

## Symbols Used in Log Interpretation

Gen-3

Gen

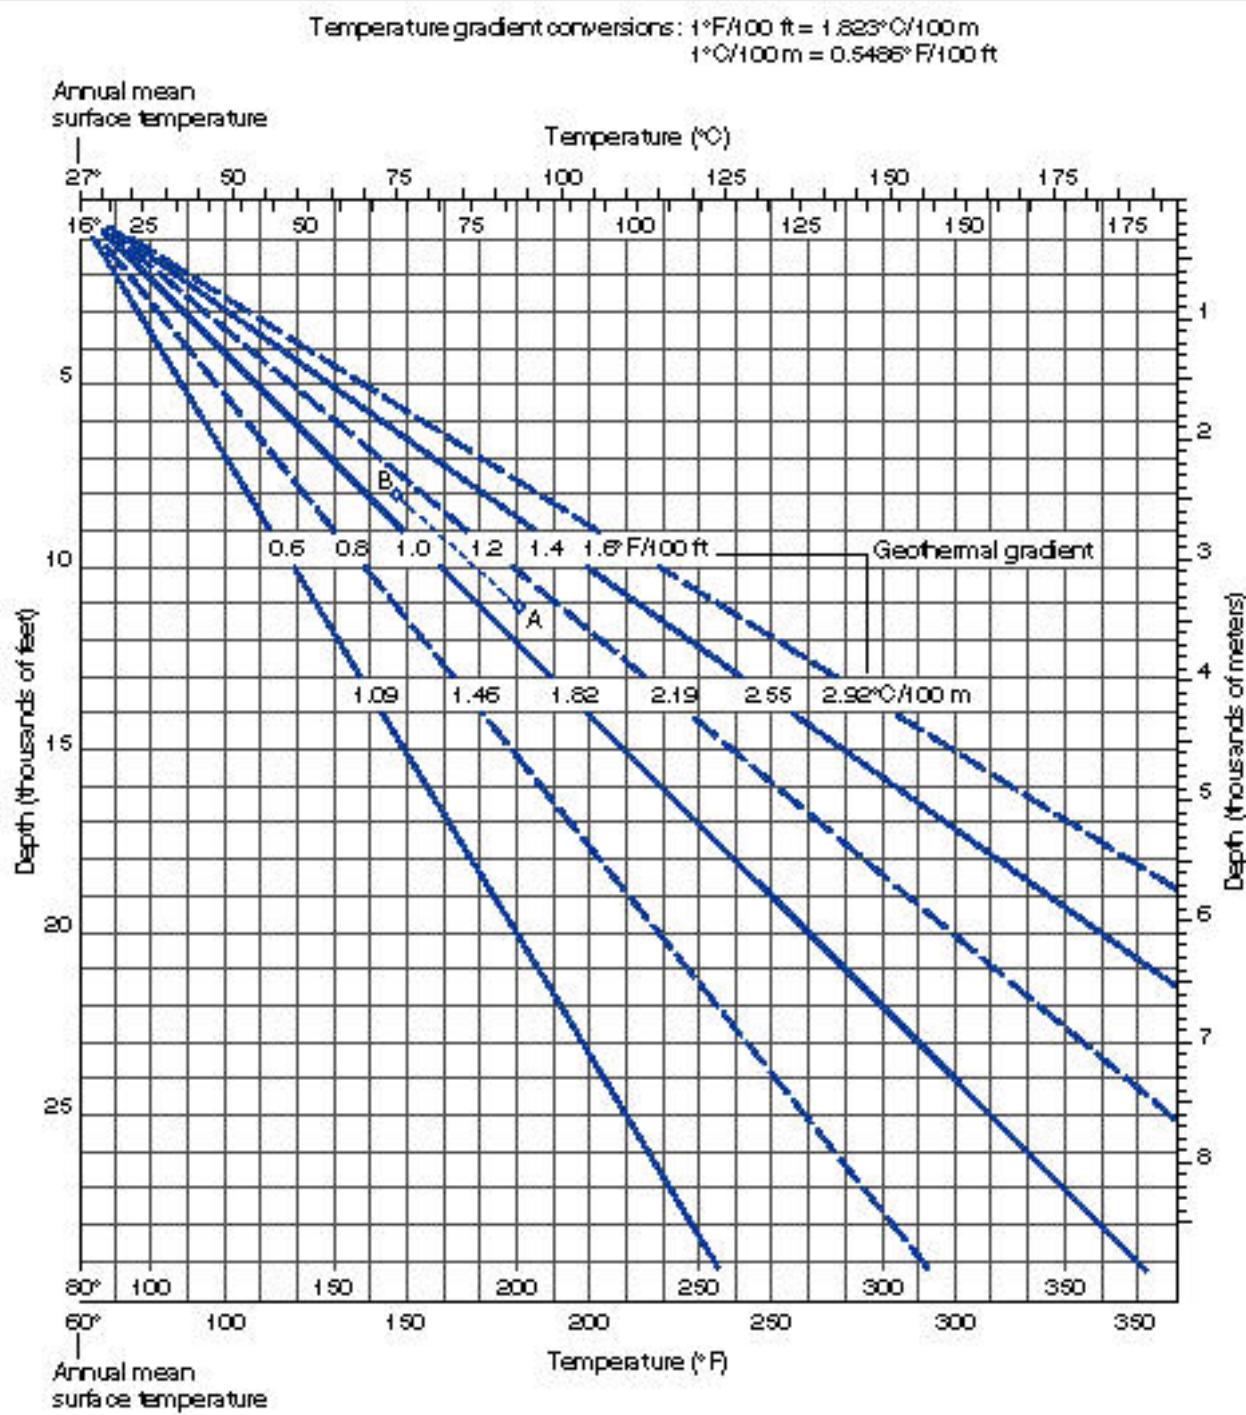

## Estimation of Formation Temperature

Linear gradient assumed

Gen-6

Gen

© Schlumberger

**Example:** Bottomhole temperature (BHT) at 11,000 ft = 200°F  
 (Point A)

Temperature at 8000 ft = 167°F (Point B)

## Estimation of $R_{mf}$ and $R_{mc}$

Gen-7

Gen

Direct measurements of filtrate and mudcake samples are preferred. When not available, filtrate resistivity,  $R_{mf}$ , and mudcake resistivity,  $R_{mc}$ , may be estimated from one of the following methods.

### Method 1

#### Lowe and Dunlap (Reference 36)

For freshwater muds with mud resistivity,  $R_m$ , in the range from 0.1 to 2.0 ohm-m at 75°F [24°C], and measured values of  $R_m$  and mud density,  $\rho_m$ , in pounds per gallon:

$$\log\left(\frac{R_{mf}}{R_m}\right) = 0.396 - 0.0475 \rho_m$$

### Method 2

#### Overton and Lipson (Reference 1)

For drilling muds with mud resistivity,  $R_m$ , in the range from 0.1 to 10.0 ohm-m at 75°F [24°C], where  $K_m$  is given as a function of mud weight in the table below:

$$R_{mf} = K_m (R_m)^{1.07}$$

$$R_{mc} = 0.69 (R_{mf}) \left( \frac{R_m}{R_{mf}} \right)^{2.65}$$

*Example:*  $R_m = 3.5$  ohm-m at 75°F [24°C]

Mud weight = 12 lbm/gal [1440 kg/m³]

Therefore,  $K_m = 0.584$

$$R_{mf} = (0.584)(3.5)^{1.07} = 2.23 \text{ ohm-m at 75°F}$$

$$R_{mc} = 0.69(2.23)(3.5/2.23)^{2.65} = 5.07 \text{ ohm-m at 75°F}$$

The calculated value of  $R_{mf}$  is more reliable than that of  $R_{mc}$ .

Mud Weight		$K_m$
lbm/gal	kg/m³	
10	1200	0.847
11	1320	0.708
12	1440	0.584
13	1560	0.488
14	1680	0.412
16	1920	0.380
18	2160	0.350

### Method 3

A statistical approximation, for predominantly NaCl muds, is  $R_{mc} = 1.5 R_m$ , and  $R_{mf} = 0.75 R_m$ .

## Resistivities of Solutions

Gen-8

Gen

Actual resistivity measurements are always preferred, but if necessary, the chart on the opposite page may be used to estimate the resistivity of a water sample at a given temperature when the salinity (NaCl concentration) is known, or to estimate the salinity when resistivity and temperature are known. It may also be used to convert resistivity from one temperature to another temperature.

**Example:** Resistivity of a water sample is 0.3 ohm-m at 25°C; what is the resistivity at 85°C?

Enter the chart with 25°C and 0.3 ohm-m. Their intersection indicates a salinity of approximately 20,000 ppm. Moving along this constant salinity line yields a water sample resistivity of 0.13 ohm-m at 85°C.

The resistivity of a water sample can be estimated from its chemical analysis. An equivalent NaCl concentration determined by use of the chart below is entered into Chart Gen-9 to estimate the resistivity of the sample.

The chart is entered in abscissa with the total solids concentration of the sample in ppm (mg/kg) to find weighting multipliers for the various ions present. The concentration of each

ion is multiplied by its weighting multiplier, and the products for all ions are summed to obtain equivalent NaCl concentration. Concentrations are expressed in ppm or mg/kg, both by weight. These units are numerically equal.

For more information see Reference 2.

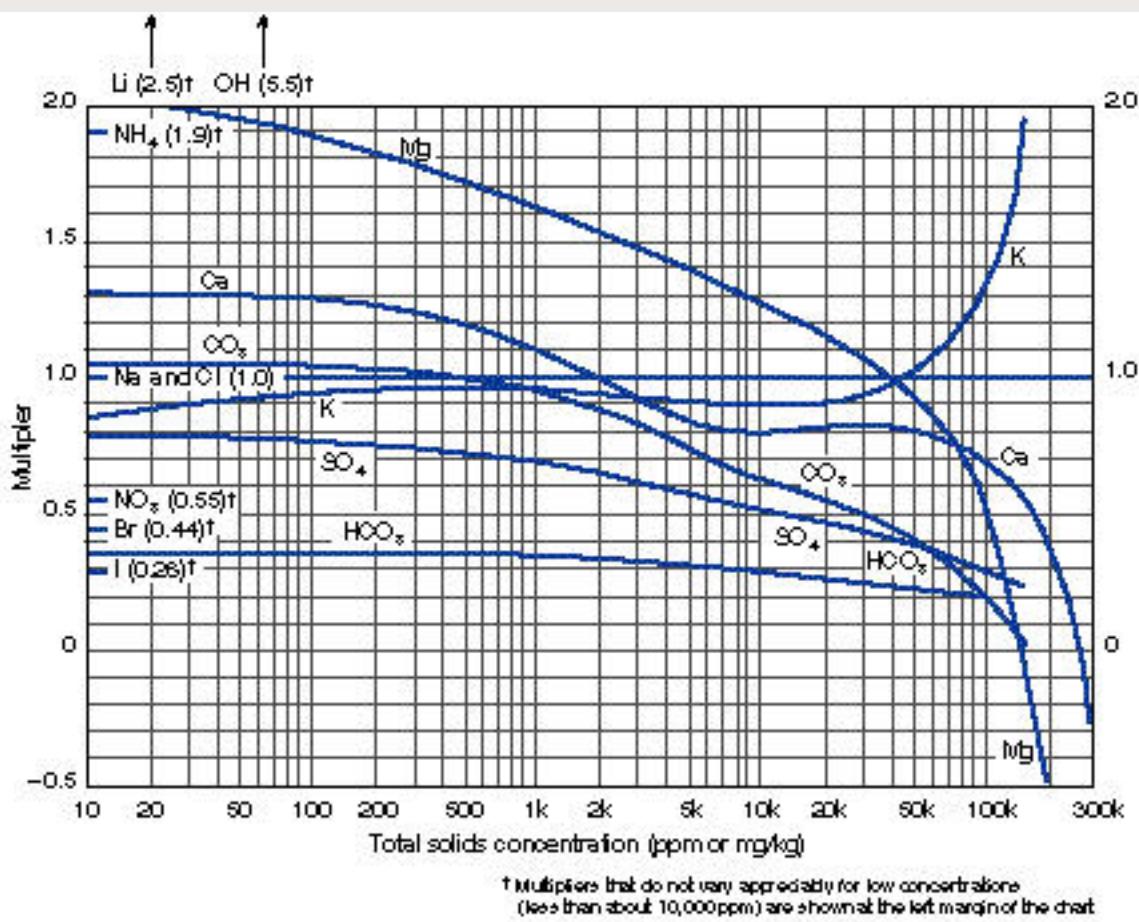

**Example:** A formation-water sample analysis shows 460 ppm Ca, 1400 ppm SO<sub>4</sub> and 19,000 ppm Na plus Cl.

Total solids concentration is  $460 + 1400 + 19,000 = 20,860$  ppm.

Entering the chart below with this total solids concentration, we find 0.81 as the Ca multiplier and 0.45 as the SO<sub>4</sub> multiplier. Multiplying the concentration by the corresponding multipliers, the equivalent NaCl concentration is found as approximately

$$460 \times 0.81 + 1400 \times 0.45 + 19,000 \times 1 \approx 20,000 \text{ ppm.}$$

Entering the NaCl resistivity-salinity nomograph (Gen-9) with 20,000 ppm and 75°F (24°C), the resistivity is found to be 0.3 at 75°F.

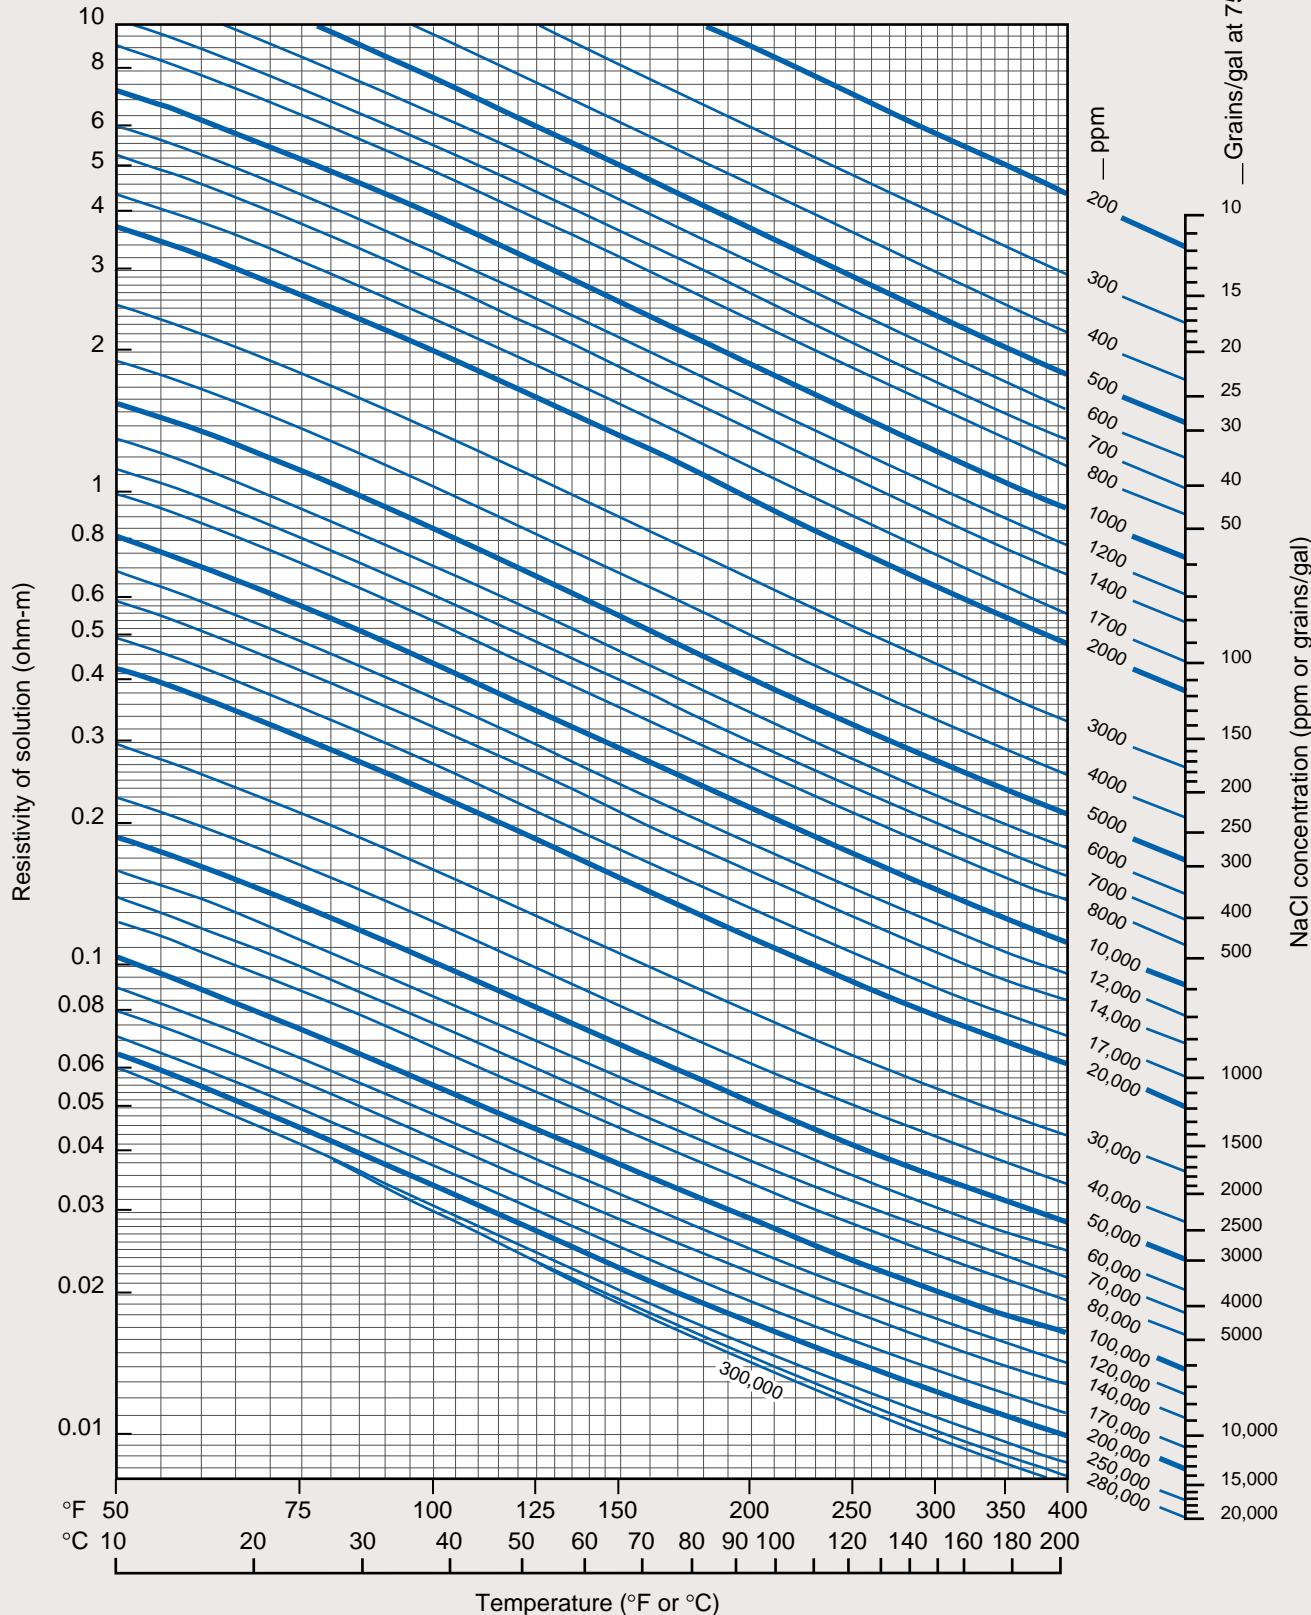

## Resistivity of NaCl Solutions

Gen-9

Gen

Conversion approximated by  $R_2 = R_1 [(T_1 + 6.77)/(T_2 + 6.77)]^{\circ}\text{F}$  or  $R_2 = R_1 [(T_1 + 21.5)/(T_2 + 21.5)]^{\circ}\text{C}$

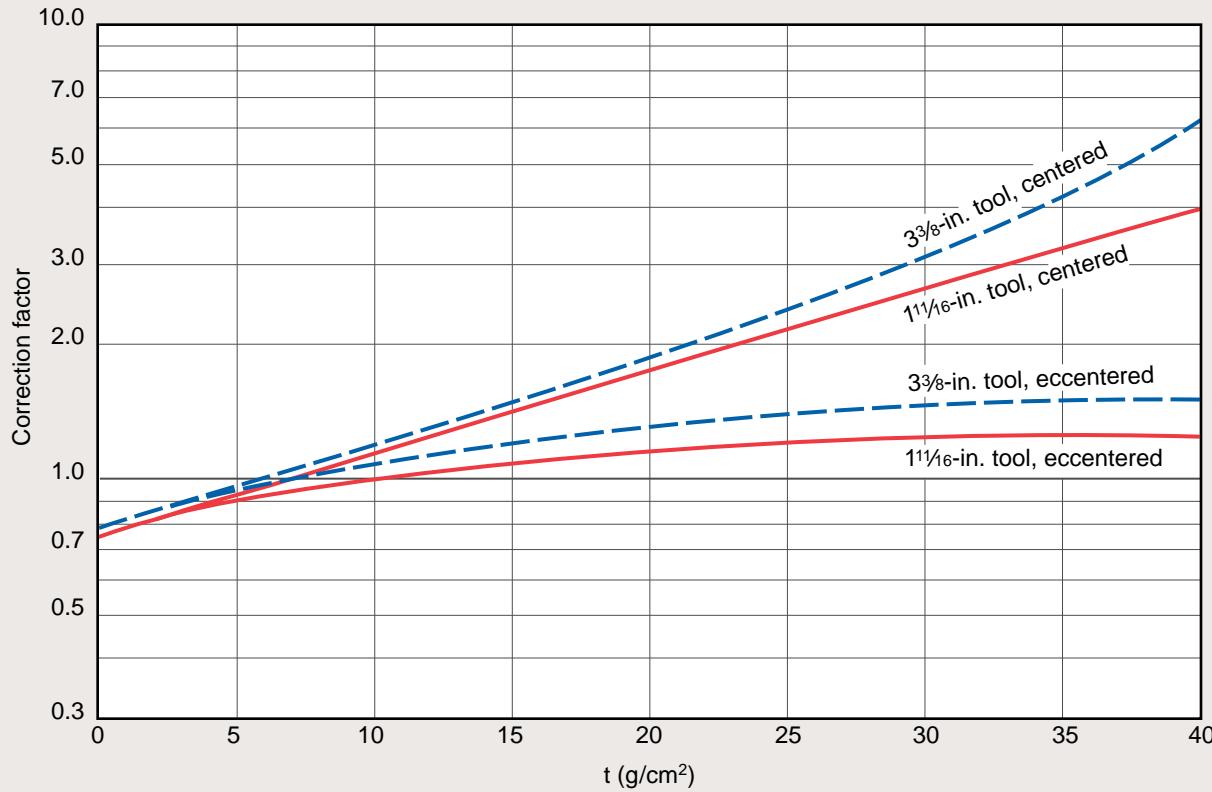

## Gamma Ray Corrections for Hole Size and Mud Weight

For 3<sup>3</sup>/<sub>8</sub>-in. and 1<sup>1</sup>/<sub>16</sub>-in. SGT wireline gamma ray tools

GR-1

GR

© Schlumberger

Log interpretation Charts GR-1 and GR-2, replacing Chart Por-7, are based on laboratory work and Monte Carlo calculations to provide improved corrections for 3<sup>3</sup>/<sub>8</sub>- and 1<sup>1</sup>/<sub>16</sub>-in. SGT gamma ray tools. The corrections normalize the response of both tools to eccentered positions in an 8-in. borehole with 10-lbm mud. Chart GR-2 provides a correction for barite mud in small boreholes.

Although these charts are more difficult to use than the ones they replaced, the results are more exact since they are normalized to current tools, no interpolation is required, and the ranges are extended.

The input parameter,  $t$ , in  $\text{g}/\text{cm}^2$ , is calculated as follows:

$$t = \frac{W_{\text{mud}}}{8.345} \left( \frac{2.54(d_{\text{hole}})}{2} - \frac{2.54(d_{\text{sonde}})}{2} \right).$$

The correction for standoff is

$$CF' = CF'_m + (CF_o - CF'_m) \left( \frac{S - S_m}{S_m} \right)^2.$$

$CF'_m$  is the correction factor for centered tools, while  $CF'_o$  is the correction factor for eccentered tools. Both are corrected for barite if it is present in the borehole.  $S$  is the actual standoff, and  $S_m$  is the standoff with the tool centered.

**Example:** GR reads 36 API units,  $d_h$  is 12 in., and mud weight is 12 lbm/gal. The tool is 3<sup>3</sup>/<sub>8</sub> in. and centered.

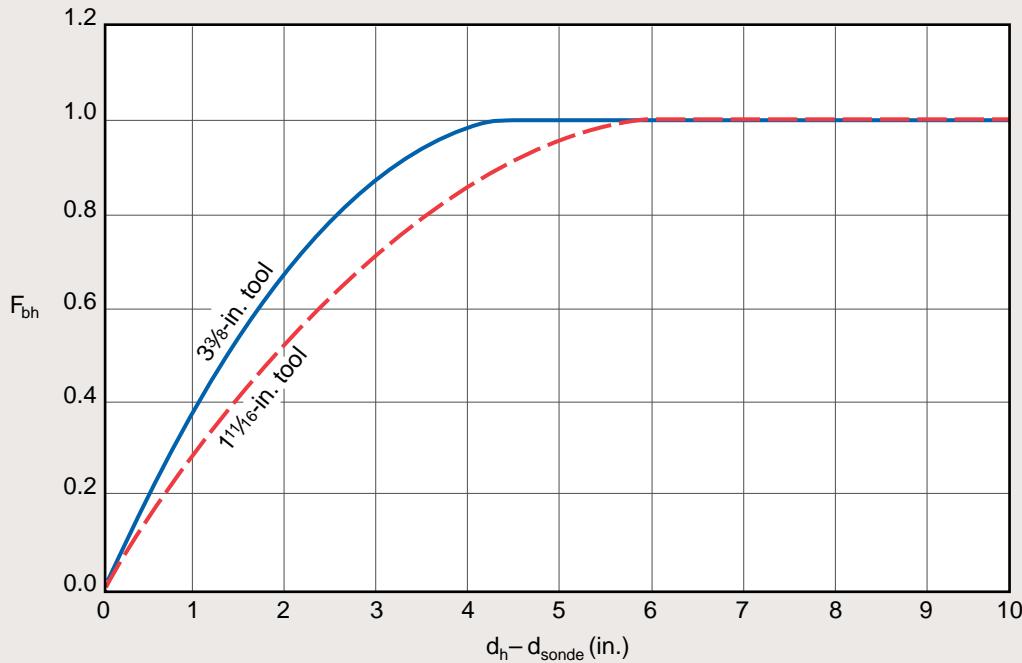

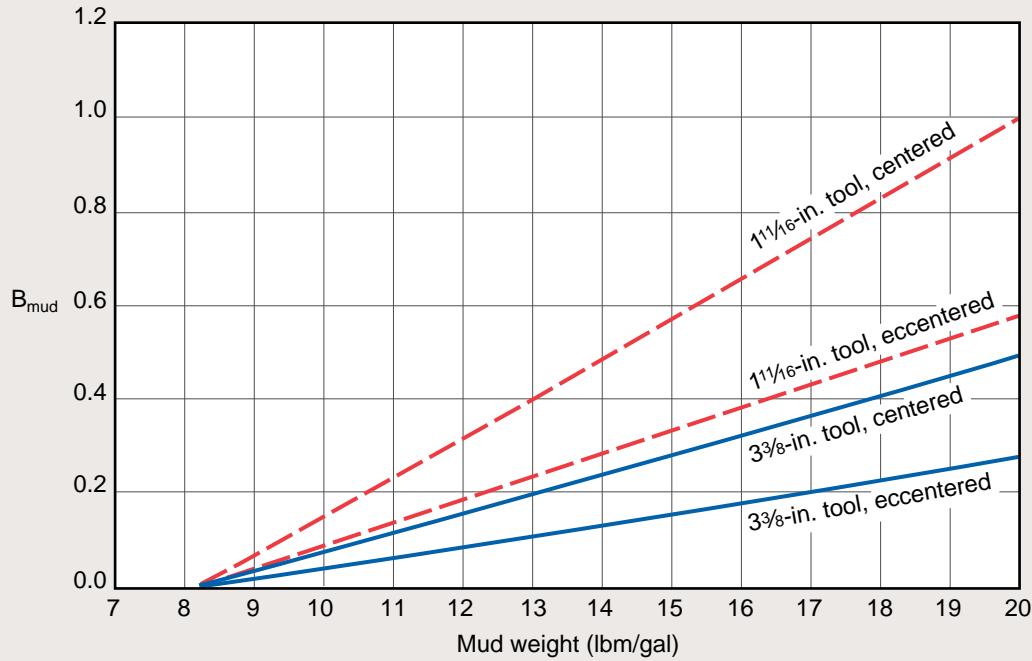

Therefore,  $t = 15.8 \text{ g}/\text{cm}^2$ , resulting in a correction factor of 1.6.

