several occasions been found to be losing accuracy in the predictions of solar and lunar eclipses. Based on the structure of the Kaihuang calendar composed by Zhang Bin of the previous Sui dynasty (AD 581–618), Wang Xiaotong criticized the adoption of the *ding shuo* method and the precession of equinoxes in the current calendar. The critique sparked a 3-year debate between Fu Renjun and Wang Xiaotong, culminating in a submission of a proposal for rectifications consisting of more than 30 errors to the Astronomer-Royal. This does not necessarily reflect Wang Xiaotong's achievement in calendrical science. On the contrary, his view of adhering to the traditional model without taking into consideration the uneven apparent motion of the sun and the precession of equinoxes in calendrical calculations was a retrogressive one. His contribution lies in mathematics.

From the late Han dynasty in the first century onward, Chinese mathematicians were familiar with quadratic equations and their solutions. But it was not until the appearance of the *Jigu Suanjing* that equations of the third degree were presented. They arose because of the special needs of engineers, architects, and surveyors of the Sui dynasty. There are 20 practical problems in the *Jigu Suanjing* consisting of a problem (No. 1) on calendrical calculation, six problems (Nos. 2–6 and 8) on engineering constructions, seven problems (Nos. 7, 9–14) on the volume of granaries, and six problems (Nos. 15–20) on right-angled triangles. The solutions of most of the problems involved equations of the third degree. For example, problem No. 15 says: "There is a right-angled triangle, the product of two sides of which is $706\frac{1}{50}$ and whose hypotenuse is greater than the first side by $36\ \frac{9}{10}$. Find the lengths of the three sides." Wang's solution amounts to the formation of the cubic equation as follows:

$$x^3 + \frac{S}{2}x^2 = \frac{p^2}{2S'}$$

where *P* is the product and *S* the surplus. As a matter of fact, most of the problems in the last three categories involved the use of the equation

$$x^3+Ax^2 + Bx = C,$$

where *A*, *B*, and *C* are positive numbers. Wang Xiaotong provided the rules for the arrangement of the equations in all these problems but did not explain the procedure for arriving at such equations. He also did not discuss the equations of higher degrees. Numerical equations of degrees higher than the third degree occurred first in the work of Qin Jiushao around AD 1245.

Wang Xichan

Liu Dun

Wang Xichan (July 23, 1628–October 18, 1682), sometimes known by his literary name, Xiao' an, was from Wujiang, Jiangsu province, China. When he was sixteen, the Ming Dynasty (1368–1644) collapsed and the door to social advancement through the imperial examination system was suddenly closed. After several unsuccessful suicide attempts, Wang abandoned his hopes for an official career and became one of the most distinguished Ming loyalists in his area. He seems to have survived by teaching literature, although his main interest was in astronomy, which he had studied on his own since his youth. Despite both poverty and illness, Wang made unremitting efforts to observe the heavens, calculate planetary positions, and write about astronomy.

Beginning in the late Ming Dynasty, Western astronomy had been disseminated intermittently into China, and subsequently it was adopted by the Qing (1644–1911) rulers. In 1646, a number of astronomical treatises, earlier written or translated by Western missionaries serving the Ming court, were published together by order of the Qing emperor under the general title *Xi Yang Xin Fa Lin Shu* (Astronomical Treatises of the New Methods of the West, 1646). Unfortunately, the "New Methods" introduced by the missionaries did not reflect the advanced achievements of modern astronomy in seventeenth-century Europe. Even worse, there were some defects and internal contradictions, especially in the parts dealing with the cosmological theory of planetary motions.

In his *Xiao An Xin Fa* (New Method of Xiao'an, completed in 1633), Wang argued that all of the Western techniques could be reconciled with classical Chinese schemes and therefore could be used to revive the lost traditional astronomy of ancient China. By means of trigonometry, which was not used in traditional Chinese astronomy and mathematics, Wang created a series of methods to calculate ecliptic positions and predict planetary occultations. Forty years later, in his *Wu Xing Xing Du Jie* (On the Angular Motion of the Five Planets, completed in 1673), Wang criticized the contradictions in the *Xi Yang Xin Fa Li Shu* and proposed instead his own model of the planetary motions which differed from both the Aristotelian–Ptolemaic and the Tychonic geostatic models. In addition, he attributed the planetary motions to an attractive force radiating from the outermost moving sphere (i.e., the *primum mobile*). Wang also suggested that there were planets inside the orbit of Mercury which might account for the appearance of sunspots. All of these thoughts, along with some of his methods, were heuristic and had considerable influence on his successors.

In general, Wang was one of a few pioneers who responded to Western science by conscientiously studying it; he was open to critical acceptance of its major ideas when suitably reinterpreted for use in seventeenth-century China. Nevertheless, some of Wang's arguments were clearly exaggerated. For instance, he assumed that Western astronomy had in fact originated in ancient China, but such claims were due to his radical nationalism and traditional reluctance to recognize any innovations from the Westf.

Water in India: Spiritual and Technical Aspects

K. N. Sharma

The subject of water has been treated spiritually, philosophically, cosmologically, medically, and poetically in the ancient Indian literature comprising the *Veda(s)*, *Brāhmaṇa(s)*, *Upaniṣad(s)*, *Purāṇa(s)*, and *Smṛti(s)*. Water is regarded as the primordial substance from which the universe came into being. Water occupies the highest place amongst the five basic elements of nature, called *pañcamahābhūta*. These are: *ākāśa* (ether, substratum, space), *vāyu* (air), *teja* or *agni* (radiation, energy, or fire), *āpa* (water), and *pṛthivī* (Earth). These five *bhūta* constitute the physical universe. Air is said to have been generated from space, fire from space, water from fire, and earth from water. Fire and water, which are said to pervade the entire universe, have a close nexus and are believed to possess procreative powers (Narayana, 1995). The tripartite nature of *agni* has been connected with the three forms of water – celestial, atmospheric, and terrestrial, called by different synonyms in Sanskrit so that they have characteristics and attributes responsible for different cosmic, atmospheric, or terrestrial actions.

In the social and religious traditions and culture of India since Vedic times, water has enjoyed a unique status. Water is the single most important tool/mode for performing daily religious rituals or social ceremonies and a primary means for purification of body and soul in Hindu culture.

From birth till death in a Hindu society, water remains an essential ingredient in performing all rituals.

Vedas and Their Chronology

The content of the Vedas is astonishingly scientific although much of it remains to be interpreted correctly. Knowledge of the Vedas is synonymous with knowledge of the science and metaphysics of creation.

The time periods of various Vedas are as follows:

Ṛgveda	6500–3100 BCE
Sāma Veda	3100–2500 BCE
Yajurveda	2500–2000 BCE

An organic chronological development in India from 6500 BCE has been suggested (Frawley 1994), taking into account both Vedic literature and recent archaeological findings:

6500–3100 BCE	Pre-Harappan (early Rigvedic period)
3100–1900 BCE	Mature Harappan (period of four Vedas)

The Myth of Aryan Invasion

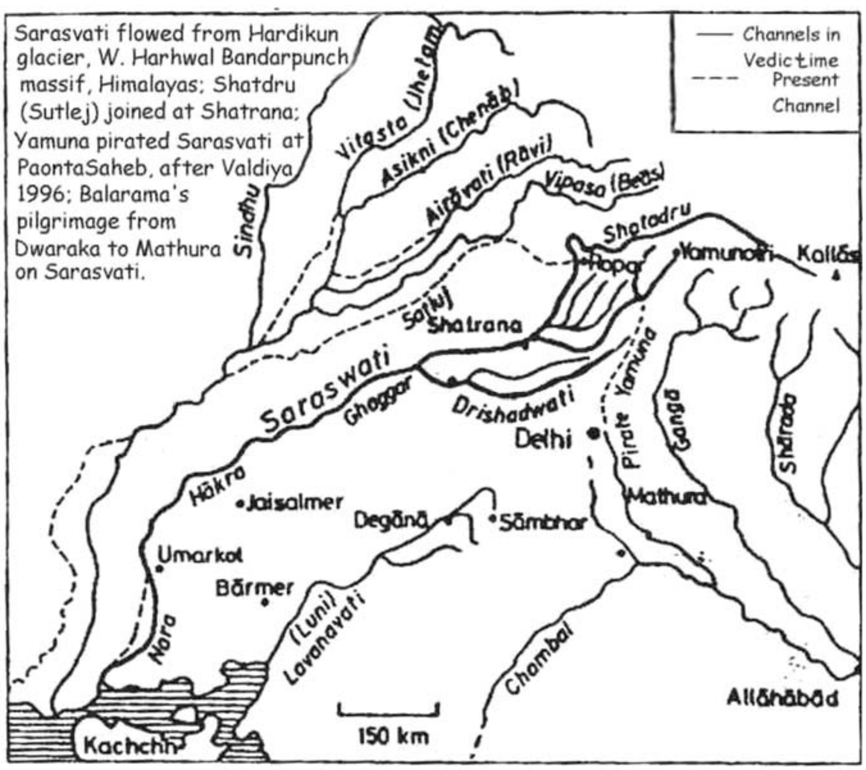
For the past hundred years or so, Mortimer Wheeler's hypothesis of "swashbuckling, horse-riding light-skinned Sanskrit-speaking people, called Aryans, coming to Northwest India from Central Asia or Central Europe in about 1500 BCE and razing to the ground the

W

highly urbanised Harappan civilization," was accepted. These so-called Aryans were supposed to have composed the Vedas over the centuries, spread Sanskrit, and built the Ganges civilization. According to this concocted theory, these "invading" Aryans destroyed the Harappan civilization which had been flourishing there for over a millennium and whose habitants were Dravidians.

References in the *Ṛgveda* point to India's being a land of mixed races. The *Ṛgveda* also states, "We pray to Indra to give glory by which the *dasyu* will become *āryan*." This statement confirms that to be an *āryan* was not a matter of birth. While the word *dasyu* meant uncultured and illiterate, *āryan* meant noble, well-cultured people. It is also used in the context of addressing a gentleman or lady (*āryaputra*, *āryakanya*). Nowhere in the Vedic literature is this word used to denote race or language. This was a notion of Max Mueller who, in 1853, introduced the word *ārya* into the English language to refer to a particular race and language. When challenged, he refuted his own theory later in 1888.

Jean-Francois Jarrige, Director of the National Museum of Asiatic Arts of Paris, the excavator of the famous proto-historic site of Mehrgarh (Pakistan) and member of the French Academy, carried out extensive work over the last 30 years in the Indian subcontinent and showed that the excavations revealed artifacts from a much older civilization of the Sarasvatī era (Pushkarna, 1998). The civilization included metropoli like Mohenjodaro, Harappa, Ganveriwala (in Pakistan), and Dholavira and Rakhigarhi; towns like Lothal, Surkotda, Banawali, and Kalibangan, and villages like Kunal, in India. The excavations exposed not just these towns or cities, but also an earlier settlement beneath it, and an even earlier one further down. Figure 1 is a map indicating rivers in the time of Sarasvatī, and Fig. 2 shows the spread of Harappan and Sarasvatī civilization sites. According to archaeologist Bisht, before the mature Harappan stage, many regional cultures like Amri, Kot Dirji, Kalibangan, Dholavira, and Lothal had coalesced into the cultural umbrella of Harappa. They were bound by common economic compulsions and cultural ethos. The site of Dholavira is an excellent example of a Harappan city that tells the history of Early, Transition, Mature, Late, and Final Phases of the Indus-Sarasvatī (Harappan) civilization in India (ca. 3500–1700 BCE). The site spreads over an area of 100 ha. This compares well with the size of Harappa, Rakhigarhi, or Ganveriwala. All these evidences have proved the invasion theory to be unfounded, showing that the Aryans were the native Indians, having an unbroken chronology of civilization.



Water in India: Spiritual and Technical Aspects. Fig. 1 Course of erstwhile Sarasvatī River (Kalyanaraman, 1998).

Place of Water in Ancient Indian Literature

Water has enjoyed a high status in the social and religious context of ancient Indian culture. It was an essential medium for performing daily religious rituals and social ceremonies and a primary means for purification of body and soul. Even after thousands of years, the rivers in India, especially Gangā (the Ganges) and Yamunā are considered divine and capable of purifying a sinful body with a few drops of water. *Agni* (fire) is said to be born from the waters. Both water and fire are said to possess procreative powers. Water is considered a mother while fire is seen as a prolific generator (Narayana, 1995).

The place of water as a life-giving and life-sustaining element was very high. It was considered a cleanser of sins and regarded as a divine protector. It was addressed by various names – nectar, honey, ambrosia – in prayers. Stagnant water was considered unhygienic.

> The cosmic energy is the generator of the universe, the embryo of waters the leader of humans, most virile defender of the human race, it remains ever illuminated by its own radiance and it provides sustenance for its beloved progeny (RV 3.1.12).

> Water verily is *arka* (essence). What was there as froth of water hardened and it became earth (the embryonic state of the Universe).

> Earth was formerly water upon the ocean of space (*Atharvaveda* AV 13.6).

Water or the water element had many names in the Vedas and other Vedic literature. It has more than 100 synonyms. These are not synonyms in a strict sense, since they have been used to indicate their different forms/states and contexts. Some names for water are: *Ambu*, *toyam*, *vāri*, *jalam*, *āpaḥ*, *bheṣajam*, *udakam*, *salila*, *madhu*, *ambha*, *ghṛtam*, and *kṣīram*. For example, *salila* is a technical word in the Vedas which is different from *āpaḥ* as mentioned in a mantra from *śatapatha brāhmaṇa* (11.1.6.1) which says that *āpaḥ*

W

were indeed *salila* earlier. *Salila* is the primordial state of the universe, when there is nothing manifest.

Nature's Forces as Deities

In Vedic cosmology, *pṛthivī* (earth) symbolizes the material base and *dyāvā* (heaven) symbolizes an unmanifested immortal source. Together and between them, they form the *paryāvaraṇa* (environment).

The seer praises Heaven and Earth (*dyāvā pṛthivī*) by saying, "You are surrounded, Heaven and Earth, by water; you are the asylum for water; imbued with water; the augmenters of water; vast and manifold; you are the first propitiated in the sacrifice; the pious (people) pray to you for happiness, that the sacrifice may be celebrated. May Heaven and Earth, the effusers of water, the milkers of water, dischargers of the functions of water, divinities, the promoters of sacrifice, the bestowers of wealth, of renown, of food, of male posterity, combine together." RV 6.70.4–5.

Water stands for all the elements, because it is really a combination of water, fire, and earth, according to the tripartite creation of the gross elements. Water is all pervading.

Waters Regarded as Having Medicinal Powers

The Vedas also mention the medicinal qualities of water. *Ṛgveda* hails water as the reservoir of all curative medicines and of nectar. It invokes water which the cows drink and offers oblations to deities presiding over the flowing waters:

> O Water, which we have drunk, become refreshing in our body. May you be pleasant to us by driving away diseases and pains – O divine immortal waters (RV 63).

The *Atharvaveda* describes various sources of waters and describes them as dispellers of diseases and as more healing than any other healer. The scriptures believed that waters avert pain that they are restorative and curing. Wherever waters fall on earth, plants grow. The hymns in *Atharvaveda* (6.23, 24, 57) hail water as possessing medicinal qualities. A hymn in *Atharvaveda* prays for waters to cure "incurable" diseases.

The scriptures, *Saṃhitā(s)*, also regard water as capable of alleviating pain. "O water which we have drunk, become refreshing in our body. Be pleasant to us by driving away diseases and pains."

The *Ṛgveda* (1.161.9) states, "There exists no better element other than water which is more beneficent to the living beings. Hence waters are supreme." Varuna is a cosmic ruler as well as the deity that dwells in waters, presides over them and is prayed to for granting strength and virility from waters.

Another hymn from the *Ṛgveda* says,

> Ambrosia is in the waters, in the waters are medicinal herbs; therefore, divine (priest), be prompt in their praise. Soma has declared to me, 'all medicaments, as well as Agni, the benefactor of the universe, are in the waters': the waters contain all healing herbs. Waters, bring to perfection all disease-dispelling medicaments for (the good of) my body, so that I may long behold the Sun. Waters, take away whatever sin has been (found) in me, whether I have (knowingly) done wrong or have pronounced imprecations (against holy men) or (have spoken) untruth. I have this day entered into the waters – we have mingled with essence – Agni, abiding in the waters, approach, and fill me, thus (bathed), with vigour (RV 1.23. 19–23).

According to *Taittareyī Āraṇyaka* (7.3.2), Agni is an antecedent form and sun the later. Water is a compound and lightning is the joining element. *Maitreyī Saṃhitā* further divides water into three places – sky, earth, and mid-region.

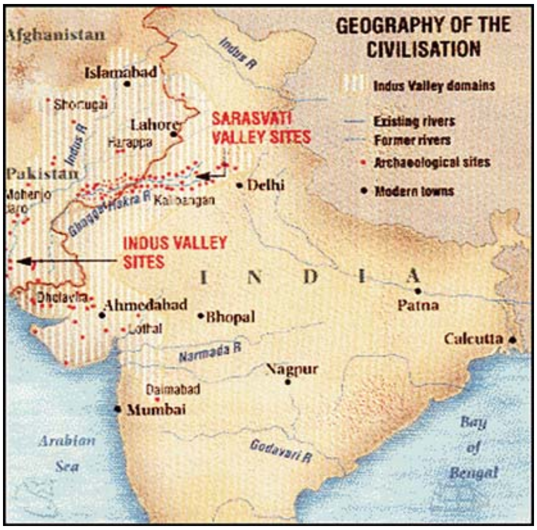
Vājasaneyī Saṃhitā describes the medicinal use of waters. "O water, which we have drunk, become refreshing in our belly. May you be pleasant to us by driving away diseases and pains." The verses are recited while touching one's navel after drinking liquid in a sacrificial procedure. Like Agni and Vāyu, *āpaḥ* (water) also serves as a purifying agent.

Rivers as Goddesses

The rivers and river waters have been treated with great reverence since ancient times. Traditionally, rivers such as Gangā, Yamunā, or Narmadā are worshipped as goddesses. Every morning and evening, on the banks of the Gangā at Haridwār, there is daily "Gangā worship" with lighted lamps in the presence of thousands of devotees, traditional holy music, and chants of mantras. The Sarasvatī River was one of the largest rivers in ancient India before 3000 BCE and drained the Sutlej and the Yamunā. By the end of Harappan culture, the Sarasvatī went dry, bringing about the end of Harappan civilization around 1900 BCE. The Vedic texts are replete with references to the river Sarasvatī and the seas.

River Sarasvatī: Myth or Reality?

Whereas the famous River Gangā is mentioned only once in the *Ṛgveda*, the River Sarasvatī is mentioned at least sixty times. Sarasvatī is now a dry river, but it once flowed all the way from the Himalayas to the ocean across the desert of Rajasthan. Research by Dr Wakankar has verified that the river Sarasvatī changed course at least four times before going completely dry around 1900 BCE. The latest satellite



Water in India: Spiritual and Technical Aspects.
Fig. 3 Archaeological sites along erstwhile Sarasvatī River.

data combined with field archaeological studies have shown that the Ṛgvedic Sarasvatī had stopped being a perennial river long before 3000 BCE (Giri).

Numerous archaeological sites have also been located along the course of this river, thereby confirming Vedic accounts. The Sarasvatī is now dated long before 3000 BCE. This means that the *Ṛgveda* described the geography of North India long before 3000 BCE. This shows that the *Ṛgveda* must have been in existence no later than 3500 BCE.

Tritium (hydrogen isotope) analysis of deep water samples taken by Bhabha Atomic Research Centre (BARC) has provided a broad spectrum dating for the waters of the Sarasvatī river now revealed as groundwater sanctuaries and aquifers. The waters range from 4,000 to 8,000 years BP (Kalyanaraman).

For over 2,000 years (6000–4000 BCE), the Sarasvatī flowed from Bandarpunch massif (Sarasvatī-Rupin glacier confluence at Naitwar in western Garhwal). Figure 3 shows the location of archaeological sites along Sarasvatī river. A remote sensing study of the India desert reveals numerous signatures of palaeochannels. The LANDSAT imagery highlights the course of the River Sarasvatī in Punjab, Haryana, and Rajasthan. The digital enhancement studies of IRS-1C data (1995), combined with radar imagery from European remote sensing satellites ERS I/2, have identified subsurface features and reorganized the palaeochannels beneath the sands of the Thar desert in northwestern India (Paik, 2000).

Ancient Weather Science

In the early Ṛgvedic period, the performance of *Yajnas* (sacrifices) as described in Vedic and Brahmanic literature has some scientific basis. These rituals were performed to ensure timely and adequate rainfall for abundant availability of food, thriving of animal and plant life and for overall human prosperity (Sharma, 2002). The *Yajnas* are very closely related to the evolution of the universe, the solar system, human procreation, occurrence of the seasons, rainfall and life on earth. Several places in the Vedic literature mention that *Yajnas* produce rain which in turn produces food.

The subject of meteorology was dealt with by several ancient sages, including Nārad, Kashyap, Garg, Parāshar, Vasishṭha, Druhin, Brihaspati, Devala, Vajra, Sahadev, and Rishiputra. *Ashṭādhyāyi* (500 BC) by Pāṇini is perhaps one of the earliest post-Vedic works giving information on rainfall measurement and droughts. The *Arthashāstra* (fourth century BC) of *Kauṭilya* gives information on rainfall distribution in the country as well as the methods of its measurement. Several of the old treatises in the form of *Purāṇas*, such as *Matsya Purāṇa*, *Vāyu Purāṇa*, or *Vishṇu Purāṇa*, dealt with the role of the sun in rainfall. Water science, which was initially based on observations, kept being refined and in the post-Vedic period from the third century BC to the sixth century AD, many of the earlier hypotheses came to be perfected. *Kauṭilya* even gave an estimate of the average rainfall in various parts of India.

In Varāhamihira's time, the units of measurement of rainfall were the *pala*, *adhaka*, and *droṇa*. The raingauge was round with a diameter of one *hasta* (18 in., 46 cm) and had marks of *pala*. When it was full, it indicated one *adhak* of rainfall. One *droṇa* means 2–1/2 in. (6.4 cm) of rain. Accordingly to Parashar, the height and diameter of the raingauge should be 8 *angulas* (6 in., 15 cm) and 20 *angulas* (15 in., 38 cm), respectively, and when it is filled to the brim it measures one *adhaka*. Parashar also gives a method of measuring rainfall on the ground. If it measures four cubits on the ground it amounts to one *droṇa*.

Ramanathan (1993) described the significance of rituals and *yagnas* (sacrifices) with their cosmic and scientific interpretations in great details. Observations and measurements of wind, clouds, lightning, thunder, rain, solid precipitation, atmospheric optical phenomena, and agricultural meteorology were presented.

> Just as the water vapours are carried higher in the form of clouds and are condensed in the presence of cold air existing in the sky, similarly one can reach the height of spiritual progress and can get strengthened due to restraining the breath through Yogic exercise (YV 23.26).

> The uniform water passes upwards and downwards in the course of days, clouds give joy to the earth; fires rejoice the heavens (RV 1.164.51).

> O all learned people, fully realise your conduct towards different objects of the universe, know ye the electricity that maintains all beautiful objects, the sun, the invisible matter brought into creation, the invigorating vital airs, thus ye become the utilisers of all objects. Homage to him who knows the science of clouds, and to him who knows the science of electricity (*Yajur Veda*).

These hymns give insight into the cloud-seeding phenomenon and occurrence of rains. Various activities occurring in the firmament were well observed and formulated in scientific terms.

Festivals Related to Water

The focal point of Hindu social, cultural, and religious rituals has been water. Indian mythology attaches a lot of importance to the bath (*snāna*) which is mandatory for participation in any important religious occasion. A dip in holy rivers is considered an essential part of Hindu culture, especially on specific occasions such as the solar and lunar eclipses or occasions specified on the basis of specific planetary configurations, which are considered to have a cosmobiological effect on the human body. In a cycle of 12 years, a great Indian festival takes place which is known as Mahā Kumbha or Great Kumbha, where millions assemble and have a dip in the waters of the sacred rivers. Every third year, a smaller water festival called Ardha Kumbha (half Kumbha) is also held, where people congregate at specified places at the banks of the holy rivers (Sharma, 1998). In the mythological scriptures it says that the elixir of life, ambrosia (*amṛt*), that emerged from the churning of the ocean by the gods and demons, splashed out of the pitcher and fell to earth at four places: Haridwār, Prayāg, Ujjain, and Nāsik. These are located on the banks of the River Gangā, at the confluence of the rivers Gangā, Yamunā, and Sarasvatī, on the banks of Shiprā, and on the banks of Godāvarī. A tussle ensued among the gods and the demons for 12 days. During this period the moon did not let the *amṛt* fall from the pitcher, the sun did not let the pitcher crack, Jupiter protected it from demons, and Saturn saved it from being whisked away. Thus, these four planets, which were responsible for saving the pitcher of ambrosia (*amṛt kumbha*), have become an integral part of the Kumbha. Various astronomical conjugations during Kumbha represent various stages of the solar cycle which have a direct influence on human beings and the biosphere. The holding of Kumbha at an interval of 12 years is symbolic of the need for purifying the body by sublimating the inherent vices of the 12 sense organs – five organs of action, five organs of perception, and the mind and the intellect – thereby arousing the six psychic centres or *chakra* separated from each other at distance of 12 *angula* (finger widths) for attaining the *amṛt kumbha* or pitcher of ambrosia (Dixit, 2001).

Water festivals are also celebrated in several other ways in North and South India. It is customary to take a dip in the holy waters of rivers on various auspicious occasions.

Water Management and Reservoirs in India and Sri Lanka

Andrew M. Bauer, Kathleen D. Morrison

Water storage and distribution technologies have played an important role in the histories of southern India and Sri Lanka. Given the variability in rainfall and the relatively dry conditions over much of the region, it would have been difficult for southern Asian agriculture, diet, and cuisine – particularly the heavy emphasis placed on rice – to have taken the forms they did without the historical development of water management techniques. Moreover, debates about the efficiency, sustainability, and equitability of modern "big dam" projects versus "traditional" methods of providing much-needed domestic and agricultural water continue to dominate Indian politics today. Here, we review historical forms of water management in South India and Sri Lanka, paying particular attention to ancient reservoir systems.

South India and Sri Lanka are dominated by a monsoonal climate, whereby the southwest (or advancing) monsoon generally brings rains between the months of June and October, and the northeast (retreating) monsoon in November and December. In addition to monsoon strength, a variety of topographic factors relate to the distribution and concentration of rainfall across the region. Parts of the southwestern and western coasts of India receive between 3,000 and 3,200 mm of rainfall a year due to the orographic (related to, or caused by, physical geography, such as mountains or sloping terrain) effects of the Western Ghats – South India's most pronounced north–south ranging mountain chain. On the eastern side of the Ghats, however, a rain shadow is created that markedly reduces the amount of precipitation in the central areas of the southern peninsula. For example, Bangalore – the capital city of the modern state of Karnataka – receives an average of around 850 mm of rainfall per year, while Hyderabad – the capital of Andhra Pradesh – receives an average of only 700 mm of rainfall. Indeed, much of the area within the orographic rain shadow of the Western Ghats can be considered a semiarid climate, with average rainfall levels falling as low as 400 mm (India Meteorological Department 1981). Sri Lanka's topography creates a similar pattern in which the southwestern coastal areas receive the bulk of the advancing monsoon and the northern and eastern coasts – largely in the rain shadow of Sri Lanka's central highlands – receive precipitation from the shorter, retreating monsoon. However, it is important to note that actual rainfall in all parts of the Indian peninsula and Sri Lanka can show significant intra- and interannual variability as a result of being dependent on the relative strength of the monsoon.

South Indian and Sri Lankan reservoirs include a range of facilities constructed for the purposes of collecting and storing water, generally for agricultural production. These consist of artificial embankments built across paths of gravity water flow, whether intermittent streams, rivers, or simply slopes that might carry runoff after a monsoon rain. Reservoirs may or may not involve excavation of a basin to contain this water, but they are all storage or storage/distribution devices built on a relatively large-scale and meant to contain water behind an embankment or dam, rather than within its major construction. In this sense, we make a distinction between cisterns (which collect and store water within a rock-cut or other constructed facility), wells (which tap the water table), reservoirs, and tanks. The term "tank" is widespread in the South Asian literature, indiscriminately used to describe almost any water-holding feature, although the term most frequently refers either to reservoirs or to temple tanks – large masonry structures that hold water for ritual ablutions and other functions associated with temple worship. Temple tanks often derive their water from the water table. As such, temple tanks and reservoirs are wholly different in construction, morphology, and operation, similar only in their capacities as water-holding devices and in certain parallels of meaning and symbolism (Morrison in press).

Early Forms of Water Management in South India and Sri Lanka

The earliest culturally significant water catchment features in South India were not constructed reservoirs (in the terminology outlined above), but seasonal pooling basins, or cisterns, which developed naturally from the differential weathering of bedrock. In geomorphological terms, these are known variably as gnammas, rock pools, or weathering pits, and are considered to be characteristic features of residual hills and inselbergs – isolated hills composed of resistant rocks (e.g., granite or gneiss) that express pronounced topographic relief from a surrounding plain – throughout the heavily weathered terrain of the tropics and subtropics (Thomas 1994; see also Porembski and Barthlott 2000). In South Asia, such basins occur on the granitic gneiss hills that characterize much of the central and southern portions of the Indian peninsula, as well as parts of Sri Lanka (e.g., Fernando 1976). Indeed, because granite and gneiss are particularly impermeable rock types, the bare hills of South India generate large volumes of runoff water during the heavy monsoon months that collects in such depressions (Fig. 1).

Water retaining rock pools appear to have taken on cultural significance as early as the Iron Age (1000–500 BCE) in several regions of South India. During this period, mortuary and ritual sites were often marked by the construction of megalith monuments, and a clear cultural association between such ritual constructions and seasonal water basins can be established. Large concentrations of elaborately constructed megaliths – ranging from dolmen cists, stone circles, rock cairns, platform enclosures, stone spirals, and more – appear to have been deliberately placed adjacent to water basins in hilltop locations. Perhaps the most striking example of such an association occurs at the site of Hire Benkal in northern Karnataka, where hundreds of megaliths are found near a broad shallow water basin that likely began as a rock pool and was subsequently

Water Management and Reservoirs in India and Sri Lanka. Fig. 1 A rock pool at VMS 579 – an Iron Age occupational site in the Koppal district of northern Karnataka. Notice the artifact debris in the foreground (photo by Andrew M. Bauer).

Water Management and Reservoirs in India and Sri Lanka. Fig. 2 The site of Hire Benkal, showing dolmen cists on the quarried banks of a basin feature that likely began as a natural rock pool (photo by Andrew M. Bauer).

expanded by quarrying activities for the construction of monuments (Fig. 2).

Additional sites also demonstrate associations between water and culturally significant ritual places. For example, a brick platform structure enclosed by granite boulders at Bandibassapa Camp, also a large megalithic complex in northern Karnataka, appears to have been situated adjacent to a rock pool that was later modified. Moreover, Gordon and Allchin (1955) reported 80 megaliths at a site near Bilebhavi where they identified two "tanks" (cisterns), one of which was "lined with stone slabs." They also recorded a similar construction on a hilltop megalith site near Koppal (Gordon and Allchin 1955: 99). The association between megaliths and water basins has also been noticed in Tamil Nadu and Sri Lanka (cf. Seneviratne 1984; Myrdal-Runebjer 1996), suggesting a ritual importance to water, and possibly a sacred dimension to early water management throughout much of the region.

Although rock pools likely served as the earliest water retention features in the region, it is clear that during the Iron Age humans began deliberately expanding pooling basins and creating them through activities of quarrying, excavation, and the construction of embankments, or bunds. This is evidenced not only at megalithic ritual sites, such as Hire Benkal, but also at settlement sites, where both cobble lined basins and constructed bunds are present. At the Iron Age habitation site of Kadebakele (northern Karnataka), for example, inhabitants modified the drainage pattern on top of a granitic hill to form a water catchment basin. Excavations in this reservoir show that it collected and held water for only part of the year, partially a consequence of the reservoir's relatively small catchment area of .027 km^2. The facility also experienced major drying episodes as well as significant siltation. Nevertheless, it certainly provided much-needed water to local residents at certain times.

It is difficult to say to what extent these early water retention features may have supported cultivation. Most are quite small and lack provisions for water distribution necessary for large-scale agriculture. Moreover, they are often perched atop high hills with little cultivable land. However, some early reservoirs do occur within natural drainage ways, occasionally in association with check dams and at the base of topographic features where seasonal water could potentially be pooled for crop production. In fact, Devaraj et al. (1995: 66) report "interlaced, hydraulically laminated" deposits behind a "rammed" earthen construction near the base of a granite outcrop at Watgal – a Neolithic (3000–1000 BCE) to Iron Age (1000–500 BCE) period settlement site in northern Karnataka.[1] It is difficult to characterize the entire range of variability in form and function of early water management constructions without more systematic work. Indeed, few regions have been systematically studied, and the patterns described above may not hold true across the entire region. Nevertheless, it is clear that water retention techniques began to be practiced in a variety of settings during the Iron Age (see also Allchin 1954). In addition, the development of water management technology during this period generally coincided with the introduction of new cultigens – including rice cultivation – suggesting that water retaining features became increasingly important to

W

[1] However, it is important to note that the authors do not identify this feature as a reservoir, or attribute it with any water retaining "function."

agricultural production by the end of the first millennium BCE.

In the first millennium AD there is stronger evidence for the construction of larger reservoirs that were used to meet the hydrological requirements of cultivation. A series of reservoir walls have been reported in the environs surrounding Sanchi – a well-known Buddhist monastic site in west-central Madhya Pradesh spanning the third century BCE to the twelfth century AD. These reservoir features are built of earthen embankments reinforced by stone masonry, with dams reaching nearly 6 m in height and expanding across drainage valleys, in some cases exceeding 1 km in length. Moreover, catchment areas range from 0.74 to 17 km^2 (Shaw and Sutcliffe 2001), potentially damming considerably more water than the Iron Age reservoirs discussed above. Artifact associations, as well as the proximity of the embankments to the site of Sanchi, have allowed scholars to suggest that several of these features were constructed as early as the second century BCE, while others were built throughout the first millennium AD (Marshall 1940: 13; Shaw and Sutcliffe 2001).

Although dating features such as reservoir walls remain problematic without direct geochronological assessment (e.g., radiocarbon, optically stimulated luminescence, etc.) or inscriptional data, textual references from the Early Historic Period suggest that reservoir construction was prevalent in some parts of India, and in South Asia more generally, during this time. For example, Chakravarti's (1998) analysis of the *Arthaśāstra* – an economic and political treatise composed sometime in the late centuries BCE or early centuries AD – suggests that Mauryan rulers (ca. 324–185 BCE) were concerned with establishing irrigation works. Moreover, numerous inscriptions and textual references indicate that the construction of reservoirs and irrigation facilities underwent remarkable development in Sri Lanka during the Early Historic Period, particularly on the island's drier north and east sides. Northeast of Sigiriya, the Minneriya reservoir built during the reign of Mahasena (AD 276–303) is particularly noteworthy. This reservoir – fed by a canal as well as surface runoff – consisted of an embankment nearly 2 km in length and at places exceeded over 13 m in height. Inscriptions dated to the reign of Mahasena's successor speak of "three harvests of [rice] paddy per year," suggesting a marked impact on agricultural production (Gunawardana 1971: 8).

Middle Period Reservoirs: The "Traditional" System

It should be clear from the above discussion that reservoirs and water storage features have a long history in South India, and South Asia more generally. However, the proliferation of large reservoir construction for the purposes of agricultural intensification is most salient in South India after the Early Historic Period, and in Sri Lanka only slightly earlier.

Numerous textual sources clearly indicate that reservoirs played an important role in the Early Middle Period (AD 500–1300). Although small dam-and-basin facilities for water impoundment continued to be built and used, Middle Period reservoirs typically consist of masonry-faced earthen dams thrown up across valleys, at the base of hills, and in other locations where seasonal runoff and small streams could be captured (Fig. 3) (Morrison 1993, in press). Like the Minneriya reservoir in Sri Lanka, some were supplied by canals, which took off via diversion weirs or anicuts, from perennial rivers or intermittent streams. Water was moved downstream from reservoirs to agricultural fields through masonry-lined tunnels under the embankments, which were regulated by sluice gates (Figs. 4 and 5). Some water was also released over specially constructed waste weirs, facilities which range from boulder-filled cuts to elaborately built spillways (Fig. 6). Although the focus was clearly on the storage and downstream distribution of water, reservoir beds were also sometimes used for cultivation and reservoirs served as important sources of fish, silt and clay, and water for livestock. Reservoirs were also used to raise the water table around them, an important function even when the bed failed to fill. In fact, we have documented a consistent (but not universal) pattern of wells down-slope from sluice gates (Morrison in press).

Reservoirs were particularly important in the far south, in present-day Tamil Nadu, where many of them were supplied by river-fed canals (Ludden 1999).

There it is possible to see perhaps the greatest elaboration of the so-called "system reservoirs" – long chains of reservoir facilities that flow one into the other, linking large areas into tightly knit watersheds (Sharma and Sharma 1990; see also Mosse 2003). Unfortunately, none of these systems has been specifically analyzed on the ground to determine precise construction sequences, so although we know of many specific single-reservoir projects dating as early as the seventh century AD, we cannot say exactly how the overall system functioned at this time or even how much of the landscape was under reservoir irrigation. It should be noted, however, that Early Middle Period reservoirs, "traditional" by any reckoning, ranged widely in size from very small ponds to vast "seas," the latter falling well within the contemporary definition of a "large dam."[2]

Similar to the "systems reservoirs" of Tamil Nadu, large Sri Lankan Early Middle Period reservoirs were linked through vast networks of canals. The Minneriya reservoir, for example, was connected to other facilities via the construction of a "great canal" during the reign of Aggabodhi I (ca. AD 571–604), and composite maps of the irrigation facilities around Sigiriya show that it fed at least two large reservoirs – the Kaudulla and Kantalai reservoirs. Moreover, detailed survey has shown that smaller dam-and-basin features were also probably constructed and maintained throughout the period (Myrdal-Runebjer 1996). Again, it is difficult to know how the overall systems functioned simulta-

[2] Crest length $\geq$ 500 m, maximum flood discharge $\geq$ 2,000 $m^3 s^{-1}$, "especially difficult foundation problems" or "unusual design" (ICOLD World Register of Dams 1998).

W

neously. However, it is clear that Middle Period rulers and elite made demonstrative efforts to construct new irrigation facilities and repair older ones. In fact, the Minneriya inflow and outflow canals were repaired at least several times in the early centuries of the second millennium AD (Myrdal-Runebjer 1996; see also Brohier 1934; Gunawardana 1971).

This pattern of extensive reservoir use in Sri Lanka and the far south of the Indian peninsula contrasts with that of drier regions in the northern interior of the subcontinent (Karnataka and parts of Andhra Pradesh). In these northern regions, reservoirs were (and are) almost exclusively runoff-fed and, given lower rainfall, they are generally not as closely spaced as those of the southern Tamil country. Still, many regions saw the use of both system and isolated reservoirs. In the area we have studied in northern Karnataka, reservoirs seem to have been only a minor component of Early Middle Period agricultural strategies. However, by the Late Middle Period (1300–1700 AD), and especially with the expansion of the large but loosely knit empire of Vijayanagara (ca. AD 1330–1600) across much of the peninsula, reservoir irrigation expanded considerably, especially in the drier zones where it had previously been limited. In and around the eponymous capital city of this empire, urban foundations in the early fourteenth century and the subsequent expansion of settlement and population explosion in the region propelled reservoirs into increasingly important components of larger agrarian and political strategies (Fig. 7). Important from the start of the Vijayanagara period, reservoirs also constituted a key form of agricultural intensification in the sixteenth century, or Late Vijayanagara period, especially in regions where canal irrigation was not feasible (Morrison 1995, 2001).

Reservoirs played variable roles in the processes of Vijayanagara agricultural intensification and change; this variation was structured as much by political factors and settlement dynamics as by environmental variables such as runoff and soil conditions. What is common to most parts of the urban hinterland, however, is the way in which the vast majority of reservoirs fell out of use after (in some cases, during) the Vijayanagara period. Very few of the reservoirs from the original system still effectively function, though there are a few notable "living" reservoirs with long histories of maintenance and reconstruction (Morrison 1993, 1995). For example, the Daroji reservoir, the terminus of one of the largest systems in our study area, continues to collect runoff from a catchment area of 955 km^2 and provides water for downstream agricultural fields (Fig. 8).

Research on Middle Period reservoirs includes analyses of pollen and charcoal from reservoir sediments (which allow the reconstruction of fire and vegetation histories), sedimentological studies of reservoir fill and changes to erosional regimes and local hydrology, and stylistic analyses of sluice and embankment construction (e.g., Morrison 1994, 1995; Myrdal-Runebjer 1994, 1996). In addition, we have also considered tens of thousands of textual and inscriptional records describing facility construction and

Water Management and Reservoirs in India and Sri Lanka. Fig. 7 Small Middle Period reservoir and sluice gate in the Daroji Valley, south of Vijayanagara (photo by Kathleen D. Morrison).

Water Management and Reservoirs in India and Sri Lanka. Fig. 8 ASTER satellite image of the Daroji reservoir first built in the sixteenth century, south of Vijayanagara. Vegetation growth is also occurring on the edges of the reservoir as receding water exposes moisture retaining sediments (data originally obtained from NASA).

maintenance as well as conflicts over water, land, labor, and rule (Kotraiah 1995; Morrison 1995; Morrison and Lycett 1994, 1997). All of these diverse lines of evidence suggest that Middle Period reservoirs, like their contemporary and colonial counterparts (Mosse 2003: 45–46), were highly unreliable sources of irrigation. Runoff-fed reservoirs, in particular, may fail to fill in dry years; in the drier districts, this meant not only that reservoirs could usually not support wet crops such as rice, but also that dry crops such as millets might not be assisted by the facility. The situation was somewhat better in areas of higher rainfall, but everywhere in southern India reservoirs are marked by high evaporation rates, high siltation rates, and ongoing maintenance challenges (Fig. 9).

Reservoirs, Politics, and Contemporary Development

Across much of South Asia, contemporary "big dam" projects have been cast as the legacies of high modernist social and environmental engineering (cf. Gadgil and Guha 2000; Scott 1998). In India, well-organized and highly visible social protests have been made against specific projects such as the Sardar Sarovar project and others along the Narmada River. Often, antidam groups suggest that the answer to sustainable and equable development lies in a return to a "traditional" system of technology and management. It is not our purpose to argue the case for "modern" or "traditional" forms of water distribution. Rather, we wish to suggest that arguments that hinge on the dichotomies of large/small, equitable/inequitable, and political/apolitical that often accompany distinctions between "modern" and "traditional" forms of water management are inappropriate.

The notion that large political dam projects are entirely a product of modernity is decidedly incorrect. This is no clearer than in South India, where some Middle Period reservoirs were created with embankments more than 3.5 km in length and over 15 m in height. As already noted, the Daroji reservoir in northern Karnataka pooled runoff over a total catchment area of nearly 1,000 km^2; however, size alone is not the issue. Both small and large reservoirs were deeply political projects, tied to networks of patronage and power. Middle Period reservoir construction was sponsored by a wide range of political leaders from kings (rarely) to local chiefs (commonly) and was also connected with Hindu temples in a number of ways (Morrison 1995; Morrison and Lycett 1994, 1997). Moreover, even during the Iron Age and Early Historic Periods, shifts from a reliance on rain-fed agriculture to reservoir irrigation would have produced a new material order on the landscape that was necessarily related to sociopolitical fields. Indeed, the questions – How was labor mobilized? Who had access to irrigation water? And how was this decided? – are entirely appropriate in examining the entire history of water management. The answers to these questions undoubtedly had sociopolitical ramifications for ancient inhabitants. This may have especially been the case when irrigation accompanied the introduction of new cultigens and cultural values of cuisine shifted. It is not difficult to imagine the profound social consequences of being a dry-farming millet producer/consumer versus a wet-farming rice producer/consumer when rice was a high status cultigen and the preferred donation to Hindu temple gods during the Middle Period, for example.

Water Management and Reservoirs in India and Sri Lanka. Fig. 9 Photo showing the accumulation of an estimated 2–3 m of silt and clay, to near the top of a sluice gate. This reservoir is adjacent to the village of Avinamodugu, south of Vijayanagara (photo by Kathleen D. Morrison).

The above considerations of the (un)reliability and the political nature of historic reservoirs of South India and Sri Lanka are not to suggest that these impressive systems have no contemporary value with regard to (re) developing water management strategies. Quite the opposite is true: work on the 3,000-year history of irrigation in southern India shows both success and failure in equal measure, portents for a reasonably hopeful future. Thus, although there is no simple solution to the water problems of the dry tropics of South Asia, surely an informed perspective on the actual historical experiences of the region must provide a more secure basis for future planning than either a romantic and unrealistic view of "tradition" or a blind faith in "modern" science and technology.

Water Management in Peru

C. R. Ortloff

The Chimu Empire of ancient South America in the time period between 900–1480 CE dominated the north Peruvian coast from the Santa to the Lambeyeque Valleys west of the Andean Cordilera Negra mountain range. This region, in terms of present-day geographical locations, extended just north of the Peruvian capital city of Lima to the Ecuadorian border and eastward from the Pacific Ocean coast to the eastern slopes of the Andes. From the central administrative center at Chan Chan in the Moche Valley, successive generations of Chimu rulers exercised political and economic control of adjacent valleys through administrative centers charged with overseeing and maximizing agricultural production and development. Within the territorial domain of the empire, many of the westward-running rivers leading runoff water from highland Andean rainfall collection zones to fertile coastal fluvial valleys were intercepted and redistributed through extensive canal distribution systems to irrigate agricultural fields. Many valleys even today still contain well preserved canal networks from this era as land under cultivation by the Chimu far exceeded present-day cultivation areas by perhaps as much as 50 per cent. While only a few of the ancient valley irrigation systems have been extensively explored, mapped and analyzed to any extent (Eling 1986; Kosok 1965; Ortloff et al. 1982, 1985; Ortloff 1988, 1993), some novel canal hydraulic control features have been recently discovered that warrant analysis as they provide a window into the level of hydraulic science existing within the Chimu empire of ancient South America.

Since most major valleys under Chimu control showed evidence of massive state-sponsored, hydraulic canal infrastructures to support irrigation agriculture, it follows that a hydraulic science was co-developed to provide tailored flow rate canals to supply field systems distant from river inlets. As considerations of soil and crop types, crop water demands, alternate field system watering strategies, valley topography and defense from drought and large rainfall runoff events influence canal design and placement, an accompanying hydraulic science with flexibility to design and modify canals according to these considerations is expected in the archaeological record. Most probably, cumulative observations of water flow phenomena over time served to provide a database for empirical design principles used for canal layout and design. Canal volumetric flow rate relies on inlet geometry, bed slope, canal cross-section, wall roughness and subcritical, critical, and supercritical flow characterization. Allied technical disciplines related to route layout, surveying, water delivery sequencing and water routing through multiple canal branches are additional key technologies vital to understanding Chimu hydraulics practice. While investigation of all aspects of applied Chimu hydraulic science would give a complete picture of their technology base, the present investigation is focused on but one facet of the Chimu engineering repertoire: hydraulic control systems.

This entry details an investigation of a recently discovered canal hydraulic feature of the Chimu Talambo-Farfán Canal located in the Jequetepeque Valley of northern Peru. While the remains of the canal system are of late Chimu origin due to association with the Chimu site of Farfán, some upstream versions of canal segments may be associated with earlier valley occupation by Gallinazo and late period Moche occupants. For the present analysis, however, only the last Chimu phase of canal construction is considered.

Analysis Results

The Talambo-Farfán Canal originates far upstream in the valley neck of the Jequetepeque River and passes late hillside Chimu occupation zones in the Talambo region through a series of aqueducts and deep canal cuts through upvalley low hills before finally emerging onto the agricultural plains east of Farfán. The canal was further extended to provide water to the extensive agricultural field zones directly south of the Chimu mountain redoubt of Farfán Sur. In the canal extension region, deep *quebradas* (canyons) were formed over time from successive El Niño rainfall runoff events sculpting deep erosion channels into the soft soil deposits that formed natural obstacles to canal extension. In order to bridge the multiple quebradas, a series of three large earth-fill aqueduct structures and many small aqueducts were constructed to extend the canal to the vast Pampa de Faclo bordering the site of Pacatnamú. Two of these (largely destroyed) quebrada-crossing aqueducts are shown in Figs. 1 and 2; the Hoya Hondada aqueduct is the largest and final aqueduct in the downstream sequence and is shown in Figs. 3–5.

Water Management in Peru. Fig. 6 Demonstration of a hydraulic jump in a hydraulic test channel induced by a supercritical flow interacting with a plate obstacle; a similar hydraulic phenomena is induced at the channel intersection point of the steep chute and low slope Hoya Hondada aqueduct channel. Photo by C. R. Ortloff.

Due to the much larger depth and width of the Hoya Hondada quebrada as compared to upstream quebradas, aqueduct design changes from upstream high fill height designs breaching narrow and deep gorges to maintain slope to a long, low height aqueduct deep within the quebrada with a steep 40 degree approach chute from the southernmost upstream bluff. After the canal passes over this low aqueduct, it continues to the downstream northern sidewall of the Hoya Hondada quebrada to field systems located on the southern boundary of Pampa de Faclo approximately 8 km south of the ancient Moche-Chimu religious center at Pacatnamú. The intent of the canal extension through difficult terrain north and west of Farfán Sur was apparently to provide water to settlements and field systems in the south part of the pampa east of Pacatmanú. While further canal extension to the city limits of Pacatnamú may have been the ultimate intent of the canal builders, traces of a continuous connection path to the many canal fragments on the Pampa de Faclo are yet to be discovered.

The canal and aqueduct design within the Hoya Hondada quebrada area contains many novel hydraulic features indicative of the state of Chimu hydraulic knowledge. As opposed to using a massive earth-fill aqueduct that would span the 150 m width and 20 m height to connect opposite sides of the quebrada with a constant slope canal, a 5 m high aqueduct is constructed low in the quebrada with a 25 m long steep chute joining the upstream high elevation part of the canal to the downstream low aqueduct. This alternate design eliminates the possibility of a massive high dam structure trapping a large height of quebrada rainfall runoff behind it that would constitute a dam breakage hazard to downstream occupation areas. The low dam design, should breakthrough occur, would be easily repairable due to its low volume of fill material and contain relatively less impounded water than the alternate design. While some Chimu aqueducts spanning quebradas contained culverts or boulder bases to let water pass underneath to alleviate water damming during heavy rainfall events, use of a low aqueduct height design reduced backwater hydrostatic pressure effects that lowered destructive transverse forces that could lead to breakthrough failure.

Continuing, with no upstream hydraulic controls, the effect of a high velocity, high volumetric flow rate down the steep 40-degree downward-sloped chute to the low slope aqueduct would be to create a massive hydraulic jump at the angle-change junction. Fig. 6 shows a typical hydraulic jump created by an obstacle placed in a high velocity, supercritical flow – in this case, the hydraulic jump is typical of that resulting from the effect of the rapid flow down the steep chute – low slope aqueduct junction. The severity and height of a large hydraulic jump is sufficient to destroy the aqueduct by turbulent erosion's acting on the unlined aqueduct structure unless a hydraulic control is in place upstream of the aqueduct to dissipate stream energy, lower stream velocity and/or remove excess water from the canal by a side weir – which is another mode of stream energy reduction. The height of the hydraulic jump also would cause sidewall overflow from the aqueduct leading to precious irrigation water loss for downstream field systems. By lowering the channel water velocity and/or volumetric flow rate, the height of the downstream hydraulic jump can be reduced to a level that does not imperil the integrity of the aqueduct structure or cause sidewall overflow water loss problems. This then constitutes the hydraulic design problem faced by Chimu engineers.

The channel upstream of the Hoya Hondada aqueduct shows that an energy dissipation hydraulic structure had been installed to influence flow leading on to the aqueduct. Figs. 7 and 8 show a ground view of this hydraulic control structure in its unexcavated state. The hydraulic structure consists of two pairs of opposing boulders with a 70 cm separation distance between boulders and with a 13.2 m downstream separation distance between boulder pairs. The channel containing this structure also had variations in width and sidewall angle. A FLOW-3D computer model (FLOW-3D 2004) incorporating field measured channel geometry is shown in Fig. 9. In the distance between the boulder pairs, a side overflow weir that activates when water height exceeds a given height is in place that led to a channel that guided overflow water into the quebrada downstream of the Hoya Hondada aqueduct. The hydraulic function of the control structure is next described by use of numerical solution of the governing equations of fluid flow; results of the solutions indicate the free surface shape and internal velocity within the channel and provide the basis to understand the hydraulic functioning of the control section.

The first upstream choke (defined as the open separation zone between boulder pairs) apparently forms a hydraulic jump at incoming stream velocities past about 7 m/s while the downstream choke apparently forms a hydraulic jump at inlet velocities about 3 to 4 m/s. The second downstream choke is therefore controlling as it actives first at a lower limiting velocity. For all cases, an increase in water velocity occurs in the zone downstream of the first upstream choke due to

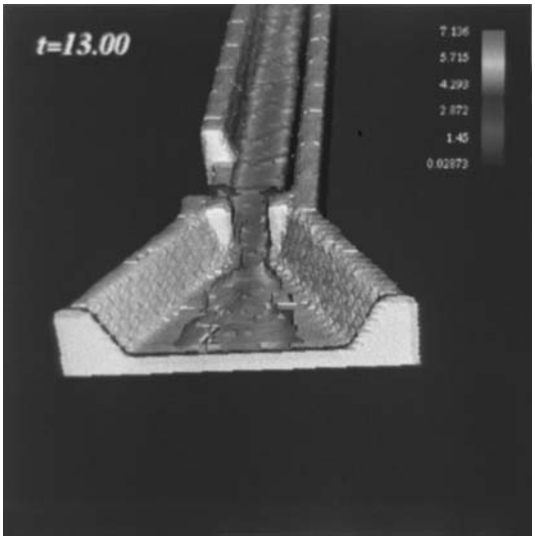
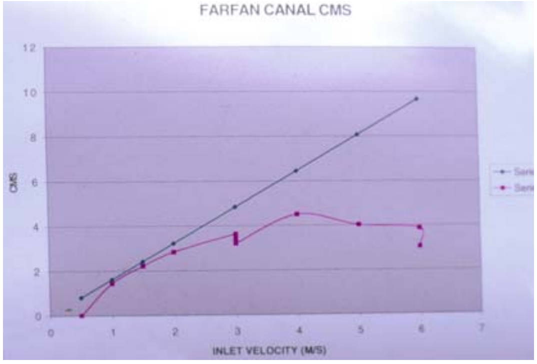
Water Management in Peru. Fig. 10 Solution results for water free surface geometry for a channel flow rate exceeding 3 m^3/sec; note the spillage over the side weir from the action of the downstream choke limiting the transmitted flow rate on to the Hoya Hondada Aqueduct. Photo by C. R. Ortloff.



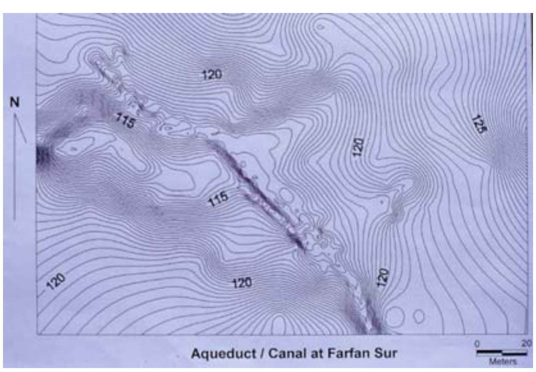
Water Management in Peru. Fig. 11 Solution results for a channel flow rate less than 3 m^3/sec; note that flow is fully contained within the channel and the side overflow weir is not activated. Photo by C. R. Ortloff.



Water Management in Peru. Fig. 12 Plot of flow rate (m^3/sec) into the control structure vs. flow rate exiting: the difference is the flow exiting over the side weir. Note that transmitted flow rate is limited past 3 m^3/sec due to the action of the choke system and overflow weir activation. Photo by C. R. Ortloff.

water gravitational acceleration on a hydraulically steep slope influenced by expansive channel cross-sectional geometry changes. These velocity changes account for the different hydraulic behavior of each choke. Since flow into the second choke is supercritical over the range of subcritical input flow rates, the second choke forms a hydraulic jump and the flow rate is limited by critical conditions at the throat. As the choked flow rate of the downstream choke is less than that of the upstream choke, the flow rate difference results in a water height change between chokes that activates water overflow from the side weir. The overflow flow rate is equal to the volumetric flow rate difference between up- and downstream chokes. Fig. 10 shows side weir over-spillage typical of inlet flows exceeding about 7 m^3/s; Fig. 11 shows conditions obtaining when the inlet volumetric flow rate is less than 3 m^3/s and the side weir is inactive. Fig. 12 shows that the flow rate passed on to the Hoya Hondada aqueduct is automatically altered past 3 m^3/sec inlet flow due to activation of the overflow weir. The upper curve represents a linear condition present when no control section is present and the input flow rate is equal to the output flow rate in the channel. The lower curve indicates that when the control section is in place, the output flow exiting from the control section is reduced by the side weir overflow to a limiting value about equal to 3 m^3/s. The limiting flow rate of 3 m^3/s then ultimately limits the height of the downstream hydraulic jump before the aqueduct to acceptable design values to control turbulence generation and contain the flow in the aqueduct channel without sidewall overflow.

The double choke system described is augmented with yet a further downstream energy dissipation system on the steep sloped chute. The Fig. 13 contour map, which shows the channel depression where the control section exists, contains a leadoff bifurcation channel that subtracts a fraction of the water downstream of the hydraulic control structure and leads it around a small hill into a low slope channel. This flow rejoins the main channel flow at a downstream junction point. The lower subcritical velocity stream from the lower slope channel acting on the main supercritical stream at the channel junction creates a further energy dissipating oblique hydraulic jump in the channel. The hydraulic jump converts velocity kinetic energy into random turbulent and potential, height change energy. This has the effect of subtracting further energy from the stream approaching the chute junction zone. Note that no energy gain exists as subtracted flow from the main channel is added back into the downstream flow to maintain the constant flow rate. The net effect of the two energy reduction controls – the first from subtracting energetic water by means of the overflow weir, the second from hydraulic jump energy dissipation – is to limit the channel flow rate and also reduce entry velocity onto the Hoya Hondada aqueduct to limit hydraulic jump erosive and overflow damage. Although a large part of the steep slope channel is no longer extant, there is indication that stones placed in the chute bed provided yet a further energy dissipation mechanism to reduce stream velocity. The totality of these hydraulic controls then serve to limit erosion damage to the Hoya Hondada aqueduct – particularly under El Niño conditions. For example, as the coastal area is frequently subject to massive El Niño rainfall runoff from the nearby Cerro Faclo mountain range, large canal flow rates arising from water washing into the canal could easily produce excessive canal flow conditions beyond the design flow rate. An excessive flow rate could destroy the Hoya Hondada aqueduct by creating a massive hydraulic jump at the channel-aqueduct junction. By diverting water over the weir into a channel leading to the downstream side of the aqueduct together with use of additional energy dissipation controls, excess water and energy is removed from the canal to provide a protective hydraulic feature for the aqueduct.



Water Management in Peru. Fig. 13 View of a minor hydraulic control system found extensively in the Pampa Faclo field system. The presence of a dual, opposing stone choke downstream of a steep chute creates a hydraulic jump ahead of the choke. This reduces the velocity of water entering a field system to promote gradual water absorption into the soil over time. The inlet from the main canal is tailored only to let a certain amount of water into the chute to make the system work as planned, indicating careful design of this irrigation system control. Photo by C. R. Ortloff.

As the canal can transport up to 3 m^3/s before weir overflow activation, this flow rate represents a sustainable maximum flow value to a location 35 km from the river inlet. This flow rate may be available to the Pampa Faclo fields and settlements, despite evaporation and seepage losses, by blocking all other canal branches from the main canal to temporarily direct all flow to the Pampa Faclo. As the needed water volume delivered through each canal branch to a field sector was a known quantity to sustain crops in that sector according to their importance, yield, and water requirements, the assignment of water volumes therefore was metered for maximum agricultural productivity effect. As settlements on the outlying southern section of Pampa Faclo were somewhat remote from the Farfán center and field systems discovered to date rather limited in size, it may be surmised that water resources reserved for this sector were proportional to its potential expansion and importance. The fact that water could be directed to this secondary location perhaps indicates that further expansion of the area's agricultural potential was anticipated but still in the construction phase. The major effort to construct multiple elaborate aqueduct structures to bring water to this zone through difficult topography perhaps indicated that a valuable agricultural resource in the Pampa Faclo land area overrode labor-to-build considerations – perhaps due to population increase pressures.

The transition to Chimu from Moche eras in the seventh century CE sees a vast expansion of population, cities, administrative centers, agricultural and settlement zones as well as a development of hydraulic technology that permits intra- and intervalley canal network development to exploit available agricultural zones. The success of the agricultural program, supported by a knowledge base of technical achievements, undoubtedly underlies this expansion. The present study adds an example of an application of hydraulic technology that played a role to protect critical aqueduct structures from flood damage to ensure field system survival through time. Other examples of steep-slope channel constrictions formed by opposing stones set with a narrow opening are numerous within the Farfán field system area (Fig. 13) indicate an understanding of creative use of hydraulics knowledge to enhance the efficient use of field systems. Basically channel constrictions of this type create a hydraulic jump ahead of a constriction with a high height, low velocity flow leaving the throat that flows slowly into downstream distributive channels within the field system to regulate water seepage rates into the soil. The channel size, slope and inlet configuration supplying water to maintain a stable hydraulic jump without overflow must therefore be intelligently constructed to allow just a sufficient flow rate for that purpose. This design capability appears to have been well understood by Chimu engineers as demonstrated by many canal design examples.

Examples of hydraulic controls in the form of flow rate limiting and velocity-reducing hydraulic structures point to a yet little explored creative aspect of Chimu irrigation agricultural practice and the Chimu hydraulic science knowledge base. While examples illustrating applications of Chimu hydraulics engineering are somewhat limited by scant exploration and analysis to date, undoubtedly more remains to be discovered as focus is given to exploration and analysis of hydraulic features. By computer analysis of such systems, aspects of Chimu hydraulic science will be revealed and point to a new evaluation of the contribution of indigenous South American cultures to the hydraulic sciences.

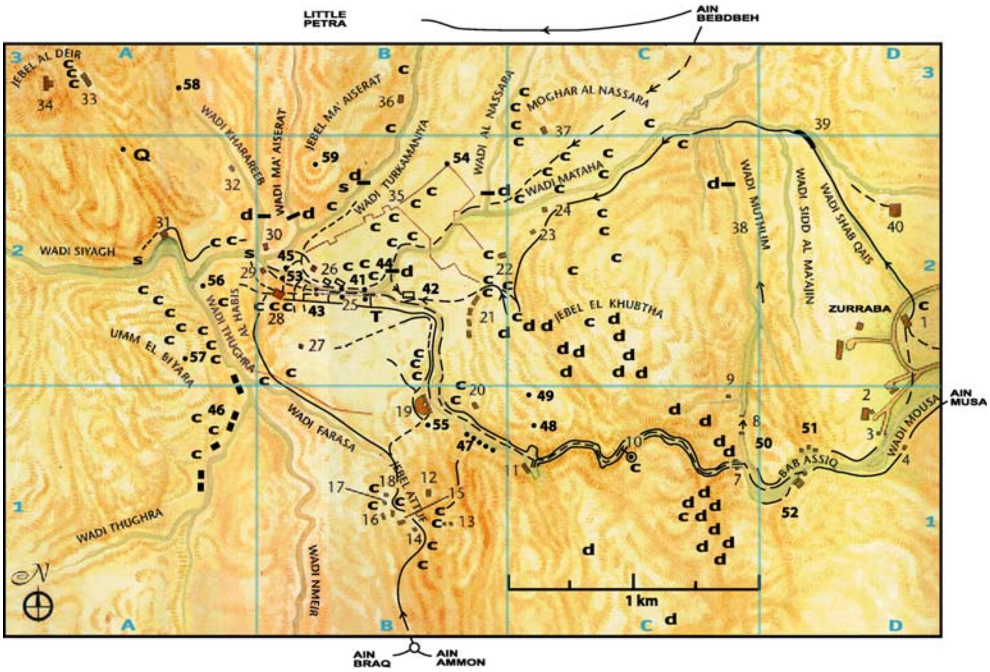
Water Management in Petra

C. R. Ortloff

Many scholars have studied the political history of Petra (Taylor 2001; Guzzo and Schneider 2002; Glueck 1959, 1965; Hammond 1973; Levy 1999; Auge and Denzer 2000; Bowersock 1983; Bourbon 1999; Markoe 2003). Despite the fact that control of water is essential to an understanding of life in the desert, there has been little scholarship on hydraulic engineering at this site. Figure 1 shows details of the supply and distribution system leading water to the urban core of Petra. Numbered locations denote major buildings, temples, and site features listed in the Appendix. Shown are major dams (d-), minor dams (d), cisterns (c), water distribution tanks (T), and springs (S). The grid system (A,B,C;1,2,3) serves to define an area coordinate system composed of 1.0 km^2 grid boxes to locate various features mentioned in the text.

The urban core of Petra lies in a valley surrounded by high mountainous terrain. Seasonal rainfall runoff passes into the valley through many canyon streambeds (wadis) and drains out through Wadi Siyagh (A;2). While water storage is a partial key to the city's survival, a number of springs internal and external to the city (Fig. 1: Ain Mousa, Ain Umm Sar'ab, Ain Braq, Ain Dibdiba, Ain Ammon, al Beidha, Ain Bebdbeh) provided water channeled and/or piped to the urban center.

The main Petra water supply originated from the Ain Mousa spring about 7.0 km east of the town of Wadi Mousa (Fig. 1, D;1) combined with waters of the minor Ain Umm Sar'ab spring; this supply still serves the associated tourist complex (2), (3) located outside of the Siq (C;1) entrance (10). The Siq is a 2 km long, narrow passage through high mountains bordering the eastern part of the city core area. Early phases of water supply utilized Ain Mousa spring water channeled through the Siq (dashed line, 29, B;2) to the urban core of the city as far as Q'asr al Bint (29) with final drainage into the Wadi Siyagh (A;2). Due to dam and flood bypass tunnel construction at the Siq entrance and infilling and paving of the Siq floor both in ancient and modern times to reduce flooding, the channel now lies under the current pavement surface attributed to Nabataean construction under Aretas IV and later



Water Management in Petra. Fig. 1 Petra site features and water distribution systems.

Roman paving efforts. Recent excavations in front of the Treasury (11, C;1) have revealed remnants of this early open channel. While this channel provided water to early, low population phases of the city, the later concentration of urban settlement areas north and south of Wadi Mousa (B;2) represented a transition towards full city status with a cosmopolitan society involved in trade and commerce. With demands to increase water supply to spreading urban settlement areas resulting from population increase and a desire to match the city's prosperity from trade with an appropriate elevation in symbols of success, extensive use of pipelines followed to bring larger amounts of water to areas not reachable by the low elevation, open channel system. Pipeline systems, however, introduced new hydraulic design complexities that involved knowledge of ways to maintain stable piping flow whose maximum transport flow rate matched (or exceeded) spring flow rate input. Flows in poorly designed pipeline systems are capable of a number of transient, self-destructive hydraulic instabilities (e.g., water hammer, pressure surges, transient wave structure, flow intermittency, or internal oscillatory hydraulic jumps). Thus analysis of Petra's piping systems provides insight into the available technical knowledge base applied to problem solution. Pipeline routing involved constant angle contour path surveying through rugged, mountainous terrain as well as choices of hydraulic technical parameters (slope, diameter, internal wall roughness, sinuosity, and supply head) that govern piping carrying capacity. Choices of these parameters, as extracted from the archaeological record, as well as insights into the management strategy of these assets, indicate the level of technical achievement of Nabataean engineers.

Water Management in Petra. Fig. 2 The Zurraba (al Birka) reservoir.