The corrected GR = 58 API units.

## Gamma Ray Corrections for Barite Mud in Small Boreholes

GR-2

GR

© Schlumberger

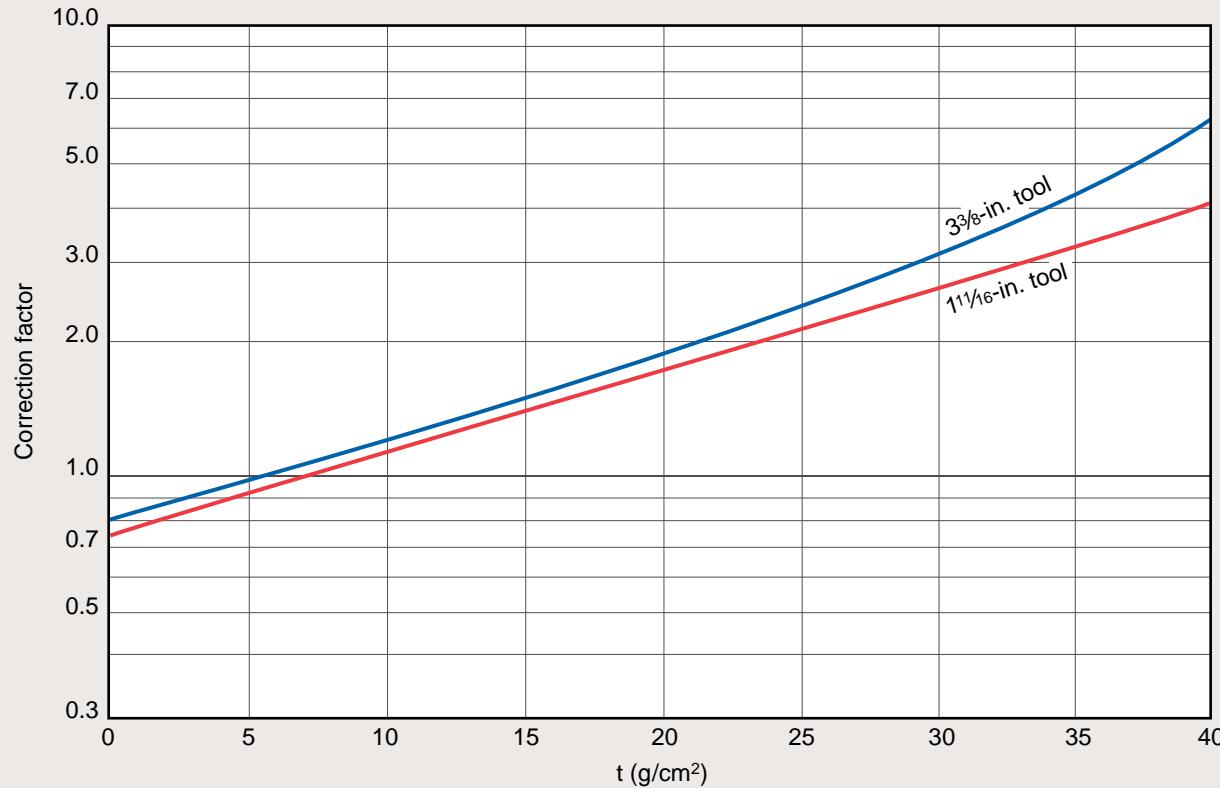

These charts correct for the barite mud effect in hole sizes smaller and larger than the 8-in. standard. In these cases, the correction factor from Chart GR-1 is multiplied by the borehole correction factor  $1 + B_{\text{mud}} \times F_{\text{bh}}$ .

*Example:* With the same conditions shown in the example on Chart GR-1 except for a 6-in. hole,  $t = 4.8 \text{ g/cm}^2$ , resulting in a correction factor of 0.95. Using Chart GR-2,  $B_{\text{mud}} = 0.15$  and  $F_{\text{bh}} = 0.81$  for a borehole correction of 1.12 and a revised correction factor of 1.06. The corrected GR = 38 API units.

## Gamma Ray Correction for Cased Holes

GR-3

GR

© Schlumberger

Log interpretation Chart GR-3 is based on laboratory work and Monte Carlo calculations to provide gamma ray corrections in cased holes. This chart is based on the openhole model in Chart GR-1. In this case,  $t$ , in  $\text{g}/\text{cm}^2$ , is calculated as the sum of density-thickness products for the casing, cement sheath and borehole fluid. The density of J-55 casing is  $7.96 \text{ g}/\text{cm}^3$ , and the density of cement is typically  $2.0 \text{ g}/\text{cm}^3$ .

$$t = \frac{2.54}{2} \left( \frac{W_m}{8.345} (\text{ID}_{csg} - d_{sonde}) + \rho_{csg} (\text{OD}_{csg} - \text{ID}_{csg}) + \rho_{cement} (d_h - \text{OD}_{csg}) \right)$$

The chart correction factor provides a corrected gamma ray to the standard reference condition of an eccentered  $3\frac{3}{8}$ -in. tool in an 8-in. borehole with 10-lbm mud.

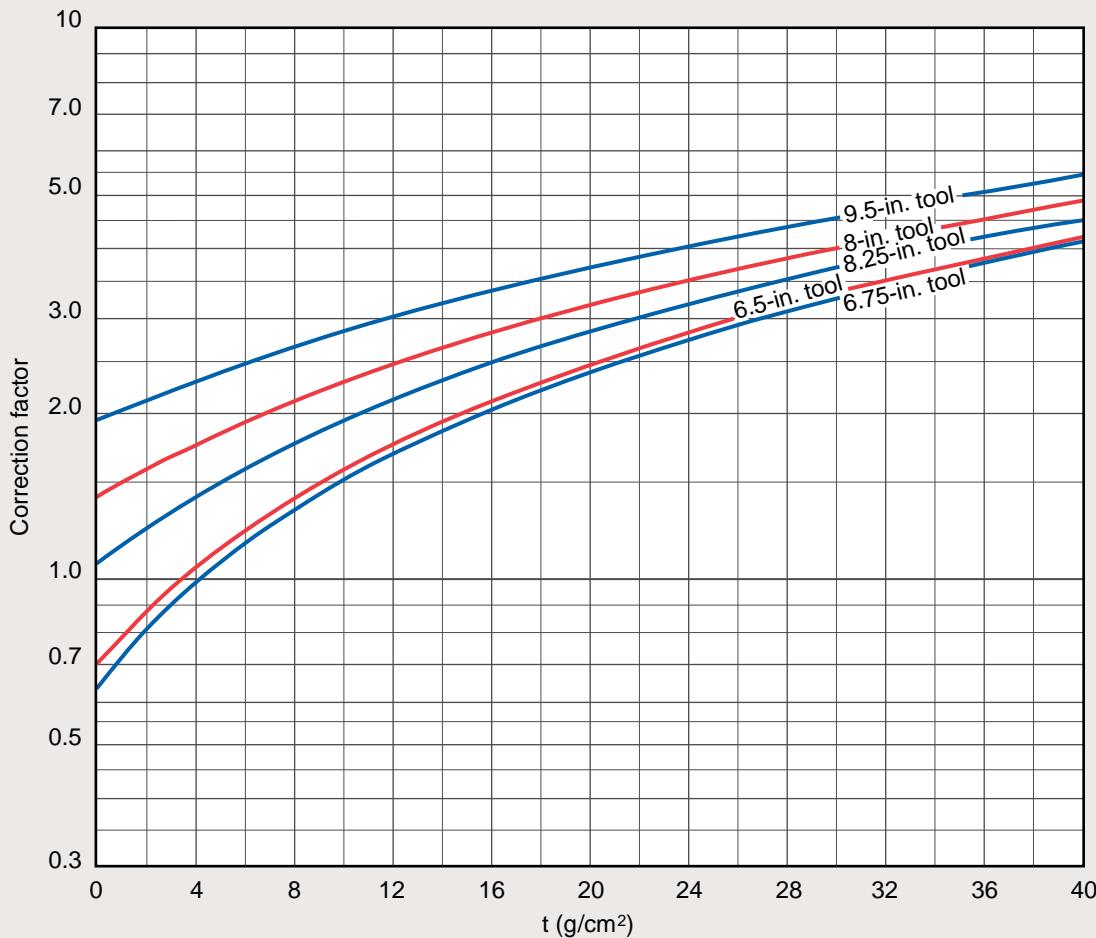

*Example:* GR reads 19 API units;  $d_h$  is 12 in.; casing is  $9\frac{1}{2}$  in.,  $43.50 \text{ lbm}/\text{ft}$ ; GR tool is  $3\frac{3}{8}$  in.;  $W_m = 8.345 \text{ lbm/gal}$ ; and  $t = 21.7 \text{ g}/\text{cm}^2$  for a correction factor of 2.1. The corrected GR = 40 API units.

## LWD Gamma Ray Correction for Hole Size and Mud Weight

For gamma ray with CDR\* Compensated Dual Resistivity tools

GR-4

GR

\*Mark of Schlumberger  
© Schlumberger

Chart GR-4 can be used to normalize gamma ray readings of the 9.5-, 8.25-, 8-, 6.75- and 6.5-in. CDR tools to the 6.5-in. tool in 10-lbm/gal mud.

The corrections illustrated by this chart are routinely applied

to LWD data before delivery; therefore, be careful not to duplicate the correction. The input parameter,  $t$ , in  $\text{g}/\text{cm}^2$ , is calculated from

$$t = \frac{W_m}{8.345} (d_{\text{hole}} - 3.5 - ST)$$

where ST varies with tool size as follows:

Tool size (in.)	ST
6.5	2.125
6.75	2.031
8.0	3.156
8.25	2.656
9.5	3.937

**R<sub>weq</sub>** Determination from E<sub>SSP</sub>

Clean formations

SP-1

This chart and nomograph calculate the equivalent formation water resistivity,  $R_{weq}$ , from the static spontaneous potential,  $E_{SSP}$ , measurement in clean formations.

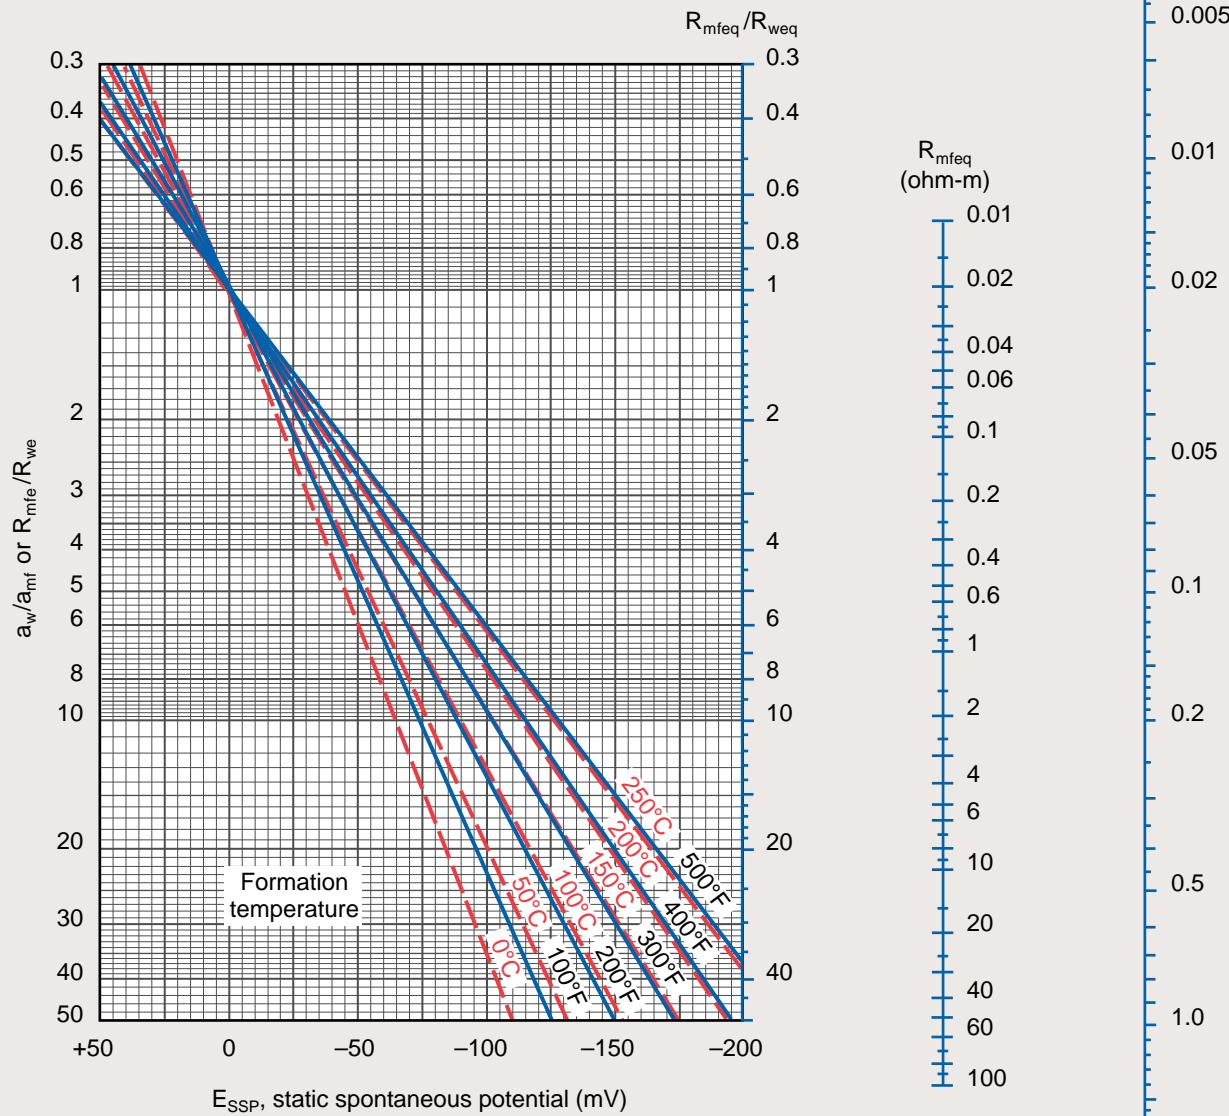

Enter the nomograph with  $E_{SSP}$  in mV, turning through the reservoir temperature in °F or °C to define the  $R_{mfeq}/R_{weq}$  ratio. From this value, pass through the  $R_{mfeq}$  value to define  $R_{weq}$ .

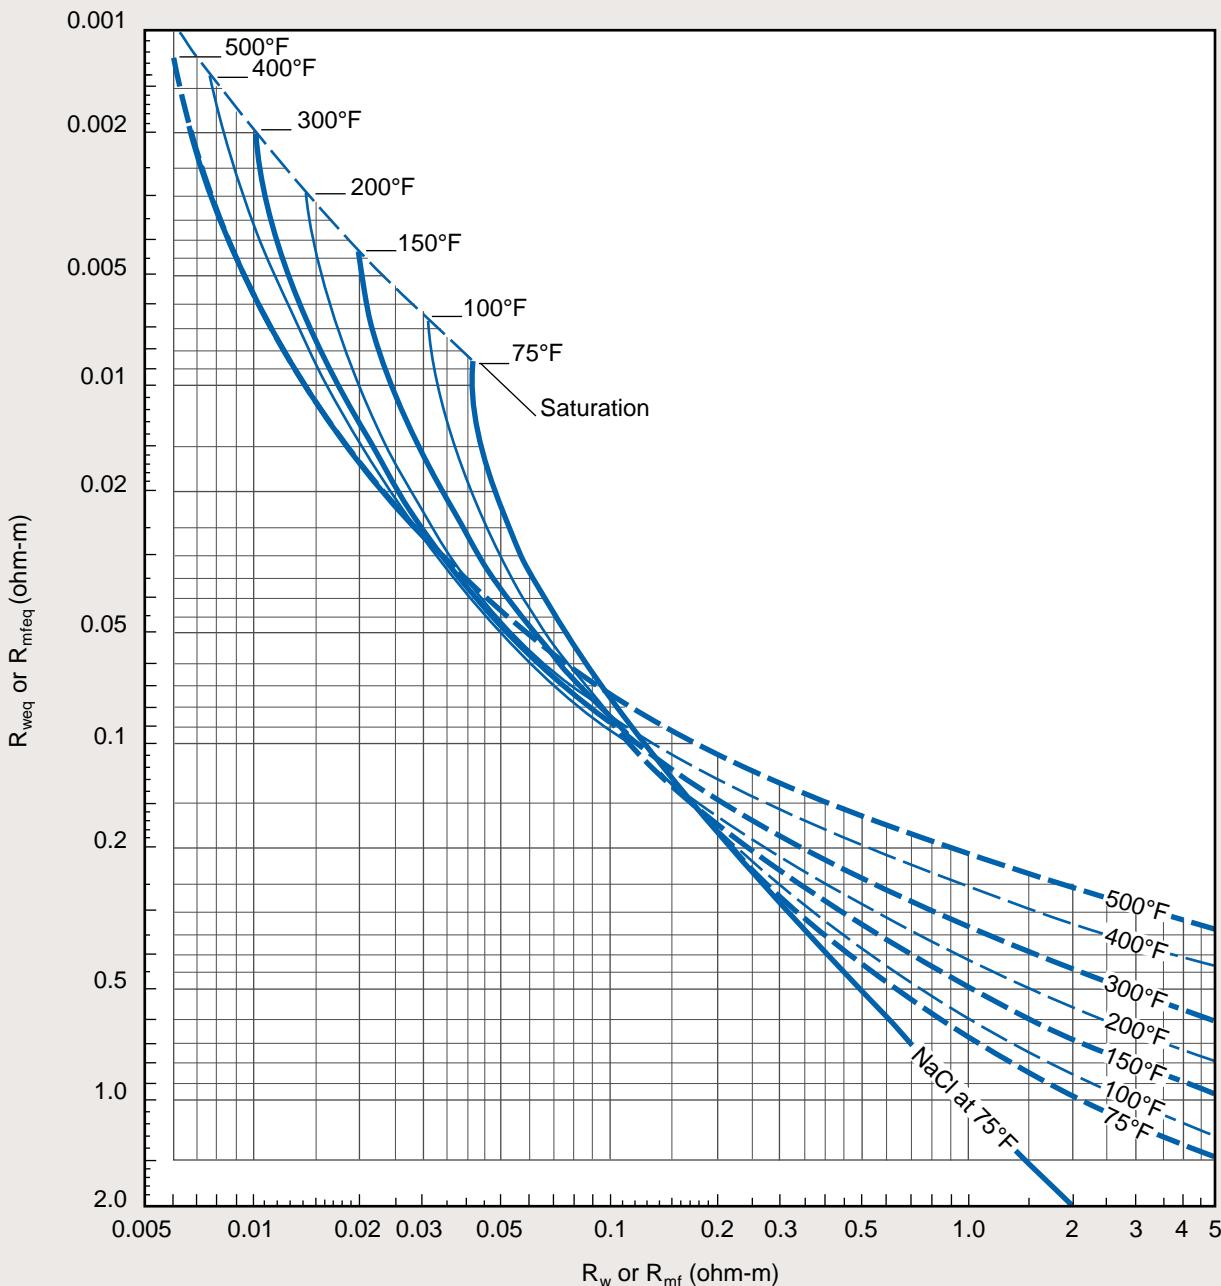

For predominantly NaCl muds, determine  $R_{mfeq}$  as follows:

- If  $R_{mf}$  at 75°F (24°C) is greater than 0.1 ohm-m, correct  $R_{mf}$  to formation temperature using Chart Gen-9, and use  $R_{mfeq} = 0.85 R_{mf}$ .
- If  $R_{mf}$  at 75°F (24°C) is less than 0.1 ohm-m, use Chart SP-2 to derive a value of  $R_{mfeq}$  at formation temperature.

**Example:**  $SSP = 100 \text{ mV at } 250^\circ\text{F}$   
 $R_{mf} = 0.70 \text{ ohm-m at } 100^\circ\text{F}$   
or  $0.33 \text{ ohm-m at } 250^\circ\text{F}$

$$\begin{aligned} \text{Therefore, } R_{mfeq} &= 0.85 \times 0.33 \\ &= 0.28 \text{ ohm-m at } 250^\circ\text{F} \\ R_{weq} &= 0.025 \text{ ohm-m at } 250^\circ\text{F} \\ E_{SSP} &= -K_c \log(R_{mfeq}/R_{weq}) \\ K_c &= 61 + 0.133 T_{^\circ\text{F}} \\ K_c &= 65 + 0.24 T_{^\circ\text{C}} \end{aligned}$$

**R<sub>w</sub> versus R<sub>weq</sub> and Formation Temperature**SP-2  
(English)

© Schlumberger

These charts convert equivalent water resistivity, R<sub>weq</sub>, from Chart SP-1 to actual water resistivity, R<sub>w</sub>. They may also be used to convert R<sub>mf</sub> to R<sub>mfed</sub> in saline muds.

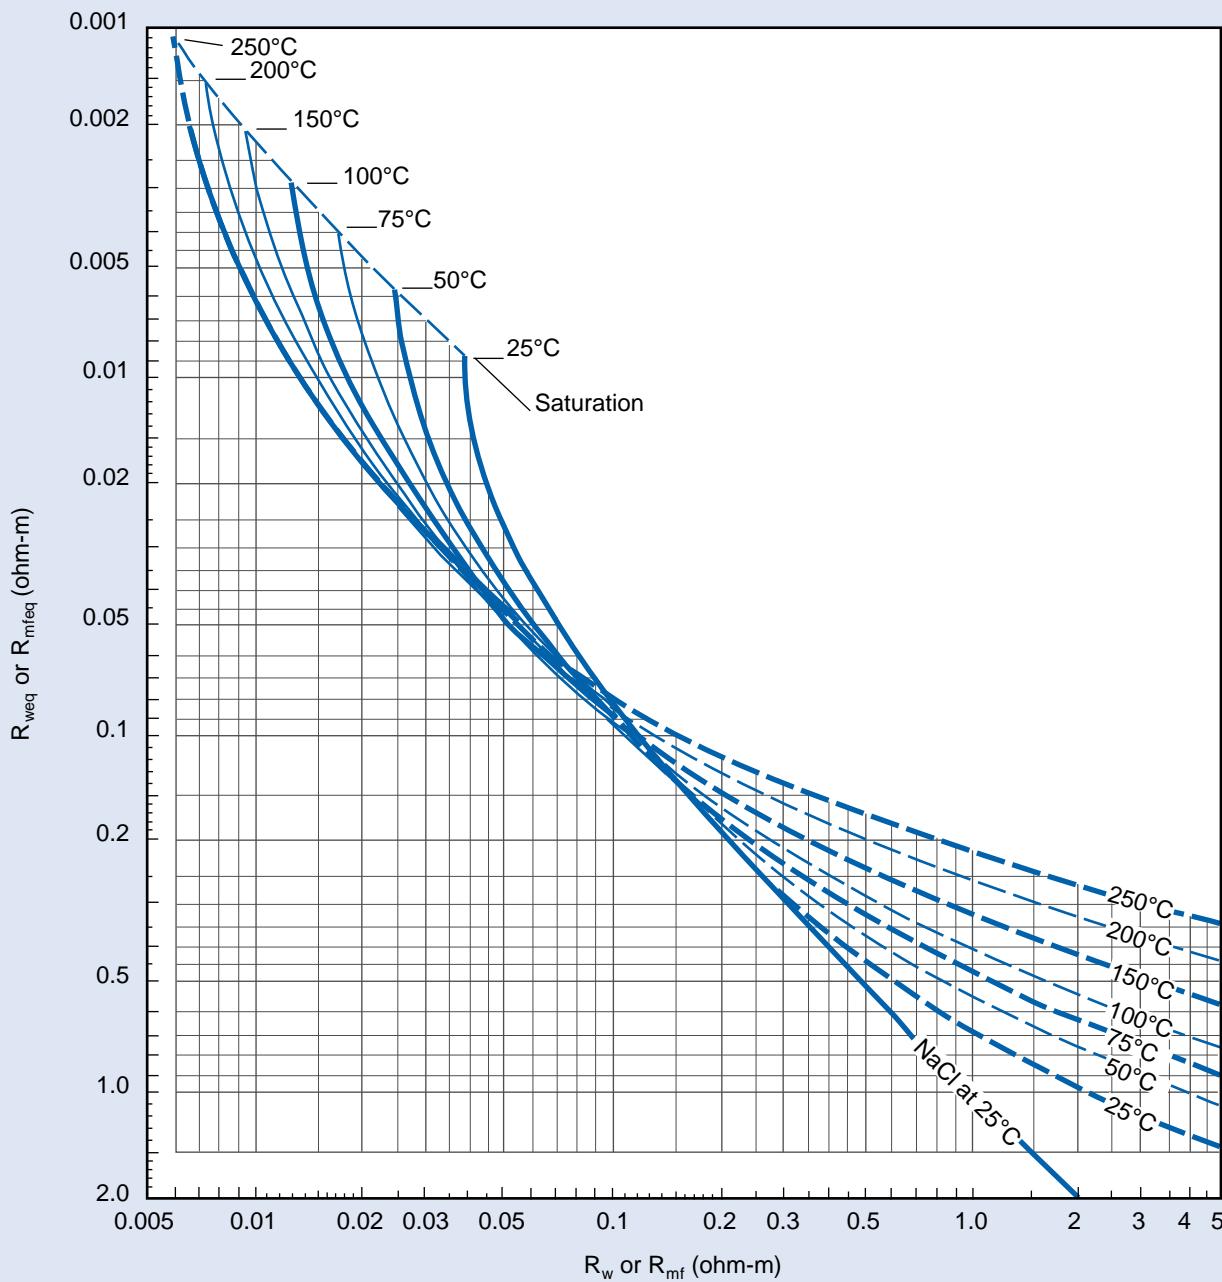

Use the solid lines for predominantly NaCl waters. The dashed lines are approximate for “average” fresh formation waters (where effects of salts other than NaCl become significant). The dashed portions may also be used for gyp-base mud filtrates.

*Example:* R<sub>weq</sub> = 0.025 ohm-m at 120°C  
From chart, R<sub>w</sub> = 0.031 ohm-m at 120°C

Special procedures for muds containing Ca or Mg in solution are discussed in Reference 3. Lime-base muds usually have a negligible amount of Ca in solution; they may be treated as regular mud types.

$R_w$  versus  $R_{w\text{eq}}$  and Formation TemperatureSP-2m  
(Metric)

SP

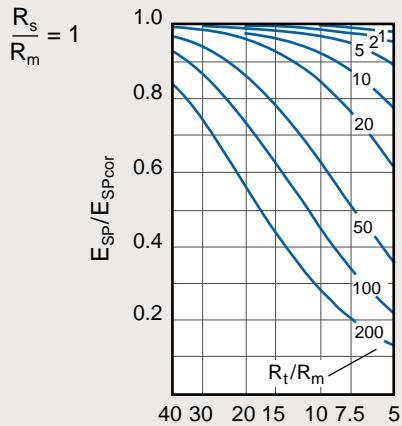

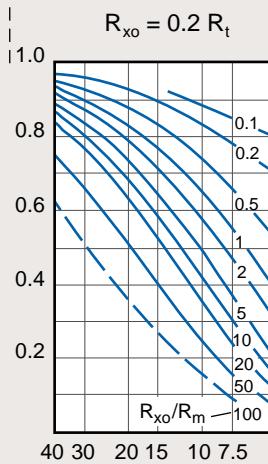

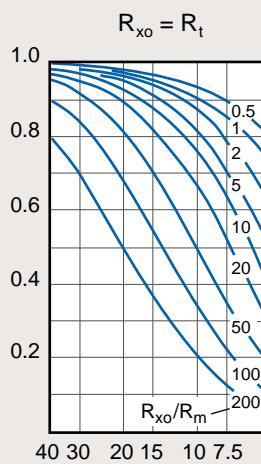

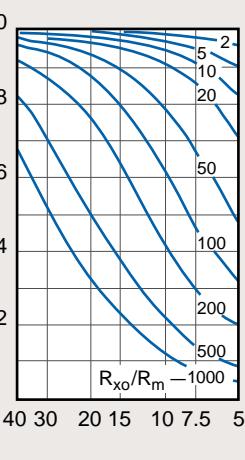

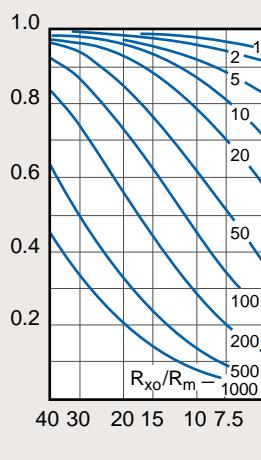

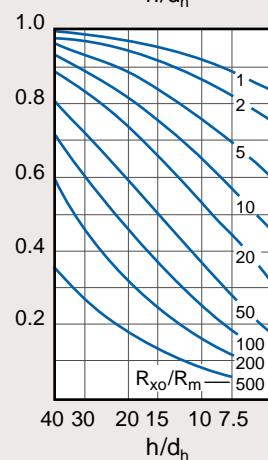

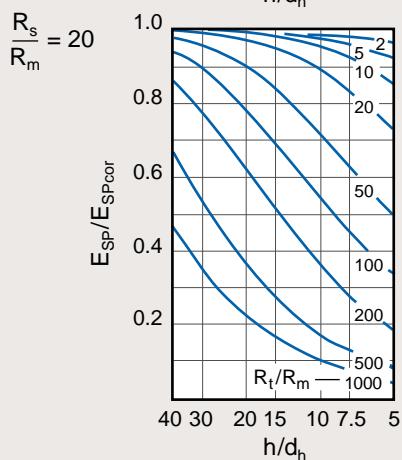

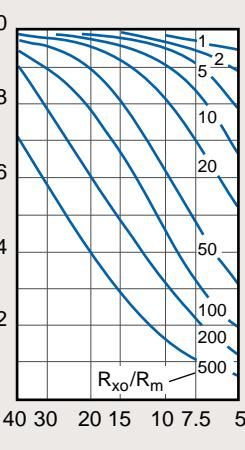

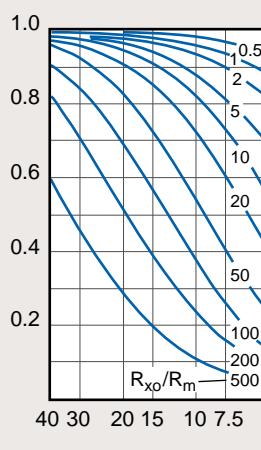

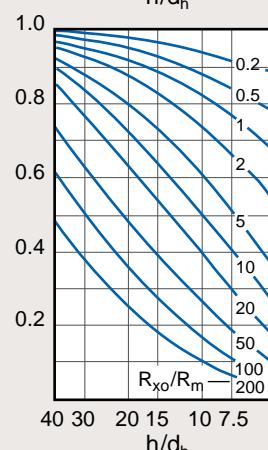

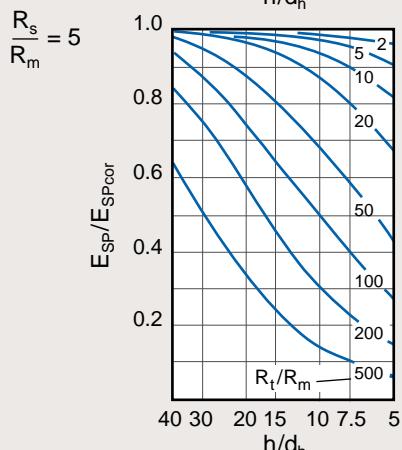

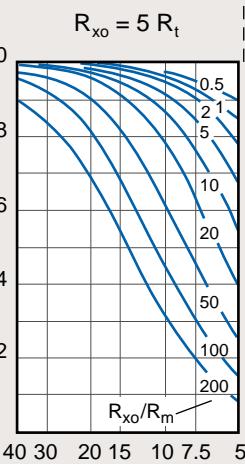

## SP Correction Charts

For representative cases

SP-3

SP

No invasion

 $R_{xo} = 0.2 R_t$ Invasion,  $d_i/d_h = 5$  $R_{xo} = R_t$  $R_{xo} = 5 R_t$ 

© Schlumberger

1. Select row of charts for most appropriate value of  $R_s/R_m$ .
2. Select chart for No Invasion or for Invasion of  $d_i/d_h = 5$ , whichever is appropriate.
3. Enter abscissa with value of  $h/d_h$  (ratio of bed thickness to hole diameter).
4. Go vertically up to curve for appropriate  $R_t/R_m$  (for no invasion) or  $R_{xo}/R_m$  (for invaded cases), interpolating between curves if necessary.
5. Read  $E_{Sp}/E_{Sp\text{cor}}$  in ordinate scale. Calculate  $E_{Sp\text{cor}} = E_{Sp}/(E_{Sp}/E_{Sp\text{cor}})$ . ( $E_{Sp}$  is SP from log.)

For more detail on SP corrections, see References 4 and 33.

## SP Correction Chart (Empirical)

SP-4  
(English)

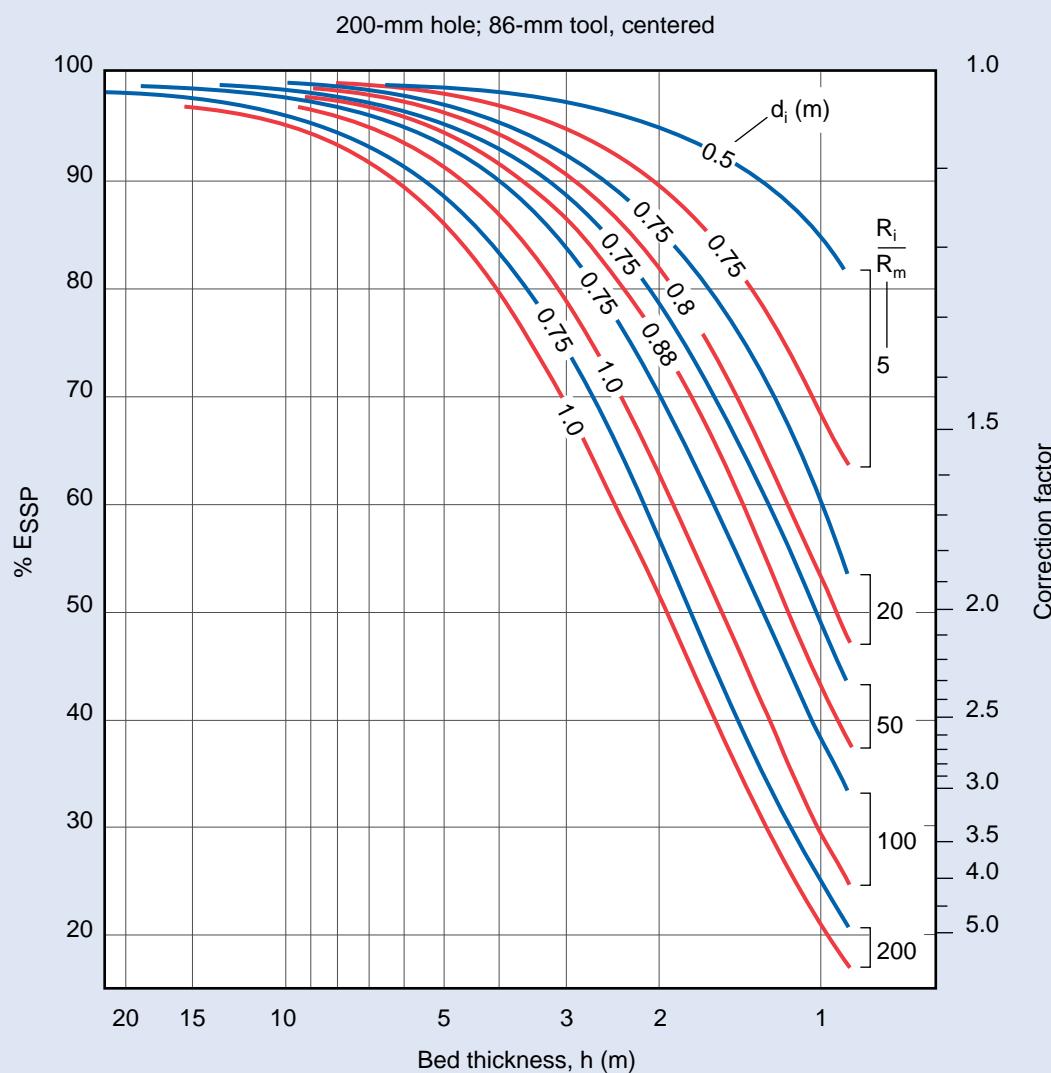

© Schlumberger

This chart provides an empirical correction to the SP for the effects of invasion and bed thickness obtained by averaging a series of thin-bed corrections in Reference 37. This chart considers only  $h$ , bed thickness, as variable, and  $R_i/R_m$  and  $d_i$  as parameters of fixed value. Hole diameter is set at 8 in.

Enter the chart with bed thickness,  $h$ ; go to the appropriate invasion diameter,  $d_i$ , and invaded zone resistivity/mud resistivity ratio,  $R_i/R_m$ . The recorded SP measurement is then corrected by the resulting correction factor.

*Continued on next page*

## SP Correction Chart (Empirical)

SP-4m  
(Metric)

© Schlumberger

*Example:* SP = -80 mV in a 3-m bed

$R_m = 0.5 \text{ ohm-m}$ , and  $R_i$  (invaded zone resistivity) =  
10 ohm-m (both at formation temperature)

Invasion diameter = 0.80 m

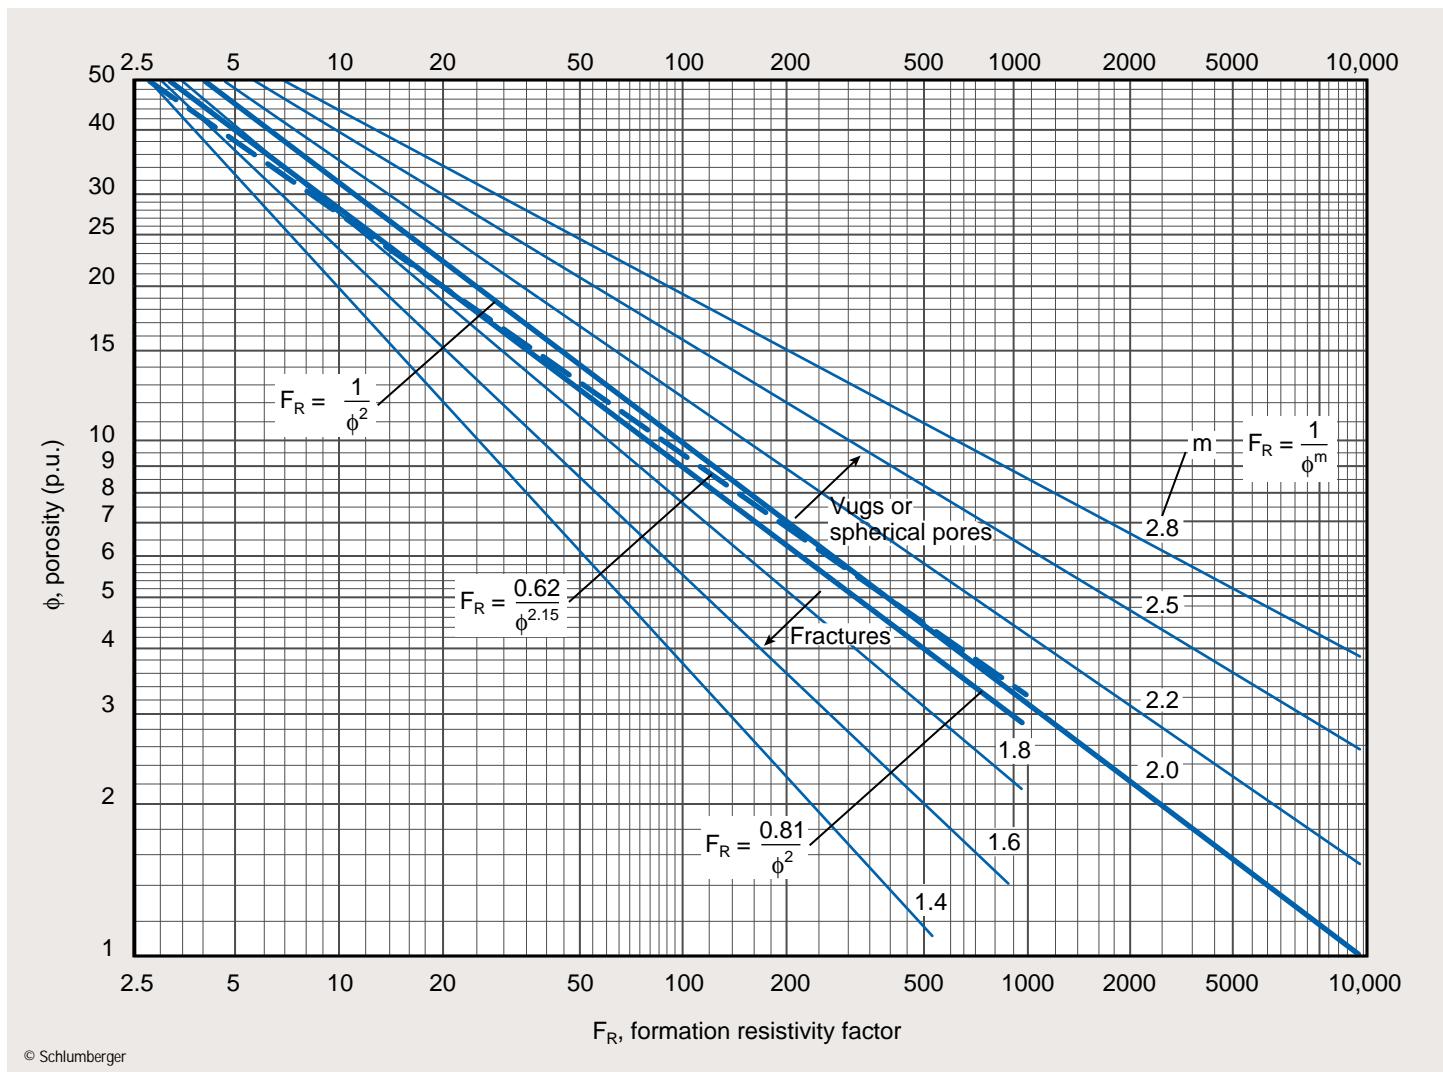

$$\text{Therefore, } R_i/R_m = 10/0.5 = 20$$

SP correction factor = 1.1

$$\text{Corrected SP, ESSP} = -80 (1.1) = -88 \text{ mV}$$

## Formation Resistivity Factor Versus Porosity

Por-1

This chart gives a variety of formation resistivity factor-to-porosity conversions. The proper choice is best determined by laboratory measurement or experience in the area. In the absence of this knowledge, recommended relationships are the following:

For soft formations (Humble formula):

$$F_R = \frac{0.62}{\phi^{2.15}}, \text{ or } F_R = \frac{0.81}{\phi^2}$$

For hard formations:

$$F_R = \frac{1}{\phi^m},$$

with appropriate cementation factor, m.

*Example:*  $\phi = 6\%$  in a carbonate in which a cementation factor, m, of 2 is appropriate

Therefore, from chart,

$$F_R = 280$$

## Isolated and Fracture Porosity

Por-1a

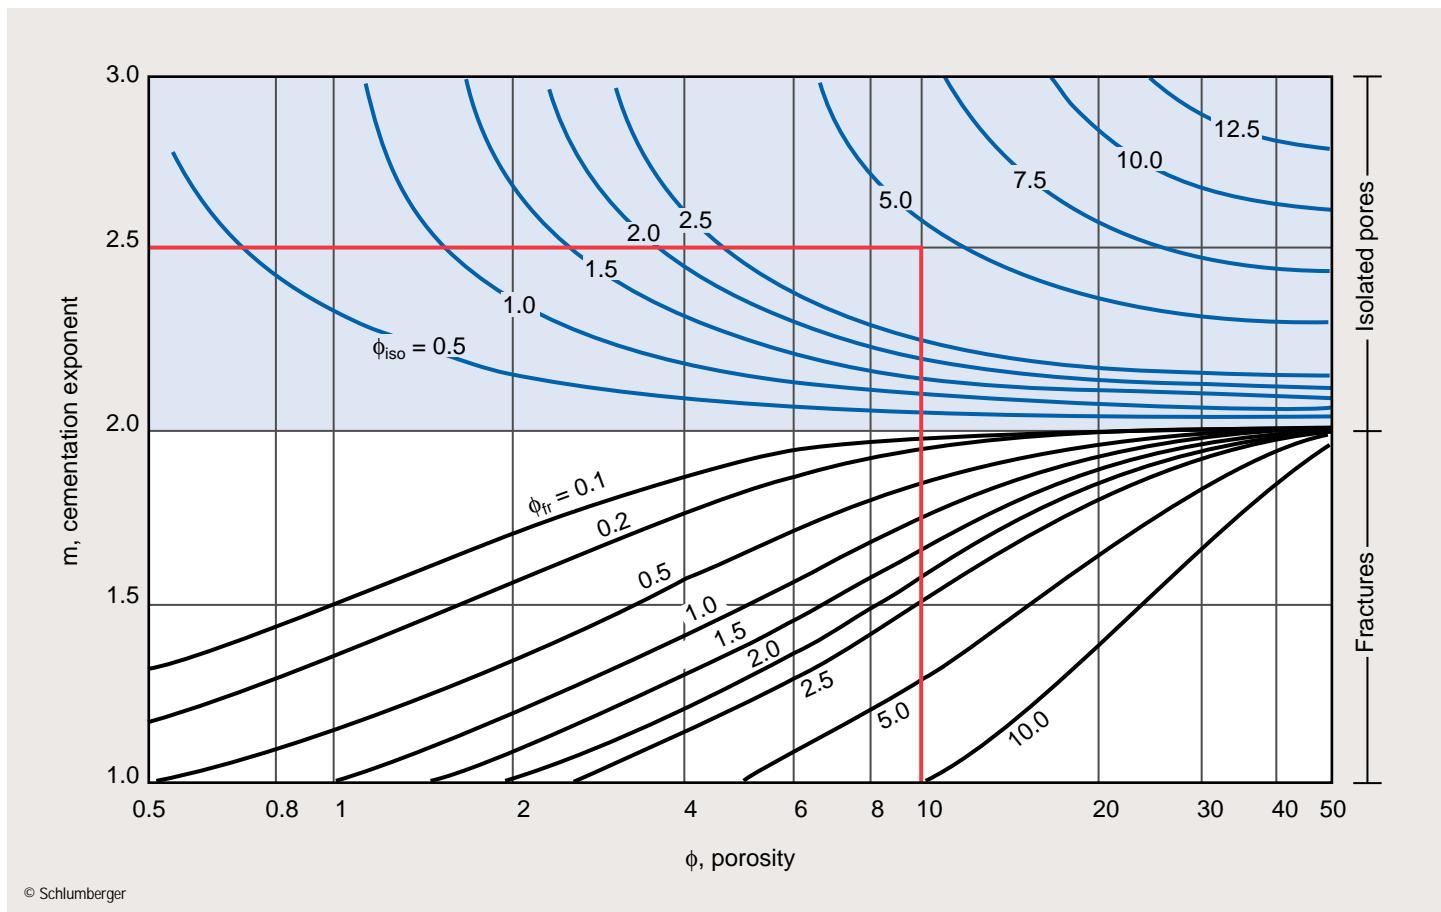

Chart Por-1a is based on a simplified model that assumes there is no contribution to formation conductivity from vugs and moldic porosity, and that the cementation exponent,  $m$ , of fractures is 1.0.

When the pores of a porous formation have an aspect ratio close to 1 (e.g., vugs or moldic porosity), the cementation exponent,  $m$ , of the formation will usually be greater than 2, while fractured formations generally have a cementation exponent less than 2.

If a value of  $m$  is available (from the interpretation of a log suite including a microresistivity measurement, such as a MicroSFL\* log, and a dielectric measurement, such as an EPT\* log, for example), Chart Por-1a can be used to estimate how much of the measured porosity is isolated porosity. In fractured

formations, the apparent  $m$  obtained from a microresistivity measurement assumes total flushing and provides an upper limit for the amount of fracture porosity in the rock.

Entering the chart with the porosity,  $\phi$ , and cementation exponent,  $m$ , gives an estimate of either  $\phi_{iso}$ , the amount of isolated porosity, or  $\phi_{fr}$ , the porosity resulting from fractures.

**Example:**  $\phi = 10$  p.u.

$$m = 2.5$$

Therefore,  $\phi_{iso} = 4.5$  p.u.

and      intergranular porosity =  $10 - 4.5 = 5.5$  p.u.

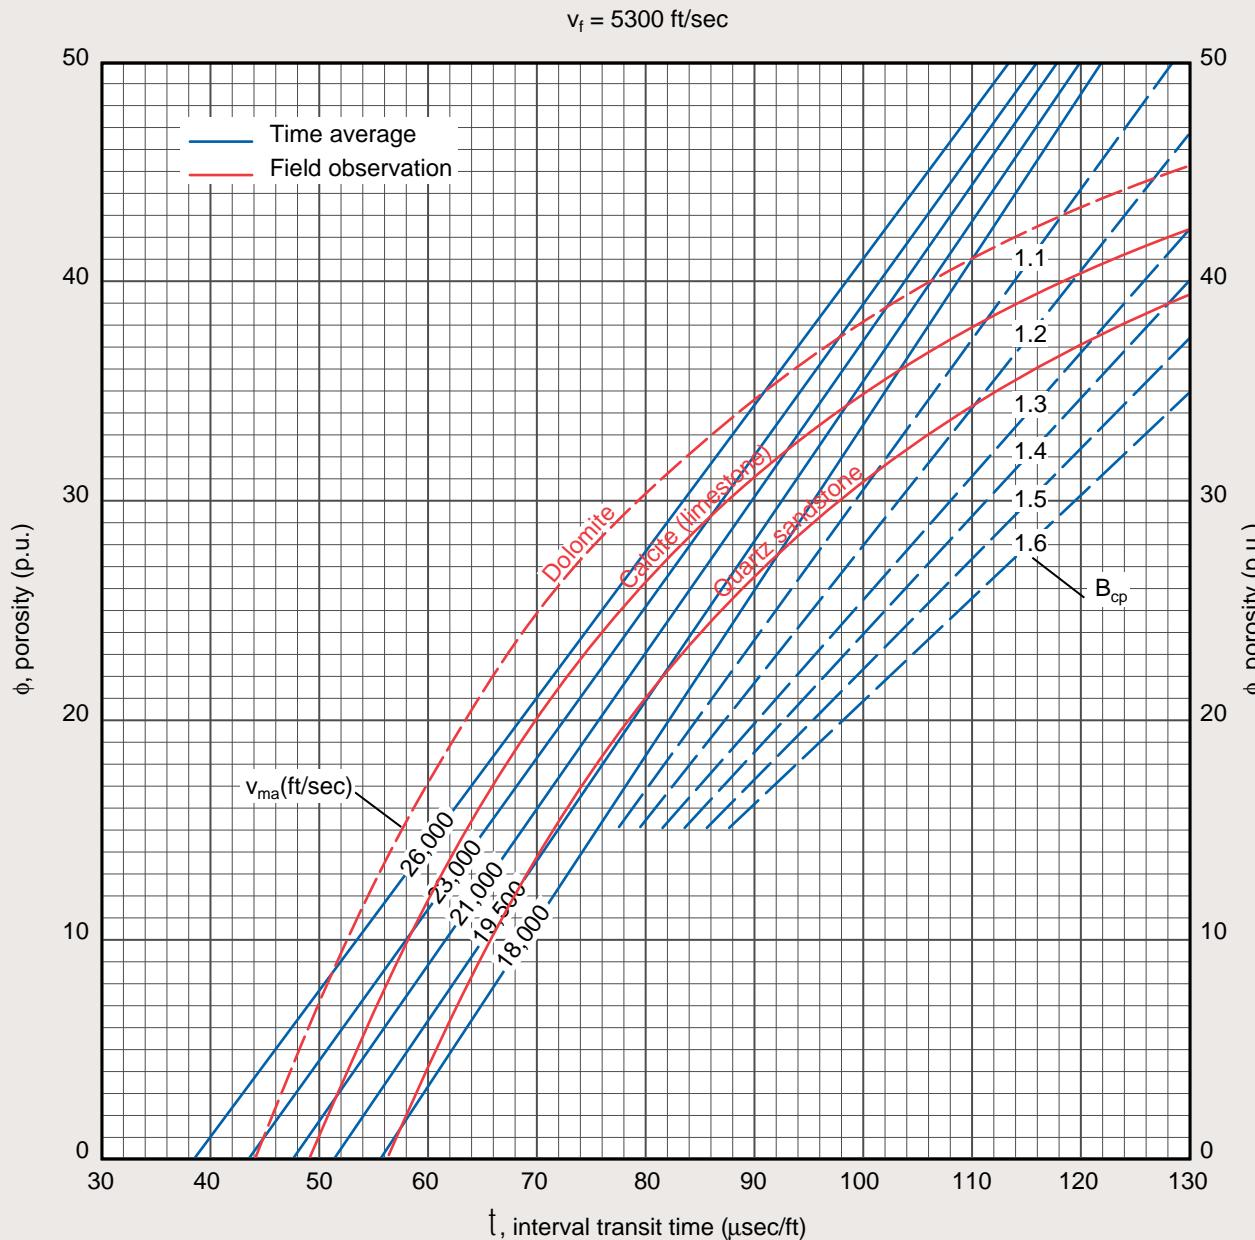

See Reference 39 for more information about the use of this chart, and Reference 40 for a discussion of spherical pores.