One example of later phase technological advances is a reservoir at Zurraba (1, D;2) (Figs. 1 and 2). It was constructed to store and transmit water along the Wadi Shab Qais (D;2) around the northern flank of the Jebel el Khubtha mountain (C;2) in an elevated channel (D;3, 40) containing piping (Fig. 3) that continued over royal tombs (22–24) to supply a typical large basin at its terminus (Fig. 4). Descending channels from this basin to cisterns at the base of the mountain added water to that collected from rainfall runoff for urban housing needs, celebratory rituals at nearby tomb complexes and for piping elements conducting water

W

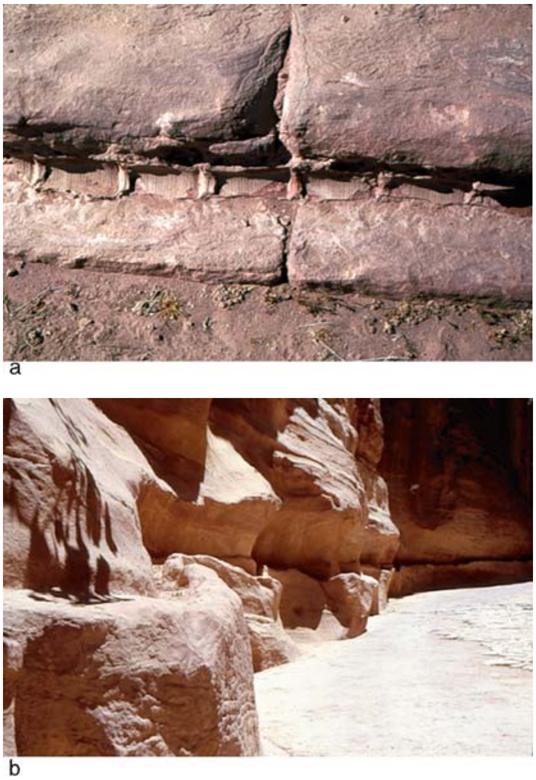
Water Management in Petra. Fig. 4 Elevated settling basin typical of the el Khubtha channel/piping system.



Water Management in Petra. Fig. 5 (a) Piping channel elements on the north side of the Siq. (b) Channel trough on the north side of the Siq for piping placement.

further on to city center locations. While runoff capture is one probable sourcing of the Zurraba reservoir, connection to local spring sources, including Ain Mousa, remains probable for additional charging. Although reservoir water could be used to supplement the Siq open channel flow, later city phases involved shifting Ain Mousa water supplies to a Siq piping system after the open channel was abandoned. In this case, rainfall runoff and spring charging still enabled the Zurraba reservoir to supplement Ain Mousa Siq pipeline flows when required. The Jebel el Khubtha pipeline appears to be the main outflow path for reservoir water along Wadi Mataha (B;2, C;2) and surplus water, after cistern topping, was most certainly directed to the main city fountain (Nymphaeum 42, B;2) through a pipeline (as some pipeline fragments in the area suggest). From a systems point of view, the reservoir served principally to maintain cistern levels by on-demand water release while the Ain Mousa spring provided the continuous spring supply source to the Nymphaeum through piping supported in a channel through the Siq (Fig. 5a, b; Ortloff 2005). The ability to provide an "on-demand" water supply from this backup source would prove most useful to large caravans entering the city that would place a sudden demand on water supply capability.

Pipeline Carrying Capacity Considerations: The Zurraba–Jebel el Khubtha System

While a spring produces a given volumetric flow rate, a limitation on how much can be transported by pipeline relates to pipeline technical characteristics (diameter, internal roughness, slope and supply head). Piping design considerations require the spring output flow rate to match (or be less than) the theoretical carrying capacity of the pipeline. Technical examination of Nabataean pipeline designs then yields insights into solutions to increase flow rate throughput. If the long Jebel el Khubtha piping system were to function in full-flow mode typical of a very low-flow rate, its flow rate would be somewhat less than that derived from an open channel, near critical flow mode due to internal wall frictional resistance; larger diameter piping would then be required to match the spring flow rate. For a steeper slope design, gravitational acceleration causes flows to become supercritical and tend to an internal free surface normal depth. Rapid supercritical flows, however, may be subject to intermittent zones of subcritical full flow induced by internal piping wall roughness and curvature resistance effects as well as transient hydraulic jumps that create pulsations in delivery flow rate at the piping exit. Such effects can lead to destructive tensile forces that weaken mortared piping joints. The best piping design to produce a stable volumetric flow rate is therefore a partially full flow at near, but below, critical conditions that empties water gently into a terminal reservoir. Selection of this piping design would then be a measure of knowledge of hydraulic principles required to achieve a steady, high flow rate to the terminal elevated basin placed far left in C;2 and would explain the high elevation positioning of this pipeline (to maintain a low slope) around Jebel el Khubtha. The Nabataean design, given its slope and piping diameter, closely matches the near critical flow rate (Morris and Wiggert 1972) and provides for the largest possible flow rate from the Zurraba reservoir to meet on-demand large flow rate requirements. Additional benefit from the Nabataean design resides in the presence of partial, open channel flow in the piping to greatly reduce the leakage rate compared to a pressurized system. Since particles settle in the reservoir, no particle transport occurs to clog piping; this is particularly important as access to the high elevation piping (25 m above the ground) on the near vertical Jebel el Khubtha mountain face would limit the possibility of cleaning procedures. The combination of all these features designed into the Jebel el Khubtha pipeline indicates that much thought went into the best placement and design of this system to achieve the multiple goals that ensured not only system longevity but also rapid, on-demand water delivery capability with minimum leakage.

From an exit pipeline leaving the basin to a ground level cistern, additional piping led to the Nymphaeum fountain to complete the Jebel el Khubtha circuit from the Zurraba reservoir. As the Nymphaeum was a major water supply to the urban core and market areas, much effort and innovation was employed to guarantee its year-round functioning from the Siq piping system (Ortloff 2005) supplemented, on-demand, by the long Jebel el Khubtha pipeline from the Zurraba reservoir.

Supplemental Water Supply Systems Supply Redundancy

A number of cisterns and dams on Jebel el Khubtha (Akasheh 2003) (C;2) captured and stored rainfall runoff. Some of the upper level cisterns appear to have channels leading to ground level cisterns that led to urban housing or field areas to the west of Jebel el Khubtha to supplement the water supply from the Zurraba system. As previously mentioned, the Siq floor open channel was abandoned in late Nabataean phases and replaced by a Siq north wall pipeline system (Fig. 5a, b) that extended to the area across from the theater district (B;1) and ended at the Nymphaeum. Thus at least two separate supply lines (Siq and Jebel el Khubtha) led to the Nymphaeum to ensure supply redundancy. The construction for the Siq pipeline system is generally attributed to Malichus II or his predecessors, Aretas IV or Obodas III, in the first century BCE or early in the first century CE (Guzzo and Schneider 2002). Since water demands south of Wadi Mousa (transecting urban Petra) are high due to the nearby marketplace, theater, temple, and housing districts and significant water resources are available from the north side piping systems, a pipeline transfer connection from the Nymphaeum to this area is logical for development of this area. While a bridge or piping from the north side of the Jebel el Khubtha system in the El Hubtar Necropolis area (20, B;2) across the Wadi Mousa may have existed in the vicinity of the theater (19, B;1) to carry water (at the same level) to the south side, traces are lost due to extensive erosion flood damage. In addition to water delivered by these means, the theater water source was supplemented from large, upper level reservoirs in the Wadi Farasa area, and pipelines originating from Ain Braq and Ain Ammon sources (Fig. 1) again indicating built-in supply redundancy from multiple sources. Some of the larger reservoirs appear to function in connection with a spring supply system and are situated to collect rainwater runoff; reservoir usage, therefore, is mainly to provide water for occasional peak requirements. Surface cisterns appear to be opportunistically placed to collect rainwater runoff; other than seasonal rain recharge, the numerous, widely scattered catchments appear to serve local community needs for supplemental supplies of lower quality water when piped water is not readily accessible.

Traces of a south side piping system (Fig. 6) are found in front of the theater. Two parallel pipelines

Water Management in Petra. Fig. 6 Dual pipelines continuing past the theater to supply tanks (T) above the Cardo.

W

Water Management in Petra. Fig. 7 Great Temple on the south side of Wadi Mousa.

continue past the theater along the ridge (B;2) above the commercial district along the Roman Cardo (25), Hadrian's Gate (43), upper and lower marketplaces and the Paradeisos water garden (Bedal 2004) to locations above the Great Temple (28, Figs. 1 and 7; Joukowsky 2001, 2003) where they form part of the water supply to structures located in (B;2). The two separate pipelines may indicate branch lines to separate destinations or a later elevation change that continues piping to Q'asr al Bint through the Great Temple to supply the Sacrificial Altar area, although no excavations exist to connect the multiplicity of subterranean canals below the altar to a specific water source. Hadrian's Gate (43) separates the secular commercial district from the western sacred temple district containing the Great Temple, Temple of the Winged Lions (26), and Q'asr al Bint. The Paradeisos water garden complex west of the gate consisted of an open house structure situated on a platform island within a large water filled basin; bridge structures connected the island to outer precincts, and greenery added to the city's elegance as indicated by reconstructions reported by Bedal (2004). The basin walls contain overflow channels as well as supply piping that may emanate from both the Nymphaeum piping extension into this area and water from a south side spring supply system. Distributed along this piping system, a number of elevated basins (T, Fig. 1) lined with hydraulic plaster (Fig. 8) served as receiving basins; earth-fill mound structures extended from these tanks to the lower Cardo area and served as pipeline support structures. As the basins are elevated 20 m on a bluff above the Cardo, sufficient head existed to provide pressurized water for fountains in the market area below as well as for the Great Temple (and possibly Q'asr al Bint). Because the south side urban core region contains the marketplace area, water requirements were high; consequently, additional supplies are channeled to this area by means of an underground channel (B;1; B;2) from the combined flows from Ain Braq and Ain Ammon. Some as yet unexcavated branch of this system running through high elevation channels may be part of the system that provided water to piping located in front of the theater.

Water Management in Petra. Fig. 8 Fragment of one of the elevated water collection basins (T) above the Cardo area.

Water from these springs may be supplemented by elevated cistern storage water from the Jebel Attuf area (B;1) in one of the many high places (12, 13, B;1) of the city. Water to the Lion Fountain (14, B;1) and al Hamman pool area in the vicinity of elite tombs (16–18; B;1) came from this supply line that continued on to the Great Temple area and clearly indicated that a continuous spring supply is part of the system due to the presence of the Lion Fountain. A large elevated cistern located on a plateau above the Tomb of the Roman Soldier (16) (Browning 1982) also contributes rainfall runoff water supplies into this system. Details of the Wadi Farasa water system in this area (B;1) have been investigated (Schmid 2000) and indicate the existence of large reservoirs and piping systems that not only serve local usage, but also have sufficient capacity to transfer water further west to the Great Temple area. Numerous channels, pipelines, and multiple cisterns within, and leading from the Great Temple, indicate that water supplies within the temple were abundant (Joukowsky 1999, 2001, 2003). Water export lines to the marketplace area and the Q'asr al Bint region from the Great Temple served as part of the water system.

Water Supply System Management Operations

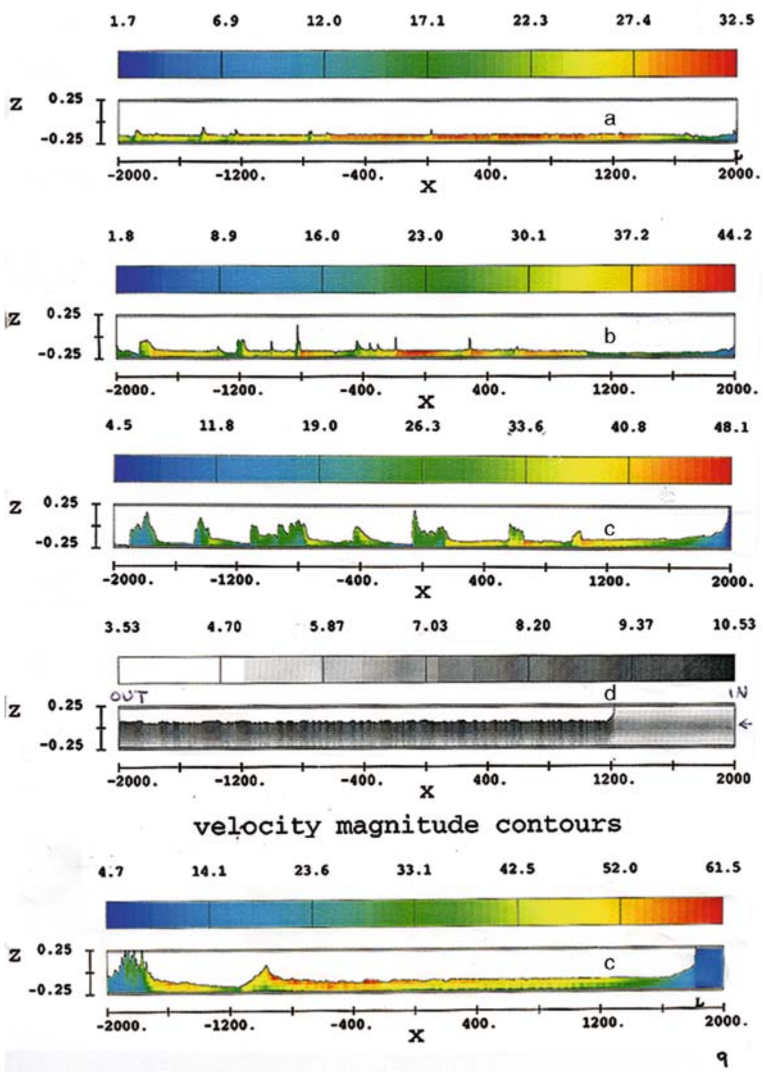
The evolution of the water system to incorporate piping networks transformed the site to meet the demands of a large urban population estimated to reach 30,000 (Guzzo and Schneider 2002). The water system incorporated both intermittent, on-demand supplies piped from large reservoirs or drawn from cisterns and continuous supply piping systems from remote springs to provide daily requirements of city inhabitants. No water could be wasted. As a consequence, transfer piping from north side systems (Jebel el Khubtha and Siq pipelines to the Nymphaeum) provided water that could be transferred to south side downhill locations for further usage or storage before final discharge into the low elevation Wadi Siyagh.

Water storage through use of major, on-site dams presented yet a further aspect of Petra's water system. For example, on the north side of Wadi Mousa, numerous high status structures exist in the B;2 quadrant [Temple of the Winged Lions, Royal Palace (41), North Defense Wall and Fortress (35), Conway Tower (54)] and are logically associated with some water supply system. A dam (d) at Wadi Turkamaniya (B;2) may have trapped and stored sufficient runoff to provide water to the lower reaches of the Temple of the Winged Lions although no excavation data is available. Excavations reveal that lower portions of both the Temple of the Winged Lions and the Great Temple spanned the Wadi Mousa stream by means of bridging. It appears then that supply redundancy derived from pipelines from different spring/reservoir sources crossing from one to another part of the city is an aspect of the design approach. This design philosophy ensures that water supply to any area may be composed from different sources depending upon variations in individual spring flow rates and reservoir/cistern storage amounts and implies that management oversight was in place to monitor and control the system network.

While cisterns are well dispersed through the urban settlement area, a main underground channel starting from Ain Bebdbeh north of (D;3) and running toward the convergence of Wadi Mataha and Wadi al Nassara (B;2), runs into the lower reaches of the north side below the temple areas. To illustrate the Nabataean mindset to utilize all water resources, a further element based upon on-site dams constituted yet further complexity to the water management picture. Local histories mention the existence of large dams – one on the Wadi Mataha (Taylor 2001), the other on the Wadi al Nassara (Fig. 1). Destroyed remains are found to verify that these dams provided water storage from rainfall runoff within urban Petra. Judging from Nabataean placement of the Wadi Mataha dam (d), piping to the nearby Nymphaeum must have been an additional third backup water source to the fountain. Since the Ain Mousa spring could also serve to place water behind the Wadi Mataha dam through the Wadi Shab Quais pipeline branch from Zurraba (in addition to seasonal rainfall runoff storage behind the dam from diversion of the Wadi Mousa stream through the bypass tunnel, 8 in Fig. 1), the water level behind the dam could be maintained to provide backup water to the Nymphaeum throughout the year. The Nymphaeum could then be supplied by contributions from stored runoff water behind the Wadi Mataha dam, a canal or pipeline from Ain Bebdbeh, the pipeline along the western face of Jebel el Khubtha feeding ground level cisterns and pipelines, and the north side Siq pipeline. This degree of redundancy indicates that planning for water supply variations was a consideration addressed by a complex design that could tap into various pipeline-water storage resources depending upon available supplies.

Flood Control, Groundwater Recharge, and the Great Temple Water Subsystem

Floodwater drainage during the rainy season was a major concern. Since heavy rainfall and flooding characterize the Petra area, measures to divert Wadi Mousa floodwater from the Siq by means of a bypass tunnel (Fig. 1, 8 at C;1), a low dam at the Siq entrance and elevation of the Siq floor near the entrance provided flood control. While this strategy had proven effective in deflecting small flood events, continuous deliberate infilling and accumulating flood deposits in the Siq helped protect against floodwater incursion.



Water Management in Petra. Fig. 9 FLOW-3D calculations of a rectilinear model of the Siq piping for entry full flow input flow rates of 1.0 (a), 2.0 (b), 5.0 (c), 10.0 (e) ft/s (0.305, 0.610, 1.52, 3.05 m/s) velocity indicating internal flow development for the observed wall roughness distribution. Fig. 9d shows results for smooth interior piping at 1.52 m/s initial, full flow inlet velocity.

While large flooding events had negative consequences, there were also ways to utilize the sudden water bounty: storage dams across the numerous wadis intersecting the urban core served to reduce floodwater entry into the city while seepage from the impoundments provided water table recharge suitable for well extraction during protracted drought. Thus a fraction of the seepage from dam storage, canals and pipelines ultimately can be recaptured and used as an ultimate groundwater defense against drought on a citywide basis.

The same idea could also be used on a more localized basis for elite structures. Within the Great Temple, an elaborate south boundary wall drainage channel system collected infiltrated rainfall seepage and directed it to a nearby underground cistern with 50 m^3 capacity located within the eastern, upper part of the temple structure. A channel connected to the upper part of this cistern conducted overflow water to lower level structures before exiting to Q'asr al Bint and Wadi Siyagh in order to regulate its maximum capacity. Large channels located in an upper room north of the Theatron (Joukowsky 2003) of the temple most likely indicate the terminus of a subterranean channel from the Ain Braq, Ain Ammon system (B;1, B;2) with water transfer access to the cistern. Some additional water sources may have been available from springs in Wadis Kharareb and Ma'Aisert (Fig. 1) although piping connections await further excavations. Channel water, supplemented by cistern water to meet peak demands, was then distributed to subsidiary open cisterns located in east and west sides of the temple and then through subterranean channels under the lower temenos (a

Water Management in Petra. Fig. 10 Typical rippled wall pattern within the interior of some Nabataean piping elements.

sacred enclosure around a temple or holy site) platform to lower level rooms near the temple entrance stairway. Thus the cistern functioned as a reservoir adding stored runoff and seepage water to the channel-delivered base supply when required – much in the same way that previously described reservoir–pipeline systems worked to meet occasional peak demand requirements. Because such a system is contained within the temple itself, its position of importance as a major canal terminus and water distribution node is clear from the complexity of hidden channels, cisterns, and piping thus far discovered. Perhaps the internal water system of the temple, capable always of providing ample water supplies for rituals, had special significance to demonstrate the premier role of religion in the lives of the Nabataeans; only later under Roman rule are these supplies used for more utilitarian Cardo marketplace purposes indicating Roman predilection to practical concerns.

While the north side piping of the Siq provided the main potable water supply, the south side channel system was probably meant for animal watering and may have been supplied by a channel from Ain Braq and supplemented from a cistern atop the bluffs with a drop hole to this channel (C0, Fig. 1).

Per Capita Water Availability

For estimates of total water volumetric flow rate into the city, conservatively assuming about a third of the north side supply rate for the south side due to the less robust south side springs, and assuming a combined flow rate between the Siq and Wadi Shab Qais reservoir release lines to be about 40 $m^3\ h^{-1}$, then the city could receive at minimum 50 $m^3\ h^{-1}$ from these sources. While additional sources [Ain Braq (0.8 $m^3\ h^{-1}$), Ain Dabdabah (2.5 $m^3\ h^{-1}$), Ain Ammon, and Ain Siyagh (<1.0 $m^3\ h^{-1}$)] add to this estimate, released storage water and additional springs would add yet further capacity to arrive at a yet higher flow rate estimate – perhaps to 100 $m^3\ h^{-1}$ total if less conservative leakage estimates are used. For about 30,000 inhabitants, then at least 0.04 $m^3\ day^{-1}$ (40 l day^{-1}) would be available on a per capita basis, which is minimal to maintain hygienic standards. Considering public use of fountains, watering troughs, baths, water gardens, and workshops, per capita water availability is well within the Rome urban water usage rate of 0.6 $m^3\ day^{-1}$ per person (Butterfield 1964). Considering hot climate survival water intake per person of about 0.003 $m^3\ day^{-1}$, then surplus water beyond human consumption/survival rates is available by these estimates. Estimates for water storage from dams and cisterns on Jebel el Khubtha alone (Akasheh 2003) is 0.36 m^3 per person; for a personal consumption rate of 0.003 $m^3\ day^{-1}$, then theoretically, considering evaporation losses, about a 2 month emergency supply was available through Jebel el Khubtha cisterns if spring flow rates declined precipitously.

A similar calculation shows that Zurraba reservoir contained about 3 weeks emergency supply and additional cisterns and dams on site, particularly those of the Wasi Farasa system (Schmid 2000) add yet further reserves totaling several month's supply. While per capita water supply for Petra is somewhat lower than Rome city standards, still the amounts supplied to the city on a continuous basis are more than sufficient to maintain quality living standards.

As the city underwent major construction in the period 50 BCE–100 CE during the reigns of Obodas II (III) and Aretas IV, Roman/Greek technologies most probably influenced water system design. The availability of advanced Roman surveying techniques used for aqueduct system design (Lewis 2001) would be particularly useful in constructing long distance lines of prescribed slope to and within Petra to maintain stable open channel flows in piping to match spring flow rates. While the design capability to achieve such balances still remains elusive due to fragmentary knowledge of ancient hydraulics practices, some hints of water flow rate measurement capability exist (Cohen and Drabkin 1966; Ortloff and Crouch 1998).

In essence, the Nabataeans utilized all possible above-and-below groundwater supply and storage methodologies simultaneously. While water storage in contemporary Hellenic cities also emphasized cistern water storage for household use, the Petra systems advanced this technology to citywide systems with elaborate dam and cistern systems that served both water storage and flood control purposes. Water storage in groundwater aquifers was also practiced by multiple dam system storage; this allowed for the possibility of constructing wells as backup systems should all other supply systems decline due to long-term drought effects.

30. Museum	60. Snake monument

A water supply system consisting of dams, cisterns, channels, pipeline networks, and groundwater storage exploited multiple spring supply systems and rainfall runoff collection. Examination of two different pipeline system designs with different slopes and delivery requirements (one on-demand, the other continuous flow) indicates that technology is in place to provide designs that minimize leakage, maximize flow rate, minimize particle transport, and eliminate transient flow instabilities that cause system vibration and prevent steady flow from developing. Further advances, as related to the Siq pipeline, relate to water purification by four easily cleanable settling basins (Bellwald 2004) whose positioning eliminates a complex flow stability problem (Ortloff 2005). The totality of solution options confirms that a hydraulic design methodology is applied with skill to solve complex hydraulic engineering problems.

While it is traditional to look for earlier Greek and Roman technical advances (Ortloff and Crouch 2001; Cohen and Drabkin 1966) that improve the Nabataean system, few are found, indicating that Roman engineers perhaps viewed the Nabataean system as optimum. In this case, it is likely that the water management techniques observed by the Romans served to increase their library of water conservation and management techniques as applied to desert cities and outposts. While details related to technical transfer and hydraulic engineering practices of ancient societies are still a matter of research, it is certain that the longevity of Petra based upon its innovative water system design constitutes a vital chapter in the history of water management (Fig. 9).

Water Procurement in the Prehistoric Caribbean

Peter Drewett

When Ceramic Age peoples arrived in the Caribbean, water was readily available on some volcanic islands like Dominica but virtually absent on most of the coral islands like Barbados. Initially this would have been a major constraint to settlement and survival. In years of regular rainfall, rainwater could be collected from rock pools, caught in foliage of plants and collected in pottery vessels or even upturned conch shells. When the rains failed, however, drought would have led to serious problems on islands without the ability to maintain surface water supplies in the form of rivers and streams. On at least three islands in the southern Caribbean, Barbados, Mustique and Carriacou, Amerindians developed a specific alternative way of guaranteeing a water supply. It may be assumed that the technique was used on other islands although archaeological evidence has not yet been located.

On coral rock islands (Machel 1999), where the bedrock is highly permeable, salt seawater may infiltrate under all of the island or at least around the coastal fringe. Rainwater falling onto the island will seep down until it reaches denser salt water. It will then flow towards the sea on this denser water. At the head of beaches it will be quite shallow before it mixes with seawater (Schultz 1995). Somehow Amerindians recognised this source of sub-surface fresh water and tapped into it. Although similar to sinking wells elsewhere in the world, the process of tapping into this water required great skill; otherwise salt and fresh water would be mixed and the water source spoiled.

Excavations at the Amerindian settlement at Heywoods (Port St Charles) on the west coast of Barbados revealed two methods used to tap into this shallow supply of fresh water (Drewett 2000). The main Ceramic Age settlement at Heywoods was occupied from about AD 600 to AD 1200 (Late Saladoid – Troumassoid). Several round houses and burial areas have been excavated together with wood- and pot-lined water holes (Drewett 2000).

Two wood-lined water holes were excavated. These consisted of wood planking some 1 m in length sunk into the soft sand and held in place by large coral rocks. Both were roughly square in shape (Fig. 1).

Water Procurement in the Prehistoric Caribbean. Fig. 1 Wood-lined water hole at Heywoods, Barbados. ca. AD 800–1000 (source by author, photo by Abel Drewett).

W

The wood used was false mastic (*Mastichodendron* sp.) and *lignum vitae* (*Guaiacum* sp.). One was dated to ca. AD 780–1020 (B-147314) and the other to ca. AD 790–1030 (B-147313). In both wells calabash (*Crescentia cujete*) remains were recovered suggesting these were used to scoop up the fresh water (Fig. 2).

More common, and possibly more successful, were the pot-lined water holes. A shallow hole was dug into the underlying wet sand and a large cooking/storage pot was sunk into the wet sand. These pots had been pre-prepared with their bases carefully removed (Fig. 3).

The pot was carefully pressed into the wet sand while more sand was scooped out of the interior. Additional pots were then stacked on top, acting as a cofferdam to stop wet sand slumping back in. The pots were held in place with coral rock boulders and/or wooded wedges. After a couple of hours any sediment in the water would settle with the pressure of the underlying water pushing the fresh water up into the pot-lined hole (Figs. 4 and 5).

It is uncertain whether these pot-lined water holes were left open or had a removable cover. None were found covered although several had large sherds of pottery in the water holes, which could have been used as lids. Flat cassava griddles found elsewhere on the site would have also made suitable lids, as would organic materials like large leaves or planks of wood. A major problem was probably local soiling of the water by domestic rubbish or even human burials, which were also within the domestic area. This might explain why holes had to be regularly replaced. Twenty three were systematically excavated during the main phase of salvage excavations at Heywoods during 1998/1999, but many more were noted during building work for the Port St Charles marina constructed on the site.

Some of the pot-lined water holes had a highly decorated pot rest resting on the top of the stack. These are like ceramic collars in which large unstable pots

were set to make them stable on uneven ground. One found was 32 cm in diameter and 17 cm high. It was red-slipped with white on red paint and grooved decoration in a concave-ended rectangle and vertical line pattern. This was among the finest pottery found on the site, so it would suggest great importance of the mouth of the hole. Tapping into this underlying source of water may have involved great perceived risk involving careful ritual, for Amerindians believed that a river of the dead ran under their houses and settlements. Ritual specialists were no doubt involved in the placing and digging of these pot-lined water holes and perhaps hallucinogenic drugs, like cohoba, were taken prior to digging rituals (Drewett 2002).

How widespread the use of pot-lined wells was in the prehistoric Caribbean remains uncertain particularly because of limited archaeological excavation in the southern Caribbean. To date they have certainly been recorded on three sites on Barbados: Heywoods, Spring Garden and Maxwell. They have also been recorded on Mustique and Carriacou. Many further examples may have been lost by coastal erosion or await discovery.

Water Systems in Bronze and Iron Age Israel

Avraham Faust

The Near East is located on the edge of the desert. Part of the region is arid\semi-arid and, as droughts are a frequent phenomenon, water is a scarce resource even in the Mediterranean climate zone. Water was therefore an important factor determining the situation of settlements in antiquity. Initially, many settlements were located near water sources, mainly springs (rivers are a rare phenomenon in Israel). However, since security was also a major consideration, larger settlements gradually tended to be situated on top of hills. In this conflict of interests, security had, in most cases, the upper hand, and alternative means of obtaining drinking water had to be secured.

Wells

A well is an artificial shaft sunk into the ground all the way to the water table. One of the earliest known wells was uncovered at the submerged Neolithic village of ‘Atlit Yam. Later wells are known from Beersheba, Lachish, Tel Zeror, etc., and it seems as if the practice became widespread from the Iron Age onward (and mainly from the Classical periods). Notably, however, wells are typical of lower regions and plains. It is more difficult to dig wells in mountainous areas because of both the depth of the water table and the hardness of the rocks. Wells were, therefore, only a partial solution, and in most cases people used different methods (but see below).

Cisterns

Cisterns were cut out of rock in order to collect and store rainwater. The first known cisterns were apparently dug into the soft limestone of the Coastal Plain in the late Chalcolithic or early Early Bronze Age at Mesar. The earliest cisterns were not plastered, but due to the softness of the stone could still hold the water. The first plastered cisterns were discovered in several Middle Bronze Age sites (e.g., Hazor and Gezer) (see Extra 1). Their use, however, was still sporadic. Plastered cisterns became widespread only during Iron Age I, and mainly in Iron Age II. The use of cisterns became even more widespread in later periods. While cisterns became common, and at times dozens of cisterns were unearthed in a single site, it appears that they were still dug at the family level. Communities, let alone cities/states, had to develop a better solution to the danger posed by the scarcity of water.

Large-Scale Water-Works

Large settlements, if not located on a large spring or a river, needed a guaranteed water source for the summer, and all the more so for periods of siege. After all, the fate of a conquered city in the ancient Near East was horrific, and any effort was done to secure the city and to enable it to withstand siege.

The earliest large-scale water works, evidently beyond the scope of the household, are dated to the Early Bronze Age – the time period when the first cities emerged in the southern Levant. These early water systems are basically large pools, usually located in the lowest part of the settlements, into which rainwater was collected. Such systems were found at ‘Arad, ‘Ai and probably also at Tel Qashish. ‘Arad, located on the edge of the desert, is a unique example. The city was built not on top of a hill, but rather on a basin, probably in order to ease the collection of water. A slightly different type of water system was located outside the city of Jawwa, in Transjordan. Here, dams were built on a dry wadi, absorbing floods, and securing water for the dry season. Such large-scale works were able to support a large population.

Still, in the climatic conditions of the Land of Israel, in which droughts are frequent, rains cannot be regarded as a secure source of water. In cases of failing rain, people would have to go to the nearest spring (usually just below the city). In times of siege, however, which began to become a major consideration as time progressed, such an enterprise was not feasible. Cities had to rely on a more permanent source of water. They developed more sophisticated methods to guarantee access to permanent sources of water, i.e., to springs (which were usually located in the valleys below the cities).

Waterworks technology seems to have advanced substantially in the first half of the second millennium BCE. The notable water system of this period (Middle Bronze Age) is that of Jerusalem (see Extra 2). Here, an attempt was made not to collect rainwater, but to secure access to the water of the nearest spring – the Gihon – which was located below the city at the Kidron valley. From within the city, a large tunnel was dug in the hard limestone. The tunnel went outside the city wall until it opened into a large pool that was located not far from the spring and was protected by fortifications. Water flew from the spring to the pool by way of two tunnels. Due to level differences, the engineers had to raise the level of the water by more than 2 m, in order to let them enter the first tunnel. This was done by the use of dams.

The real "breakthrough" in water systems, however, was accomplished during the Iron Age, and mainly during Iron Age II. A relatively large number of Iron Age water systems were unearthed over the years, and these can be divided into the following types:

1. Covered stairways (galleries). This is the simplest form of Iron Age water work. A shallow tunnel was dug on the tell's[1] slope, from beneath the city wall, all the way down to the spring. The tunnel was then covered. Thus, in times of siege, city inhabitants could sneak from the city to the spring through the covered stairway, without being seen by the enemy. Such systems were discovered in Megiddo and Tell es-Saiyidyeh. Obviously, these systems had their limitations. The spring was known to the enemy, and the gallery could easily be discovered. Once discovered, it could not have been used anymore.

2a. Tunnels. Many Iron Age water systems were dug under the ground, from within the city to the spring. Initially, a large shaft was dug through the earlier layers of the tell. Since these were pretty loose, the shaft was supported by massive retainer walls that prevented their collapse. After reaching bedrock, a smaller tunnel was dug in the rock, at an angle that lowered it toward the spring. Such systems were discovered for example in Gibeon and Megiddo (early phase of the tunnel).

2b. A modification of this type of water system is also known. In some cases, a tunnel brought the water from the spring toward the bottom of the shaft (i.e., toward the city). Such systems are known, for example, at Megiddo (a later phase); the Warren Shaft system in Jerusalem (see note: Jerusalem water system during the Iron Age) is a variation of this type.

While in many cases the enemy who besieged the city could still enjoy the water supplied by the spring, such systems provided (1) a secure approach to the water by the defenders; (2) a better chance of concealing the system from the enemy. Still, such systems were still susceptible to discovery, and the enemy could harm the water source itself (e.g., poison it). Furthermore, the enemy could even use the tunnels as a mean to approach the city in surprise.

3. "Tunnels" dug to the water table. This type is very similar in its form to the previous one. A wide vertical shaft was dug through the tell's layers to bedrock, and this was followed by a narrow diagonal tunnel that was dug in the rock. This diagonal tunnel, however, did not reach the spring; it descended until it reached the water table. While very similar in form to type b, this is simply a large and complex well. Such systems were not only concealed from the enemy, but were also completely secured. Some were discovered, for example, at Hazor and Gezer.

4. The last type of large scale Iron Age water works is that of large underground reservoirs, dug into bedrock (inside the cities). Rainwater was collected through an extensive system of plastered tunnels (e.g., at Beth Shemesh), or from floodwaters in nearby wadies[2] (Beersheba). Smaller reservoirs are also known in this period, e.g., in the fort at 'Arad. While not as reliable as permanent water sources, it appears as if such large reservoirs could absorb enough water underground, to overcome the limitations discussed above (regarding the dependence on rain water).

[1] A tell is an artificial mound formed by the accumulated remains of ancient settlements.

[2] A wadi is a valley, ravine or channel that is dry except in the rainy season.

The galleries (type 1) were the simplest type, and indeed they were used earlier in the Iron Age. It appears as if type 2 was developed to overcome the limitation of the galleries. Type 3 was seemingly the most advanced system. We do not know if these systems were developed on the basis of the knowledge that there was a water table "down there" (the people of the time had to have had this knowledge, as they were familiar with wells), or whether hewers of a type 2 system accidentally reached the water table, and this discovery gave rise to the development of this type (structurally, type 3 is very similar to type 2). This reconstruction is of course speculative, and we need more detailed chronological information in order to confirm or refute it.

Various water systems are also mentioned briefly in the period's written sources, e.g., the Bible (e.g., II Kings 20: 20; Isaiah 22: 9–11; II Chr. 32: 30), and ancient inscriptions (e.g., the Mesha inscription).

The most sophisticated Iron Age water system is Hezekiah's tunnel, which was dug in Jerusalem during the late eighth century BCE. A 533 m. long underground tunnel brought the water from the Gihon spring to a lower point that was located in the other side of the city, in order to collect the water in a pool in a secure place.

In later periods, and especially from the Hasmonean and Roman period onward, larger water systems, e.g., ten km of aqueducts were built, but this is beyond the scope of this entry.

Extra 1: The Open Cisterns of the Negev in the Tenth Century BCE

During the tenth century BCE, the period of the biblical United Monarchy, dozens of settlements were built in the Negev desert of southern Israel. The exact nature of these sites is debated: some view them as royal forts, others believe that only the initiative was royal, while some consider that the entire phenomenon resulted from the settlement of the desert's nomads. Notably, these sites were located away from the few springs that exist in the Negev, and their main source of water was large open cisterns that were discovered at practically every site. These large cisterns were probably covered with skins in order to minimize evaporation. It is also likely that when the rains failed, the inhabitants of many of the sites could go back to the springs, located several kilometres away, and bring drinking water from them.

Extra 2: Jerusalem's Water Systems During the Iron Age

The Gihon spring of Jerusalem is one of the major springs in the central hill country. It is likely that it was one of the causes for the establishment of the city on the low hill, later known as the City of David. Notably, the spring was used by the inhabitants of the city from earliest times. The most ancient water systems are two tunnels, probably dated to the Early or Middle Bronze Age. During the Middle Bronze Age an impressive water system was dug in Jerusalem (above in the text). It is during the Iron Age, however, that the most famous water-works were constructed. As many issues are still debated, the following is only a brief summary that is intended to give a succinct overview (and it cannot deal with all the debated details). The earlier Iron Age system, known as the Warren Shaft (after Captain C. Warren who rediscovered it in the nineteenth century), enabled free access to water through a system of underground tunnels and a shaft. In the past, many scholars believed that it is through this shaft that David conquered Jerusalem (II Samuel 5: 6–9). It appears, however, that this system was constructed only in the eighth century BCE. At this time, improvements were made in the existing system of tunnels (that were cut in the Middle Bronze Age). The works included lowering the bottom of an existing tunnel that led from within the city wall, outward (henceforth, the upper tunnel), thus, exposing a natural karstic shaft that was not known before. Once the shaft was discovered, its significance was apparently observed, previous works ceased, and it became the central part of a new system. A lower tunnel, connecting the spring and the bottom of the shaft, was dug, enabling the water to flow from the former to the latter. Thus, people could walk in the upper tunnel, from within the city walls to the top of the shaft, and draw water. The level of the water at the bottom of the shaft was increased through the use of dams, making water drawing easier. Notably, this system was not very convenient, and was probably intended to be used only at times of siege. The Warren Shaft system, however, was not in use for long, and it went out of use in the late eighth century BCE, when Hezekiah's tunnel was constructed. Hezekiah's tunnel involved the digging of an underground tunnel that led from the spring to a pool at the other side of the City of David ridge, within the city walls. Hence, all the water from the spring was secured. The last stage of the enterprise involved the meeting of two groups of hewers who worked from both sides of the tunnel simultaneously; this is commemorated in the famous Siloam Inscription[3]. Hezekiah's tunnel is an impressive engineering enterprise. Even today, some of the accomplishments still raise questions as to how they were achieved. Among the intriguing questions are, for example, how the workers had enough air during the work, how were the two groups able to meet, and how were they able to maintain such a shallow sloping angle.

Weaving Cotton in Ethiopia and Nubia

Michael Gervers

Archaeological material finds provide invaluable information about the nature and source of textiles and textile fibres in Nubia in the early Christian era. In the half century since Griffith and Crowfoot first identified cotton among the textile fragments excavated at Karanog and Meroe, much more cotton fabric has been retrieved from the rescue excavations of early habitation sites along the Nile subsequently inundated by Lake Nasser; i.e., between Aswan in Upper Egypt and Wadi Halfa in northern Sudan. The oldest fragments identified as cotton have been dated to the Roman period and may be as early as the first century AD. The great majority are attributable to the late Meroitic period, ca. 200–ca. 330 AD, at which time cotton appears to have been the most commonly available fabric. The following period, from ca. 330 to ca. 550 AD, sees a swift and remarkable change in the predominant textile fibre in the region. The use of cotton plummets and is replaced by animal fibre, largely camel's wool.

The quantity of cotton found in excavations of the Roman and late Meroitic periods has led many to conclude that the fibre reached Lower Nubia from the south, where it is thought to have been grown, since this area lies in the rain belt and could have provided the environment necessary for growth. However, no specific sites for cotton cultivation in Nubia and the Sudan at this period have been identified and in view of the chronology of the archaeological evidence, and of what is known of the political and economic situation and agricultural production of the period, there is good reason to suppose that vegetable fibres for textiles were not then grown in Nubia or even in the Sudan. Rather, the Nubians, lacking any such indigenous source of raw material, were obliged to import whatever they required either as cloth or raw fibre. These goods included linen, which, throughout much of the Middle Ages under the provisions of the *baqt* agreement, was one of the principal items received by the Nubians in exchange for slaves. The *baqt* was first formulated in the seventh century, by which time, in the absence of adequate supplies of cotton, the Nubians seem to have sought imported linen as an alternative. The cotton would have been *gossypium arboreum*, and its ultimate source would have been the west coast of India. How it reached Nubia is uncertain. It could have come via the eastern desert trade routes from such ports as Suakin on the Red Sea, or via the kingdom of Axum, which by 300 AD. enjoyed a thriving trade with India. The costs and difficulties of overland transport, however, make it more likely that cotton reached Nubia through the Roman world to the north via the Nile. Since the archaeological cotton remains from Nubia were not made from locally grown fibres, there can be little question of cotton reaching Ethiopia from the Sudan. One early reference which is universally accepted speaks of the direct importation to the Red Sea Axumite port of Adulis of cotton from India in the first century AD. The first indication we have of the production of fine cotton cloth in Abyssinia occurs at the end of the thirteenth century in the commentary of Polo: "Good cotton and buckram cloths are woven here". If his source for the supply is accurate, one can reasonably conclude that by that time cotton cultivation and weaving was well established in the highlands.

Textiles, especially imported, have always been an expensive commodity. Their distribution through the ranks of a society depends directly on the geographical diffusion of the raw material, the quantities produced and the availability of mechanisms to spin and weave it into cloth. An Egyptian source for cotton grown in India would explain why a blue and white cotton tapestry decorated with Egyptian symbols was among the Meroitic finds from Qasr Ibrim. It would also explain why the cotton, if imported raw from India and locally spun, would appear different in texture from contemporaneous cotton cloth of Indian origin discovered at Palmyra. Cotton cloth woven in the humid atmosphere of India could be much finer than that produced in the arid climate of Egypt or Upper Nubia. The latter, if woven on the warp-weighted loom, as is supposed, would have to be much thicker and coarser to prevent it from breaking under the stress of the weights. Consequently, it would have appeared softer than the material from Palmyra and more like wool. When cotton became less available from the fourth century and was replaced by wool, the warp-weighted loom would have been all the more appropriate for weaving it. Weaving in Ethiopia today is carried out almost entirely on a pit-treadle loom, whose treadles are suspended in a hole in the ground. The weaver sits at the edge of the pit with his legs inside so that his feet can operate the treadles. The origin of this loom in Ethiopia is uncertain, although numerous writers have noted how closely it parallels the Hindu loom, and some suggest that the technology is the result of direct importation from the Indian subcontinent. Endrei believes this loom originated in India for the purpose of cotton weaving. The specific characteristics of the Abyssinian loom, according to Boser, are its sturdy frame, the width of the comb and consequently of the cloth produced, and the depth of the pit. Boser goes on to say that regardless of how this loom got to Abyssinia, it did not spread thence to other parts of Africa. It did not spread, until recent times at least, even to southern and western Ethiopia. A close relative is the warp-weighted pit loom which is found frequently in Persia, Syria and Egypt where it was, and is, used particularly for weaving woollen, and in Egypt at any rate for weaving linen thread. It does not seem to be appropriate for weaving with a cotton warp as the strain placed by the weights on the thread would cause it to break. This restriction would explain the absence of the warp-weighted loom in Ethiopia, where cotton is by far the principal fibre used for weaving today. The technical association of the Ethiopian loom with cotton would also argue in favour of a common development, if not introduction, of cotton growing and weaving to the Abyssinian highlands.

Wei Boyang

Fabrizio Pregadio

Although many Chinese works relate the name of Wei Boyang to the origins of alchemy, nothing is known about him from a historical point of view, and his figure may be entirely legendary. Some sources, which place him in the second century, relate that he came from Shangyu (in modern Zhejiang) and transmitted his teaching to Xu Congshi, who in turn handed it down to Chunyu (alternative spelling: Shunyu) Shutong. The text deemed to embody the gist of this transmission is the *Zhouyi cantong qi* (Agreement of the Three According to the Book of Changes), a scripture in verses that is attributed to Wei Boyang. The commentaries usually interpret the "Three" as Heaven, Earth, and Man, or as Daoism, cosmology, and alchemy. The *Book of Changes* is the *Zhouyi* (or *I Ching*, also spelled *Yijing*), the renowned divination manual, which also includes a classical exposition of cosmology in its section commonly known in the West as "Great Treatise."

The genesis of the *Cantong qi* is as obscure as its putative author. Current research tends to consider that an originally Han text on cosmology may have been elaborated into an exposition of alchemical doctrines, perhaps at different dates until the seventh century. The very few references to a *Cantong qi* before that time seem to refer to the original cosmological treatise, whose circulation may conceivably have been restricted due to its association with an unofficial and proscribed body of writings propounding esoteric interpretations of the Confucian classics.

Since the late Tang, however, the *Cantong qi* began almost abruptly to exert a far greater influence in the history of Chinese alchemy than that of any other text. Hidden in the highly allusive language, and the thick layers of symbols and images that characterize this scripture, is an exposition of the doctrine that inspired a variety of commentaries (about 30 of which are extant) and other texts, written between the eighth and the nineteenth centuries, in both Daoist and Neo-Confucian traditions. One of the most well-known exegeses was written by the Neo-Confucian philosopher Zhu Xi, who commended the high literary quality of the text.

The *Cantong qi* would hardly be intelligible without recourse to the related literature. Although it was occasionally read as a treatise on cosmology, most commentaries agree that it articulates the theories found in the tradition of the *Book of Changes*, applying them to the alchemical work. The *gua* (trigrams and hexagrams) of the *Book of Changes* are used both to construct a cosmological model and, at the same time, to represent phases of the process performed by the alchemist. The various possible levels of reading of the text possibly mean that it was used within both the main traditions of alchemy in China, i.e., *waidan* or “external alchemy” and *neidan* or “internal alchemy.”

Weights and Measures in Africa: Akan Gold Weights

GEORGES NIANGORAN-BOUAH

The subject of gold weights is complex and multidimensional. It can be understood only when placed in the context of its original cultural environment, which was linked intimately to gold for its physical substance and to the package (*dja*) in which it came for its sociocultural identity.

The Akan country, on the Gulf of Guinea in West Africa, was and is an area of gold deposits. This metal is both feared and worshipped. Well before the first contacts with Europeans in the fifteenth century, the Akan people used gold dust as a medium of exchange. However, the concept of “gold weights” came from Western traders (Dutch, Portuguese, English, and French).

The first question to ask is: are the figures really weights? In describing these figures, the Baolé use several different terms: *Dja-yôbwê*, *sika-yôbwê*, *shindra-yôbwê*, *nsangan-yôbwê*, *ngwa-yôbwê*. Let us look at the meaning of each of them.

- *Dja-yôbwê* (dja stone). Here the term refers to the contents; it designates what is contained in the package or *dja*. These original elements would be in stone and would be concerned with different realms of human knowledge deemed worthy of interest.
- *Sika-yôbwê* (stone of gold) money. In this second case, the term describes a price or a monetary total. These elements would deal with economics, calculation, and mathematics.
- *Nsangan-yôbwê* (stone of a fine). This term describes the price of a fine, a tax, or a tribute, and is concerned with elements of economics and finance.
- *Ahindr-yôbwê* (proverb stone). This term evokes the notion of speech, thought, and discourse, the fields of literature and philosophy.
- *Ngwa-yôbwê* (game stone). This term refers to the figures comprised of graphic signs. The exercise of reading or deciphering the signs was considered a kind of game, involving elements of imitation and intellectual training.

As we see, the term “weights” appears nowhere in these descriptions.

The *dja* or *sanaa* was originally a package made of animal skin or thick cloth in which the Akan placed their figurines and certain accessories. It seems to have been a kind of encyclopedia written in miniature figures. The package and its contents symbolized the economic power of the living king and the spirits of the dead sovereigns. The act of taking possession of the *dja* signified for a new ruler that he was assuming the power to raise taxes, impose fines, and take measures to increase the state treasury. For his subjects, knowing that the ruler was in possession of the *dja* of the state meant that they judged him capable of administering the financial and economic heritage of the country.

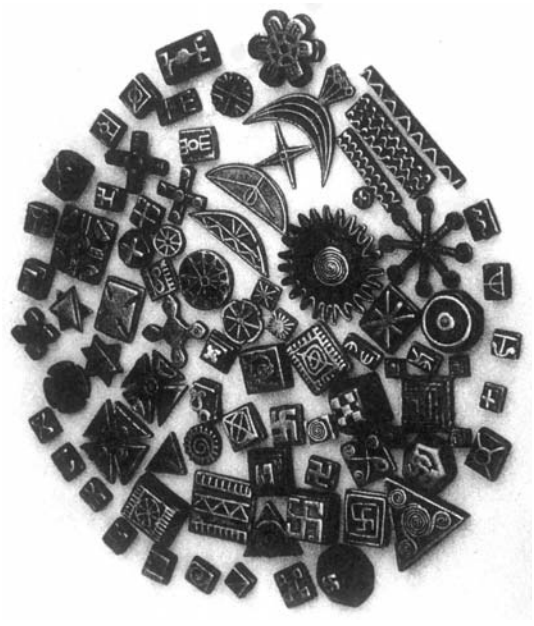
Many different objects can be found in a *dja*, but we will mention here only the essential, original ones.

The equipment is a group of accessories used to manipulate the gold power. They consist of (1) balance scales, used to determine the weight value of different quantities of gold dust used as a medium of exchange; (2) spoons to put the gold dust on the plates of the scales; (3) boxes of many different kinds, their covers often decorated with graphic designs. They are used to hold gold dust already weighed or about to be weighed; (4) winnowing baskets used to separate and rid the gold powder of any impurities; and (5) sieves to separate the different grains of gold dust.

The weights provide knowledge of the weight and monetary value of the quantity of gold powder placed in the plate of the scale. There are three kinds of weights – figurative weights, weights with graphic designs, and geometric weights (Figs. 1, 2 and 3). Gold weights were (usually) made of an original alloy whose composition was similar to that of bronze and brass. However, there are also weights made of silver, copper, and solid gold.

The weights were made by the Tounfouê, an artisans' group, different from blacksmiths and jewelers. These artisans used the lost wax method to produce the weights.

The Akan used a system of computing weight consisting of 11 units. It began at *dama* and ended with *bèna*. It was possible to multiply *bèna* by infinity and the values went from single to double or were



Weights and Measures in Africa: Akan Gold Weights. Fig. 2 Weights with Graphic Designs. Photographs by the author. Used with his permission.

Weights and Measures in Africa: Akan Gold Weights. Fig. 1 Weights with Figurative Elements.

Weights and Measures in Africa: Akan Gold Weights. Fig. 3 Weights with Geometric Elements.

multiplied by two. There were three series of weights – small, medium, and large. They could be added and multiplied.

The small weights series consisted of ten monetary units and was used for all sorts of small transactions:

ba = unit = 0.148 g
ba (*gnon*) = ba × 2
ba (*nsan*) = ba × 3
ba (*nan*) = ba × 4
ba (*nou*) = ba × 5
ba (*nzien*) = ba × 6
ba (*nzo*) = ba × 7
ba (*motchué*) = ba × 8
ba (*brou*) = ba × 10

The medium weights series consisted of 7 units. The computation is done from simple to double, and each unit has multiples and submultiples.

Assan = 4 m.v.
Gbangbandia = 4 m.v.
Tya = 5 m.v.
Anui = 5 m.v.
Gua = 5 m.v.
Anan = 5 m.v.
Tyasue = 5 m.v.
Total = 33 m.v.

These 7 units comprise 33 monetary values. The smallest value is *météba* which equals 12 *ba* or 1.77 g. The largest value is the *ta*, which equals 348 *ba* or 51 g of gold.

In practice, the system worked as follows. For example, the *gua*, the fifth unit, comprised the following five monetary values:

Météba = 12 ba = 1.77 g of gold
Adjratchui = 24 ba = 3.55 g of gold
Tra = 48 ba = 7.54 g of gold
These are all sub-multiples of *gua*.
Gua = 96 ba = 14.20 g of gold (Unit of this series)
Guagnan = 192 ba = 28.40 g of gold (Multiple of *gua*)

The large weight and monetary values series had only 3 units. They were:

Banda = 384 ba = 56.80 g of gold
Banna = 432 ba = 67.44 g of gold
Pereguan = 478 ba = 71.92 g of gold.

In considering the weights and numeric representation, we will consider here only those weights with graphic signs which correspond with calculation and mathematics.

Concerning the signs and marks, the anthropologist François H. Abel has written: "A. Amélékia, a well known man named Diénélou confirmed for me that the Ancients knew how to read from the weights… In the village of Lomo-north, in the region of Toumodi, the village chief knew that the signs on the weights had meaning."

Savary, the Director of the Department of Black Africa in the Museum of Ethnography in Geneva has written: "Each weight is the product of two signs written on it… Reading it is sometimes simple, but often difficult. This is because some Black Africans had a different concept for numeric figuration and for the representation of the product of two numbers. [Also] zero did not exist…". In the system, figures and numbers are represented by vertical and horizontal lines, such as marks and arrows similar to those still seen in charcoal in the houses of African villages.

Commenting in 1605 on the Akan system of accounting and calculating, the Dutch explorer and historian Pieter de Marées made this remark: "The Negroes have weights of copper and tin which they have cast themselves, and, although they do not divide in the same way we do, it comes out the same, and the accounting is always correct."

For the people of the Akan civilization, the gold weights contained in the *dja* constitute a fundamental cultural text, comparable to the Christian *Bible*, the Islamic *Quʾrān*, or the Hindu *Veda*. It is within this sacred package that they had consigned, in idiogrammatic letters and signs, their knowledge and values to be passed on to posterity. In this way, their descendants would not have to reinvent that which had been known by their ancestors and which constituted the foundation of their civilization.

Weights and Measures: Animal-shaped Weights of Burma

Donald Gear, Joan Gear

The royal animal-shaped weights of the Burmese Empires appear to be unique not only as a weight system, but also as one of the most important artifact series, especially in a country with but few durable artifacts. Their shape motifs are mythically leonine

W

(lion-like), elephantine, anserine (goose-like), and gallinaceous (poultry-like). They symbolize Buddhist and pre-Buddhist beliefs, and the Burmese institution of monarchy and its continuity, dynastic, and imperial changes.

For the purpose of this account the Burmese empires comprise those regions of the Southeast Asian peninsula now known as Myanmar (Burma) and northern Thailand (Siam).

Buddhist art in India gave rise to the Burmese choices of animal motifs to use on the weights. The anserine weight, in a tenth century Indian style, apparently was chosen first during a period of Theravāda revival. However, the motifs were ancient even then, originating before the Burmese entered Burma. Shamanistic and animistic influences, both of the post-1000 BCE steppes and China, are also evident. Even more obvious is the use of Chinese models and execution for most of the style groups. Moreover, the decision to use Buddhistic symbolic animals may also have been influenced by the enduring association of Indian and Chinese Mahāyāna Buddhists with commerce.

The mass units and scales reached Burma from India before the twelfth century AD, but India itself obtained them from Achaemenid Persia, which in turn, obtained them from Assyria and Babylonia. However, with the growth of Chinese trade in Southeast Asia from the thirteenth century onward and the adoption in Burma of Chinese mass standards, the Indian mass system was displaced. (A mass unit is defined here as that which was used in multiples to form weights mainly used for heavy trade goods and in fractions mainly for bullion or small amounts of other valuable items, the multiples and fractions together forming the mass scale).

A Burmese term often given to the animal-shaped weights is *shway arlay* (gold weights) which may have been derived from the expression *sri arlay* (king's weights). However, in the East the word gold has customarily been associated with royalty. Also, until the late eighteenth century the weights of Burma were mainly used on behalf of the king, who enjoyed monopolies in trade and was the chief import/export broker.

Of the three main weight shapes, the leonine and anserine were used throughout the empires, while those of elephant shapes were used only in north Siam. The first two shapes were still in use in 1970 along the more remote routes that pass from northeast Burma into Yunnan, north Siam, north Laos, and the Thai cantons of Vietnam.

Most commonly, the diameters and heights of the weights do not exceed about 70 × 120 mm. In shape they occur in three leonine- and seven bird-weight style groups which can be placed in stylistic sequence. A sequence in the elephant-shaped weight styles has not been identified with certainty (Fig. 1).

Weights and Measures: Animal-shaped Weights of Burma. Fig. 1 Weights of different shapes. Photograph by the author.

The leonine shape, called *to* (taw = "royal" in Burmese) is a stylized combination of the parts of four animals. The lion of west and south Asia supplied the model for the open-mouth, bearded head and probably for the crouching torso. The horns were either bull-like or were adapted from the antlered muntjac deer of eastern and southern Asia. The tail of two of the styled groups is usually lion-like, but it is occasionally horse-like. With one exception, all the tails are characterized by the artificially raised tail base of the ancient Yunnanese horse. The legs and feet were modeled upon those of the elephant. All these animal representations are present on the abacus of the Asokan pillar at Sarnath.

The standing bird shapes of six of the bird style groups are in the form of a stylized Chinese mandarin drake (*aix galericulata*) having a knobbed crest and known as a *hintha* (Pali). The model for the squatting/brooding, gallinaceous style group has not been identified.

The elephant shapes are naturalistic. In Siam, the weights of elephant shape, known as *chang* in Thai, are difficult to separate from those figurines of similar shape intended for other purposes. The animal representations stand on usually pyramid-shaped bases which may be rectangular, octagonal, circular, or hexagonal.

Frequently, impressed signs 4–19 mm in size are found, usually on the front or right side of the base. In shape they may be script-like circular, square, bird- or feline-like or in patterns normally of 4, 5, 6, 8, and 9 rays, diverging from a central point. These also can be placed in sequence.

The weights are made of a metal alloy, the essential components being copper (50–80%), lead (3–30%) and tin (0–20%). In some of the nineteenth century weights zinc may amount to as much as 35%. The alloy, formally known as *ganza* (Tamil *kamsa*), was imported either in the form of broken vessels from Canton or as the coins known as *cash* (Sanskrit, *karsha*) from Yunnan.

The *kyat* was the mass unit of the *to* and *hintha* weights and varied with time from about 14 g in the fifteenth century to over 16 g in the eighteenth century.

The 20 *kyat* (320 g) weights constitute about 50% of all weights, while weights with a mass of about 250 *kyats* (3,750 g) amount to about 2%. About one-half of the elephant weights weigh less than 45 g and 2% have a mass greater than 130 g. The average mass unit of the upper part of the gallinaceous mass scale is about 11.2 g and that of the lower part is about 13.9 g. The average mass unit of the elephant-shaped weights is about 12.7 g (Fig. 2).

The essentially decimal mass scale of the *to* and *hintha* weights, based on the mass unit of one *kyat* is 1/8 (or 1/10); 1/4 (or 1/5); 1/2; 1; 2; 5; 10; 20; 50; 100; 250. The elephant-shaped weights occur on the following scale: 1/8; 1/4; 1/2; 1; 2; 5; 10; 20; 40; ?; 60. The gallinaceous scale, at about 37 g, separates into an upper binary scale (1; 2; 4; 8; (?); 32 and what may be a lower trinary scale, 1/9; 1/3; 1. Bengalese and Chinese mass scales of the period are similar in part.

Ninety-nine percent of the *to* and *hintha* weights fall within ± 12% of the mean mass of a particular style group while about 51% of them fall within ± 2%. These variations lie in the making of the weights not in additions, subtractions, oxidation, nor wear. The accuracy of the elephant weights (and figurines) is less.

During the nineteenth century the weights were made at a village near the capital under the supervision of the Chief Minister. These standard weights were stored in the treasury and issued to officials in other towns. It was a criminal offense to use weights other than those made "at the palace". Special sets of weights were kept for the purposes of comparison and the settling of disputes. Though only two nation-wide "standardizations" have been recorded, the earliest in the eleventh century, nevertheless it was the required duty of each new monarch, upon ascending the throne, to verify the weights.

Copies of animal-shaped weights, usually somewhat crude, are still made today in eastern Burma (Shan States) using techniques similar to those of thirteenth century AD and second century BCE Burma and Yunnan. The weights were made by the lost-wax technique, using clay to surround the wax model and metal molds to shape the wax model. The high-melting point wax used was produced in Yunnan by an insect.

Among the goods imported from India which may have required weighing were opium, indigo, and mercury. From Yunnan came gold leaf, silver ignots, copper-alloy, cash, salt, white insect wax, cinnabar, and tea. Burma exported gems, including pearls and coral, costly medicines, musk camphor, gums, resins, waxes, ivory, rhinoceros horn, and rare woods. Considerable trade would have been done with other Southeast Asian states, e.g., tin from Malaya and Laos, arsenic, lead, and silver from the Shan States, zinc from Laos.

Seeds and a Chinese type of equal-arm balance were used for the weighing of small highly valuable articles and the steelyard or datchin for large masses. For moderately valuable articles, e.g., foreign silver coins and ingots, the animal-shaped weights would have been used.

Until after the middle of the eighteenth century ordinary village commerce was conducted by barter, counting, purchase with cowries, and by measurement of volume or length. Weights were rarely necessary. However, from the last quarter of the eighteenth century onward, it was the ordinary Burman, rather than the king's officers, who made use of the weights, mainly to weigh currency ingots. This change was caused by the Burmese wars of the time. These resulted in the cessation of the supplies of copper alloy and cowries, led to the Burmese capture of the large lead and silver mines of the Shan States and so to the copying of the Chinese practice of using chopped lead as a low value currency. As a result of the increased need for weights to weigh the abundance of lead and silver ignots, there was a flood of copies from the formerly Burmese north Siam region, now occupied by south Siam (Ayuthya). This new domination also led to the replacement or adjustment of the animal-shaped weights to agree with those of south Siam.

Weights and Measures: Animal-shaped Weights of Burma. Fig. 2 Weights of different sizes. Photograph by the author.

W

Each of the weight shapes together with its base, and each of the parts of the weights, was intended to convey a particular meaning. The meanings had to be understood by illiterate speakers of many different languages. Though they were intended to be understood primarily by animists and Buddhists, they would also have been understood by Confucianists, Daoists, and others. Characteristic of animist/Buddhist Southeast Asia (though originating much further away in space and time) was the belief in the earthly, semidivine king. This is what the *to* weight was intended to symbolize. It combined the physical characteristics of a potential Buddha (*bodhisattva*) and a universal monarch (*cakravartin*). These, in turn conveyed the idea of secular power both to animist and Buddhist, being associated with earth, fertility, and healing, with legitimacy of rule and righteousness of conquest (a prerogative of a universal monarch). New styles of *to* weights were issued only at the times of the "righteous conquests" of a Burmese king, usually at the beginning of a dynasty with the accompanying empire-building.

The *hintha* weight symbolizes, among other things, the heavenly perfection and purity of the Buddhist faith, especially that of the Theravāda belief characteristic of Burma and Siam.

The association of feline and anserine representations for symbolic purposes has an origin more remote than Buddhism. The lion–duck association is present on some Asokan pillars. Lion-shaped weights were in use in Assyria about 1500 BCE and duck-shaped weights in Sumeria and Babylonia.

Concerning the elephant weights the kings of Burma and Siam (Ayuthya) were the incarnations of Indra, the chief of the gods, who was ancient before Hinduism, and who rode on an elephant. Thus, one reason (among several) for the choice of the elephant was to symbolize these kings.

The most generally useful of the techniques for establishing the chronological sequence of the weights were the style and sign sequences; the relation of the *to* weight styles, through their symbolism, to the dates of the dynastic changes and territorial expansions; the sequence of increase in the average unit mass of each style group; the dates of the unit masses obtained from the weighings recorded by many European traders from AD 1515, and their relation to the average unit masses of the style groups.

Weights and Measures in China

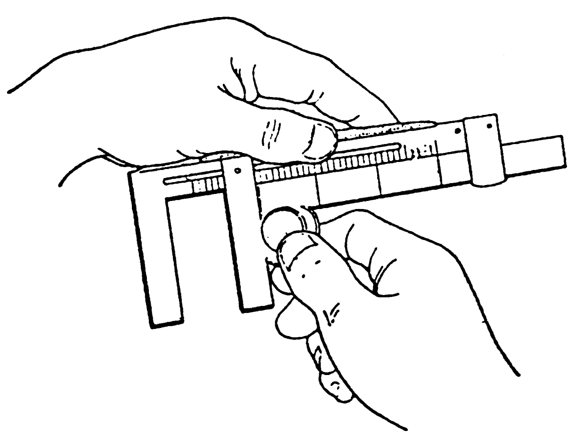
Hans Ulrich Vogel

Metrology means the "science of weights and measures." But when referring to premodern periods the term "knowledge of weights and measures" is more appropriate. In a more concrete sense, metrology is the art of calculation with number, weight, and measure units in the economic and fiscal domains as well as in science. "Metrosophy" may be defined as "number speculation within cosmological philosophemes," but from a more inclusive perspective the relationships between magical, religious, and political thought on the one hand and metrology on the other also have to be taken into account. In both metrology and metrosophy, numbers are of great importance. In metrology, they are used for defining and counting measure and weight units, while in metrosophy they serve as basic stuff for the creation of systems of number symbolisms, magical numbers, and correlative numerologies.

For the study of metrosophy and metrology, two different types of sources are basically available. First, we may mention sources of the tradition type, like the metrosophical and metrological sections in chapters of the dynastic histories. Although these sections also contain information of a metrological nature, it is clear that they are principally metrosophical in character. The second important types of sources are concrete remains, especially the relatively great number of real ancient weights and measures which either have been excavated at archaeological sites or which survived by having been handed down from generation to generation. While the sources of the tradition type are closely related with metrosophical thought and number systems, concrete remains inform us almost exclusively of metrological aspects and realities. The tension between these two clusters of information and data is of particular importance and is rewarding to be investigated.

Chapter 21A in the *Hanshu*, written in the first century AD, contains one of the first surviving texts that gives evidence of a system integrating metrology with such diverse fields as numerology, musical pitch, astronomical phenomena, astronomy, cosmology, historiography, and political, ethical, and moral thought. The textual arrangement of this chapter makes clear that metrology belonged to the traditional Chinese science of mathematical harmonics (*lü* or *lülü*).

Chapter 21A of the *Hanshu* states that harmonics consist of five categories: number, musical pitch, length measures, capacity measures, and weights and balances. All five had their origin in the *huangzhong* pitch-pipe, which had been created and standardized by the legendary Yellow Emperor. Obviously, the antiquity of these conceptual and technical devices was an important criterion for their purported eternal validity. Within the five categories a certain hierarchy is expressed, ranking numbers above, followed, in descending order, by pitch, length, capacity, and weight measures. Numbers are obviously of primary importance, because they provided the basic counting units for the other four categories. Metrology was grounded on a numerological system combining the numbers of the Five Phases (*Wuxing*) and other numerological concepts with the numbers derived from the changes of *yin* and *yang* as they are described in the *Yijing* (I Ching Book of Changes) and its commentaries. Moreover, weights and measures were conceived as an integrated system. With grains of medium-sized black millet, the length and capacity of the *huangzhong* pitch-pipe were measured and thus the basic length and capacity measure units derived. The weight of the grain filling of the pitch-pipe also served as the basis for fixing the weight units (Fig. 1).



Weights and Measures in China. Fig. 1 Handling the Wang Mang proto sliding callipers. From Liu Dong-rui, "The Earliest Slide Ruler in the world – the Bronze Slide ruler of the Xin Dynasty (AD 923). *Bulletin of the Museum of Chinese History* 1 (1979): 96 (in Chinese).

Concrete remains of ancient Chinese weights and measures are of great importance for supplementing the information contained in the largely normative written sources. A spectacular example are the proto sliding callipers of the Wang Mang period (AD 9–23), of which apparently three pairs survived.

The intaglio inscription on the movable part says: "Manufactured at the first day of the first month of the first year of the Shijian guo reign-period." This corresponds to March 15, AD 9, the first day of Wang Mang's interregnum. The front side of the fixed part of the sliding callipers is divided into 5 in. (*cun*), that of the movable part into 5 in. In addition, the 4 in. of the fixed part are further subdivided into ten parts (*fen*) each. With the Wang Mang proto sliding callipers outer diameters of less than 4 in. could be measured. The most conspicuous difference between modern sliding callipers and the Wang Mang piece is that the latter does not have the differential scale of the vernier.

No less spectacular is the great number of other Chinese metrological remains. For instance, more than 240 ancient length measures are known, which can serve as a basis for ascertaining the "true" length of a length measure unit of a given period. This is no easy task as may be shown in the case of the length measure unit *chi* of the Eastern Han period. Modern measuring has shown that the actual lengths of 85 concrete *chi* measures of this period vary from 20.49 cm to 24.73 cm. Obviously, state efforts at unification and standardization of weights and measures were of limited success and collided with diverging interests having their origin in different regional, local, political, economic, fiscal, and social conditions. Small wonder that in the *Suishu*, the dynastic history of the Sui dynasty written in the early seventh century, 15 different *chi* measures are listed.