\*Mark of Schlumberger

## Porosity Evaluation from Sonic

Por-3  
(English)

Por

© Schlumberger

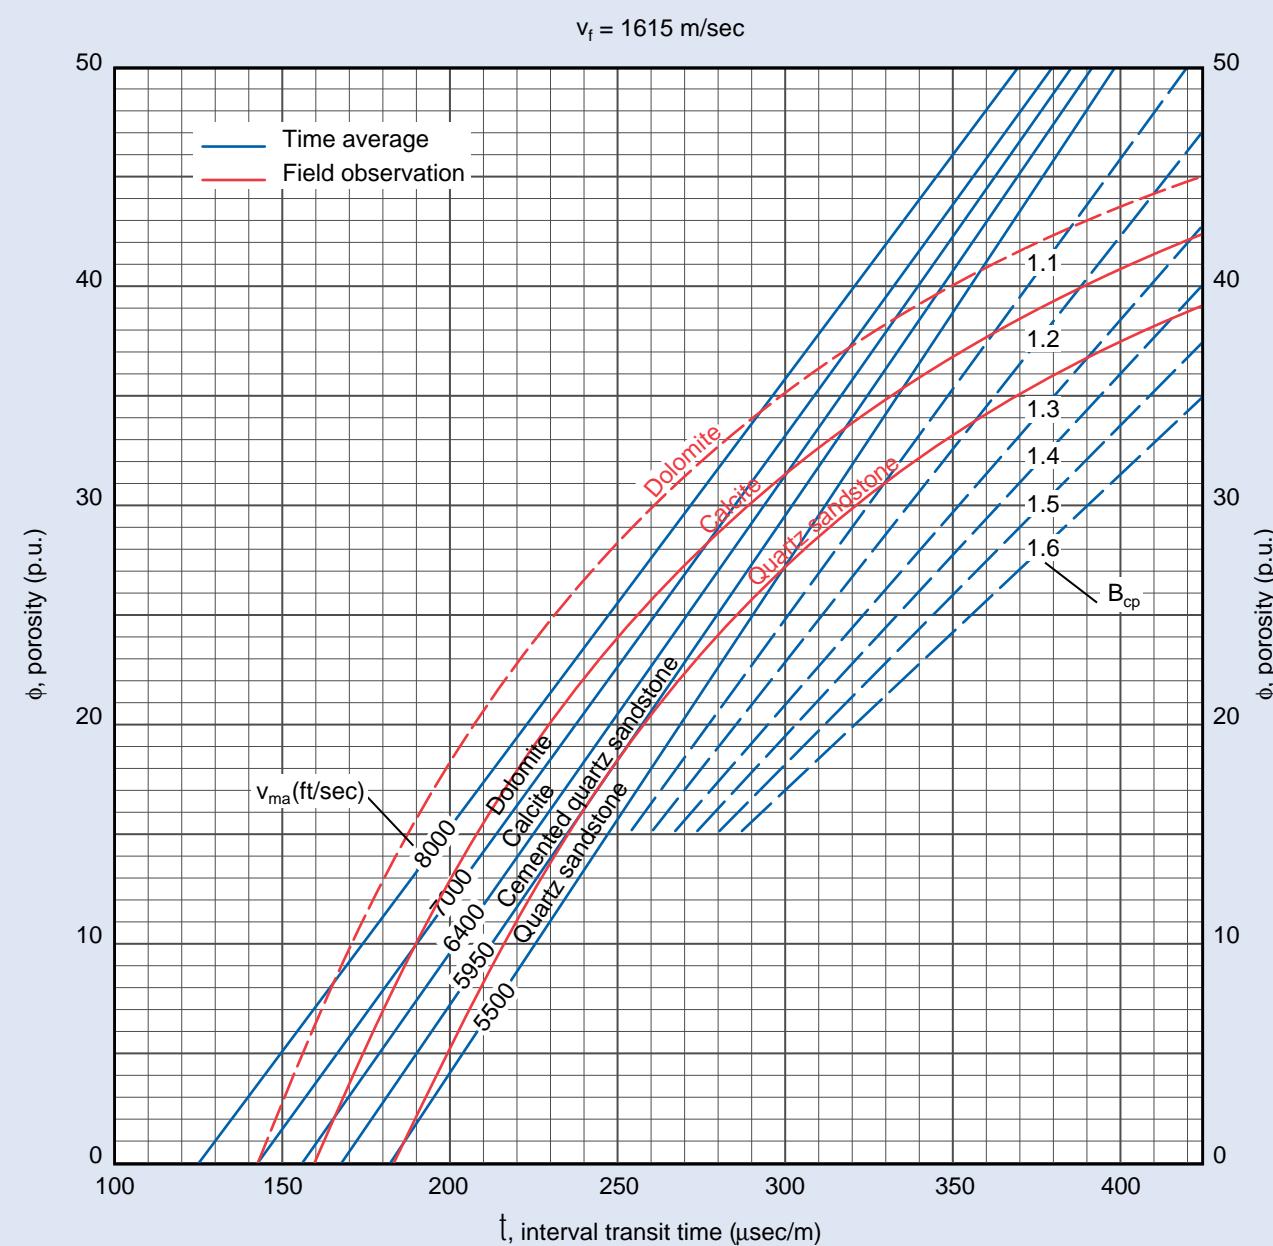

These two charts (Por-3) convert sonic log interval transit time,  $t$ , into porosity,  $\phi$ . Two sets of curves are shown. The blue set employs a weighted-average transform. The red set is based on empirical observation (see Reference 20). For both, the saturating fluid is assumed to be water with a velocity of 5300 ft/sec (1615 m/sec).

To use, enter the chart with the interval transit time from the sonic log. Go to the appropriate matrix velocity or lithology curve and read the porosity on the ordinate.

For rock mixtures such as limy sandstones or cherty dolomites, intermediate matrix lines may be required. When using the weighted-average transform in unconsolidated sand, a lack-of-compaction correction,  $B_{cp}$ , must be made. To accomplish this, enter the chart with the interval transit time; go to the appropriate compaction correction line, and read the porosity on the ordinate. If the compaction correction is unknown, it can be determined by working backward from a nearby clean water sand whose porosity is known.

Continued on next page

## Porosity Evaluation from Sonic

Por-3m  
(Metric)

© Schlumberger

*Example:*  $t = 76 \mu\text{sec}/\text{ft}$  [ $249 \mu\text{sec}/\text{m}$ ]

$v_{ma} = 19,500 \text{ ft/sec}$  [ $5950 \text{ m/sec}$ ]—sandstone

Therefore,  $\phi = 18\%$   
(by either weighted average or empirical transform)

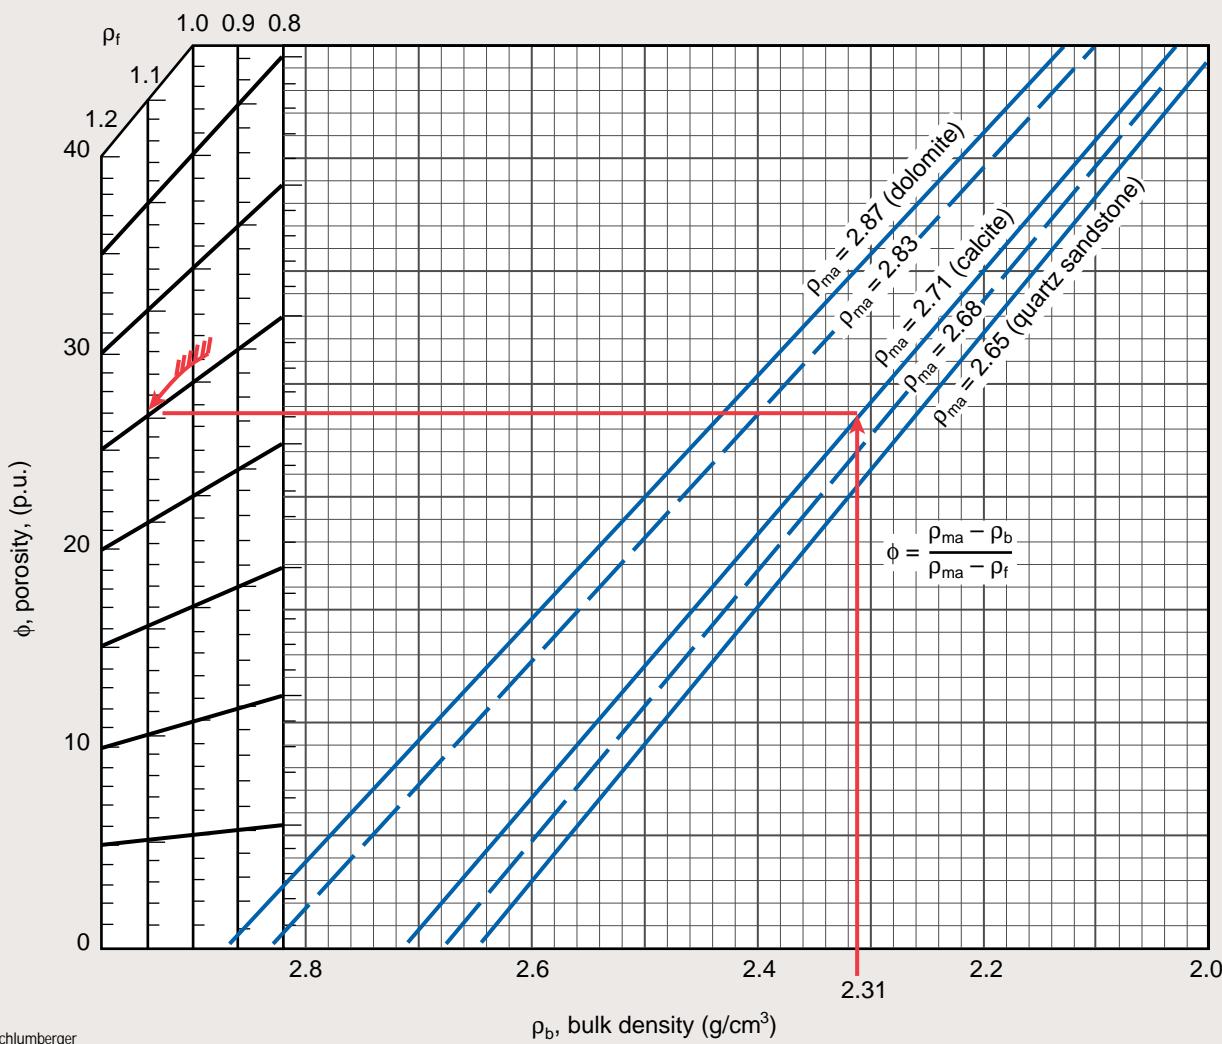

For more information see References 18, 19 and 20.

Lithology	$v_{ma}$ (ft/sec)	$t_{ma}$ ( $\mu\text{sec}/\text{ft}$ )	$v_{ma}$ (m/sec)	$t_{ma}$ ( $\mu\text{sec}/\text{m}$ )
Sandstones	18,000–19,500	55.5–51.3	5486–5944	182–168
Limestones	21,000–23,000	47.6–43.5	6400–7010	156–143
Dolomites	23,000–26,000	43.5–38.5	7010–7925	143–126

## Formation Density Log Determination of Porosity

Por-5

Por

Bulk density,  $\rho_b$ , as recorded with the FDC\* Compensated Formation Density or Litho-Density\* logs, is converted to porosity with this chart. To use, enter bulk density, corrected for bore-hole size, in abscissa; go to the appropriate reservoir rock type and read porosity on the appropriate fluid density,  $\rho_f$ , scale in ordinate. ( $\rho_f$  is the density of the fluid saturating the rock immediately surrounding the borehole—usually mud filtrate.)

*Example:*  $\rho_b = 2.31$  g/cm<sup>3</sup> in limestone lithology  
 $\rho_{ma} = 2.71$  (calcite)  
 $\rho_f = 1.1$  (salt mud)

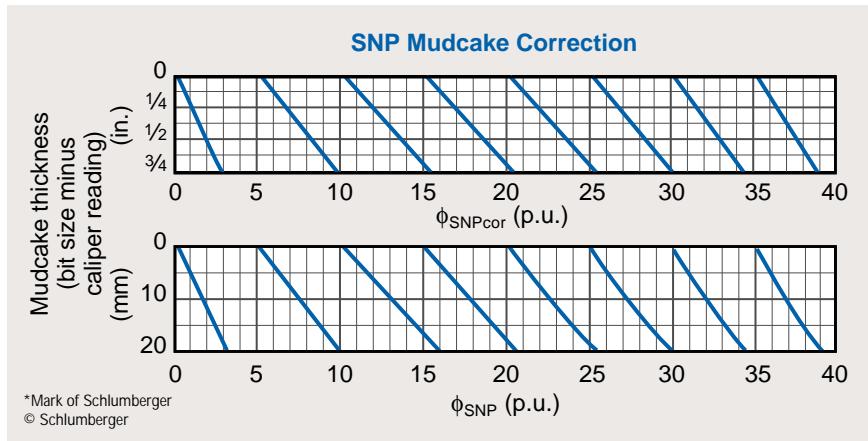

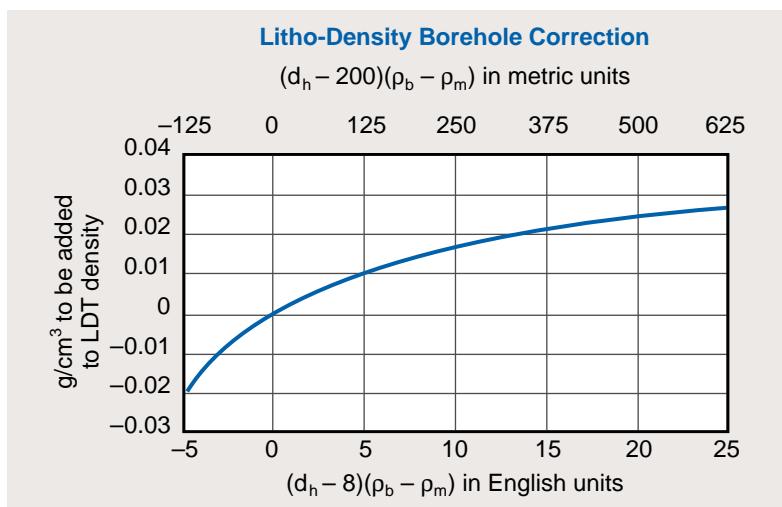

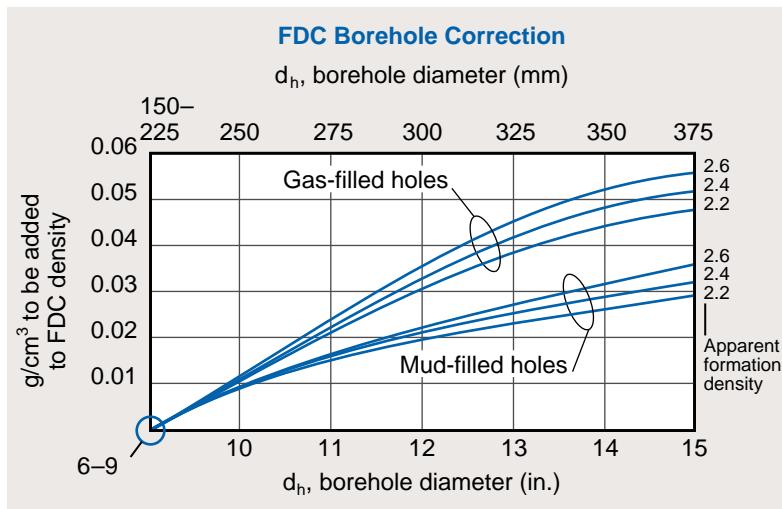

Therefore,  $\phi_D = 25$  p.u.

## Environmental Corrections to Formation Density Log, Litho-Density\* Log and Sidewall Neutron Porosity Log

Por-15a

Under some circumstances, the FDC\* Compensated Formation Density log and Litho-Density log must be corrected for borehole size, and the SNP sidewall neutron log must be corrected for mudcake thickness. These charts provide those corrections.

For the FDC log, enter the chart with borehole diameter,  $d_h$ . Go to the apparent formation density,  $\rho_b$  (FDC log density reading), and read, in ordinate, the correction to be added to the FDC log density reading.

*Example:*  $d_h = 12$  in.

$$\rho_b = 2.20 \text{ g/cm}^3 \text{ (mud-filled borehole)}$$

Therefore, correction =  $0.02 \text{ g/cm}^3$

$$\rho_{bcor} = 2.20 + 0.02 = 2.22 \text{ g/cm}^3$$

For the LDT log, enter the chart abscissa with the product of the borehole diameter,  $d_h$ , less 8 in. [200 mm] and the LDT density reading,  $\rho_b$ , less mud density,  $\rho_m$ . Read, in ordinate, the correction to be added to the Litho-Density bulk density reading.

*Example:*  $d_h = 325$  mm

$$\rho_b = 2.45 \text{ g/cm}^3$$

$$\rho_m = 1.05 \text{ g/cm}^3$$

giving  $(d_h - 200)(\rho_b - \rho_m) =$

$$(325 - 200)(2.45 - 1.05) = 175$$

Therefore, correction =  $0.014 \text{ g/cm}^3$

$$\rho_{bcor} = 2.45 + 0.014 = 2.464 \text{ g/cm}^3$$

*Note:* If the borehole diameter from the FDC or LDT caliper is less than bit size, use the bit size in the above charts.

For the SNP log, enter the bottom of the chart with the SNP apparent porosity,  $\phi_{SNP}$ ; go vertically to the bit size minus caliper reading value; then, follow the diagonal curves to the top edge of the chart to obtain the corrected SNP apparent porosity.

*Example:*  $\phi_{SNP} = 13$  p.u.

Caliper =  $7\frac{5}{8}$  in.

Bit size =  $7\frac{7}{8}$  in.

giving Bit size - caliper =  $7\frac{7}{8} - 7\frac{5}{8} = \frac{1}{4}$  in.

Therefore,  $\phi_{SNPcor} = 11.3$  p.u.

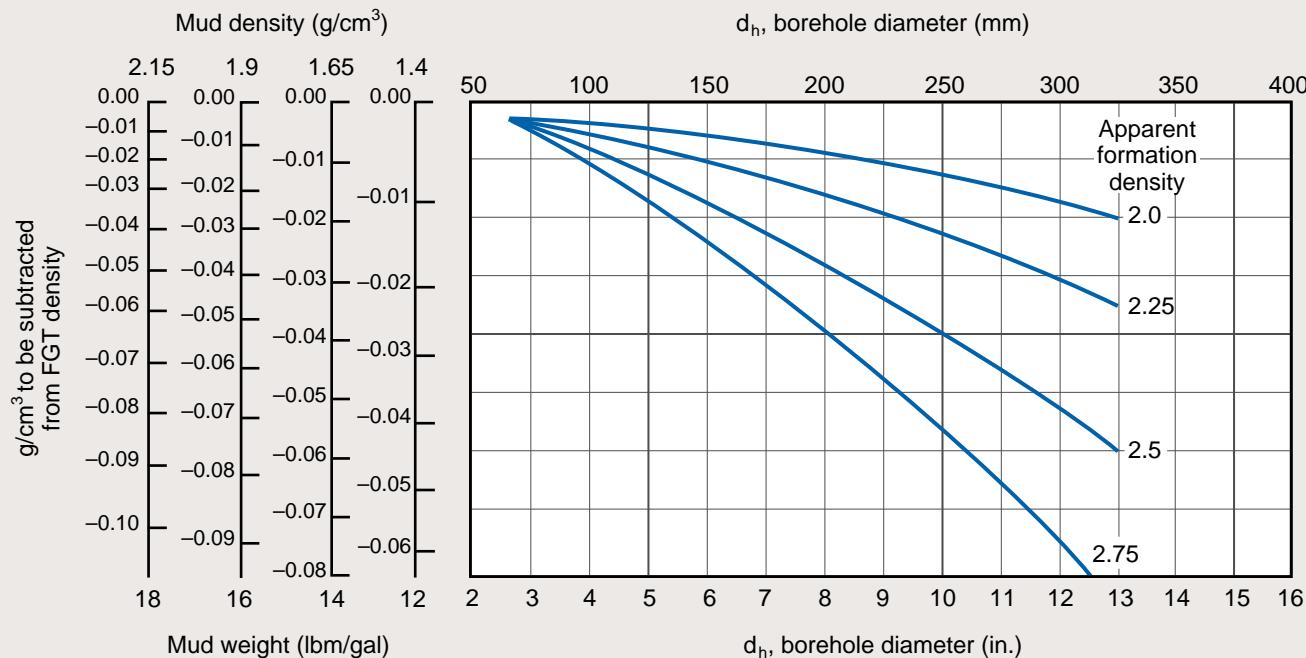

*Note:* The full borehole diameter reduction shown on the SNP caliper is used as mudcake thickness, since the SNP backup shoe usually cuts through the mudcake.

# Environmental Corrections to FGT Density Log

FGT borehole correction

Por-15b

Por

\*Mark of Schlumberger  
© Schlumberger

Borehole corrections of the slimhole 2 $\frac{3}{4}$ -in. FGT formation density log can be made automatically by the logging unit. To determine if corrections have been made, refer to the log. "ALLO" (for allowed) following the constant "MWCO" indicates the FGT log was recorded with borehole correction. "DISA" (for disallowed) indicates that no borehole corrections were made.

In case the FGT log was recorded without automatic borehole correction, this chart provides the correction. Enter the chart abscissa with borehole diameter. Go to the apparent formation

density and read in ordinate, as a function of mud weight, the correction to be subtracted from the FGT log bulk density reading.

*Example:*  $\rho_b = 2.53 \text{ g/cm}^3$   
 $d_h = 260 \text{ mm}$   
Mud density =  $1.65 \text{ g/cm}^3$

Therefore, correction =  $-0.040 \text{ g/cm}^3$

$$\rho_{\text{bcor}} = 2.53 - 0.040 = 2.49 \text{ g/cm}^3$$

## Dual-Spacing CNL\* Compensated Neutron Log Charts

This section contains interpretation charts to cover the latest developments in CNL Compensated Neutron Log porosity transforms, environmental corrections, and porosity and lithology determination.

CSU software (versions CP-30 and later) and MAXIS\* software compute three thermal porosities: NPHI, TNPH and NPOR.

NPHI is our “classic NPHI,” computed from instantaneous near and far count rates, using “Mod-8” ratio-to-porosity transform with a caliper correction.

TNPH is computed from deadtime-corrected, depth- and resolution-matched count rates, using an improved ratio-to-porosity transform and performing a complete set of environmental corrections in real time. These corrections may be turned on or off by the field engineer at the wellsite. For more information see Reference 32.

NPOR is computed from the near-detector count rate and TNPH to give an enhanced resolution porosity. The accuracy of NPOR is equivalent to the accuracy of TNPH if the environmental effects on the near detector change less rapidly than the formation porosity. For more information on enhanced resolution processing, see Reference 35.

Cased hole CNL logs are recorded on NPHI, computed from instantaneous near and far count rates, with a cased hole ratio-to-porosity transform. Chart Por-14a should be used for environmental corrections.

### Using the neutron correction charts

For logs labeled NPHI:

1. Enter Chart Por-14e with NPHI and caliper reading to convert to uncorrected neutron porosity.
2. Enter Charts Por-14c and -14d to obtain corrections for each environmental effect. Corrections are summed with the uncorrected porosity to give a corrected value.
3. Enter corrected porosity in Chart Por-13b for conversion to sandstone or dolomite.
4. Use Crossplots CP-1e, -1f, -2c and -2cm for porosity and lithology determination.

For logs labeled TNPH or NPOR, the CSU/MAXIS software has applied environmental corrections as indicated on the log heading. Refer to Charts Por-14c and -14d to gain an appreciation for the relative importance of each correction prior to using crossplot charts. If the CSU/MAXIS software has applied all corrections, TNPH or NPOR can be used directly with the crossplot charts. In this case, follow these steps:

1. Enter TNPH or NPOR in Chart Por-13b for conversion to sandstone or dolomite.
2. Use Crossplots CP-1e, -1f, -2c and -2cm to determine porosity and lithology.

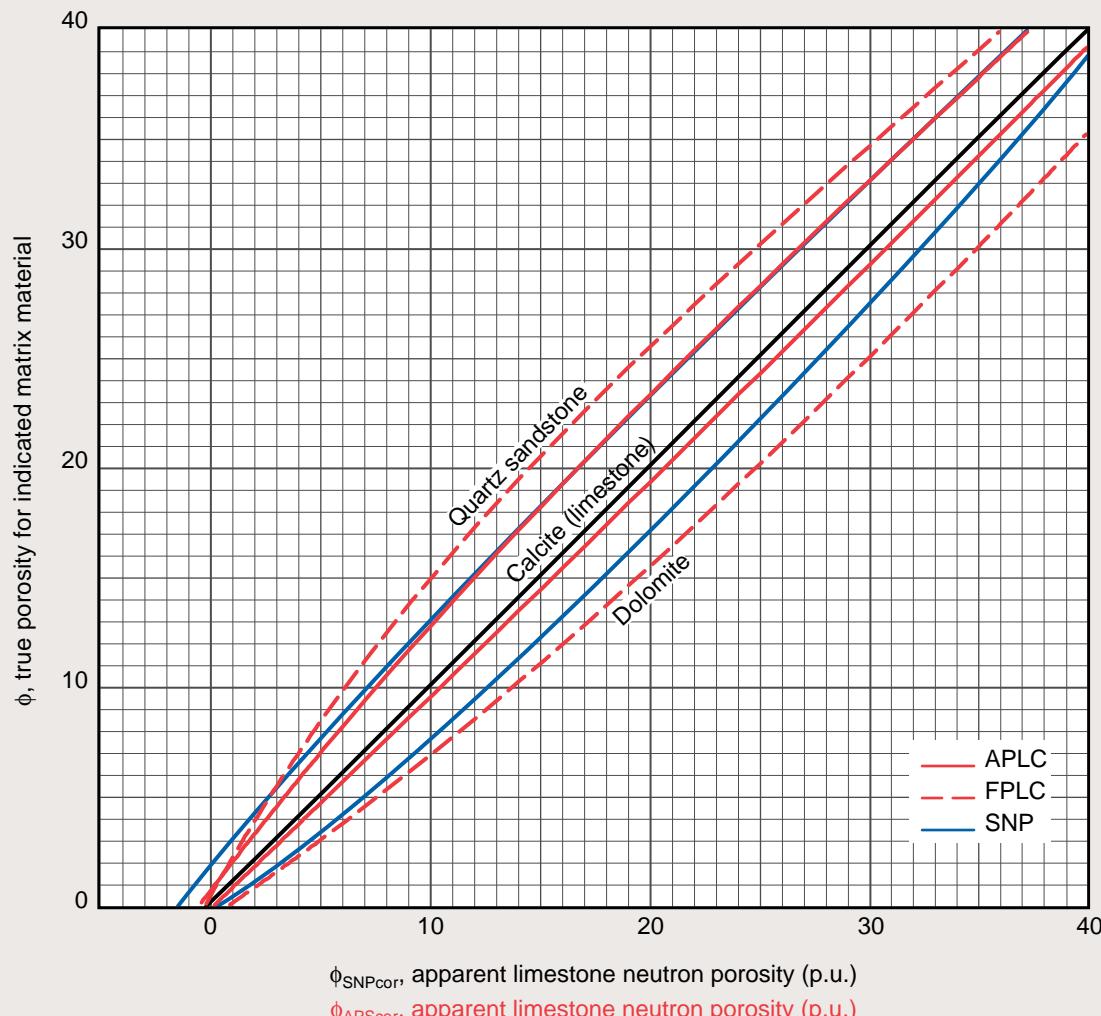

\*Mark of Schlumberger

## Epithermal Neutron Porosity Equivalence Curves

Sidewall Neutron Porosity (SNP) log;

Accelerator Porosity Sonde (APS) Near-to-Array (APLC) and Near-to-Far (FPLC) logs

Por-13a

\*Mark of Schlumberger  
© Schlumberger

When the APS or SNP log is recorded in limestone porosity units, this chart is used to find porosity in sandstones or dolomites. First, correct the SNP log for mudcake thickness (Chart Por-15a).

This chart can also be used to find apparent limestone porosity (needed for entering the various CP crossplot charts) if the APS or SNP recording is in sandstone or dolomite porosity units.

*Example:* Sandstone bed

$\phi_{SNP} = 13$  p.u. (apparent limestone porosity)

Bit size = 7 $\frac{7}{8}$  in.

SNP caliper = 7 $\frac{5}{8}$  in.

giving  $h_{mc} = \frac{1}{4}$  in.

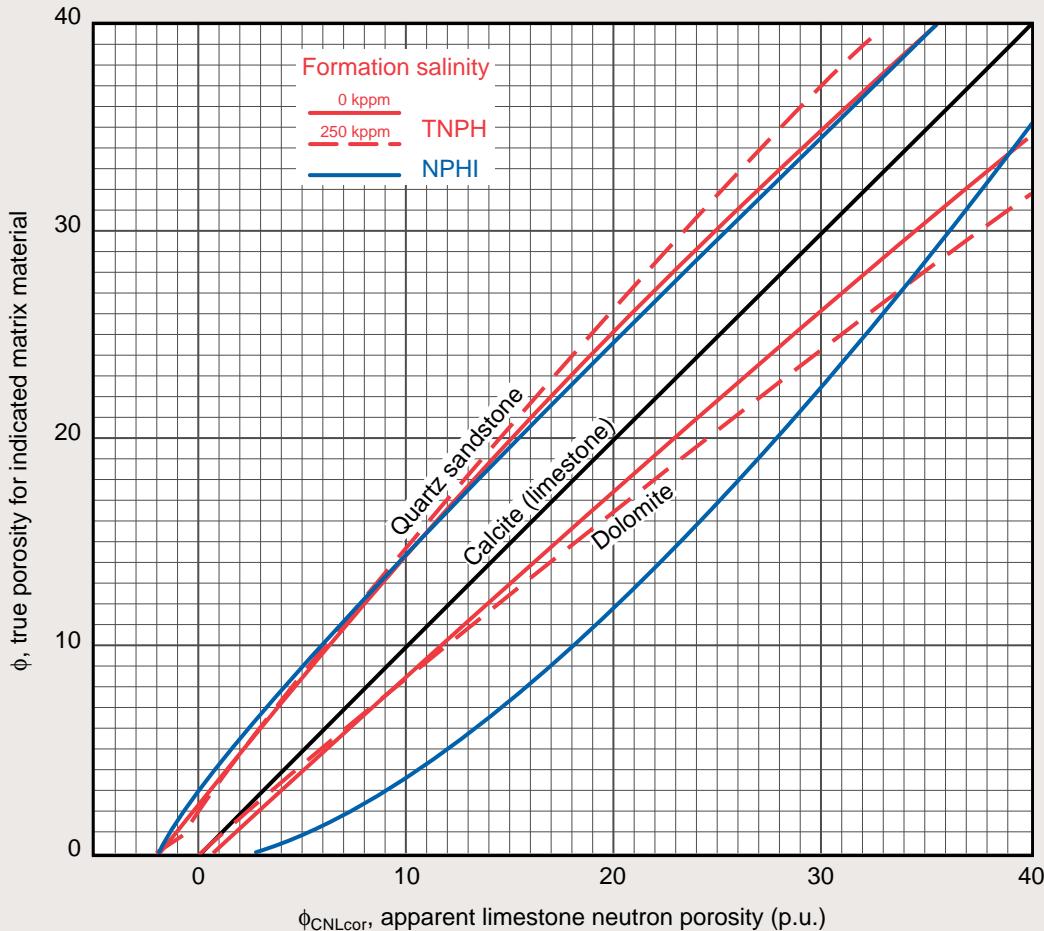

$\phi_{SNP} = 11.3$  p.u. (corrected for mudcake)

and  $\phi_{SNP}$  (sandstone) = 14.5 p.u.

## Thermal Neutron Porosity Equivalence Curves

CNL\* Compensated Neutron Log; TNPH and NPHI porosity logs

Por-13b

\*Mark of Schlumberger  
© Schlumberger

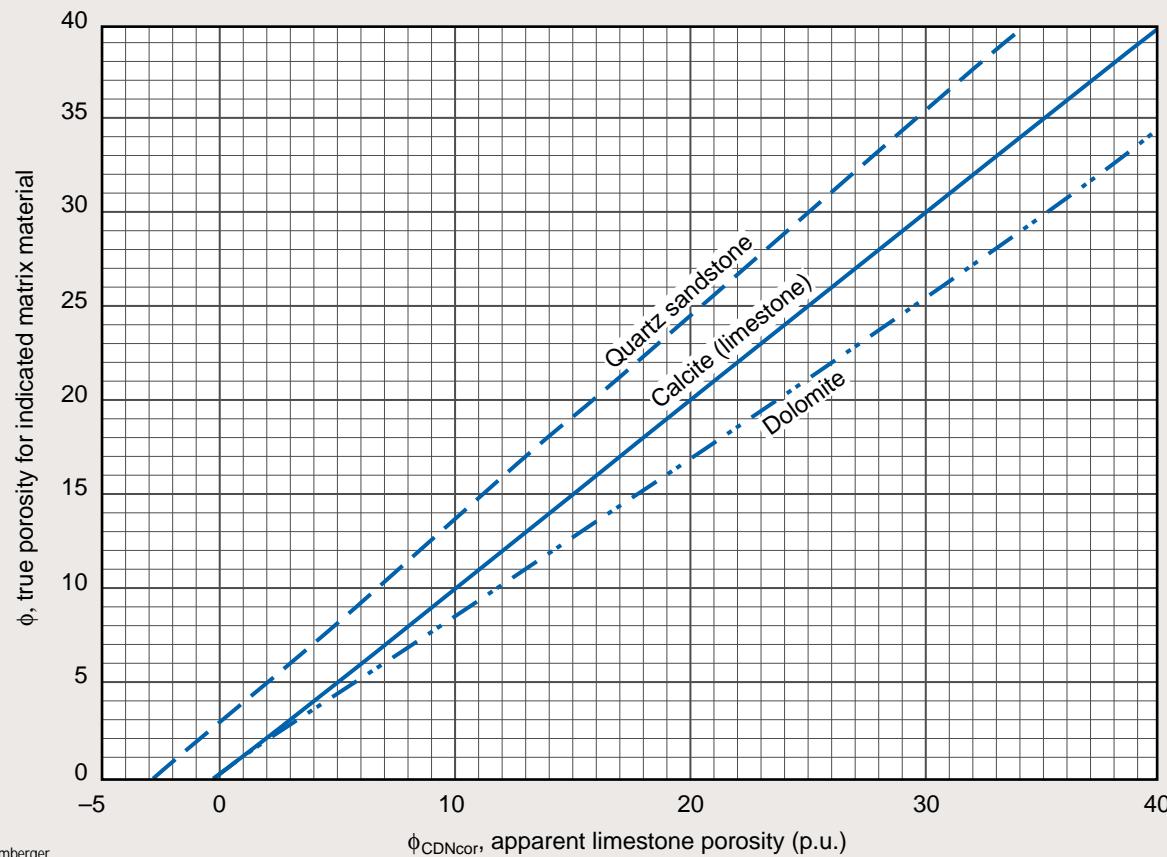

Chart Por-13b can be used in the same way as Chart Por-13a, on the previous page, to convert CNL porosity logs (TNPH or NPHI) from one lithology to another. If a log is recorded in limestone porosity units in a pure quartz sandstone formation, the true porosity can be derived.

*Example:* Quartz sandstone formation  
 $TNPH = 18 \text{ p.u.}$  (apparent limestone porosity)  
 Formation salinity = 250 kppm  
 giving      True porosity in sandstone = 24 p.u.

## LWD Neutron Porosity Equivalence Curves

## Dual-Spacing CNL\* Compensated Neutron Log Environmental Corrections for Cased Hole

The nomographs of Charts Por-14 provide environmental corrections for the CNL Compensated Neutron Log when run in cased hole or openhole. Before using the nomographs, CNL log values must be corrected for matrix effect (Chart Por-13b).

### Cased hole (Chart Por-14a)

For cased hole logs, enter the appropriate Chart Por-14a with the matrix-corrected CNL reading; draw a vertical line through the chart blocks. Find the corrections, relative to the reference lines (dashed lines indicated with asterisks), for each block. Then, go to Chart Por-14c, and starting with the borehole salinity block, continue through the remaining blocks. Algebraically sum all the corrections to obtain the correction to the CNL reading.

*Example:*  $\phi_{CNL} = 27$  p.u. (matrix corrected)

Borehole size = 10 in.

Casing thickness = 0.255 in.

Cement thickness = 1.4 in.

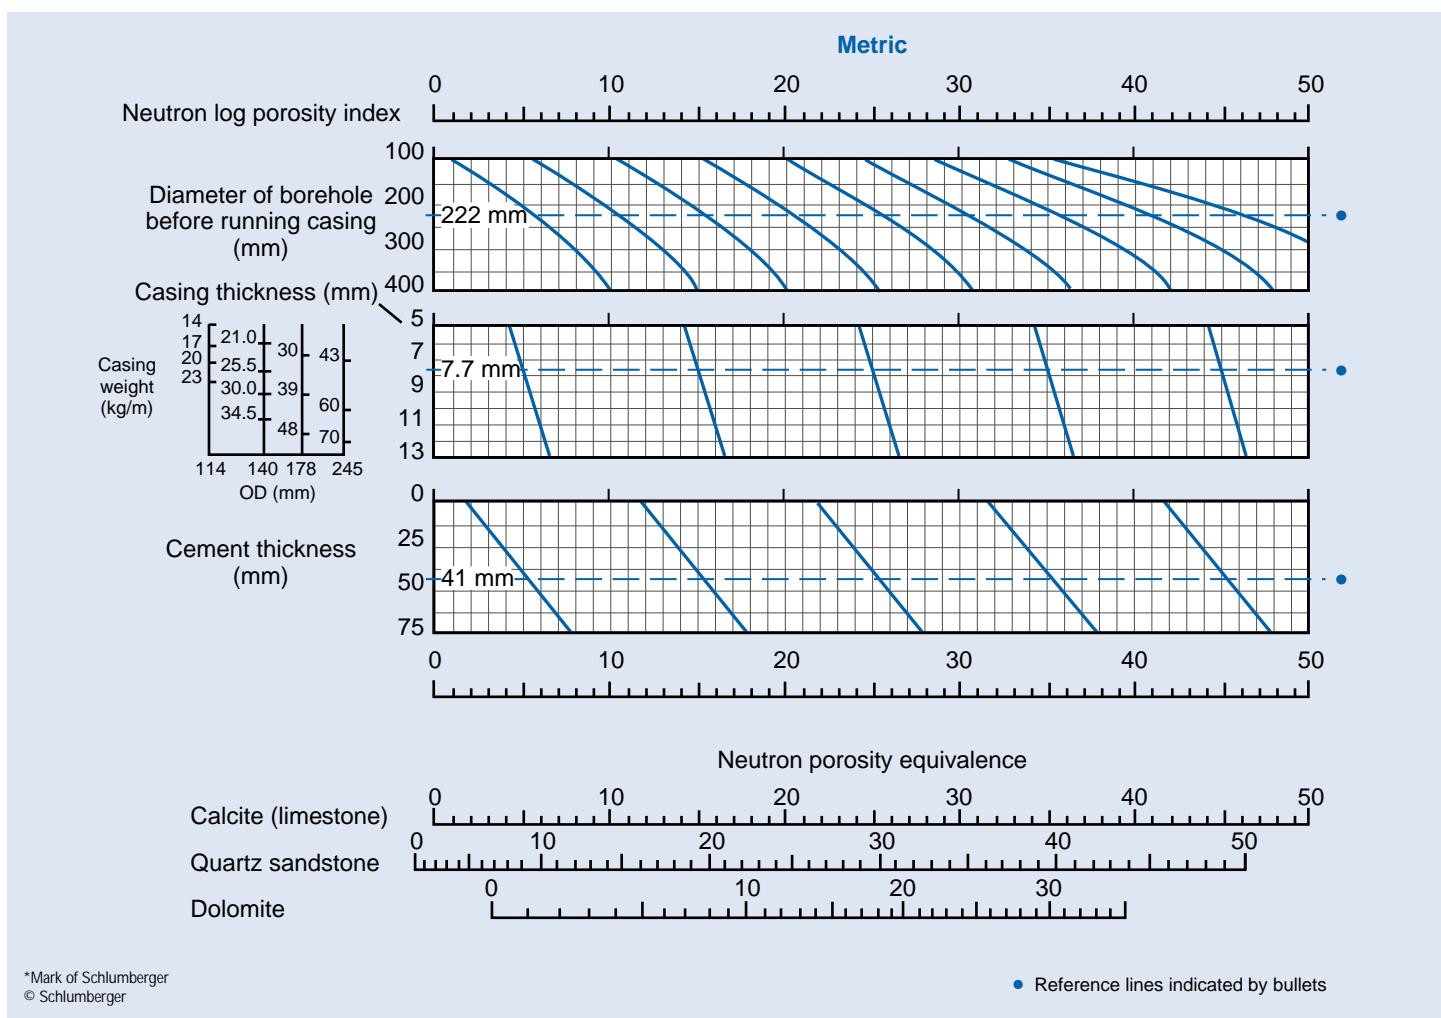

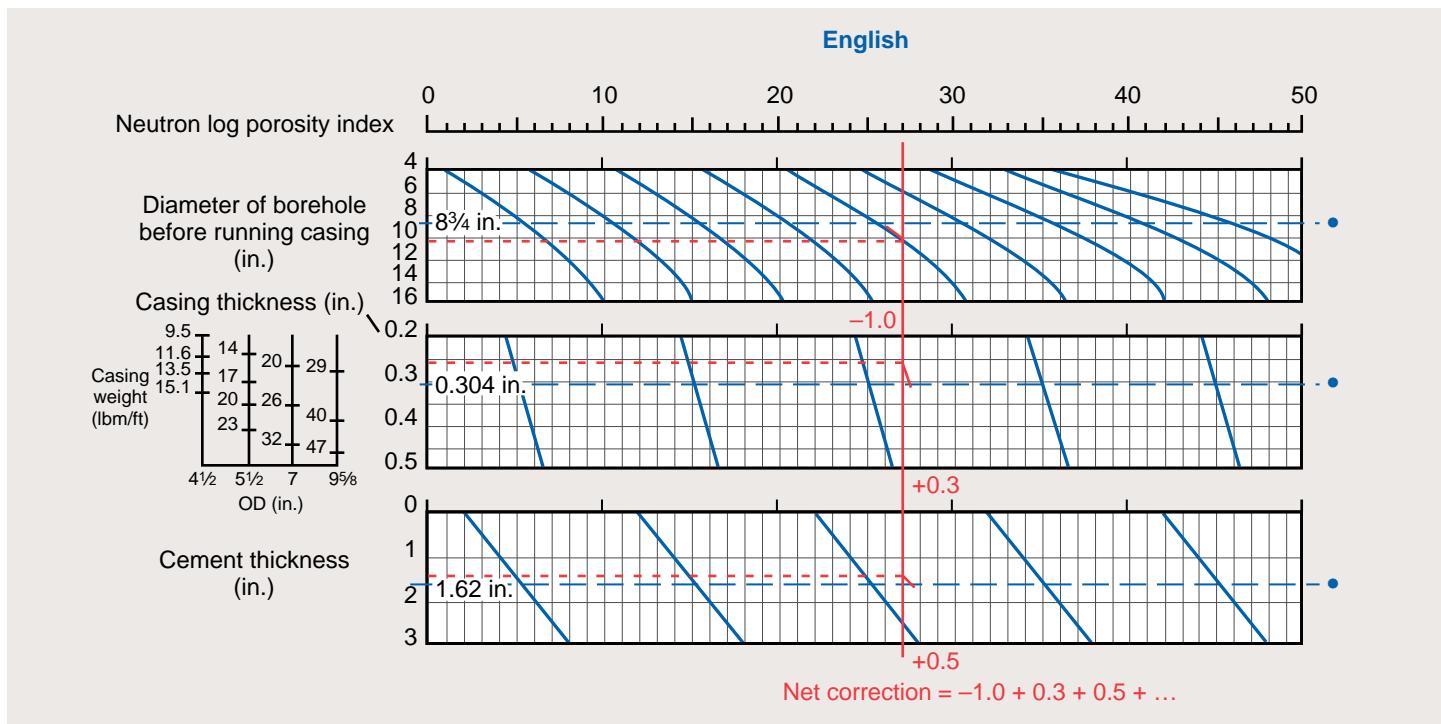

giving  $\Sigma\Delta\phi = -1.0 + 0.3 + 0.5 + \dots$

This provides casing, cement and borehole corrections for the cased hole CNL log. Continue to Chart Por-14c for salinity, borehole fluid, pressure and temperature corrections.

\*Mark of Schlumberger

# Dual-Spacing CNL\* Compensated Neutron Log Correction Nomograph for Cased Hole

Por-14a

## Dual-Spacing CNL\* Compensated Neutron Log Correction Nomograph for Openhole

The CNL tool is normally run with only a caliper correction applied. Refer to the CNL log heading to determine whether the log was run with or without automatic caliper correction. To use Charts Por-14c and -14d, this borehole correction must be removed.

The way the “automatic” borehole correction is “backed out” depends on whether the NPHI or TNPH and NPOR curves are used. With NPHI, the correction is backed out with Chart Por-14e. For TNPH or NPOR, follow these steps:

1. Enter the top block of Chart Por-14c or -14d, labeled “actual borehole size,” with the matrix-corrected CNL porosity.
2. Go to the 8-in. standard condition borehole size indicated by the bullet (•).
3. Follow the trend lines to the borehole size used to correct the log—usually the caliper reading. This value is the uncorrected TNPH value, which should be used to determine the rest of the environmental corrections.

**Example:** Assume TNPH on the log was 32 p.u. (apparent limestone units) in a 12-in. borehole. This gives an uncorrected TNPH of 34 p.u.

The rest of the example assumes the following:

Uncorrected neutron porosity = 34 p.u.  
(apparent limestone units)  
12-in. borehole  
¼-in. thick mudcake  
100-kppm borehole salinity  
11-lbm/gal mud weight (natural mud)  
150°F borehole temperature  
5-kpsi pressure (water-base mud)  
100-kppm formation salinity  
½-in. standoff

Enter Charts Por-14c, -14cm, -14d and -14dm at the top with the uncorrected log reading in apparent limestone units, and project a line downward through all the correction nomographs. For each correction, enter the environmental parameter at the left

of the nomograph and project a line to the right. Then, follow the trend lines from the intersection of the uncorrected porosity reading and the environmental parameter to the intersection of the trend line and the standard condition (for example, for the borehole size correction, the trend line would be followed downward from 12 in. and 34 p.u. to intersect the 8-in. line at 32 p.u.).

The porosity reading where the trend line intersects the standard conditions is the corrected porosity considering only that effect; the difference between the corrected and uncorrected porosity values, or  $\Delta\phi$ , represents the magnitude of the correction for each environmental effect. Since several environmental effects are usually made, a net correction to the uncorrected log reading is computed by summing the individual  $\Delta\phi$ 's for all effects. Once the net correction has been determined, it is added to the uncorrected log value to obtain the environmentally corrected neutron porosity in apparent limestone units.

For the conditions listed above, the corrections are

	$\Delta\phi$
Borehole size	-2 ¾ p.u.
Mudcake thickness	≈0
Borehole salinity	+1
Mud weight	+1 ½
Borehole temperature	+4
Pressure	-1
Formation salinity	-3
Standoff	-2
Net correction	-2 ¼
Corrected porosity	34 p.u. - 2 ¼ p.u. = 31 ¾ p.u. (apparent limestone units)

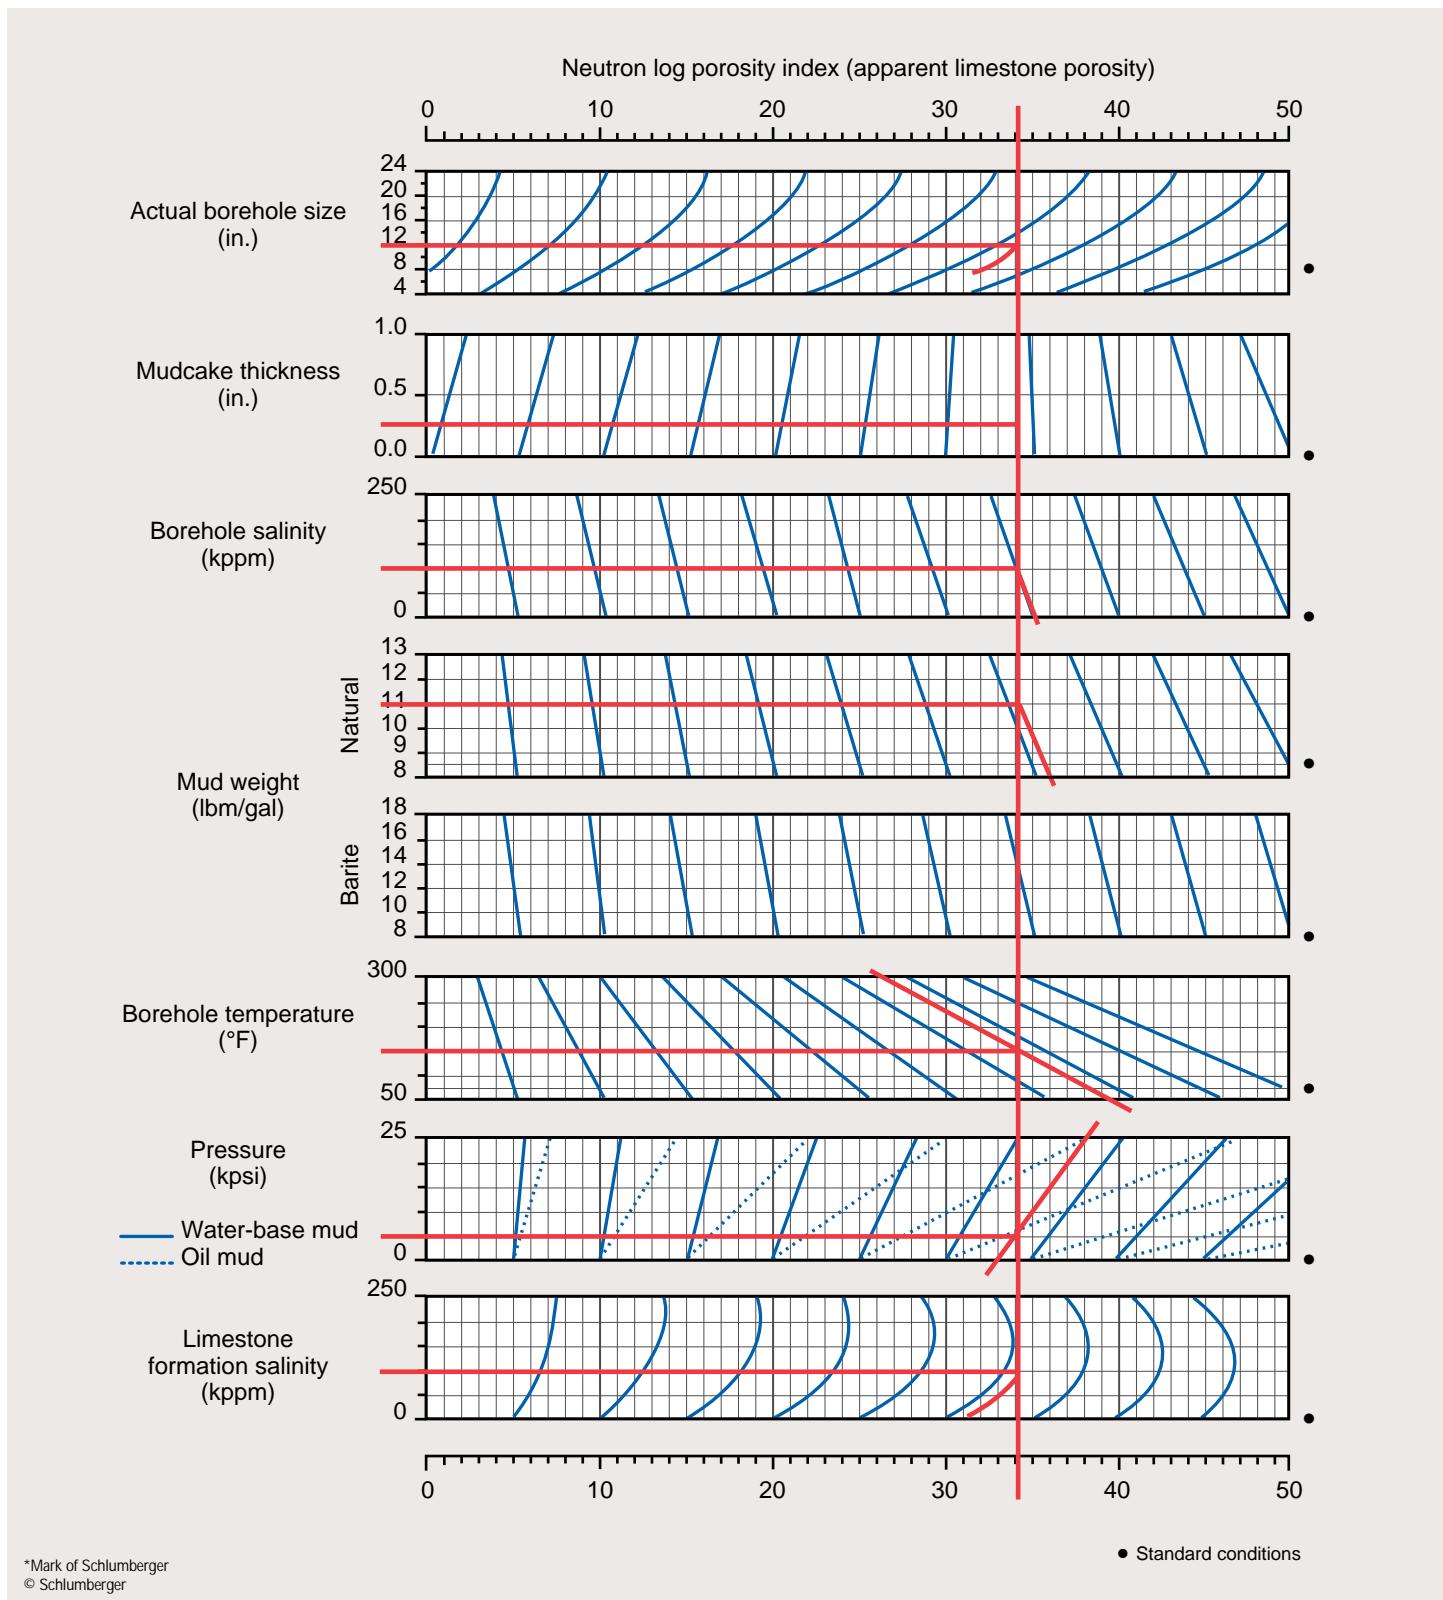

The “oil mud” curves in the pressure correction panel are appropriate for liquid components whose compressibility is four times that of water. The correction for other cases can be obtained by multiplying the WBM correction by the ratio of the OBM/WBM compressibilities.