The development of the types of weighing apparatuses can be divided into three stages. From the fifth century BCE to the second century AD balances with equal arms prevailed. In the period from the third to the ninth centuries the steelyard with unequal arms appeared and was used together with the ancient balances. Finally, the third stage from the tenth to the early twentieth centuries was characterized by the emergence of the highly accurate *deng* steelyard and the introduction of a decimal system of weighing units. An important promoter in the introduction and improvement of the *deng* steelyard was the eunuch Liu Chenggui (950–1013). Liu was in charge of the court treasury and fiscal affairs. The purpose of the introduction of the *deng* steelyard was to reduce disputes in the weighing of precious metals, which arose between different officials involved in fiscal affairs.

Weights and Measures in Egypt

Ruth Hendricks Willard

The gradual change from a nomadic to a settled existence, which began about 8000 BCE, marked humankind's determination to shape the environment to their requirements. Needing units of measure for both building and agriculture, people chose the most readily available and useable references – simple parts of the human body in various positions. The need for uniform measurements was recognized, and as early as 3000 BCE official reference standards of length, volume, and weight were being maintained in temples and royal palaces in Egypt, Mesopotamia, and around the eastern seaboard of the Mediterranean.

The standards developed in these ancient cultures moved westward, mostly as a result of trade, to the Greek and Roman empires, thence to Gaul and Britain via the Roman conquest. Egypt, by virtue of its geography a great trading nation and of its climate a preserver of archaeological treasures, has provided an incomparable record of this metrological heritage.

Measures of Length

Throughout the ancient Middle East, the basic unit of linear measure was the cubit, which was defined as the length of the forearm from the point of the elbow to extended fingertips. In Mesopotamia, the cubit was generally subdivided into 2 ft each of 3 or 4 palms, a palm having 4 digits. In Egypt, however, the most ubiquitous standard was the royal cubit. It was subdivided into 7 palms (28 digits), these divisions having significant mystical relationship to the four 7-day phases of the 28-day lunar month by which time was reckoned. The basic sub-unit was the digit (finger width): 4 digits = a palm; 5 digits = a hand; 12 digits (outstretched forefinger tip to little finger tip) = a small span (1/3 cubit); 14 digits (outstretched thumb tip to little finger tip) = 1 large span (1/2 cubit). Measurements smaller than a cubit were expressed in digits (up to 10), in palms and digits, or rarely, as 1/2 or 1/3 cubit.

Surveys of the Great Pyramid confirm its construction according to the royal cubit of 20.62 in (52.4 cm). The skill of the Egyptian workmen is shown by the fact that the sides of its base vary no more than 0.05% from the mean length of 440 cubits (9069.45 in or 230,364 m). The Egyptians also employed a short cubit of 6 palms (24 digits) = 17.68 in (44.9 cm) for general purposes including calibration of the Nilometers (masonry stairwells leading down to the river at points where the priests recorded the rise of the annual floods).

Egyptian measuring scales are square rods with one face half-beveled to form a reading surface. The fractions of the digit are shown by dividing the first into halves, the second into thirds, and so on down to sixteenths. The oldest extant cubit rods date from the 18th Dynasty, 1550–1307 BCE; none are longer than the double cubit, 41.2 in. Most of those used by the workmen are made of wood with deeply cut notches of division. The stone cubit rods are generally ceremonial, belonging to the temples and crowded with inscriptions referring to the religious aspects of the digits as connected with the gods and with the signs of the nomes. On these, the calibrations are often carelessly marked.

Land was measured by a linear unit called *khet* or *khet u nu* (reel of cord) 100 royal cubits in length.

Measuring cords were made of palm-fibre or flax-fibre and knotted at 5-cubit intervals. For long distances the foot (12 digits) and the pace (double step) were used; 2 paces measured heel to toe = the extended arms (4 cubits), and 100 paces = a stade. This distance later used by the Greeks in the Olympic foot races known as a stadium.

Measures of Area

The basic unit for reckoning areas of fields and nomes [a name given to regional divisions in Egypt] was the *setat*, the square of the khet, containing, therefore, 10,000 square cubits. Such an area was called a cubit of land, but was visualized as 100 parallel strips of land each 1 × 100 cubits. Ten setats were called a thousand of land. In devising ways to re-establish field boundaries after the annual flooding of the Nile, the Egyptians discovered the rudiments of geometry. A new unit formed from the diagonal of a square with sides equal to the royal cubit was found to be divisible by 40 digits of 0.73 in, twice the length of the *remen* (forearm from elbow to clenched knuckles) and consequently named the double remen. Half of the area of 100 × 100 cubits was also called remen in land measure. By having two standards, one the diagonal on the square of the other, it was possible to denote areas in squares equal to one-half or double the area of others.

Measures of Time

Through studies based primarily on the movements of the heavenly bodies in relation to the regular flooding of the Nile the Egyptians established two calendars. The priests followed an exact year of 365 1/4 days, while the civil year was subdivided into 3 seasons of four months each having 30 days – inundation, cultivation, and harvest – plus 5 days-upon-the-year.

Measures of Volume

In establishing standard units of capacity for barter, taxation, and medication convenient reference was made to human factors such as a mouthful (tablespoonful), handful, cupful (two handfuls) and sack- (hide-) ful for easy carriage. The principal Egyptian standards from small to large were the *ro, hin, hekat*, and *khar*.

Medications were prescribed in terms of the ro (mouthful, tablespoonful) = 1/2 fl oz (14.5 cc). By the usual Egyptian method of doubling this standard produces 2 ro = 1 handful (fl oz, jigger); 4 ro = 2 handfuls (jack, jackpot); 8 ro = 4 handfuls (gill); 16 ro = 2 hands cuppedful (cup); 32 ro = jugful (pint, *hin*); 64 ro = pitcherful (quart) and, by extension, the old English measures including the gallon, peck, bushel, barrel, hogshead, and tun.

The hin for liquids was subdivided dimidially down to 1/32 = 1 ro. There was also 1/3 hin known as the *khay*, thirds being a peculiarity of Egyptian metrology occurring also in the subdivision of the cubit and *qedet* standards. There were two principal standards for larger volumes. Multiples of the hin were decimal: 10 hin = 1 *hekat* (4.7 L). The hekat was the official corn measure: hekat = 10 hin; 30 hekats = 1 cu cubit. The khar, orginally a hide or sackful, was a special standard = 20 hekats (94 L). Subdivisions of the hekat in the dimidial series 1/2 to 1/64 (=5 ro), an amount frequently prescribed for internal medications) were always written in symbols now known as the Horus-eye notation. The Rhind Mathematical Papyrus, attributed to the 12th Dynasty (1991–1783 BCE), provides the following conversion table: 9,600 ro = 300 hin = 30 hekat = 3/2 khar = 1 cubic cubit (37 U.S. gallons).

The early use of additional capacity standards is documented by wall paintings in a Mastaba tomb of the 3rd Dynasty, ca. 2630 BCE. Two series of cylindrical capacity measures, one of copper, for measuring wine and oil, and one of hooped wood staves for grain, have been shown to conform to a mixed series in binary progression based on the standards of both the Egyptian hin and the Syro-Phoenician *kotyle* (21.4 cu in or 350 cc). Other standards of volume used in Egypt include the Syro-Babylonian *log* (33.1 cu in or 542 cc), the Attic kotyle (17.2 cu in or 282 cc), and the Persian *kapetis* (74.9 cu in or 1227 cc).

Measures of Weight

A search for the origins of weighing reveals that this intuitive use of the lever evolved independently in at least three ancient civilizations – Mesopotamia, the Indus Valley, and Egypt – and that all three were routinely employing balance and weights by the middle of the third millennium BCE. The weights, made in durable stone, have survived in sufficient numbers to permit study of the ancient weight standards. However, very few balances, which were usually constructed of wood in the earliest periods, exist today.

It is possible, nonetheless, to trace not only the evolution of weighing instruments but also the uses to which they were put in dynastic Egypt during the period 2700–650 BCE. As a means of enhancing the quality of the afterlife of their leaders, Egyptian artisans carved or painted scenes from their earthly life in tombs and temples. Because of a mild, dry climate, many of those monuments survived into modern times. While it is still possible for visitors to experience the excitement of discovering the weighing scenes in situ, not all of the tombs and temples have survived the two centuries of study and tourism to which they have been subjected. Colors have faded; walls and in fact entire structures have disintegrated or been destroyed or closed. We turn, therefore to the remarkable work of the

Egyptologists of the nineteenth and early twentieth centuries, a period of intensive recording and copying of Egyptian inscriptions, reliefs, and paintings. Hence, it becomes necessary to consider not only possible errors in the original, but also the errors resulting from the deterioration of the works being copied.

For information regarding the practice of weighing, we are indebted primarily to Sir W. M. Flinders Petrie. He was the first Egyptologist to identify, collect, and study the ancient weights for the insights they could provide into the cultural and trade relations among the various nations of the Near East. His numerous publications include chapters on the metrological findings of each site excavated. Most large museums have specimens of ancient Egyptian weights.

The practice of weighing began with the discovery of metalworking. The earliest weights are of a small order, suggesting that at first only small quantities needed to be weighed. Egyptians developed two indigenous weight standards and as an international trading center employed at least six more. The Egyptian national standard was based on the qedet, which varied over time from 138 to 152 gr giving a median value of 144 gr (9.33 gm). It was multiplied decimally: 10 *qedet* = 1 *deben*; 10 deben = 1 *sep*, as first recorded in a 3rd Dynasty tomb painting. The unit was sometimes divided into thirds as evidenced by a series of graves from the 1st Dynasty (2920–2770 BCE). The qedet is the basis of nearly all statements of weight from the 18th Dynasty onward. The qedet and deben were also known as the *kite* and *uten* when applied to pieces of copper used as a medium of exchange.

Less well known but more influential in world affairs was the *beqa*, which was associated with the weighing of gold and silver from pre-Dynastic times and used in Egypt for nearly 4,000 years. Although the standard is seldom mentioned in Egyptian inscriptions, numerous beqa weights have survived. These are sometimes marked with the hieroglyph for gold (*nub*) perhaps recalling its origin in the Nubian gold fields. As in most Middle Eastern standards, the basic unit was called a *shekel*; 50 beqa shekels = 1 *mina*. The beqa shekel was multiplied decimally to 7,000 shekels and subdivided dimidially down to 1/16. Over time, the several distinct values merged into a single standard of 192 gr (12.4 g), which was adopted by the Greeks around 700 BCE as the standard of Aegina. From it evolved two of the Roman pounds, the silver denarius and the gold aureous coinage. In the seventh century AD it was adopted by the Arabic Empire for bulk gold and it ultimately became the basis for the English troy weight standard.

Other standards in use in Egypt included the Palestinian *peyem*, 120 gr (7.78 g); Mesopotamian *daric*, 129 gr (8.36 g); Attic *stater*, 135 gr (3.75 g); Persian *khoirine*, 178 gr (11.53 g), and Phoenician *sela*, 218 gr (14.13 g).

The Evolution of the Equal Arm Balance

All of the balances used in Egypt before the Roman occupation in 30 BCE were equilateral, doubtless inspired by the yokes with which men balanced heavy loads on their shoulders. During the Old Kingdom (2686–2181 BCE) most balance beams were flat and rectangular, pierced vertically for support at the fulcrum and for the hangers, which were single cords hooked at the end to hold baskets or bags of gold dust. With but one exception, shown in (Fig. 1), they were made of perishable wood until about 1550 BCE. Hence, the only records of their design and use come from reliefs, paintings, and inscriptions.

Significant innovations during the Old Kingdom include specialized tongs to hold metal vessels, counterweights of a predetermined mass, tongues, and plummets to help in sighting the vertical. Nearly all of the 5th and 6th Dynasties weighing scenes come from the tombs of royal officials, and depict the

Weights and Measures in Egypt. Fig. 1 This is the earliest known Egyptian balance. It was skillfully cut from pinkish brown limestone, a material commonly used for making vessels in prehistoric times, but seldom later. The three suspension holes were drilled with a primitive bow drill and flint point. The beam is 3.35 in long. Its width varies from 1.6 in to 2.0 in and its depth from 1.7 in to 2.0 in. The diameter of the central hole is .03 in and that of both end holes is .07 in. As to sensitivity, a change of 1 in 500 can be seen by the change of level. A plaster model of this balance was tested at the Science Museum in London. Photo at the Petrie Museum, University College, London by O. W. Willard in 1993.

weighing of metal in the course of manufacturing. There is no evidence of buying selling, or exchanging goods by weight in this early period.

The decline of the Old Kingdom was followed by the First Intermediate Period, an epoch of chaos, civil war, hunger, violence, and invasion. No evidence of weighing has been found from this period, which encompassed the 7th to 10th Dynasties and lasted from 2134 to 2040 BCE. Eventually Theban warlords gained supremacy and established the Middle Kingdom with its capital first at Thebes and later at Itjtawy, a newly built city near Memphis.

The Middle Kingdom

Weighing scenes are found at Beni Hasan, the most noteworthy necropolis of the Middle Kingdom, where 39 tombs are cut out of the rock cliffs at Beni Hasan, on the east bank of the Nile. The tomb paintings here depict balances with an improved suspension system. The beam is suspended from a bracket near the top of the upright and can swing more freely because of a ring added to the top of the tongue. As in the fifth and sixth Dynasties, the plummet appears to hang from a point near the bottom of the tongue suggesting that the tongue and beam are rigidly attached and move together. The baskets are now suspended by multiple cords, depicted as two but presumed to be four, since that is also the case in the New Kingdom, from which we have extant pans with four holes. One representation shows workers weighing two sets of objects against one another. Another representation shows the introduction of shallow, concave pans made possible by the multiple suspension cords. Weight boxes are shown below each standing balance.

A totally new aspect of weighing appears in one 12th Dynasty relief. Here we see a jeweler who has left the workplace to show his finished product to the nomarch (local ruler). Reading between the lines, we note that he has suspended the balance from a full-length stand, but by using an extension cord, he has brought the scale and its contents down to a level he can reach while kneeling before his ruler.

During the Second Intermediate Period, from 1640 to 1532 BCE, the political situation was unstable, with several dynasties ruling in various areas simultaneously. While there was undoubtedly turmoil during the takeover, Egyptian life was enriched by the introduction of horses, wheeled chariots, hump backed cattle, and new tools, weapons and musical instruments. Innovations relevant to metrology included the working of bronze and weights cast in the shapes of animals.

The New Kingdom 1550–1070

Both the equipment and the philosophy of weighing underwent major changes during the New Kingdom (1550–1070 BCE). While the equal arm balance of the Old and Middle Kingdoms had been modified in ways that made using it more convenient, there was still the problem of accuracy. The end suspension cords could wander in holes drilled vertically through the beam and those holes, even if exactly equidistant from the fulcrum initially, might not remain so after the wearing away inherent in use. Either early in the New Kingdom (or possibly late in the Second Intermediate) a radically different scale beam made its appearance. Constructed of either wood or bronze, it was round in section. Suspension cords entered at the beam end through longitudinal bores and emerged through intersecting radially drilled holes, being knotted on top of the beam. Any inequality in the distance of the beam ends from the fulcrum could be adjusted by simply filing the longer end, restoring the balance to accuracy. This principle was later improved upon in the large standing balances with flared beam ends that allowed the four strings to diverge from the lowest point on the flange, making for even greater accuracy.

While the great majority of representations from this period depict large, stately standing balances, the extant specimens are all small and portable. The beams, which may be of bronze or wood, are invariably round in section. The Cairo Museum displays several. A hand-held balance at the Science Museum in London was excavated at Amarna and dates from the reign of Akhenaten, 18th Dynasty, c. 1331 BCE. The length of the round, tapering wooden beam is 30 cm and the diameter of the copper pans is 7.4 cm; the sensitivity is plus or minus 2 gr per hundred in each pan. Bronze animal weights characteristic of the 18th Dynasty are shown with this balance. Two previously unpublished specimens were found at the University of California's Phoebe Apperson Hearst Museum of Anthropology. Both were excavated at Naga ed-Deir during the 1899–1904 Hearst Expedition led by G.A. Reisner. While it is impossible to date either one with certainty, both have the general characteristics of New Kingdom balances (see Fig. 2).

Specimen 6-13624, from a cemetery dating from the late Old Kingdom through the Middle Kingdom, was found near the entrance of tomb 434 with the excavator's notation *ghadim* (fill). The wood is acacia,

Weights and Measures in Egypt. Fig. 2 Two New Kingdom-type balance beams. Photo by O. W. Willard by permission of the Phoebe Apperson Hearst Museum of Anthropology, University of California.

W

sub-species not identified. The round, tapering beam is 50.3 cm long with a diameter of 2.7 cm at the center, drilled in the New Kingdom manner for central and end suspensions. Unlike the Amarna balance above, the beam has a definite arch in the middle. There is the imprint of a narrow saddle or support of some kind at the fulcrum. The ends are knobbed, with a decorative channel around each. On each side of the suspension holes, there is a decorative double annulet with a channel between. No pans were found.

Specimen 6-2702 is believed to have come from a cemetery dating from early dynastic to Roman times. The wood is acacia, sub-species not identified; the round beam is 31.2 cm long and 2.0 cm in diameter at the center. There is a bulge in the center of the beam and the ends are slightly flared, foretelling the more pronounced flanges of the large ceremonial balance. There is also an unexplained diametric hole about 1.0 cm from the fulcrum hole. No pans were found.

The most magnificent weighing scenes are those representing the brilliant 18th Dynasty, which ruled Egypt from 1550–1307 BCE. The ceremonial balances, sometimes 10 ft tall, are often adorned with the head of a god as a finial. The beam hangs from a bracket that may be in the shape of the feather representing Maat, the goddess of truth. The bronze tongue, which has evolved into a pointer, moves with the beam. In many examples, the operator holds the plummet in his hand as if to inspect it for flaws before beginning the weighing procedure. Shallow concave pans, usually of metal, are suspended by multiple cords thought to be four in number although sometimes depicted as two or three. The conventional stone weights, geometric in form, have been replaced with handsome animal shapes in cast bronze.

Ambiguities in the drawings coupled with the lack of physical specimens have fostered intense interest in the central suspension and indicator system. The explanation most generally accepted was offered by Petrie in 1888:

> The beam was suspended by a loop or ring from a bracket projecting from the stand; this bracket is shown in side view though at right angles to the beam just as the Egyptians drew a full eye in a side face. Then below the beam, a long tongue was attached, not above the beam, as with us. To test the level of the beam, a plummet hung down from the tongue, and it was this plummet which was observed to see if the tongue was vertical and the beam horizontal. The weigher is often shown steadying this plummet with his hand, as it would be set swinging by the motions of the beam. Such is the whole system, which is so simple that it seems strange that any mistake could be made about it to say nothing about the mechanical absurdity of the explanation which has been current for so long.

The "mechanical absurdity" theory to which Petrie referred had been offered by Wilkinson in 1837. Referring specifically to an illustration showing the balance being used by the *Qabbaneh*, or Public Weighers, he wrote,

> The beam passed through a ring suspended from a horizontal rod immediately above and parallel to it, and when equally balanced, the ring, which was large enough to allow the beam to play freely, showed when the scales were equally poised. It had the additional effect of preventing the beam tilting when the goods were taken out of one, and the weights allowed to remain in the other. To the lower part of the ring a small plummet was fixed and this being touched by hand and found to hang freely indicated, without the necessity of looking at the beam, that the weight as just.

Though acclaimed for his understanding of the Egyptian artistic canon and for the accuracy of his copies, Wilkinson overlooked the obvious fact that the vertical plane of the bracket, shown in profile, would have been perpendicular to that of the beam. The single-ring hanging mechanism as shown could not possibly have worked. It would appear that either the original drawing was erroneous, or deterioration in the ancient surface caused Wilkinson to miscopy it.

Recent research has centered in the nature and function of the triangular shape bisected by the plumb line that project below the beam. Spiegler postulates an arrangement of three strings fastened at the beam and equipped at the tip with a plummet. As the beam is tipped, a slack string allows the plummet to swing. Jenemann and Robens note that such a mechanism would work only with large deflections that could be seen more easily by visual observation. Furthermore, in colored drawings the triangle is clearly opaque, indicting a solid object. They then suggest that the flat side of the triangular plane, while shown frontally in the drawings, is actually perpendicular to the beam, while the plummet hangs independently in front of the tongue, an arrangement considered to be more sensitive than one in which the tongue pierces the beam longitudinally.

Skinner states, "For larger wooden or bronze beams a bronze tongue was driven vertically through the center of the beam with a ring on top for suspension from a bracket. The tongue protruding below the beam acted as a swinging index, which was sighted against a freely-suspended plum-bob to denote when the beam was horizontal and in balance." In the absence of New Kingdom specimens, perhaps conclusions can be drawn from a small bronze goldsmith's balance dating to the Greco-Egyptian period, 304–30 BCE. The beam is suspended from a ring in the bracket intersecting a ring in the top of the tongue or pointer, which pierces the beam and extends below it. The plummet hangs from the bracket, behind the tongue. The original is in the Cairo Museum and its replica, a plaster cast, is in the Science Museum, London.

Expanding Roles for the Balance: Trade, Tribute, Offerings

With Egypt's transformation to an international power, new roles evolved for the balance. Along with the customary depictions of jewelers and other metal workers there are scenes of the balance used in weighing tribute to the pharaoh and offerings to the national god Amun and, for the first time, in domestic and foreign trade. Short gold or silver cylinders about five inches in diameter served as a sort of currency. Variable in mass, these must have been weighed in each transaction. Medicine however, continued to be measured rather than weighed.

The earliest known depiction of the balance in commerce is found in a remarkable painting from the tomb of Kenamun, Mayor of Thebes and Superintendent of the Granaries of Amun under Amenophis III, 1391–1353 BCE. Syrian ships were anchored on the Nile off Thebes, while on shore two male shopkeepers engage in private trading with the sailors. Since the commodities – sandals, apparel, and various objects – are too large to weigh on the hand balances shown, the sellers are obviously weighing out the amount of gold needed to make the purchases.

Among the various public officials were the Qabbaneh, or public weighers, who erected their balances in the market place while a notary stood by to record the details. They were required by law to adjust the sale of each commodity with the strictest regard to justice, without favoring either the buyer or the seller. The penalty for falsification of weights or records was the loss of both hands, inflicted upon the seller, the weigher, and the notary alike. The Qabbaneh were still functioning in early twentieth century Thebes.

Hatshepsut, who ruled as Egypt's only female Pharaoh (1473–1458 BCE) built at Deir el Bahari a magnificent temple with extensive terraced gardens facing the Nile. She dispatched an expedition to the fabled land of Punt in search of treasures to be offered to the sun god Amun, to whom the temple was dedicated, and recorded the presentation in a monumental relief on the south face of the second terrace. In the weighing scene, a massive balance is piled high with cylindrical gold ingots being weighed against some loaf-shaped weights of the Middle Kingdom and some bronze animal-shaped weights characteristic of the 18th Dynasty. In the background are trays holding additional loaf shaped weights and quantities of electrum (a naturally-occurring alloy of gold and silver) in bars and rings. The inscriptions read,

> The balances accurate and true of Thoth, which the King of Upper and Lower Egypt (Hatshepsut) made for her father Amun, lord of Thebes, in order to weigh the silver, gold, lapis lazuli, malachite, and every splendid costly stone, for the sake of the life, prosperity, and health of her majesty. Weighing the gold and electrum, the impost of the southern countries, for Amun-Re, lord of Thebes. Recording in writing, reckoning the numbers, summing up in millions, hundred of thousands, tens of thousands, thousands, and hundreds.

Thutmose III, successor to Hathepsut, so extended the Egyptian holdings in Asia and northern Ethiopia that he has been referred to as the Napoleon of Egypt. During this period, the coffers of the state were greatly enriched by both tribute from and trade with the nations they had subdued. A weighing scene in the tomb of his Vizier, Rekhmire, is inscribed in part, "This great heap of electron, which is measured by the heket, making 36,692 deben.

The Papyrus Harris, now in the British Museum, represents the testimony of Rameses III, Pharaoh (1194–1163 BCE) as he nears the end of his life and affords an understanding of both the physical nature and the significant role of the ceremonial balance in the New Kingdom. Describing his stewardship as the god's representative, he states as part of the prayer and recital of the king's benefactions,

> I made for thee splendid balances of electrum, the like which had not been made since the time of the god. Thoth sat upon it as guardian of the balances, being a great and august ape of gold in beaten work. Thou weighest before thee, O my father Re, when thou measurest of gold and silver by the hundred thousands, brought as tribute before thee from their coffers, and given to thy august treasury in the house of Atum. I founded for it (namely the balance; evidently offerings were made to it) daily divine offerings in order to supply its altar at early morning.

In another section, Rameses describes the king's gifts to Re including (in part), "Fine mountain gold and gold for the balances 1,278 deben, 9 2/3 kedet[1]. Crude silver for the balances and silver in vessels 1,891 deben, 1/2 kedet. Black copper for the balances 67 deben, three kedet.

[1] The gold amounts to some 311 3/4 pounds troy, and the silver to nearly 461 pounds troy.

Weights and Measures in Egypt. Fig. 3 The Judgment Scene: Ani's heart being weighed in the balance (the first three of six panels). Left to right, top: The company of the gods, who hear Ani's testimony. Lower register, left to right: Ani and his wife Thuthu entering the Hall of Judgment; Rehenet and Meskhnet, the Goddesses of birth; (small figures. L 2 r) Ani's soul, Ani's Embryo, Ani's luck or destiny; Anubis testing the tongue of the balance; Thoth recording the result of the weighing, The Devourer of the Unjustified; Not shown here: Horus, the falcon-headed god, introducing Ani into the presence of Osiris; Ani kneeling before Osiris, Osiris enthroned within a shrine. Behind him are Isis and Nepthys, and before him upon a lotus stand, the children of Horus (Budge 1969). The original Papyrus of Ani is in (the British Museum, No. 10470 Sheet 3 and 4).

Weighing the Soul

Souls too were weighed. The Egyptian concept of right conduct as a prerequisite for admission to paradise grew out of the cult of the god Osiris, which with its promise of immortality began to flourish during the First Intermediate Period. But it was first represented pictorially in the New Kingdom, when an elaborately illustrated roll of papyrus known as the Book of the Dead (or, more properly, The Book of Coming Out by Day) was placed in the tomb. Along with spells and instructions for entering into the kingdom of the gods, each Book of the Dead included a weighing scene in which the heart of the deceased, often represented by the hieroglyph for heart, was weighed against the feather of truth, symbol of the goddess Maat. The deceased was required to make a "negative confession" denying the commission of 42 specific sins such as giving short measure or falsifying the scales of the balance. The jackal-headed god Anubis tested the plummet of the scales, while the ibis-headed god Thoth prepared to record the results and a beast called the Devourer of Souls stood by to perform his duty, should the applicant's heart be found wanting (see Fig. 3).

This allegorical concept, first presented graphically by the Egyptians, persisted in the Christian world through the Middle Ages as demonstrated by surviving legends, stained glass windows, and paintings in which Anubis is replaced by St. Michael and the feather replaced by a toad. In 1901, Dr. Duncan McDougal of Haverhill, Massachusetts conducted the first of several experiments to determine whether the soul has weight. He found that in addition to the gradual weight loss related to the loss of body fluids as death approached, at the exact moment of death there were sudden weight losses of 3/8 oz, 1/2 oz, and 3/4 oz. He attributed this weight loss to the departure of the soul. In his book, *Weighing the Soul*, Fisher relates other scientific research dating from Leonardo da Vinci in 1515 to American and European physicists in modern times. As recently as 1972, according to Agence France Press, a Swedish doctor set out to determine the mass of the human soul by placing the deathbeds of seriously ill patients on extremely sensitive scales. As each died and the soul left the body, the needle dropped 21 g, he reported.

The reliefs and paintings with which the Egyptians adorned tombs and temples celebrate the enduring values of their culture over a period of more than 3,000 years. The 18th Dynasty weighing scenes with their monumental balances and graceful animal-shaped weights are generally considered the apex of the genre. After this period of artistic and religious ferment Egypt returned to the old familiar ways, recasting their weights in geometric shapes. And as time went on, the illustrations grew more and more fanciful, as if the artists preparing them were not familiar with the actual instruments. While these enigmatic drawings, at once lively and serene, do not reveal all the technicalities of the Egyptian balance, they do provide a window into an ancient culture whose achievements in many fields are still reflected in modern life.

Whether constructed of wood or of bronze, the improved Egyptian balance became the standard weighing instrument of the Near East until Roman times. Glassmaking, another technical innovation of the 18th Dynasty, was applied to metrology with the production of a few weights during the Roman and Byzantine periods. The Arabs, after their conquest of the country in AD 640, continued the tradition, issuing a fine series of reference weights for their coinage.

These are circular discs of transparent glass in various colors molded with a thick rim surrounding a central depression and civil inscriptions in Arabic. The Arabic standard of metrology continued to be dominant through the nineteenth century with standards varying city by city and by commodity. The metric system was made permissible in Egypt in 1873.

Weights and Measures of the Hebrews

Lionel Holland

Weights

The earliest Biblical reference to a unit of weight is in Genesis 23:16: "Abraham came to an agreement with him and weighed out… four hundred shekels (of silver) of the standard recognized by merchants." Abraham was a new immigrant in Canaan. The *shekel* units which he used to weigh out the silver for Ephron the Hittite may have been those of his native Mesopotamia, with which he would have been most familiar.

The Mesopotamian shekel weighed about 8.3–8.5 g. Sixty shekels = 1 *maneh* (Greek: Mna, mana. English translations of the Bible often render *maneh* as "pound") of 497–508 g. Sixty *maneh* = 1 *kikar* (Greek: Talanton; English: talent) of 29.8–30.5 kg. This system, which was originally Sumerian, in the fourth or third millennium BCE, was used with little change for thousands of years by the peoples of Mesopotamia; the terms SH-Q-L, M-N-H, and K-K-R are Semitic in origin and were first used by the Akkadians. Systems similar in structure, though varying in detail and in the absolute mass of the units, were used by most of the peoples of the Eastern Mediterranean, well into Roman Imperial times.

The term shekel is, in short, a generic one, and in this context could apply to any one of a number of units (including the Mesopotamian) in use in Canaan in the Bronze Age. Since the price of 400 shekels for the Cave of Machpelah was quoted by Ephron himself (Genesis 23:14), these may very well have been shekels of the Syrian standard (also called Ugaritic), weighing about 9.4 g. Weights on this standard were used throughout Canaan and northern Syria, and are found at Bronze Age sites in the Aegean sea, as far north as Troy. The standard also reached Egypt, where its unit became the qedet. Three thousand Syrian shekels made one *talent*.

Genesis 24:22 says: "…the man took a gold nose-ring weighing half a shekel, and two bracelets for her wrists weighing ten shekels…" The Hebrew word rendered in English as "half a shekel" is *beka*'. The word means "half," and appears on certain Iron Age weights described below.

W

The next mention of units of weight in the Bible is in the Book of Exodus. Several hundred years have passed; the Children of Israel, now a numerous people, have received the Law at Mt. Sinai. This includes instructions for the payment of taxes and the performance of religious ritual, which call for clearly defined units of measurement. The first specifically Hebrew unit of weight is *shekel ha-kodesh*, which the King James version translates as "shekel of the sanctuary" and the New English Bible as "shekel by the sacred standard," "twenty *gerahs* to the shekel" (Exodus 30:13). This unit is referred to repeatedly (Exodus 30:24, 38:24–26, Leviticus 5:15, 27:25, etc.). Reference is now also made to *talents* of silver and gold: the *talent* weighed 3,000 shekels (Exodus 38:25, 26). There are no surviving artifacts of this period from which the absolute mass of these units might be inferred.

It should be stressed that the *shekel ha-kodesh* and its fractions were used by the Hebrews for religious purposes, but not necessarily in commerce. In the ancient world, as in medieval Europe, there were many weight systems in simultaneous use in international trade. Weights representing all the major systems of the ancient Near East are found at all important archeological sites in Israel, and were obviously in use there. These systems are often linked by networks of interrelationships, with multiples of different units having a common mass and being used interchangeably.

The oldest extant weights bearing Hebrew inscriptions date from the period of the Kingdom of Judah (tenth to sixth centuries BCE). They are normally of limestone, dome-shaped with a flat bottom; a few bronze specimens exist. There are several types, all rare. The total number of known specimens of all groups is a few dozen. They are:

- *Necef*. Average mass about 9.8 g. The *necef* is not mentioned in the Bible. The name means "half": it may have originally been half of some more ancient unit. Scholars today identify the *necef* with the Canaanite/Syrian/Aegean unit already described. It is also equivalent to 1 Egyptian *qedet* and to four-fifths of the royal *shekel* of Judah (see below).
- *Beka*'. This word also means "half" (Genesis 24:22, see above). The mean mass of this group is about 6 g. The beka' is one-half of the "shekel of the king" first mentioned in II Samuel 14:26.
- *Pym* (Petrie: *peyem*). Mean mass about 7.8 g. The word appears once in the Bible (I Samuel 13:21): "The charge was two-thirds of a shekel (Hebrew: pym) for (sharpening) ploughshares and mattocks, and one-third (of a shekel) for sharpening the axes and setting the goads." The pym is two-thirds of the royal shekel.
- *Shekel*. Weights of this group are inscribed, not with a word, but a sign γ. Its meaning has been variously interpreted as being an official adjuster's mark, a symbol of the bag (*tsror*) in which lump silver was often carried, and a stylized representation of the royal scarab emblem of the kings of Judah. Sir Flinders Petrie read it as a monogram composed of the Greek letters *chi* λ and *omicron* ο, and on this basis, erroneously attributed these weights to a (supposed) system which he called Khoirine. The mean mass of the shekel, calculated from all known marked specimens, is about 11.4 g.

The shekel sign is accompanied by a mark indicating the denomination: 1, 2, 4, 8, 16, 24. Since numbers of shekels are given in the Bible in multiples of 50, this binary multiplication seems illogical; it is explained by the fact that this shekel is equal in mass to one and a quarter Egyptian qedets. Hence, 4 shekels = 5 qedet, 8 shekels = 10 qedet, etc. The denomination marks on the shekel weights are, in fact (apart from simple strokes to indicate 1 and 2), Egyptian hieratic decimal numerals, the sign for 4 shekels meaning in Egyptian 5, that for 8 meaning 10, and so on. These weights thus could be conveniently used interchangeably to weigh either in shekels or qedets. In fact, it can be seen that all the units here described are closely related. The Canaanite/Syrian/Aegean maneh of about 940 g can be divided into either 80 royal shekels, 100 necef (or qedet), 120 pym, or 160 beka', providing simple arithmetical relationships between the systems prevalent in different regions.

The name "royal shekel" is confirmed by the existence of a two-shekel weight inscribed in Hebrew "L-M-L-KH" (of the king). A series of fractional weights also exists, both for the shekel and for the necef, showing that both were divided into 20 units (*gerah*). The denominations of these are also indicated by Egyptian hieratic numerals.

Scholars attribute most of these weights to some time near the end of the seventh century BCE, leading some of them to suggest that the religious reforms of Josiah (II Kings 22, 23; II Chronicles 34, 35) were accompanied by a reform of weights and measures. There is no direct documentary evidence of this. In fact, biblical references are less than enlightening. Ezekiel, foreseeing the rebuilding of the Temple, orders that the maneh shall consist of "twenty, and twenty-five, and fifteen (i.e., 60) shekels." This is so inconsistent with other data that the translators of the New English Bible assume a misspelling in the Hebrew text, and render *essrim* as "ten" (Ezekiel 45:10), giving 50 shekels to the maneh as before. After the Temple was rebuilt, the people of Israel pledged to pay an annual tax of one-third shekel, not one-half as in Moses' time (Nehemiah 10:32).

Nothing more is heard of the *shekel ha-kodesh*; it is last mentioned in Numbers 18:16. Yet the correct weight of the Temple tax was a subject of deep concern to the Jewish religious authorities; it is discussed at length in the Mishnah, the textbook of Jewish laws. By the first century BCE it had been decided that all religious taxes should be paid in "shekels of the sacred standard, of the maneh of Tyre." The Tyrian shekel at that time weighed a little over 14 g and was famous for its purity of metal and uniformity of weight. No other coin would do. This is the reason why Jesus found so many money-changers in the Temple precinct (Matthew 21:12): Jewish pilgrims arriving from foreign parts and wishing to pay their dues needed Tyrian shekels in order to do so.

From AD 66 to 70, when Jerusalem was besieged by the Romans, and Tyrian coin was no longer obtainable, the shekels struck throughout the siege by the embattled Jews (probably for religious use) were of the Tyrian standard.

The use of Hebrew weights and measures for secular commerce almost certainly ended with the fall of the Kingdom of Judah and the destruction of the Temple by Nebuchadnezzar in 586 BCE. There is no evidence from the successive periods of Persian, Hellenistic, and Roman domination of the Land of Israel (or from times of relative independence, under the Hasmonean and Herodian dynasties) of the use of any specially Jewish units. Rabbinical discussions of weights and measures usually center on attempts to define Biblical units in terms of contemporary non-Jewish systems, in order to ensure the proper performance of the Mitzvoth (commandments).

Measures of Length and Area

The Hebrew unit of linear measure was the *ammah* or cubit – the length of a man's forearm, from the elbow to the tip of the middle finger. Deuteronomy 3:11 actually uses the expression *le-ammat ish* – "by the forearm of an adult male." The measurement of length by units based on parts of the human body is universal among ancient cultures.

The Bible mentions no unit greater than a cubit. *Kaneh ha-midah*, the surveyor's measuring rod (or reed), was six cubits in length (Ezekiel 40:5). The measurements of the inner temple are given by Ezekiel as 500 × 500 *kaneh* (Ezekiel 42:16–20): the Authorized Version translates these as "reeds", the New English Bible as "cubits". Surveyor's measurements of up to 25,000 cubits are on record (Ezekiel 45:1). Long distances are expressed in terms of a day's journey, *derekh yom* (Genesis 30:35; Numbers 11:31; II Kings 3:9).

The Hebrews used two cubits, one a hand's breadth (*tefah* or *tofah*) longer than the other (Ezekiel 40:5, 43:13). The longer cubit was used in the rebuilding of the Second Temple (Ezekiel 40–48), and also, presumably, in building the Temple of Solomon, since the dimensions quoted for the Holy of Holies and the Sanctuary are the same in both cases (20 × 20 cubits and 20 × 40 cubits, respectively: I Kings 6:14–28, Ezekiel 41:1–4).

The use of two cubits suggests an association with Egyptian linear measure. The greater ("Royal") Egyptian cubit was of seven hands, each hand of four fingers (also four spans of seven fingers each). Its length of about 52.5 cm is attested by many surviving measuring rods and by records of the dimensions of surviving monuments. The lesser Egyptian cubit was of six hands.

The Biblical fractional units of length are the span (*zeret* – Exodus 28:16, 39:9; I Samuel 17:4), the hand (*tefah* or *tofah* – Exodus 25:25, 37:12; I Kings 7:26; II Chronicles 4:5), and the finger (*etzba* – Jeremiah 52:21). The only direct clue to the absolute value of the Hebrew cubit is the Siloam inscription (ca. 700 BCE) from which Conder estimates a value of 17.1 in. (43.4 cm); he warns, however, that this estimate may be in error by 10% or more.

The Mishnah (second to third century AD) states that the greater cubit was of six hands, the lesser of five; the hand is of four fingers. Six hands of Egyptian dimensions would measure 45 cm. Most rabbinical estimates, however, are in the range 58–66 cm.

There are no specially named units of area in the Bible. Ezekiel, discussing the layout of rebuilt Jerusalem, speaks of "twenty-five thousand cubits square (*revi'it*)" (Ezekiel 48:20).

Measures of Cubic Capacity

> …your bushel (Heb. *ephah*) and your gallon (Heb. *bath*) shall be honest. There shall be one standard for each, taking each as the tenth of a *homer*, and the *homer* shall have its fixed standard (Ezekiel 45:11).

Solid and liquid measure are thus given a common basis. The volumetric measures mentioned in the Bible are *Ephah* (Leviticus 19:36; Deuteronomy 25:14 ("measure"); Judges 6:19; Ezekiel 45:24); *S'ah*, *seah* (Genesis 18:6; I Samuel 25:18; I Kings 18:32 (always "measure")); *Kab*, *cab* (II Kings 6:25); *Omer* (Exodus 17:36 – "An *omer* is one-tenth of an *ephah*"); these are always associated with solid measure. *Letekh* (Hosea 3:2 – AV: "a half *homer* of barley"; NEB: "a measure of wine") is mentioned only once. *Homer* – (Ezekiel 45:11, see above) and *Kor*, *cor* (I Kings 4:22, 5:11) are associated with both solid and liquid measure. *Bath* (I Kings 7:26, 38; I Chronicles 2:10) and *Log* (Leviticus 14:10, 12, 15, 21, 24) are associated with liquid measure. The relations between any of these measures are only mentioned once or twice. The Mishnah gives a table relating some of them: 1 *ephah* = 3 *se'ah*; 1 *se'ah* = 6 *kab*; 1 *kab* = 4 *log*; 1 *log* = 6 eggs. The water displaced by 1 egg is about 55 ml (there are differing rabbinical views on the precise quantity), which would give the *log* a volume of 330 ml and the *ephah* and *bath* each about 24 l.

Attempts to establish mathematical relationships between ancient units of length, mass, and volume were popular a century ago, but today are not taken seriously. Reliance on post-Biblical authors such as Josephus Flavius is also risky: Josephus lived more than a thousand years after King Solomon, and is more likely to have been concerned with giving his (mainly non-Jewish) reading public a notion of orders of magnitude than with achieving a maximum of mensural precision. Hebrew weights and measures will always remain a subject fraught with uncertainty, which will be dispelled only when archeologists are able to recover the actual instruments of measurement.

Weights and Measures in the Indus Valley

Shigeo Iwata

The golden era of the Indus civilization in ancient India extended from 2300 to 1750 BCE. This vast civilization had significant uniformity and standardization in its material culture, as reflected in its town planning, building construction, pottery, metallurgy, and system of weights and measures.

The prosperity of the Indus cities depended to a large extent on trade. Many raw materials were brought by land and sea routes from within and outside the Indus valley. Inland trade must have extended beyond the Baluchistan to Afghanistan route and the Iranian highlands on the one hand, and to the Punjab and Aravalli hills on the other. Overseas trade covered the Makran and Persian Gulf ports on the west and the Gujarat and Konkan ports, if not those of the Malabar coast in the south. The writing system has not yet been deciphered, and the names of their measuring units are still unknown.

Length

A unit of length, which corresponds to a fathom, was revealed in the process of analyzing the city plans of Lothal, Surkotada, Kalibangan, Dolavira, Harappa, and Mohenjo-daro. The mean value with standard deviation of the units used in these cities was 168 ± 1.1 cm.

The minimum division of graduation found in the segment of an ivory-made linear measure excavated in Lothal was 1.79 mm (that corresponds to 1/940 of a fathom), while that of the fragment of a shell-made one from Mohenjo-daro was 6.72 mm (1/250 of a fathom), and that of bronze-made one from Harapa was 9.33 mm (1/180 of a fathom).

Area and Volume

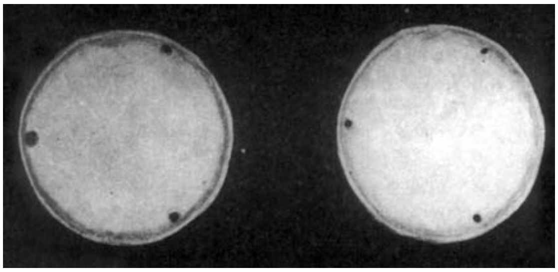
The use of area measures should have been quite common. There is, however, no piece of evidence that could be connected with an area measure. In the excavations carried out at various sites of the Indus civilization a variety of pots made of clay, and sometimes of metal, have been discovered. No systematic determinations of the volumes of pottery seem, however, to have been made.

Mass

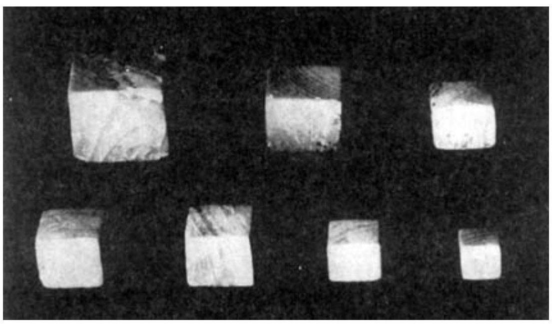
The oldest known weight in the Indus measuring system was excavated from Dashli Tepe, south Turkmenia in Russia. This era dates back to the fifth millennium BCE. The other three weights belong to the fourth millennium BCE and were discovered in northern Iran. These weights belong to pre-Indus civilization. In the third millennium BCE the Indus measuring system was further developed in the ancient regions of Iran and Afghanistan.

A total of 558 weights were excavated from Mohenjo-daro, Harappa, and Chanhu-daro, not including defective weights. They did not find statistically significant differences between weights that were excavated from five different layers, each measuring about 1.5 m in depth. This was evidence that strong control existed for at least a 500-year period. The 13.7-g weight seems to be one of the units used in the Indus valley. The notation was based on the binary and decimal systems. Eighty-three percent of the weights which were excavated from the above three cities were cubic, and 68% were made of chert.

Balance pans were made of copper, bronze, and ceramics. A bronze beam was found with the two pans in Mohenjo-daro. The fulcrum was the cord-pivot type (Fig. 1).



Weights and Measures in the Indus Valley. Fig. 1 Balance pans (photograph by the Maninichi Newspapers, 1961; used with permission).



Weights and Measures in the Indus Valley. Fig. 2 Weights (photograph by the Mainichi Newspapers, 1961; used with permission).

The measuring system used in the Indus valley was different from the Mesopotamian and Egyptian measuring systems, but the sensitivity of precision balances used in these regions is assumed to have been comparable. The weights excavated from Taxila (sixth century BCE to seventh century AD) descend from the system of weights used in the Indus civilization (Fig. 2).

Weights and Measures in Islam

ULRICH REBSTOCK

In the sphere of Islamic influence the Quranic injunction "to give full measure and to weigh with the right scales" (*Qur'ān* 17:35), led - in the long run - to systems of measuring that were subjected to the authority and control of politics and law. But only a few measuring standards were substituted by new Islamic prescriptions. The most lasting novelty set off through the Quranic revelation affected the measure of time. It assumed a dual character. The natural solar year gave way to the ritual lunar year (29–30 days of the month), except in some fields of public administration and astronomical science. Within the sphere of the metrological systems of measures and weights, however, the *Qur'ān* remains vague. Among the terms most often mentioned, *kayl* or *mikyāl* (Sura 12:12 and *passim*, 'measure of capacity'), *mīzān* and *mithqāl* (Sura 6:152, 21:47 and *passim*, 'weight'), range first. Others, like *qinṭār* (3:75, 'hundredweight'), *darāhim* (3:75, pl. of *dirham*), *dīnār* (3:75) and *ḥabba min ḫardal* (21:47, 'grain of mustard'), are used in a metaphorical sense. A more systematic elaboration of metrical definitions and ratios, mainly for juridical purposes, was effectuated in the 'traditions of the Prophet' (*ḥadīth*, pl. *aḥādīth*). The characteristic aspects of the genesis of Islamic law – a cumulative development until the fourth and tenth century, geographically restricted proliferation of the various law schools (*madhāhib*), lack of normative authority – did, however, not allow for the introduction of uniform and ubiquitously accepted Islamic metric systems. Thus, the weights and measures which were used in Arabia and outside it, in the lands conquered by the Muslims, co-existed side by side, replaced each other, sometimes only by function, or by name, or intermingled. The striking feature of the metric systems that were in use in the early, medieval and pre-modern Islamic countries was their diversity. Neither in time, nor in space, could standard values develop that were accepted beyond their regional borders and their rulers' period. Although some names of units of measure, e.g. *dhirāʿ, dirham* or *raṭl*, were widely diffused throughout the Islamic world, their absolute values and use in practice differed considerably. Notwithstanding this bewildering array of measures, a few basic terms that have survived until modern times stand for the cultural continuity between the Ancient Orient and the Islamic world: *raṭl* (Greek litron, 'litre'), *irdabb* (Greek artabe, Persian 'measure of capacity'), *maṭar* (Greek metretes, 'measure of 40 L'), *ḳisṭ* (Greek xestes, Latin sextarius, 'jug'), *ḳinṭār* (Latin centenarius, 'hundredweight'), *ḳafīz* (Persian 'measuring cup'), *ḳīrāṭ* (Greek

W

keratios, 'carat'), *istār* (Greek stater, 'weight of gold coin'), *dirham* (Greek drachme), *dīnār* (Latin denarius), *kayl* (Aramaic measure of capacity), *mann/mannā* (Babylonian unit of weight), *kurr* (Babylonian measure of capacity).

The development of systems of measure was influenced by the interplay between cultural tradition and the order of authorities. Until the tenth century, the spread of Islam brought about an intercontinental economic and cultural sphere which amalgamated measuring standards of Egyptian, Arabic, Greek, Roman-Byzantine, Mesopotamian and Persian origin. This resulted in a multiplicity of regional and functional systems of measurement, which were constantly modified by power politics, institutional reforms or, simply, by the rulers' autocratic order. Quite often, the advent of new dynasties brought about the introduction of new metrological standards, mainly in the field of the basic weight units of currency of gold (*mithqāl*) and silver (*dirham*), and the exchange rate of gold *dīnār* and silver *dirham,* which were fixed at a very early state by the canonical texts of the *Qur'ān* and the prophetic tradition (*ḥadīth*). Contrary to the more or less stable weight rate (10 weight *dirham*s equal 7 weight *mithqāl*), which everyday use polished into the handier ratio of 3:2, the prescribed rate of value (10 silver *dirham*s equal 1 gold *dīnār*) incessantly deteriorated over the course of time. Ratios of 12:1, 16 4/5:1, 20:1,

30:1 and even 50:1 are recorded. Nevertheless, modern Islamic jurists insist on referring to the canonical rates (10:7; 10:1) when, for example, fixing the minimum income (*niṣāb*) for the obligatory alms payment (*zakāt*) by Muslims of a determinate portion of their lawful property. The canonical ratio of the value of gold and silver (10:1) reflected the historical situation in the Mediterranean region and the Middle East after the Roman period (12:1). During the Il-Khānid period (thirteenth to fourteenth century), silver from Central Asia was massively imported to the West, the price of silver sank again, for a short period, to the Roman value. Gold, in contrast, remained remarkably stable over the millennium. Under the Persian king Darius the Great (522–486), mutton cost the same as in Anatolia in 1340: the equivalent of 1.9355 g pure gold.

The overall cultural diversity of the Islamic world corresponds to the diversity of the metric systems, which came into use between the Atlantic and the Indian sub-continent. Three geographical units can be differentiated: The Islamic Arab West, from Andalusia to Iraq, Persia and the adjacent areas under Persian influence, and India. The following comments omit the metric systems of India (see *EI* [2] VI, pp. 121a–122a, s.v. *makāyīl*, and VII, pp. 138a–140b, s.v. *misāḥa*) and concentrate on the development in the Arab West, in consideration of the situation in Persia. Emphasis is laid on the early Islamic and medieval period. The absolute equivalents in modern metric values stem back to archaeological evidence or observations of European travellers.

Measures of Length

Along with the basic unit of length, the *dhirā*ᶜ, several other units were used, some of them only for particular purposes (construction, geometry, etc.). In theory, i.e. without considering their actual common occurrence or precise values, these units could be arranged to the following equation:

1 *ash* = 1 *si* = 10 *bā* = 10 *ḳaṣ* = 15 *bā‘* (or *ḳām*) = 60 *dh* (= Persian *gaz*) = 360 *ḳab* = 1,440 *iṣ* = 3,600 *fa* = 8,640 *sha.*

The ‘black ell’ (*al-dhirā‘ al-sawdā’*), being ca. 54.04 cm, is said to refer to the length of the ell (from the elbow to the tip of the middle finger) of a slave of the Caliph al-Manṣūr (r. 754–775) or the Caliph al-Ma’mūn (r. 813–833). Another etymology links the measure to the unit by which the ‘Nilometer’ of the island of al-Rawḍa was operated. There are almost thirty variants of the ell, some varying 30-fold from the original. By the eleventh century, at least 11 different types of *dhirā’* can be differentiated:

- 1 *dhirā‘ sawdā’* = 1 + 1/7 + 2/3 ·1/7 *dh al-yad* (of the hand)
  = 1 + 1/8 +1/9 *dh al-ḥadīd* (iron ell)
- 1 *dh fiḍḍīya* (silver) = 1 – 1/7 *dh al-sawdā’*
- 1 *dh yūsufīya* (of Abū Yūsuf, d. 798) = 1− 2/3 ·1/7 *dh al-sawdā’*
- 1 *dh hāshimīya* (of the Banū Hāshim) = 1 + 1/8 + 1/10 *dh al-sawdā’*

W

- 1 *dh bilālīya* (of Bilāl b. Abī Burda, d. 739) = 1 *dh al-sawdā'* + 2 + 2/3·1/7 *iṣ*
- 1 *dh fiḍḍīya* (al-misāḥa) = 7 or 8 *dh al-yad*
- 1 *dh ʿumarīya* (of ʿUmar b. ʿAbdalʿazīz, d. 720) = 1 + 1/2 *dh al-yad*
- 1 *dh mīzānīya* (surveyor's ell) = 3 *dh al-yad*
- 1 dh *mābahrāmī* = 1 + 1/2 *dh al-ḥadīd*

In addition to these different norms of the *dhirāʿ*, a multitude of ells was used depending on the profession involved: carpenters, cloth-makers, constructors etc. Moreover, the ells used in different cities under the same name differed: the medieval cloth-ell of Damascus (ca. 63.035 cm), for example, was 1/12 longer than the cloth-ell of Cairo (58.187 cm).

Measures of Area

The calculation of the surface of (straight) areas operated with the conventional measures of length. The basic units, however, were the *ḳafīz* and the *djarīb*, two specific measures of surface area. Originally and throughout the Islamic period, both units also served as measures of capacity. One *djarīb* was conceived of as representing the surface area of agricultural land which could be sown with the amount of seed one *djarīb* contained.

Based on the ratio of the length units (1 *ash* = 10 *bā* = 60 *dh* = 360 *ḳab* = 1440 *iṣ*), the following ratio of units of surface area measurement can be generated:

$$1\ ash = 60\ dh \cdot 60\ dh = 3{,}600\ dh^{2} = 1\ dj$$

and:

$$1\ dj = 10\ ḳa = 10 \cdot 360\ dh^{2}$$
$$= \text{[in Persia] } 60\ ka = 600\ ʿas = 600 \cdot 6\ dh^{2}$$
$$= 100\ ʿas = 100 \cdot 36\ dh^{2}$$

This *djarīb* was called the 'small' *djarīb*, being 100 square *ḳabaḍa* (or *ḳaṣaba*; the units being often exchangeable) which renders: 100 · (399 cm · 399 cm)^{2} = 1,592 m^2. The 'big' *djarīb* had 5,837 1/3 m^2, i.e. 3 2/3 'small' *djarīb*, and corresponded roughly to the predominantly Egyptian *faddān* which was calculated as 400 square *ḳaṣaba*, i.e. 6,368 m^2. During the nineteenth century, the *faddān* was reduced to 4,200.833 m^2.

If multiplied with one another these units render the matrix (see above).

There is substantial evidence that the professional surveyors during the Abbasid period used a specific system of calculation. They divided the biggest unit, the *azla*, into 100 *dh mīzānīya* which corresponded to 48 *iṣ ʿumarīya* (see above), hence:

$$1\ az = 100\ dh^2 = 100 \cdot 12^2\ ḳab^2 = 100 \cdot 12^2 \cdot 4^2\ iṣ^2$$

In the Turkish lands of the Ottoman Empire (Minor Asia, Iraq, Syria and Palestine) the *dönüm* (turn), Arabic *dūnam,* was – until recent times – the standard measure of area. Originally measuring 939 m^2, it has been adjusted in colonial times to 1,000 m^2 (in Iraq to 2,500 m^2).

Measures of Capacity

Most of the confusion about the system of the Islamic measures of capacity, both in primary medieval and in modern secondary texts, dates back to the Oriental practice to measure grain, pulse, and some liquids in capacity, but not in weight. The Arabic term *mīzān* does not clearly differentiate between the two. The transition from volume to weight needs the related quantity of the litre of water: the volume of approx. 75–77 kg of wheat and 60–72 kg of barley correspond to the volume of 100 kg/L of water.

From this economic and agricultural use of measures of capacity the proper mathematical and technical calculation of volumes must be set apart. This calculation is built on the calculation of the surface area multiplied by the third dimension. The names used for the cubic units of measure do not change. Related to the *dhirāʿ mīzānīya* and based on the ratio 1 *az* = 100 *dh* ^{3} = 100 *ku*, the following values are produced: (see matrix below)

Most of the units of measures of capacity are regarded as units of weights too. It is therefore impossible to separate the two systems properly. Depending on

	ashl	bāb	dhirāʿ	ḳabaḍa	iṣbaʿ
ashl	1 *dj*	1 *ḳab*	5/3 *ash*	1/6 + 1/9 *ash*	1/24 + 1/36 *ash* = 2 1/2 *dh* ^{2}
bāb		1 *ash*	1 *ash* = 6 *dh* ^{2}	1/36 *ash* = 1 *dh* ^{2}	1/144 *iṣ* = ¼ *dh* ^{2}
dhirāʿ			1/36 *ash* = 1 *dh* ^{2}	1/216 *ash* = 1/6 *dh* ^{2}	1/864 *ash* = 1/24 *dh* ^{2}
ḳabaḍa				1/1,296 *ash* = 1/144 *dh* ^{2}	1/5,841 *ash* = 1/576 *dh* ^{2}

	azla^3	dhirāʿ^3	ḳafīz^3	ḳabaḍa^3	iṣbaʿ^3
azla^3	1	100	6,000	172,800 = 10^2 · (12 *ḳab*)^3	11,059,200 = 10^2 · (48 *iṣ*)^3
dhirāʿ^3				1,728	110,592

the material measured, additionally different types of the same unit, e.g., a ‘honey-*farḳ*’ or a ‘barley-*irdabb*’, were used. The absolute values of these types differed considerably in different regions and periods. In order to allow a comparative overview, units that are related to each other by practical use are grouped together. Minor local variations and temporal changes are ignored.

Few of these units have a canonical background: 1 *was* = 60 *ṣāʿ* = 240 *mu* = ca. 252 L. Far bigger than this *mudd* (ca. 1.05 L) of Medina were the *mudd* of Egypt and Iraq (2.5 L), of Syria (3.67 L), of the Maghreb (4.32 L), and that of Jerusalem (100 L). The prophetic *ṣāʿ* was exactly 4.2125 L. Being the quantitative lower limit (*niṣāb*) for the liability for the *zakāt* (alms) taxes, the measure of 5 *wasḳ* of dates, for example, was equated in value with 5 *ūḳīya* (= 200 *dir* = 529.9 g), 20 *dī* (or *mithḳāl,* = 84.7 g, see later), 5 *dhawd* (camels), the *niṣāb* of cotton (5 *was* = 1,600 *dir ʿirāḳī* à 130 g), or 50 *kay.* Therefore, the values given for one *wasḳ* greatly differ. In the time of Hārūn al-Rashīd (around 800), a short-lived *wasḳ* (1 *was* = 2 1/2 prophetic *was*) was introduced.

Towards the end of the seventh century, the *ḳafīz* (usually corresponding to 1/10 *dj* = 1/60 *kurr*) was used instead of this prophetic *ṣāʿ* in Iraq. Another specific *ḳafīz* of capacity is recorded from Iraq around 990: 1 *ḳa* = 1 *ḳaffa* (basket) = 1/2 *zabīl* (basket made of palm leaves).

In Egypt grain, but in particular wheat, was measured by *irdabb*: 1 *ir* = 6 *wa* = 24 *ru* = 48 *ḳad* = 90 *ma* = 96 *ḳad* (small) = ca. 90 L. Different values extant for the *irdabb* (between 72.3 kg, modern 182 L) may be explained also by the difference of volume between, for example, wheat, barley and lentils (100:80:104).

Egyptian flour was measured in *tillīs*: 1 *ti* = 3/2 *wa* = 3 *ba* = 15 *ma* = 24 *ḳad* = 22.5 L. There, the *waiba* of rice (1 *wa* = 8 *ḳad* = 24 *r kabīr*), as observed around 1665, contained only 12.5 l. Three centuries before in Tunis, it was equal to 12 prophetic *mudd* (ca. 12.6 l).

In Medina and Iraq, honey but also wheat was measured in *farḳ* : 1 *fa* = 3 *ṣa* = 36 *r bagdādī* = 19 L. In Egypt and Syria, the *mudy* – not to be confused with the *mudd* - replaced the *ḳisṭ* when not oil but food was measured. It is sometimes called ‘the Syrian *djarīb*’, sometimes equated with the *ḳafīz*. The practice in Syria, however: 1 *ḳa* = 8 *mak* = 12 *ṣa*, the indication: 1 *mud* = 15 *mak* = 22 1/2 *ṣa* does not confirm this. In Palestine, a square *mudy* was known (1 mud^2 = 1 *ḥab* · 1 *ḥab*).

Olive oil was merchandised in *maṭar* (1 *maṭ* = 2 *ḳu* = ca. 17 kg) in the Maghreb, in *ḳulla* (1 *ḳu* = 12 *th* = 27 *r* = 13.6 kg) in Andalusia. In Egypt, the *thumn* corresponded to 1/8 *ḳad* (today 0.29 L), in Qayrawān to 6 prophetic *mu* = 6.32 L. Oil and other liquids were also measured in *ḳisṭ*: In Iraq, the ‘small’ *ḳisṭ* (1 *ḳi* = 3 *r* = 1.22 L) was half of the ‘great’ *ḳisṭ,* in Egypt it was half of a *ṣāʿ*: 211 L; elsewhere the *ḳisṭ* is given as: 1 *maṭ* = 4 *ḳi* = 21 1/3 *r djarwī* (see below) = 192 *ūḳ* (capacity) = 256 *ūḳ* (weight). In Andalusia, wine and vinegar were sold in *rubʿ* (1 *ru* = 1/4 *ḳad* = 18 *r* = 216 *ūḳ* = 1,728 *mi* = 8.16 L, in Persia the *peymāne* (bowl, 8.3 L) was in use for this purpose. In Iraq, wine, but also oil and honey, were measured by *makkūk* or *mishḳāʿ* (drinking-vessel): 1 *mak* = 48 *th* à 50 *dir* = 64 *mish* à 37 1/2 *dir* = 7.5 L.

Another widespread unit of capacity was the *ghirāra*, mainly used for grain: 1 *ghi* = 3 *ir miṣrī* = 12 *kay* = 14 *mak* = 72 *mu dimashḳī* = 73 1/2 *mu miṣrī* = 265 L. In Egypt, the *kayla* = 8 *ḳad* was 7.5 L (modern 16.5 L).

This *kayla* is not identical with the *kayladja*, presumably an originally Persian unit of capacity measure: 1 *kayl* = ½ *ṣa* = 1/3 *mak* = 3/14 *ghi* = 1/6 *ḳa* wheat = 1/5 *ḳa* barley = ca. 1 7/8 *ma* = 2.5 L (or 2 L in East Iran).

The most basic of all grain measures, especially in the Islamic East, was the old Babylonian *kurr.*

> 1 *ku* = 30 *kā* = 60 *ḳa* = 480 *mak* = 600 ‘*ush*/‘*as* = 1,440 *kayl* = 5,769 *ru* = 7,200 *r* = 11,520 *th* = 2,925 kg (wheat).

Smaller than this ‘big’ *kurr* of Baghdad was the *kurr* of Wāsiṭ and Baṣra (1 *ku* = 60 *ḳa* = 480 *mak* = 1,440 *kayl* à 600 *dir* of wheat = 2,700 kg); a ‘reformed’ *kurr* even amounted only to: 1 *ku* = 60 *ḳa* à 25 *r baghdādī* = 609.375 kg (wheat). Moreover, depending on the kind of grain measured, different *akrār* were used: In fourteenth century Baghdad, the *kurr* of wheat weighed 2,925 kg, that of barley 2,437.5 kg, and that of rice 3.656,25 kg. The common sub-units of the *kurr*, the *ḳafīz*, *makkūk*, *kayladja,* and *thumn* differed respectively, sometimes not only proportionally. Thus, in twelfth century Aleppo, a quite different *makkūk* existed: 1 *mak* = 19 *sun* = 28.5 *r* à 684 *dir* à 3.125 g = 60.92 kg. About the same time, the *ḳafīz* of Ḥamāh was 7/8 *ḳa* of that of Shayzar. In Aleppo, 4 *mak* made one *marzbān* (1 *mar* = 1/4 *mak* = 19/4 *sun* = 57/8 *r* = 4,873 1/2 *dir* = 15.23 kg).

Towards the end of the tenth century, the mathematician al-Būzdjānī compared the new ‘reformed’ (Arabic *muʿaddal*) *djarīb* - this *djarīb* was not measured with 10 but with 2 1/2 *ḳa* only – which was introduced after 978 by his Lord, the Būyid ʿAḍud al-Dawla, with four different common types of the *kurr*. His systematic treatment of the issue will throw some light on the complex variety of the units used and their specific relation when being transformed from one into another (see matrix below).

Besides *simsim* (sesame), *ḥinṭa* (wheat), *djahkandam* (mixture of 1/2 *ḥinṭa* + 1/2 *shaʿīr*), and *shaʿīr* (barley), a fifth category is formed to include all kinds of grain and dry goods that do not belong to one of the aforementioned categories: nuts, like almonds, pistachios and hazelnuts, dried pears, plums etc. From the

1. Ratio of *kurr*-Variants

Types of *kurr*	***mu‘addal***	***kāmil***	***fālidj***	***hāshimī***	***sulaymānī***
mu‘addal	1	2	2 1/2	3	3 1/2 + 1/4
kāmil	1/4	1	1 1/4	1 1/2	1 1/2 + 1/4 +1 1/8
fālidj	2/5	4/5	1	1 1/5	1 1/2
hāshimī	1/3	2/3	5/6	1	1 1/4
sulaymānī	1/6 + 1/10	1/3 + 1/5	2/3	4/5	1
[ratio]	60	30	24	20	16

2. Djarīb per *kurr*

Types of *kurr*	***mu‘addal***	***kāmil***	***fālidj***	***hāshimī***	***sulaymānī***
djarīb/kurr	24	12	9 3/5	8	6 2/5
fraction	1/3 · 1/8	1/2 · 1/6	1/2 · 1/6 + 1/6 · 1/8	1/8	1/8 + 1/4 · 1/8

3. Ratios Between sub-units (as indicated by Al-Būzdjānī)

	makkūk	***‘ushr***	***kayladja***	***rub‘***	***raṭl***	***thumn***
kurr	480	600	1,440	5,760	7,200	11,520
makkūk		1 1/4		12	15	24
‘ushr			1/4 + 1/6			
kayladja					5	8
ḥubūb	4	5			60	
rub‘		1/12 + 1/48			1 1/4	
thumn		1/20 + 1/60			1/2 + 1/8	

4. Ratio of Capacity Between Different Kinds of Grain

	simsim	***ḥinṭa***	***djahkandam***	***sha‘īr***
simsim	1	2	2 2/3	4
ḥinṭa	1/2	1	1 1/3	2
djahkandam	1/4 + 1/8	1/2 + 1/4	1	1 1/2
sha‘*īr*	1/4	1/2	2/3	1
[ratio]	8	4	3	2

matrixes 1–4, exactly 280 possible combinations result by which the transfer of one given quantity (and value) of one commodity into another can be calculated.

Example: If 24 *ku* of oats (*ḥurṭumān* = category of *sha‘īr*) should be transferred into *kurr sulaymānī* of pepper grass (*ḥabb al-rishād* = category of *ḥinṭa*), then the rule of seven is required, in short:

24 ku kāmil sha‘īr – 1/6 · 24 = 22
ku sulaymānī ḥinṭa + 30 *ḳa*.

Measures of Weight

The entire Islamic system of weights is based on the *dirham* and the *raṭl*. The *raṭl* is the most common smallest unit, or reference, of weight. The weight of the *dirham* is used for two different purposes. The two values differ correspondingly:

a) *dirham al-fiḍḍa* (silver *dirham*)

Calibration of the silver (*dirham*) and gold (*dīnār*) coins was done with the help of glass weights. The earliest preserved exemplars date back to the second half of the eighth century. The *dirham* weight defined the weight of the *dirham* coin, the *mithḳāl* weight the weight of the *dīnār*. The most precise glass weights of the *mithḳāl* have an average weight of 4.233 g (max. tolerance 1/3 mg). Archaeological finds affirm both the weight of the *dirham* in accordance to the canonical ratio of *dirham: mithḳāl* (= 10:7): 2.97 g, as to the ‘rounded’ ratio (= 3:2): 2.82 g. An exceptional *mithḳāl* weight was in use in Egypt under the Ayyubid dynasty and in the Maghreb under the Almohad dynasty (4.722 g).

The *mithḳāl* gold and the *dirham* silver were divided into *ḳīrāṭ* and *ḥabba*.