# Dual-Spacing CNL\* Compensated Neutron Log NPHI-TNPH Conversion Nomograph for Openhole

Por-14e

*Example:* NPHI = 12.5 p.u.

Caliper = 16 in.

Enter the chart from the top at 12.5 p.u.; drop down to  $7\frac{1}{8}$ -in. hole size, labeled with a bullet (•) for standard conditions. Follow the trend lines upward to 16 in. From that point drop straight down to the TNPH scale and read the uncorrected TNPH = 17.25 p.u.

If NPHI is recorded in units other than limestone units, it must be converted using Chart Por-13 before it can be used in this chart. The NPHI scale is for use with logs recorded after January 1976.

## Accelerator Porosity Sonde (APS) Corrections

Openhole APLU and FPLU logs

Epithermal neutron detection with borehole-shielded detectors considerably reduces the environmental effects on the APS response and simplifies their correction.

The near-to-array porosity measurement (APLU in apparent limestone porosity units) and the near-to-far porosity measurement (FPLU in apparent limestone porosity units) require different mud weight and borehole size corrections, so there are individual sets of correction nomographs for each measurement. Formation temperature, pressure and salinity effects are, however, the same on each measurement, so there is only one set of nomographs for these corrections.

Chart Por-23a includes corrections for mud weight and borehole size for near-to-array and near-to-far porosity measurements in both English and metric units.

The borehole size correction is slightly mudweight dependent, even with natural muds, so there are two sets of splines—solid lines for light muds (8.345 lbm/gal) and dashed lines for heavy muds (16 lbm/gal). Intermediate mud weights can be interpolated.

The nomograph for formation temperature, pressure and formation salinity correction of both APLU and FPLU curves appears in Chart Por-23b. The formation salinity correction is dependent on the amount of salt (NaCl) in the formation. This is a function of both the salinity of fluid in the formation and its volume. The last part of the nomograph, therefore, applies to the correction a multiplier proportional to the true porosity of the formation.

Standoff between the APS detectors and the formation is computed from measurements acquired while logging. This real-time standoff measurement allows realistic standoff corrections to be made to the porosity measurements for the first time.

The standoff correction is automatically applied during acquisition but is difficult to represent accurately on two-dimensional charts. No standoff correction charts are currently available, so the automatic correction should be used.

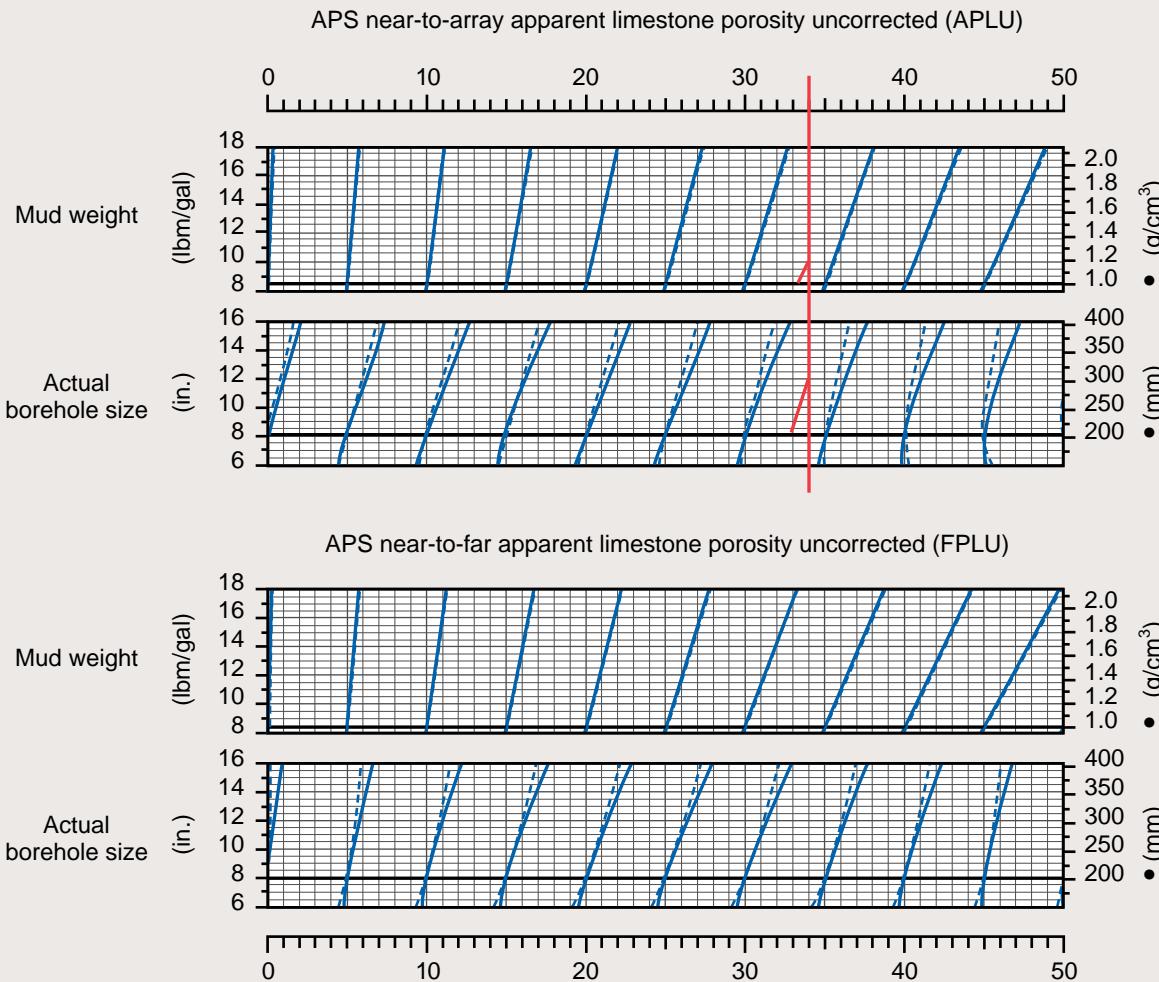

*Continued on next page*

## Openhole APS Corrections for Mud Weight and Borehole Size

For APLU and FPLU curves without environmental correction

Por-23a

Por

© Schlumberger

Charts Por-23a and -23b are used to apply environmental corrections to APLU and FPLU measurements.

Enter at the top of each nomograph on Chart Por-23a with the relevant uncorrected log reading in apparent limestone units and project a line down through the nomographs. For each correction to be applied, enter the environmental parameter at the left of the nomograph if using English units or at the right if using metric units. Draw a horizontal line to meet the uncorrected log reading, then follow the direction of the trend lines downward to meet the standard condition (for example, 8 in. for the borehole size

correction). At this point, you will have moved to the left (minus) or the right (plus) by a distance readable on the porosity scale. Make a note of this correction,  $\Delta\phi$ , to be applied to the uncorrected log reading for that environmental effect.

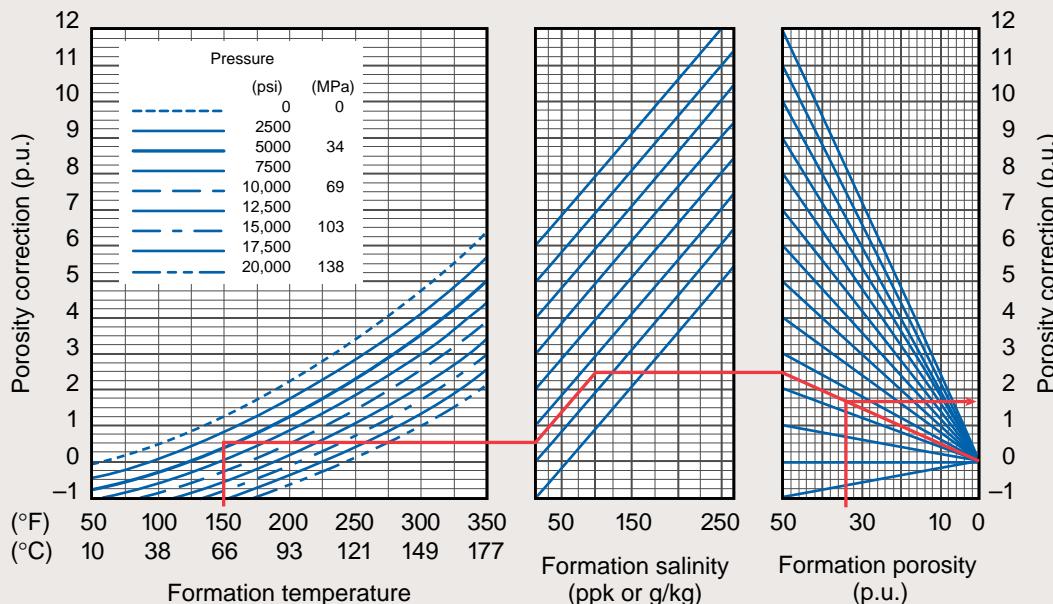

Since several small corrections are usually made for different environmental effects, including mud weight and borehole size using Chart Por-23a, and formation temperature, pressure and formation salinity using Chart Por 23b, the small corrections,  $\Delta\phi$ , for each relevant environmental effect are added together.

*Continued on next page*

## Openhole APS Corrections for Temperature, Pressure and Formation Salinity

Por-23b

For APLU and FPLU curves without environmental corrections

© Schlumberger

For pressure, temperature and salinity corrections, enter the bottom of the left-hand part of Chart Por-23b with formation temperature, and project a line up to the relevant pressure curve. Draw a horizontal line to the left-hand edge of the formation salinity part of the nomograph, then follow the trend lines to the correct formation salinity. Draw another horizontal line to the left-hand edge of the porosity part of the nomograph, and follow the trend lines to the approximate porosity. A horizontal line from here to the right-hand scale gives the porosity correction,  $\Delta\phi$ , to be applied for temperature, pressure and salinity effects. If the correction,  $\Delta\phi$ , given by Chart Por-23b is large and the first estimate of porosity is incorrect, it may be necessary to reiterate this correction with an improved porosity estimate.

**Example:** Assume an uncorrected APLU = 34 p.u. (apparent limestone porosity)  
 Borehole size = 12 in.  
 Mud weight = 11 lbm/gal  
 Borehole temperature = 150°F  
 Pressure = 5 kpsi  
 Formation salinity = 100 kppm

 $\Delta\phi$ 

Then, using Chart Por-23a,

Mud weight correction (none)	-0.7
Borehole size (interpolate mud weight)	-1

and using Chart Por-23b,

Temperature/pressure/salinity	+1.6
Net correction	-0.1

Corrected porosity	34 p.u. - 0.1 p.u. = 33.9 p.u. (apparent limestone units)
--------------------	--

The overall correction is small. If this is a limestone formation, the first estimate of porosity used in Chart Por-23b is good and no reiteration is required.

## Dual-Spacing CNL\* Compensated Neutron Log Formation $\Sigma$ Correction Nomograph for Openhole

When measured formation  $\Sigma$  data are available, Chart Por-16 may be used for correcting thermal neutron porosity from the CNL log for the effect of total formation capture cross section. At the bottom of the chart, an additional nomograph is provided to correct the resulting porosity for salt displacement in cases where elevation of formation  $\Sigma$  is due to salinity. This chart can be used instead of the salinity correction on Chart Por-14c or Por-14cm. Do not use both charts.

In each of the lithology panels, the nominal situation for freshwater pore fluid is drawn to correspond to the values of  $\Sigma_{ma}$  of the formations used to calibrate the porosity response. For reference, the sloping dashed line indicates the value of  $\Sigma$  for the formations filled with salt-saturated water.

To use Chart Por-16, enter the apparent porosity and measured  $\Sigma$  into the appropriate lithology box. Follow the equiporosity trend lines down to the nominal  $\Sigma$  line, and read the corrected porosity there. If at least some of the  $\Sigma$  reading is caused by salt water, a correction for salt displacement is made as follows:

1. Enter the top of the formation salinity box at 0 ppm with the corrected porosity from the previous step.
2. Follow the equiporosity trend lines down to the known water salinity value, and read the final corrected porosity there.

If other environmental corrections are required, the amount of correction for formation  $\Sigma$  and formation salinity should be

calculated by taking the difference between the final corrected and apparent porosity values. This difference can then be summed with corrections for other environmental effects to determine the total correction for all effects.

*Example:*

Given:	Apparent neutron porosity	37.9 p.u. (sandstone)
	Formation $\Sigma$ from log	32.7 c.u.
	Formation water salinity	160.0 kppm
Results:	Porosity corrected for $\Sigma$	32.9 p.u. (sandstone)
	Final corrected porosity	35.0 p.u. (sandstone)

The total formation  $\Sigma$  and salinity effect in this example is 2.9 p.u.

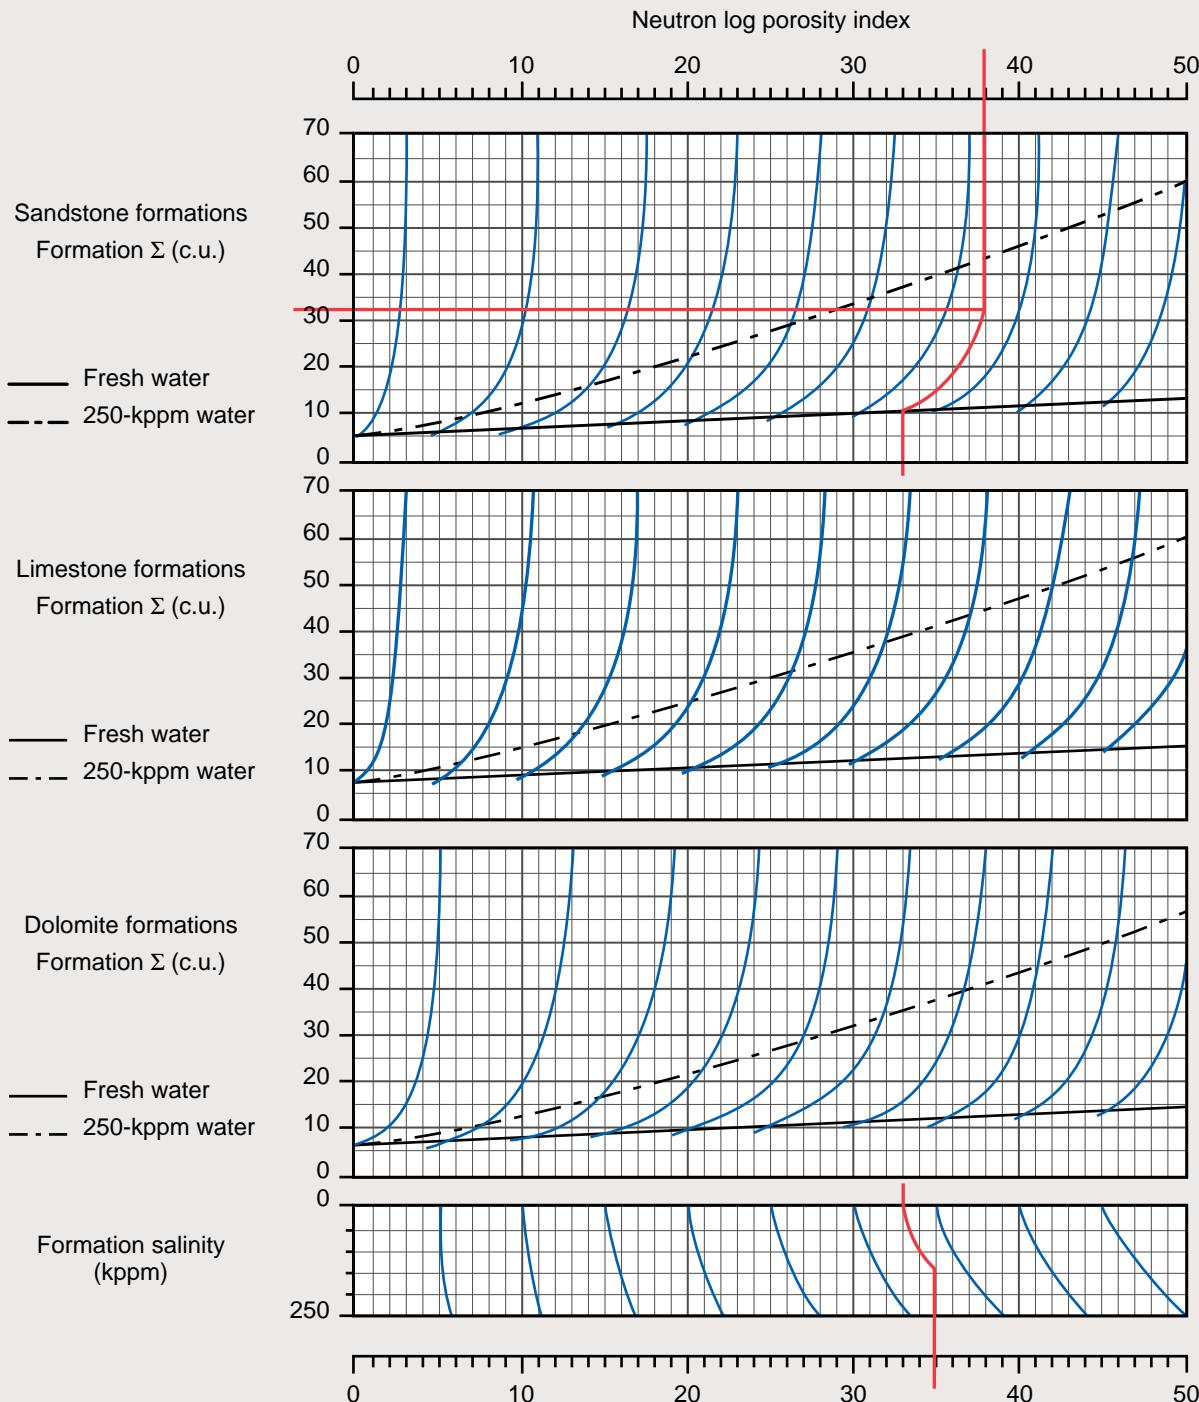

As an alternate approach, with Chart Por-17 it is possible to correct the neutron porosity for the matrix capture cross section in freshwater-filled formations if matrix  $\Sigma$  is known from auxiliary measurements. Chart Por-18 provides corrections for CNL thermal neutron porosity for  $\Sigma$  of the formation fluid and, optionally, for hydrogen displacement in saltwater-filled formations.

For more information see Reference 38.

## CDN\* Compensated Density Neutron Log Correction Nomographs

This section contains log interpretation charts for the logging-while-drilling CDN neutron porosity measurement. Correction Nomographs Por-19 through Por-21 provide an environmentally corrected neutron porosity referenced to the appropriate lithology matrix. The neutron-density crossplot, Chart CP-22, provides insight into the formation lithology and permits the determination of porosity. The following example illustrates the procedure for using the charts.

*Assume the following:*

Uncorrected neutron log porosity	40 p.u. (apparent limestone units)
Tool size	6.5 in.
Borehole size	10 in.
Mud weight	14 lbm/gal (barite mud)
Mud salinity	100 kppm
Mud temperature	150°F
Mud pressure	5 kpsi
Formation salinity	100 kppm

First, determine the temperature and pressure-corrected hydrogen index of the mud ( $H_m$ ). Enter the left of the bottom chart of Nomograph Por-19 at the 14-lbm/gal mud weight. Project a line to the right until it intersects the line for barite mud (point A). From this point, draw a line straight up until it intersects the bottom of the middle chart (point B). Follow the trend lines up to the mud temperature of 150°F (point C), then go straight up to the bottom of the top chart (point D). Follow the trend lines up to the line for 5-kpsi mud pressure (point E) and then straight up to the top of the chart to read the value of 0.78—the corrected hydrogen index of the mud.

Second, determine the environmental corrections with the appropriate Por-20 or -24 chart. Since the hydrogen index of the

mud, mud salinity and formation salinity effects is strongly dependent on the hole size, correction nomographs are provided for 8-, 10-, 12-, 14- and 16-in. borehole sizes and for 6.5- and 8-in. tools.

Since the borehole size in the example is 10 in. and the tool size is 6.5 in., Chart Por-20b is selected for the corrections. Enter the top of the chart with the uncorrected CDN neutron porosity of 40 p.u. and drop a line straight down to the 10-in. borehole size (point B). Follow the sloping trend lines down to the standard conditions (8-in. borehole), and then drop straight down to the  $H_m$  value of 0.78, as determined from Chart Por-19. From here (point D), follow the trend lines to the standard conditions of  $H_m = 1.0$  (point E). Then, drop straight down to the mud salinity value of 100 kppm (point F). Follow the trend lines to the standard conditions of 0 kppm. Drop straight down to the 100-kppm value for formation salinity (point H) and follow the trend lines down to 0 kppm—the standard condition value (point I). There, read the environmentally corrected apparent limestone porosity of 31 p.u. for this example.

The porosity equivalence curves in Chart Por-21 are used to find the porosity of sandstones or dolomites. Enter the chart in abscissa with the environmentally corrected apparent limestone porosity as determined from Chart Por-20, go up to the appropriate matrix line, and read true porosity on the ordinate.

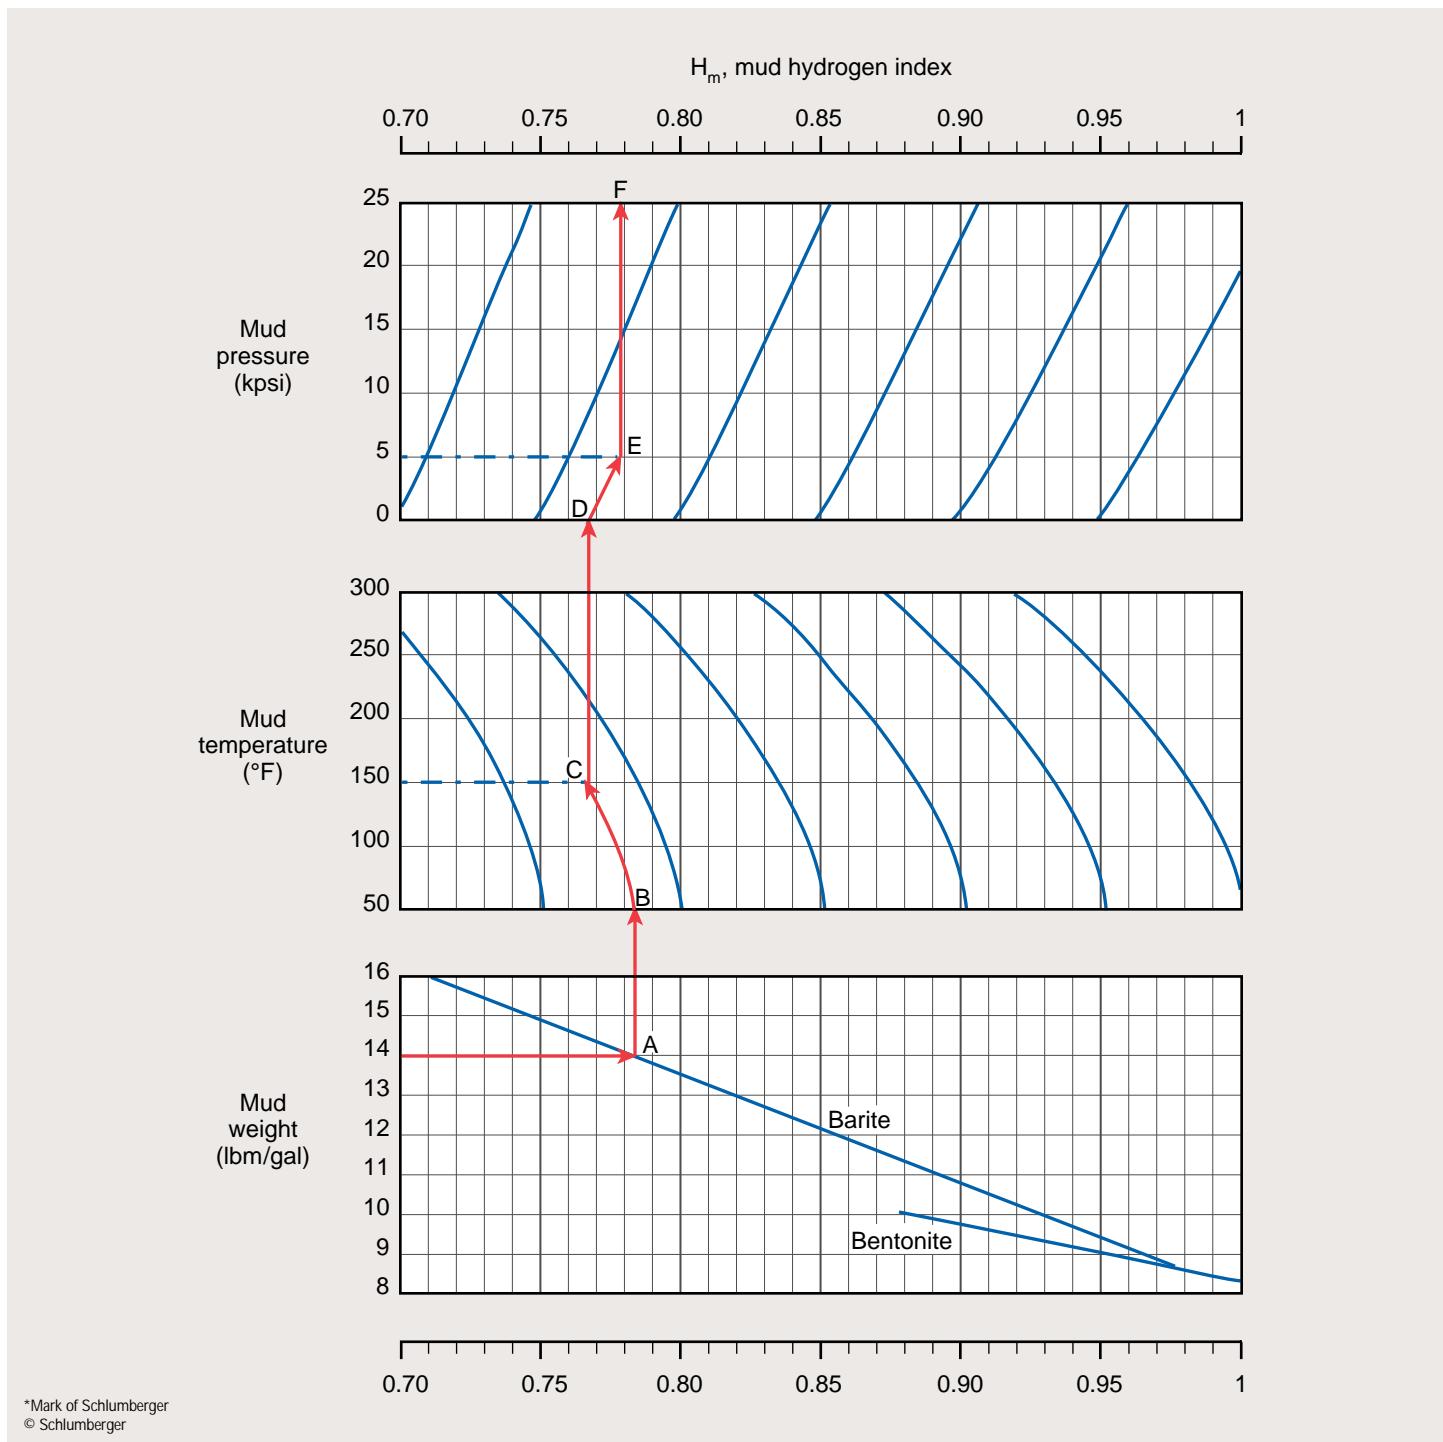

If the lithology is unknown, the neutron-density crossplot, Chart CP-22, can provide insight into lithology and permit the determination of porosity. To use this chart, enter the abscissa with the environmentally corrected apparent limestone porosity and the ordinate with the bulk density. The point of intersection defines the lithology (mineralogy) and the porosity.

## ADN\* Azimuthal Density Neutron Log Correction Nomographs

This section contains log interpretation charts for the logging-while-drilling ADN azimuthal neutron porosity measurement. It is assumed that the tool is stabilized in the borehole. Correction Nomographs Por-19, Por-26a and Por-26b provide an environmentally corrected neutron porosity referenced to the appropriate lithology matrix. The neutron-density crossplot, Chart CP-24, provides insight into the formation lithology and permits the determination of porosity. The following example illustrates the procedure for using the charts.

Por

### *Assume the following:*

Uncorrected neutron log porosity	40 p.u. (apparent limestone units)
Borehole size	10 in.
Mud weight	14 lbm/gal (barite mud)
Mud salinity	100 kppm
Mud temperature	150°F
Mud pressure	5 kpsi
Formation salinity	100 kppm

First, determine the temperature and pressure-corrected hydrogen index of the mud ( $H_m$ ). Enter the left of the bottom chart of Nomograph Por-19 at the 14-lbm/gal mud weight. Project a line to the right until it intersects the line for barite mud (point A). From this point, draw a line straight up until it intersects the bottom of the middle chart (point B). Follow the trend lines up to the mud temperature of 150°F (point C), then go straight up to the bottom of the top chart (point D). Follow the trend lines up to the line for 5-kpsi mud pressure (point E) and then straight up to the top of the chart to read the value of 0.78—the corrected hydrogen index of the mud.

Second, determine the environmental corrections with the appropriate Por-26 chart. Since the hydrogen index of the mud,

mud salinity and formation salinity effects is strongly dependent on the hole size, correction nomographs are provided for 8- and 10-in. borehole sizes.

Since the borehole size in the example is 10 in. and the tool size is 6.5 in., Chart Por-26b is selected for the corrections. Enter the top of the chart with the uncorrected CDN neutron porosity of 40 p.u. and drop a line straight down to the 10-in. borehole size (point B). Follow the sloping trend lines down to the standard conditions (8-in. borehole), and then drop straight down to the  $H_m$  value of 0.78, as determined from Chart Por-19. From here (point D), follow the trend lines to the standard conditions of  $H_m = 1.0$  (point E). Then, drop straight down to the mud salinity value of 100 kppm (point F). Follow the trend lines to the standard conditions of 0 kppm. Drop straight down to the 100-kppm value for formation salinity (point H) and follow the trend lines down to 0 kppm—the standard condition value (point I). There, read the environmentally corrected apparent limestone porosity of 31 p.u. for this example.

The porosity equivalence curves in Chart Por-27 are used to find the porosity of sandstones or dolomites. Enter the chart in abscissa with the environmentally corrected apparent limestone porosity as determined from Chart Por-26b, go up to the appropriate matrix line, and read true porosity on the ordinate.

If the lithology is unknown, the neutron-density crossplot, Chart CP-24, can provide insight into lithology and permit the determination of porosity. To use this chart, enter the abscissa with the environmentally corrected apparent limestone porosity and the ordinate with the bulk density. The point of intersection defines the lithology (mineralogy) and the porosity.

The neutron-density-sonic crossplot charts (Charts CP-1, CP-2 and CP-7) provide insight into lithology and permit the determination of porosity. Chart selection depends on the anticipated mineralogy. Neutron-density can be used to differentiate between the common reservoir rocks [quartz sandstone, calcite (lime-stone) and dolomite] and shale and some evaporites.

Sonic-neutron can be used to differentiate between the common reservoir rocks when clay content is negligible. Sonic-density can be used to differentiate between a single known reservoir rock and shale and to identify evaporate minerals.

## M-N Plot for Mineral Identification

For CNL\* curves that have been environmentally corrected

CP-8

© Schlumberger

This crossplot may be used to help identify mineral mixtures from sonic, density and neutron logs. (The CNL neutron log is used in the above chart; the time average sonic response is assumed.) Except in gas-bearing formations, M and N are practically independent of porosity. They are defined as:

$$M = \frac{t_f - t}{\rho_b - \rho_f} \times 0.01 \text{ (English)}$$

$$M = \frac{t_f - t}{\rho_b - \rho_f} \times 0.003 \text{ (metric)}$$

$$N = \frac{(\phi_N)_f - \phi_N}{\rho_b - \rho_f} \text{ (English or metric)}$$

Points for binary mixtures plot along a line connecting the two mineral points. Ternary mixtures plot within the triangle defined by the three constituent minerals. The effect of gas, shaliness, secondary porosity, etc., is to shift data points in the directions shown by the arrows.

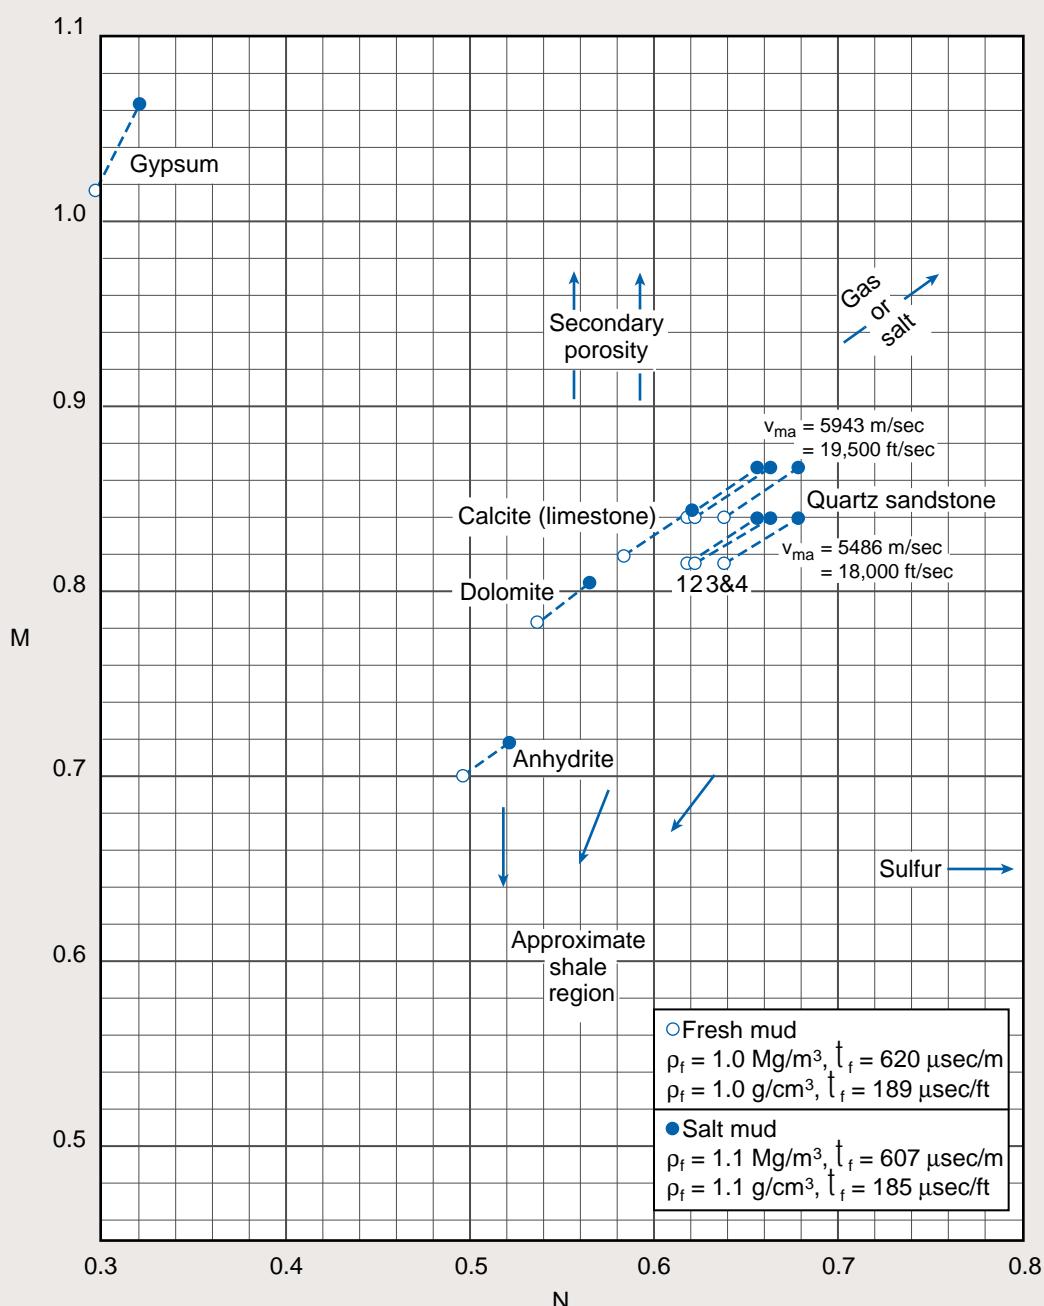

The dolomite and sandstone lines on Chart CP-8 are divided by porosity range as follows: 1)  $\phi = 0$  (tight formation); 2)  $\phi = 0$  to 12 p.u.; 3)  $\phi = 12$  to 27 p.u.; and 4)  $\phi = 27$  to 40 p.u.

## M-N Plot for Mineral Identification

For APS curves that have been environmentally corrected

CP-8a

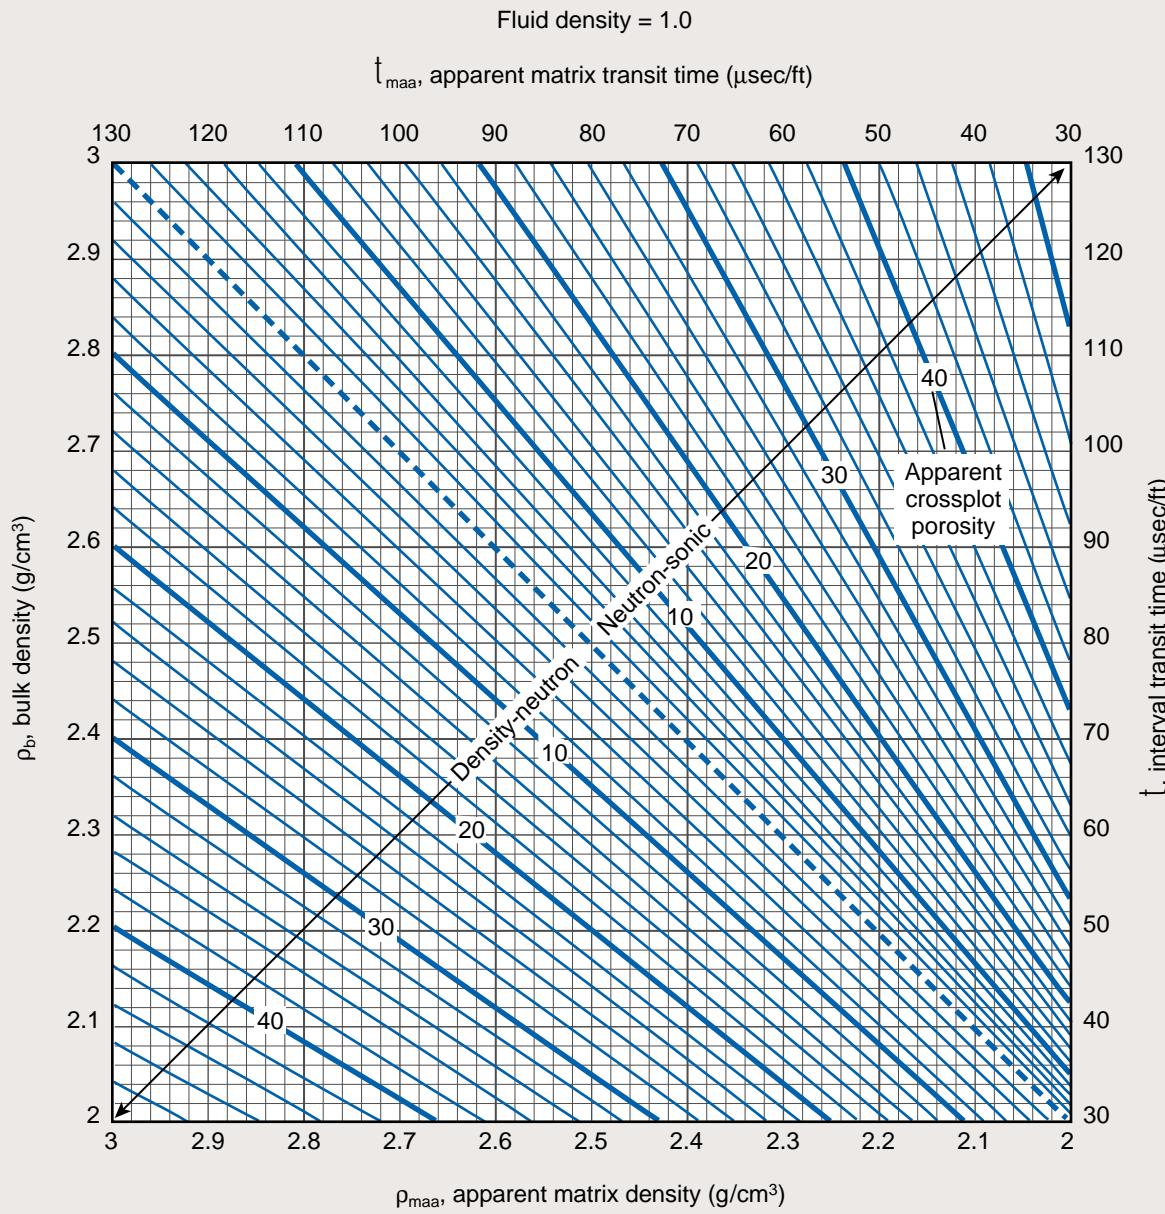

CP

On Chart CP-8a, the APS apparent limestone porosity (APLC) replaces the CNL\* apparent limestone porosity (NPHI) used on Chart CP-8.

Since there is negligible dolomite spread, a single dolomite point is plotted for each mud.

# Determination of Apparent Matrix Parameters from Bulk Density or Interval Transit Time and Apparent Total Porosity

CP-14  
(English)

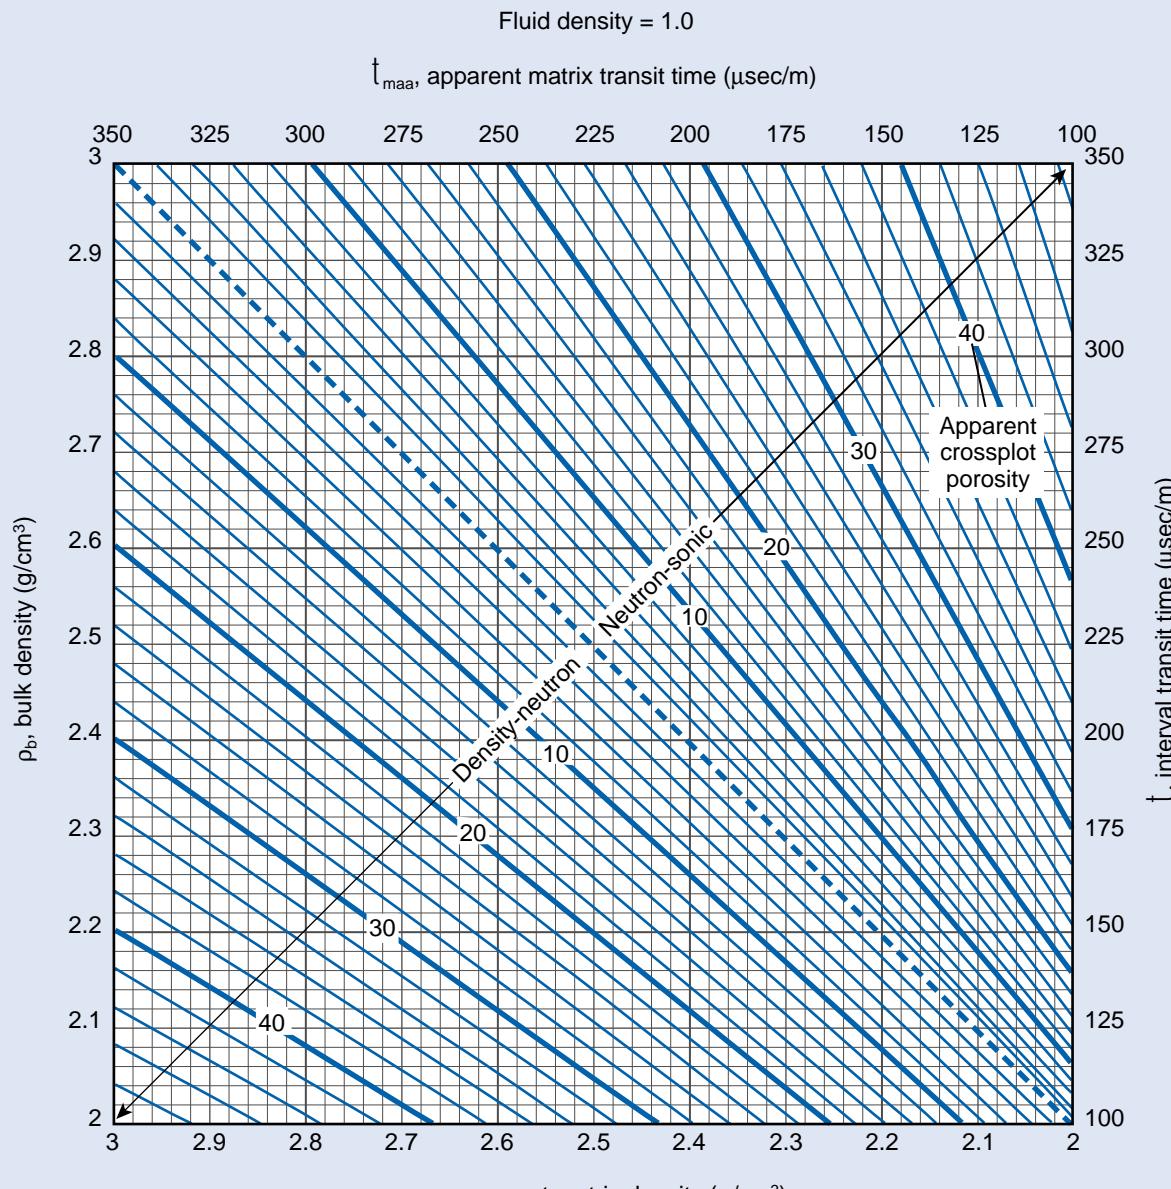

The MID plot permits the identification of rock mineralogy or lithology through a comparison of neutron, density and sonic measurements.

To use the MID plot, three steps are required. First, an apparent crossplot porosity must be determined using the appropriate

neutron-density and empirical (red curves) neutron-sonic cross-plot (Charts CP-1 through CP-7). For any data plotting above the sandstone curve on these charts, the apparent crossplot porosity is defined by a vertical projection to the sandstone curve.

*Continued on next page*

## Determination of Apparent Matrix Parameters from Bulk Density or Interval Transit Time and Apparent Total Porosity

CP-14m  
(Metric)

© Schlumberger

Next, enter the appropriate CP-14 chart with the interval transit time. Go to the apparent crossplot porosity previously found on the appropriate neutron-sonic crossplot chart. This defines an apparent matrix interval transit time,  $t_{maa}$ . Similarly, enter the same chart with the bulk density,  $\rho_b$ . Go to the apparent crossplot porosity previously found on the appropriate density-neutron crossplot chart. This defines an apparent matrix grain density,  $\rho_{maa}$ .

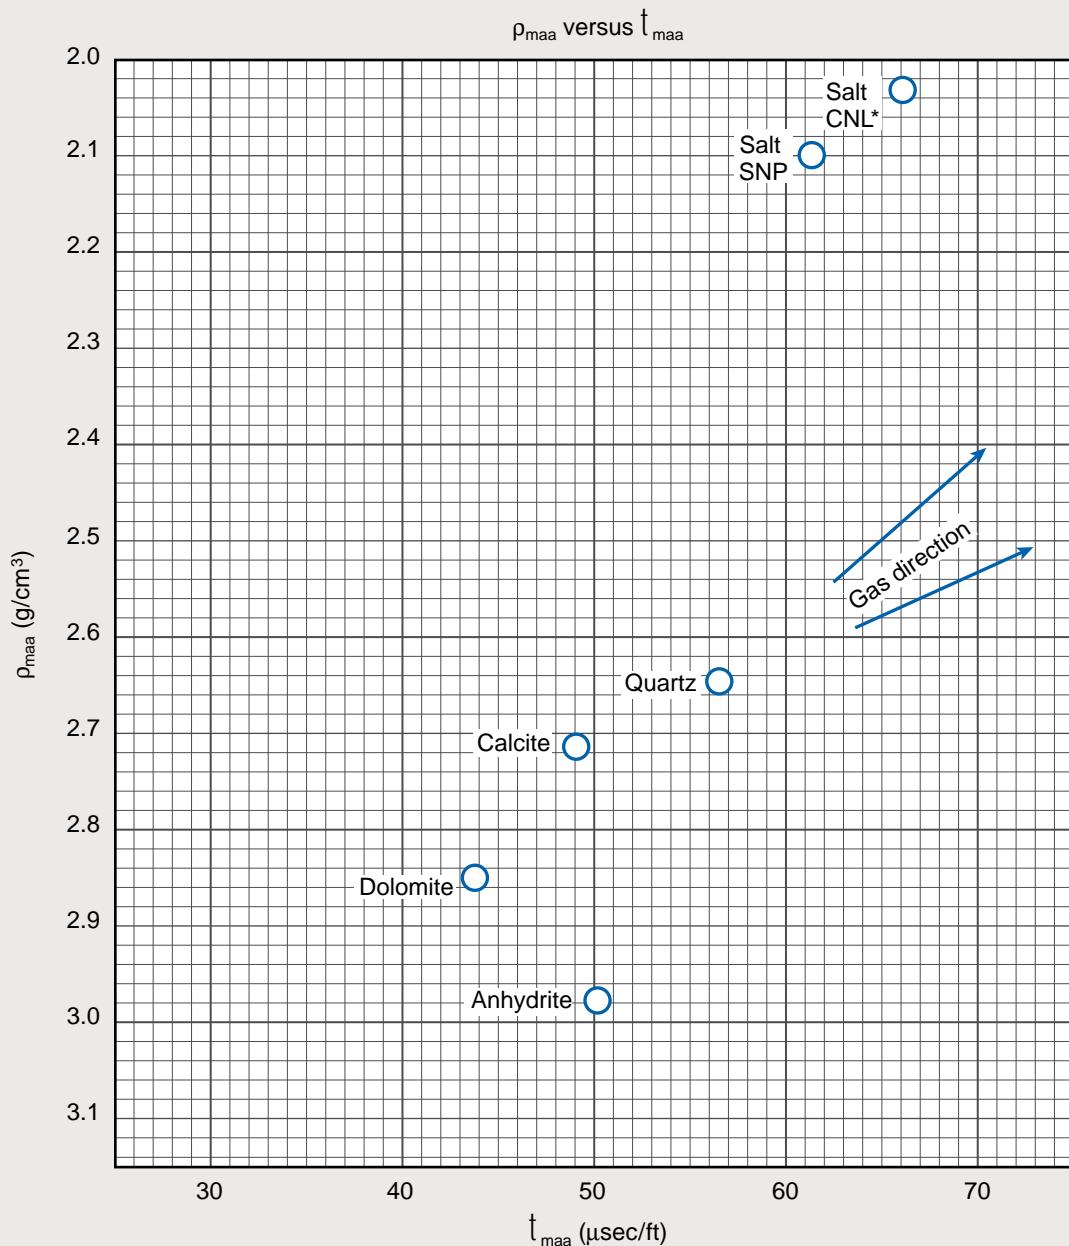

Finally, the crossplot of the apparent matrix interval transit

time and apparent grain density on the MID plot (Chart CP-15) identifies the rock mineralogy by its proximity to the labeled points on the plot.

The presence of secondary porosity in the form of vugs or fractures produces displacements parallel to the  $t_{maa}$  axis. The presence of gas displaces points as shown on the MID plot. Identification of shaliness is best done by plotting some shale points to establish the shale trend lines.