1 *mi* gold = 20 *ḳī* = 60 *ḥa*;
1 *dir silver* = 12 *ḳī* = 48 *ḥa* (Iraq)
1 *mi* gold = 24 *ḳī* = 60 *ḥa*;
1 *dir silver* = 16 *ḳī* = 60 *ḥ* (Arabia, Egypt, Syria)

Hence, the values (see matrix below).

In addition to these general systematic differences a variety of deviating systems from different regions, authors and periods are recorded (tenth to thirteenth century; indicated as I–V), that integrate sub-units like the *dāniḳ, ṭassūdj, ‘ashīr, fals, and aruzza* (which

	gold *ḳīrāṭ*	gold *ḥabba*	silver *ḳīrāṭ*	silver *ḥabba*
Iraq	0.212 g	0.0706 g	0.247 g	0.062 g
Egypt etc.	0.176 g	0.0706 g	0.186 g	0.0495 g

	dāniḳ	*ḳīrāṭ*	*ṭassūdj*	*ḥabba*	*ʿashīr*	*fals*	*aruzza*
I. Dīnār	12 1/2	20	24	60			
Dirham		12	24	48	60		
II. Dīnār	6	20 *baghdādī*		60 *baghdādī*	60		
		24 *baṣrī*		72 *ḫurās./shāmī*			
Dirham	6			48 *baghdādī/baṣrī*	60	96	
				36 *ḫurās./shāmī*			
III. Dīnār	[12]	[20]	24	60			240
IV. Dīnār		24/20	576	[72] 600/7		600	

elsewhere corresponds to 25 *ḥa ḫardal*, grains of mustard, i.e. ca. 0.0186 g); one author defines the ḥa *ḫardal* as 1/70 of a *ḥabba* (which is sometimes replaced by *'ḳamḥa'*, grain of wheat), 60 of which make one silver *dirham*, i.e. 1 *ḥa ḫardal* = 0.0007 g. From the vague comments of sources, it must be assumed that most of these different systems were in use as weight measures too (see matrix below).

According to the actual ratio of value between gold and silver currency, the moneychangers had to take several factors into consideration when transferring amounts of money from one currency into the other. This could result in thirteenth century Egypt, for example, when 16 4/5 *dir* were equivalent to 1 *dī*, in the following calculations:

1 *dī* = 1,440 *ḥa fiḍḍa* [10 · 60/7· 16 4/5 = 1,440]; and
1 *ḥa* gold = 1/5 + 2/25 ḳī = 16 4/5 *ḥa silver*; or
1 *fa* = 2 2/5 *ḥa silver* = 1/7 *ḥa gold* [2 2/5: 1/7 = 16 4/5].

b) *dirham al-kayl* (weight *dirham*)

In contrast to the homogeneous evidence of the weight of the 'silver *dirham*' the extant values of the weight of the 'weight *dirham*' deviate considerably from one another. They range from 3.086 g to 3.148 g. When not indicated otherwise, the following comments will be based on the established average standard value of 1 *dir* = 3,125 g with which the 'canonical' (ratio 10: 7) *mithḳāl* of 4.464 g is corresponding. From textual evidence some of which are included in the matrix above, different regional values of the *dirham/mithḳāl* weight can be deduced:

Egypt 3.125/4.68 g; Syria (Aleppo twelfth century) 3.14/4.427 g, (Aleppo nineteenth century) 1 *dir* = 3.167 g, Damascus 3.086/4.62 g; Anatolia (Ottoman period) 3.086/4.81 g; Iraq 3.125/4.46 g; Iran (fourteenth century) 1 *mī* = 4.3 g, (sixteenth century) [3.26]/4.639 g; Maghreb 3.3/4.722 g; East Africa (sixteenth century) 1 *mī* = 4.41 g.

With the exception of Persia, where the *mann* dominated the system of weight measures, the *raṭl* became the most common and widespread unit of weight measure in the Islamic world, comparable in size and function to the European 'pound' (Pfund, livre, libra, Italian loan word 'rotolo'). The *raṭl* was measured in *dirham*. Depending on what was measured, and where and when, the *raṭl* could take different numbers of *dirham* (values between 96 and 1.040 are recorded) of different *dirham* weights (standard value: 1 *dir* = 3.125 g).
If integrated into the early Meccan system:

1 *r* = 2 *ma* [à 130 *dir*] = 12 *ūḳ* = 480 *dir* = 1/100 *ḳin*,

the *mithḳāl* weights produce the following (fictitious) relation:

1 *mi* = 20 *ḳī* = 60 [or 100] *ḥa* = 10/7 *dir* = 1/336 *r* (for Iraq; 1 *ḳī* = 0.223 g)
1 *mi* = 24 *ḳī* = 96 *ḥa* = 3/2 *dir* = 1/320 *r* (for Mecca, Egypt etc.; 1 *ḳī* = 0.195 g).

From archaeological (glass weights) and textual evidence, several hundred *raṭl* weights are known. The following list enumerates (in order of size, with '[...]' values developed) some of the standard *raṭl* weights repeatedly recorded (see matrix below).

Besides the *raṭl*, the *mann* was an important unit of weight everywhere in the Islamic world, in particular in the Persian East, where it weighed between 260 *dir* (= 816.5 g) and 2,080 *dir* (= 6,656 g). A similar variety of *mann* weights was used In Asia Minor (twelfth century onwards). Until the fifteenth century it was used instead of one half of a *raṭl* à 130 *dirham*. Then a 'big' *mann* (ca. 3 to 3.25 kg), and a 'middle' *mann* of 1.920 g came into use. During the Safawid period (sixteenth century), a 'super' *mann*, later called the 'royal' *mann* (between 5.7 and 6 kg), was introduced. The Ottomans used the *oḳḳa* (1 *oḳ* = 2 *nu* = 400 *dir* à 3.207 g = 1.2828 kg) instead of the *raṭl*. Its stability was proverbial: *Okka her yerde dört yüz dirhem gelir* (… to be no different from anybody else).

Egypt (Abbasid period)	96 dir	300 g
Rūmī (Asia Minor) I	102 6/7 *dir*	321.43 g
Umayyad period	[110 *dir*]	340 g
Rūmī (Asia Minor) II	120 *dir*	375 g
Iraq (medieval)	128 4/7 *dir*	401.79 g
Abbasid period (Egypt, Baghdad)	130 *dir*	406.25 g
Maghreb	130 *dir*	406.25 g
Maghreb	137 1/7 *dir*	428.57 g
Umayyad period (Egypt)	[140 *dir*]	437.5 g
Maghreb (Fāṭimid period)	140 *dir*	437.5 g
Egypt (later Abbasid period)	144 *dir*	450 g
Fulfulī	150 *dir*	468.75 g
Maghreb (Ibn Baṭṭūṭa)	150 *dir*	468.75 g
'big' Egypt (Abbasid period)	160 *dir*	500 g
Maghreb (Ibn Baṭṭūṭa)	180 *dir*	562.5 g
Laithī	200 *dir*	625 g
Djarwī	312 *dir*	975 g
Turkestan (fourteenth century)	330 *dir*	1,031.25 g
Fes/Marrakesh (fourteenth century; = 16 ūḳ)	336 *dir*	1,050 g
Aleppo (twelfth and thirteenth century)	480 *dir*	1,500 g
Syria/Palestine (fourteenth century)	592 1/2 *dir*	1,851.56 g
Ḥimṣ (twelfth century)	684 *dir* [sic]	2,137.5 g
Aleppo (after thirteenth century)	[724 *dir*]	2,273 g
Jerusalem (medieval)	800 *dir*	2,500 g
Ḥimṣ (Syria, medieval)	864 *dir*	2,700 g
Constantinople (eighteenth century)	876 *dir*	2,800 kg
Jerusalem (nineteenth century)	900 *dir*	2,812.5 g
Iran (Shīrāz, Fārs; in *mann*)	1,040 *dir*	3,250 g

The biggest unit - besides the rather colloquial *ḥiml*, camel-load (1 *ḥi* = ca. 250 kg) -, was the *ḳinṭār*, the hundredweight (= 100 *r*). Depending on the type of *raṭl* it was based on, the *ḳinṭār* weights differed. In medieval Egypt, different *ḳinṭār* weights were common: *fulfulī* (pepper) = 100 *r* à 144 *dir* = 45 kg; *laithī* = 100 *r* à 200 *dir* = 62 kg; *djarwī* = 100 *r* à 312 *dir* = 96.7 kg; *mannī* = 100 *r* à 260 *dir* = 81.25 kg; 'big' = 24 *ru* = 240 *r* à 160 *dir* = 38,600 *dir* = 120 kg. In a treatise composed by a customs officer in the thirteenth century, additional *ḳinṭār* names, but no values, for specific goods are mentioned. While the *ḳinṭār* of Syria (Aleppo, Ḥimṣ, Ḥamāh) was always equivalent to 100 local *raṭl*, it was taken for 100 *mann* in late medieval Iraq. In Iran (fifteenth century) and Asia Minor (Ottoman period) 1 *ḳinṭār* weighed ca. 57 kg.

The smaller weight unit of *istār* (1 *is* = 4 1/2 *mi* = 6 3/7 *dir* = 20.07 g), only known from Egypt, was used there to weigh silk: 1 *s-ḳ-ṭ* [?] = 3 *ru* = 90 *man* = 180 *is*.

The Quranic '*ḥabba min ḫardal*' (the 'grain of mustard', see above), being 1/70 ḥa of 1/60 *dir* each (= ca. 0.0007 g), seems to have remained the smallest unit of weight in use in the Islamic world. If calculated properly, the fictitious *naḳīr* (1*djo* = 6 [*ḥa*] *ḫardal* = 72 *fa* = 432 *fāl* = 2,592 *na* = 1/96 *mi* = 0.045 g) would correspond to ca. 5 ng.

al-Ḳurashī

The research of the history of weights and measures and their use in the Islamic world is based on a variety of sources. Unfortunately, no particular literary type of text developed that could claim to be called 'professional'. The information available is scattered over texts on law, social and economic history, administration and geography. They generally lack a systematic character, i.e. ignore comparative and proportionate references. The most recent endeavor to collect all information available in the historical sources was undertaken by Maḥmūá Fākhūrī and Ṣalāḥ al-Dīn knawwām in: *Madjmūᶜat waḥdāt al-qiyās al-ᶜarabīya*

Aleppo: Weights

al-islāmīya, Beirut: Maktabat Lubnān Nāshirūn, 2002. Only occasionally, external sources, records of both European and Oriental travellers, allow the fixation of absolute values. With regard to their geographical and chronological diversity, the reconstruction of entire systems of measurement and of their relation to each other has just begun.

During the tenth century, mathematicians became aware of the complexity of the metric systems in use. Their particular perspective on the issue differed from what their legal and other colleagues had been noting down hitherto. They not only tried to present a systemized enumeration of all units related, but also endeavoured, for pedagogical reasons, to systematize the usage of measuring units in popular treatises. They sometimes even expressed efforts to standardise and facilitate the conversions customs, market and tax officers had to enact. Thus, stimulated by theoretical manuals, mathematically standardised methods of measuring and of converting quantities from one system into another became popularised. To some extent, these devices even had retroactive effects on the practice of Islamic laws.

Among these manuals, the “Book on the Basis of Arithmetic and the Division of Inheritances” (*Kitāb* *al-Tadhkira bi-uṣūl al-ḥisab wa l-farā'iḍ*), written by the Damascene mathematician ʿAlī b. al-Khiḍr al-ʿUthmānī al-urashī (1030–1067 AD) contains the most coherent information on the metric systems that were in use in the Islamic Middle East up to the lifetime of the author. The following list of units of weight, currency, capacity and length, together with the localities they refer to arranged in alphabetical order, is extracted and, if indicated by '[...]', concluded from different chapters of this *Kitāb al-Tadhkira*.

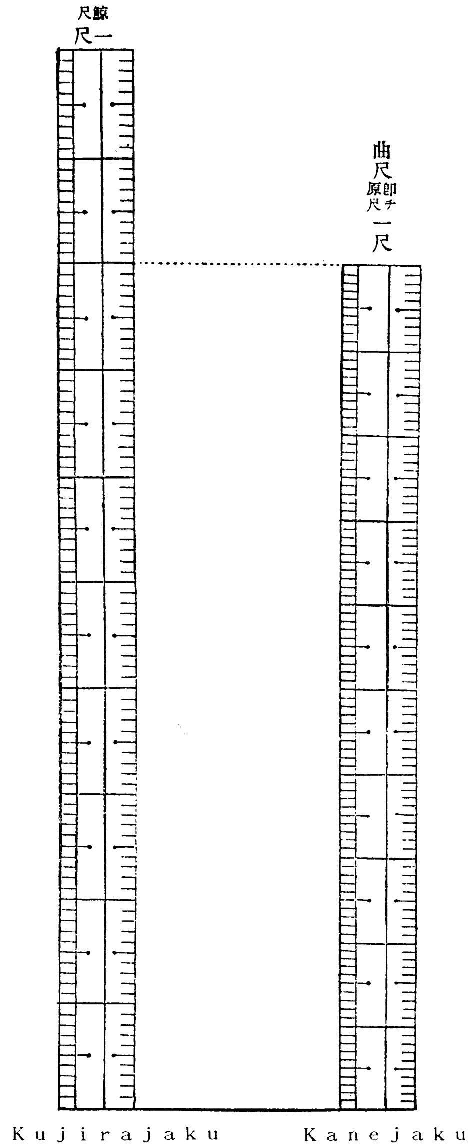
Weights and Measures in Japan

Shigeo Iwata

Japan used the 17.3 cm-long linear measure unit that was common to all the regions in East Asia for a period of 25,000 years. Under the influence of China, the Japanese measuring unit gradually lengthened during the period from the end of the eleventh century BCE to the middle of the third century BCE. Then, the length of the Japanese measure *shaku* was stabilized at 23 cm and remained unchanged until the end of the second century AD. Various civil disturbances in China had the effect of lengthening the linear measure substantially to 29 cm until the middle of the seventh century, and no more significant variation has since been observed (Fig. 1).

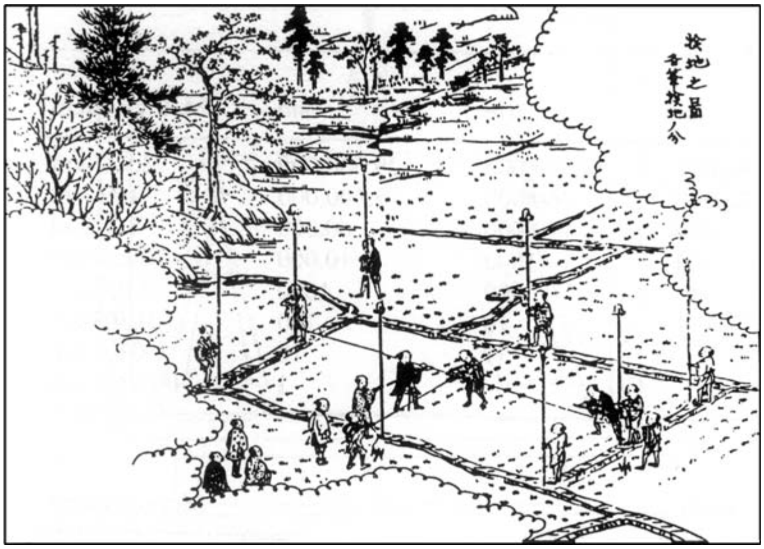


Weights and Measures in Japan. Fig. 1 Linear Measure. Drawing by The Ministry of Finance. *Doryoko Shurui Hyo* (The Classification Table of Weights and Measures) Genbei Kinokuniya, 1875. Chos 1, 4–6, 9–11.

Length

Under the Chinese Tang dynasty, a law was enacted mandating the use of two methods based on large and small linear measures. The large scale was 1.2 times as long as the small scale, which we refer to as the ancient linear measure. The small scale was used for music, astronomy, and ceremonial items.

Japan introduced this Chinese measuring system in 701. The large scale later became known as *kanejaku*, which refers to an L-shaped ruler used by architects. The small scale gradually dropped out of use. Linear measurement tools were mainly made of wood, though



Weights and Measures in Japan. Fig. 2 Land Surveying. From *Tokugawa Bakufu Kenchi Yoryaku* (Essential Summary of the Government of Prefectures, Tokugawa Shogunate). Tokyo: Kashiwa Shobo, 1915.

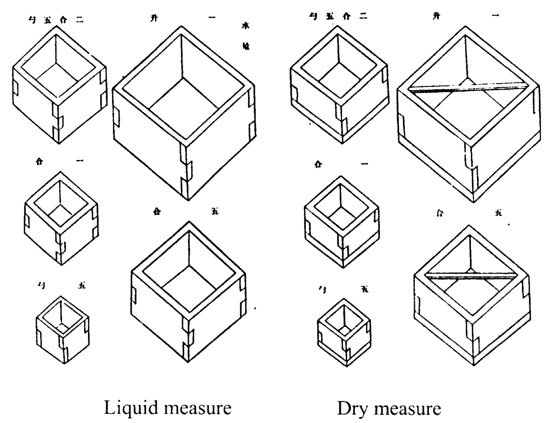
ivory was also used in ancient times. The largest unit of length in ancient times was the *ri*, which was 5–70 *cho* (a *cho* was 109.1 m). The *ri* was set to 36 *cho* in the seventeenth century. One *shaku* was one-tenth of a *jo*. Metal linear measurement tools began appearing in the medieval era.

The average value of one *shaku* was 29.6 cm in the seventh century, 29.7 cm in the eighth century, 29.8 cm in the ninth century, 29.9 cm in the tenth century, 30.1 cm in the twelfth century, 30.2 cm in the fourteenth century, and 30.3 cm in the eighteenth century. The rate of elongation was slower than in China.

Several linear measures for sewing appeared in the medieval era. The length of one *shaku* ranged from 1.15 to 1.27 times that of a *kanejaku*. These linear measures for sewing were neatly arranged into two kinds of scales. One scale, 1.20 times as long as a *kanejaku*, was called *gofukujaku*, while the other was 1.25 times as long as the *kanejaku* and called a *kujirajaku*. The *gofukujaku* gradually dropped out of use in the first half of the eighteenth century and was finally abolished in 1875.

Area

The earliest area unit we know of was the *shiro*, which was in use before the sixth century. One *shiro* was 30 *shaku* square. In 646, new units were defined: the *bu*, which was six *shaku* square; the *tan*, equal to 360 *bu*; and the *cho*, equal to ten *tan*. One *tan* has been equal to 300 *bu* since the end of the sixteenth century. For land surveying purposes, one *bu* was defined as six *shaku* five *sun* square, rather than six *shaku* square. At the end of the sixteenth century, a *bu* was defined as six *shaku* three *sun* square. Despite this, the *bu* was commonly considered to be six *shaku* square, and was finally defined as such in 1891. A *se* was ten times as large as a

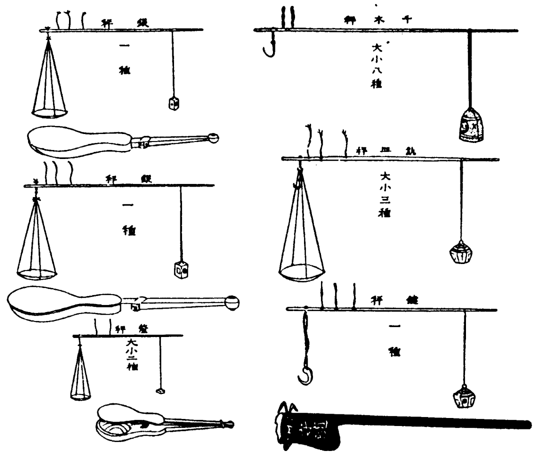


Weights and Measures in Japan. Fig. 3 Measures. Drawing by The Ministry of Finance. *Doryoko Shurui Hyo* (The Classification Table of Weights and Measures) Genbei Kinokuniya, 1875. Chos 1, 4–6, 9–11.

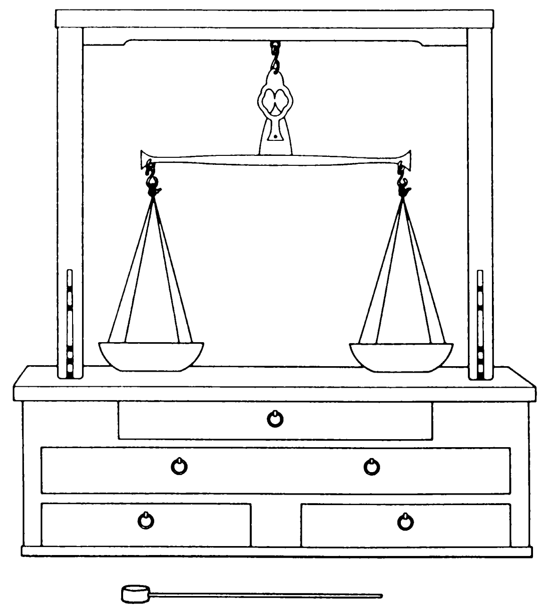
bu, which was also referred to as a *tsubo*. These names appeared in the medieval era. Land surveyors made their measurements using flax string measures and wood measuring poles (Fig. 2, 3).

Volume

The names for most units of volume also came from China. The basic unit was the *sho*. One *sho* averaged 750 cm^3 in the eighth century, 800 cm^3 in the ninth century, 970 cm^3 in the eleventh century, 1,400 cm^3 in the fifteenth century, and 1,650 cm^3 in the sixteenth century. Since the seventeenth century, the average value has remained constant at 1,804 cm^3. During the medieval era, different measures of volume were used for goods, taxes, and financial transactions (Fig. 4).



Weights and Measures in Japan. Fig. 4 Steelyard. Drawing by The Ministry of Finance. *Doryoko Shurui Hyo* (The Classification Table of Weights and Measures) Genbei Kinokuniya, 1875. Chos 1, 4–6, 9–11.



Weights and Measures in Japan. Fig. 5 Balance. Drawing by Shigeo Iwata (1981).

The Tokugawa-Shogunate (1603–1867) established the East and West Measure Guilds in 1655, and exerted strong control over the new standard. Use of *sho* continued until 1958, when the *shaku-kan* system was abolished.

Rectangular measures were made of wood. The brims of many dry measures were protected by bamboo or iron laminae. Most of the large dry measures also featured a narrow iron bar positioned diagonally across the top. Round wooden sticks were used to level off the tops of measures. Liquid measures had lacquered surfaces to prevent the contents from leaking.

Standard sizes for measures have been one *to*, seven *sho*, five *sho*, one *sho*, five *go*, two *go* five *shaku*, and one *go* since 1655, and one *to*, five *sho*, one *sho*, five *go*, two *go* five *shaku*, one *go*, and five *shaku* since 1875.

Mass

Between the eighth century BCE and the fifth century AD, the Chinese expressed mass in terms of the *liang*, which was equal to 14 g. In this measuring system, one *jin* was equal to 16 *liang*, and one *liang* to 24 *zhu*. The civil disturbances of the third and seventh centuries also had their effect on the *liang*, which tripled in mass. Under the Chinese Tang dynasty, a law stipulating two measuring scales was enacted, which fixed the mass of the new large *liang* at three times that of the mass of the older *liang*, which became used only for medicine.

Japan adopted this Chinese measuring system as well, changing the names of *jin*, *liang*, and *zhu* to the *kin*, *ryo*, and *shu*, but retaining the same characters. The absolute mass of the *ryo* in the large scale decreased year by year, while that in the small scale became rather unclear. The average mass of one *ryo* was 42 g in the eighth century, 40 g in the tenth century, 39 g in the twelfth century, and 37.47 g at the end of the sixteenth century. Under the strong control of the Tokugawa-Shogunate, the average mass of the *ryo* remained almost unchanged until the end of the nineteenth century. The *kan* and *monme* appeared in the medieval era. One *kan* was equal to 100 *ryo*, and one *monme* equal to one-tenth of a *ryo*. These units gradually became standard.

Chinese use of the steelyard dates back to at least several centuries BCE. The steelyard was also used in Japan, where the Tokugawa-Shogunate established the East and West Steelyard Guilds in 1653. Steelyard beams were made of white oak, persimmon wood, ivory, horn, and bone. The beam had from one fulcrum to eight fulcra, which were made using string, cord, or rope. A copper pan or bronze hook was installed on the end of the beam, and the bob-weight was made of bronze or iron. Steelyards were used for most commercial transactions (Fig. 5).

Balance makers did not belong to a guild, so standards for making balances were never formulated. The most famous balance makers were members of the Nakabori family, who lived mainly in the western counties of Japan. The balance beam was suspended by its pointer from the center of a box-mounted rectangular wooden stand. A central pin was used for the main fulcrum, and during the final stages of weighing, bearing friction was overcome by tapping on the pin with a small wooden hammer. Balances were mainly used in the manufacture of gold, silver, and copper coins, and in money-changing transactions.

Beginning in the seventeenth century, users of the balance had to be supplied with weights made by the Goto family. Two sets of weights were available: one consisted of weights of 20, 10, 5, 4, 3, 2, 1 *ryo*, 5, 4, 3, 2, 1 *monme*, and 5, 4, 3, 2, 1 *fun*, and the other was identical to the first but for the addition of 50 and 30 *ryo* weights. Weights were made of bronze, and engraved on the surface with the inspector's mark and maker's crest, leaves and flowers of the Japanese paulownia. The Goto family belonged to the Guild of Goldsmiths, and were inspectors authorized by the feudal government. They examined user's weights periodically by comparing them with standard weights.

Transition to the Metric System

In 1886, Japan signed the Treaty of the Meter, and promulgated the Law of Weights and Measures. As a result, the *shaku-kan* system and metric system began to be used jointly in 1891. The conversion coefficients between these two measuring systems were also fixed at the same time (Table 1). The law went into formal effect in 1893. In 1903, the Central Inspection Institute of Weights and Measures was established in Tokyo. Japan also adopted the units of the foot-pound system as legal in 1909.

A Measurement Law was passed by the Diet in 1951, and went into effect on March 1, 1952. It mandated that measuring units be based on the metric system. The *shaku-kan* system and foot-pound system were abolished in 1958.

A new Measurement Law was promulgated on May 20, 1993, and went into effect on November 1, 1993. The law made a sweeping revision of the regulations by adopting the Système Internationale d'Unités. The units of the other measuring systems on commercial transactions and certifications were abolished by the end of the twentieth century.

Weights and Measures in Mesoamerica

JEAN-CLAUDE HOCQUET

Mexico is said to have used an incredible variety of weights and measures changing according to the region and the period. Different uses of the weights and measures increased the complexity of the situation. The task of the historian consists of restoring the ancient systems and understanding their use by posing the questions: who was using the weights and measures and for what purpose? The more powerful of the two parties in the exchange would impose upon the other modes of measuring and counting to his own advantage.

Indian Measures

In 1520, Hernan Cortes had the opportunity to see the market of Tlalecolco and the transactions which went on there. He wrote, "Everything is sold by count and measure, and up till now I haven't seen anything sold by weight." Antonio de Herrera y Tordessilas reported that the Indians "have measures for everything" and that the judges controlled the weights and measures and punished the cheaters. But his information has not been confirmed. However, the level of development attained by the Mesoamerican people before the Conquest makes it very probable that they had an ensemble of measures and standards used in the apportionment of land, commercial transactions, levying of taxes, construction, pharmacy, etc., and that these measures constituted a unified and coherent system.

After the Conquest, the Spanish imposed Andalusian and Castilian measures such as *brazas*, *codos*, and *pal-mos*, that the Indians adopted easily, as, like their own, they were anthropometric. The result of this adoption was that Mesoamerican symbols of measure were transcribed in European terms on the pictograms of indigenous manuscripts written in the Nahuatl language. Bars represented digits, little black circles were for 20s, and other signs represented hands or feet. Thus, for example, the Indians gave the name *tlamamalli* to the load (*carga*) that a man (porter, *tameme*) could carry on his shoulders during a day's work. In the *novohispano* system, this load had the name *tameme*, by a simple movement of language and meaning. It was equivalent to a Spanish half-*fanega* or to two *arrobas*. This indigenous load varied in weight, in the function of the weighed merchandise, and with the strength of the carrier; for cocoa it was equivalent to three *xiquipilli* of 8,000 grains each.

Among the measures of capacity, of great diversity, the smallest was the *centlachipinilli*, which literally means "a small something" (*una gota de algo*) and which was itself a multiple of *centlachipiniltontli* (*una gotilla de algo*). There were also small measures used in pharmacy, such as spoonsful (*cemixcolli*, *cenxumatli*, etc.). *Testal* designated the quantity of cornmeal necessary to make a tortilla for one person.

To measure dry materials, in particular for grains, they were often able to use measures equivalent to those imported from Spain: the *acalli*, for example, of which we do not know the weight, was part of an arithmetic system with the *cencaauhacalli* equal to a half-*fanega* and with the *cuauha-caltontili* equal to a *celemin*. Such equivalent approaches make it possible to conclude that the conquerors tried to impose their own system while at the same time adopting the native terms.

Measures of length were used for the preparation of clothing, especially for ponchos, made of bands of different widths. Most measures of length were land measures, based on proportions of the human body: *cemiztetl*, *cemmapilli*, and *cemmatl*, literally a finger, a palm, and a span. This "span" designated the height of a man, from foot to raised hand, but it also measured the diagonal, from the left foot to the raised right hand, and it stood for three Spanish *varas* (yards or cubits). Such a dimension proves that the span was a geometric measure and not an anthropometric one; it was obtained by attaching an anthropometric measure such as a digit, measured by its length, to a coefficient. European measures of length did not have the same way of varying, in which a "foot" could vary between 28 and 60 cm. However, for land measures, certain spans were smaller, and the *vara* was therefore equal to two spans. In Tula, there was a division of land in order to reform the tax law, and "each Indian was given one hundred *varas* in length and twenty in width. Each one of these *varas* made two spans; this is the measure which the

W

Indians use" (Castillo Farreras 1972). It is possible that this text makes reference to an Indian *vara* and a Spanish *braza*. Standards of measure and length existed, and, to measure land, poles or cords were used, just as European surveyors did.

Road measures also existed, which were used by travelers, soldiers, and merchants. These were the *cennecehuilli* and the *cennetlalolli*, which Spanish authors tended to translate as "leagues."

Weights and Measures of New Spain

In the sources of the eighteenth century the range of different names involved – *carga*, *fanega*, and *arroba* – hides the numerical relations which link multiples and submultiples. The *carga* is made up of two *fanegas*, composed in turn of six to eight *arrobas*. In general the historian goes from the largest to the smallest, whereas in practice, the peasant, the muleteer, or the trader proceeds in the reverse order. In the same way that the metric *quintal* is made up of grams and kilograms between which the factor 10 governs all relations, in the eighteenth century, 2 and 6 (equals two multiplied by three) governed the relations of the *carga* with its submultiples. The decimal metric system is a scientific system, mathematic in character, invariant, exterior to humans. In contrast, previous systems were based on people or on observations concerning them, or on their work and capacity to complete certain tasks with the aid of animals. That is, if a mule must climb steep paths with its load, the muleteer compensates for this by lowering the weight of the load by one or two *arrobas*. At times, the sources mention *cargas pequeñas* in contrast to *cargas regulares de mula*.

> As long as freighting relied chiefly on pack trains and carts, the weight of the loads was determined by distances to the customer, the availability of pasture *en route*, as well as by the nature of roads and tracks. In the case of steep mountain paths, broken country or long distances, the *carga*, the traditional load of a mule, could be lowered in weight. So a mule load could comprise one and a half or two *fanegas*. In 1832 the Governor of Oaxaca stated that because of the poor roads the *carga* could never consist of more than eight *arroads* (Ewald 1985).

Generally the custom of mentioning the number of *arrobas* making up a *fanega* or a *carga* does not eliminate the uncertainties which surround all quantitative data. In 1751, the *carga* of salt in Tehuantepec consisted of 14 *arrobas*. Another eighteenth-century source stated that moist Tehuantepec salt was 16 *arrobas*, while drier salt was computed at 12–14 *arrobas*.

The dampness or dryness of goods being transported markedly affects their weight. The presence of water increases the weight of light goods such as grains, but it lessens the weight of heavier ones, in particular salt. In Tehuantepec, the variation in weight often reached a quarter. Other variations were also noticeable between the different regions: "In eighteenth century Yucatan, one *fanega* of old salt weighed approximately 9 *arrobas*, one *fanega* of new salt 10–11 *arrobas*" (Ewald 1985). The measure known as *carga* in the valley of Mexico was often mistakenly referred to as *fanega* in Yucatan.

But there is another trap: Ralph Roys, for example, noted that a *fanega* "is variously defined as 1.6 bushels, and a load of 100 pounds of grain," which is an example of recent efforts to align traditional measurements with those of the national market governed by the decimal metric system, whilst at the same time conserving the ancient names. But "this statement has led a number of scholars to assume that a *fanega* weighs 100 pounds, which is not necessarily the case. The *fanega*, like the bushel, is a measure of capacity, not weight. Hence, the weight of a *fanega* will vary enormously depending on the goods being measured by this standard. A *fanega* of corn may weigh close to 100 pounds, but salt is much heavier. An extensive survey of the literature on weights and measures used in the Maya area – from Yucatan to El Salvador suggests that a *fanega* of salt commonly weighed about 115 kg" (Andrews 1983). It is important not to confuse measures of capacity, which are volumes, and units of weight which measure mass; weighing the contents of a volumetric measure can only lead to considerable distortions, since each body has a specific weight by which it distinguishes itself from all others.

The foreigners who traveled or worked in nineteenth-century Mexico reported that a *fanega* of salt weighed approximately 70 kg and a *carga* 140 kg. J. Buschmann stated that the *carga* consisted of 138 kg. In 1912–1913, however, the business records of Salinas, Mexico calculated the *carga* of Colima salt at 161 kg. In 1916–1917, the *carga* was again lowered to the more customary 140 kg. The nineteenth-century sources gave 300 pounds as the equivalent of a *carga*. In summary, here are some of the results found in the historical literature on the subject.

In Mexico, on the central plateau (Tehuantepec salt):

carga	1		
fanega	2	1	
arroba, dry salt	14	7	1
arroba, moist salt	16	8	1
pounds, dry salt	300	150	21.4
kg	138	69	

In Yucatan, the substitution of the *fanega* for the *carga* does not modify the system.

β	1		
arroba, old salt	9	1	
arroba, new salt	11		
pounds	300	33.33	1
kg	138		0.460

The historian will recognize the mule load of 300 pounds and the 16 ounce pound, such familiar territory that he would think he was in Castile in the time of the Catholic Kings.

Weights and Measures in Peru

Shigeo Iwata

Ancient Peru covered most of the Andes, where the Peruvian culture lasted for more than 10,000 years. Because most of the region was in the highlands, more than 3,000 m high, their metrology was slightly different from other civilizations. Also, they had no form of writing until 1532. For calculation and for recording metrological units decimally, they used *quipus*, spatial arrays of multicolored knotted cords. The names of the units and the values differed significantly depending on the period, the people, and the region.

Length

Peruvians used linear measurements that were related to human measurement patterns. Examples are listed in Table 1.

Peruvians chewed lime and *lipta* with coca leaves as a stimulant. They invented a measure called *cocada*, which measures how far one can walk while under the drug's influence. This distance is 3 km on level ground or 2 km on an uphill slope when carrying a 45 kg load for 35–40 min in Pataz county.

A twelfth-century pre-Inca site in Puruchuco, located about 6 km from Lima, was recently restored. The linear measurements of each part of the structure showed that the average stature of men from head to toe was 1.701 m, while the height from the middle fingertip to one's toe was 2.106 m. They used a geometrical design of proportions based on the golden section (1:1.618) between the sides of the rectangles.

Area

The Aymara called the area where they could raise one or two heads of cattle the *callapa*. *Tupu* was the Incan name for an area of cultivated land or pasture where a married couple could live. The Inca called the area, which was equal to 625 m^2 *huiri*. This was the area a man could cultivate in 1 day. The Cuzco called the area equal to 282 m^2 of sweet potatoes or corn *papacancha*.

Volume

The Peruvians used a single hand-cupped gowpen to measure small portions of grain. They also used gourds, dried pumpkins, pots, and jars to measure things. The names of the units and the values are shown in Table 2.

The Quechua called a broad crate filled with coca or red pepper a *runcu*. One-half of a *runcu* was called *checta runcu*, one-fourth was called *cutmu*, and one-eighth was called *sillcu*.

Mass

Because fewer weights have been discovered in the Peruvian region than in other civilizations, it has been difficult to estimate the mass standard accurately. We assume that the average mass of unit was 23.1 g. The notation was based on the decimal system. The maximum unit was assumed to be 23.1 kg, which is about 80% of the maximum units from other civilizations, 27–30 kg in Egypt, Mesopotamia, Indus, and China. This is probably because of the low concentration of oxygen in the atmosphere in the Andean highlands.

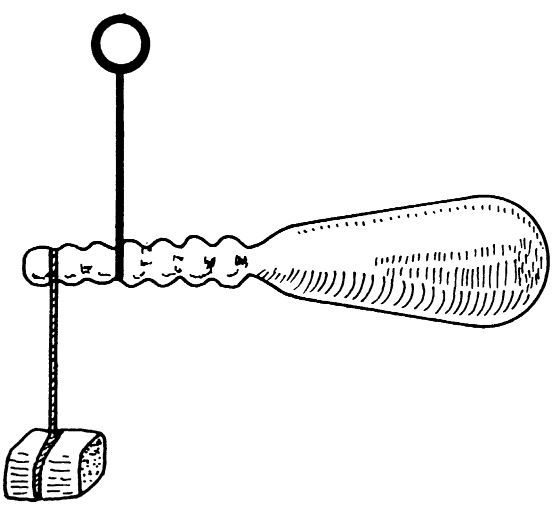
Thirty-nine percent of the weights were made of stone, 32% of iron, 24% of lead, and 5% were made of other nonferrous metals. One-third of the weights were globe-shaped; the others were conical, cylindrical, or in spindle and other irregular forms.

Weights and Measures in Peru. Table 1 Examples of Peruvian linear measurements

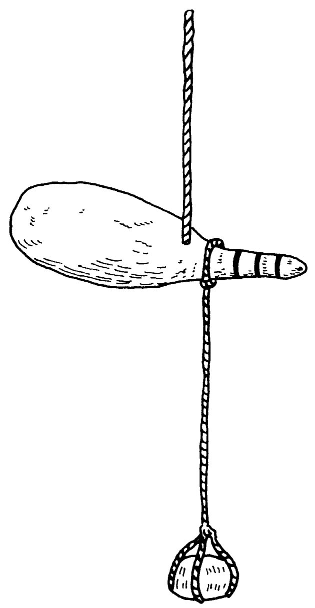
	Quechua	Aymara	Inca	Ratio	Metric system
Handbreadth		*ttkhlli*		0.051	8.5 cm
Link	*yaku*	*vicu*		0.107	18 cm
Span	*capa*	*chia*		0.125	21 cm
Cubit	*cuchuch tupu*			0.25	42 cm
Yard	*sikya*			0.50	84 cm
Pace		*chillque*		0.89	150 cm
Fathom	*rikra*			1.00	168 cm
		loca		10^2	168 m
		ecca		10^3	1.68 km
	cocoda			$1.19–1.79 \times 10^3$	2–3 km
League	*tupu*		*tupu*	3.33×10^3	5.6 km
		yapu		5.00×10^3	8.4 km
		chuta (sayhua)		10^4	16.8 km
			guamanin	10^5	168 km

Weights and Measures in Peru. Table 2 Hand-cupped "gowpen" measure of the Peruvians

	Quechua	Aymara	Ratio	Metric system (cm^3)
Gowpen (double hand-cupped)	*poktoy*	*iuu*	0.043	300
		laqui	1.00	7,000
	pokcha	*hullu*	2.00	14,000



Weights and Measures in Peru. Fig. 1 Bismar (adapted by the author from M. Uhle. La Balance Romaine au Pérou. *Journal de la Société des Américanistes de Paris* 17 (1925): 335).



Weights and Measures in Peru. Fig. 2 Movable load scale (adapted by the author from P. Rivet. La Balance Romaine au Pérou. *L'Anthropologie* 33 (1923): 535).

All types of scales, namely balance, steelyard, bismar, and movable load, were discovered in the northwest region of South America. The fulcrum was the cord-pivot type. Balance beams were made of wood, horn, and bone with humans, monkeys, birds, and geometrical patterns engraved on them. The two items supporting the load and weights were mostly nets, and partly pans of metals. The balance might have been invented by the ninth century (Figs. 1 and 2).

Weights and Measures in Peru. Fig. 3 Balance (from the Museo Amano).

Miquel de Estete, who attended Francisco Pizarro, found a steelyard on the coast of Ecuador in 1531. The steelyard was graduated from the middle of the beam to the end, and had a bob-weight suspended from the arm. The steelyard was used to weigh gold and silver. The bismar was discovered at the market in Tarma, 170 km northeast of Lima. The total length was 27.8 cm, and the capacity was assumed to be 924 g. The movable load scale, called *wipe* in the actual place, was discovered in Huarochiri, 90 km to the east of Lima. The scale was made of wood, and was used to weigh coca leaves (Fig. 3).

Western Dominance

Michael Adas

Scientific curiosity was a major motive behind Western overseas expansion from the fifteenth century onward and technological innovations, particularly in shipbuilding, navigational instruments, and firearms, made that expansion possible. But early European explorers and conquistadors did not rely heavily on evidence of scientific or technological achievements as gauges of the worth of the peoples they encountered or as explanations for their growing dominance in the Americas and maritime Africa and Asia. In encounters with the great centers of civilization in Africa and Asia, European superiority in these endeavors was highly selective, marginal, or in many areas nonexistent. In fact, travelers to China and the Indian subcontinent in the early centuries of expansion were as likely to dwell on the technological deficiencies of the West, when compared to these great civilizations, as to boast of European advantages. As in India, China, and Japan, the Europeans were able to make little headway into the heartlands of the Islamic world in this era. That standoff and the fact that they had borrowed so heavily from the scientific learning and technology of Muslim cultures in the centuries of Europe's emergence as a global force, rendered it unlikely that material standards would supplant the long contested religious differences that the Europeans had employed to set themselves off from and above the followers of Islam.

In Africa, disease and geographical barriers and the power of coastal kingdoms prevented the Europeans from translating their technological edge into significant conquests. Failure to move into the African interior also meant that the Europeans had only the vaguest notions about African epistemologies or understandings of the natural world, which were usually dismissed as superstition or fetishism. In sharp contrast to their experience in Africa, European invaders encountered few disease barriers in the Americas. In fact, diseases from smallpox to the measles became powerful allies of the Spanish conquistadors in their assaults on the heavily populated and highly advanced civilizations of Mesoamerica and the Andean highlands. The long isolation of the Amerindian peoples from the Afroeurasian people and cultures left them highly vulnerable to both the microbes borne and the Iron-Age technology wielded by the European invaders. Nonetheless, the Spanish tended to attribute their startling successes in battle against seemingly overwhelming numbers of Aztec or Inca adversaries and the rapid conquests that followed to supernatural forces and to the superiority of their militant brand of Christianity over the “heathen” faiths of the indigenous inhabitants of the “New” World.

Lacking in-depth knowledge of the epistemologies and scientific learning of most of the peoples they encountered in the early centuries of overseas expansion and often enjoying only very selective (but at times critical) technological advantages over them, European explorers, missionaries, and Crown or Company officials were unlikely to rely on material standards to judge the level of development attained by other cultures or to compare overseas civilizations to Europe itself. Until at least the end of the seventeenth century, religious beliefs, or the Europeans’ certitude that they possessed vastly superior understandings of the transcendent world, predominated as the gauge by which other cultures and peoples were assessed and ranked. Additional cultural variables, such as the position and treatment of women, were frequently cited as evidence of advancement or savagery; and physical features, especially skin color, were sometimes emphasized in attempts to distinguish and rank the peoples encountered overseas.

Scientific and technological gauges of past attainments and present abilities remained peripheral to most evaluations of the peoples and cultures that the Europeans encountered as they expanded across the globe. None the less, signs of material advancement – the existence of large cities, sophisticated techniques of fortress construction, or evidence of complex scientific instruments – were often noted and even cited to support arguments regarding the level of development achieved by different peoples. In two areas in particular, in the perception and measurement of time and in perspectives on space associated with artistic and mathematical advances of the Italian Renaissance, European overseas observers began to see a clear divide between the West and all other civilizations and cultures. In addition, as early as the sixteenth century, European commentators began to rank African cultures beneath those of Asia and the Americas, not so much because of skin color or other physical features, as has often been argued, but due to what was perceived as a markedly lower level of material culture in Africa than that found by European travelers and traders in India, China, or central Mexico.

Although ideologies justifying overseas expansion and the domination of non-European peoples from the fourteenth to the early eighteenth century were rooted in religious belief and were generally culture – rather than racially – oriented, material accomplishment, including the assumed capacity for invention and scientific thinking, was increasingly associated with racist defenses of the enslavement of Africans. Defenders of the slave trade sought to counter the abolitionists’ objections with often lurid descriptions of the alleged savagery of African life and the debased level of African material culture. Along with skin color and other physical differences, racist writers, such as Samuel Estwick and Dominique Lamiral, emphasized material backwardness and ignorance of the workings of the natural world as proof of the subhuman nature of Africans that justified their subjugation as slaves.

By the last decades of the eighteenth century, this rather broad association between racial ideology, material culture, and the defense of slavery was refined and enhanced by the rise of racist theories allegedly grounded in scientific experimentation and reasoning. Physicians and ethnologists devised a variety of measurements – from skull size and shape to genital configurations – in efforts to prove that there were innate physical, mental, and moral differences between human racial groups. The fact that the measurements reflected a priori assumptions and were based on small and suspect samples, and that even the racial categories themselves were hotly contested, did not prevent “scientific” racism from winning widespread support from European scientists, social commentators, and politicians throughout the nineteenth century. The tenets of scientific racism were popularized among the middle and working classes by practitioners of phrenology, whose booths could be found at county fairs and on the promenades of seaside resort towns, and by the pulp press, where allegedly scientific proofs of European racial superiority were linked to social evolutionist arguments for imperialist expansion.

By the first decades of the nineteenth century, scientific and technological gauges of human achievement and worth were clearly in the ascendant. Earlier measures of the level of development achieved by different cultures continued to be cited. Religious belief, for example, remained of paramount importance to missionaries active in overseas lands. But even missionaries increasingly linked Europe’s advances in the sciences and invention to the rhetoric of Christian proselytization. Ignoring past and contemporary tensions between science and religion in Europe itself, prominent missionaries, such as the Abbé Boilat and David Livingstone, argued that Christian culture had been particularly receptive to scientific investigation and technological innovation, and that conversion to Christianity would promote the scientific and material development of colonized peoples. The growing numbers of ethnologists and professionally trained anthropologists, who found in the colonies relatively safe and fertile environments for their research, also privileged nonscientific or non-technological standards, such as modes of political organization or gender relations, in assessing the level of development attained by African, Asian, Amerindian, and Pacific Island peoples. But evidence of material culture was increasingly linked to societal advance, and indigenous “superstitions,” or at best magical beliefs, contrasted with the scientific mindset that was seen as typical of the educated West.

A number of factors account for the dominance of material standards, particularly those linked to science and technological innovation, in nineteenth-century ideologies of European global hegemony. Most critically, the transformations wrought by industrialization from the middle of the eighteenth century in England and somewhat later in Belgium, Germany, France, and Italy made the gap in scientific and technological capacity and material development between western Europe and non-Western societies increasingly apparent to European and non-European observers alike. Maxim guns, steamboats, and railway lines carried elements of Europe's industrialization to colonized areas, and champions of imperialist expansion reasoned that these wonders could not help but impress subjugated peoples with the unprecedented degree to which European societies had advanced over their own. Not only did European superiority in science and technology seem obvious, but also it could be empirically tested in ways that claims of higher religious understanding or moral probity could not. Europeans had vastly more firepower, could produce incomparably greater quantities of goods much more rapidly, and could move both these products and themselves about the globe with much greater speed and comfort than any other people, including the once highly touted Chinese. In an age when what were held to be scientific proofs were authoritative, attainments that could be measured statistically were viewed as the most reliable gauges of human ability and social development. Mechanical principles and mathematical propositions could be tested; cast iron or steel bridge spans could be compared for size and strength with the stone or wooden structures of non-Western societies; and human skulls could be quantified in seemingly infinite ways to assess the highly variable mental capacity of the "races of man."

The preeminence gained in the nineteenth century by scientific and technological standards of human worth and ability not only bolstered proponents of theories of European racial supremacy, but it also proved vital to various formulations of the civilizing mission ideology that both inspired and rationalized European imperialist expansion from the early 1800s to 1914. Chauvinistic politicians in the metropoles and imperial proconsuls in the colonies increasingly stressed the importance of the diffusion of Western science and technology to what they viewed as the benighted peoples and backward lands that had come under European control. Proponents of the civilizing mission confidently predicted that the world would be remade in the image of industrializing Europe. Given Europe's material advancement, it was seen as appropriate that Europe and North America serve as the sources of capital, both machine and financial; of entrepreneurial, scientific, and managerial expertise; and of manufactured goods for the rest of the globe. In this view, the non-Western world, including both areas that had been formally colonized and those that had come under the informal sway of the Great Powers, were best suited to provide abundant and cheap land, labor, and raw materials that were required to fuel the industrial economies of Europe and North America.

According to the "improvers" or nonracist advocates of the civilizing mission, the spread of Western education among colonized peoples – emphasizing the inculcation of at least rudimentary Western scientific learning and technological skills – would provide the critical means by which the material level of non-Western societies would gradually be raised. Though they approved of the diffusion of essential Western technology to overseas areas under the paternalist supervision of European colonizers, racist apologists for imperialism had little faith in the ability of subjugated peoples to master the sciences or engineering of the West. Thus, they envisioned the period of European "tutelage" extending for centuries, if not indefinitely, into the future.

The non-Western peoples who were the targets of the European colonial enterprise were very often awed and overwhelmed by their initial encounters with the science and technology of the industrializing West. Whether they were indigenous leaders resisting the growing encroachments of European forces or scribes and merchants who allied themselves with the invaders, the colonized could not help but be impressed with the clear and increasing advantages in power that the Europeans gained through their superior capacity to tap the resources of the natural world, to produce material goods, and to devise more deadly weapons. As surveys taken as late as the post-World War II era, such as those which form the basis for G. Jahoda's *White Man*, the science and technology of the colonizers gave them an aura of magical power among the colonized masses in many areas. Though Western-educated Africans, Asians, or Polynesians were likely to scoff at such expressions of popular admiration, most came to accept that Western science and technology were not only on the whole superior to their own but essential for the future "development" of societies they hoped someday to rule. Therefore, nationalist critiques of imperial domination often deplored the fact that colonialism had severely constricted the flow of science and technology from the West to dominated areas, and demanded that technical education and scientific facilities for indigenous peoples be expanded and improved.

By the last decades of the nineteenth century, however, a number of influential African, Asian, and Caribbean thinkers were mounting cogent challenges both to notions of European racial superiority based on evidence of scientific and technological achievement and to the advisability of the wholesale transformation of non-Western cultures and societies along Western, industrial lines. Much of this resistance to the hegemonic ideologies of the Western colonizers focused on efforts to reassert and revitalize indigenous epistemologies, modes of social organization, and approaches to the natural world. Thinkers such as Vivekananda and Aurobindo Ghosh contrasted an Indian spiritualism with the deadening abstractions of Western materialism. African writers, such as the Caribbean-born Edward Blyden, deplored the devastating impact of the Atlantic slave trade on African cultures and celebrated the Africans' strong sense of community, reverence for and care of the elderly, and sophisticated artistic creations.

Ironically, these defenses of colonized cultures were buttressed by contemporary European anthropological studies, usually carried out under the auspices of colonial administrations; by the intense interest in "Oriental" religions fashionable among European intellectuals in the decades before World War I; and by the "discovery" of the abstract power of African masks and other forms of "primitive" artistic expression by Picasso, Derain, Matisse, and other avant-garde artists in the early 1900s. Inadvertently, however, the works of these first generations of Indian and African critics of European hegemonic ideologies often validated the very materialistic standards they sought to contest. For example, Indian thinkers, particularly Vivekananda, repeatedly stressed the scientific accomplishments of India's ancient civilizations, while African and West Indian writers, most notably Anetor Firmin, claimed Egypt, with its impressive engineering and architectural feats, as a civilization that black Africans had done much to build.

With the coming of the First World War, non-Western critics of what had been characterized as the excessively rationalistic, impersonal, and materialistic West found numerous, and highly vocal, European intellectual allies. The horrific trench slaughter on the Western Front and the multitude of ways that Western scientific knowledge and experimentation were harnessed to the war effort as a whole raised profound doubts for noted thinkers, such as Paul Valery, Sigmund Freud, and Georges Duhamel, about the long-assumed progressive nature of Western science and technology.

After such a savage and suicidal war, the tenets of the civilizing mission rang hollow, and "scientific" racist thought came under increasing assault in both western Europe and the United States. Collaboration with indigenous elites was increasingly stressed in the governance of the colonies, and a rhetoric of science and technology as agents of development through cooperation with indigenous peoples permeated colonial policy making.

European doubts about the directions taken by the industrial West and its global hegemony gave new impetus to African, Asian, and Caribbean critiques of European global hegemony. René Maran's *Prix Goncourt*-winning novel, *Batouala*, mocked the pretensions of racial superiority held by European colonizers, and idealized village life in French West Africa. The poets of the *négritude* movement, most powerfully L. S. Senghor and Aimé Césaire, mourned the suffering and destruction wrought by European science and technology in Africa and the lands of the slave diaspora, and inverted racist epithets by exulting blackness, intuition, affinity for the natural world, and indifference to inventiveness. Aurobindo Ghosh and Rabindranath Tagore viewed the war as the fulfillment of earlier Indian prophecies of a coming cataclysm in the aggressive and materialist West, and proof of importance of India's spiritual mission in the modern age. Mohandas Gandhi also cited the senseless violence and colossal destructiveness of the war in support of his sweeping assaults on industrial society. In the decades after the war, he sought to formulate for India (and implicitly for other colonized areas) a community-centered, low tech, and conservationist alternative to industrialized society as it had developed in the West. In this same period, Gandhi also worked out a strategy for confrontational but nonviolent protest that repeatedly proved an effective antidote to the advanced technologies of repression employed by Western overlords in the decades of decolonization from the 1920s onward.

Though battered and under assault, the scientific and technological underpinnings of ideologies of Western dominance survived the crisis of two global wars and the powerful critiques of Gandhi and the *négritude* writers largely due to the emergence of the United States as *the* global power from the 1920s onward. Entering the First World War late and just when new technologies had restored a war of motion and decision, Americans continued their long-standing infatuation with science and technology after the conflict. Faith in the essentially progressive nature and beneficence of science and technology informed the development (later called *modernization*) theory that came to dominate both American thinking on colonial issues and that of the European and Japanese imperialist rivals of the United States. After World War II, America's chief rival, the Soviet Union, also championed a rhetoric of development that privileged science and large-scale industrialization. With modernization theory (in a number of capitalist and socialist versions) in the ascendant, non-Western alternatives to social development and economic well-being, such as that formulated by Mohandas Gandhi, were marginalized or openly spurned by the Western-educated elites that governed the new states that emerged from the collapsing colonial empires. Though alternative approaches have gained significant support in some of these new nations, most notably India and Tanzania, international agencies and Western and non-Western planners continue to rely upon modernization schemes, based overwhelmingly on Western precedents, to solve the problems of poverty and growing wealth differentials and the demographic and environmental dilemmas that have been building on a global basis for centuries.

Windpower

Richard L. Hills

There is little doubt that the first practical use of the wind as an energy source other than as the motive power for sailing ships occurred in the East. Those of Persia were probably the first but precisely when is uncertain. According to a story of al-Ṭabarī, writing around AD 850, and later writers, the second orthodox Caliph, Umar ibn al-Khaṭṭāb, was murdered in AD 644 by a captured Persian technician, Abū Lu'lu'a, who claimed to be able to construct mills driven by the power of the wind and was bitter about the taxes he had to pay. This early date cannot be confirmed but Arabic geographers of the tenth century all confirm the existence of windmills in the region of Seistan in north eastern Iran. For example, al-Masᶜūdī around AD 950 wrote of the wind driving mills and raising water from streams.

Nothing has survived to show how such mills pumped water but later drawings of one type of windmill suggest that it could have been derived from horizontal corn-grinding watermills. In the lower part of such watermills, the water fell down a chute and struck blades placed radially around a vertical shaft. The top of the shaft passed into a higher room and carried the upper millstone and so rotated it above the bedstone which was set on a floor in the middle of the mill. When developed into a windmill, the wind rotor was situated in the bottom of the mill. The building was constructed with four "loop holes" to direct the wind on to the blades from whichever quarter the wind might be coming. There might be eight or ten blades, and the wind was directed by the loop holes onto one side of the rotor. In this way the sails were pushed round on that side away from the direction of the wind while those advancing into the wind on the other side were shielded by the walls around the loop holes. The grinding stones were placed in an upper room with the upper stone turned by an extension of the rotor shaft in the "underdrift" manner. None of these mills has survived.

The type which may still be in use today had the grinding stones situated in a room below the rotor with the sails above. This necessitated a change to the "overdrift" method of driving the stones where the spindle passed down through the bedstone to a bearing underneath, which had to support the weight of both the upper stone and the sails. It was possible to disconnect the driving shaft at the place where it was connected to the upper stone at the "rynd" to allow for the stones being separated for dressing. The layout for grinding was similar to other corn mills with a hopper mounted on the wall from which the grain was fed into the central hole of the upper stone through a chute or shoe while the flour was passed out around the circumference of the stones.

The advantage of this second layout was that the rotors with the sails could be greatly enlarged. Mills near Seistan and on the borders of Iran and Afghanistan might have rotors approximately 5 m (16.4 ft) high by 3 m (9.8 ft) in diameter. There could be six or eight sails which had wooden framing that was interlaced with straw or covered with wooden boards. The upper parts of these mills were built with one wall that directed the wind on to one side of the rotor while another wall shielded the other half. Sometimes matting screens were erected to help channel the winds to the sails. There were no brakes, but more screens might be placed across the slots between the walls to regulate the wind reaching the sails; to secure the mill when out of use, the rotor and upper millstone were lowered to rest on the bedstone. A wind speed of 22.40 m s^{-1} (50 mph) was needed to drive these mills at only 30 rpm. Such a mill, working with intermittent wind for about four months of the year, would grind enough flour for about 15 families. Seistan was known as the land of the winds and between mid-June to mid-October the wind regularly blew from the north for a period of 120 days.

The mills were built in line to face these winds and the famous example at Neh had a long row of 75 mills.

Because these horizontal mills needed such strong and regular winds to power them, they did not spread in this form much beyond the borders of Iran and Afghanistan. They were invented earlier than the Western vertical type but it is doubtful whether there is any connection between the two. Those in the West, which have been described as the “full admission, axial flow type,” first appeared around AD 1150 possibly either in the southeast of England, the northwest of France, or Flanders. However these Persian mills were probably the source of the later Chinese mills and possibly the Tibetan wind-powered prayer wheels.

The wind-powered Tibetan prayer wheels were not surrounded by elaborate buildings to guide the wind onto the rotors. The most common form had a vertical axle with horizontal spokes at its top, on the ends of which were fixed sails shaped like cups so that they caught the wind on one side of the rotor, but were smoothed or curved to present less resistance on the other. The wind would be caught in the concave part of the cup, or a curved sheet, during half the circle to turn the rotor, while in the other half, the convex or streamlined side would be advancing into the wind and so present less resistance. Power output was minimal but was sufficient to turn the prayer wheels which was the only use to which they were applied.

Prayer cylinders designed for automatic repetition of the Buddhist mantra are unlikely to have been produced before the reign of K’ri-srong-Ide-brtsan in AD 755 to 797 when Buddhism conquered Tibet. It is unlikely that such cylinders were turned by the wind at this period, although no doubt there were prayer flags fluttering in the wind from around this time. Early in the twelfth century, a new fashion for mechanical piety swept China, but again it seems doubtful whether this included wind-powered prayer wheels, which must therefore be placed later, and certainly therefore after the Persian mills.

More is known about the adoption of the windmill in China. Once again early dates for this have been suggested, but these are doubtful. In about AD 1230, Yelu Chu Zai was captured by Jinghi Khan and became his minister. He was an extremely good scholar, administrator and mathematician. An accurate description of the Persian windmill has been discovered in his memoirs, with a comment on how good it would be if the Chinese used it. A Chinese book of the seventeenth century, the *Zhu Qi Tu Shu*, describes the windmill as if it were a European invention, which could be a mistake for Persia. In China, these mills were used for raising water and evolved into an entirely different form from the ones in Persia or Tibet.

Chinese horizontal windmills are still used today along the eastern sea coast north of the Yangtze and in the region of Thangku and Taku near Tientsin to operate chain pumps through gearing for raising salt water for salt pans or fresh water for irrigation. Once again they have no elaborate structures for directing the wind onto the rotors but are closely linked to the way the sails of junks operate. Canvas-covered sails are mounted at the ends of radial arms, each with its own mast, in such a way that they can be spread to catch the wind on the side of the rotor turning away from the wind and be feathered to present the least resistance on the side turning against the wind. The sails can pivot on these masts, and, as on a junk, the sail extends to the front of the mast. The longer, or driving, side of the sail is tied to the rotor framework by a piece of rope of such a length that, when the sail is turning with the wind, it is held into the wind, but can rotate out of the wind when advancing against the wind. The angle of the sail can be set by the length of rope to a position in which the wind can do useful work on it for more than 180°.

These mills must have been the most efficient of the horizontal types developed before the twentieth century, but all horizontal windmills suffer from the same problem, that only a small part of the wind rotor can be used to its maximum efficiency at any time. The theoretical maximum power coefficient for a simple horizontal windmill is only one third, but in practice it will be much less. These are the reasons why the horizontal windmill has not been developed further and few examples remain at work today.

In the eastern Mediterranean, at some period during the Middle Ages, vertical windmills appeared with a different type of sails from those normally used in the West. The horizontal wind shaft was extended in front of the mill like a ship’s bowsprit so that ropes from it could help to stay six or eight radiating spars. The sails were triangular pieces of canvas like the sails of a modern yacht and worked in the same way. The leading edge of each sail was attached to the spar, round which it could be wrapped to reef it in strong winds. The free corner was secured by a rope in much the same way as a ship’s boom. These sails were much lighter than those of a conventional western windmill and have found a new application in water pumping mills in some developing countries today.

Wine in Anatolia

Alexia Smith

The quest for the earliest evidence of viniculture has led many scholars to Transcaucasia and Anatolia, the latter of which spans the Asian portion of modern-day Turkey and derives its name from the Greek for "Land of the Rising Sun". It is not known precisely when viniculture (the cultivation of grapes for wine) or viticulture (cultivation of the vine) as were first practiced, but both were well established in Southwest Asia by the beginning of the third millennium BCE. Several lines of evidence have provided insight into early wine production, including textual accounts, archaeological data such as drinking vessels, chemical analyses of residues within vessels, and ancient plant (archaeobotanical) data, as well as modern biogeographical observations.

The modern distribution of wild grapes is useful for demarcating the area within which grape domestication could have occurred in the past. Today, wild grape (*Vitis vinifera* L. subsp. *sylvestris* [C.C. Gmelin] Berger), is found as a forest climber along the coastal regions of central and southern Europe, areas surrounding the Black Sea, and the southern reaches of the Caspian Sea, with isolated patches growing in Turkmenistan and Tadzhikistan. Anatolia clearly falls within this natural range.

Archaeobotanical remains provide more detailed information. (See Agriculture: Ancient Methods of Agriculture by Alexia Smith in this volume for a more detailed description of archaeobotanical remains and their recovery.) In general, wild berries are smaller and more acidic than their domesticated counterparts. While entire grape berries can be found, archaeobotanists most typically encounter charred pips which tend to become shorter and rounder following domestication. In practice, however, distinguishing between wild and domesticated grape pips is challenging, since considerable overlap in their shape and size exists. Consequently, determining the precise point in time when grapes became domesticated is difficult. What is clear from the archaeobotanical record is that wild grapes have been collected for millennia to be eaten fresh or dried. Fermentation of grapes into wine requires fruit with a minimum sugar content of 10% and the presence of the principal wine yeast, *Saccharomyces cerevisiae,* which naturally occurs on grape skins. Experiments with wine making may have taken place as early as the Neolithic period (ca. 10,500–5500 BCE), well before viticulture developed as a specialized venture. Some of the earliest grape finds come from Öküzini Cave in southwest Anatolia, and date to the Late Palaeolithic (16,000–10,500 BCE). Grapes also appear consistently during the Neolithic and Chalcolithic (5500–3000 BCE) periods at sites such as Can Hasan III, Çayönü, and Korucutepe. From the Chalcolithic to the Early Bronze Age (ca. 3000–2000 BCE), a rapid increase in the presence of grapes at sites such as Kurban Höyük in southern Anatolia reflects the growth of viniculture.

Changes in the range of Early Bronze Age pottery vessels are also linked with an intensification or expansion of viniculture. At this time chalices and other forms associated with drinking such as the *depas amphikypellon* (a tall, narrow, two-handled tankard) began to increase in number. Other drinking vessels associated with wine include *rhyta* (sing. *rhyton*), which were fashioned out of metal or ceramics in the form of an animal's head. Storage vessels include amphorae[1] and large pithoi[2]. At sites such as Boğazköy and Alişar Höyük, containers fashioned after a cluster of grapes have been found. The association of vessels with wine can be affirmed using infrared spectroscopy through the detection of tartaric acid, a compound that occurs naturally in grapes and forms the primary acid within wine. Tartaric acid was detected in a large ceramic tub found in Early Bronze Age levels at Titriş Höyük in southeastern Anatolia, linking it with activities such as grape pressing.

Early texts written in Assyrian dating to the Old Assyrian Colony Age (ca. 2000–1750 BCE, corresponding with the Middle Bronze Age) and the Hittite period (ca. 1600–1200 BCE, Late Bronze Age) have been synthesized by Ronald Gorny and provide additional insights into early wine production. Texts from Cappadocian trading colonies refer to the months of September and October as *qitip karānim,* the "harvesting of grapes" season. Grape harvesting festivals are also mentioned in Hittite texts (EZEN ^{GIŠ}GEŠTIN *túh-šu-u-wa-aš*). In Hittite, grapes or grapevines were called *wiyana* (which features in the etymology of the word "wine") and are represented in texts with the Sumerogram ^{GIŠ}GEŠTIN. The official position of "GAL.GEŠTIN" is mentioned in the *Palace Chronicle,* an Old Hittite text that documents the court during the reigns of Hattušili I and Muršili I. The early responsibilities of GAL.GEšTIN included supervision of vineyards and their products, which underscores the importance of vineyards as an elite enterprise. Since the majority of the texts document political, economic, and

[1] An amphora is a jar, usually made of clay, with a narrow neck and two handles, used by ancient Greeks and Romans for holding oil or wine.

[2] Pithoi were large ceramic storage jars, mainly used for storing agricultural produce such as olive oil, wine, olives, raisins or grain. Such large jars must have been made in several sections and joined together before firing.

religious matters, bias in the records exists, and little is known about grape production or wine consumption among the general populace. It seems fair to link early viniculture with the elite, however. Since grape vines require a number of years to become established and yield fruits, only people of means could make such a commitment outside of a garden setting. Alexander Joffe even argues that production of alcoholic beverages may be linked to the rise of the state by allowing emerging elites to increase their level of power through surplus production and control over craft production.

A number of Hittite laws pertaining to viniculture bear testimony to well established practices and likely reflect concerns of earlier time periods. The laws clearly outline relative worth of various commodities and assign appropriate penalties for theft or damages to property. Damage to a vineyard is covered by Law 113, whereby the guilty party must take the damaged grapes and provide grapes from their own vines. Penalties for theft are discussed in Law 101 and combine monetary compensation with corporal punishment involving a spear. Over time corporal punishment was stricken from the law and the fine increased from one shekel per vine to six shekels for a free individual and three shekels for a slave. One Hittite shekel is roughly equivalent to 12.5g of silver and could purchase 2 *parīsu* of wine, 3 *parīsu* of emmer wheat, 6 *parīsu* of barley, or 160 shekels of copper. Each *parīsu* is believed to correspond with 30 liters.

While wine was undoubtedly valued as a pleasing beverage, its earliest uses were restricted to Hittite rituals, festivals, and religious ceremonies, which in general were conducted to gain favor of the gods with respect to the particular issue or problem at hand. Offerings of wine to the gods are mentioned in several Hittite prayers, including the *Prayer to Tešub of Kummani,* the *Prayer to the Sungoddess of the Underworld,* and the *Prayer of Muwatalli to the Stormgod Piḫašašši*. A number of myths, such as the *Ašertu Myth* and the Myth of the Serpent Illuyanka, discuss the inebriating power of wine and the potential dangers of becoming intoxicated. The cleansing nature of wine is stressed in several medical rituals, and similarly in rituals intended to purify land and prepare ground for the founding of a new palace. Soldiers also used wine as a metaphor for blood during an oath pledging ritual intended to secure their loyalty.

The association of wine with ritual and religious beliefs perpetuated for some time. During the Lydian period (687–546 BCE) in western Anatolia, Bacchus was celebrated as the god of wine. During Byzantine times in the early part of the first millennium A.D., wine was believed to be blessed by the sky-god; vineyards and stored wine afforded protection from evil spirits. Wine production decreased significantly following the conversion of Anatolia to Islam, although wine has continually been drunk. Today wine production is increasing again and grapes are widely cultivated in many parts of Turkey, including the Mediterranean coast and Central Anatolia.

Winemaking and Viticulture in the Ancient Near East and Egypt

Virginia Badler

In the ancient Near East and Egypt the development of winemaking and viticulture has a discontinuous record due to the nature of both historical and archaeological evidence. Historical records include texts and pictorial evidence illustrating grapes, grape vines, wine production, and wine consumption. Tracing winemaking and viticulture to its more distant origins in prehistory is now possible through careful archaeological investigations and scientific and chemical analyses. A significant step toward understanding how scant prehistoric evidence could contribute to reconstructing the presence and manufacture of such a specific, delicate and liquid substance as wine emerged with the observation of stains on the interiors of certain pottery jars and the subsequent chemical analysis and identification of key components of these residues. Badler et al. (1990) pioneered chemical residue analysis (the identification of tartaric acid as a marker for grapes and wine) coupled with archaeological evidence to establish new data points in ancient winemaking history. Guasch-Jané et al. (2004) have further differentiated red from white wine by the presence of malvindin-glucoside and its unique by-product, syringic acid.

Prehistoric Wine and Ancient Viticulture

Because of extensive cultivation, crossbreeding, seed dispersion, and deliberate transplantation, it is difficult to determine by grape genetics alone the geographic origins of winemaking and viticulture. Probably they are located in the general area of the wild Eurasian grapevine (*Vitis vinifera sylvestris*) that presently grows from Spain to Lebanon, inland along the Danube and Rhine Rivers, around the Black Sea and southern Caspian Sea, at the headwaters of the Tigris and Euphrates Rivers, and farther east in Central Asia (McGovern 2003: 7). Winemaking preceded viticulture, as grape cultivation is not necessary to make wine – it can be made from the wild grapes that were plentiful in certain areas of the Near East. The development of winemaking could have followed a similar path as that of breadmaking and the cultivation of grains. The motivation for both grape and grain cultivation would have been to provide convenient local sources and a stable supply of raw materials for the end products. Viticulture, the purposeful cultivation of grape vines, would have also provided the opportunity to exercise more control over both grape quality and quantity. If there were no wild grapes in the area, a taste for wine imported from other regions would motivate the transplantation of grape vines to secure a local supply of the beverage.

If burnt or carbonized, grape pips (seeds) can be preserved for many centuries. However, it is difficult to determine whether these ancient grape pips are from wild or cultivated grapes, due to variations in the pips themselves and the shape changes that occur when they are carbonized. Carbonized grape pips have been found in many areas of the Near East and Egypt, dating to 3000 BCE or earlier: Susa and Hajji Firuz Tepe in Iran; Hama, Mureybit, Abu Hureyra, Aswad, Jawa, Tell esh-Shuna, Ohalo, Jericho, "En Besor and Bab edh-Dhra" in the Syro-Palestinian area; and Buto, Minshat Abu Omar, Tell Ibrahim Awad and Abydos in Egypt (McGovern 2003: 2, Map 2). Many of these areas (Egypt, most of the Syro-Palestinian region, and southern Iran) are now too arid to support the wild grape.

Neolithic Wine ca. 5400–5000 BCE: Hajji Firuz Tepe, Iran (►http://www.museum.upenn.edu/new/exhibits/online_exhibits/wine/wineneolithic.html)

Viticulture was likely first established in the Neolithic period (from about 8000 to 4000 BCE), when for the first time in human prehistory there were numerous sedentary villages established in the Near East and Egypt supported by domesticated plants (such as grains) and animals (such as sheep and goats). Fired ceramic vessels first made their appearance ca. 6000 BCE, and it is within these vessels that we can find chemical evidence for the earliest wine.

Hajji Firuz Tepe is located southwest of Lake Urmia in northern Iran, in the Zagros Mountains at an elevation of over 1,200 m above sea level, along the eastern periphery of the wild grapevine's modern distribution. Jars with yellowish and reddish interior residues have been analyzed, and both residues are that of resinated wine. The resin was from the terebinth tree (*Pistacia atlantica*) that grows throughout the Middle East and would have been added as a preservative (McGovern et al. 1996).

Late Chalcolithic Wine ca. 3500–2900 BCE: Godin Tepe, Iran

The chemical analysis of residues in jars from Godin Tepe established that the technique could be used to determine the existence of wine in prehistoric contexts (Badler et al. 1990; Badler 1995). Wine was found in a distinctive jar type (piriform, with rope decoration in an inverted U shape on opposite sides of the vessel) from two different contexts dating from 3500–3100 BCE and 3100–2900 BCE. The complete vessel from

W

the later period has a bung hole a short distance from the base drilled after firing, presumably to decant the beverage.

The homeland of viticulture may be Transcaucasia (the region of modern Georgia, Armenia, and Azerbaiijan located between the Black Sea and the Caspian Sea). An early sixth-millennium BCE Shulaveris-Gora jar was shown to have contained resinated wine, making it the earliest known wine jar (McGovern 2003: 75). At Godin Tepe there is an intriguing link between winemaking and the appearance of the first Transcaucasian type pottery. The earliest sherd with wine residue dates from 3500–3100 BCE, when there are significant numbers of Late Uruk type artifacts suggesting contact with sites in southern Iraq (such as Nippur and Warka/Uruk) and Iran (Susa). However, the earliest evidence for wine production (a funnel, heavy lid and empty wine jars, as well as a bin perhaps used for treading grapes) date from 3100–2900 BCE, when there is a marked increase in the number of Transcaucasian type sherds. In fact, the funnel itself is similar to the Transcaucasian sherds in its method of manufacture (handmade and fired in a reduction atmosphere), and the heavy lid is a Transcaucasian pottery type.

Late Uruk Wine ca. 3500–3100 BCE – Susa, Iran and Warka/Uruk and Tello/Girsu, Iraq

The residues of ancient resinated wine have been detected in Late Uruk type jars (a droop spouted jar, a piriform jar, and a stone vessel with vertical rope decoration) from Susa in southern Iran (McGovern et al. 1997), a droop spouted jar from Warka/Uruk (Badler et al. 1996), and a droop spouted jar from Tello/Girsu in southern Iraq (McGovern et al. 1997). Since grapes will not grow in the hot dry climate of southern Iraq (there are no grape remains from this area), the wine was most likely an import from further north, and perhaps an important commodity in the Late Uruk trade network (Algaze 1995).

The Early History of Wine in Syro-Palestine and Egypt

Whereas the Near East looked north to Transcaucasia for the introduction of wine and winemaking, archaeological and clay pottery jar composition evidence clearly suggests that the origins of Egyptian wine and winemaking were to its east from the Levant: modern Israel, Palestine, and Jordan (McGovern 2003: 85–103). Hundreds of jars containing chemically attested wine and wine yeasts were found in tomb U-j of the first Scorpion king (Dynasty 0) dated by radiocarbon determination to ca. 3150 BCE. The closest stylistic parallels to these jars are from Early Bronze I sites in the Levant, later confirmed by additional scientific analyses. Although the wild grapevine does not grow there today, it flourished in the region in ancient times, beginning in the Epi-Paleolithic period nearly 20,000 years ago (McGovern 2003: 212). By at least 3500 BCE, the domesticated grapevine (*Vitis vinifera vinifera*) had taken hold in the region. Very little archaeological or chemical evidence for winemaking has been found so far, although small spouted Iron Age vats could have been used to tread the grapes.

Although there was a royal winemaking industry in the Nile Delta region from as early as Dynasty 3 (ca. 2700 BCE), the wild grape never grew in ancient Egypt. It seems most likely that both the grape vines and the technology for making wine were imported from the Levant. The earliest "wine labels" in the world belong to Dynasties 1 and 2 of the Early Dynastic period (ca. 3100 – 2700 BCE), and show an already well developed viticulture tradition (McGovern 2003: 85ff.).

Once local viticulture and winemaking were established in the Nile Delta, it became a source for royal wine. When there were disruptions, however, such as the Hyksos invasion (ca. 1670–1550 BCE), wine was again imported in large quantities from the Levant and, in particular, Southern Palestine. Exceptionally large quantities of wine were imported into the Hyksos capital of Tell el-Dab'a/Avaris located in the east Delta region of Egypt. The Egyptian winemaking industry rebounded (as evidenced by increasing quantities of native Egyptian wine jars) beginning in the earliest Middle Bronze IIA phases (ca. 1950 BCE) at Avaris. There is evidence that the Egyptian Delta supplied the New Kingdom towns and cities at that time. Avaris also has the only excavated winemaking installation in Egypt, predating Hellenistic times (McGovern 2003: 119). Detailed tomb paintings provide additional evidence for the Egyptian wine industry, from picking and crushing the grapes to filling the jars (the tomb of Nakht at Thebes [1550–1295 BCE]), the addition of additives and stoppering (the tomb of Khaemweset, son of Ramesses II [1279–1213 BCE], at Thebes), and a sequence of grape picking, crushing, pressing, and wine storage (tomb of Intef, Royal Herald under Thutmosis III [1479–1425 BCE], also at Thebes). Chemical analysis of the residues in the wine jars from the tomb of Tutankhamun (d.1327 BCE) established that this wine was made from red grapes (Guasch-Jané et al. 2004).

Wine in the Ancient Near East

There are chemically identified ancient resinated wine residues in a small jar from Warka/Uruk dating to the late Jemdet Nasr/early Early Dynastic period (beginning of the third millennium BCE; McGovern et al.

1997). In the early third millennium BCE, there are grape pips and even grapevine wood identified from the site of Tepe Malyan (ancient Anshan) in the Shiraz region of the southern Zagros mountains (McGovern 2003: 165). Elamite seals depict drinking scenes (most likely of wine) under grape arbors (McGovern 2003: 165–166). Texts from the city of Ur mention a jar full of *geštin* (the Sumerian word for wine). At Tello/Girsu, *geštin* was stored in rooms, and *geštin* was imported from the eastern (presumably the southern Zagros) mountains. Texts mention grapevines growing within walled gardens in and around the region of the city of Tello/Girsu by the end of the third millennium BCE (McGovern 2003: 150). The law code of the Babylonian king Hammurapi, dating to ca. 1790 BCE, mentions wine shops. There are detailed accounts of the wine trade (with cities further north) in the archives of the Syrian city of Mari, located along the Middle Euphrates, and dated to ca. 1750 BCE when the city was destroyed by King Hammurapi, and in the archives of the eighteenth century BCE site of Tell al-Rimah/Karana'a in upper Mesopotamia (McGovern 2003: 169–173).

In the first millennium BCE, the Assyrian rulers not only consumed large quantities of wine, but also undertook an ambitious program of planting new vineyards in their territories. The "Assyrian Doomsday Book" recorded tens of thousands of vines planted in the upper Balikh River to the east of Carchemish, in the eastern part of their territory at Yaluna, probably northeast of Nineveh, and in the land of Zamua in the district of Sulaymanyah. The Assyrians produced wine described as sweet, good, aged, or strong, and in both red and white varieties. Additionally, some wines were spiked with other ingredients (McGovern 2003: 190–191). The Nimrud wine lists contain detailed accounts of the distribution of wine rations. In a wall relief of the palace at Nineveh, Assurbanipal and his wife are shown beneath a grapevine bower drinking what is probably wine, similar to the Elamite scene mentioned above. Chemical analysis of residues from a bronze drinking cup from Nineveh, a bronze goblet and pottery "beer jug" with built-in strainer spout, from Uruk (all from seventh to sixth century BCE tombs) tested positive for resinated wine (McGovern 2003: 201).

Woodcarving in Malay Architecture

Ismail Said

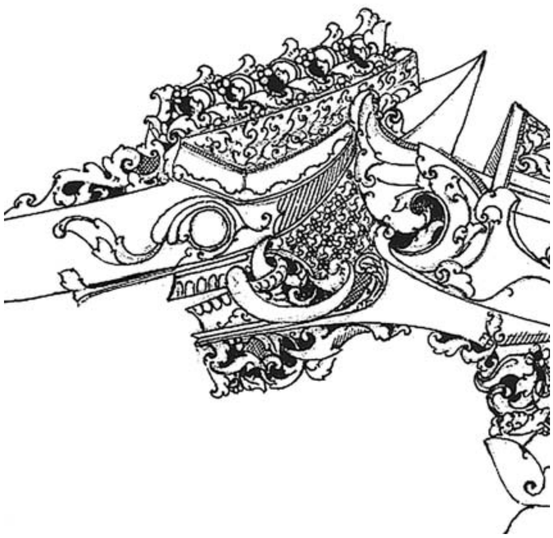
Meaning and Significance

Malay vernacular architecture is characterized by timber as the main building material, pitched roofs and woodcarving on some of the building components. As early as the fourteenth century, woodcarving was a significant craft in the vernacular architecture practiced by Malay craftsmen in Peninsular Malaysia and Southern Thailand (Ismail and Ahmad 2001). Palaces, houses, mosques, gateways, tombs, and *wakafs* (pavilions) are adorned with more than 20 types of carved components (Ismail 2002). The craft is an abstract manifestation of craftsmen's ideas into architectural timber components, symbolizing artistic expression into three architectural components: structural, elemental, and decorative (Ismail 2002). The craftsmen or woodcarvers depict five types of motifs, in order of importance: floral, geometric, calligraphy, fauna, and cosmic. These motifs are laid in six geometrical or floral shapes including oblong, square, circle, octagonal flora, semicircle and triangle. In definition, woodcarving is an art of partially removing wood from a board, a block or a plank following specific motifs, patterns, and orders. The art originated from two fronts: the kingdom of Langkasuka from the north, and the Srivijaya empire from the south of the peninsula (Nik Rashidin 1999; Nik Hassan and Nik Abdul Rahman 1998). In historical and geographical contexts, Malay timber architecture and carving in peninsular Malaysia stretches from the north in the province of Pattani in Southern Thailand to the south in the state of Johor.

Similar floral, geometric, fauna, and calligraphic motifs appear on nonarchitectural components such as boats, weapons, furniture, grave-markers (Fig. 1), house utensils, and musical instruments. The most elaborate carving on a boat is the *makara* carved in relief and perforated styles depicting mostly flora and sometimes figurine motifs. The hilts of kris (Fig. 2), *badek* (small dagger), and spears are some of the weapons that are intricately carved on timber such as *kemuning* (*Murraya paniculatum*), *leban* (*Vitex pubescens*), *sena* (*Pterocarpus indicus*), or *nibong* (*Oncosperma tigillarium*). The craftsmen also showed their ideas and skills on more than 15 types of furniture and house utensils.

In carving Malay craftsmen demonstrated high skills of art changing abstract ideas into physical beauty. This developed through a long apprenticeship whereby the skills and knowledge of woodcarving were passed on. By imitating a carved masterpiece, a woodcarver gradually modified the motifs and produced his own design onto the timber piece. For example, a motif of leaves and buds of *ketumbit* or *getamguri* (two shrubs) are gradually modified by the carvers to demonstrate their own stylish identity called *air-tangan*, but they keep the fundamental motif form (Nik Rashiddin 1999). This pattern becomes the trademark, both for the craver and

Woodcarving in Malay Architecture. Fig. 1 A grave marker (Nik Rashiddin 2003).



Woodcarving in Malay Architecture. Fig. 2 A kris hilt (Nik Rashiddin 2003).

for his architecture or craft. Differences in motifs, layouts and perforations occur from one region to another. For example, craftsmen in the northeastern states of Kelantan and Terengganu depicted different floral motifs from the central states of Negeri Sembilan and Melaka. The motifs of woodcarving signify the identity of the carvers in a region. In spite of the differences, Malay craftsmen observed three common aspects: (a) applying four principal design forms, (b) deducing motifs from home landscape elements, particularly flora and fauna, and (c) manifesting natural beauty as a devotional act to the Creator and as a gift to his fellow men (Mohd Taib 1997).

The degree of complexity in carving varies from one component to another; intricate, or complex ones include door leaves and wall panels, and simple carvings include gable board and fascia board. From the carving characteristics including motifs and types of perforation and incision, one could differentiate the architecture of one state from another. For example, a large gable board distinguishes a Terengganu house, whereas a large-latticed gable portrays a Perak house. As one gets closer to the carved components, the distinction is further distinguished by the composition of the motifs. The elevation of the Terengganu house is adorned with perforated wall and ventilation panels of varying sizes carved in floral motifs: leaves, tendrils, and flowers of local plants such as *ketumbit, getamguri, keraknasi, jari buaya,* and *bakawali* (Ismail 2000; Ismail and Ahmad 2001). The panels of Perak houses are carved in different floral motifs including sunflowers and *ketola*, sometimes mixed with cosmic motifs. These are regionally specific motifs found in Malay woodcarvings in Peninsular Malaysia. However, similarities occur in depicting geometrical motifs on veranda railings or tall window and fascia boards. Likewise, similar Arabic calligraphy motifs are depicted on door and window ventilation panels.

Architectural Components

Carved building components can be categorized into three types: structural, elemental and ornamental. The structural components include *pemeleh* (bargeboard), *tunjuk langit* (king post), cross beams, stringers of stairs and braces. The *pemeleh* is the most prominent component in palaces, aristocratic houses and mosques in the state of Terengganu and in Kelantan. These differentiate the vernacular architecture of this region from other states in peninsular Malaysia. For example, a palace known as tele house, built by Sultan Zainal Abidin in 1868 in the city of Kuala Terengganu, Terengganu, has two pairs of pemelehs, one at the *rumah ibu* (main building) and the other at the *rumah tengah* (subsidiary building). Likewise, Langgar Mosque in the city of Kota Bharu, Kelantan, also has two pairs of elegant pemelehs with a simple motif of barking deer on its three-tiered roof (Marsiti 1976). This exterior component handsomely extends the profile of the building toward the sky, making the mosque a landmark in the settlement.

The next important structural carved component in a house or a mosque is the *tunjuk langit* (kingpost). It supports the roof by holding the ridge beam and rafters. The Kampong Laut mosque in Kota Bharu has eight carved tunjuk langits (Zahar 1989). This timber mosque is perhaps the oldest timber mosque, perhaps 170 years old, in Peninsular Malaysia (Ismail 2001). The tunjuk langit distributes the roof load to the tie beams. The lower end usually is attached with a carved component called *buah buton*. This is an ornamental piece which covers the tenon and mortise joint of the *tunjuk langit* to the tie beam. In contrast, the Telok Manok mosque in Southern Thailand has three tunjuk langits, joining the three-tiered roof to the tie beam one above another (Ahmad 1998) (see Fig. 3). They are beautifully carved with lotus blossom motifs and their ends are equipped with *buah butons* using similar motifs. The tunjuk langits and buah butons greatly enhance the beauty of the interior. Apart from the tunjuk langit as a structural member distributing the roof load to the tie beams, braces, or brackets are also structural components supporting the tie beam load to the post. In the Kampong Laut mosque, braces are elaborately carved in shallow relief with lotus blossoms as centerpieces framed by leaves of a different plant in an intricate arabesque.

There are at least five carved elemental components in Malay houses and mosques. These are essential components that make up the entrances and fenestrations. They are the ventilation panels of doors or windows, door or window leaves, walls, railings and

W

gates. Ventilation panels characterize the architecture of a region. For example, the Tengku Long palace in Kuala Terengganu has 15 tall windows at its *rumah ibu*, the main house, with perforated ventilation panels (Fig. 4a,b). Each panel was designed with different floral motifs in symmetrical and asymmetrical layouts. They are part of the fenestration of the building, allowing air and light in. These perforated boards are placed on top of doors, windows, or walls allowing circulation of air and light into the building. More elaborate motifs, a combination of Quranic calligraphy bordered by floral motifs, are carved for interior door ventilation panels as can be seen in Fig. 5a.

Some ventilation panels are carved in simpler forms, as in the Telok Manok mosque (Fig. 6). A floral motif of a weed called *ketumbit* is abundantly carved on the ventilation panels which are located around the building and are placed above the walls, windows and doors. The carvings transformed tender leaves of *ketumbit* into an arabesque form both in relief and perforated styles. The perforations not only allow air to flow into the building but also permit light to illuminate the interior. This is often dark because the interior is covered by the pyramidal roof and also because of the dark hue of the timber walls and the underside of the roof. The late afternoon sun casts intricate shadows on the praying space when light passes through the carved panels. This phenomenon adds beauty to the interior setting of the mosque. At night, the scene would be reversed when light from lamps passes through the perforations casting a silhouette of the carved panels. The silhouettes of arabesque and geometric forms can be clearly seen from outside especially in the absence of light from other surrounding buildings. Therefore the perforated panels add to the characterization of the mosque architecture.

Inside a timber mosque, the *mimbar* (pulpit) demands the most appreciation from the congregation. It is a piece of liturgical furniture from which the *iman* delivers his sermon (Yacub Zaki 1978). The *mimbar* of Kampong Laut mosque is profusely decorated with perforated

a

b

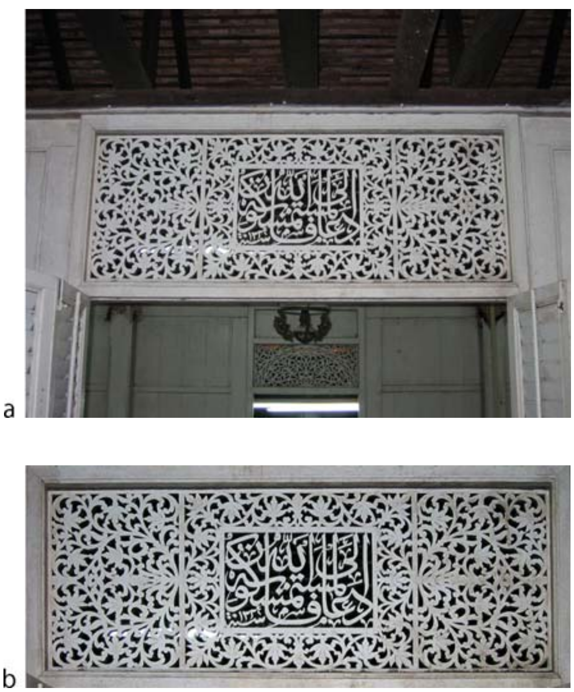
carvings of floral motifs. The most prominent panel is the front carved board attached to the canopy carved in *gunungan*, one of four principal forms. It resembles the form of the headdress worn by Malay women in the marriage ceremony. The side and back walls of the *mimbar* are fully furnished with perforated carved panels as part of the structural component of the four posts.

The gate is also an elemental component for vernacular Malay architecture; it demarcates the access to a palace or an aristocratic house. It is installed as part of the wall or fence in single or double-leaf doors. The leaf is generally carved in simple floral motifs with straight railings, as in the gate of Kota Lama Duyong, an aristocratic house built in 1920 in Kuala Terengganu (Mohd Hanif 1997). This house has five types of gate incorporated with a concrete wall surrounding the building. Big and double-leaf gates are meant for honored guests located at the front yard of the building compound (Fig. 7a). Smaller single or double-leaf gates are located near to the kitchen and deck leading to the rear of the house and are used by the residents and neighbors (Fig. 7b).



Woodcarving in Malay Architecture. Fig. 5 (a) A ventilation panel on top of an interior door of Tengku Long palace. (b) A panel with Quranic calligraphy and arabesque floral motifs.

The third type of carved components found in Malay vernacular houses and mosques are ornaments. *Som* and *buah buton* are ornaments that are carved and attached to the structural members of the building. *Som* is the decorative component located at the ridge end of the pyramidal roof (Fig. 8). Each roof tier has four *soms.* Langgar mosque has the largest and most elaborate *soms* on its first and second roof tiers. A pair of pemelehs accentuates the third tier roof. From a considerable distance the *soms* and *pemeleh* accentuate the profile of the mosque, giving it a distinctive vernacular style. Telok Manok mosque has the most *soms*; each ridge end and minaret roof is decorated with floral motif soms. Another ornament that gives character to the timber mosque is the *buah buton* – a decorative component attached to end of *tunjuk langit* jointing the tie beam or rafter to the tie beam. The attachment hides the tenon and mortise joint and is not a structural part of the building. Telok Manok Mosque has the most buah butons – 18 at the tie beams and three at the end of the *tunjuk langits*. All the carvings are in lotus blossom motif, but each differs in form, resembling the natural form of the flower that shrinks in the morning and gradually opens during the day (Fig. 9). The differences in form resulted from the interpretations of several craftsmen.

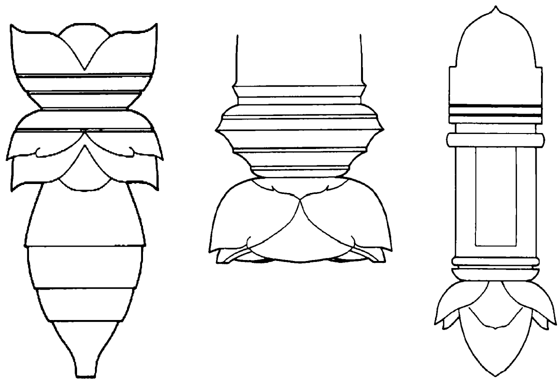
Types of Motif

Malay craftsmen applied five types of motif: floral, geometric, calligraphic, faunal, and cosmic onto the carved components. Flowers dominated Malay woodcarving; the carvers used the fruit, stems, tendrils, leaves, and of course the flower. Fruit of pomegranates, lotus flowers, sunflowers, *ketumbit*, *ketola* and *bakawali*, leaves of *getamguri*, and stems and tendrils of *ipomea* are depicted in a variety of abstract forms. The pomegranate is chosen as a motif because of its interesting shapes and bright orange flowers. The lotus is selected because of its auspicious status and sacredness. Furthermore, weeds such as ketumbit with bright yellow flowers and getamguri with wavy foliage are recognized by Malay craftsmen in Terengganu and

Woodcarving in Malay Architecture. Fig. 6 Floral motif on ventilation panels at the door and wall of Telok Manok mosque (KALAM, Universiti Teknologi Malaysia 1997).

Woodcarving in Malay Architecture. Fig. 7 (a) A gate at Kota Lama Duyong for residents and neighbors. (b) A larger gate at Kota Lama Duyong for honored guests.

Woodcarving in Malay Architecture. Fig. 8 Image of soms at Masjid Telok Manok (KALAM, Universiti Teknologi Malaysia 1997).



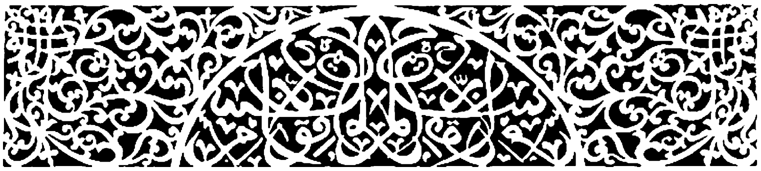
Woodcarving in Malay Architecture. Fig. 9 Lotus blossom motif on *buah butons* at Masjid Telok Manok (KALAM, Universiti Teknologi Malaysia 1998).

Woodcarving in Malay Architecture. Fig. 10 A ventilation panel of Kota Lama Duyong in Kuala Terengganu carved in floral motifs, getamguri and sulur kacang (KALAM, Universiti Teknologi Malaysia 1997).

Kelantan; they translated their beauty into the tangible art (Fig. 10). Craftsmen in Perak and Negeri Sembilan favored bright yellow flowers and the intertwining character of *ketola* and large, bright sunflowers on their door leaves and ventilation panels. Malay craftsmen observed the beauty of their surroundings and transferred their intangible value into a physical product that could be appreciated by others.

Fauna are rare in Malay woodcarving because Islam prohibits depicting figurine motifs. However, a few craftsmen still carved fauna motifs such as: (a) a pair of fighting cockerels on a window ventilation panel of a Negeri Sembilan house, (b) a group of ducks waddling in a row on a stringer of a Malacca house, and (c) a lizard head on a corner of a fascia board of a Perak house (Abdul Halim 1986). These motifs are generally carved in abstract forms, hiding the real figure of the fauna.

Calligraphy is also applied as a motif at wall and ventilation panels on Kelantan, Terengganu and Negeri Sembilan houses. It is either carved in relief, perforated or a combination of both. The Malay craftsmen put Quranic verses into wood panels written in several Arabic styles. An excellent example is a wall panel at a house in Kampung Pulau Panjang, Kelantan where a Quranic verse is carved in perforated form and laid symmetrically on an axis (Fig. 11).



Woodcarving in Malay Architecture. Fig. 11 A wall panel carved in traditional calligraphy motif at a house in Kampung Pulau Panjang, Kelantan.

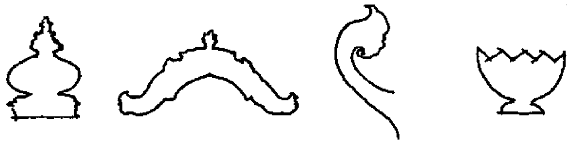
This carving demonstrated the craftsman's devotion to Islam and adoration of the *Quran*. The legacy of calligraphy in Malay letter writing has contributed woodcarving, which has selected it as one of its motifs (Syed Ahmad 1992).

In addition to arabesque motifs, Malay craftsmen also apply geometric motifs on door leaves, ventilation panels, wall panels, railings, and partitions. The configuration can be a series of diagonals repeatedly copied throughout the component. Swastikas and stars are more complex motifs that dominate the carving configurations, for example, on a ventilation panel of a wall. Repetition of similar motifs creates a sense of beauty and contrast against adjacent foliate or calligraphic motifs. The motif of the swastika, which originated from Chinese woodcarving, can be seen in ventilation panels of Kota Lama Duyong (Mohd Hanif 1997). Geometrical motifs are easier to carve than the other four types and thus repetitive components such as railings are done by apprentices or sometimes wives of the master craftsmen (Nik Rashiddin 1999).

The motif of the cosmos is seen the least in Malay woodcarving. The depiction of this motif in Malay carving illustrates the influence of Chinese craftsmanship and the pluralism of cultural values in vernacular architecture. A ventilation panel at Mohd Ali Kulup Mat Yassin's house in Perak is an example where leaf and flower are combined with a cloud.

Principal Forms and Shapes of Carved Components

In terms of iconography, Malay woodcarving depicts four principal forms including *stupa*, *makara*, lotus and *gunungan* (Fig. 12).



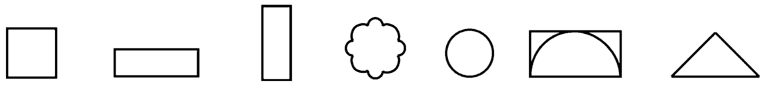
Woodcarving in Malay Architecture. Fig. 12 Principal forms of Malay woodcarving.

The stupa form can be found in house components such as buah buton or on the newel posts of stairs or gates. These are decorative components that enliven the interior of the building. Buah buton is attached to the end of the kingpost hiding the tenon and mortise joint to a tie beam of the roof structure. It is the only volumetric component that becomes the jewel of carving, beautifying the interior of the house. The *gunungan* is a silhouette of a mountain or tree of life, a symbol of status. The gateway of a house compound is carved in gunungan, but other components including the ventilation panel of the door or window and door leaf also used this form. The *makara* reflects the center of the cosmological imagination for a mythological sea monster in Pattani and Kelantan. Gable-end boards on Terengganu or Kelantan houses depicted the form of makara that enhanced the façade of the building. This component differentiates the form of the house in Terengganu and Kelantan over houses in Perak and Negeri Sembilan. The lotus is a symbol of purity, and its form is applied to a variety of house components, including door leaves, fascia boards, ventilation panels and buah butons. Apart from house components, the form is carved at the foot of tombstones and bases of kris hilts (see Farish and Khoo 2003).

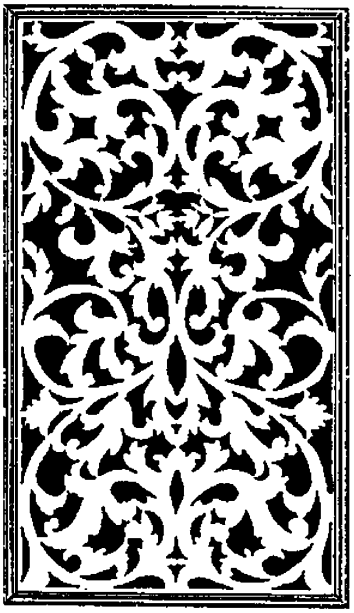
The carved components are designed in six geometrical or floral shapes including oblongs, squares, circles, octagonal flora, semicircles, and triangles (Fig. 13).

Squares and oblongs are common layouts for many components, particularly door leaves and ventilation and wall panels. They are easier to carve than flowers or circles since their outlines are straight. Ventilation panels on doors, windows, and walls of Terengganu and Kelantan houses are dominated by these perforated components in floral motifs. The layout and size of the components are proportionate with the elevation of the building and volume of its interior space. The house builder and craftsmen carved sufficient amounts of fenestration to allow cross ventilation to give thermal comfort to residents without depending on mechanical means (Ismail and Ahmad 2001).

Occasionally, a floral octagonal or circle layout is carved for special components such as the base of a ceiling lamp. Such carving can be found in aristocratic houses such as Kota Lama Duyong. The intricacy of the shape and carving denotes the skillfulness of the Malay craftsman and wealth of the house owner.



Woodcarving in Malay Architecture. Fig. 13 Shapes of carved components in the Malay houses.



Woodcarving in Malay Architecture. Fig. 14 A perforated, arabesque wall panel carved in a symmetrical layout with a vertical axis.

Apart from the shapes, the carvings are generally symmetrical on at least one axis. The axis orientates the carving pattern, repeating the pattern from left to right or from the top to the bottom of a component. Fig. 14 illustrates a perforated carving of a wall panel of Wan Embong house in Kuala Terengganu. Most ventilation panels, wall panels, door and window leaves, and flat railings are done in symmetrical formats with floral motifs.

Factors Influencing Timber Selection

Generally, Malay craftsmen would apply three factors in selecting appropriate timber for their carvings. The factors include availability of timber, its physical characteristics and durability, and the craftsmen's spiritual beliefs toward the timber species. The hierarchy of selection depends on the type of carved components. For example, the making of house components such as door leaves or ventilation panels is clearly determined by the availability of timber which could easily be obtained in large volume. On the other hand, the Malay craftsmen chose only kemuning or kenaung for making kris hilts and sheaths because of their fine interlocked grains and deep yellow sapwoods overlapping with dark brown heartwood. In addition, these timbers are regarded as possessing good spirit that must be respected and that will accompany the weapon (Faris and Khoo 2003; Ismail and Ahmad 2001).

Availability of Timber

Tropical rain forests of Peninsular Malaysia produce a variety of quality, durable timber grown in the low-lying undulating land and hills of the Main Range (Appanah 1993). Heavy hardwood species such as *chengal* (*Balanocrpus heimii*), *balau* (*Shorea spp.*), and *merbau* (*Intsia palembanica*) are the favorites. They are durable species that resist attacks from termites, powder-post beetles and fungi, which would harm their structural properties including flexibility, stiffness, and hardness. These are suitable for making large building components such as door leaves, barge-boards, kingposts, wall, and ventilation panels as well as small ones including railings and buah butons. The same timber species are used to make structural building components such as posts, beams, and floor-boards as well as the carved components. It is common to find an entire house made from chengal, balau, or merbau in the states of Terengganu, Kelantan, Perak, and Pahang in the peninsula. For example, a house at Kampong Bolok in Pahang built in the 1920s, was constructed wholly from merbau.

The timbers are air-dried under a shed or under the houses, allowing prevailing winds and the sun to dry them while protecting them from the rain. No preservative treatment is applied to the timber since the resins of most dipterocarps are able to resist the powder-post beetles, termites, and fungi attack (Farmers 1987). The drying (seasoning) process may take months or even years for some timber species particularly kemuning, kenaung, and sena.

Medium hardwoods from the forests such as *medang* (*Litsea grandis*), *kundang hutan* (*Bouea macrophylla*), and *keladan* (*Drybalanops oblongifolia*) are sometimes used for carving door leaves, furniture such as beds and cabinets, and musical instruments such as the *kenong* and *kompang*. These timbers are more prone to attacks from powder-post beetles and fungi and thus they are placed where they will not come into contact with moisture.

Craftsmen would optimize timber choice by harvesting readily available fruit trees grown in house compounds and orchards. They would cut large branches or sometimes the trunk of mature trees including *ciku* (*Achras zapota*), jackfruit (*Artocarpus heterophyllus*), *rambai* (*Baccaurea bracteata*), *belimbing* (*Averhorra belimbii*), *bacang* (*Mangifera foetida*), and *kundang* (*Bouea macrophylla*). Since these timber pieces are relatively small, the craftsmen would carve them into household tools and utensils and musical instruments in floral and geometrical relief motifs. The tools and utensils include coconut graters, ladles, food containers, biscuit moulds, and *rehal* (a cradle in which to place the *Quran* during readings). The practice of consuming timber from cultivated trees suggests that the Malay craftsmen were attentive to their environment.

Timbers for carving were also extracted from the secondary and coastal forests where mixtures of heavy, medium, and light hardwood species grow. *Leban* (*Vitex spp*.), a heavy hardwood, and *sena* (*Pterocarpus indicus*), a light hardwood, are the common species obtained from the secondary forest for making sheaths of badek or kris and for carving some utensils. The craftsmen living in coastal villages would harvest timber from *penaga laut* (*Calophyllum inophyllum*) and *kelat jambu laut* (*Syzygium grande*) from the beach forest. They were carved for boat paddles and grave markers. Malay craftsmen optimized the timber found within or adjacent to their environments.

Physical Characteristics and Durability

In woodcarving, the physical characteristics that govern the suitability of timber are durability, color, grain and texture, and luster. Before working on the timber, the craftsmen select a timber piece that is free from all defects, namely, knots, pith flecks, resin streaks, brittlehearts, checks and splits, decay, bowing and cupping (Nik Rashiddin 1999). Durability of hardwood is directly related to density; high density generally suggests strong resistance against fungi decay and boring insect attacks. Therefore, chengal, balau, resak, and merbau are the preferable species for most house components including structural, elemental, and decorative types (Watson 1928). Buildings made from these species are known to last for more than 150 years. Their resistance is possibly due to the silica deposits in their storage tissue (Desch 1981).

In some heavy hardwoods there is no color distinction between sapwood and heartwood, but usually the heartwood is more deeply colored (Desch 1981). On exposure to the air, chengal and balau are light brown to dark red-brown and become darker as they age. On the contrary, the merbau's sapwood is pale yellow sharply defined from the dark red-brown heartwood. Generally, the final finish of the carved timber components made from these heavy hardwoods is finished with sandpaper. In carving house components, the craftsmen is less critical about the timber color but very selective when carving weapon hilts and sheaths, furniture and musical instruments. Only kemuning and kenaung, with bright yellow sapwoods and dark brown heartwoods, are chosen for the hilts of kris, badek and *kerambit* (a small knife). These weapons are considered auspicious tools and used only for ceremonial events or special occasions.

Grain and texture are two distinct characteristics of timber. The grain refers to the direction of the fibers, and texture applies to the relative size and the amount of variation in the size of the cells (Desch 1981; Smith 1999). The chengal timber is easy to cut and incise because it has straight fibers and it does not give rise to ornamental figuring. It has a fine and even texture and is thus suitable for almost all carvings, from large features such as a boat's figurehead, to a building's wall panels, to small objects such as rehal. The merbau has a more interesting appearance than the chengal or balau since it has interlocked and sometimes wavy grain and a coarse texture with large vessels and coarse rays (Farmers 1987). But it is more difficult to incise since it is denser and has a higher hardness, thus it is used for large building components such as posts and seldom used for small crafts such as house utensils.

Lustrous woods such as merbau, kemuning, tempinis (*Sloetia sideroxylon*), and kenaung have cell walls that reflect light, particularly on quarter-sawn surfaces (Desch 1981). The luster is a natural asset that craftsmen exhibit in carved furniture and small crafts such as kris hilts, knife sheaths, walking sticks, and picture frames. The luster, however, does not last long without a finishing coat over the timber surface. Craftsmen apply several layers of shellac or varnish to a kris hilt to retain the lustrous surface of the kemuning.

Spirit of Wood

In addition to the tangible characteristics of the timber, Malay craftsmen also select timber based on its possessing either a beneficial or malignant value (Farish and Khoo 2003). Kemuning and kenaung are regarded as the most auspicious species because the craftsmen believe that they possess strong spirits that will accompany a weapon such as a kris, badek, kerambit, or spear. A few craftsmen in Kelantan believe that this spirit is compatible with the iron blade. These timbers are reserved for creating hilts and sheaths of weapons. As work begins, a craftsman cannot be definite on what style of kris hilt that a piece of kemuning or kenaung will finally become. Gradually, during the incision process, the timber reveals its grain, texture, and luster and only then will the craftsmen know the hilt style the timber will become. The motifs on this hilt would be similar to large architectural components such as leaves of getamguri and jaribuaya, flowers of ketumbit and keraknasi; these are shrubs or weeds commonly found in Malay house gardens (Syed Ahmad 1992; Ismail and Ahmad 2001).

Woodcarving is a significant craft in Malay vernacular architectural and nonarchitectural elements. It is a manifestation of craftsmen's imagination using floral, geometrical, calligraphic, faunal, and cosmic. It signifies the identity of a regional architecture as well as a pattern of the craftsmen from a region. In intangible perspective, it illustrates the belief of the Malay craftsmen toward architecture, devotion to god and their contribution to society. To understand the significance of the craft, one needs to investigate its physical forms in term of motifs, principal forms and layouts. In addition, it is important to know the characteristics of the timber species from which the carvings are made.

Woodworking in Egypt

Geoffrey P. Killen

More is known about woodworking in Egypt than anywhere else in the ancient world. By the New Kingdom, Egyptian woodworking had reached its zenith with examples of woodworking such as furniture being highly prized and often sent as tribute to the rulers of neighbouring countries.

Many Pre-dynastic burials in the Nile valley have the body placed on wooden poles and covered with matting made of plant fibre, while some burials are found in primitive wooden boxes. By the unification of Upper and Lower Egypt we find bed frames, Plate 1, in common use with many examples being found in 1st dynasty (3100–2890 BCE) tombs. The quality of these bed frames ranged from conveniently shaped branches

Woodworking in Egypt. Plate 1 Bed frame, 1st Dynasty, Metropolitan Museum of Art, MMA 12.187.52.

that were lashed together to sophisticated examples made from rounded poles that were jointed together and supported on finely carved bovine shaped legs (Petrie 1913, Pl. VIII–IX).

At the beginning of the Old Kingdom, which opens with the 3rd Dynasty (2686–2613 BCE), we see major advances in building and the associated trade of carpentry. The quality of royal furniture made during this period can be seen in those examples discovered by the American Egyptologist George Reisner, in the 4th Dynasty tomb of Queen Hetepheres (ca. 2600 BCE) at Giza (Reisner 1955). When he opened the tomb, he found that the wooden elements from which the furniture had been made had rotted away to powder. However, it proved possible to reconstruct much of the Queen's furniture by studying the positions of the gold sheaths, which had encased the furniture, and the inlays that had fallen free and lay on the tomb's floor. Hetepheres' furniture consisted of two armchairs, bed frame, bed canopy, carrying chair and two boxes. What Reisner and his team achieved, from a pile of unrelated fragments of gold and faience is remarkable for it has given us a small but superb collection of early furniture, which rivals Tutankhamun's, manufactured over a thousand years later.

We see the introduction of the wooden box at the end of the Old Kingdom. They were manufactured with flat, gable, barrel and shrine shaped lids. Some were very large and were designed with a pair of poles that enabled the box to be carried by a team of porters. In one tomb scene 14 men are carrying a box. During the Middle Kingdom we find boxes were customised to hold cosmetics. Many were designed like crates to hold small alabaster jars, which held perfumed oils. Other boxes have been found to contain mirrors, kohl containers, combs and even a pair of slippers! A box made for Sithathoriunet (ca. 1800 BCE) (Winlock 1934) was decorated with gold fittings and bezels in which were set with polished carnelian stones. Other elaborate boxes held cosmetics or; these were usually inlaid or veneered with sheets of ivory or exotic timbers bought from lands south of Egypt (Plate 2). Scribes even had boxes in which they stored their writing implements and palettes. Their boxes were usually painted to imitate the stringing and veneered panels found on more ornate boxes.

Important directional changes in Middle Kingdom furniture can be seen by studying the large collection of stelae, which are preserved in the Egyptian Museum, Cairo. These Middle Kingdom stelae show that tables were widely used for the display of vases or holding water pots. Many are low with straight legs and have a single stretcher strung below the tabletop. We also see that Egyptian carpenters were constructing splay-legged tables, which had cavetto cornice mouldings below the edge of the tabletop (Plate 3). Slender vase stands were made from thin strips of timber braced with cross and angled struts. They were fitted with a shaped collar, which held the round base of a single vase. They were covered with a gesso foundation before being painted to imitate carnelian and faience inlay. Those chairs made during the Middle Kingdom had either short backs over which was draped a cover or cushion or they had backs of full height. Such chair backs were curved and made from angled slats of timber. They stood on slender gazelle-shaped legs. Often chairs were painted to simulate animal skin, which were painted with a technique, which resembles cow skin and was used on an arrow quiver case, which is preserved in the Egyptian Museum, Cairo.

By the New Kingdom, the homes of officials and nobles would have been furnished with a wide range of wooden furniture, the most common of which would have been the stools. Egyptians used a large number of different types of stool. The most commonly used were lattice stools that were made from thin struts of timber

Woodworking in Egypt. Plate 2 Cosmetic Box, 18th Dynasty, Metropolitan Museum of Art, MMA 26.7.1438.

with angled braces supporting a double cove seat (Plate 4). Round-legged stools appear in some of the more important Theban tombs. The majority of legs from these stools were hand rounded although there is a small corpus of material, which have legs that appear to be turned. During the New Kingdom we see carpenters sitting on three legged stools, which allowed the stool to rest evenly on the workshop floor. The folding stool originated in the Middle Kingdom and was made from two interlocking frames with a leather seat. New Kingdom examples are more elaborate having the floor rails and crossing spindles finished with carved goose head terminals, which are inlaid with ivory to imitate the eyes and neck feathers. We also see that lion legged stools and chairs were used in the homes of high-ranking officials.

The wooden furniture manufactured in the royal workshops was not very different in design to that used by the middle classes. However, they were exquisitely embellished with gold sheet, inlaid with coloured stones and faience or veneered with ebony and ivory. They were also adorned with the uraeus [the sacred serpent found on the headdresses of Egyptian rulers and divinities, representing sovereignty] and the symbols of kingship. Other pieces are inlaid with thousands of slivers of coloured wood in either marquetry or parquetry patterns. In the tomb of Yuya and Tuyu (ca. 1400 BCE), the parents of Queen Tiy and the wife of Amenhotep III (1390–1352 BCE), a small armchair made for Princess Sitamun was discovered. The illustrious examples of furniture discovered in the Tomb of Tutankhamun (1336–1327 BCE) show the outstanding quality of design and construction achieved by 18th Dynasty carpenters.

Wound Healing in Ancient Egypt[1]

Hedvig Győry

Representations of injuries are relatively infrequent in ancient Egypt. However, the accuracy in the depiction of accidents in the joiner's shop drawn on the wall of the tomb of Ipui in Deir el-Medineh, and the representations of the battle of Qades in Abu Simbel, Luxor and Ramesseum temple, reveal exceptional medical details and the consequences of specific injuries. The exact identification of injuries on the battle scenes is possible in two-thirds to three-fourths of the injured (only Hittite) soldiers. Most of them were inflicted on the chest and abdomen, or neck and head, respectively, these being the largest targets in bow-and-arrow warfare or in hand-to-hand fighting. For instance, a 'decelebrate rigidity' is shown in a Hittite soldier struck by an arrow on the top of his head, or a haematoma (accumulation of blood) is shown deep in the abdominal wall caused by an arrow entering another Hittite soldier's right lower-chest or abdomen below the rib cage. An examination of skeletons show that arrowheads severed most of the spinal cord, resulting in instant paralysis of the body below the neck.

[1] In the text, the following abbreviations are used for two medical papyri: Eb is Ebers papyrus and SM is Edwin Smith papyrus.

Types of Wounds

We can differentiate several types of wounds depending on their characteristic look, origin or severity. The same is true for ancient Egyptians. Moreover, medical papyri, especially the Edwin Smith papyrus, are very accurate and detailed in the description of various types of injuries and their treatments. They tell us that the healer was able to characterise the most important types of injuries, impressive even by today's standards. They differentiated various types of swellings, wounds, fractures and joint injuries.

The general word for an injury, where the protective function of the skin was disturbed or hurt, i.e., a wound, is *wbn.w*. Without any explanation it means the commonest form of injury, the rupture of the soft tissue overlying the bone and leaving a constricted orifice. Beside this simple form, they spoke also about a *wbn.w n kft*, (a gaping wound) describing an open wound with a well-defined gash as, for instance, in Sm 28, where the most important clinical sign for an open oesophagus, drinking water regurgitating through the wound, is mentioned. The axillary could also be open (Sm 47). Another type of *wbn.w* could be *wbn.w sd* (*sg*), (a wound smashing (sg) or contusion), or *wbn.w jsp (r3-r)*, [a wound cutting (through)]. Another description of wound, known only from the Smith papyrus, is *wbn.w jsdb (r)*, [a wound piercing (to)], which seems to be nearly synonymous with *wbn.w ͑r* (*n*), [a wound penetrating (to). According to the examples we have, the penetration reached a solid body part as bone, while the piercing came through into a void. For a simple perforation the common word was *thm*. Finally, in pEbers 877c we find the *wbn.w sḥm*, (a crushing wound), laceration and rupture, and in pEbers *494 wbn.w n wbd.t* (burn wound), although for designating this last type it was enough to write *wbd.t* – (burn) alone, or to give the word for the actual phase of its development. Ancient Egyptians differentiated various types of fractures. Beside the *ḥsb*—simple, open fracture—there was the closed *sd* fracture, where the bone was broken in two inside the body, or the commuted compound or impacted *pšn* fracture, where the bone was broken in several places. The above-mentioned *thm* and *sḥm* could also occur below the skin. As a diagnostic clinical sign of fracture, *nẖbẖb*, meaning, in all probability, 'crepitation' [the noise made by rubbing together the ends of a fractured bone], is mentioned.

Treatment

During the repair of any type of wound, the practitioner has to face three basic factors: pain, bleeding and infection. The ancient Egyptians realised only two of them, since they regarded infection as part of the recovery process. The most common complaints, swelling and fever indicate that wounds were often infected.

Interestingly, they never mention anaesthesia for use in surgical interventions although painkilling must have been an important part of the repair procedure. The possibility of anaesthesia was there because we know that they collected rush, which can be used as a narcotic, that they knew very well the effects of alcohol, that they cultivated mandrake and poppy from the New Kingdom on, and that the medical papyri reveal a knowledge of hyoscyamus [henbane, a genus of poisonous herbs] and scopolamine as well. Their use of analgesia was thus theoretically possible, either in the form of a type of food or concoction, and their use as hypnotic agents might also be hypothetically suggested. The only words, however, which might hint at anaesthesia accompanying the Old Kingdom circumcision scene where the use of local anaesthesia can be deduced from a promise to make it *nḏm* – 'sweet, agreeable', when the region is rubbed with a piece of stone. Some consider that water was mixed with vinegar over Memphite limestone, resulting in the formation of carbon dioxide, which may have had an analgesic effect; the process would then resemble today's cryo-analgesia.

Ancient practitioners were more deeply concerned with arresting haemorrhages, since the *mtw* (Eb. 871), tumours (Eb. 875) and wounds were susceptible to bleeding.

Medical Protocol

In preparation for medical treatment in ancient Egypt a medical protocol was first issued by describing the symptoms, making a diagnosis and giving the form of treatment. This process was usually followed by the medicine man, who was usually a physician or probably a priest of Sachmet.

Diagnosis could be divided into three categories: (1) "an ailment, which I will treat"; (2) "an ailment which I will contend with"; (3) "an ailment not to be treated". The main wound repairing methods were bandaging with an ointment or poultice, scorching (Eb. 876, Eb. 872) and surgery. In doubtful cases, enforced bedrest and normal diet were often recommended to the patient until he reached the decisive moment when the healer could give either a positive or negative prognosis. At the end of the treatment sometimes the verdict was also given as (a) "until he recovers"; (b) "until the period of his injury passes" by; (c) "until you know that he has reached decisive point".

Relatively fewer examples are given for incurable ailments. Only 5 out of 48 cases in the Smith papyrus, and a few in the tumour section of the Ebers papyrus, as Eb. 874, may be leprosy, or Eb. 873, a possible cavernous haemangioma, or a twisted vascular swelling forming knot (in this case, however, the *mtw* should be straightened). The first two steps in Eb. 877 are still unidentified, although cancer, cutaneous leprosy, bubonic plague or neurofibromatosis has already been suggested. In the last step in Eb. 876, the ball-shaped extensions have tentatively been identified by Regöly-Mérei as varicosities.

The cause of wounds can be varied. They are most often trauma by accident or battle, blows or knocks, scratching or scraping, bites, burns or a symptom or stage of an illness. The preferred treatment was drug therapy accompanied by bandages, which was supplemented in severe cases by small surgical interventions. Some mechanical treatments are also known.

Surgery also took place sometimes for religious (circumcision) or aesthetical reasons (ear or nose restitution) and prosthetic surgery was also known, although not all that often.

Types of bites, such as those from crocodiles (Eb. 436, H 239–40, 243), lions (H 244) and humans (Eb 432–435, H 21), were treated like any other wound, preferably by applying fresh meat on the first day and, subsequently, honey, wax and oil or grease as in Eb. 435 or by using other herbal remedies, occasionally with the addition of some animal ingredients. Snake-bites, however, were treated differently, and by different medicine men, mainly by the snake-charmer priest of Selket, because of the venom inflicted by the bite into the body. Tumours were well differentiated. Several sorts of tumours, abscesses, cysts, swellings, and boils (*ḥnḥn.t, ꜥꜣ.t, sfṯ, ꜥnw.t, šfw.t, ḫsd, twꜣ.w, bsj, ḥmꜣ, sḫ, bnw.t, wnm-snf*) are mentioned mostly in the Ebers, Hearst and Berlin papyri, with very brief medical instructions. These were treated by the same methods as wounds caused by mechanical injuries.

In the Ebers papyrus there is a complete book on wounds originating in burns: 482–509. No. 482 lists a sequence of remedies which, it says, should be applied consecutively. In other cases, remedies applying an ointment or bandage are always the same.

Methods

Drug Therapy

Egyptian drug therapy can be regarded as having evolved from a system rooted in magic that developed from empirical observations. Sometimes a sequential approach was used (Eb 522). In the 182 cases given in the Smith, Ebers, Berlin, Hearst and Ramesseum III papyri regarding wound repair, almost 130 types of materia medica were used. All were applied externally. More than 60% of them were herbal remedies; the remaining types were mineral or substances originating from animals (both in about the same degree), with a few undetermined components. The only human remedy was urine.

Very often (in every 6th case), fresh meat was applied to a wound on the first day as an efficient haemostatic and mechanical agent. It was bound on the wound on the first day only, and was usually followed by the application of a lint saturated with ointment composed of grease and honey, also bound on. In specific cases, many other ointments and poultices were also applied (e.g., Eb 510–42). In other cases the treatment started with these materials. Almost 80% of the prescriptions contained oil or grease in either the form of *mrḥ.t* or *ꜥd*, both prepared from various plants or animals, closing off the wound from air and introducing some minerals or vitamins into the injured tissues. In almost half of the prescriptions honey was used, which can be beneficial as a wound dressing because it inhibits the growth of micro-organisms and is hygroscopic, thus attracting an abundant secretion of leukocytes and antibodies. Taking into account that the wax, which was also frequently mentioned in these cases, must have also contained some honey, its use was as popular among Egyptian drugs in wound healing as oil or grease.

ḏꜣr.t was often used (ca. 25%), probably because of a disinfectant effect; this has been determined from the analysis of its use in various ancient Egyptian prescriptions. Unfortunately, the identification is not fully resolved: colocynth[2] and carob are suggested, although the last one seems to be more probable. Besides these basic medicaments, some others are also characteristic. Typical poultice materials were beans, peas, leeks, a sort of fibre (*dbj.t*), faïence powder, *bsn*-clay, *wšꜥ*-mineral, *jmrw* – eventually gypsum or plaster, and linen (both the usual colour and *jrtj.w* -a red one).

Several other materials were used for their antibiotic, antiseptic, astringent, rubefacient (for internal pain), antiphlogistic (counteracting inflammation), analgesic, fever reducing, hygroscopic or wound sealing effects, or because they could contribute to the formation or development of the epithelium. Most of them are listed, but infrequently. Only a few are common: incense, salt, acacia, sycamore, barley, millet, faeces of various animals, Christ thorn, celery, cumin and a few unidentified ones. Some of the materials used only rarely might also be very effective. This can be stated for instance for the willow (*ṯrt*) having salicyl as its analgesic, fever reducer, anti-inflammatory effects, and being also anti-rheumatoid. It is, however, only mentioned in three prescriptions. Another such component is onion, listed only once, but being a good anti-inflammatory and very effective against staphylococci,

[2] The colocynth is the light spongy pulp of the fruit of the bitter cucumber (Citrullus, or Cucumis, colocynthis), an Asiatic plant allied to the watermelon. It comes in white balls, is intensely bitter and a powerful cathartic. Also called bitter apple, bitter cucumber, bitter gourd.

streptococci and some sorts of dermatomycosis [fungal infections of the skin].

The question can be raised, however, how often a certain prescription was used, as we can surely attest that the medical knowledge of ancient Egyptians was slowly but continually developing, incorporating new methods and materials in their papyri, although they continued to practice medicine as they had earlier times. One of these new materials was also the willow.

Mechanical Treatment

Treatment for Joints

Dislocations (*wnḫ*) and sprains (*nrw.t*) were treated. In the tomb of Ipuj in Deir el-Medineh, there is a picture of industrial accidents. Among them the use of Kochers method for dislocated shoulders[3] can be clearly discerned. Other methods are described in the Smith papyrus, for instance, treatment for the dislocation of a jaw (Sm 25). For neurological complications resulting from the dislocation of a cervical vertebra, the inability to move the limbs, priapism, urinary incontinence, and intestinal dilatation with gas (paralytic ileus) are mentioned (Sm 31). In another case, a positive Lasague sign is described, i.e. pain due to a sprain of the vertebral column when the legs are extended (Sm 48), which indicates a prolapsed lumbar intervertebral disc with nerve involvement.

Bandages

For drawing together a gaping wound they applied strips of adhesive plaster, putting them on both sides of the wound (Sm 10, 27). Splints could be used for administering medicament into the mouth, as it could be held open with them. The same supporting use is attested at nose and ear operations. The common application of splints was for fractures. Wounds were usually bandaged after ointment was put on them, or the bandage was saturated with it. The linen for bandaging (Sm 2, 9, 10, 27, 47) varied in texture from the finest silk-like gauze to a canvas-like coarseness. Ancient Egyptians had special knowledge in this field, which was explained in a specific book, as a note in the Smith papyrus says. The skill was first taught for the bandaging of mummies.

Treatment for Fractures

Based on many relatively good healing settings, we can assume that ancient Egyptian bone setting was advanced. Among the skeletal remains from ancient Egypt, there are innumerable completely healed limbs with good realignment of the bone, but most other bone settings often show gross shortening and misalignment. Since fractures of the femoral bones often healed without complication, it may indicate, on the one hand, that the virulence and incidence of pyogenic [producing pus] pathogens was lower than they are today, although their existence is proved by the frequency of osteomyelitis. On the other hand, based on the skeletal remains of pyramid workers and other Egyptians, it is obvious that fractured limbs were splinted using an advanced technique. Cleverly, if only one of the bones of the lower leg or forearm was broken, the remaining intact bone served as a splint for the broken one, and healing was satisfactory. In instances where the damage was so severe, amputation was an alternative course of action.

The standard procedure for the reduction of fracture was traction (Sm 12, 35, 36). And, indeed, many humeri set in splint remained. The first procedure was, after realigning the broken limb, to set it either with a splint wrapped in bandages, or encased in a healing poultice-cast that could be made of various (often unidentified) materials, as, for instance, (to mention some known substances) cow's milk mixed with barley (H 219) or acacia leaves bound together using gum and water (H 223). For reducing a fracture of the clavicle (Sm 35), the ancient Egyptians also used a modern method, first described among Greek physicians by Hippocrates, by stretching the patient 'on his back with a folded cloth between the shoulder blades' and pulling 'on his two shoulders until the fracture falls into position'. Among the neurological complications, as in the case of an impacted fracture of the cervical vertebrae (Sm 33), aphasia, unconsciousness and tetraplegia, are mentioned.

Surgical Processes

- Wounds were often surgically treated by suturing with *jdr* stitching (Sm. 3, 10, 14, 23, 26, 28, 47). The Smith papyrus has the first mention in history of 'stitching' a wound. Other wounds were not sutured, but kept open.
- The *ṯḥn*—piercing with the *ḥmm* instrument—was prescribed for opening the ascites [fluid in the abdomen] in Eb 865. Regarding the only surgical procedures for burns, Eb 504 speaks about opening a blister, this time with a sharp thorn.
- Sandwiched between two pharmaceutical prescriptions, also for a blister in Eb. 501, an incision is suggested, but, as usual, without any details.
- The *ḏw-ᶜ*-'knife-treatment', meaning, probably, excision, was fairly popular, as the many prescriptions show: Eb. 866 for a vascular tumour (haemangioma?), Eb. 867 for a presumably subcutaneous lipoma, Eb. 868 for a possible sebaceous swelling with metathesis (*ᶜꜣt nt sꜣ*), Eb. 869 for an abscess,

[3] Kochers method of reduction involves bending the elbow to 90°. The arm is slowly rotated 75° laterally, then the point of the elbow is lifted forwards, and finally the arm is rotated medially.

W

Eb. 870 for a swelling. The identification of the latter has several possibilities, such as a dermoid cyst lined with skin appendages, pilonidal sinus located in the midline or sebaceous cyst of the scalp, as, for instance, atheroma, Eb. 871 for an abscess in the axillary lymph glands.

- Sometimes, the *ḏw-ˁ*-‘knife-treatment’ was applied with a heated (*sšmm*) knife as in Eb. 872 for a probable haemangioma.
- In some cases ‘fire’ is mentioned, treated ‘with the *s3-ḥmm* (firebolt?–man)’s treatment. This scorching was used in the case of the skin-like flesh protrusion in Eb 863 or that of the (umbilical or epigastric?) hernia in Eb 864.
- The method was applied according to the state of the cause, as in the first two cases of Eb. 876, where the tumour was eliminated either by excision or by scorching fitted to its state.

In all the above cases, procedures are not described and thus nothing definite is known. The only complex and detailed surgical process is given in the Ebers papyrus (Eb. 875)—with various knife and forceps devices—and is, in all probability, the month-long treatment for dracunculiasis (which may be the origin of the medical emblem with snakes), and thus a very atypical surgical invention.

Skull Repair

According to the Edwin Smith papyrus, the ancient Egyptians recognised brain disorders and performed skull repair. They were also the first in the history of medicine to identify the inner parts of the cranium. They also provided vivid descriptions of the brain and cerebrospinal fluid. Parallel to the development of weapons, the number of head injuries increased, thus making the discussion of the many cranial injuries in the Smith surgical treatise fully understandable. The dominant factor in healing, however, seems to be the *vis mediatrix naturae*, the expectant healing power of nature. It is also manifest by the signs of treatment on heads with cranial injuries found by Elliot Smith, Wood Jones, Courville, and recently, Nerlich.

The ability to recognise the classic sign of a base fracture in the skull, i.e. bleeding from the nostrils and ears (Sm 4–5, 7–8, 17, 21–22), or the basic sign of meningeal irritation, i.e. the inability to flex the neck to the breast (Sm 3–5, 7), indicates a sound basic medical understanding. And, indeed, pathological descriptions give clues to the identification of cases, like classic meningitis in Sm 3 or cerebral prolapse and nucleal rigidity in Sm 6. In Sm 7, a complex case scenario is given dealing with a fracture at the base of the skull. First, trismus and meningeal irritation (cured by palliating treatment with an unknown hot material, allowing the patient to be able to open his mouth), then infection of the wound causing tetanus is diagnosed, again treated by palliative treatment with *mḏ3.t* – ‘wooden chisel’ and tigernut drink (*wˁḥ*), since recovery was hopeless. The Smith papyrus also discusses a *contracoup* case with a pulsating swelling protruding through the cranial fracture (Sm 8), where, besides the symptoms of the eyes looking in the direction of the affected side, the ears and nose are bleeding and nuclear rigidity with a hemiplegia on the injured side is documented.

Snakebite

According to the Brooklyn Herpetological Papyrus, snakes and the effect of their bites were accurately identified, and their bites treated with rational medical care. The treatments comprised the application of bandages with salt and natron, both being anti-agglutinant and anti-hemolytic, thus hindering the absorption of the venom; drinking of emetic remedies with various drugs to get rid of venom by vomiting; fumigation as adjuvant; magical spells for general and specific divine help and/or the *ḏw-ˁ*-knife-treatment and the *tštš* incision in the swelling. For drug therapy many earlier, not medically attested, substances were used, which may be explained by the 30th Dynasty date of the papyrus or by our missing knowledge of empirical snakebite treatment, but eventually by both of them.

The simple cut (*ḏw-ˁ*) was applied there twice, in the case of a ‘male viper’ (Br. 31) and of a uraeus/cobra (Br. 32); the wound is attributed to Seth and the prognosis is positive in both cases. The action is not specified, and, for the first case, there is nothing else to do. In the second case, however, the knife treatment is preceded by a remedy (‘every thing for …) with a missing part, which is thought to be by Sauneron ‘emetics’). These two procedures resulted in vomiting, thus saving the patient’s life. The word *tštš* originally meant ‘crush’; in these cases, however, the knife determinative finishes the hieroglyphs. Thus, here the ‘*tštš* with many cuts’ means, in all probability, the cutting of the area of the bite into pieces by a knife, applied to the bite swelling of any type of serpent (Br. 72a) or, specifically, to that of an unidentified cobra(?) ‘male snake’ (Br. 81). The next step was, however, the bandaging of the wound with salt or natron, or, in the second case, a medicament with the addition of incense, an unidentified liquid, and cobra blood. The latter one, in addition to the venom, also contains the antitoxins.

Surgical Devices

We do not know very much about medical implements. The earliest tools come from the tomb of Qar of the 6th Dynasty, including forty scalpels and tweezers as well as other medical tools whose purposes are still unknown.

For cutting the flesh they used knives of particular shapes and sizes. Various ancient Egyptian names are also known, such as *ds, ẖpt, šꜣs, ḥmm(?)* or *swt*. There was also a peculiar fish-tailed knife, called *psš-kf*, used for cutting the umbilical cord after delivery. In the beginning the knife was a ‘disposable’ stone, most likely made of flint or obsidian, which was still used for cutting up dead bodies for mummification in the first century AD (Diod. I. 91) or blades fashioned from reed stems. However, cuttings on the body were made from the New Kingdom on, also with a metal knife. This innovation led to a new procedure: the blade was heated until it was red hot before an incision was made so that the knife both cut and sealed at the same time.

If a bone broke, bark or cartonnage cases padded with vegetable fibre or linen for securing the injured member by splints might be used, but Eliot Smith also mentions splints made of reeds connected by a linen band.

For taking out pieces of bones or any other foreign bodies, tools such as hooks and forceps were used. There was also a pair of small leather forceps, called *hnw(ḥ)*. For discarding pus or other amorphous formations, tweezers or spoons and spatulas or vegetable ‘knives’ (*sw* = bulrush) were used. Other plants were used in other ways; for instance, the thorn of an acacia was used for cutting up blisters (Eb. 504 = L 52 = L56).

For cauterising there was the *ḏꜣ* – ‘fire drill’ and sometimes heated metal cauteries. For closing open wounds, various types of bandages (*hꜣyt, sšd*) or needles for suturing by *jdr* stitching were employed. Linen strips coated on one side with a gummy substance were used, for instance, as strips of adhesive plaster (*ꜣwy*). They had a sort of cotton wool made of fibres of the plant *dbj.t*, which was soaked in drugs (Sm 28) and enclosed by linen bandages (*sšd*). To prevent the dislocation or slipping of the bandage, they applied a gummy substance or varnish taken from embalmers. A wedge covered with layers of cloth is described in Smith 7 for use in prying open the jaw.

Medical devices seem to be varied and fairly specialised, each used according to its function or to the requirements of a particular stage of the operation. Their refinement was, however, primitive, although the technical skill existed to make complex instruments, as we know that some cosmetic devices are astonishingly complex and of high quality. The repertoire, naturally, continually changed and developed. The state of our current source material, however, does not allow us to deduce details. At the temple of Kom Ombo, a box of instruments for a general practitioner, carved into the outer corridor wall and originating from the Roman Period, contains 37 instruments, identified as metal shears, knives, saws, suction cups, probes, a saw, tweezers, pincers, small bags, retractors, a small scale, lances, specula, chisel, dental or cleaning tools,

spatulas and spoons, together with some objects having connections with magic. The ensemble presents a good example of the last period of Egyptian medical praxis, when Pharaonic Egyptian and Graeco-Roman medicine were completely fused.

Mythological Background

The medical papyri point to the fact that pernicious beings could enter and leave the organism through the openings of the body and thus harm people. From the Egyptian medical perspective, the wound was also an opening. Thus wound management had to be twofold. The first task was to repair the harm already occurred, by closing the opening and repelling the demons who had entered. Prevention was essential too, to assure the defence of this gate by magical rites and material feared by these illness-causing intruders. Seth often personified their negative power. The association of Seth with wounds was close, whether the wound was received in battle or as a consequence of the mythical fight between Horus and Seth for the succession to the throne of Osiris. According to this concept, any illness could only be healed with religious rites.

Material in connection with a plant or an animal might dispose some magical power and be a device through which people could get in contact with the gods. And the same is true for minerals. Thus any medical material could also express the protective role of a deity itself. This view is the most manifested in 'magical' components of the prescriptions. But even their choice was based with all probability on long empirical observations. Many of the materials are still (may be forever) unknown for us, but most of the identified ones have proved to be reasonably explained, and are appropriate in terms of their effect. The explanation of their effectiveness could only be given at that time, however, by mythological–theological reasoning.

Various material combinations could be used for seemingly the same type or state of illness or health, having the same or similar effect. There were several routes of drug administration, with a wide range of formation for use. They were usually determined by the choice of ingredients applied both for their physical–chemical properties and magical assumptions. The sycamore was, for instance, the tree of Hathor, Nut or Isis, the Christ thorn that of Thot of Pnubis, malachite was the mineral of Hathor, the donkey belonged to the god Seth, excrement was disgusting even for illness-demons, the *s3-wr* resin bore in its name ('great of magic') its magical connotation. For patients who were wounded, bandages were also used as magical devices. They were traps, so that invisible beings could be kept off or removed.

Another way of making a treatment more effective was religious–magical rite. Similar to cases in the London papyrus (15–21, 46–48, 53–61) and also among the Ebers papyrus prescriptions (482–500), magic spells had to be cast, referring to Horus having been burnt in the desert. According to the incantation of Eb. 499, which had to be recited with mother's milk, Isis used 'water in her mouth' and 'Nile springing between her thighs'. Then mother's milk, gum and ram fur (having a high cholesterol content) were put on the burnt wound.

The mythological background worked as a psychological support as well, which recent studies have shown can reduce pain perioperatively and increase patient's satisfaction.

Writing

Martha J. Macri

Writing ranks among the most important of human inventions. Yet it is only one of many forms of visual communication. Others include sign language, dance, and bodily adornment, notched tally marks, stones signposts, as well as the more complex painting and carving of complex narrative scenes. Some of these are, like writing, ways of recording information, that is, of creating a more or less permanent record available to persons outside the immediate time or space. All visual communication depends upon at least minimal familiarity with the cultural conventions of those producing it. Specifically, writing is a technique for recording human speech. Today speech, both the aural and the visual aspects of it, can be recorded and reproduced electronically. However, prior to the invention of the wax cylinder phonograph, human language could only be recorded, however imperfectly, in written texts.

Writing is an entirely arbitrary system in which each symbol in a script has an agreed upon value. The symbols may or may not have any association with a real world object. Thus, all scripts must be learned within the context of a specific culture, and within the context of a specific speech community. Although the Chinese script can be read by speakers of a number of different languages, the conventions of the script and the way it relates to a speaker's own language must be painstakingly memorized.

Writing seems to have been invented at least three times in human history: in Mesopotamia, in China, and in Mesoamerica. It may be that there were other independent inventions, or it may be that all the other writing systems have been the result of stimulus diffusion – the spread of a good idea. An evolutionary theory of writing sees a development from pictures to complex symbol systems to scripts with word signs to phonetic (sound based) writing systems.

Logographic scripts (ones in which a picture or symbol represents a specific word) make use of rebuses, that is, of using a picture of an object to represent a word that sounds like the object pictured. Such a script is always language specific. For example, using the picture of a honey bee for the verb *to be* works only in English. Logographic scripts nearly always include additional elements to clarify meaning (semantic determinatives) or to indicate the sound of a word (phonetic complements). Ancient Egyptians had sets of consonant signs indicating one or two or three consonants, as well as hundreds of logographic signs and semantic determinatives. Other examples of logographic scripts are Sumerian, Chinese, Naxi (southern China), and Mi'kmaq (Canadian maritime provinces).

The next step in an evolutionary theory of writing is the addition of a significant phonetic component. In phonetic scripts most signs refer not to words, but simply to sounds. Of phonetic systems there are two types: syllabaries and alphabets. A syllable is composed of a vowel and any consonants that immediately precede or follow it. In practice, in most syllabic scripts, each sign represents a simple consonant–vowel combination. There are, for example, individual signs for *pa, pe, pi, po,* and *pu* instead of a single symbol for the sound *p* and symbols for each vowel. Syllabic systems often include a set of logographic signs (such as the *kanji* component of Korean and Japanese), and may have one or two symbols for a single consonant (in Japanese there is a symbol for *n*, in Cherokee a symbol for *s*). Although early students of writing considered syllabaries to be merely a step toward the culmination of the alphabet, syllabic systems have had a long history of success. Japanese, Linear B, Akkadian, West African scripts, and Cherokee are only a few examples.

In contrast to multiple inventions of syllabic scripts, the alphabet seems to have been invented only once. Certainly there are hundreds of distinctive alphabetic scripts, but the history of each one can be traced from a single origin in the Mediterranean region some 3,500 years ago. In alphabetic systems, each sign represents a single sound – a single consonant or vowel (the earliest alphabets were largely consonantal systems). The Proto-Sinaitic, Ugaritic, and Phoenician scripts are the immediate ancestors of the Greek and Roman alphabets. Alphabets have an advantage for languages with consonant clusters such as English. The word *split*, for example, in a syllabary would have to be written with four syllabic signs: *si-pi-li-ti*, suggesting the presence of more vowels than the word has. The sequence of syllabic signs could also spell *spilt*, or any of a variety of nonsense words. Alphabetic systems generally include at least a few logographic symbols, such as the symbols for numbers.

Any script with a history – one in use longer than a single generation, or used for more than one language or one dialect – suffers from the effects of standardization and carries a baggage of archaic spellings. *Aunt* and *ant* may or may not be pronounced the same. *Beau* and *bow*, *bough* and *bow* reflect language history, and show clearly that English writing is not a purely phonetic system. Standardized spellings are much easier to read than technical transcriptions, in which linguists using a system such as the IPA, the International Phonetic Alphabet, try to capture the precise details of a specific utterance.

Although no script is ever a pure example of the above categories, each category differs in the usual number of total signs. Counting the number of individual signs can sometimes suggest the nature of an unknown script. Logographic systems contain the most signs, sometimes numbering in the thousands. Syllabic systems require only as many signs as there are consonant + vowel syllables in a language, usually in the range of 40–150 signs. Mixed logographic-phonetic scripts can range from hundreds into the thousands. Alphabets have the fewest – only enough to represent the sounds of a particular language. Only 13 letters are needed to write the Hawaiian language, compared with 24 symbols in the Germanic runic script and 44 for Cyrillic. The total number of signs in an alphabet does not necessarily match the number of distinctive sounds in a language. The alphabet used for English has only seven vowel letters (*a, e, i, o, u, w,* and *w*) that are used alone or in various combinations to represent at least 12 distinct vowel sounds.

Another way that script types differ is in their longevity. Two of the best known logographic scripts, Chinese and Egyptian have had far longer life spans than the alphabet. An identifiable Chinese script was functional at least by 1200 BCE, and continues in use by millions of people today. Egyptian hieroglyphic writing ceased by the tenth century CE, but has a history of nearly 4,000 years. Akkadian in Mesopotamia was used for over 2,000 years. Syllabaries seem to have briefer lives. Linear B in Mycenaean Greece was used for about 200 years. The two syllabic components of the Japanese script, *hiragana* and *katagana*, are slightly over a 1,000 years old, developed by the eighth and ninth centuries CE, respectively. The Cherokee syllabary dates only from 1820. What of the alphabet? Probably dating no earlier than the first or second millennium BCE, its future seems promising. As a tool of the electronic age, the alphabet is a system adaptable to any language and is maximally efficient for keyboard use (this may be, however, because keyboards were invented for the alphabet).

One of the errors in an evolutionary theory of scripts is the notion that they become increasingly abstract, i.e., that over time scripts become more efficient, using fewer signs and simpler sign forms. Scripts with a heavy logographic component tend, however, to develop in the opposite direction, collecting baggage over time. Egyptian grew from 700 signs in Middle Egyptian (ca. 2000 BCE) to more than 5,000 signs by the fourth century CE. The ancient Maya script added hundreds of logographic signs over the 700 years of the Classic period (200–900 CE), while the core of syllabic signs grew at a much slower rate. Chinese characters have increased from 9,000 in the first century CE to about 60,000 by the end of the twentieth century, though today only about 2,400 are in common use.

These dramatic increases happened for several reasons. First, cultural and historical events bring additions to a script over time. This can be seen in the archaic spellings of many English words that reflect pronunciations no longer used or used only in certain dialects. Second, although a purely alphabetic script is easier to learn and easier to write, logographic scripts, once mastered, can be read more rapidly. The debate of whether to teach English-speaking students to learn to read through phonics or through word recognition reflects the fact that even readers of alphabetic scripts make use of both its phonetic and logographic aspects. Third, universal literacy has not always been an ideal, and a difficult logographic script has sometimes been seen as a tool for limiting access to knowledge and prestige. Finally, and probably most significantly, languages rarely add a new sound to their sound inventory and rarely add new syllables. Words, however, are constantly being added. Since vocabulary is an open-ended component of language, any logographic script, one in which symbols represent words, is going to have to grow as new words come into use.

Some scripts owe their invention and development directly to contact between neighbors. One example is the Japanese writing system. Initially Chinese characters were used to approximate the Japanese language, then syllabic features were added to provide more specific phonetic information. Today the combination of *kanji* (Chinese logographs) with the *hiragana* and *katakana* syllabaries, make Japanese a script with one of the world's most arduous learning curves. Sumerian, a largely logographic system, was adopted by the Akkadians who like the Japanese added syllabic features, resulting in a mixed logographic–syllabic system that had a large syllabic component.

Some students of writing see the adoption of a logographic script by speakers of a foreign language as an explanation for the development of phonetic scripts. Foreign users reinterpret logographs that carry semantic and phonetic information as phonetic symbols representing sounds without the specific meaning, or as representing the same meaning but with the sounds it has in the new language, or they may invent phonetic signs to add phonetic information or grammatical detail. Such progressions can be seen in the development of Akkadian from Sumerian writing, or of Japanese syllabaries, and the Korean script – both influenced by Chinese.

The vocabulary used to characterize a script varies from one to another. C*haracters*, *hieroglyphs, glyphs, letters, symbols, icons, signs,* and *graphemes* all describe units of written language. The forms of the signs may be described as *pictographic*, *representational*, *linear*, *cuneiform*, *abstract*, and *geometric*. The organization of the units may be *columnar*, *clustered*, *horizontal* (*left to right or right to left*), *boustrophedon* (back and forth, literally, *as the ox plows*). Within the texts themselves divisions between words, phrases, sentences, and larger units may be ignored or may be indicated by spaces, larger symbols (e.g., upper case letters), or a variety of punctuation conventions.

Language that is recorded in writing represents only a small subset of language that is spoken. Nearly every culture places specific limits on the kinds of information presented and on the manner of presentation. Commercial records, calendrical notations, prayers, magical spells, laws, census records, land deeds, court records, sacred and political histories, diaries, personal letters – these are among the earliest written materials. Novels, commercial advertising, and to-do lists are relatively more recent developments. The surviving examples of some ancient scripts are limited only to one or two genres.

Spoken language reflects an awareness of the speaker's audience, while written language may ultimately reach audiences never dreamed of. Written language tends to be more deliberate, generated at a much slower pace than speech. Nor does it have the meta-linguistic features that add dramatic force and subtle nuances to a speech act. Efforts to indicate variation in tempo, volume, and pitch (such as with underlining, boldface, accent marks, exclamation, or question marks) fall far short of the tools available to a speaker. Missing, too, are facial expressions, body posture, and hand gestures.

In contrast to recording language, there have developed a number of systems that approach writing, but do not fit the strictest definition of writing. Several of these hieroglyphic scripts are or were, in fact, readable within the culture that produced them, but with no or with only minimal phonetic components they can have only uncertain meaning to the uninitiated. One example is the Mixtec writing known from eight pre-Columbian screenfold books. In these a complex iconography is tied to narrative images recording sequences of historical events and genealogies. Although the meaning is often clear, it is impossible to know exactly how the texts would have sounded when they were read – impossible to know precisely what words were associated with the images. Another example is the Naxi Dongba writing of southern China dating from the thirteenth century. This hieroglyphic script is still used and studied today. The meanings of the signs are complex, with minimal phonetic information indicated. Mixtec and Naxi represent yet another challenge to the evolutionary model. Rather than pictographic scripts always preceding true writing, some of them were created by cultures imitating neighboring scripts.

Also implied in the evolutionary theory of writing is a gradual development from picture signs to syllabic signs. Many books on the history of writing show charts of simple pictures for objects next to related but more abstract forms that exist in a particular script – the most common scripts pictured are Chinese, Akkadian, and sometimes even the Greek alphabet. However, direct evidence of this gradual development from pictures to a phonetic script is seldom available. An alternate scenario is that at some point in time one person, or a small group of persons, took an existing symbol system, and from it chose a set of signs to produce a phonetic system, usually a syllabary. We know that this happened with Sequoyah, the man who invented the Cherokee syllabary. History also tells us that this is what happened in the fifteenth century when King Sejong, or a committee created by him, developed the Korean *Han'gul* script. Because a phonetic script is a complex interdependent system it can only function when a complete set of phonetic signs are in place. For most scripts, this crucial moment of creation remains a conjecture.

Some have asserted that writing, specifically the alphabet, gave humans the ability to order and to classify information. Linguistic and cognitive anthropologists, however, have demonstrated repeatedly that complex categorization also exists in societies without writing. What then does writing contribute? Certainly it contributes a memory beyond the life span of a single person, knowledge that is independent of oral transmission. This enables an accumulation of knowledge across time and across cultures. Writing has given us detailed insight into earlier societies. Several languages, such as Sumerian, Hittite, Etruscan, and Tocharian, have no direct descendants, and are known only through their written texts.

This essay speaks about script types and script developments. For those who are interested in the variety of the world's scripts there are a number of excellent introductory texts, some generously illustrated. For example, see Coulmas (1989, 1999), DeFrancis (1989), Pope (1999), Robinson (1999, 2002), Rogers (2005), and Sampson (1990). One volume stands out for its quality and comprehensive coverage: *The World's Writing Systems,* Daniels and Bright (1996). Also excellent are the individual volumes of the *Reading the Past* series: Bonfante (1990) Chadwick (1987), Cook (1987), Davies (1987), Healey (1990), Houston (1989), Page (1987), and Walker (1987). Two dramatic stories of decipherment are Chadwick (1967) for Linear B and Coe (1999) for the Maya script. Boone (2000) and Boone and Mignolo (1994) offer enlightened discussions of nonphonetic systems. The potential of the as yet undeciphered Inca knotted *khipu* as a record of detailed information, perhaps including speech can be found in Urton (2003) and Quilter and Urton (2002).

Recent years have seen a growing number of websites, both about scripts in general, as well as sites devoted to a single script. Below are listed two general websites for writing systems, both with links to many other resources, and several sites relating to specific scripts or regions. Searching on the web for *writing systems*, or for any country, language, or script name will yield a large number of sites. Some of these are sponsored by academic institutions, a few are commercial, and a few are sponsored by individuals. Their quality varies, though even sites with incomplete or nonstandard information often provide useful images.

Writing in China

Uta Lauer

The origin of a comprehensive writing system in China is a matter of debate. According to an ancient Chinese legend, writing was invented by the three mythical emperors between the twenty-ninth and the twenty-sixth centuries BCE. The earliest evidence for some kind of script is marks on pottery excavated from the Banpo site near Xi'an in Shanxi-province, dating from the Neolithic Age. Proof for a highly developed writing system comes from oracle bones (*jiagu wen*). Datable to around 1300 BCE, inscriptions on bovine, pig, deer shoulder blades or on turtle shell were used for divination. The elite of the Shang dynasty (sixteenth to eleventh century BCE) employed a question and answer model, through which those in power would ask a question, incise it into the bone, and the shaman or priest would drill holes into it, insert a piece of burning coal, interpret the cracks produced by the hot coal, and then write down the answer. About 2,000 different characters have been found on Shang oracle bones, but only half of these have so far been deciphered. Another form of surviving document is short texts cast on the inside of bronze vessels. There are numerous examples of late Shang inscriptions, typically rather short, whereas in the succeeding Zhou period (eleventh century BCE to ca. 771 BCE) inscriptions on bronze ritual vessels were considerably longer. The type of script employed during the late Zhou period was called great seal script (*dazhuan*).

One of the most important steps towards the development of a comprehensive writing system was the unification of the empire under the rule of emperor Qin Shihuang (r. 221–206 BCE) in 221 BCE. Under the jurisdiction of his Prime Minister Li Si, writing was standardised into the small seal script (*xiao zhuan*). This script comprised about 12,000 characters (*zi*). Today, small seal script is still in use on seals and in advertisements. Seals had been made since at least the late Zhou period. They were used instead of a signature and served official, commercial, personal and literary purposes.

With the advent of the Western Han dynasty (206 BCE–9 CE) a new type of script came into use, clerical script (*lishu*). It was easier to write than the angular small seal script and thus more suitable for the ever-increasing amount of official, government related texts. Based on clerical script a kind of shorthand developed for less formal occasions like writing letters or jotting down notes. Literally translated into English it is called grass script (*caoshu*), but is also frequently referred to as draft script, running script or fully cursive script. To avoid confusion of technical terms, it is best to use the unambiguous Chinese terminology. During the Han dynasty, the potential of writing as a medium for artistic expression was fully recognised. It was then, that the art of calligraphy (*shufa*) was born. Another less abbreviated form which emerged from clerical script is semi-cursive script (*xingshu*).

During the fifth century, the last type of script was codified, regular script or standard script (*kaishu*), which is still in use today. After that, the evolution of the Chinese writing system was complete. This had a culturally unifying effect this had to a high degree. Chinese characters serve as a binding element, as an identification factor and as bearers of an uninterrupted tradition.

With the end of imperial rule and the founding of the Republic of China in 1912, a debate about the simplification of characters began. Some argued to abolish Chinese characters entirely and to replace them with a romanization system in order to promote literacy. Several reforms followed until finally in 1964 a list of simplified characters (*jianti zi*) was approved. Today simplified characters are used in the People's Republic of China whereas other countries which employ Chinese characters have maintained the complex characters (*fanti zi*).

In 1979 the government of the People's Republic of China adopted the Hanyu Pinyin system, a phonemic notation and transcription to Roman script. Pinyin is very useful as a cataloguing method and for writing Chinese on computers.

Essential for the development of the art of calligraphy was the material used for writing, namely the pliable brush, absorbent paper and ink. The earliest surviving documents written with a brush and ink on strips of bamboo date to the third and second centuries BCE. Already by the fifth century BCE silk was also in use as a writing ground. Silk existed in China since Neolithic times. Archaeological evidence shows that paper was being made from the first or second century BCE. Paper was much cheaper than silk, relatively easy to make and less cumbersome than bamboo strips. The availability of paper made possible the steady increase in writing throughout the empire. The earliest examples of ink are found in traces of writing dating to the fourteenth century BCE. Chinese ink is made from carbon, lampblack and glue which is then dried and moulded into the form of sticks or cakes. To obtain liquid ink, the ink stick has to be ground by hand on an inkstone with the addition of water. During the tenth century CE, writing equipment (brush, paper, ink and inkstone) came to be known as the "four treasures of the scholar's studio" (*wenfang si bao*).

Since ancient times, calligraphy belonged to the six liberal arts (*liu yi*) practised by the social elite of the country. When looking at a work of calligraphy, the viewer can relive the process of its creation. The writing speed, pressure, energy, any moment of hesitation remains visible on the paper. The flexible brush allows for an endless variation of stroke shapes. Soon, the styles of individual masters of calligraphy were canonized. For transmitting calligraphic styles, various copying methods and the formation of collections were important. Before the invention of printing in the Tang dynasty (618–906 CE), several techniques for copying were employed. Exact copying (*mu*) is basically a tracing technique. To make a free copy (*lin*) the original is placed next to the sheet of paper on which the calligrapher reproduces the work at his own speed. Essential for a wider circulation of calligraphy styles were ink rubbings. For this reproduction method, a copy of the original written in ink is pasted to a stone or wood surface and then meticulously engraved into the surface through the copying paper. Then, a moistened paper is placed over the engraved calligraphy and pushed into the incised areas with a brush. Finally, a pad soaked in ink is dabbed over the surface. The background of such a rubbing appears black and the characters white.

All types of script are employed in calligraphy but semi-cursive script and grass script are the two most suitable for artistic expression. Among the most notable calligraphers are Wang Xizhi (307–365) and his son Wang Xianzhi (344–388), Yan Zhenqing (709–782), Huaisu (725–785), Su Shi (1036–1101), Huang Tingjian (1045–1105), Mi Fu (1051–1107), Zhao Mengfu (1254–1322), Wen Zhengming (1470–1559) and Dong Qichang (1555–1636). Since the fourth century CE records and art historical treatises on calligraphy exist. Calligraphy as the embodiment and a highlight of Chinese culture forms an important part of the imperial art collection.

In 1949, when the People's Republic of China was founded and the Guomindang defeated, the Guomindang took a substantial part of the former imperial art collection to Taiwan, where it was housed at the National Palace Museum Taipei. The remainder of the collection stayed at the Palace Museum Beijing. From the beginning of the twentieth century onwards, collectors outside Asia developed a keen interest in calligraphy. Private collections and museums in the USA and in Europe now own a number of representative works of Chinese calligraphy. Research at universities on the history and the aesthetics of the art of writing is particularly prominent at some major US universities and in Germany.

In China, both the practise and theory of calligraphy are taught at art academies. Exhibitions and competitions are held regularly. Some contemporary Chinese calligraphers have gained recognition outside Asia and their works are on display in museums. Calligraphy is an art that is very much alive. Not only is the tradition passed on but there is also experimental writing. Young artists explore and challenge the basic principles of writing in their works. The brush might be replaced by a neon light, ink by water, thus highlighting the act of writing and pointing towards the perishable material.

Writing in Egypt in its Literary Context

William S. Arnett

The evolution of Egyptian writing (hieroglyphs) is traditionally dated to Dynasty 1 of ancient Egypt's Proto-Dynastic Period ca. 3100–3000 BCE. Until recently,

Writing in Egypt in its Literary Context. Fig. 1 Funerary Papyrus of Hunefer. The Sun god is shown in the form of a great cat killing the serpent of darkness. British Museum (EA9901.8). Photo by Jon Bodsworth. Used with his kind permission.

priority of first place in the history of writing seemed to belong to the Sumerians of ancient Mesopotamia (now southern Iraq). However, the recent discovery of labels in tomb U-j at Abydos, Egypt, tomb of the Scorpion King, have provided evidence of writing in Egypt as early as 3250–3200 BCE. The earliest Egyptian attempts at writing consisted of potmarks, designs painted on jars, and of motifs carved on the surfaces of cosmetic slate palettes and other artifacts found in the graves of Predynastic Egyptians at a number of sites (ca. 4500–3000 BCE) and in temple deposits at Hierakonpolis. These examples were clearly precursors to the classical Egyptian hieroglyphs (Arnett 1982; Elkins 1999; Casson 1965: 141–148; Gardiner 1978).

The hieroglyphs worked best on stone, although they were also written on papyrus and other materials. Papyrus was a parchment-like paper made from the reed plant of that name which once grew in abundance along the banks of the Nile River. It was the most common material used for official record keeping, correspondence, literary works, administrative documents, etc. For these purposes the Egyptians developed a more cursive style of writing. This occurred early in the development of hieroglyphs. Scholars call the earliest type of this writing hieratic (literally "priestly" writing), although it was not used exclusively by the priests. The scribes used lampblack and wrote with reed pens when writing on papyrus and brushes when using wood and other materials such as ostraca.[1] Later, in the seventh century BCE, the Egyptians developed another even more cursive system that is known as demotic, or popular. Generally, both of these more rapid writing systems were written on papyrus (Figs. 1–3).

The quantity of such examples of Egyptian proto-writing suggests that Egyptian writing may have evolved as early as (if not earlier than) the Sumerian cuneiform system so prominent in Mesopotamia and much of the ancient Near East from ca. 3000–1000 BCE. It certainly proves that the Egyptians developed their own, unique writing system and that, if they borrowed anything from the Mesopotamians, it was the idea of writing (Arnett 2004; Stiebing 2003: 110–112) (Fig. 4).

The earliest extant Proto-dynastic writings consist of numerous brief texts: funerary stelae, ivory labels and plaques, and a few official monuments and royal inscriptions found in situ at locations both in Egypt proper and in the Sinai Peninsula. These early texts reveal a hieroglyphic writing system that was already fully developed, which led earlier scholars to believe that the Egyptians had borrowed their writing system from the outside world, presumably Mesopotamia. The earlier use by the Sumerians of "symbolic tokens and ideographic inscriptions" as means of the accounting and recording of quantities of products and livestock was assumed to have led to the development of the earliest phonetic writing system in ancient Sumer. But the labels of Tomb U-j at Abydos can be read phonetically and may be earlier than the earliest known Sumerian writing (Stiebing 2003: 112–113). We have evidence of early trade and cultural exchange between late Predynastic Egypt and southern Mesopotamia, and it is highly likely that ideas as well as goods and materials were being exchanged. However, the fact remains that the two earliest systems of writing (Sumerian cuneiform and Egyptian hieroglyphs) use entirely different signs and methods of inscription. While some Mesopotamian writing has survived on stone artifacts, the majority was inscribed upon clay tablets. In Egypt, stone stelae and walls of tombs or temples, stone chips (or ostraca), pieces of wood, and papyrus paper (the use of which dates back to late Predynastic times) were the primary media upon which the Egyptians did their writing. It is more likely that writing evolved in both areas at about the same time (Mark 1997; Wilkinson 2001: 150–182) (Fig. 5).

These early texts provide only minimal details of official political and historical events as well as the accomplishments of the owners of the tombs in which they were found (Lichtheim 1975: (vol. 1) 3; Pritchard 1955; Breasted 1906; Lewis 2003). It is the general consensus that Egyptian writing was initially created for the sole purpose of satisfying the needs of the state

[1] An ostracon is a piece of pottery usually broken off from a vase or other earthenware vessel. In archaeology, ostraca may contain scratched in words or other forms of writing which may give clues as to the time when the piece was used. The word is derived from Greek *ostrakon* meaning a shell or a shard of pottery used as a voting tablet. The plural of ostracon is ostraca.

to record all of its administrative, political, economic, diplomatic, and military activities and transactions (Aldred 1998).

King Lists constitute a genre of Egyptian writing reflecting the above – stated purposes. The earliest, the Palermo Stone, provides the names of kings of the Late Predynastic period through early Dynasty 5. Primarily a list of yearly events and statistics, the main value of this monument is in the ordering of kings by the length of reign and the listing of their achievements as well as recording annual Nile flood heights, a periodic census of men and livestock, and occasional references to public works projects and foreign trade. For instance, there is a reference to forty shiploads of cedar wood imported to Egypt in 1 year during the reign of Snefru of Dynasty 4 (Gardiner 1978; St John 2003; Wilkinson 2000). Other important king lists include the Turin Canon, the lists of royal ancestors of Sety I and Ramses II at Abydos, the Royal List of Karnak, and the Royal List of Sakkarah (Clayton 1994; Shaw 2000) (Figs. 6 and 7).

But, according to Lichtheim, the "first major application" of Egyptian writing was in the omnipresent Offering Lists found in the tombs of the well-to-do Egyptians of the Old Kingdom (Figs. 8–10).

These offering lists consisted of the names of the tomb owners, their family members, a record of the offices and titles held by them, and an accounting of the funerary offerings they required. By Dynasty 5, the Offering List was shortened into a Prayer for Offerings (Lichtheim 1975: 3; Breasted 1906: Vol. 1, 75–175) (Figs. 11–13).

As a result, wall space was freed for the development of a descriptive narrative containing historical and autobiographical material which the Egyptian nobles (administrators, prophets, judges, "overseers of the King's land," viziers, architects, soldiers, scribes, priests, etc.) had written/sculpted/painted on the walls of their tombs and/or tomb chapels. These texts and accompanying illustrations provide us with portrayals of the tomb owner, his family, and his servants (Figs. 14–17).

These texts, also called "Biographies of the Nobles," often contain gross exaggeration and considerable boastfulness, and were meant only for their family, priests, and the gods they were meant to impress. Their discovery in modern times has given historians access to important primary source material for the reconstruction of ancient Egyptian history. They provide us with glimpses of the public careers and achievements of the administrative, bureaucratic, and military

personnel who served the kings throughout the history of Dynastic Egypt. Tomb biographies also exist for nobles and some commoners throughout the rest of ancient Egyptian history. Lichtheim notes that, from the First Intermediate Period on, for many individuals, a shortened biography would be relegated to the tomb stela which also contained an offering prayer and an offering scene, making the stela a "self-contained memorial" (Breasted 1906; Lichtheim 1975: 8; 15–28).

A second literary genre, Instructions Literature, is among the Old Kingdom's greatest contributions to

Writing in Egypt in its Literary Context. Fig. 8 Mastaba (tomb) of Mereruka. The tomb of Mereruka is the largest extant noble's tomb at Saqqarah. Mereruka was the vizier of Pharaoh Teti, first king of Dynasty 5 (2345–2333 BCE). Photo by William S. Arnett. Used with his permission.

Egyptian writing. This category is also known as Wisdom Literature, which Miriam Lichtheim calls the "second major literary genre created in the Old Kingdom" (Lichtheim 1975: 5). They are written in the guise of the advice of a King, Prince or Vizier to his son. The earliest known example is the *Instructions of Hardjedef*. The sage Hardjedef (Hordjedef) was the son of Kheops (Khufu) in Dynasty 4. He also figures as a participant in the *Three Tales of Wonder* (from the Papyrus Westcar in the Egyptian Museum of Berlin). Prince Hardjedef claims to have written the instructions for his son, Au-ib-re. Not too much of his Instruction has survived, but his name is always listed among those of the great sages of Egypt (Simpson 1973: 340–341). Lichtheim (1975: 5–7 and 58–59) considers all three of the earliest Instructions (Hadjedef, Dynasty 5, and Kagemni and Ptahhotep, late Dynasty 6) to be pseudepigraphical[2] works.

Another well-known example of this genre is the *Instructions of Ptahhotep*. The sage Ptahhotep, who, supposedly, was the vizier of the Fifth Dynasty pharaoh Izezi (2388–2356 BCE), provides maxims of good and polite conduct and of good speech.

These works constitute a form of political propaganda in a literary format. They posit that order and *ma'at* (justice and balance) are only possible when there is a

Writing in Egypt in its Literary Context. Fig. 9 Ka statue of Mereruka in the Offering Chapel of his mastaba. Writing in Egypt in its Literary Context. Fig. 10 Mereruka Wall Scene. The diminutive figure of Meri-Teti, son of Mereruka, is seen at the feet of the Vizier Mereruka. Mastaba of Mereruka (Dynasty 5) at Saqqarah. Photo by Brian Anderson. Used with his kind permission.

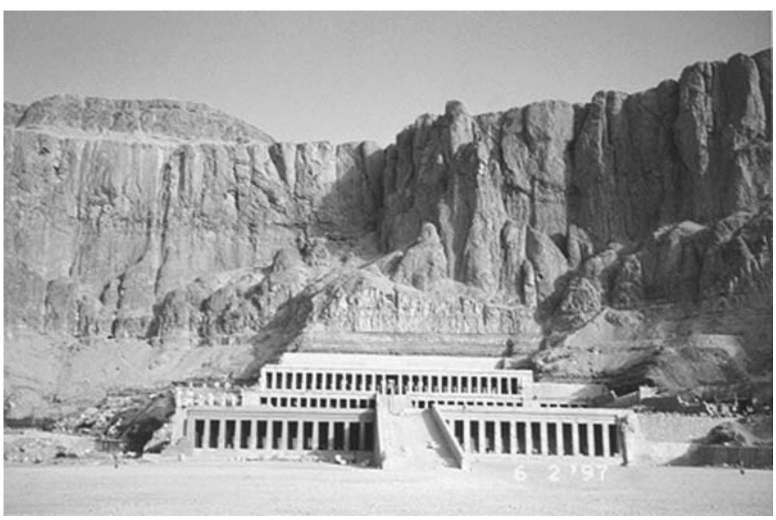
strong and benevolent monarch on the throne of a united Egypt. In addition, they offer advice on proper behavior that reflects the mores of nobles of Dynasty 5 and Dynasty 6.

[2] Pseudepigrapha (from the Greek words pseudos = false and epigrapho = write) describes texts whose claimed authorship is unfounded in actuality. The authenticity or value of the work itself, which is a separate question for experienced readers, often becomes sentimentally entangled in association. Yet few Hebrew scholars would insist that the Song of Solomon was written by the King of Israel, or ascribe the Book of Enoch to the prophet Enoch.

Writing in Egypt in its Literary Context. Fig. 11 Deir el-Bahri Offerings. In the private tombs of the nobles of the Old Kingdom, the List of Offerings consisted of prayers and items meant to provide sustenance to the decedent in the afterlife. In a similar manner, the royal temples of the New Kingdom, Kings portrayed themselves making offerings to the gods (see Fig. 6). Here we see a wall relief from Hatshepsut's funerary temple that depicts her offerings to the god Amun. Photo by William S. Arnett. Used with his permission.

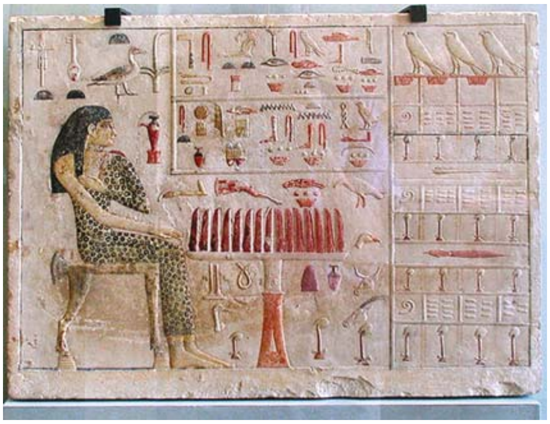
Writing in Egypt in its Literary Context. Fig. 12 The female Pharaoh Hatshepsut presents offerings to the God Amun. Funerary Temple of Hatshepsut at Deir el-Bahri. Photo by William S. Arnett. Used with his permission.



Writing in Egypt in its Literary Context. Fig. 13 The Funerary Temple of Hatshepsut at Deir el-Bahri (Dynasty 18). Photo by William S. Arnett. Used with his permission.

A third example, *The Instruction to Kagemni*, most likely written during Dynasty 6, alleges to be the advice given to Kagemni, the vizier of Huni, the last king of Dynasty 3 and of Snefru, the founder of Dynasty 4. The beginning of Kagemni's Instruction is lost, and its true date and authorship are unknown.

The Instruction of Merikare was supposedly written by King Khety II (ca. 2100 BCE), the father of



Writing in Egypt in its Literary Context. Fig. 14 Stele of Nefertiabet. Merikare of Dynasty 10. His (Merikare's) capital was at Herakleopolis. However, most scholars believe that it was actually written by scribes at the court of Merikare. Its uniqueness lies in its new dimension as a royal inscription in which a dying king bequeaths the throne to his son and successor and offers him advice on how to be a good king (Lichtheim 1975: 9–10).

The Instruction of Amenemhet I (*or* Amenemes I), supposedly written by Amenemhet I to his son Sesostris I (Senwosret I), of the Middle Kingdom (Dynasty 12), is a more famous example of this genre. The serenity and balance in Egyptian society as it appeared during the Old Kingdom had been replaced by the political and economic turmoil and social upheaval of the First Intermediate Period. Even though order had been restored by the Kings of the Middle Kingdom, our literary evidence suggests that the crown represented a heavier burden for the monarchs of the Middle Kingdom, and that the dangers of civil strife and revolution were lurking just below the surface. The apparent assassination of Amenemhet I (alluded to in both the *Instruction of Amenemhet I* and *The Story of Sinuhe*) suggests that things had gone awry and that men were doing evil things. In the *Instruction of Amenemhet*, the dead King (Amenemhet I) appears as a ghost to his son Sesostris I (or Senwosret I), tells of his assassination in the palace at the hands of his own palace guard, and suggests that it was instigated by someone in the harem. He advises his son to rule with a strong hand and to trust no one in the "day of evil" (Erman 1927: 72–74; Pritchard 1955: 418–419; Simpson 1973: 193–197; Parkinson 1997: 203–211; Lichtheim 1975:135–139).

The Teaching of Duaf's Son Khety, elsewhere known as the "Satire of the Trades," also dates to the Middle Kingdom and proclaims that the most exulted profession is that of the scribe. The writer belittles all other occupations by listing all the hardships experienced by those employed in them (Parkinson 1991: 72–76).

The Prophecies of Neferti (James 1979:102; Lichtheim 1975: 8–9 and 139–145; Erman 1927: 110–115; Pritchard 1955: 444–446; Simpson 1973: 234–240), the *Admonitions of Ipuwer,* and the *Prophecy of Nefer-rohu* represent a new departure in Egyptian literature. Neferti was a lector priest (literally, "he who carries the ritual") at Bubastis during the reign of Amenemhet I. This composition purports to be the prophetic vision of someone at the court of Snefru of Dynasty 4 who predicted the coming of the troubles of the First Intermediate Period and of Egypt's savior, Amenemhet I, the first king of Dynasty 12. In other words, this piece was probably written to justify the seizure of the throne of Egypt by Amenemhet I. Neferti and Ipuwer address the problem of evil and proclaim that a strong monarchy is the only way to protect Egypt from its dangers. The pronouncements of the sage Ipuwer are reminiscent of those of the Biblical Prophets who chastised the Kings of Israel for not doing their religious and political duties.

The Admonitions of Ipuwer was probably written in the early years of Dynasty 12 and is generally interpreted as being either a warning to a king about the disastrous consequences of misrule or else as a means of contrasting the faithfulness of a good king (presumably one of the Dynasty 12 rulers) with the inadequacies of a bad king whose failure to tend to the religious and political duties of the throne resulted in the chaos and anarchy of the First Intermediate Period.

Nefer-rohu foresees the coming of Amenemhet I and speaks of him in such familiar terms that scholars are convinced that his prophecy was actually written during the reign of Amenemhet (Erman 1927: 110–115; Pritchard 1955: 444–446).

The Song of the Harper dates to the First Intermediate Period, the era of disunity and civil and social unrest following the collapse of the Old Kingdom. It reiterates the above-mentioned concern for the loss of order and expresses the sense of futility in providing and protecting the "houses of eternity" (tombs) of the kings and nobility. In addition, the song offers an unprecedented philosophy of pessimism and skepticism concerning the shortness of life and the uncertainties of life after death (Lichtheim 1975: 193–197, 222–235; James 1979: 98; Pritchard 1955: 18–22; Parkinson 1991: 36–37; Simpson 1973: 57–74; Erman 1927: 14–29). Was this pessimism truly reflective of a new Dawn of Conscience, as Breasted suggested (1976), or was it simply an irreverent farce from some popular poem or drinking song?

The Middle Kingdom (considered by later generations of Egyptians to have been the golden age of Egyptian culture and history for its art, calligraphy and literature) also produced a popular piece of prose, known as the *Story of Sinuhe*, a work of historical fiction. It depicts the adventures of an Egyptian nobleman who fled into exile in Palestine, perhaps because he feared he would be implicated in the murder of King Amenemhet I, and only returns near the end of his life to be buried in his homeland. The story also presents Senwosret I (Sesostris) as a benevolent king who restores *ma'at* (truth, the world order, justice, etc.) and welcomes Sinuhe back to Egypt with open arms. It provides the earliest literary description of Palestine and portrays it in Bible-like fashion as a land of milk and honey: "Abundant was its honey, many sweets were made for me, and milk dishes of all kinds."

Scholars are fairly certain that they know the identity of the author of this famous story. His name was Achthoes. *The Papyrus Chester Beatty IV*, in the British Museum (#10684) avers that, "It was he who made a book as the Instruction of King Sehetepibre." The latter is the name taken by Amenemhet I when he assumed the throne. Achthoes is also known to have written the previously mentioned Instruction book entitled the *Satire of the Trades (*James 1979: 98; Parkinson 1997: 21–53; Erman 1927: 14–29; Pritchard 1955:18–22; Simpson 1973: 57–74; Lichtheim 1975: 222–235).

The Tale of the Eloquent Peasant, like so many of our surviving Egyptian literary texts, is also a product of the Middle Kingdom. In fact all of the manuscripts containing this story come from that era. It may be the mere chance of discovery, but it could also mean that, unlike other tales from the 12th Dynasty, this particular example did not enjoy continued popularity during the later New Kingdom. Social equity and the right of commoners to expect fair treatment at the hands of the nobility and the government are the central themes along with the unexpected eloquence of a peasant (Pritchard 1955: 407–410; Parkinson 1991: 64–65; Erman 1927: 116–131; Lichtheim 1975: 169–184; Simpson 1973: 31–49).

The Tale of the Two Brothers, a work composed in Dynasty 19 (ca. 1210 BCE), has elements similar to the story of Joseph and the wife of Potiphar in Genesis 39. But, as the noted Coptic scholar Plumley pointed out in 1958, the two stories have some common aspects, "but it would require much greater similarity of detail between the Egyptian and the Hebrew stories to justify the oft-made suggestion that the Egyptian story is the origin of the incident described in Genesis."

Writing in Egypt in its Literary Context. Fig. 18 Golden Bowl of Djehuty. A solid gold bowl from the tomb of the General Djehuty. He served the Pharaoh Tuthmosis III. His tomb was found at Saqqara in 1824 but the contents were distributed and the site of the tomb is now lost. Louvre Museum. Photo by Jon Bodsworth. Used with his kind permission.

The Capture of Joppa, found with the *Story of the Doomed Prince* on the same papyrus (Harris, # 10060, Br. Museum), is an historical romance dealing with General Djehuty, who served Thutmosis III in his campaigns in Syria–Palestine (ca. 1504–1450 BCE) and depicts an event otherwise unknown in the official Egyptian annals. Djehuty outwits the city's defenders by having him and several Egyptian soldiers smuggled into Joppa in baskets (James 1979: 112; Erman 1927: 167–169; Pritchard 1955: 22–23; Simpson 1973: 81–84) (Fig. 18).

Space permits only the briefest listing of several other categories of Egyptian writing that have survived in great quantities on papyri and ostraca, as well as in the form of inscriptions and paintings on the walls of tombs and temples. The reader interested in further study will find more scholarly information and examples of texts in the linked sites. These additional genres of Egyptian literature include both secular and religious songs. In addition to the above-mentioned Harper's Songs, Egyptian love songs, dating to the New Kingdom, have also survived. These have a timeless quality and can be very romantic and erotic (Foster 1974; Simpson 1973: 296–326).

Egyptian Poetry is found in several forms, including: hymns to the gods and king; love poetry that is both beautiful and passionate, and the above-mentioned Songs of the Harper, filled with uncharacteristic pessimism and practical questioning of time-honored beliefs. Some of this poetry has been compared to the Biblical Song of Songs. It has also been noted that

Egyptian love lyrics "are part of the same ancient tradition of erotic verse which we find in the cultures of the Fertile Crescent" (Kaster 1968: 220–233; Erman 1966: xxxi–xxxviii; Erman 1927: lviii–lxii; Lichtheim 1975: 11–12; Simpson 1972: 169–326) (Figs. 19 and 20).

Egyptian hymns are not only dedicated to the gods of Egypt, but also to the kings. The most famous Egyptian hymn is the Hymn to the Aton (Aten), which, allegedly, inspired the wording in Psalm 104 in the Hebrew Bible. It is the earliest known monotheistic text in history (Pritchard 1955: 370–371; Simpson 1972: 289–295).

Egyptian letters have survived on papyrus dating as early as the Sixth Dynasty (ca. 2250 BCE). Many of the surviving letters were used as models in the education of scribes who were trained to master the style necessary for official, business, and interpersonal communication.

Egyptian Religious Texts constitute by far the greatest number of written Egyptian texts that have survived. The most common examples of this genre include the famous Pyramid Texts, the Coffin Texts, The Book of the Dead, Myths and Creation stories, Oracles and Prophecies, Hymns and Prayers, etc.

The most famous of the Egyptian Mathematical Papyri and texts is the *Rhind Mathematical Papyrus* (ca.1580 BCE). It is believed to have been composed by a scribe named Ahmose during the reign of King Ahmose Auserre in the Hyksos era. It is in the British Museum.

Egyptian Medical papyri and texts are fairly plentiful. The British Museum alone has eight examples. Three of the more important ones include *The London Medical Papyrus* (#10059) which dates to the 18th Dynasty, *The Chester Beatty Medical Papyrus VI* (#10686) and *Chester Beatty X* (a 19th Dynasty text dealing with aphrodisiacs). Perhaps the most famous medical text is the *Edwin Smith Surgical Papyrus*, which is housed in the New York Academy of Medicine. Breasted published a folio-sized edition on this papyrus in 1932. It is a remarkable, scientific

W

approach to the practice of medicine that deals with 48 different kinds of injury cases and covers surgical treatments for the head and thorax. Ancient Egyptians even knew that a mother's urine is the secret to the determination of the sex of an unborn baby. One of the remedies that it recommended for the treatment of facial wrinkles was described as a lotion that had "proved effective myriads of times." Another very important medical text, the *Ebers Medical Papyrus* (in Leipzig) offers some insights into Egyptian surgical techniques. There is a section on the heart and its vessels, and one of its remedies calls for the use of castor oil as a laxative.

The Egyptian concern with the stars and planets led to serious study of astronomy. From the alignment of the pyramids with the stars to the many myths associated with the day and nighttime journeys of the sun, they have left us both physical and textual

Writing in Egypt in its Literary Context. Fig. 23 The Goddess Nut and the Book of Gates. This painted scene (from the ceiling of the tomb of Ramses VI (KV 9) in the Valley of the Kings, ca. 1141–1133 BCE) shows the upper half of the goddess Nut as she prepares to swallow her "son," the sun god Ra, at the end of his daily journey across the sky. The ceiling paintings portray astronomical themes as well as the various stages of the night journey of the sun god through the underworld. Photo by Brian Anderson. Used with his kind permission.

This scene is a continuation of the previous figure and shows the lower half of Nut's body where she gives birth to Ra at the beginning of each new day. The Book of Gates illustrates the Egyptian interest in astronomy and the universe as well as a new departure in their obsession with the afterlife and the underworld. Photo by Brian Anderson. Used with his kind permission.

evidence documenting their obsession with the universe in which they lived. The earliest evidence of Egyptian astronomical observation takes the form of a series of texts in the lids of coffins dating to the Ninth Dynasty (ca. 2150 BCE) (James 1979: 124–126).

In the New Kingdom, many of the royal tombs in the Valley of the Kings were decorated with scenes from the Amduat ("that which is in the netherworld") (Figs. 21 and 22).

These are found in the form of the *Book of the Day* and the *Book of the Night* in a burial chamber in the tomb of Ramses VI (1144–1136 BCE). These books deal with the day and night journeys of the sun god Ra – in the night, as he travels through the body of his mother, Nut, the goddess of the heavens, and in the day, as he travels across her body, after she gives birth to him once again in the endless cycle of birth, death and regeneration (Silliotti 1997: 64–6); Allen 1988: 38–49; Hornung 1992: 95–113; Shaw and Nicholson 1995: 29, 62, 79, 106, 273, 290, and 299) (Figs. 23 and 24).

Examples of Egyptian writing have survived in fairly great quantities but there are considerable lacunae in our textual knowledge. These lacunae are the result of damage to portions of extant texts as well as to the destruction of tremendous quantities of texts recorded on perishable materials which did not survive the ravages of nature and time. We are indebted to the Egyptians for their strong desire to record their history, religious and philosophical beliefs, as well as the fruits of their imagination and scientific, astronomical, medical, mathematical, and biological inquiries. When considering the great intellectual and cultural debt that the modern world owes to this Egyptian legacy, we can only regret that we have thus far been unable to attain the even greater quantities of writings that remain outside of our reach and understanding.

Writing in India

This article deals first with the evolution of writing in India in chronological order, then with the uses of writing.

Indus Civilization (c.2600–1900 BCE): A Forgotten Logosyllabic Script

The Indus or Harappan Civilization flourished in and around the Indus River in present-day Pakistan and western India c. 2600–1900 BCE. The most extensive urban culture of its time, it had its own script, which perished without descendants when the Indus cities and their urban life-style collapsed. Thousands of short inscriptions have been preserved, mostly seal stamps and their impressions (Fig. 1). Because the Indus script has no obvious affinity with any other script (a debated issue) and because there are no multilingual texts, it is exceedingly difficult to decipher.

Writing in India. Fig. 1 A seal stamp (size 20 × 20 mm) from Mohenjo-daro, engraved with the figure of a bison feeding from a trough and above it, a row of Indus script signs. The impression (in mirror image) was read from right to left. Photo Erja Lahdenperä for the University of Helsinki, courtesy Archaeological Survey of India.

Indus merchants sailed to the Gulf and Mesopotamia, where about 40 seal stamps with Indus script have been found. Like the Mesopotamian seal cylinders, they were used to seal containers of goods to prevent unauthorized opening. The Mesopotamian seal inscriptions contain names and titles of the seal owners, and so do probably the Indus seal inscriptions. It is also likely that the Indus script functioned like the Mesopotamian cuneiform script.

Cuneiform writing started as the world's oldest script, Archaic Sumerian (c. 3300–2900 BCE). Initially pictographic, its signs depicted human beings and animals and their body parts, plants and other things. Written on clay with wedge-shaped lines, however, the original shapes became unrecognizable, but the cuneiform script remained a logosyllabic writing system. Each sign either denoted the depicted word (*logos* in Greek)—an arrow-shaped sign Sumerian *ti* 'arrow'—or 'syllabically' its sound irrespective of its meaning —the arrow-shaped sign could also stand for Sumerian *ti* 'life' or *ti* 'rib'.

When the Indus script was created c. 2600 BCE, all the existing scripts were of the logosyllabic type. The Egyptian hieroglyphs and the proto-Elamite script (used widely in the Iranian plateau) were both inspired by the Archaic Sumerian script in the late fourth millennium BCE. The Indus people probably got the idea of writing from the proto-Elamites, but used their own traditional symbols and invented new ones while devising their own script.

In 2004 it was asserted that the Indus script is no real writing system reproducing speech, but only a collection of non-linguistic symbols. However, it radically differs from such symbols widely used in and around the Indus Valley for centuries right until the Indus script came into being. These earlier symbols, called 'potter's marks' because they are mainly found on ceramic vessels, usually occur one by one, whereas the signs of the Indus script occur in long and regular rows, with repeated sign sequences. The script emerged when the weights and measures were standardized and the society became more stratified and completed large and complex building projects.

The Indus script has been "deciphered" more than a hundred times. Most attempts assume the underlying language to be Indo-Aryan, which however was hardly spoken in South Asia before 2000 BCE. The horse is a very important animal in the Rigveda, the oldest surviving Indo-Aryan text composed by 1000 BCE, but the horse is not found among the many animals represented in the Indus art. On the other hand, the Rigveda contains some Dravidian loanwords. Dravidian languages such as Tamil are now mainly spoken in South India, but one (Brahui) survives in Baluchistan and the Indus Valley. Systematic and cross-checked interpretations for more than twenty signs (out of c. 400) based on the Dravidian hypothesis have been presented and won some recognition, but generally speaking the Indus script is still considered undeciphered.

Vedic Times (c. 1300–500 BCE): Accurately Memorized Oral Literature

After the collapse of the Indus Civilization c.1900 BCE its script was forgotten. The Indo-Aryan speakers, who came to South Asia from the northwest during the second millennium BCE, were illiterate, but created sophisticated oral poetry. Over thousand hymns were assembled into a collection called Rigveda c. 1000 BCE. Elaborate repetition techniques developed to assist its accurate memorization have safeguarded the Rigveda from the hazards of oral transmission. Learning the Rigveda by heart takes five years of hard work in early youth, and keeping it in mind requires daily repetition. This way of memorizing Vedic texts still goes on, and their human repositories often are more reliable than manuscripts. The rules created for the preservation of oral literature have been scrupulously observed, and their further development led to astonishing achievements in the study of phonetics and grammar without the aid of writing in the first millennium BCE.

As their standard beginning ("Thus have I heard…") indicates, the earliest Buddhist texts of the fourth and third centuries BCE were likewise orally transmitted.

Old Persian Rule (c. 500–326 BCE): Writing Re-introduced — Aramaic and Kharoṣṭhī

Around 518 BCE, Darius the Great conquered the northern and southern parts of the Indus Valley: they were attached to the Persian Empire as the provinces of Gandhāra and Hinduš for the next two centuries — until Alexander the Great took them over and soon thereafter died in 323 BCE. The Persian bureaucracy used the *Aramaic script* all over the Empire, from Egypt to India.

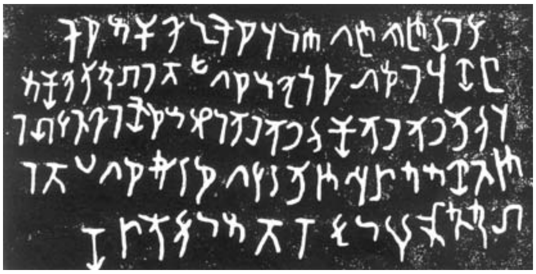
Aramaic is a variant of the Semitic consonantal alphabet which had been created in ancient Syria much earlier (c. 1600 BCE) on the basis of the uniconsonantal signs of the Egyptian script (where signs could express words that contained 1, 2 or 3 consonants). Semitic and Hamitic (i.e., Egyptian) languages can be understood even if the vowels are left unwritten, as they usually are, but the consonantal alphabet is not so suitable for writing other languages.

The Aramaic script was adjusted for writing Indo-Aryan languages by adding markings that express vowels to the consonantal signs; if such an additional sign was missing, the respective consonant was understood to be followed by the most frequently occurring short vowel *a;* consonant groups were expressed by combining consonant signs together. Signs for consonants not represented in the Aramaic script were also created. Why this new syllabic alphabet is called *Kharoṣṭhī* is a much debated question. Kharoṣṭhī greatly resembles the Aramaic script, also in being written from right to left. It was used in the northwest of the Indian subcontinent until c. 200 CE, and in Central Asia until c. 600 CE. (Fig. 2).

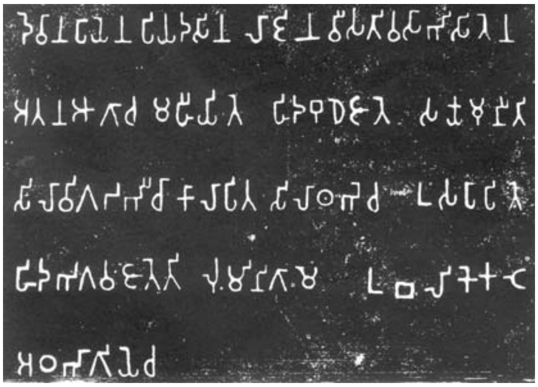
From the Mauryas to the Guptas (c. 320 BCE—550 CE): The Brāhmī script

After Alexander's death, the Persian provinces Gandhāra and Hinduš were quickly incorporated in his emergent empire by Candragupta, the founder of the Maurya dynasty (c. 325–183 BCE). Candragupta's grandson Aśoka (in power c. 268–232 BCE) is one of the most famous rulers of India. Aśoka's rock and pillar edicts, distributed all over his large empire, are the earliest directly preserved historical records of ancient India. Written in local dialects they also provide precious information about the prevailing linguistic situation. Aśoka's inscriptions were written in the Kharoṣṭhī script, in the *Greek script* (introduced by Alexander and used by the succeeding Indo-Greeks in the Indo-Iranian borderlands) and in the *brāhmī script,* which is the basis of most writing systems used in South Asia in later times. The Indian tradition considers brāhmī as an invention of the creator god Brahmā, who is depicted as holding a palm leaf book in the hand.

The brāhmī script is a syllabic alphabet functioning like the Kharoṣṭhī, but with its distinction of short and long vowels and different initial vowels still more perfectly adjusted to Indo-Aryan languages, and written from left to right. It may have been commissioned by Aśoka for his rock edicts around 260 BCE; some improvements in the script appear in the pillar edicts about two decades later (Fig. 3). In that case the brāhmī script is based on the Kharoṣṭhī and Greek

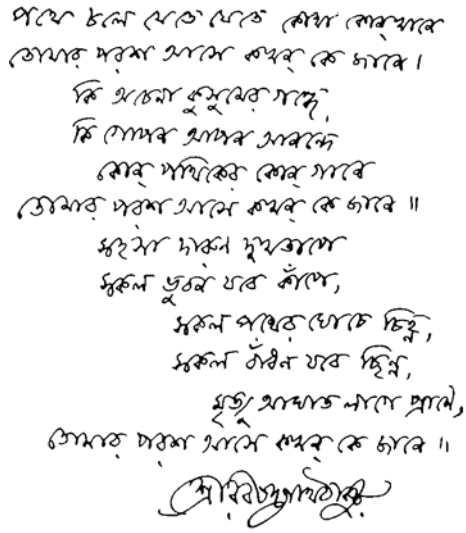


Writing in India. Fig. 2 Kharoṣṭhī script in the Shahbazgarhi rock edict of Emperor Aśoka (c. 260 BCE). Read from right to left.



Writing in India. Fig. 3 Brahmi script in the Rummindei pillar edict of Emperor Aśoka (c. 240 BCE). Read from left to right.

Writing in India. Fig. 4 Siddham script in the "autographed signature of me, Śrī-Harṣa, the overlord of great kings", preserved in a Sanskrit inscription engraved on a copper tablet from Banskhera, dated 628 CE.



Writing in India. Fig. 5 Bengali script in an autographed poem by the Nobel laureate Rabindranath Tagore (1861–1941).

अभ्यावहति कल्याणं विविधं वाक्सुभाषिता ।
सैव दुर्भाषिता राजन्ननर्थायोपपद्यते ॥ ३५५३ ॥

Writing in India. Fig. 6 Devanāgarī script in a quotation from the Sanskrit epic Mahābhārata (Otto Böhtlingk, Indische Sprüche III, St. Petersburg 1895): "O King, a kindly spoken word brings along many kinds of blessings, a harshly spoken word causes misfortune."

முகத்தா னமர்ந்தினிது நோக்கி யகத்தானும்
இன்சொலி னஃதே யறம்.

Writing in India. Fig. 7 Tamil script in an edition of the Old Tamil classic Tirukkura (aphorism 93): "Virtue consists in speaking sweet but truthful words with a smiling face and a friendly look".

scripts. This recent conception about the origin of the brāhmī is however contradicted by the likewise recent discovery of potsherds inscribed with brāhmī characters in stratum J (c. 450–350 BCE) at Anurādhapura in Sri Lanka. If the dating is correct, these finds support the traditional derivation of the brāhmī script from the Phoenician consonantal alphabet long before Aśoka. Alexander's admiral Nearchus speaks of Indians sending each other letters written on cotton cloth, but this statement limited to the northwest may refer to Persian administration in Aramaic. According to other Greek authorities quoted by Strabon, the Indians did not use writing. The Greek ambassador Megasthenes stationed in the Mauryan capital c. 300 BCE specifies that the Indians had only unwritten laws.

Post-Classical Period (550 CE Onwards): Diversified Scripts

Almost all the writing systems that are nowadays being used to write South Asian languages go back to the brāhmī script, which remained in use until the collapse of the Gupta Empire c. 550 CE. The late variety of brāhmī used in North India was c. 600 CE transformed into two principal types of script.

The *siddham* or *siddhamātṛkā script* (Fig. 4) was in general use in North India until c. 1000 CE, and the *Bengali* (Fig. 5) and *Tibetan scripts* and the *śāradā script* of Kashmir are derived from it. The siddham script spread also to Central and East Asia, being still used to write Sanskrit magical formulae in Japan.

The *nāgarī* (later called *devanāgarī*) script has been used to write especially Sanskrit (Fig. 6), Hindi, Marathi and more recently Nepalese. The *gurumukhī script* of the Punjabi language and the *Gujarati script* also go back to early variants of the nāgarī script. The southern Vijayanagara empire (1336–1565) used the *nandināgarī script* imported from Maharashtra.

Tamil was written in the brāhmī script from the second century BCE. This South Indian variant of brāhmī is the basis of the relatively simple *Tamil script* used today (Fig. 7), as well as of the much more complex *grantha script* used in Tamil Nadu for writing Sanskrit, which in turn is the basis of the *Malayāam script* used in Kerala. *Kannada* and *Telugu,* the two further literary members of the Dravidian language family in South India, are written in closely related script derived from the Cālukya kingdom. The Sinhala language of Sri Lanka is written in the *Sinhala script* that has evolved from the Sri Lankan variant of brāhmī.

The *Arabic script* imported to South Asia from Persia by the Muslims since the 8th century CE has been used to write especially Persian — the court language of the Moghuls — and (with important modifications) Urdu — the Muslim variant of Hindi — and Kashmiri, and various minor Indo-Aryan and Iranian languages spoken in Pakistan. The *Roman alphabet* was brought to South Asia by the European colonialists who came to stay with the Portuguese in 1498, and which is used for writing not only European languages but also Konkani spoken around Goa.

Uses of Writing

Inscriptions and Coins

Because they usually can be exactly located and also dated, inscriptions engraved in stone are very important sources of political and cultural history in India. There is a continuous inscriptional tradition ever since Aśoka's edicts (from c. 258 BCE), but their number increases substantially only c. 700 CE. From c. 300 CE, royal grants of villages and the like were engraved on sealed copper tablets. Altogether c. 100.000 inscriptions in stone or metal are known today. Thousands of inscriptions in Indian languages and scripts have been discovered also outside South Asia, in Egypt, Afghanistan, Central Asia, China and most parts of South East Asia.

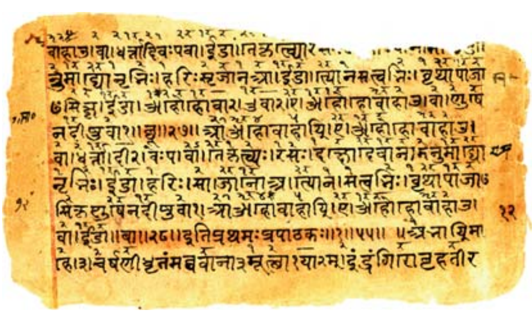
Numismatic material plays a crucial role also in the history of the dynasties of Iranian origin in the centuries around the beginning of the Christian era. The Indo-Greek kings are known almost exclusively from their coins. Being bilingual, these coins moreover opened up the ancient history of India. The text written in the Greek script and language on the obverse side is rendered in the Prakrit language written in the Kharoṣṭhī script on the reverse side. James Prinsep in the 1830s worked out how to read Kharoṣṭhī and applied the results to the Kharoṣṭhī inscriptions of Aśoka. These readings in turn opened up the secrets of the forgotten brāhmī script.

Manuscripts

The book in ancient India was usually written on long leaves of the wine palm *(Borassus flabelliformis),* which had first been cut into regular rectangular form. Wooden covers of the same size were usually put on both sides of the bundle to protect the leaves from breaking. The ready bunch of leaves and covers was then pierced in one or two or three places in the middle, so that a rope could be inserted through the leaves to bind them together into a bundle. The long binding rope had some stopper at both ends which prevented it from coming out when the book was opened and the rope loosened: the reader places the bundle on the ground, and then turns the leaves over from one pile to another. When the book is closed, the leaves are collected together, the rope is tightened, and its long loose end is wound many times around the bundle. "Binding" the leaves thus together has given the ancient Indian book one its Sanskrit names, *grantha.*

While writing on the empty leaves the scribe would leave some margin around the edges and the cord-holes. This was a precaution to secure that no text would be lost if the leaf was broken at its edges. The leaves would also be numbered, by putting a running number in the right or left margin of the obverse or reverse side. The margins could also be used for inserting in them corrections (for letters marked in the text with symbols of cancellation or painted over), supplementary texts (parts of text accidentally omitted in copying but noted afterwards), glosses (explanations of difficult words or expressions) or subtitles (indicating the contents of the text at that place) (Fig. 8).

The colophon at the end of the manuscript often contains not only the name of the work and its author but also the name of the scribe and possibly his genealogy and domicile and the date of completing the manuscript. Just as the author of a literary work, the scribe also starts with an auspicious word and a prayer, most frequently an obeisance to Gaṇeśa, the elephant-headed god of success, who is expected to see the task to its conclusion and to remove any obstacles. Gaṇeśa is thought to have written down the great epic Mahābhārata at the dictation of its compiler Sage Vyāsa: as the



Writing in India. Fig. 8 Verso side of leaf 12 of a paper manuscript written in the devanāgarī script, dating from the 17th century. The manuscript contains the Āraṇyaka Gāna of Sāmaveda. Sāmavedic songs composed c. 1000 BCE are the world's oldest known music. The small numeral signs over the lines of text are musical notation. Textual divisions are highlighted with red colour. Photo Asko Parpola.

W

divine scribe he broke one of his tusks and used it as a stylus. This agrees with the South Indian practice of scratching signs on the surface of the leaf by means of a sharp iron stylus. The incised lines were afterwards made more visible by means of the juice of plants rubbed over the leaves. In North India, the scribe would use ink (made of soot) and either a brush or a pen made of reed (Fig. 8). The same methods were used if the manuscript was illustrated with miniature pictures — painted in several colours in North India, incised in South India (from Orissa to Tamil Nadu and Kerala).

In northwest India, parchment may have been used for writing during the Iranian rule, since Sanskrit *pustaka* 'manuscript' or 'book' is an Iranian loanword denoting 'book' and 'hide, parchment, bark' in the donor language. Birch bark was used as writing material in Kashmir. Paper started being used in North India around 1000 years ago, but in South India much later. Paper used to be cut in long rectangular leaves which imitate the shape of the traditional writing material, the palm leaves (Fig. 8). The same applies to thin wooden plates that have likewise been used as writing material, especially in Sri Lanka and in communities of Indian origin in South-East Asia.

Normally manuscripts did not survive long on account of the climate and insects, even if they were treated with vegetable oils or kept in smoky places avoided by insects. Palm leaves usually last maximally some three or four hundred years. In exceptional circumstances palm leaves have survived much longer, however: the oldest manuscripts are from the first centuries CE and come from the dry climate of Central Asia. There they have been kept in pottery vessels — exciting discoveries of Buddhist birch bark and palm leaf manuscripts have been made in recent years in Afghanistan and northern Pakistan. Reed baskets *(piṭaka)* have provided another and more usual implement for storing manuscripts: at one time the entire Buddhist canon could be put into three baskets. In ancient India, temples, monasteries, royal palaces and even private persons had manuscript libraries, which could contain even tens of thousands of volumes. Today millions of Indian palm leaf or paper manuscripts survive in public and private libraries in and outside South Asia.

On account of their poor durability, texts to be preserved in writing had to be copied over and over again, which led to accumulating mistakes. Such copying mistakes have distorted literary texts, but if a number of manuscripts are available, their comparison may enable reconstructing a genealogy of copying and reconstituting the original text.

Palm leaves have been used in South India until the early twentieth century not only for writing literature, but also for book keeping and for legal documents, with seal impressions attached. On the other hand, literature — especially voluminous Vedic texts — has been handed down also in a millennial oral tradition until the present day.

Writing in Japan

Christopher Seeley

The modern Japanese writing system employs predominantly a combination of Chinese characters (1945 are taught in school education) and syllabic signs called *kana* (close to 100 in total, in two sets, viz. the angular *katakana* and the more rounded *hiragana*) (Henshall 2003). These are used together with an admixture of other signs such as Arabic numerals and Roman letters. The following sentence is an example of how the different elements function together:

□□□□□□□□□□□、□□□□□□□□□ □□□□□□□□□□□□。*Otōto wa sugoi esu-eru mania de, jūnigatsu ni mata Suisu e iku koto ni natte imasu.* 'My younger brother is a huge fan of steam locomotives, and it has been arranged for him to go to Switzerland again in December.' Chinese characters are used for the noun *otōto* 'younger brother', the suffix *-gatsu* 'month (of the year)' and the first part of the stem of the verb *iku* 'to go'. *Hiragana* are employed for elements which include particles such as *wa* (topic indicator), *e* 'to, towards', for the adjective *sugoi* 'great; awful' and the second syllable of *iku* and also for the post-verbal construction *koto ni natte imasu* 'it has been arranged to ---'. *Katakana* represent two European loanword items (*mania* 'fan, enthusiast' and *Suisu* 'Switzerland'), while an acronym-type European loan (*esu-eru*) is represented by upper case Roman letters. Arabic numerals are used here to represent *jūni* 'twelve' in *jūnigatsu* 'December', which can otherwise be written all in characters, viz. □□□ (id.).

Although still very complicated, the system in use today represents a substantial simplification of that which was employed in the early part of the twentieth century. It reflects a heritage of cultural and linguistic history in Japan that extends back to early in the first millennium AD.

Around 400 AD the Japanese, who at that time had no writing of their own, actively adopted Chinese writing. At this very early period, it was the Chinese language, not Japanese, which was represented directly in written form. Due to the difficulties associated with using what for the Japanese was a foreign language, together with a very large and complicated character set, initially there was heavy reliance on Chinese and Korean scribes (Seeley 2000: 3–15).

As time went by, the Chinese script was adapted to represent the Japanese language, sometimes directly, but often in a convoluted manner. The *Kojiki* (*Record of Ancient Matters*) of 712, notable as the earliest large-scale compilation to have survived to the present, constitutes a useful example of such adaptation. The *Kojiki* preface is in Chinese, which was appropriate as the most formal style in a document addressed to the sovereign; the main part of the text is in a hybrid form which reflects Japanese influenced by Chinese (selected by the compiler with the stated aim of ease of reading [!]). The Japanese songs interspersed in the text are represented by Chinese characters employed for their sound value so as to minimise the ambiguity of reading in material of an oral nature (Seeley 2000: 40–46). At an early period, the Japanese had the means to represent their own language directly in writing, but the overwhelming prestige of Chinese culture meant that more often than not they chose a Chinese-orientated style.

Despite the high standing of written Chinese in Japan (and Japanese attempts at Chinese composition), direct representation of Japanese also had its place, and this more straightforward form of writing enjoyed a substantial rise in popularity from around 900 AD. This was due to a development early in the ninth century in the context of Buddhist works in Chinese. Abbreviated Chinese characters employed for their sound value as phonograms – the forerunners of modern *katakana* (used today for such purposes as representing loan-words of mainly European origin) and *hiragana* came to be used quite extensively as a convenient means of annotating the text, albeit sometimes only minimally and sporadically, to help read or 'decode' it as Japanese. Abbreviation was achieved through a process of (1) writing rapidly (cursively) and thereby omitting strokes (e.g., □›□ *me*,□□›□ *ha*) or (2) isolating one part of a character phonogram and taking it to represent the whole (e.g. □□□ *ho,* □›□ *ka*). After a time, *katakana*-type signs tended to be favoured for utilitarian purposes such as annotation, while *hiragana*-type signs came to be used extensively for Japanese poetry and prose. Women were seldom given the opportunity to acquire grounding in Chinese characters, and the convention arose whereby writing in phonograms of the cursivised variety tended to be associated with women. This is reflected in the early term for *hiragana*-type signs, *onna-de*, and 'women's hand/script'. This is best understood as meaning the script typically used by women rather than exclusively by them, for men certainly sometimes employed kana of this type (Seeley 2000: 59–89).

W

While some Japanese texts were written entirely in kana, much more commonly there was at least a small admixture of Chinese characters. In the early period, characters were sometimes employed as a convenient means of representing Chinese loan morphemes which involved sound segments difficult to represent in a still emergent system of kana signs. Orthography of this general type, which involved a combination of characters and kana, gradually assumed a position of increasing importance; the role played by Chinese characters as a guide to disambiguating what would otherwise be a Japanese text consisting of a long string of kana signs spaced equidistantly should not be underestimated.

In spite of the above developments, broadly speaking, the cultural and linguistic importance of China continued to be very strong. Written Chinese, or rather an approximation of it, continued to be widely perceived as highly prestigious until modern times, is being used even at the beginning of the Meiji period (1868–1912) in some Japanese newspapers. Increasingly, though, the leaders of Japanese society were being influenced by the West. As a result of extensive debate on language and script, a movement evolved around the end of the nineteenth century with the aim of bringing written language more in line with spoken language (the *Genbun itchi* [Unification of Speech and Writing] movement) (Twine 1991), and there was also support in some quarters for reducing the number of different Chinese characters in general use. In the year 1900 the Education Ministry (Monbushō) published a list of about 1,200 characters for use in primary school texts, together with a standardised set of kana signs and a partially simplified form of kana usage. However, there was still strong opposition from conservative elements to reform the writing system.

A radical turning point in the Japanese writing system occurred in the 1940s, following Japan's defeat in the Pacific War. In that very different environment, simplification of the written language and script was espoused as part of the movement to promote democracy. Changes effected included the adoption and promulgation in 1946 of a list of 1850 Chinese characters approved for active general use called the *Tōyō kanjihyō* (List of Interim Use Chinese Characters), followed by several supplementary lists aimed at restricting the number of readings associated with individual characters and increasing the number of officially approved simplified character shapes (e.g., □□□, □□□). A more rigorous restriction took place in the area of given names which parents chose for newborn children: whereas previously it was permitted to use any Chinese characters out of a potential corpus of tens of thousands, from late 1947 parents found themselves restricted by law in choosing from just the 1850 in the Interim Use List, or alternatively to use kana. This change was seen by many as excessive, and in 1951 this restriction was eased through a supplementary list of additional characters for use in names. 1970 onwards a significant relaxing of guidelines and regulations regarding the range of Chinese characters were used. The year 1981 saw the Interim Use List replaced by a modestly expanded new list (1945 characters) called the *Jōyō kanjihyō* (List of General Use Chinese Characters), which was given the status of a guide (*meyasu*) for usage, and the name character list has been repeatedly expanded, consisting now of close to 300 characters (Seeley 2000: 152–87).

In the Interim Use List era and before, advocates of script reform argued that kana or Romanisation should be adopted for Japanese because of the difficulties associated with mechanical production of text. A manual typewriter for Japanese was devised early in the twentieth century, but it required a specialist operator, and only about ten pages a day at most could be produced. The strength of the argument for script simplification was, however, compromised in the late 1970s with the development of a word-processor which featured Japanese language input in Romanisation or kana and output in conventional (character and kana) Japanese text. The mid 1980s then saw the appearance of portable and affordable machines which gave consumers the ability to handle Japanese text with output which encompassed the Chinese characters contained in a standard corpus of about 6,300 Chinese characters determined for universal data exchange by the Japan Industrial Standards Institute (Gottlieb 2000; Seeley 1994).

The popularisation of word processors and computers from the 1980s for Japanese has led to a significant rift between the number of characters taught in the school system and the corpus by more than three times the size accessible via computer-generated text. This discrepancy needs to be addressed and somehow accommodated. Despite associated problems such as this, what seems certain is that the position of Chinese characters as a central feature of the Japanese writing system is assured for the foreseeable future.

Writing: Maya Writing

Tom Jones

Some dozen or so writing systems have been identified as having been in use at one time or another in ancient Mesoamerica, all sharing a number of general traits that include (1) pictographic signs, clearly derived from things seen, used in combination with wholly abstract signs, the derivations of which remain obscure; (2) a reading order that generally proceeds from top to bottom and from left to right; (3) a vigesimal number system (base 20) with a dot representing the unit, generally in conjunction with individualized signs for numbers of higher orders of magnitude, though in certain areas, in conjunction with bars for "5" and other signs for "0" to express higher numbers; and (4) a shared, compound, cyclical calendar of 260 × 365 (18,980) days' duration, expressed with readily identifiable calendrical elements such as numbers, day names, year signs, and periods of various magnitude.

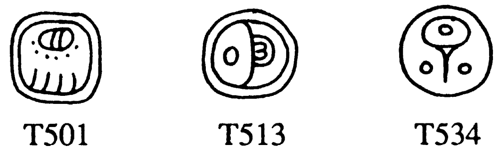
The most sophisticated writing system – and certainly the most intriguing – of Mesoamerica, and that which will serve as the basis for this discussion, is the "hieroglyphic" writing of the Maya region. Examples of Maya hieroglyphic writing are known from many sources: from carved monumental inscriptions in stone and wood, painted stucco-coated, screen-fold, paper books, or "codices", painted and carved ceramic pots, cups, bowls, and dishes, and from other portable artifacts of stone, shell, ceramic, and bone. The visual style, syntax, and content of the writing was shaped by both the nature of the medium upon which it appeared and the message to be conveyed.

Though open to doubt for many years, there is no question today of the Maya writing system not being true writing. It follows linguistically logical rules of syntax, phonetic construction, and semantic expression, although with the same willful departure from those rules as that of creative writers of our own culture – even, at times, to the point of whimsical defiance. The Maya hieroglyphs were capable of accommodating the full range of both the sounds and the syntactical structures of spoken Mayan. Indeed, the relatively narrow range of subject matter of extant Maya writing is surely more of a reflection of its differential survival on imperishable artifacts than of any limitations in the writing system itself.

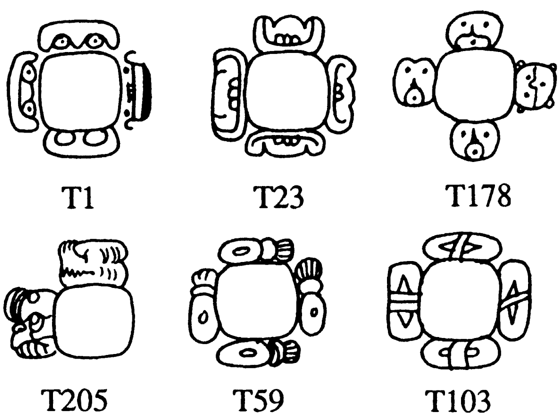
The typical Maya monument inscription is composed of a number of tightly formed glyph-blocks arranged in vertical columns and horizontal rows, with the glyph-blocks formed of glyphic elements of two general sorts: relatively large ones – known as "main signs" – generally positioned at the center of glyph-blocks and occupying most of the area (Fig. 1), and smaller ones – known as "affixes" – often positioned before, atop, after, or beneath the main signs, and sometimes (in the absence of a main sign) forming clusters of their own (Fig. 2). In his 1962 *Catalog of Maya Hieroglyphs*, Eric Thompson attempted a classification of all the known glyphs of his time, assigning to "affixes" the numbers 1–370, and to "main signs" the numbers 501–856, with what he called "portraits" receiving the numbers 1000a–1087. The study and discussion of Maya writing have benefited enormously by the preferred use of these *T*-numbers (as they are called) over the arbitrary nicknames and labored descriptions of individual glyphs that once necessarily dominated their study.

Nevertheless, epigraphic study since the publication of Thompson's *Catalog* has shown that this main sign/affix distinction is an artificial one. For while it is true that certain glyph designs seem only to have been employed as main signs and that certain others were used exclusively as affixes, a considerable number of glyphs are known to function in both categories with no apparent change in their semantic or phonetic value. This is easily seen in the variety of ways in which the well-known *bakab* title is recorded in the inscriptions (Fig. 3). Size, then, is not necessarily correlated with significance.

While not entirely true, it is generally the case that both the reading order of the glyph-blocks that comprise a text (typically laid out in a grid-like



Writing: Maya Writing. Fig. 1 Main signs with *T*-numbers.



Writing: Maya Writing. Fig. 2 Affixes with *T*-numbers.

arrangement of columns and rows) (Fig. 4) and the internal elements of the glyph-blocks themselves proceed from upper-left to lower-right (Fig. 5).

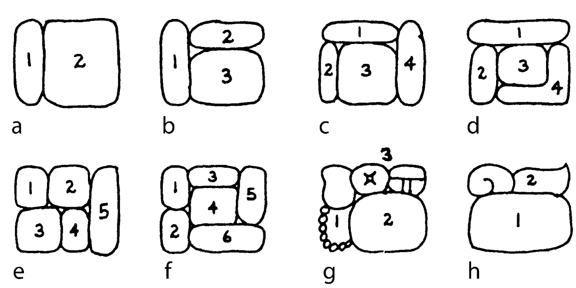
Texts composed of more than one column and one row are usually read from the upper-left corner, two glyphs from each row, descending two columns at a time to the bottom. The next two columns are read in the same manner, and so forth, to the end of the text. The reading order of uneven or exceptionally disposed texts necessarily depart from the ideal form just described (Fig. 4). Departure from the general principle of upper-left to lower-right is probably more common in the reading order of glyphic elements within the glyph-blocks than in the organization of the latter in the texts. This is, no doubt, due in some part to what were apparently culturally prescribed arrangements of certain hackneyed terms such as the **AHPO** superfix on emblem-glyph titles that identify lords of specific Maya cities (Fig. 5g) or the -**NAL** superfix on certain Maya place-names (Fig. 5h), in greater part to the flexibility of the glyphic elements in both size and shape, and in large part to the creativity of individual scribes.

Though an argument over whether the hieroglyphic signs were of ideographic, morphemic, or phonetic value raged for decades in the world of Maya scholarship, today there is general agreement that there are glyphs of both morphemic and phonetic kinds, and that there is at least one glyph that always functions as a semantic determinitive. About 180 distinct glyphic elements have so far been demonstrated to carry the phonetic values of some 77 consonant–vowel (cv) syllables, leaving undetected but 23 of the 100 probable sounds employed in the ancient script. At the same time, in addition to the signs for the 20-day names, about 90 glyphic elements have been demonstrated to represent consonant–vowel–consonant (cvc), or even more complex, morphemes. Thus, words can be recorded by using a single morphemic sign (should there exist one that signifies the desired word), by assembling a phonetic construction from cv-signs that sound it out, in which case the final vowel sound is dropped, or by combining the two, perhaps using a cv-sign as a (silent) phonetic complement to reinforce the pronunciation of the intended word.

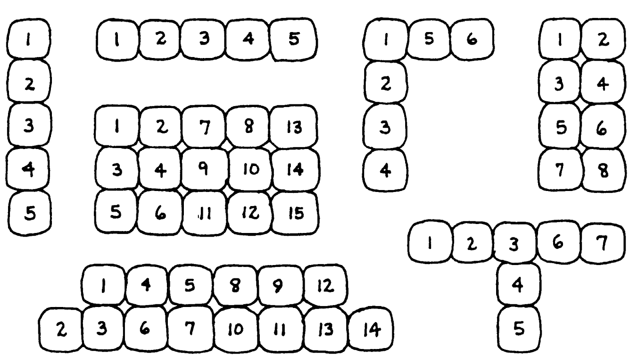
In addition to the aforementioned options available to the Maya scribe, there were four further features of the writing system:

1. Allographs are multiple signs that were used interchangeably to express the same phoneme. The sound *u*, for example, could be expressed by any one of at least a dozen different allographs (Fig. 6a).
2. Puns are single signs used to express homophonous words of multiple semantic value. As an example, the Mayan word *chan* means "snake", "sky", and "four". The glyphs for these three meanings could be used interchangeably to convey the sound *chan*, with

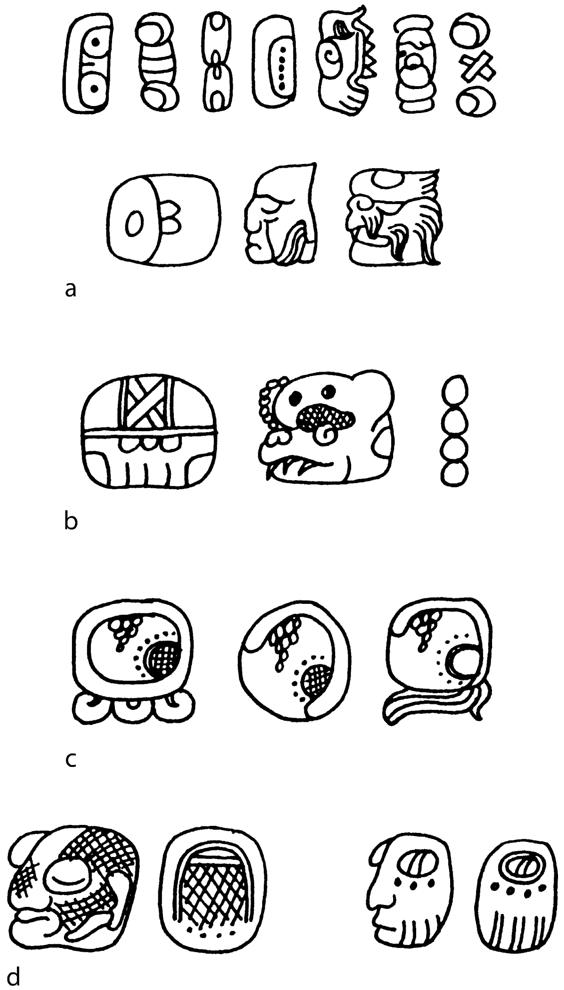
Writing: Maya Writing. Fig. 3 Three spellings of the title *bakab*. All are constructed *ba-ka-ba*. Note the variation in size of the elements, substitutions and the use of head variants.



Writing: Maya Writing. Fig. 5 Reading order for the elements within a glyph-block.



Writing: Maya Writing. Fig. 4 Reading order for the texts.



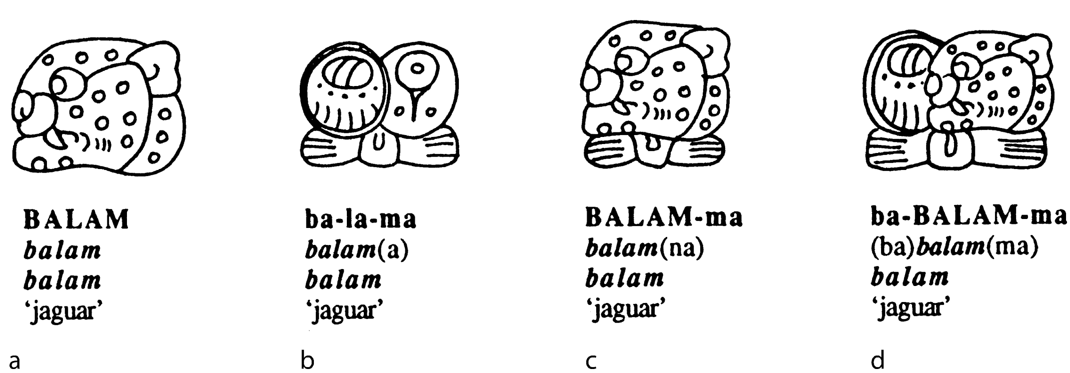
Writing: Maya Writing. Fig. 6 (a) Ten allographs for the phoneme *u*. (b) Three signs for chan: “sky”, “snake”, and “four”. (c) Polyvalency of T528, as the day-name *Kawak*, the phoneme *ku*, and with phonetic complement **ni** to spell **TUN**-(ni). (d) Head variants for the phonemes **pa** and **ba**.

the intended semantic value, which was sometimes multiple, to be inferred from the context (Fig. 6b).

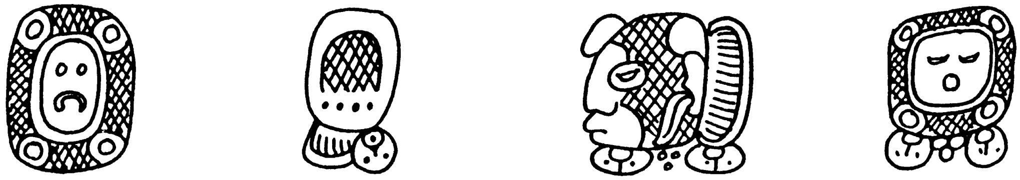
3. Polyvalent signs are single signs of multiple phonetic and/or semantic value which, again, are best understood from their context. Thus when the sign T528 appears framed by the day-name cartouche (serving as a semantic determinant), it is understood to represent the name of the day *Kawak*; when it appears suffixed with T116, the sign for **ni** (serving as a phonetic complement), it is understood to represent the term **tun** (“stone” or “year”); and when it appears with no affixes, it *usually* represents the syllable *ku* (Fig. 6c).
4. Head variants are main signs modified from their generally rounded forms into the profile heads of persons or monsters that retain their diagnostic markings (Fig. 6d).

The range of possible sizes of the various glyphic elements, their substitutability and variety of appearance (anthropomorphic, zoomorphic, and abstract), their use as cv syllables, cvc morphemes, and phonetic complements, all go toward accounting for the rich variety of visual expression that characterizes the Maya hieroglyphic writing system. Though many words could be written with a single glyph, those same words could also be expressed in other ways. As an example, the word for *balam* (jaguar) was variously expressed by using the sign that represents both the word and the concept (Fig. 7a), by using the signs for the syllables *ba*, *la*, and *ma* (Fig. 7b), by using the sign for **BALAM** with *ma* as a phonetic complement (Fig. 7c), or by using the **BALAM** sign with both **ba** and **ma** complements (Fig. 7d).

Similarly, *pakal* (shield) was expressed by using a sign that portrays a shield (Fig. 8a), by the signs for the three syllables *pa*, *ka*, and *la* (Fig. 8b,c), or by the **PAKAL** sign with a *la* phonetic complement (Fig. 8d). It will be noted that, in spite of their difference in visual effect, both the second and third of these examples are phonetic constructions of the syllables *pa-ka-la* – the second example substituting a head variant of the more usual *pa*-glyph.

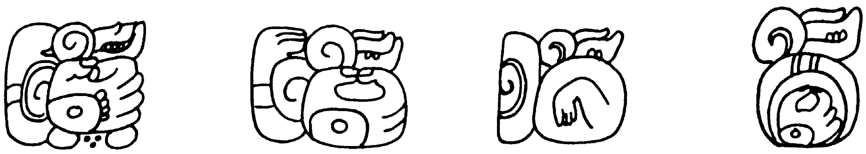


Writing: Maya Writing. Fig. 7 Four ways of spelling **balam** (jaguar).



a	b	c	d
PAKAL	**pa-ka-la**	**pa-ka-la**	**PAKAL-la**
pakal	**pakal**(a)	**pakal**(a)	**pakal**(la)
pakal	***pakal***	***pakal***	***pakal***
'shield'	'shield'	'shield'	'shield'

Writing: Maya Writing. Fig. 8 Four ways of spelling **pakal** (shield).



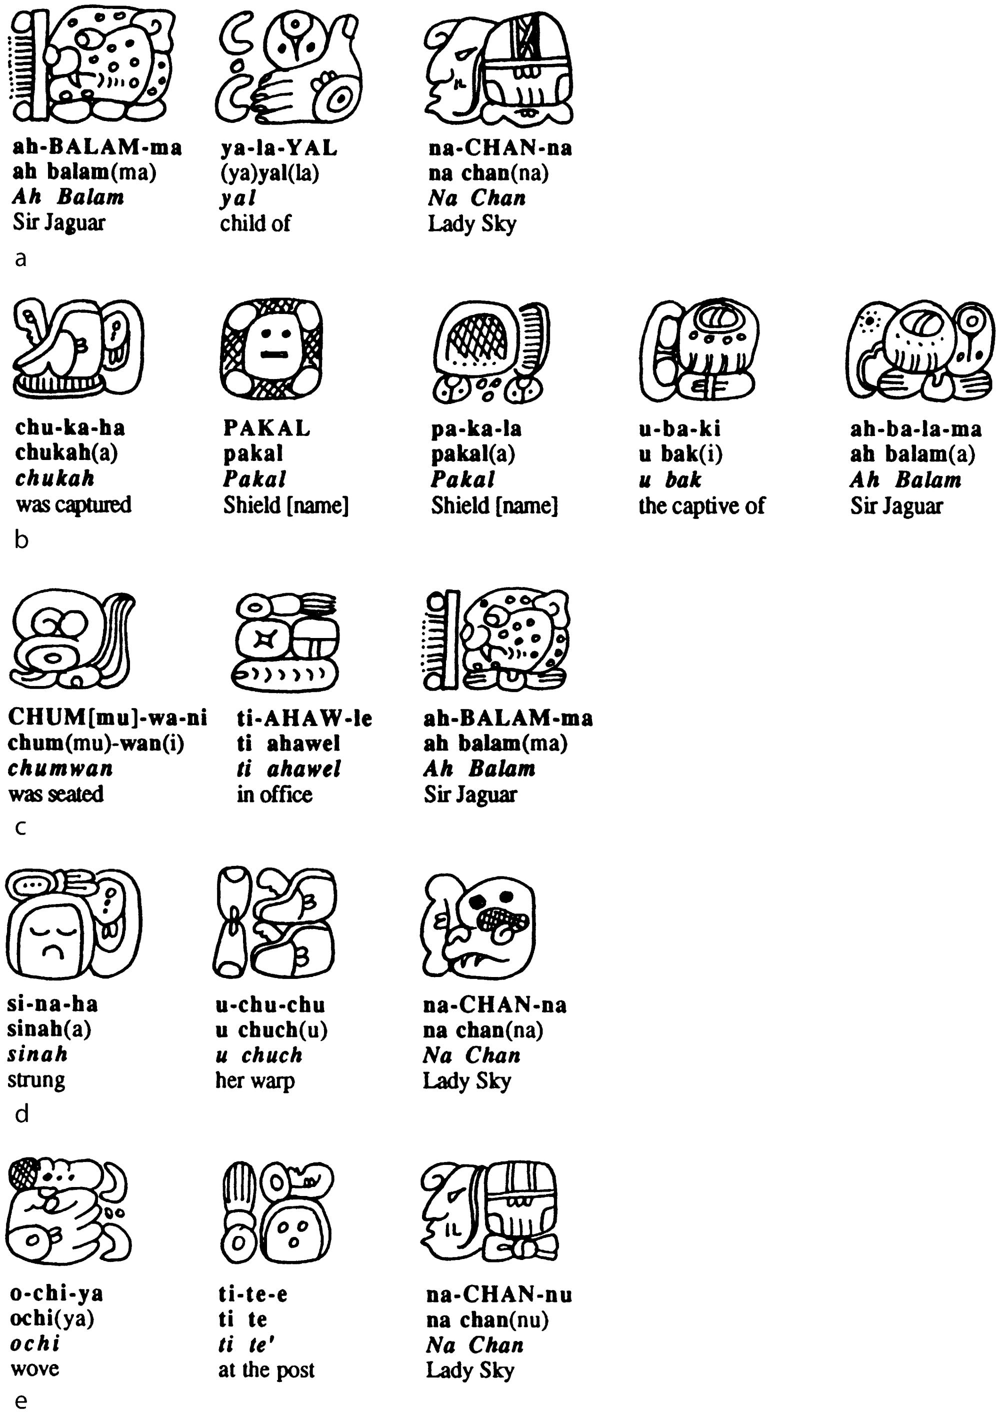
a	b	c	d
yi-NAL-chi-la	**yi-NAL-chi**	**yi-NAL-YICH**	**Nal-yi-chi**
yichnal(la)	**yichnal**	(yi)**yichnal**	(yi)**yichnal**
yichnal	***yichnal***	***yichnal***	***yichnal***
'together with'	'together with'	'together with'	'together with'

e	f	g
NAL-YICH-la	**NAL-YICH**	**NAL-yi-chi-la**
yichnal(la)	**yichnal**	(yi)**yichnal**(la)
yichnal	***yichnal***	***yichnal***
'together with'	'together with'	'together with'

Writing: Maya Writing. Fig. 9 Seven ways of spelling **yichnal** (together with).

Despite these general principles, there were words for which there was no single sign and the organization of which often defied the general upper-left to lower-right reading order. The word **yichnal** (together with) is a particularly interesting example of such a construction, in part because it always includes the previously mentioned -**NAL** ending superfixed to its main sign (Fig. 9). The latter might be either the standard sign for phonetic *chi* or the "torso-and-left-arm" sign that represents the sound **YICH**. The several ways of recording **yichnal**, with the elements read in the usual order, were **yi**-*NAL-chi-la* (Fig. 9a), **yi-NAL**-*chi* (Fig. 9b), **yi-NAL-YICH** (Fig. 9c), *NAL-yi-chi* (Fig. 9d), **NAL-YICH-la** (Fig. 9e), **NAL-YICH** (Fig. 9f), and *NAL-yi-chi-la* (Fig. 9g).

Among the tasks to which a Maya scribe might be called upon to apply his skills was the execution of commissions to inscribe in stone the dynastic history and military achievements of his city's royal family. Commissions of this sort would typically involve the recording of a variety of genealogical relationships such as *Ah Balam yal Na Chan* (Sir Jaguar is the child of Lady Sky), where the two names are separated by a glyph-block that defines their relationship, with the subordinate person named first (Fig. 10a). A military encounter might be expressed with two phrases such as *Chukah Pakal. Pakal u bak Ah Balam* (Pakal was captured. Pakal was the captive of Sir Balam), the first being a typical verb-initial Mayan sentence followed

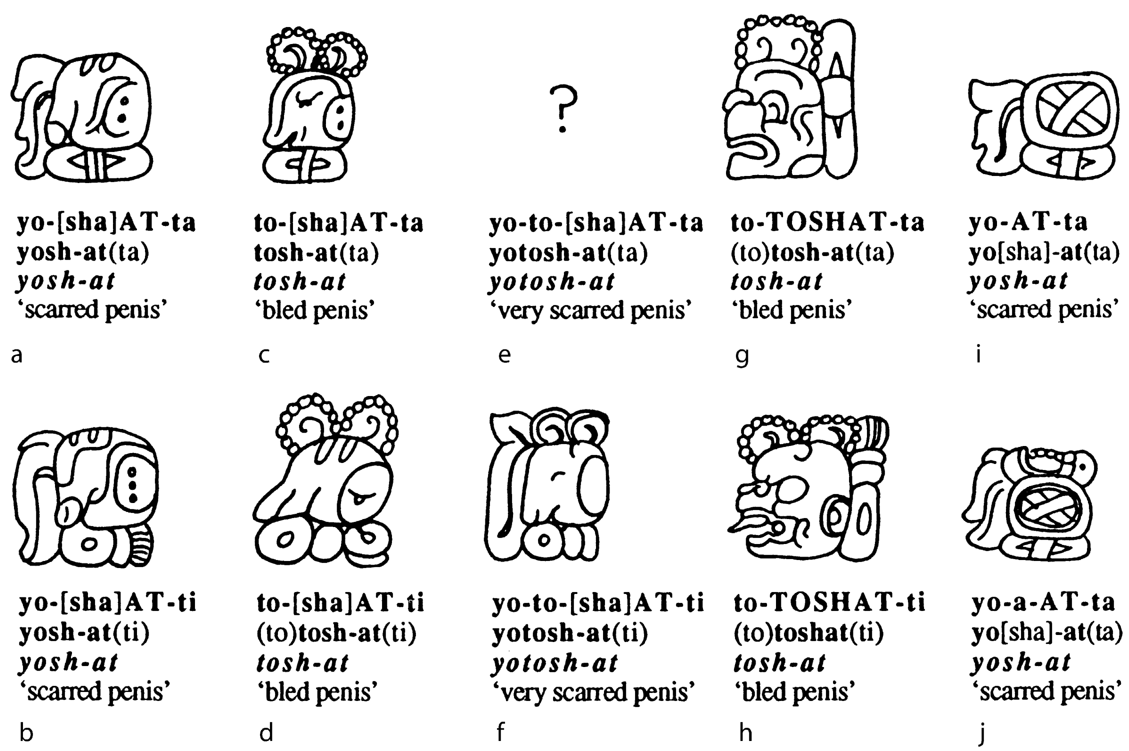


Writing: Maya Writing. Fig. 10 The construction of Maya sentences.

by the subject, the second defining another relationship with the identical syntax as the earlier example (Fig. 10b). Accession to political office might be recorded as *Chumwan ti ahawel Ah Balam* (Sir Jaguar was seated in the Lordship), in another typical verb-initial Mayan sentence where a positional verb is followed by a prepositional phrase with the subject named last (Fig. 10c). Were our scribe to turn from his work on public monuments to the designing of a personal book for and about Lady Sky, he might record such sentences as **Sinah u chuch Na Chan** (Lady Sky strung her warpboard) or **Och-i ti te' Na Chan** (Lady Chan wove at the post), the first a verb-initial sentence with a transitive verb followed by a possessed object and the subject (Fig. 10d), and the second a verb-initial sentence with the verb followed by a prepositional phrase and the subject (Fig. 10e). It should be clear from the preceding examples of inscriptions on public monuments that Maya hieroglyphic writing is indeed a true writing system, fully capable of recording the language it represents.

However, for all of the marvelous achievements of recent Maya epigraphy, much work remains. Many glyphs are undeciphered and problems still linger amongst glyphs for which solutions have been offered. An understanding of the kinds of difficulties encountered by epigraphers in deciphering individual glyphs can be gained from a close look at a fairly common lordly title, the five basic forms of which preclude ready demonstration of their homophony, and suggest instead the presence of both phonetic and semantic substitutions. Known to scholars as the "penis" title, the three most widely distributed forms consist of a main sign that has the appearance of a profile representation of male genitalia infixed with the sign for **sha** and suffixed alternatively with **-ti** or **-ta** affixes (Fig. 11a–f). Desirable as it might be to have a homophonous reading for the three forms – and their interchangeability in the texts is beyond doubt – the conflicting sounds of their initiating prefixes would appear to preclude any such solution. One form is prefixed with the sign for **yo-** (Fig. 11a,b), and second with **to-** (Fig. 11c,d), and a third with both **yo-** and **to-** (Fig. 11e,f). Because these substituting sounds are prefixed, the words that they signify must begin with the sounds **yo**, **to**, and **yoto**, respectively. The likelihood that the male genitalia-main sign is intended to convey the sound **AT** (the pan-Mayan word for penis) is confirmed by the interchangeable **-ti** and **-ta** suffixes that invariably accompany it, apparently serving as phonetic complements. If, then, the **sha** infix is read before the presumed sound of the main sign, the sound sequence should be **sha-AT** (ti/ta), or the not too promising **shat**. However, if the previously mentioned **yo-** prefix is added to this, the result is **yoshat**, or **yosh-at** (scarred penis); if **to-** is added, the result is **toshat**, or **tosh-at** (bled penis); and if **yo-to** is added, the result is **yotoshat**, or **yotosh-at** (very scarred penis). Though any such title might strike those of us with a background in Western European culture as bizarre, nevertheless given the wealth of evidence for the presence of penis-perforation ceremonies in which Maya lords engaged and the occasional portrayal of a scarred penis on figures in Maya art, the existence of a hieroglyphic form of a title that testified to a lord's personal sacrifice perhaps ought not to surprise anyone.

Understanding of the remaining two of the five forms which this title assumes is less certain. The first of these is a head variant that is always superfixed with **to-** and postfixed with **-ti** or **-ta** (Fig. 11g,h), suggesting the possibility that the head represents the full term



Writing: Maya Writing. Fig. 11 Semantic substitutions in the "penis title."

TOSHAT, or **TOSH-AT**, with both affixes serving as phonetic complements. The second (of which there are but two examples) is a phonetic construction that is in clear contradiction to the previously discussed **yosh-at** renderings: one reads **yo-ta-ta**, the other **yo-a-ta-ta** (Fig. 11i,j). Not only is the **ta** sound doubled in each, but there is also nothing present that could be construed to represent **sha**, the necessary middle consonant of **yosh-at**. Nor is there an easy resolution of this difficulty; either the previously proposed **yosh-at**, **tosh-at**, and **yotosh-at** readings are in error and the arguments in support of them faulty, or the Maya scribe that recorded the two purely phonetic constructions (they are both at Copan) failed to include all the sounds of the word he intended to record, or – and this is a solution that preserves both the earlier **yosh-at**, **tosh-at**, and **yotosh-at** readings and the literary reputation of the Copan scribe – the scribe deliberately omitted the middle (**sh**) consonant, as is thought to have been done with other two-syllable words. One can only hope that further research and further field discoveries will someday throw stronger light on this and similar difficulties. Nor has there ever been a time when Maya scholars were more optimistic about the possibilities of their ultimate decipherment of this poetically conceived, strikingly beautiful, and wonderfully complex ancient writing system.

Postscript. Since the preceding was written and submitted to the publisher, an alternative to the reading of the penis title presented above has been proposed by Linda Schele based upon a recently recognized example that appears to include a sign for the sound **ho**. Schele proposes a **yoh-at** reading for the **yo**-prefixed form and phonetic construction, a **toh-at** reading for the **to**-prefixed form (and its head-form), but is silent regarding the **yo-to**-prefixed form. This should convey some idea of the difficulties raised in the closing paragraphs above.

Writing in the Middle East

Alan Millard

Writing and the alphabet were two of the major inventions of the human mind. They were conceived and developed in the Middle East between about 3500 and 1000 BCE. Other writing systems appeared in China about 1200 BCE and in Central America during the first millennium BCE, probably independently, although the Chinese may have been indirectly influenced from Babylonia.

Cuneiform Writing

Writing began over 5,000 years ago in the developing urban culture of southern Mesopotamia known as the Uruk IV period. At first simple pictures were scratched on stone or clay tablets held in the hand. Some showed a complete object, such as a fish, others part of an object, such as the head of a cow, while others cannot be identified. More than 1,200 signs were used in the oldest known texts, which deal with the income and expenditure in kind of temples. The number of signs soon shrank to about 600 and as well as serving as word-signs (logograms), many also came to be used phonetically (phonograms) on the rebus principle. Thus in English the picture of a thin man beside a king read as ideograms could mean "The thin man is king" or "The king is a thin man," but taking their values phonetically could yield the two syllables of "thinking," a concept harder to express pictorially. The rebus principle enabled the script to express any words, including foreign terms and names. The syllabic signs are vowels (*a*, *e*, *i*, *u*), "open" (e.g. *ba*, *gi*, *du*, *am*, *ir*, *uz*) and "closed" (e.g. *bab*, *gim*, *dur*) and some longer ones (e.g. *alad*, *gibil*) (Fig. 1). Additionally, a small number of signs were placed before or after word-signs to indicate their class. These determinative signs mark categories such as "man," "woman," "wooden object," "fish," "pot," and plurality. By 3000 BCE the language of the texts is evidently Sumerian, a language unrelated to any other now known, and it is likely the script was invented by Sumerians. The Sumerian language appears to have many homophonous words, which suggests it may have been tonal, and so several signs can have the same phonetic value when transcribed into roman letters, which scholars distinguish by accents and subscript numbers (thus *sá* "to be equal," sa_4 "to name," sa_{10} "to buy"). Simplification for speed and impressing a reed stylus on clay produced angular strokes and resulted in the signs rapidly losing their pictorial form, so becoming the wedge-shaped or cuneiform script. The range of texts expanded over the centuries from the

Writing in the Middle East. Fig. 1 Cuneiform signs: their meanings and their development. Column 1 pictorial, ca. 3000 BCE, Column 2 cuneiform ca. 2500 BCE, Column 3 ca. 1800 BCE, Column 4 ca. 650 BCE. Line 1, Meaning "hand," Sumerian *shu*, Akkadian *qåtum*, syllabic values *shu*, *qat*. Line 2, Meaning "mouth," Sumerian *ka*, Akkadian *pûm*, syllabic value *ka*. Line 3, Meaning "wood," Sumerian *gish*, Akkadian *its*, syllabic values *gish, its, ets*.

accounts and lists of words by category of the earliest period to embrace almost every type of written composition. By ca. 2500 BCE archives of clay tablets include hymns and prayers, proverbs and wise advice, riddles, legends and myths and brief historical records. At that time the script was adapted for writing the East Semitic Akkadian language (ancestral to Babylonian and Assyrian). Word signs could now be read in Akkadian and a much wider use of phonetic values of signs became common as words were written syllabically (e.g. the word-sign "bull's head," read in Sumerian as *gud*, in Akkadian as *alpum*, could be written *al-pu-um*). While some texts were written almost wholly with syllabic signs, especially in the early second millennium BCE (the Old Babylonian period), scribes usually wrote with a mixture of syllabic and word signs, preceded or followed by the determinative signs. This system continued until the beginning of the Christian era, spread across the Near East, especially in the second millennium BCE, and was adopted for writing unrelated languages such as Elamite in Iran and Indo-European "Hittite" languages in Anatolia. The tens of thousands of clay tablets in modern museums attest the activity of scribes in writing down almost every aspect of life, but the script never lost its complexity and so writing remained a specialized craft, usually the monopoly of the trained scribe.

Egyptian Writing

Egyptian hieroglyphic writing began almost simultaneously with the ancestor of the cuneiform script in Babylonia and was possibly influenced by it. (There are clear signs of other influences from Mesopotamia in Egyptian culture at the end of the fourth millennium BCE, e.g. the distinctive cylindrical seal.) The hieroglyphs are pictures and from the first were closely associated with narrative art, as is evident in predynastic carvings (e.g. the Narmer Palette) and thousands of later sculptures and objects of all kinds. They were employed both as word-signs (ideograms) and, through the rebus principle, as sound-signs (phonograms). In the early stages over 1,000 signs occur, a number soon diminishing to 600 or 700 which were in regular use until Hellenistic and Roman times when the number multiplied enormously. In their day-to-day activities, clerks, writing rapidly on papyrus, reduced the hieroglyphic script to a cursive form, known as hieratic, examples occurring from the earliest dynasties onwards. A highly cursive and abbreviated script, demotic, developed in the first millennium BCE and continued beside the hieroglyphs well into the Christian era. Both hieratic and demotic were written from right to left; the hieroglyphs could run in any direction. The hieroglyphs are, to modern eyes, purely consonantal; the ancient readers supplied the appropriate vowels, facilitated by the structure of the language, as in the West Semitic "alphabet" (see below). There are three classes of hieroglyphs giving phonetic, apart from their ideographic, values. The 26 with a single consonant are often called the Hieroglyphic Alphabet, but it is important to recognize that the Egyptians did not separate them from the other signs. Each of these seems to denote the dominant sound of the word represented (e.g. *n* from *nt*, "water," *dz* from *w'dzyt*, "cobra"). About eighty signs are biliteral and seventy triliteral. These phonograms often followed an ideogram, in effect "spelling out" its value, thus accompanying the sign for "pyramid," *mr*, could be the two consonant sign *mr* and the "alphabetic" signs *m* and *r* (Fig. 2). In addition, a range of determinative signs marked categories of terms, the best known being the oval cartouche enclosing

Writing in the Middle East. Fig. 2 Egyptian hieroglyphs: *mr* + *m* + *r* + pyramid = "pyramid".

pharaohs' names. Problems in representing foreign names in the early second millennium BCE led to a special combination of signs to produce syllabic spellings, called "group writing" or "syllabic orthography." Egyptian scribes normally wrote on papyrus which decays rapidly when buried except in very dry situations, so most of their work is lost. Enough survives to show that, although appearing needlessly complex, the Egyptian writing system could express as wide a range of ideas as the Babylonian. Its complexity meant that it remained a specialist skill, practised by, it is estimated, less than 1% of the population.

Other Ancient Scripts

The second millennium BCE – the Middle and Late Bronze Ages in archaeological terms – saw a proliferation of writing systems. In Anatolia, the Indo-European speaking Hittites invented a hieroglyphic script for writing the Luwian language, about 1600 BCE. It is known from stone monuments, seals and a few documents engraved on lead strips, but it is likely it was written more extensively on wooden panels, now perished. It has a basic syllabary of 70 consonant + vowel signs, a few more complex syllabic signs and 78 logograms for commonly occurring terms (e.g. king, country) and so is similar in concept to the Cretan scripts (see below). The values of the syllabic signs appear to derived acrophonically from the initial syllable of the word each picture depicted. After the Hittite empire ended ca. 1200 BCE, smaller kingdoms in Turkey and north Syria continued to write with the hieroglyphs until the seventh century BCE.

Similar to the Hittite hieroglyphs are the scripts found in Crete, the Cretan hieroglyphs and, perhaps descended from them, Linear A and Linear B. Only the last has been convincingly deciphered, revealing a simple syllabary of 54 consonant + vowel signs and five vowel signs, with numerous logograms which sometimes have their names written syllabically beside them, all recording an early form of Greek. Linear B was scratched awkwardly on clay tablets and was probably also written on wax tablets and other perishable materials. Apparently an offshoot of Cretan writing is the Cypro-Minoan system current in Cyprus in the Late Bronze Age, with rare examples found in the Levant. Like Linear B, surviving examples are on clay, but impressed with a stylus rather than scratched. They seem to record notes of ownership or delivery and longer compositions, but the script remains unread. Later in the first millennium the Cypriot syllabary of 50 consonant + vowel signs and five vowel signs survives on stone, pottery and coins. It is clearly a continuation of the Cypro-Minoan signs, probably applied to a different language, and can be read, thanks to texts with parallel versions in Greek.

A clay disk found at Phaistos in Crete is a unique representative of a pictographic script impressed on the surface by 45 separate dies in various arrangements, a precursor of printing. It may have been brought to Crete from Turkey, but without other examples, there is little likelihood that it can be understood.

At Byblos, north of Beirut, a dozen documents were unearthed inscribed with signs evidently forming a large syllabary of 114 signs, fairly clearly based upon the Egyptian hieratic script. These "pseudo-hieroglyphs" of the mid second millennium BCE await convincing decipherment. There are other, isolated, specimens of writing systems which cannot yet be read. Short texts scratched on clay tablets about 1200 BCE at Tell Deir 'Alla in the Jordan Valley are reminiscent of Cretan Linear B, but clearly not the same script.

The Alphabet

Out of this medley of scripts, one arose early in the second millennium BCE which would ultimately have the greatest impact since the invention of writing. A scribe working in the Levant, perhaps in Byblos, found none of the scripts available to him, Egyptian and cuneiform, suitable for registering his West Semitic language, so he created a system in which each sign stood for a major consonantal sound (phoneme). It seems that he drew a series of simple pictures, and used each to stand for the initial sound of its name, thus "door" = d (the acrophonic principle), yielding between 20 and 30 signs. In the West Semitic languages (e.g. Canaanite, Aramaic, Hebrew, Phoenician) no word began with a vowel and it proved possible to represent the languages adequately without signs for vowels, so at first they were not marked at all. That continues to be basically true for Arabic and Hebrew today. The system was not, therefore, a true alphabet, which should have a sign for each major sound in the language, whether consonants or vowels, but the term can be applied to it and its descendants for convenience. The scribe was accustomed to the Egyptian practice of writing with ink on papyrus and followed the Egyptian direction, writing from right to left, as Arabic and Hebrew are still written. The use of perishable papyrus sheets and wooden tablets coated with wax means that most examples of this Canaanite Linear Alphabet are lost. A few specimens scratched on metal, stone and pottery have been found at Middle Bronze Age sites in Canaan and two were discovered on a rock at Wadi el-Hol on the desert road across the bend of the Nile north of Thebes. The date of these two is debatable, but they certainly belong to a very early stage in the history of the script. More extensive examples come from the area of turquoise mines at Serabit el-Khadem in western Sinai. They were apparently written in the middle of the second millennium by workmen imported from Canaan who revered the mother-goddess, Egyptian Hathor, whom the Egyptians entitled “lady.” Although brief or badly damaged, so far as these inscriptions can be read, they refer to “lady” also (West Semitic *ba‘alat*). The signs in these “Proto-Sinaitic” inscriptions appear in more developed forms scratched or painted on various objects from Late Bronze Age Canaan, and by about 1000 BCE they are almost standardized across the Levant, their number reduced to twenty-two, as examples from Byblos and other sites show (Fig. 3).

Two or three centuries earlier, scribes at Ugarit (now Ras Shamra) on the coast of Syria, trained in Babylonian tradition, realised the Canaanite Linear Alphabet was better suited to their West Semitic language than Babylonian cuneiform and imitated it by creating a cuneiform “alphabet” of twenty-seven signs, then adding three to mark sounds necessary for recording the completely different Hurrian language. Scribes at Ugarit used their script to write every type of text, letters and administrative documents, rituals, legends and myths, on clay tablets. Their survival in the ruins of the city illustrates the sort of documents which it can be surmised were written also in Canaan, but they have perished. A very few pieces of Ugaritic writing from other sites in the Levant, as far south as Beth Shemesh west of Jerusalem, demonstrate its spread, but the script disappeared with the collapse of the Late Bronze Age city states.

It was the Canaanite alphabet that survived the chaos at the end of the Late Bronze Age to be adopted widely. One form spread into Arabia where it became the North and South Arabic scripts, the former being known mainly from graffiti which shepherds and travellers left on rocks from the sixth century BCE to the Islamic period, the latter being attested in thousands of inscriptions on stone in the Yemen and Hadhramaut from the ninth century BCE until the seventh century AD. An offshoot of the South Arabic script survives in the Ethiopic alphabet which has augmented the letters to mark vowels. The other form of the Canaanite alphabet was adopted by the new West Semitic speaking kingdoms and eventually eclipsed all other writing systems in the region. The Israelites occupying Canaan found the script appropriate for Hebrew (except that it did not provide two signs to distinguish the phonemes *s* and *ś*). They used this “Phoenician” or “Old Hebrew” alphabet until the Persian period, continued it for some literature and revived it for nationalistic purposes in the Roman period. Aramean kingdoms wrote their language with the same alphabet, despite the lack of signs to distinguish certain sounds (e.g. *t* and *t*). Already in the ninth century BCE Aramaean scribes gave some characters a double value, noting both consonants and long vowels (e.g. one sign for *w* and *û*, one for *y* and *î*). Under the Persian Empire (539–331 BCE), the Aramaic language and form of script, which had been spreading widely under Assyrian and Babylonian rule, became the common vehicle of administration from the Indus to the Aegean, from the Black Sea to Egypt and the Red Sea (Fig. 4). The Jews used it for writing Hebrew and, slightly developed, it has been the Hebrew alphabet ever since. Aramaic speakers in southern Turkey, in the area around Urfa and Haran, derived from it the forms of cursive script known as Syriac (Estrangelo and Serto) still read among Christian churches of the Middle East. Another form arose in the caravan city of Palmyra (first to third centuries AD.). Most significantly, Nabataean Arab tribes in southern Syria and Jordan began to write with the Aramaic alphabet in the last centuries BCE and their cursive letters, known from a few papyri surviving dehydrated in caves near the Dead Sea and some other examples, are clearly the origin of the Arabic alphabet (Fig. 5). Thus the modern Arabic and modern Hebrew alphabets have the same ancestor. However, in the cursive Nabataean of the early Christian centuries, the

shapes of some letters had become almost indistinguishable (e.g. *r* and *z*) and the Arabic language distinguished more consonantal sounds than the Aramaic alphabet marked, so dots were added above or below certain letters to distinguish some and to create new ones. In Syriac, Arabic and Hebrew, beside some signs for consonants marking long vowels as well, small marks were added in the early Middle Ages above, below and occasionally within the letters to indicate all the vowels necessary for public reading of sacred texts such as the Gospels, the Torah and the Qurʾān. As Islam spread it carried the Arabic script with it and so it came to be applied to non-Semitic languages. For Persian additional diacritical marks were placed on four letters to mark Iranian phonemes and for Ottoman Turkish modifications were needed for six. In 1928, Kemal Atatürk's modernization programme, the Ottoman script was replaced with roman letters, augmented by diacritical marks to 29 characters (Daniels and Bright 1996).

The Aramaic, Hebrew and early Arabic scripts are known today from haphazard collections of inscriptions on stone and other hard surfaces and from rare groups of texts on papyrus, mostly found in Egypt. The reduced number of signs, 22–28, made the tasks of writing and reading simpler than for Babylonians, Egyptians or Hittites, and so more people may have learnt to read and write, but widespread literacy did not result. For most people there was no need for either skill, and if they had the need, they could find a professional scribe. Nevertheless, there is some evidence for a proportionately wider distribution of writing in ancient Israel than in neighbouring lands (Millard 1995).

On the coast of Lebanon scribes in the Phoenician cities (Tyre, Sidon, Beirut, Byblos) continued to write with the Canaanite linear alphabet. Their products are almost entirely lost, only a few texts on stone, metal and potsherds surviving. It was from them that the Greeks learnt it. Greek could not be written intelligibly without marking vowels (otherwise there was no way to write the Greek word for "no," *ou*), so signs for Phoenician, Semitic, phonemes alien to Greek were given new values as vowels, partly in line with the use of some consonants to mark long vowels in Aramaic (e.g. *w* for *û*, *y* for *î*). That yielded the first true alphabet (Fig. 6).

W

Xiahou Yang

ANG TIAN SE

Much of the life story of Xiahou Yang remains unknown, and so is the date of *Xiahou Yang Suanjing* (Xiahou Yang's Mathematical Classic), a text purported to have been written by him. When Zhang Qiujian wrote his mathematical text some time between AD 468 and 486, he criticized the inaccuracy of the solution of a "rectangular granary" problem from Xiahou Yang's work. This shows that Xiahou Yang was either Zhang's contemporary or his predecessor. The text also mentioned a change of volume standard which took place in AD 425, thus affirming that both Xiahou Yang and Zhang Qiujian were mathematicians of the Northern Wei dynasty (AD 386–535) and that the text of Xiahou Yang was written between AD 425 and 468.

The *Xiahou Yang Suanjing* appeared to be an important text as it was selected by Yu Zhining in AD 656 for use in the National Academy during the Tang dynasty (AD 618–906). In AD 662, the text was annotated by Li Chunfeng along with nine others for use in the imperial examinations. However, when the text was reprinted and included as one of the *Ten Mathematical Classics* in AD 1084 during the succeeding Song dynasty, it appeared to have been rewritten, probably by Han Yan (AD 780–804) in the Tang dynasty. This is evident in the text itself where a number of statutes governing the Tang systems of land, taxation, and official hierarchy were mentioned.

The present version of the text has three chapters consisting of 82 problems. It deals with percentages and roots, as well as the ordinary logistic operations. Xiahou Yang seemed to have understood both the positive and negative properties of powers of 10 such as $10{,}000 = 10^4$ and $1/10{,}000 = 10^{-4}$. He also seemed to have understood the developed conception of decimals. In one problem, he suggested the conversion of the last four metrological units to simply writing down the numbers in four successive places as they would be expressed in modern decimal notation. Though Xiahou Yang provided some modified forms for multiplication and division in some problems, he also repeated some inaccurate solutions found in the *Wu Cao Suanjing* (Mathematical Classics of the Five Government Departments) of the fourth century, the most glaring of which was the rule for determining the area of a figure consisting of two congruent trapezoids and a quadrilateral.

Xu Yue

ANG TIAN SE

Xu Yue, whose literary name is Gonghe, was a native of Donglai (in present Ye District, Shandong Province). Very little is known of his background except that he was a follower of Liu Hong, an eminent mathematician and calendar expert of the second century. He studied mathematics and astronomy under Liu Hong and had frequent discussions with him and the Astronomer-Royal of the Astronomical Bureau on matters pertaining to calendrical astronomy. He was said to have written a commentary on the *Jiuzhang Suanshu* (Nine Chapters on Mathematical Art) and a mathematical text known as *Shu Shu Ji Yi* (Memoir on Some Traditions of Mathematical Art) around AD 190. The commentary had long been lost while the *Shu Shu Ji Yi* was handed down with a commentary written by Zhen Luan (fl. AD 570). There are a number of Buddhist references in Zhen Luan's commentary.

Xu Yue. Table 1 The three classes of large numbers following Xu Yue

	wan	*yi*	*zhao*	*jing*	*gai*	*zi*	*rang*	*gou*	*jian*	*zheng*	*zai*
Upper	10^4	10^8	10^{16}	10^{32}	–	–	–	–	–	–	–
Middle	10^4	10^8	10^{12}	10^{16}	10^{20}	10^{24}	10^{28}	10^{32}	10^{36}	10^{40}	10^{44}
Lower	10^4	10^5	10^6	10^7	10^8	10^9	–	–	–	–	–

The *Shu Shu Ji Yi* was written in a terse and obscure style, tinged with Daoism and divination. Xu Yue mentioned that the mathematics he learnt from Liu Hong was that transmitted directly by a Daoist adept called Tian-Mu Xiansheng (Mr Eye-of-Heaven). The text mentions 14 old methods of calculation, many of them bearing the names taken from the *Yijing* (*I Ching*, Book of Changes). Of special interest is one called "ball-arithmetic," a trough-and-ball instrument similar to an abacus. Three other methods also involved the use of "balls". The first involved the use of one ball per column moving up and down a board or a trough. The second used two balls of two different colors, one relating to a *y*-axis on the left and the other to a *y*-axis on the right. Both these methods seem to have utilized a map-like grid of lines, similar to that of Cartesian coordinates. The third utilized balls of three different colors for use on three horizontal positions only. Joseph Needham has commented that this system of calculation "shows an interesting appreciation of coordinate relationships."

Another interesting aspect of *Shu Shu Ji Yi* is its reference to large numbers and to their representation in three forms of arithmetical series. Xu Yue called them the "upper, middle, and lower" classes of numbers, all beginning with *wan* (10^4). The three classes of large numbers may be summarized in Table 1.

The *Shu Shu Ji Yi* also gives a description of the "calculations of the nine balls", which according to the commentary provided by Zhen Luan was a simple magic square of order 3.

Though brief, obscure, and couched in religious nuances, Xu Yue's *Shu Shu Ji Yi* was selected as a prescribed mathematical text for imperial examinations during the Tang dynasty (AD 618–906). It was a difficult text, and candidates had to learn it by heart in order to pass the examinations.

Yaᶜqūb ibn Ṭāriq

Jan P. Hogendijk

Yaᶜqūb ibn Ṭāriq was one of the earliest astronomers in the Islamic tradition. Very little is known about his life. He worked in the last quarter of the eighth century, when Arabic astronomy was not yet influenced by Ptolemy's *Almagest*. The works of Yaᶜqūb are lost, but some fragments have come down to us in later astronomical treatises and handbooks. The following information is based on such fragments. Yaᶜqūb authored three works:

1. A *zīj* (Astronomical Handbook with Tables), which was influenced by Indian and pre-Islamic Persian astronomy. For example, he took the zero meridian and the mean motion of the planets from India, and he seems to have adopted the planetary equations from a Persian source. In the lunar visibility theory, Yaᶜqūb used an Indian method to measure the width of the lunar crescent in "digits." His lunar visibility table is extant.
2. The *Tarkīb al-Aflāk* (Composition of the Heavenly Spheres) is summarized in some detail in al-Bīrūnī's *India*. In this work Yaᶜqūb discussed the size of the earth and the distances of the planets.
3. In the *Kitāb al-ᶜllal* (Book of Reasons), Yaᶜqūb explained trigonometrical rules, which he probably used in his *zīj*. A few citations of this work are given by al-Bīrūnī. Yaᶜqūb based his trigonometrical calculations on a sine table with base 3,438.

Yaḥyā ibn Abī Manṣūr

Emilia Calvo

Yaḥyā ibn Abī Manṣūr was an astronomer from an important family of Persian scientists (his father was an astrologer). Yaḥyā spent his life casting horoscopes and trying to determine the positions of the stars with precision. He began working for al-Faḍl ibn Sahl, the vizier of the Caliph al-Maᵓmūn and, after his death, for the Caliph himself. He taught the Banū Mūsā and died near Aleppo, Syria in AD 832.

Yaḥyā was the director of a group of astronomers working under the Caliph al-Maᵓmūn, in the observatories of Shamāsiyya in Baghdad and Dayr Murrān in Damascus. The scholars included in the group were al-Marwarrūdhī, al-Khwārizmī, Sanad ibn ᶜAlī, the Banū Mūsā and al-Jawharī. They measured 1° of meridian by using two different procedures. The results of the observations were recorded in various *zīj*es (Astronomical Handbooks with Tables), one of which is the *Zīj al-mumtaḥan* (The Tested Tables) that was written by Yaḥyā himself. The observations ended when Yaḥyā and the Caliph died almost simultaneously.

Yaḥyā's *zīj* is preserved in one manuscript (Escorial 927) which is badly bound and comprises many folios that are not from Yaḥyā's work. It contains an explanation of calendars and chronological eras. The elements to calculate planetary longitudes are the result of the combination of Hindu–Iranian and Ptolemaic methods.

Yaḥyā's tables exerted a great influence on later astronomers: Thābit ibn Qurra wrote an introduction to them, Ibn Yūnus adapted them to Egypt, and Ibn al-Zarqāllu derived from them certain values such as the inclination of the ecliptic.

Yang Hui

Ho Peng Yoke

Yang Hui (fl. 1261–1275), a native of Qiantang (in modern Hangzhou), ranks with Qin Jiushao (ca. 1202–ca. 1261), Li Zhi (1192–1279), and Zhu Shijie (fl. 1280–1303) as one of the four great mathematicians during the golden age of mathematics in thirteenth-century China. Of the four we know the least about Yang Hui's life, yet he has left behind a much larger number of writings than the others, showing that his mathematical interest also covered a wider field than any of his contemporaries known to us.

In the year 1261 he wrote the *Xiangjie jiuzhang suanfa* (Detailed Analysis in the Mathematical Rules in the Nine Chapters and Their Reclassifications). The original work comprised 12 chapters and an Appendix, which included an arrangement of numbers which he attributed to the eleventh-century mathematician Jia Xian and which in 1654 came to be known as Pascal's Triangle. Although the original work is no longer extant in its entirety, sections of it are quoted in the early fifteenth-century Imperial Compendium, the *Yongle dadian*.

Yang Hui also wrote the *Xiangjie suanfa* (Mathematical Methods with Detailed Explanations) on the processes of multiplication and division. Then in 1262 he produced an elementary text for beginners called the *Riyong suanfa* (Everyday Mathematics). In 1274 he wrote the *Chengqu tongbian suanbao* (Precious Reckoner for Variations in Multiplications and Divisions). In 1275 he wrote the *Tianmou bilei chengqu jiefa* (Practical Rules of Arithmetic for Surveying). The same year he assembled some old and forgotten materials and published the *Xugu zheqi suanfa* (Continuation of Ancient Mathematical Methods for Elucidating the Strange Properties of Numbers). This is the earliest Chinese monograph that we have on magic squares. The last three works mentioned above were published together in 1378 under a single title *Yang hui suanfa* (Yang Hui's Mathematical Methods). A full study of this book was undertaken by Lam Lay Yong in 1977.

Like his contemporaries Yang Hui used numerical equations of higher degree. His *sanchengfang* (quartic root) method is very similar to that rediscovered by Horner and Ruffini in the early nineteenth century. He employed freely the concepts of "dummies" and substitution in his algebra. At the same time his attention was on the practical side, always trying to provide the quickest working method. It seems that Chinese mathematicians were quite active during the eleventh and twelfth centuries, but none of their writings remains. At least we have come to know something about them through Yang Hui's writings.

Yavaneśvara

K. V. Sarma

The name Yavaneśvara, meaning Lord of Greeks, referring to one of Greek descent, is said to be the author of a number of Indian astrological works. He is mentioned for the first time by Sphujidhvaja who wrote his *Yavanajātaka* in AD 269–270. Towards the close of his book, Sphujidhvaja states that his work was based on that of Yavaneśvara. Yavaneśvara, who had been blessed by the Sungod, is stated to have rendered a Greek work on genethlialogy (divination by the influence: The Stars at birth) into Sanskrit in AD 150, at the instance of the ruler of the land. This work shows the position and influence of the stars at one's birth. The date mentioned by Sphujidhvaja is a little after the Kṣatrapa dynasty of Greek descent had established itself in the region of Saurashtra and Gujarat and ruled with its capital at Ujjain. The patron of Yavaneśvara has been identified, on the basis of coins and inscriptions, as Rudradāman I. Sphujidhvaja states that he (Rudradāman I) was quite conversant with the said Greek work.

Though the original work of Yavaneśvara is apparently lost, it is possible to get an idea of its extent and contents from *Yavanajātaka* which is its redaction. The *Yavanajātaka*, as it is available now, is an extensive work in 79 chapters, and takes under its purview a large variety of topics on horoscopy and natural astrology, including the delineation of the planets, their lords, their characteristics, the major and minor influences they exert on human beings at different periods, predictions relating to professions, experience of happiness and sorrow on account of planetary combinations, and predictions of the future on the basis of questions, omens, and military astrology. Most of these would have been depicted by Yavaneśvara as well. This is borne out also by several later texts, which are ascribed to Yavaneśvara. Among such works might be mentioned: The *Candrābharaṇahorā*, an extensive work in 101 chapters, prevalent in South India, and a shorter work with the same title prevalent in North India; two texts with the title *Yavanasaṃhitā*; a work called *Bhāvadīpikā* or *Bhāvādhyāya*, making predictions on the basis of the placement of the planets in the horoscope; *Nakṣatracūḍāmaṇi*, being predictions on the basis of the 27 constellations; and, a *Yavanapārijāta* depicting the results of good and evil deeds in life. It is clear from this that a regular school of the Yavana tradition of astrology had developed in India.

What is significant is that in all these texts which ostensibly go under the authorship of "Yavana," Hellenistic practices have been Indianized, both in the matter of content and presentation. Hindu caste distinctions and social orders are duly taken note of in making predictions; Hindu deities and their descriptions are duly invoked, and suitable modifications are made to their Greek counterparts. In effect, these texts seem to be wholly indigenous but for the ascription of their authorship to Yavana (Greek).

Yinyang

WEIHANG CHEN

Yinyang is a Chinese term composed of two words. *Yin* means the shade and *yang* the sunshine. It is the most important concept in the traditional Chinese way of thinking, the basic concept for classification and explanation in Chinese science, medicine, and philosophy.

The word *yinyang* designates a special method for looking at things as well as for describing the phenomena of the world, including the human body. *Yin* and *yang* make a pair which exist together. In their coexistence, these two oppose each other in their different functions and at the same time help each other. They both contribute and are necessary to the other's existence. All phenomena can be looked at and described using the *yinyang* paradigm. This is the typical methodology of Chinese science.

The concept of *yinyang* can be compared with the Western dialectic method. However, in Chinese science this way of thinking has developed into a very complicated system of knowledge, in which *yin* and *yang* are represented in every real object. Therefore, *yinyang* is more than a way of thinking; it is also a theory that provides guidelines for human action.

The use of the concept of *yinyang* can be best illustrated by examples. The earliest example which can be found in extant Chinese ancient texts is from the Confucian classic *Yijing* (*I Ching*, The Book of Changes). It is not to be found in the *Yijing* proper, but in the commentaries (so-called *Yizhuan*, *I Chuan*, or the Ten Wings). It is generally accepted that *Yizhuan* was complied during the Warring States period (the fifth to the third century BCE), so that is the earliest date we can attribute to the origin of the concept of *yinyang*. *Yizhuan* uses *yinyang* to explain the *Yijing* proper in such a way that the binary notation for every possible movement (change) in the real world is explained as representing the actual acting of the two opposing factors (or forces in the Western sense of the word) that substantiate the situation under consideration. Thus in the relation of men and women, *yang* represents man and *yin* represents woman. Likewise in the relation of heaven and earth, of sun and moon, of day and night, etc., *yang* represents the former and *yin* the latter. Furthermore, *yang* and *yin* are used to represent opposite qualities including natural attributes like hot and cold, hard and soft, bright and dark, odd and even, as well as human dispositions like aggressiveness and submissiveness, or activeness and inactiveness.

Two points need to be emphasized here. The first is that the designation of *yang* or *yin* to an object is only effective in certain relationships. Relative to the woman, the man is *yang*. But there are other traditionally important relations that man comes into, such as that of heaven and man, of man and gods, of man and his fate, or of individual man and his family or society. In any of these, "man is *yang*" does not apply. Therefore, the traditional designation of *yang* and *yin* forms the hard core of a knowledge about the world. The second is that the use of the concept of *yinyang* is a pragmatic one. To say something or some quality is *yang* and the opposite is *yin* will be meaningful only if this designation classifies these two objects or qualities into two existing categories into which many other things or qualities are already classified. A wrong designation will make a real difference in human action when using this knowledge of classification to make a decision according to a certain theory.

According to Chinese historical records, especially the authoritative *Shi Ji* (Records of Historians) by Si Maqian (b. 145 or 135 BCE), during the Warring States period one of the six most important schools of ideas was called the *yinyang* school. It is generally accepted that, beside its political and philosophical relevance, this school brought about two important developments, which somewhat related to each other throughout the 2,000 years afterward. One is the Daoist practice of alchemy and physical immortality; the other is Chinese traditional medicine, or more accurately, Chinese body science.

From both the Chinese traditional viewpoint and from the modern Western point of view, the most important use of the *yinyang* concept can be found in the theory and practice of Chinese traditional medicine. The earliest extant medical literature was unearthed in 1973 from the Han Tomb No. 3 at Mawangtui, Changsha, Hunan Province, China. There are records which show that these texts were buried in the tomb with the dead Marquis in the year 168 BCE. In these texts the *yinyang* concept is used as the most basic classifying concept. It is the same with the *Huangdi Neijing* (Yellow Emperor's Classic of Internal Medicine), which contains medical essays edited in the first centuries AD. From these texts we know that the *yinyang* concept was used in Chinese medical theory much earlier than the second century BCE.

In Chinese medical theory, *yin* and *yang* are two different kinds of *qi* (literally "breath" but occasionally translated as meaning "vital force"), which function within the human body contradictorily and complementarily, and thus make the body alive. Human health is attained by keeping these two *qi* in a good, natural balance. All health problems are caused by the lost of this balance. All medical theories, diagnoses, and therapies can be understood as practical knowledge of how to classify the imbalance into a certain system of categories and how to use different means, which are classified into corresponding categories, to retrieve the natural balance. For a simplified example, two common health problems are diagnosed as *yang*-deficiency–*yin*-excess and *yin*-deficiency–*yang*-excess, which correspond to cold and heat syndromes. In diagnosis these two syndromes are related to two categories of symptoms which include every possible change in the pulse, the complexion, the tongue, the breath, the excrement and urine, etc., of the patient. In therapy, herbal medicine, or the method and location of acupuncture points are correspondingly classified.

There are two other concepts which are closely connected with the *yinyang* concept. They are the *wuxing* (five phases), which is extremely important in Chinese science, and the *taiji* (the ultimate beginning), which is more important in Chinese philosophy. The *yinyang* concept is also the basic concept used in Chinese fortune telling such as astrology (*suanming*, literally "calculating the fate") and geomancy (*fengshui*, literally "wind and waters").

Yoga

A. V. Balasubramanian

Yoga is one of the six principal systems of Indian thinking known as *darśanas*. The word *darśana* is derived from the Sanskrit root *drs*, meaning "to see." Fundamentally, *darśana* means "view" or "a particular way of viewing." Yoga, as one of the six *darśanas*, has its source in the Vedas. In the traditional Indian view these are called *vaidika*, or Vedic *darśanas*. These are *nyāya*, *vaiśeṣika*, *saṅkhyā*, *yoga*, *mīmāṃsā*, and *vedānta* (there are other *darśanas* that do *not* accept the supremacy of the Vedas, such as Buddhism and Jainism). While the source of Yoga was the Vedas, Yoga was formalized by Patañjali, one of the great Indian sages. His classic text is *Yoga Sūtra* (Aphorisms on Yoga). Although there are many other major treatises on Yoga that postdate Patañjali's, his work is the most authoritative.

All the *darśanas* proclaim that it is their aim to help human beings achieve clarity and balance of perception and action. Yoga is unique in as much as it offers practical suggestions and guidelines to achieve this end. According to the tenets of Yoga, human beings are under the influence of *avidyā*, which is what prevents correct perceptive analysis. Sage Patañjali suggests practical ways to reduce and remove *avidyā*. In his *Yoga Sūtra*, three things are suggested to help us explore the meaning of Yoga and therefore feel *avidyā*. These are *tāpas*, *svādhyāya*, and *īśvara-pranidhāna*. *Tāpas* is a means by which we keep ourselves fit and clean. Often *tāpas* is defined as penance, mortification, and dietary austerity, but what is meant is the practice of *āsana* (postures), *prāṇāyama* (control of the breath), and other disciplines. These practices aid in the removal of impurities from our systems. In so doing we gain control of our whole system. It is the same principle as heating gold to purify it.

The next part of Yoga is *svādhyāya*, the study of the self. Where are we? What are we? What is our relationship to the world? It is not enough to keep ourselves fit; we should know who we are and how we relate to others. This is not easy because we do not have an actual mirror for our minds as we do for our bodies. We must use reading, study, discussion, and reflection as a mirror to the mind.

The third means of exploration is *īśvara-pranidhāna*. It is usually defined as "love of God" but it also means "quality of action." We must carry out our jobs, and all our actions must be done with quality. Since we can never be certain of the fruits of our labors, it is better to remain slightly detached from them and pay more attention to the actions themselves.

Together, these three cover the whole of human action: fitness, inquiry, and quality of action. Taken together, these practices are known as *Kriyā Yoga*, the Yoga of action. Yoga is not passive. We must be involved in life, and preparation is necessary for this involvement.

Patañjali's Yoga is sometimes called *Aṣṭāṅga* Yoga, which literally means Eightfold Yoga. These eight are *yama*, *niyama*, *āsana*, *prāṇāyāma*, *pratyāhāra*, *dhārāṇa*, *dhyāna*, and *samādhi*.

Patañjali considers five different attitudes (*yamas*) or relationships between an individual and "the outside." The first is *ahimsā*. While the word *himsā* means injury or cruelty, *ahimsā* means more than merely the absence of *himsā*. It means kindness, consideration, or thoughtful consideration of people or things. The next *yama* is called *satya*, "to speak the truth." The third *yama* is *asteya*. *Steya* means "to steal"; *asteya*, the opposite, means if we are in a situation where people trust us, we will not take advantage of them. The next yama is *brahmacarya*. The word is composed of the root *car* (to move) and *brahma* (the truth). If we move toward the understanding of truth, and sensual pleasures get in the way, we must keep our direction and not become lost. The last *yama* is *aparigraha*, "hands off." *Parigraha* is the opposite of the word *dana*, which means "to give." *Aparigraha* means "to receive exactly what is appropriate."

Niyamas, like *yamas*, are attitudes and are not to be taken as actions or practices. The five *niyamas* are more intimate in the sense that they are the attitudes we have toward ourselves. The first *niyama* is *śauca*, or cleanliness. There are two parts to this, external and internal. External *śauca* has to do with simply keeping ourselves clean. Internal *śauca* has to do with cleanliness of the internal organs and mind. The practice of *āsanas* or *prāṇāyāma* could be an internal *śauca*. The second *niyama* is *santosa*, a feeling of contentment. The next is *tāpas*, a word we have already discussed. With *tāpas* the idea is to bring out *asuddhi*, "dirt" inside the body. *Svādhyāya* is the fourth *niyama*. As we defined it earlier, *sva* means self; *adhyaya* means study or inquiry. Actually, *adhyaya* means to go near. *Svādhyāya* means to go near yourself, i.e., to study yourself. Any study, reflection, or contact that helps us understand more about ourselves is *svādhyāya*. The last *niyama* has also been mentioned before. *Īśvarapraṇidhāna* means "to leave all our actions at the feet of the Lord." Since our actions often come from *avidyā* it is possible that they might go wrong. That is why contentment is so important. This attitude suggests that we have done our best, and can leave the fruits of our actions in the hands of something higher than ourselves.

The third *aṅga* is *āsana*. In the theory of *āsana* practice, there are two aspects, *sukha* and *sthira*. We must be comfortable and at ease (*sukta*) and we must be steady and alert (*sthira*). We must be involved and at the same time attentive. Yoga suggests ways to achieve these qualities in *āsana*. The fourth *aṅga* is *prānāyama* which is conscious regulated breathing. *Pratyāhāra*, the fifth *aṅga*, involves the senses. The word *āhāra* means "food." *Pratyāhāra* means "withdrawing from that on which we are feeding." This refers to the senses: when the senses refrain from "feeding" on their objects, i.e., *pratyāhāra*.

Dhāraṇā comes from the root *dhr*, "to hold." *Dhāraṇā* occurs when we create a condition so that the mind, normally going in a hundred different directions, is directed toward one point. *Dhāraṇā* is a step leading toward *dhyāna*. In *dhāraṇā* the mind is moving in one direction; nothing else has happened. In *dhyāṇa*, when we become involved with a particular thing and we begin to investigate it, there is a link between ourselves and this object; i.e., there is a perceptual and continuous communication between the object and our mind. This communication is called *dhyāṇa*. Further, when we become so involved with an object that our mind completely merges with it, that is called *samādhi*. In *samādhi* we are almost absent; we become one with that object.

There are many varieties of Yoga. Some people say that *dhyāna* is the means to *Jñāna Yoga*. In this context, this means inquiry about the truth, the real understanding that we attain in a state of *samādhi*. Inquiry in which we hear, then reflect, and then gradually see the truth, is *Jñāna Yoga*. In the *Yoga Sūtra* it is said that in the state of mind where there is no *avidyā*, automatically there is *Jñāna*.

Bhakti Yoga comes from the root *bhak* which means "to serve that which is higher than ourselves." This means an attitude of devotion. In *Mantra Yoga*, a teacher who knows us very well might give us a *mantra* which has a particular connotation because of the way it has been arranged. If that *mantra* is repeated in a certain way, if we are aware of its meaning, and perhaps if we want to use a particular image, *Mantra Yoga* brings about the same effect as *Jñāna* or *Bhakti Yoga*. In *Rāja Yoga*, the word *Rāja* means "the king who is always in a state of bliss, who is always smiling." Any process through which we achieve greater understanding of the mysterious and the obscure is *Rāja Yoga*. In the Vedas there are many references to the word *Rāja* in relation to *īśvara*.

It is best to explain *Laya Yoga* in a context of *samādhi*. When the meditator completely merges with the object of meditation, that is *Laya*. We merge with the object and nothing else exists.

In recent times, much has been written about Hinduism, and a lot of it pertains to and derives from the viewpoint of *Vedānta*. It is important to see that the viewpoint of Yoga differs in some crucial respects from the viewpoint of *Vedānta*. Brahman is considered the "*Pāramārthika Satya*" or ultimate truth, and the world we live in and experience through our senses is granted the status of truth at an operational level, i.e., "*Vyāvahārika Satya.*" In a sense, this carries the implication that the world is false and illusory. According to Yoga, everything we see, experience, and feel is not an illusion but is true and real. This concept is called *satvāda*.

Everything, including *avidyā*, dreams, and even fancy and imagination, is real. However, all these are constantly in a state of flux. This concept of change is called *pariṇāmavāda*. In Yoga, although everything we see and experience is true and real, changes do occur either in character or in content.

Yuktibhāṣā of Jyeṣṭhadeva

K. V. Sarma

Jyeṣṭhadeva (fl. 1500–1610) was a Nambūthiri Brahmin from the Ālattūr village, an important Brahmin settlement near Cochin. He was probably a student of Dāmodara, the son of Parameśvara, who also taught Nīlakaṇṭha Somayāji. His fame rests on the authorship of one of the most important texts of the Kerala school of mathematics and astronomy, the *Yuktibhāṣā* (An Exposition of the Rationale [of mathematics and astronomy]) also called *Gaṇita-nyāya-saṇgraha* (Compendium of Mathematical Rationale). It is a unique work on the rationale of Hindu mathematics and astronomy as it was understood in medieval India. It is unique in the sense that it is neither a textbook nor a commentary, but a work which is wholly devoted to a systematic exposition of mathematical rationale, written in Malayalam, the local language of Kerala.

Born about 1500, Jyeṣṭhadeva probably composed the *Yuktibhāṣā* about 1530, since it is known that a little after 1534, Śaṅkara Vāriyar, another contemporary astronomer, used it in his commentaries. Another work of Jyeṣṭhadeva, the *Dṛkkaraṇam*, also in Malayalam, was composed in AD 1608.

At the outset of the work, the author states that he is attempting "to set out in full the rationale useful for understanding the planetary motion according to the *Tantrasaṅgraha* of Nīlakaṇṭha Somayāji" (b. 1444). But he actually goes much beyond that and subjects to rationalistic analysis the entire gamut of mathematics and astronomy. In fact, he takes up the treatment from the very fundamentals, the concept of numeration and the theory of numbers. The work is made up of two divisions, each one divisible into several sequential chapters.

The first deals with the following subjects (1) the eight fundamental operations, from simple addition to the roots of sums and differences of squares, wherein several methods, including diagrammatic solutions are offered; (2) algebraic problems; and (3) operations on fractions. The other chapters deal with: (4) the general nature of the Rule of Three (direct proportion) and (5) application of the Rule of Three in the computation of mean planets; (6) elaborate rationalizations of the circumference of the circle; and the last chapter: (7) the rationales of the derivation of the R sines, R versed sines, and their addition, properties of cyclic quadrilaterals, and the surface area and volume of a sphere. Many of the rationales are demonstrated both algebraically and geometrically.

Part Two is devoted to the exposition of rationales in astronomy, including (1) the computation of mean and true planets by means of two types of epicycles, supplemented by corrections; (2) the celestial sphere, the related great circles and secondaries, the precession of the equinoxes, and the armillary sphere; (3) declination, right ascension, and related matters; (4) problems related to spherical triangles; (5) problems connected with direction and shadow; (6) computation of the rising and setting points of the ecliptic, the ecliptic having constant variation. A direct method, enunciated in Indian astronomy for the first time, is used; (7) eclipses and the attendant parallax corrections; (8) the *Vyatipāta*, which is the moment when the sun and the moon have equal declinations, but in different quadrants; and (9) reduction of computed results to observation and with the phases of the moon.

Some points are of special interest in the *Yuktibhāṣā*. One is the rationale for three or four steps for true planets, although the result can also be obtained in two steps; the derivation of inverse declination and inverse right ascension; novel solutions for some of the problems on spherical triangles and on shadows; refinements for parallax corrections; and an alternate method with a novel correction for the computation of the moment of *Vyatipāta*. A noteworthy characteristic is its elucidating rationale from the fundamentals, first setting out the axioms and postulates involved, then developing the arguments and methodologies step by step.

It might also be noted here that Śaṅkara Vāriyar provided a valuable service by incorporating rationales from the *Yuktibhāṣā* into Sanskrit, the language of scholars. This he did in two elaborate commentaries called *Kriyākramakarī* on the *Līlāvatī* by Bhāskarācārya, and *Yuktidīpikā* on the *Tantrasaṅgraha*, a work on astronomy by Nīlakaṇṭha Somayāji. There is also a highly corrupt rendering of *Yuktibhāṣā* into Sanskrit.

Y

Zacut, Abraham

José Chabás

Abraham bar Samuel bar Abraham Zacut was the most prominent astronomer of the late Middle Ages in the Iberian peninsula. He was born in 1452 in Salamanca (Spain), a Castilian town whose university had established a renowned chair of astrology (including astronomy) in the mid-fifteenth century.

Although he is chiefly known for his astronomical activity, Zacut wrote on other subjects such as lexicography (*Hosafot lasefer ha-'arukh*) and history (*Sefer Yuḥasin*).

Zacut's most outstanding work is *Ha-ḥibbur ha-gadol* (The Great Composition), a text in Hebrew consisting of more than fifty astronomical tables and lengthy canons explaining their use. The tables have 1473 as radix, they are arranged for the Christian calendar, and their entries are computed for the meridian of Salamanca. The tables give the positions of the Sun, the Moon, and the five planets presented in the form of an almanac. Of special interest are the tables listing the daily positions of the Sun (for 4 years from 1473) and the Moon (for 31 years from 1473). All the entries are computed according to the Alfonsine Tables, well known in Salamanca since the arrival of Nicholaus Polonius, the incumbent of the chair of astrology at the University of Salamanca ca. 1460. Another table lists all true syzygies (new and full moons) for 31 years; it is based on the cycle of 767 syzygies discovered by the Catalan astronomer, Jacob ben David Bonjorn, author of astronomical tables for Perpignan (1361), and a follower of Levi ben Gerson (1288–1344). Among others, both these Jewish astronomers are mentioned in Zacut's *Ḥibbur*. In fact, the only Christian scholar mentioned in the *Ḥibbur* is king Alfonso of Castile. The work was finished around 1478, and 3 years later it was translated from Hebrew to Castilian, with the help of Zacut himself, by Juan de Salaya, who held the chair of astrology after Nicholaus Polonius.

At the request of his new patron, Juan de Zúñiga, Master of the Order of Alcántara, in 1486 Zacut wrote a book on medical astrology: *Tratado de las influencias del cielo* (*Treatise on the Influence of the Heavens*), followed by a short text on eclipses: *Juicio de los eclipses* (Judgment on Eclipses). Two other works on astrology have been attributed to Zacut: *'Oṣar ḥayyim* (Treasure of Life) and *Mishpeteị ha-'iṣṭagnin* (Judgment of the Astrologer).

Because of the expulsion of the Jews decreed by the rulers of Spain (1492), Zacut moved to Portugal and entered the service of King João II as an astronomer and chronicler.

A version of Zacut's *Ḥibbur* was published in Leiria, Portugal, under the title *Tabulae tabularum coelestium motuum sive Almanach Perpetuum* (1496). The Portuguese scholar, José Vizinho, was responsible for this version, which contains a summary of the canons of *Ha-ḥibbur* and most of its tables. Actually, two editions came out of the Portuguese printing house that year: one with the canons in Castilian, the translation of which was made by Vizinho, the other in Latin. The *Almanach Perpetuum* is said to have played a significant role in the navigation projects of the kingdom of Portugal, and especially the tables giving the daily positions and declinations if the Sun. For a facsimile of the tables, see ►http://www.fondoantiguo.us.es/obras/200/index.html.

After the practice of Judaism was declared illegal in Portugal in 1496, Zacut traveled to Northern Africa and settled in Tunis. He adapted his tables for the year 1501 and he compiled another set of tables, beginning with year 1513, arranged for the Jewish calendar and the meridian of Jerusalem where he then lived. Both sets of tables only survive in fragmentary texts. Zacut died in 1515, probably in Damascus.

Zacut's work had a considerable impact on the astronomical community. All, or some of, the tables in the *Almanach Perpetuum* were reprinted several times in astronomical texts published in 1498, 1502, 1525, and 1528. All four editions were printed in Venice, in three different printing houses. Further evidence for the fame of Zacut and his tables is found in many authors in the late fifteenth and sixteenth centuries, and even later, among Jewish, Muslim, and Christian scholars.

Zero

R. N. MUKHERJEE

Mathematics today owes its existence in part to the discovery of zero. For the purpose of calculation it needed a short symbol, which is at present denoted by a small circle in nearly every part of the world. In India in the early period the form of short symbol which represented zero (*śūnya*) was both a dot and a small circle.

In the Vedic literature, in the *Amarakosa*, zero (*śūnyam bindau*) was represented by a dot. The form was also suggested by the word *kṣudra* (very small) in the *Atharvaveda*. The word *randhra*, used in the Hindu *Gaṇita Sastraka*, indicated a small hole. There are many examples of zero being represented as a dot in the Kashmirian *Atharvaveda*, both in the marginal notes and in the text itself.

In the marginal notes, the numbers are as follows:

Symbol	Number	Folio	Page
◊●●	100	100b	192
◊●◊	101	101b	194
◊2●	170	170b	310

The symbols in the marginal notes represented the Folio numbers. In most of the pages of the book there are examples of the above type. In the text itself the following numbers are found:

1
2
3
4
5
6
7
8
9
10

Small circles in pairs have been used to denote blank spaces in the text. In Folio No. 178a, page 323 in the last line, pairs of small circles are found as follows:

○○ ○○ ○○ ○○ ○○

The numbers in the marginal notes may be taken from a later period, but the symbols in the text itself must be from the time of the *Atharvaveda* (500 BCE).

In the Bakhshālī Manuscript, the oldest extant manuscript in Indian mathematics (AD 200), the symbol  represents the number 4000, while the symbol  represents 500,000,000. The fourth zero in the manuscript is a small circle; the others are dots. In the Shahpur Stone image Inscription of Aditya Sena Bihar, India (AD 672), the symbol  stands for 60, and zero is represented as a dot. In the Malay Inscription at Katakapur (AD 686), symbol  represents the number 608 (Śāka), and zero is represented as a circle with a deep circumference.

In the above examples it is found that zero has been exhibited either as a dot or as a small circle to fit in numbers in the place value scale, or to represent absence. In the inscriptions at Sambor, Palembang, and Kotakapur, which were Indian colonies of the Far East, the numbers have been written to represent the Śāka era. Hence undoubtedly they also represent an Indian origin.

Now the question arises as to why zero has been represented as dot or a small circle and not as a square or rectangle or anything else. Two reasons can be assigned: one is spiritual or metaphysical, the other is physical or atomic.

`In the spiritual sphere, *śūnya*, or zero or nothing, the symbol of absence of everything, identifies itself with *Nirguṇa* Brahma, the absence of all qualities. The no-quality (*Nirguṇa*) in Brahma represents the fact that He is not guided by any of the qualities or constituents of nature. But at the same time Brahma is the source of all qualities, energy, power, and strength. Similarly *śūnya* or zero itself signifies absence when placed independently, but it represents fullness when it is placed in the decimal system of numeration. (Placing zeros on the right side of a number increases the value to an infinite step.)

Since the conception of *śūnya* identifies with the conception of Brahma both in absence and fullness, the symbol of *śūnya* (zero) must be guided by the symbol of Brahma. The conception of Brahma lies in meditation on a particular point or small circle in the space between the two eyebrows.

Swami Sivananda has given concentration the name "one-pointedness". Concentration can also start by fixing one's gaze on a black dot on the wall and later on a bright light first of the size of a pinpoint and later of the size of a sun coming out from the space in between the two eyebrows. Hence the symbol of Brahma can be taken to be a dot or a small circle, and therefore the symbol of mathematical zero is either a point or a small circle.

There are also physical reasons for the symbol for zero. Planets seen from the earth look just like dots. From Vedic times Indians excelled in astronomical observations as we can see in the *Vedāṅga Jyotiṣa* (1200 BCE). So the physical reason for zeros being represented as a dot or a small circle lies in the fact that the sun, moon, and planets were seen as dots or small circles to an observer on the earth.

Now why should a planet be chosen to represent zero? It is because of the other interpretation of mathematical zero, the absence of atoms. The idea of the atom was mentioned in ancient times in the Buddhist work *Lalita Vistara* (500 BCE). The nucleus of the atom is so small that it is a *kṣudra* (minute), a synonym for zero in the *Athravaveda*. Thus the absence in mathematical zero is guided by the absence inherent in the smallness of an atom or its nucleus. The concept of the fullness of mathematical zero is also present in the infinite motion of the planets and of the electrons around the nucleus of an atom.

The electron has no mass in the material sense, and the mass which it has developed from electrical energy is negligible. This guides the concept of mathematical zero. The movement of electrons around the nucleus with a very high velocity and in an infinite motion is identical with the concept of fullness of mathematical zero which guides the numbers to move in an infinite journey like 10, 100, 100, 10,000 to 10^n.

Thus the double interpretations, absence and fullness, of mathematical zero are identical with the double interpretations in a planet, and the symbol of zero is guided by the symbol of a planet which is observed either as a dot or a small circle and whose path is almost circular.

Zero has a double meaning in Vedic literature. Etymologically the word *śūnya* comes from the word *śūna* (*śūna* + *yat*). The word *śūna* has two meanings. One is the killing of animals or the slaughter house, which represents absence; the other is increase, which leads to the conception of fullness.

The synonyms of zero, *randhra*, *tuccha*, *kṣudra*, and *ritka* project a concept of nothingness, while the synonyms *vyoma*, *diba*, *akasa*, *antariksa*, and *jaladhra patha* mean infinite expanse of sky. *Purna* means full, and *ananta* means infinite. *Drabinam* and *balam* mean strength, vigor, and force.

Zero, though it signifies nothing, has a full voltage battery charge when used in the decimal place value system.

The German mathematician Van der Waerden (1961) opines that the symbol of zero as a small circle came from the first letter "o" of the Greek word *ouden* meaning nothing. This claim can be compared with a parallel claim (apparently convincing but far from the truth) that 4 in Brahmi Numerals written as 𑁕 comes from the first letter 𑁕 of the word 𑁕 (our four in English). Similarly in India one may say that the symbol ५ (5) in Deonagri script comes from the first letter of the word पांच (five), ६ (6) in Deonagri comes from the first letter of the word छः (six). But these are not so. Every number symbol has a heritage and a path through which it has come down to its present form. That "o" is the first letter of the word is just a coincidence. Rather the symbol of a small circle (o) was used for the numbers 10, 70, and 100 in Greece.

Zhang Heng

JIANG XINOYUAN

Zhang Heng was a Chinese astronomer, writer, and machinist (AD 78–139). As a man of noble descent, he assumed many official positions, and from

Z

AD 115, twice was the head of the imperial astronomical organization for a total of 15 years. He was a versatile man who contributed greatly to Chinese astronomy.

The title of one of his works is *Ling Xian* (Mystical Laws); it is very possibly an outline of astronomy–astrology, but only part of the beginning has been handed down. He made an astronomical instrument like a planetarium to demonstrate the motion of the sun, moon, and planets with stars in the background, and to give the correct time. According to historical records he provided this instrument with an automatic mechanical installation, but the detailed information has not been preserved.

Zhang Heng made a wonderful invention for earthquake measurement. In AD 132 he invented a seismoscope called *Hou Feng Di Dong Yi* (Instrument for Earthquake), and at Luoyang (the capital of the empire) he successfully determined that an earthquake had occurred at a place in the northwest of China more than a thousand kilometers from the capital. We have the following information about this seismograph.

This instrument was cast in copper. Its main body is a standing egg-shaped shell with an erect pendulum in the center. It links eight dragons each of whom, with some dexterous mechanical installations, keeps a small copper ball in its mouth. When an earthquake happens somewhere, the dragon in that direction spits out its ball, so that people know where the earthquake has occurred.

This famous seismoscope was not preserved, so scholars have tried to reproduce it since the nineteenth century. Many reconstructive schemes on the basis of modern seismological principles have been published. Up to now, the most successful was by Wang Zhenduo (1963) of which a model has been made.

Zhang Heng is also an important writer. His *Si Chou Shi* (Four Chapters of Distressed Poems) and *Gui Tian Fu* (To Live in Seclusion) are literary masterpieces and his *Tong Shen G* (Song of Love) is one of the most important early documents for the history of Chinese sexual culture.

Zhang Ji (Zhang Zhongjing)

Fabrizio Pregadio

The Chinese physician and medical author Zhang Ji (ca. 150–220), also known as Zhang Zhongjing, was born in the Nanyang commandery (in modern Henan). As stated in the preface to his main work, he was prompted to study medicine and collect prescriptions by the spread of epidemic diseases which caused the death of several members of his own clan. The preface adds that he was Governor (*taishou*) of Changsha (modern Hunan), but this detail is not independently confirmed by other sources.

Zhang Ji's main work, completed in the first or second decade of the second century, was originally entitled *Shanghan zabīng lun* (Treatise on Cold Damage and Miscellaneous Disorders) and included 16 chapters. The rather intricate bibliographic history of the text cast doubts on its authenticity. About one century after its compilation, Wang Shuhe (ca. 265–317) produced a revised, expanded version. The final six chapters, lost by the Song period, were replaced on the basis of an abridged version, and published as a separate work. The two main parts in which the text is extant today are entitled *Shanghan lun* (Treatise on Cold Damage) and *Jingui yaolüe* (Essentials from the Golden Casket), respectively. The latter is based on the "Miscellaneous Disorders" section of the original text.

The *Shanghan lun* is the first Chinese medical text devoted to a specific etiology. It is concerned with a class of diseases symptomatized by acute fevers, and named "Cold Damage" after one of their factors. Their diagnosis is based on the identification of symptoms (*zheng* or "evidence") that indicate the stage reached by the disease in its progression toward the vital centers of the body. These stages of development are defined according the Six Warps (*liujing*) system, one of the frameworks used to describe the cyclical flow of energy within the body (others are *qi* and *wuxing*, Five Agents or Phases). The text emphasizes the practical rather than the theoretical aspects of healing. Therapy is based on the administration of medicines (the whole work includes more than 300 prescriptions for specific diseases), and to a lesser extent on acupuncture, moxibustion, and other methods such as baths and massages.

Zhang Ji's work gave rise to the second most important tradition within Chinese classical medicine after the one represented by the texts of the "Inner Canon of the Yellow Emperor" corpus (*Huangdi neijing*). Although Zhang refers to this corpus in the preface, even the most basic notions of the Inner Canon – e.g., the

Five Agents or Phases, the visceral systems (*zangfu*), and the circulation tracts (*jing*) of acupuncture – are absent from his work. As has been pointed out, this is not necessarily a sign of alternative or competing traditions. An extended commentatorial tradition, in fact, has tried to bring together the respective basic notions. Only recent research has shown the ways and extent to which the general framework of the two works differs.

Zhang Qiujian Suanjing

Lam Lay Yong

Zhang Qiujian suanjing (The Mathematical Classic of Zhang Qiujian) is the only known work of the fifth century mathematician, Zhang Qiujian. It is one of ten mathematical books known collectively as *Suanjing shishu* (Ten Mathematical Classics). In AD 656, when mathematics was included in the official examinations, these ten outstanding works, which covered a period of over a thousand years, were specially selected as textbooks.

Jiuzhang suanshu (Nine Chapters on the Mathematical Art) and *Sun Zi suanjing* (The Mathematical Classic of Sun Zi) are two of these texts that precede *Zhang Qiujian suanjing*. All three works share a large number of common topics. Though *Sun Zi suanjing* was intended as a primer, it now provides significant documentation of the rod numerals and their use in multiplication, division, and other mathematical methods. *Jiuzhang suanshu* is undoubtedly the most important and influential of the early mathematical texts. Both works occupy prominent places in the history of Chinese mathematics with one showing the initial learning stage and the other manifesting an evolutional culmination. *Zhang Qiujian suanjing* demonstrates the continuation of the development of mathematics from here, and provides an important bridge of knowledge on the evolution of traditional mathematics to its apogee in the thirteenth century. It is all the more important as such surviving works are few and far between.

Zhang Qiujian regarded fractions of primary importance; he mentioned the difficulty of the subject in his preface and provided more complicated problems than those in *Jiuzhang suanshu*. There are only very brief general descriptions of finding the square root and the cube root of a number in *Jiuzhang suanshu* and these are written with the use of technical phrases. It is a relief to scholars to find that examples are employed in *Zhang Qiujian suanjing* to illustrate the step by step procedures of both methods and also to show how the solution of a nonintegral approximation is obtained.

Zhang Qiujian continued with the tradition of the development of arithmetic by supplying problems involved with what is known in the west as the Rule of Three and extending to problems concerned with proportions, compound proportions, and proportional parts. Other problems are involved with relative speed, different shaped frustums and granaries, the Rule of False Position, the arithmetical progression, the computation of interests and taxes, similar right-angled triangles, and the quadratic equation. There are a number of problems concerned with the well-known *fang cheng* method, which is the Chinese way of solving a set of simultaneous linear equations. The last problem of the book is the famous problem of a hundred fowls. In this problem, somebody is to buy 100 fowls for 100 monetary units, given that a rooster costs five units, a hen 3, and chicks are sold three for one unit. Even though the answers given in the book are correct, it is not clear how the answers were obtained.

Zhang Qiujian's lucid style has been a great help to the scholar's understanding of how the ancient mathematicians manipulated the rod numerals to arrive at the answer. The existing edition of the book has three chapters with 92 problems; the last portion of the second chapter and the beginning of the third chapter are incomplete. The book has been translated into English by Ang Tian Se.

Zhang Qiujian suanjing has an important place in the world history of mathematics: it is one of those rare books before AD 500 that manifests the upward development of mathematics fundamentally due to the notations of the numeral system and the common fraction. The numeral system has a place value notation with ten as base, and the concise notation of the common fraction is the one we still use today.

Zheng He

Sally Church

Zheng He was originally from Kunyang in Yunnan province, in Southwest China. Born around 1371 to a Muslim family, he was surnamed Ma, a common Muslim surname derived from the Chinese transliteration of the name Muhammed. During the 1380s, the Ming government sent troops to Yunnan on an expedition to pacify the region, expel any remaining Mongol influences, and incorporate it solidly into the newly founded regime. At the age of about 10, Zheng He (then Ma He) was captured by Chinese troops, taken prisoner, and selected to become a eunuch. We know that by 1382, when an inscription was written for his father who had passed away, he was taken into the service of Prince Zhu Di, fourth son of the Ming founder, Emperor Hongwu (Zhu Yuanzhang, r. 1368–1398). There Ma He served Zhu Di in his principality of Yanjing (the region of present-day Beijing). Zhu Di was later to become the third Ming emperor, Yongle (r. 1403–1424).

In his early career, Ma He accompanied Zhu Di on military campaigns against Mongol forces in the Yanjing region. He distinguished himself as a military commander in a campaign against the Mongols outside the Great Wall (1393–1397), and then in the civil war (1399–1402) launched by Zhu Di against Hongwu's successor, Jianwen. This war ended in victory for Zhu Di, who usurped the throne from Jianwen in 1402. For loyal service to him during the civil war, and as a reward for suppressing a rebellion in Yunnan, Zhu Di, then Emperor Yongle, conferred the Chinese surname Zheng on his trusted eunuch. This occurred on New Year's Day in 1404. From then on he was known as Zheng He.

Soon after ascending the throne, Yongle began planning the maritime expeditions which have made Zheng He famous. In some respects they were a continuation of the regular conduct of foreign relations – the sending and receiving of envoys to and from foreign countries, particularly in Southeast Asia – which had occurred during Hongwu's reign (1368–1398) and in previous dynasties. As early as the ninth month of 1402, only three months after proclaiming himself Emperor, Yongle sent ambassadors to these countries to announce his accession. We are told that envoys came to China from Calicut and Chola (the Coromandel coast) for the first time in 1403. In the eighth month of that year, Yongle reopened the three maritime supervisorates in Zhejiang, Fujian, and Guangdong that had operated under Hongwu. Ambassadors came and went, and regular tributary and diplomatic relations proceeded as normal.

In the meantime, there were signs that the emperor had a larger-scale of activity in mind. As early as 1402 he had ordered the construction of ocean-going ships in substantial quantities – first 137 ships, and then 200 in that year alone. A further 188 vessels were to be converted (presumably from ocean-going grain transports) the following year, and 55 more new ships were ordered at the beginning of 1404. Emperor Yongle appointed Zheng He commander of the fleet and on 11 July 1405 issued the order for the first expedition to the "Western Oceans" (Xiyang).

The ultimate purpose of these expeditions is not entirely clear, though there were probably diplomatic, military, and economic motivations. The main reason given in the Ming History (*Ming shi*) – that of finding the deposed emperor Jianwen – was probably not the true purpose. It would not have been necessary to send out a fleet of over a hundred ships and 27,000–28,000 men to search for a single person in the vast oceans of Southeast Asia and beyond, nor does this explain the expeditions' political, military and diplomatic activities in the regions they visited.

In all there were seven major expeditions, each one taking approximately 2 years from departure to return.

The dates of the seven were (1) 1405–1407; (2) 1407–1409; (3) 1409–1411; (4) 1413–1415; (5) 1417–1419; (6) 1421–1422; and (7) 1431–1433. The first three departed quickly in succession, with one leaving in the same year as the previous one returned. After the third, there was a 2-year gap between each. Between the sixth and seventh expeditions a space of 9 years intervened because of the death of Emperor Yongle in 1424. He was succeeded by Emperor Hongxi (r. 1424–1425), who saw the expeditions as unnecessary extravagances and called a halt to them. The final expedition was not launched until the reign of Hongxi's successor, Emperor Xuande (r. 1425–1435). In addition to the seven major expeditions, there were also branch or side expeditions to such countries as Bengal and Thailand.

Because of the monsoon, which Chinese sailors seem to have understood quite early on, the expeditions followed a regular seasonal pattern in their departure and return. They left the port of Taicang (near present-day Shanghai) in the autumn, and sailed down the coast to the port of Changle in Fujian province. There they waited for the monsoon until December or January, before sailing on to Champa (Xinzhou, present-day Qui Nhon), Java, Palembang, Melaka (Malacca), and various places on the island of Sumatra, including Samudra-Pasai. After crossing the Bay of Bengal, they reached Ceylon (present-day Sri Lanka), and then proceeded to Quilon, Cochin, and finally Calicut, a major emporium of the Indian Ocean trade network at the time. The first three expeditions did not go beyond this point. The fourth went further, to Hormuz, and the fifth, sixth, and seventh expeditions traveled to the Arabian Peninsula and East Africa. The journeys beyond Calicut were probably undertaken by portions of the fleet.

The main scientific and scholarly issues involved are the dates of the various expeditions and their implications for such issues as speed of travel, the numbers and types of ships that sailed on the voyages, the logistics of carrying out such a major operation, the routes the expeditions followed, and the techniques and instruments that were used for navigation. The equipment used for military purposes is also of interest, although details are scarce. With regard to the dates, there is some disagreement in the sources, but the discovery of two stone inscriptions in the 1930s in two separate locations on the Chinese coast, each corroborating the other on the years of departure and return for the seven major voyages, has settled the matter for the most part, thanks to the careful elucidation of the issue by Duyvendak (1938). The numbers and types of ships on the voyages cannot be known exactly, but it is highly unlikely that they were the size given in the *Ming shi* of 44 *zhang* long and 18 *zhang* wide, equivalent to 447 × 183 ft. Moreover, there are serious practical reasons for thinking that the ships could not have been of that size. They would have been proportionally much too wide. Moreover the available timber would not have allowed a longitudinal strengthening member to have been made in one continuous length, nor could masts of the height required have been made of a single tree trunk. It has also been estimated that as many as 8,000 men would have been needed for the crew, and there is no evidence for ships carrying more than 500 men on them; more likely there were 200–300 crew members. The "Mao Kun map" (see below) shows conventional ships with only three or four masts, although it has been estimated that a ship of 44 *zhang* in length would need nine masts. There are references to 48, 62, or 63, and 100 ships used on individual voyages, and the initial order for ships to be built in 1403 was for 250. Thus it is difficult to be precise as to the size of the fleet, though there were probably over 100 ships on each expedition. The ships must have been of various sizes for different purposes, including ships for military uses, the transport of supplies, and the transport of personnel. More research needs to be done on the question of logistics, to understand how so many sailors and other specialists (including doctors) were recruited, and how supplies were requisitioned and managed on the voyages. Further study of local histories and gazetteers of the coastal regions around ports such as Taicang and Changle may perhaps shed some further light on this question.

The routes and navigation techniques are perhaps the most rewarding issues for scientific investigation. For this, the most important source is the Mao Kun map, called thus by Mills because it appears in a collection of military preparedness materials (*Wu bei zhi*) compiled by Mao Yuanyi (1597–1661), a grandson of Mao Kun (1512–1601). In Chinese, the map is usually called *Zheng He hanghai tu* (Zheng He's navigation map). It probably came from Mao Kun's library of military materials, which he collected because of his interest in naval matters deriving from involvement in the coastal defense of Fujian. Significant work on this map has been done in the West, particularly by Mills (1970) in his book on Ma Huan, who accompanied three of Zheng He's expeditions and wrote an account, entitled *Yingyai shenglan*, of the places they visited. It is a strip map in 40 folios arranged from right to left, beginning in Nanjing and ending in Hormuz, also showing the east coast of Africa. It depicts not only the places roughly in their geographical locations along the contours of the coast, but also the routes from place to place, marked by dotted lines, and accompanied by sailing directions along the route markings. The sailing directions are expressed in terms of compass points and distances, with occasional references to navigation techniques, such as the need to take soundings in certain areas to avoid shallow waters. Distances are expressed in lengths of time according to the Chinese system of counting watches, or 2-h periods.

The use of astronomy in navigation is evident in some of the sailing directions, particularly those for the north–south route along the coast of Africa, where latitude is indicated by the height of constellations measured in number of fingers at arms' length above the horizon. The Arabs also used this technique in seafaring. The work concludes with four "stellar diagrams" giving precise instructions for positioning a ship in relation to certain stars and constellations on two key segments of the route – between Sumatra and Ceylon and between Hormuz and Calicut. This was in order to ensure arrival at the correct destination over long expanses of ocean.

The expeditions provided regular contact and involvement with distant countries over the course of almost 30 years. Through the accounts not only of Ma Huan but also of Fei Xin and Gong Zhen, certain circles in China were exposed to foreign ideas, practices, and customs. Needham (1971) suggested that one of the aims of the expeditions was the "search for rarities of all kinds… gems, minerals, plants, animals, drugs and the like" for the court, and that knowledge of foreign science, particularly medicine, was transmitted to and from China during this time. This contact seems to have led to some exchange of information and technology between China and other cultures and civilizations – the Arabs and Indians for example – and could have led to more if it had not been for the suppression of information about the voyages in China due to internal politics. Fearing an increase in eunuch power, and citing the extravagant expense of the expeditions, the official Liu Daxia, who later became president of the Ministry of War, discredited the first-hand accounts, calling them "deceitful exaggerations of bizarre things far removed from the testimony of people's ears and eyes." He destroyed all the documents in the official archives that concerned the voyages.

A question much discussed by scholars is why these expeditions, which showed such a high level of scientific and technological expertise, as well as energy, curiosity, and interest in other countries, stopped abruptly after 1433. Did China simply turn inward, cast aside her quest for knowledge of "the other," reject science, technology, and progress, and willingly forfeit a prominent role in international relations, thus sealing her fate in the nineteenth and twentieth centuries? Such a view not only relies too much on hindsight but also seriously underestimates the intelligence of the Chinese people. There was also no amorphous "China" that made such a conscious decision. A handful of people with political power took certain steps for their own short-term reasons. To conclude that China at any point in her history rejected technology and progress simply ignores reality. There were engineers, mathematicians, astronomers, and scientists in many fields during all periods of Chinese history who for practical reasons as well as theoretical interest pursued scientific investigation and activities, sometimes in conjunction with, but more often independently of government policy. Instead, a more likely explanation for the cessation of the maritime expeditions is financial – the expeditions were expensive and there were other demands on the imperial coffers at the time, including not only defense against invaders in the north, but also domestic concerns such as famine relief and dyke repair.

Zheng He's precise time and place of death is not known for certain. It is now accepted in scholarly circles that he did not die abroad, but returned to China and passed away in Nanjing in approximately 1435. A tomb in Nanjing is now conventionally accepted as his.

Despite the destruction of the documents in the official archives, many sources of information about these voyages still survive. Of prime importance are the three first-hand accounts by Ma Huan, Fei Xin, and Gong Zhen, which are remarkable for their attention to the political, economic, social, and religious conditions of the lands they visited, as well as for their frank observations and open attitudes toward the unfamiliar customs and practices they found. In addition to the Mao Kun Map and the various inscriptions on stone steles, including three in China (the Liujiajiang, Changle, and Jinghai temple inscriptions) and others in the countries they visited, an itinerary for the seventh voyage also survives, preserved in a work by Zhu Yunming, giving the dates of arrival and departure from each place visited by the main portion of the fleet. From this itinerary it is possible to calculate the length of the various legs of the journey and the speed of travel. In addition there are numerous references in the *Ming Shilu*, or "Veritable Records" of the Ming dynasty, particularly to the exchange of ambassadors to and from China. References occur in many other Chinese historical documents as well. In the 1980s Zheng Hesheng and Zheng Yijun collected voluminous references to the voyages in Chinese historical and other documents and included them in their monumental multi-volume work entitled *Zheng He xia Xiyang ziliao huibian* (A Collection of Resource Material on Zheng He's Voyages to the Western Oceans), a convenient resource for anyone interested in pursuing research on the expeditions.

In 2002 the British submarine commander (retired) Gavin Menzies, in a popular book entitled *1421*, claimed that the expeditions sailed beyond East Africa to "discover" America and circumnavigate the globe. This theory, though presented as historical fact, remains entirely undocumented. Serious scholars continue to pursue the truth about Zheng He's voyages, and interest in them is currently at a height because it has now been 600 years since their initial launch.

Zhenjiu Dacheng

Richard Bertschinger

The *Zhenjiu Dacheng* (Great Compendium of Acupuncture and Moxibustion) is a digest of acupuncture and moxibustion writings from the Han to the Ming dynasties. As such, it forms the greatest comprehensive survey of acupuncture in China ever to be produced during classical times. Much of its greatness is due to its selection of works from the Song and Yuan. It was edited by Yang Jizhou in 1601, as the culmination of his life's work. He was then close on 80-years old and obviously still active.

An early title for the work had been "Secrets of the Dark Inner Mechanism of Acupuncture and Moxibustion for the Preservation of Health." In this text Yang Jizhou included mainly the traditions of his own family, but later he enlarged the book to include earlier literature, and so changed the title. Generally he selected the best of the old, and reedited it, adding a certain amount of his own material where it suited.

The Grand Compendium comprises some ten volumes, covering all aspects of acupuncture and moxibustion. It also contains an appendix on massage techniques particularly suited for children, entitled *Biaoying Shenshu* (The Divine Art of Protecting Infants), taken from an earlier book which is now lost. The work includes listings of channels and points; many point-formulae for medical conditions, particular systems for choosing points; refined needling techniques such as those developed during the Song, Yuan, and Ming; detailed formulae for calculating the precise time and exact point for treatment; glossaries of point names; and selections from the classics, especially the *Huangdi Neijing* and its slighter companion the *Nan Jing*. This all constitutes a great wealth of historical material.

Particularly striking are the exquisite verse poems selected for the second volume. These include the "Ode to the Golden Needle," which focuses on needling techniques, the *Liuzhu Zhiwei Fu* (Ode to Intricacies in the Circulating Flow), which outlines the Law of Midday–Midnight in which the choice of points is determined by the particular hour and day of treatment, and the *Biaoyou Fu* (Ode to the Streamer out of the Dark), the longest and most comprehensive of these poems, which contains an extensive commentary by Yang Jizhou.

A gradual increase in prosperity was spawned by better social conditions during the Ming. These in turn created an interest in the old ideas. Undoubtedly influential on Yang's work were the *Zhenjiu Sunan Yaozhi* (Essentials of Acupuncture and Moxibustion, 1536) and the *Zhenjiu Juying* (Gatherings of Outstanding Acupuncturists, 1546), both issued by Gao Wu during the earlier century. Gao Wu's work was particularly commendable as he made a stand against any superstitions in medicine. Where he was uncertain he would simply state it, without comment. From Gao Wu's work Yang took both an uncluttered approach and a grand overview of the acupuncture tradition. In many places Yang Jizhou pays debt to Gao Wu by copying his selection of classical extracts exactly.

Another great influence was the *Shenying Jing* (Classic of Divine Resonance, 1425) by Chen Hui. From this work Yang Jizhou borrowed his simple and practical approach, cutting great swathes through confusing systems of point selection by adhering strictly to the Divine Resonance's printed lists. This compendium is an invaluable treasure for all acupuncturists and has become well-known abroad as well as in China.

Zhenjiu Jiayijing

Richard Bertschinger

The *Zhenjiu Jiayijing* (The A–Z Canon on Acupuncture and Moxibustion) was written by Huangfu Mi (AD 215–282), during the short-lived Jin Dynasty. Needham dates the book as being finished some time between AD 256 and AD 282.

This is the oldest surviving text devoted exclusively to acupuncture and moxibustion. It was produced after the fall of the Han nation, during a time of violent turmoil and disruption in Chinese society. Huangfu Mi summarized the knowledge of his day concerning acupuncture and moxibustion, and ordered the many texts then current. He drew from both sections of the *Huangdi Neijing* as well as the *Mingtang Kongxue Zhenjiu Zhiyao* (Therapeutic Essentials of the Acupuncture Points Revealed in the Clear-Lit Hall), of unknown authorship, a book now lost. Huangfu Mi took up medicine in middle age because of his own family's illness and his own arthritis.

This book's most impressive character lies in its systematic outline of the subject (as revealed in the title). The many points are grouped under the various channels to which they belong, with number, name, point location, and tips for finding each. Additionally there are listings of the illnesses, or syndromes, for which each can be used, detailing how deep the needle should be inserted and the number of breaths for which it should be retained in position. Tonification or reducing techniques are also described, as well as angling the needle shaft along or against the direction of energy flow down the channel. In addition, Huangfu mentions the use of moxa, the number of cones for each point being duly recorded. All this had never been so accurately or clearly laid out before.

This book, quite justifiably, has had an enormous influence throughout China and abroad. It became *de rigueur* reading for the Japanese imperial colleges from the seventh century, and found its way to Korea even earlier. Its texts have been the foundation of acupuncture teaching and practice for some 70 generations in the East. As yet, there has been no translation into English.

The book's 128 chapters comprise medical theory, the examination and diagnosis; characteristics and pathology of the channels; a complete catalogue of the points; pulse diagnosis; needling technique; outline of pathology and transmission of disease; types of fevers; pains, swelling, coughing, rheumatism, wasting diseases, and dumbness; eye, nose, and throat problems; woman's and children's illness; and appendices.

Huangfu Mi's approach, in particular, stressed the need for a proper adjustment of the patient's emotions. He knew that physical and environmental factors played a part in illness, that treatment should proceed with great care, and that signs and symptoms should be precisely differentiated. All show a clear and intelligent approach to practice.

Very little has changed in the location and identification of acupuncture points since the publication of this text some 1,800 years ago. For instance, it is mentioned in the preface to the *Essentials of Chinese Acupuncture*, the first acupuncture book produced by the Chinese for a Western audience.

Zhoubi Suanjing

Christopher Cullen

The *Zhoubi suanjing* (frequently also romanized as *Zhoubei suanjing*), is an anonymous Chinese work on astronomy and mathematics. It is a composite work which probably reached its final form in the first century AD under the Western Han dynasty.

The contents deal mainly with calendrical astronomy, and the shape and size of heaven and earth according to the *gaitian* (umbrella [-like] heaven) cosmography. It opens with a brief dialogue between the Duke of Zhou (fl. ca. 1000 BCE) and Shang Gao, an otherwise unknown figure, who explains the use of the try-square *ju* and refers briefly to a round heaven lying above a square earth. In connection with the try-square Shang Gao refers cryptically to the relationship between the sides of a 3–4–5 right triangle. The text then continues with a long and fairly coherent section which may be the original core of the book.

In this section an otherwise unknown Chen Zi discusses the use of a gnomon (a vertical pole) for observing the shadow cast by the noon sun. It is claimed that the shadow of a pole 80 *cun* (inches) long changes by one *cun* for every 1,000 *li* (about 400 miles) moved north or south in relation to the point on the earth where the sun is directly overhead. The use of this rule, which does not correspond to actual observation, enables the dimensions of the heavens to be calculated. Most of the rest of the book contains calculations relating to the operation of lunisolar calendrical systems of the *si fen* (quarter [remainder]) type. The text bears an important commentary by Zhao Shuang, probably written ca. AD 270–280, and has further annotations by Li Chunfeng, who prepared an edition for use in the State College in AD 656. The book was first printed under the Song dynasty in AD 1084.

Zhu Shijie 朱世傑

Karine Chemla

Virtually nothing is known of the life of this Yuan 元 mathematician, except the little we can learn from the prefaces to his two books, *Suanxue qimeng* 算學啟蒙 (*Introduction to Mathematical Studies*, 1299) and *Siyuan yujian* 四元玉鑒 (*The Jade Mirror of the Four Unknowns*, 1303). The first preface was written by Zhao Cheng and the second one by Mo Ruo 莫若 and Zu Yi 祖乙. From those we can surmise that Zhu came from Yanshan 燕山, near modern Beijing, that he traveled around China for more than 20 years in the last decades of the thirteenth century, after China had been unified under the Mongol rule, and that numerous students came to study with him.

His books attest to the fact that he inherited – from the northern milieu of the Hebei 河北 and Shanxi 山西 provinces which developed the "procedure of the celestial unknown (lit.: origin)" (*Tian yuan shu* 天元術) – how to use polynomial algebra to build an equation with which to solve a problem. This achievement seems to have been unknown in South China and benefited from the potentialities of the counting instrument on which it is based: the surface for computing, on which numbers were represented with counting rods which could be moved or changed in their values throughout the computations. The earliest book that has come down to us and attests this procedure, though it is probably not the first to have dealt with it, dates from 1248. It is Li Ye 李治's (or Li Zhi 李治's, according to the name chosen for this scholar) *Ceyuan haijing* (測圓海鏡 Sea Mirror of the Circle Measurements). Yet Zhu Shijie does not mention this author or any other one. On the basis of extensions to polynomials with two and three indeterminates "that the procedure of the celestial unknown had received previously to him", according to Zu Yi's preface, Zhu Shijie developed it to what was to remain an unsurpassed peak in Yuan and Ming China: the use of polynomial algebra with four indeterminates to establish an equation to solve a given problem. As Hoe (1977) has stressed, the language and notations with which Zhu Shijie developed this algebra can, in their conciseness and precision, stand comparison with aspects of modern algebraic symbolism. Still, he notices some ambiguous modes of expression that do not make it entirely independent from the context. This very language might help us to make the historical connections between Zhu Shijie and such previous authors as Li Ye more precise, since as far as topics such as right-angled triangles are concerned, both use the same terminology. On the other hand, as regards the expression of formulas, they present differences even though their languages share the same basic features. For the expression of formulas or algorithms, Li Ye uses a language whose syntax is restricted in such a way that the understanding of a formula is unambiguous, which makes it context-free, in contrast to Zhu Shijie's (Chemla 2006).

Moreover, Zhu's writings demonstrate that he shared bits of knowledge (for instance, finite difference procedures for the summation of series, a topic to whose development he made crucial contributions) with the authors of the calendar *Shoushili* 授時曆 commissioned by the Mongol Court, the foremost being Guo Shoujing 郭守敬.

In addition to this – is it a reflection of his travels in South China? – his books reveal his interest in algorithms for quick, daily-life computations, or for mercantile and bureaucratic mathematics. In the surviving writings from this period, such topics had mainly been treated by mathematicians from South China, such as Yang Hui 楊輝. At the same time other topics which developed in South China, such as research connected with the Chinese remainder theorem, seem not to have found their way into his writings.

Still, Du Shiran 杜石然 (1966) called attention to the fact that Zhu seems to represent a kind of synthesis of traditions that, for at least decades, had been developing in isolation from each other in North and in South China, though they shared a common basis in the same fundamental characteristics and knowledge, including algorithms to find "the root" of any algebraic equation with positive, negative or null coefficients.

Zhu Shijie's books do not seem to have had any impact on the development of mathematics in China; not only we do not find any mention of his name or achievements after their publication, but also the books themselves would eventually be lost, to be found again in China and reprinted only at the beginning of the nineteenth century. This merely reflects the progressive loss of mathematical knowledge from the Song–Yuan period. In contrast to other writings of the same period, his *Introduction to Mathematical Studies* was to influence the development of mathematics in Korea and Japan. It was probably printed in 1433 in Korea, where it became a textbook for studying mathematics, and was eventually recovered thanks to a Korean edition of 1660. Moreover, its introduction to Japan in the second half of the seventeenth century, where it was reprinted and commented upon many times, allowed Japanese mathematicians to reconstruct the procedure of the celestial unknown, by that time forgotten in China, and to improve it until it became a tool in some ways comparable to the algebra developed in Europe during the same period. Horiuchi (1994) studies this aspect of the mathematics developed in Japan with great care and compares it with elements of the contemporary European algebra. Indeed, Japanese mathematicians' use of the surface for computing for their computations was probably instrumental in that respect, whereas in China this instrument had fallen into oblivion and was completely replaced by the abacus.

Zīj

Raymond Mercier

The term *zīj* is used everywhere in the study of Islamic culture to signify an astronomical handbook. These handbooks consist of a collection of astronomical tables together with such textual material as the reader would need in using the tables. The material is often divided into the following sections:

1. Calendrical conversion
2. Mean motions of the sun, moon, and planets
3. Equations of the sun, moon, and planets
4. Positions of fixed stars
5. Trigonometrical tables (sine, tangent)
6. Spherical astronomy
7. Parallax
8. Eclipses of the sun and moon
9. Geographical coordinates
10. Astrological quantities

The underlying theoretical model of planetary equations was almost invariably Ptolemy's, and to a large extent *zījes* represent a continuation of the *Handy Tables* of Ptolemy (ca. AD 140). However the earliest Arabic *zīj is that of al-Khwārizmī* (ca. AD 830), which was based on procedures derived from the Indian treatise *Brāhmasphutasiddhānta* of Brahmagupta (AD 628). A large number of such works survive intact in Arabic and Persian manuscripts, and many others are known by name only. The most notable modern edition (Nallino 1907) is that of the *Zīj* al-ṣābi' of al-Battānī' (fl. AD 880). For the long Islamic period the *zījes* are a vital repository of data, primarily through the constant improvements in the parameters of mean motions reflecting new observations, and also of improvements in mathematical methods.

In most *zījes* the textual material was generally restricted to instructions in the use of the tables. Larger astronomical treatises, such as the *Qānūn al-Masūdī* of al-Bīrūnī (ca. AD 1030), included all the material which would be found in a *zīj*, but went further in its detailed treatment of the whole subject.

A number of *zījes* were translated into Latin and Greek, and initially at least, the term *zīj* was transcribed as *ezich*, *ezeig*, etc. (=*al-zīj*), and ***, respectively. In Latin the term was soon replaced by *tabulae*, while in Greek one finds ***, reminiscent of Ptolemy's *Almagest*.

The term *zīj* is originally Middle Persian, where it means "stretched cord." The sense "astronomical handbook" goes back to the early sixth century when Sanskrit works were introduced into Iran. The name *zīj* may have arisen as a literal translation of the Sanskrit term *tantra* (from *tan* "to stretch") literally "warp, loom," but which is used in the sense of "system" or "text book." The word is singled out by Varāhamihira (ca. 580) as the name of the branch of astronomy which is concerned with planetary calculations. In a Middle Persian tract of the ninth century, the *Epistles of Manuščihr*, there are references to the *zīg ī hindūg* (Indian Astronomy), and also to a *zīg ī śahriyārān* (Royal Astronomy), a Sasanid compilation probably of the sixth century, referred to later by Arabic authors as the *Zīj al-Shātroyārān*. The former may be one of the works of Āryabhata (ca. AD 5250), which were referred to as Tantras by an early commentator.

Zodiac in Indian Astronomy

Yano Michio

The signs of the zodiac originated in Mesopotamia. In the first stage of development, 12 constellations along the ecliptic (i.e., the apparent course of the sun in the sky) were roughly marked out and each was named after the animal whose shape it resembled. Later, with the need for a rigid coordinate system for planetary positions, the zodiacal sign assumed a new meaning: the length of 30° along the ecliptic, so that 12 equal signs comprised a complete circuit (360°) of the ecliptic. The change from the older irregular constellations to the signs of regular spacing took place somewhere around 500 BCE.

In the cuneiform texts the ecliptic coordinates were sidereally fixed, and the vernal equinox was several degrees off "the first point of Aries": at the tenth degree of Aries in System A and at the eighth in System B. The Mesopotamian idea of 12 zodiacal signs of equal length was transmitted to Greece about 300 BCE, where the iconography of the signs was modified by their mythology.

With the discovery of the precession of equinoxes by Hipparchus in about 150 BCE, the significance of the zodiacal signs changed drastically. The first point of Aries was equated with the vernal equinox. Since this is in constant retrograde motion relative to the fixed stars (the shift being about 51 min of arc per year), the original relation between the constellations and signs was completely severed and the zodiacal signs became a purely mathematical reference system.

With the development of astrology, which preserved the old association of zoomorphic shape with zodiacal signs (except Libra), the zodiacal signs assumed new meanings. They were classified in various ways: by sex, the ownership of the house of planets, seasons, tastes, four humors, four elements, the governorship over parts of the body, plants, animals, geographical regions, etc.

All these ideas were transmitted to India in the second century of the Christian era. The very Sanskrit names of the zodiacal signs show that they were translated from Greek. In some texts even phonetic translations of Greek words are found. The earliest Sanskrit text which contains a list of these names is the *Yavanajātaka* (ca. AD 269), a Sanskrit version of a Greek book on horoscopic astrology (Table 1).

Three iconographic modifications in the process of transmission are worth mentioning. (1) While Gemini are the twin boys in Western iconography, *mithuna* in Sanskrit is a couple consisting of a male and a female, and this was interpreted as "husband and wife" in

Z

Zodiac in Indian Astronomy. Table 1 The signs of the zodiac

Degrees	English	Sanskrit
0	Aries	*meṣa*
30	Taurus	*vṛṣan*
60	Gemini	*mithuna*
90	Cancer	*karkaṭa*
120	Leo	*siṃha*
150	Virgo	*kanyā*
180	Libra	*tulā*
210	Scorpio	*vṛścika*
240	Sagittarius	*dhanus* or *dhanvin*
270	Capricorn	*makara* or *mṛga*
300	Aquarius	*kumbha*
330	Pisces	*mīna*

Chinese texts on Buddhist astrology. (2) The Sanskrit word *makara* stands for a kind of sea monster, and *mṛga* for a "forest animal" such as a deer. Thus Capricorn was divided into two separate animals. (3) The word *dhanvin* (one who has a bow) is a better translation of Sagittarius (archer), but the simpler *dhanus* (bow) without a human figure is more frequently used in Sanskrit texts.

In spite of the similarity of the names, the astronomical meaning of Indian zodiacal signs is different from that of the Western ones, because the precession of the equinoxes was not taken into account in India, and the first point (*meṣādi*) of the ecliptic coordinates was sidereally fixed sometime in the third or fourth century AD. The difference (*ayanāṃśa*) between the vernal equinox and the *meṣādi*, which has accumulated in the present day, is about 23°40′; thus the sun's entry into *meṣa* now falls on the 14th of April, and the *makarasaṃkrānti*, originally a winter solstice festival, on the 15th of January.

This seemingly conservative attitude is closely related to the Indian system of naming the lunar month. A year is divided into 12 solar months by the sun's entry (*saṃkrānti*) into a new zodiacal sign. The lunar month is named after the *saṃkrānti* which falls during that month. For example, the lunar month Caitra is defined as the month during which the sun's entry into *meṣa* occurs. The full moon of that month has to be located near the diametrically opposite point on the ecliptic, i.e., at the lunar mansion *citrā*. Thus, in order to keep the relation of the month name and the constellation name, they had to stick to the sidereal (*nirayana*) system even at the sacrifice of the correspondence between the seasons and month names.

The Western system has ignored the original association between constellations and zodiacal signs, and the word *Aries*, for example, has two meanings, one as an actual constellation and the other as the first 30° in the ecliptic longitude. The former is used in astronomy and the latter in astrology. This is not the case in the traditional Indian system.

In South India and Nepal the solar month is still used in the civil calendar. Since a solar month is the time during which the true sun stays in one zodiacal sign, the length of a month varies from 28 to 32 days.

As mentioned above, Indian zodiacal signs were transmitted to China in the eighth century by Buddhist astrology and ultimately to Japan in the ninth century. The iconography of the Indian zodiacal signs was preserved in the star *maṇḍalas* (especially in the temples belonging to the Shingon sect) which were used in the ritual of worshipping the planetary deities.

Zodiac in Islam

Paul Kunitzsch

The zodiac, i.e., the band or zone around the sky through which the sun, the moon, and the planets travel in their apparent revolutions, was first established by the Babylonians. They formed the constellations along this zone and instituted its division into 12 equal portions, the "signs." This knowledge was then handed on, in a northern branch of transmission, to the Greeks and through them further on into modern astronomy. In a southern branch of transmission, some of the zodiacal constellations reached the Arabs in the Arabian peninsula. In their folk astronomy they knew some of the zodiacal constellations – though not the complete system of 12 – which, in their astronomical lore, were sometimes located differently. For example the constellation *al-jawzā'* (standing for Gemini) is located in the Greek (and modern) Orion, *al-dalw* (Aquarius) in Pegasus, and *al-ḥūt* (Pisces) in Andromeda.

With the reception of Greek astronomy, through the translation of the most important Greek writings in astronomy and astrology, the system of the 12 zodiacal constellations and the 12 signs was also received and continued to be used by Arabic–Islamic astronomers and astrologers. For some constellations the translators introduced new names (derived from Greek) besides the names inherited from the old Arabs. The names for the 12 constellations of the zodiac in Arabic are:

1. Aries: *al-ḥamal*
2. Taurus: *al-thawr*
3. Gemini: *al-jawzāʾ* (old), *al-tawʾamān* (transl.)
4. Cancer: *al-saraṭān*
5. Leo: *al-asad* (both old and transl.)
6. Virgo: *al-sunbula* (old), *al-ʿadhrāʾ* (transl.)
7. Libra: *al-mīzān*
8. Scorpio: *al-ʿaqrab* (both old and transl.)
9. Sagittarius: *al-qaws* (old), *al-rāmī* (transl.)
10. Capricornus: *al-jady*
11. Aquarius: *al-dalw* (old), *sākib al-māʾ* (transl.)
12. Pisces: *al-ḥūt* (old), *al-samakatān* (transl.)

The zodiac was treated by the Arabic–Islamic astronomers and astrologers according to the teachings of the Greeks. When Arabic astronomical and astrological works were translated into Latin in Europe in the Middle Ages, the Arabic names of the 12 zodiacal constellations were also sometimes borrowed. But they did not gain the same popularity as the Arabic star names and the names of the lunar mansions; most Latin authors used the well-known Latin names for them.

Zou Yan

Christompher Cullen

Our only source on Zou's life that has any chance of being reliable is the entry in Sima Qian's universal history *Shiji*, completed ca. 90 BCE. According to this, Zou (fl. 250 BCE) was a successful member of the group of wandering scholars who moved from one feudal court to another in China's Warring States period (fifth–third centuries BCE), offering expertise in statecraft and useful arts. He came from the northeastern seaboard state of Qi, where he became a member of the "academy" set up by the ruler of that state to house his more favored scholarly retainers. Although he is said to have written several voluminous books none of them has survived.

According to the *Shiji*, Zou "looked into the rise and fall of the Yin and Yang" and wrote on their "strange transformations." His method of reasoning "started by checking some small thing, and then extrapolated to a large scale." On this basis he is said to have reasoned his way back to the state of affairs "before the origin of heaven and earth" on the basis of his knowledge of more recent times. Similarly, he claimed that China only occupied one-ninth of a large continent, which was itself only one out of nine giant land masses surrounded by a vast ocean.

One source of the seventh century AD (Li Shan's commentary on the Wen Xuan anthology) quotes a work said to be by Zou Yan, in which it is stated that he taught that the successive dynasties ruling in China had each come to power by virtue of the cyclical dominance in the cosmos of one of the *wude* (Five Powers) of earth, wood, metal, fire, and water. (These are more commonly called the *wuxing*, Five Phases.) While such a view is not inconsistent with Zou Yan's thought as known from the *Shiji*, it is by no means certain that he originated it. Whatever its origins, this theory of the cosmological determination of political dominance was adopted by the first emperor of the Qin dynasty when he came to the throne in 221 BCE, and remained important for several centuries thereafter.

Zu Chongzhi

Ang Tian Se

Zu Chongzhi, whose literary name was Wenyuan, was born in Jiankang (present Nanjing of Jiangsu Province) in AD 429 into a family of bureaucrats. His great grandfather, a native of Hebei Province, was an official during the Eastern Jin dynasty (AD 317–420), and his grandfather and father were officials of the Northern and Southern dynasties (AD 479–581). Interestingly enough, the Zu family had, for successive generations, been involved in studies of astronomy and calendrical science. Subsequently, they moved south and settled in Jiankang, the political and economic center of the fifth and sixth centuries. From a very young age, Zu Chongzhi received instruction in a variety of subjects. He was particularly interested in mathematical astronomy. While examining many past and existing astronomical systems, he found many errors and discrepancies. This prompted him to compile a calendrical system known as the Daming calendar (Calendar of Great Brightness). However, when he presented this calendar to the throne for promulgation in AD 462, he met with vehement opposition from the emperor's minister Dai Faxin. Zu Chongzhi's innovation and improvement in the astronomical system was branded as "distorting the truth about heaven and violating the teaching of the classics." The Daming calendar was shelved for about half a century before it was finally promulgated for official use in AD 510 when Zu Chongzhi had been dead for 10 years.

The Daming calendar was the epitome of Zu Chongzhi's mathematical and astronomical skills. He was the first person to take into account the fact of precession of the equinoxes discovered by Yu Xi, an astronomer in the fourth century AD. By applying the precession of equinoxes, Zu Chongzhi differentiated the tropical year from the sidereal year (the time at which the sun's center, departing eastward from the ecliptic meridian of a given star, returns to that meridian). As a matter of fact, he determined several astronomical constants with remarkable accuracy. For example, he gave a value of 365.24281481 days for the tropical year, only about 50 s off the modern value. He also gave a value of 27.21233 days for the length of a nodal month, the modern value being 27.21222 days. For planetary motion, he found that the planet Jupiter completes seven and one-twelfth circuits of the heavens in every 7 cycles of 12 years. This gives Jupiter a sidereal period of 11.859 years, which differs from the modern value by only 1 part in 4,000.

In order to make the lunar year tally with the solar year, ancient Chinese calendar makers inserted 7 intercalary months in every 19 years. This rule of intercalation had been in use for more than a thousand years until AD 412 when Zhao Fei changed it to 221 intercalary months in every 600 years. Zu Chongzhi did not find the rule satisfactory and improved it by introducing 144 intercalations in every 391 years.

The most significant contribution by Zu Chongzhi is in the evaluation of π. He gave two approximating ratios for π: a coarse one of 22/7 and a fine one of 355/113. The true ratio, according to him, lies between 3.1415926 and 3.1415927.

Zu Chongzhi also wrote a mathematical text known by the title *Zhui Shu*. This text, prescribed as a textbook for advanced students of mathematics in the official examinations of the Tang dynasty, was unfortunately lost in the wars of the early twelfth century. Only fragments of the text still exist in the Calendrical and Astronomical Chapters of the Sui and Tang dynasties. Zu Chongzhi was said to have worked out an evaluation of the volume of a sphere. He considered a sphere as a pile of circles of varying sizes and arrived at a formula, which in modern mathematical language, could be expressed as $V = 4/3\pi r^3$.

Zu Chongzhi was a versatile person. Apart from being a celebrated astronomer and mathematician, he was well versed in engineering. He produced a "south-pointing vehicle" worked by a set of five differential cog wheels, a "thousand-mile boat" propelled by paddle wheels, a hydraulic mortar-mill, worked by a combination of separate water-driven mortars and mills, and a brass ruler for measuring the pitch of musical instruments.

Zu Chongzhi's remarkable achievements are acknowledged internationally. A crater on the reverse side of the moon, just south of the Sea of Moscow, is named after him.