*Continued on next page*

## Matrix Identification (MID) Plot

CP-15  
(English)

© Schlumberger

*Examples:**Level 1*

$$t = 67 \mu\text{sec}/\text{ft}$$

$$\rho_b = 2.04 \text{ g}/\text{cm}^3$$

$$\phi_{\text{CNL}} = -3$$

$$\rho_f = 1.0 \text{ g}/\text{cm}^3$$

*Level 2*

$$t = 63 \mu\text{sec}/\text{ft}$$

$$\rho_b = 2.46 \text{ g}/\text{cm}^3$$

$$\phi_{\text{CNL}} = 24 \text{ p.u.}$$

giving

$$\phi_{\text{aND}} = -1$$

$$\phi_{\text{aNS}} = -1$$

and

$$t_{\text{maa}} = 66 \mu\text{sec}/\text{ft}$$

$$\rho_{\text{maa}} = 2.03 \text{ g}/\text{cm}^3$$

$$\phi_{\text{aND}} = 21$$

$$\phi_{\text{aNS}} = 21$$

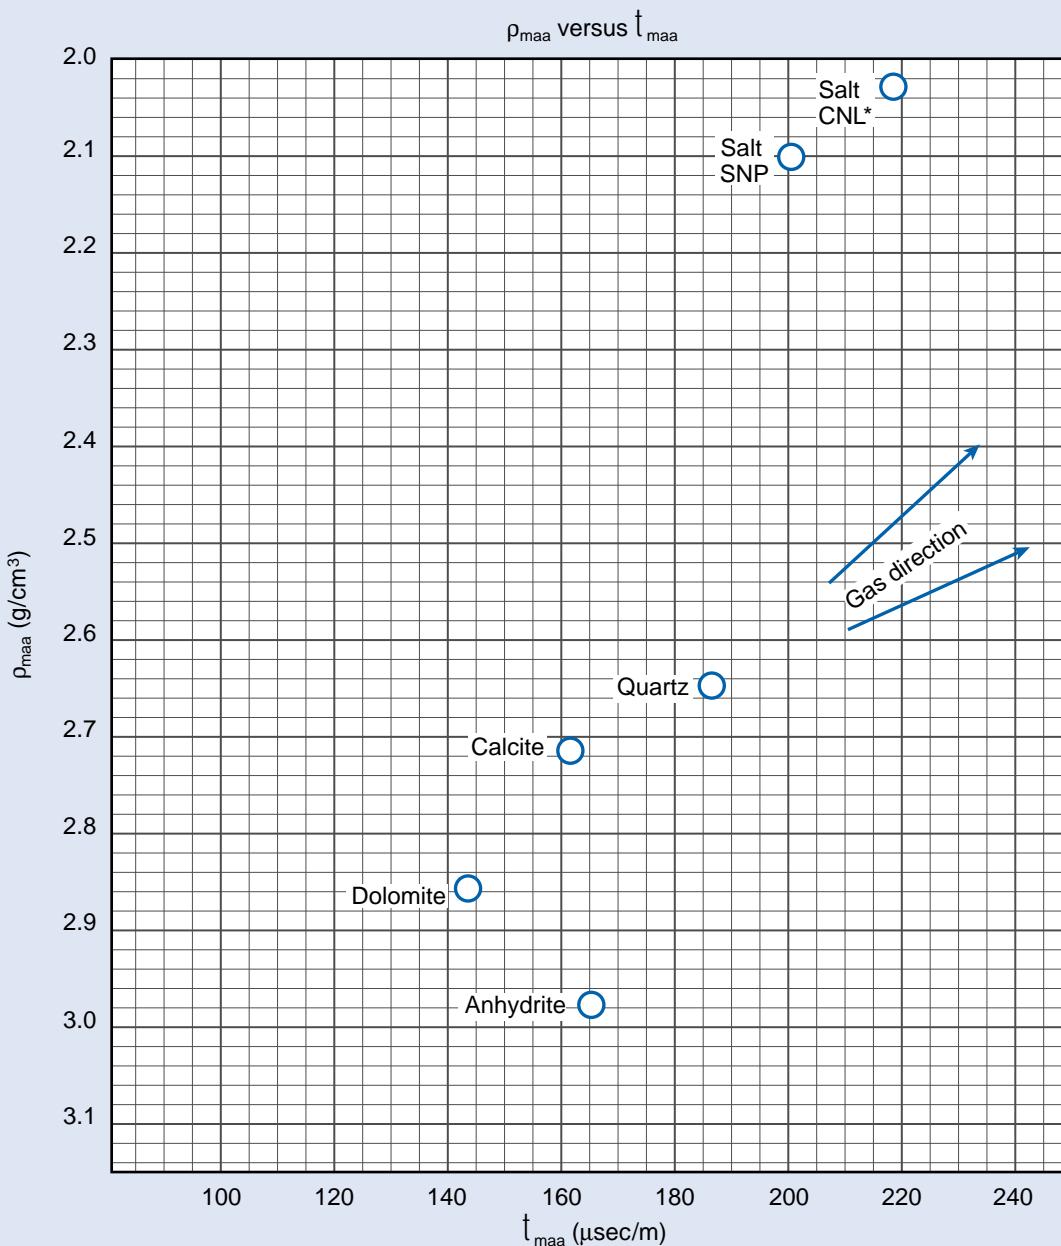

$$t_{\text{maa}} = 43.5 \mu\text{sec}/\text{ft}$$

$$\rho_{\text{maa}} = 2.85 \text{ g}/\text{cm}^3$$

From the MID plot, Level 1 is identified as salt and Level 2 as dolomite.

## Mineral Identification from Litho-Density\* Log and NGS\* Natural Gamma Ray Spectrometry Log

Chart CP-18 provides clay mineralogy information using NGS Natural Gamma Ray Spectrometry and Litho-Density measurements. Because the porosity and the composition of many clay minerals may vary, the minerals plot on these crossplots not as unique points but as general areas.

After environmental correction, the appropriate parameters are plotted to provide qualitative information about the mineralogy.

*Example:*  $\text{Th}_{\text{NGS}\text{cor}} = 10.6 \text{ ppm}$

$\text{U}_{\text{NGS}\text{cor}} = 4.5 \text{ ppm}$

$\text{K}_{\text{NGS}\text{cor}} = 3.9\%$

$P_e = 3.2$

giving  $\text{Th}/\text{K} = 10.6/3.9 = 2.7$

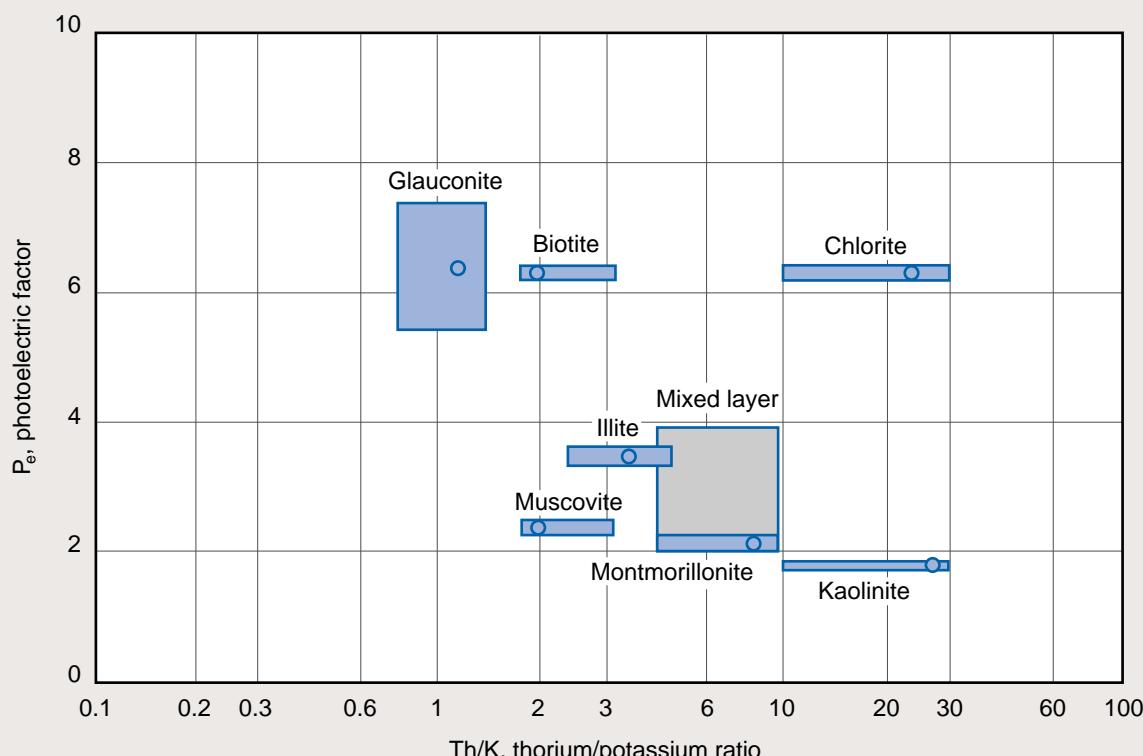

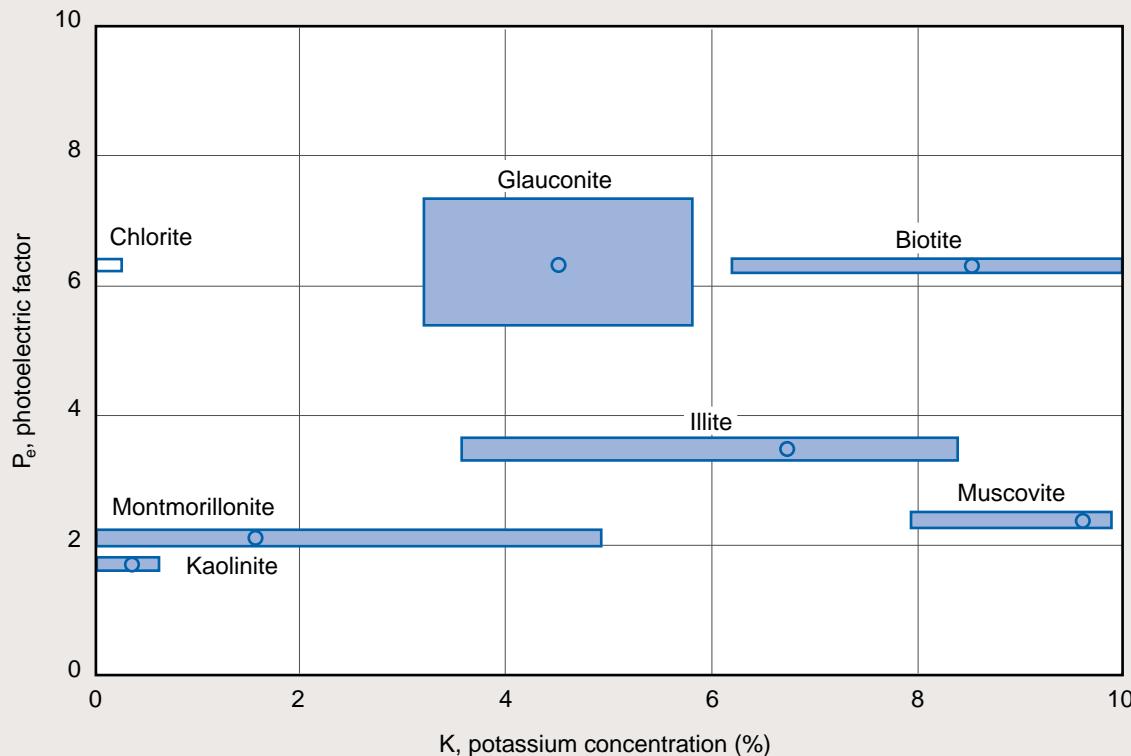

Plotting these parameters on Chart CP-18 suggests that the clay mineral is illite.

\*Mark of Schlumberger

# Mineral Identification from Litho-Density\* Log and NGS\* Natural Gamma Ray Spectrometry Log

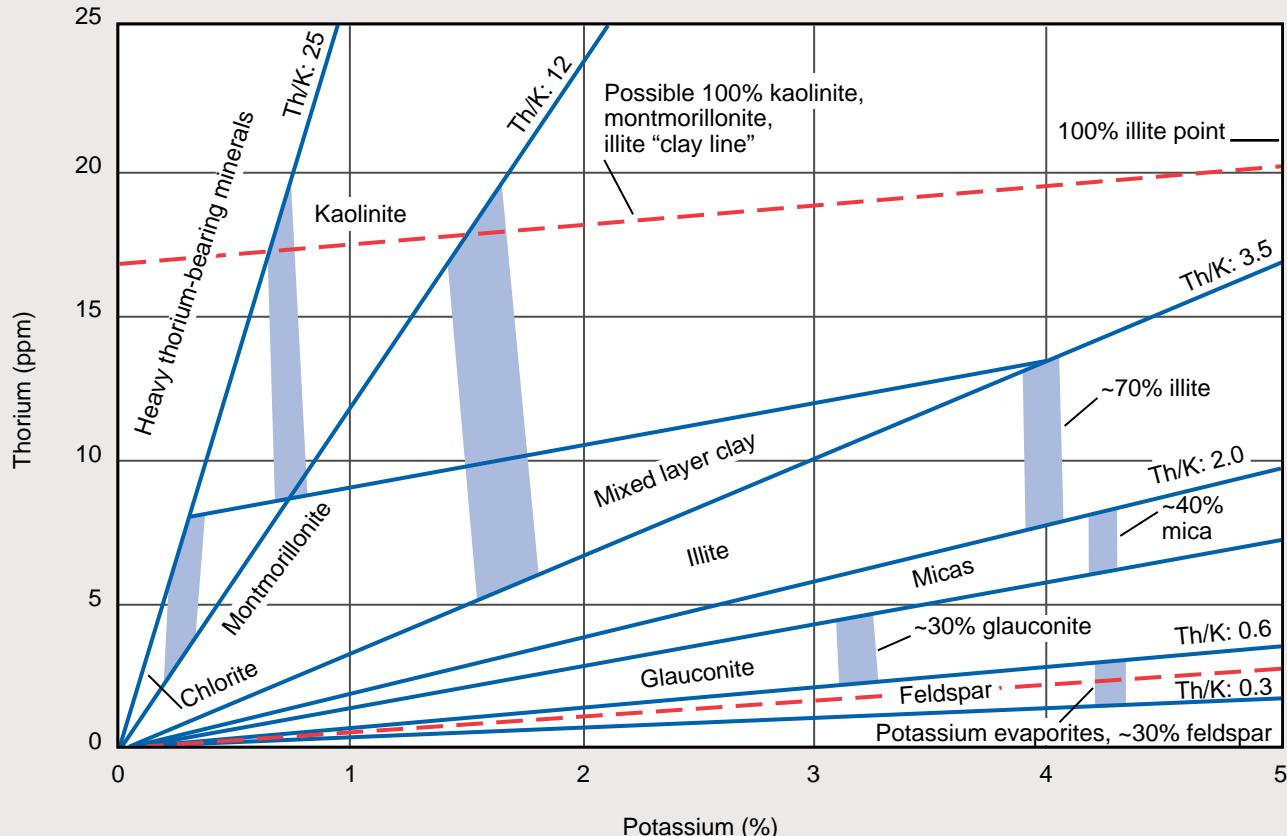

CP-18

CP

# Mineral Identification from NGS\* Natural Gamma Ray Spectrometry Log

CP-19

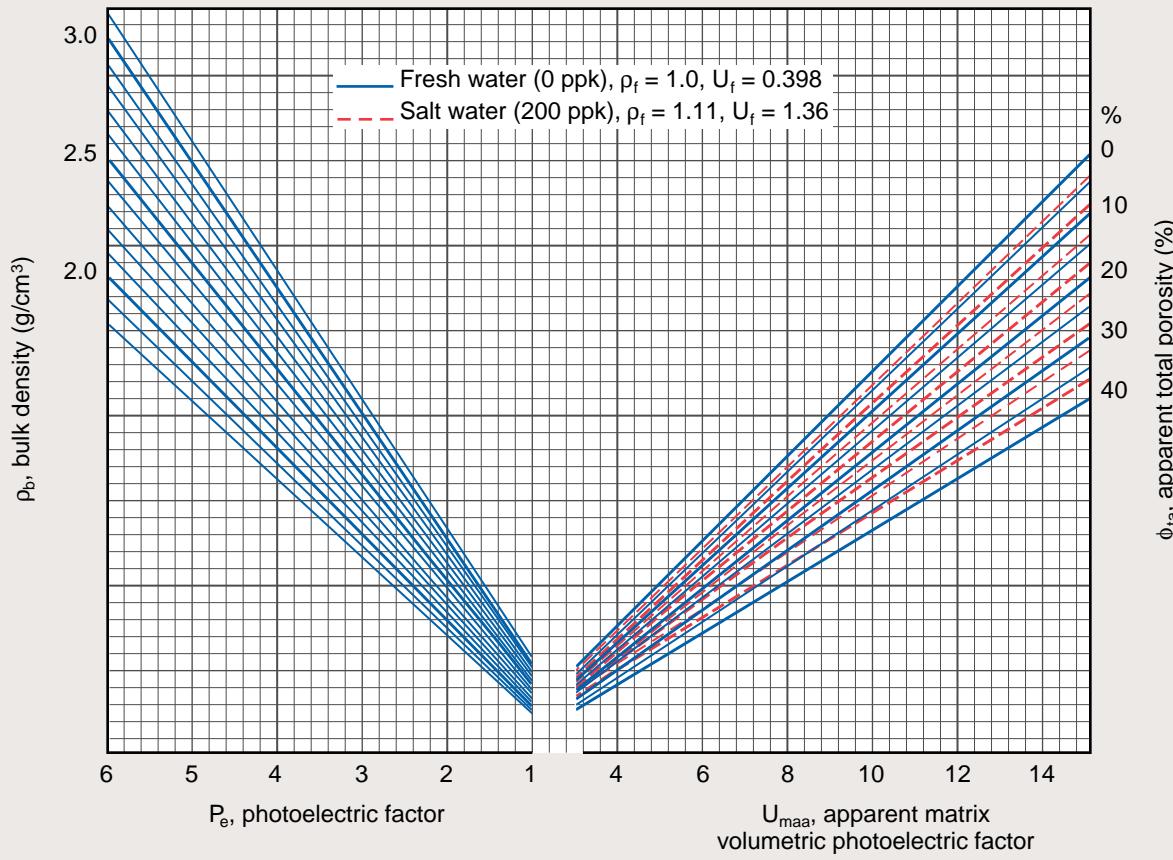

Radioactive minerals often occur in relatively small concentrations in sedimentary rocks. Even shales typically contain only 30 to 70% radioactive clay minerals.

Unless there is a complex mixture of radioactive minerals in the formation, Chart CP-19 can be used to identify the more common ones. The ratio of thorium to uranium activity—the

thorium/potassium ratio, Th/K—does not vary with mineral concentration. A sandstone reservoir with varying amounts of shaliness, with illite as the principal clay mineral, usually plots in the illite segment of the chart, with Th/K between 2.0 and 2.5. Less shaly parts of the reservoir plot closer to the origin, and more shaly parts plot closer to the 70% illite area.

## Determination of Apparent Matrix Volumetric Photoelectric Factor

CP-20

© Schlumberger

CP

## Lithology Identification Plot

Plot CP-21 identifies rock mineralogy through a comparison of apparent matrix grain density and apparent volumetric photoelectric factor.

To use, apparent matrix grain density,  $\rho_{maa}$ , and apparent volumetric photoelectric factor,  $U_{maa}$ , are entered in ordinate and abscissa, respectively, on Plot CP-21. Rock mineralogy is identified by the proximity of the plotted data point to the labeled points on the plot.

To determine apparent matrix grain density, an apparent total porosity must first be determined (using, for example, a neutron-density crossplot). Then, Chart CP-14 may be used with bulk density,  $\rho_b$ , to define the apparent matrix grain density,  $\rho_{maa}$ .

To find the apparent matrix volumetric photoelectric factor,  $U_{maa}$ , enter Nomograph CP-20 with the photoelectric factor,  $P_e$ ;

go vertically to the bulk density,  $\rho_b$ ; then, go horizontally across to the total porosity,  $\phi_t$ ; and finally, go vertically downward to define the matrix volumetric photoelectric factor,  $U_{maa}$ .

*Example:*  $P_e = 3.65$

$$\rho_b = 2.52 \text{ g/cm}^3 (\rho_f = 1.0 \text{ g/cm}^3)$$

$$\phi_{ta} = 16\%$$

giving  $\rho_{maa} = 2.81 \text{ g/cm}^3$  (from Chart CP-14)

and  $U_{maa} = 10.9$

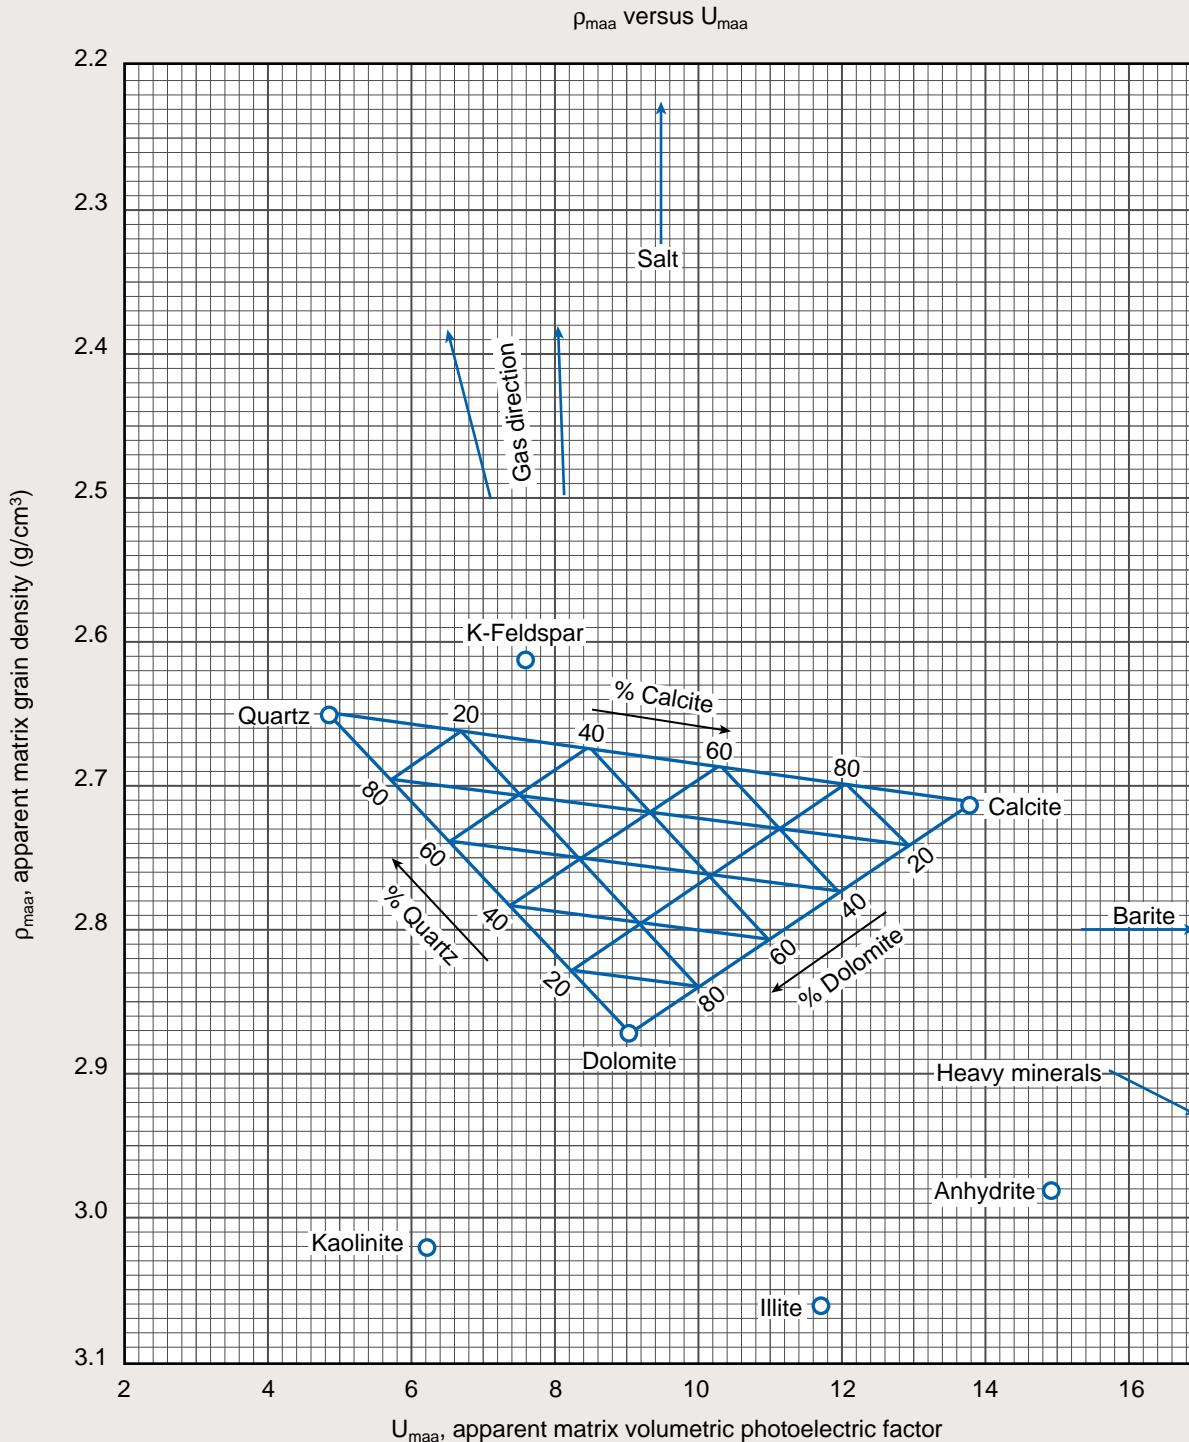

Plotting these values indicates the level to be a mixture of approximately 60% dolomite and 40% limestone.

For more information see Reference 27.

## Lithology Identification Plot

CP-21

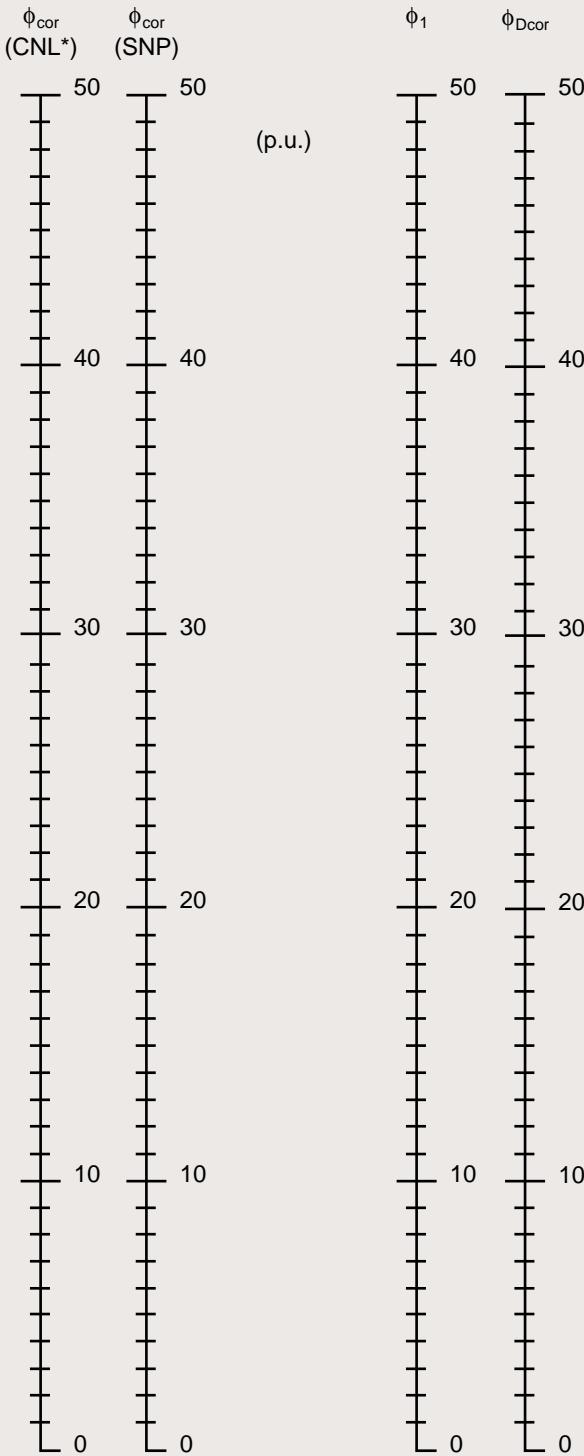

CP

# Porosity Estimation in Hydrocarbon-Bearing Formations

From neutron, density and  $R_{xo}$  logs

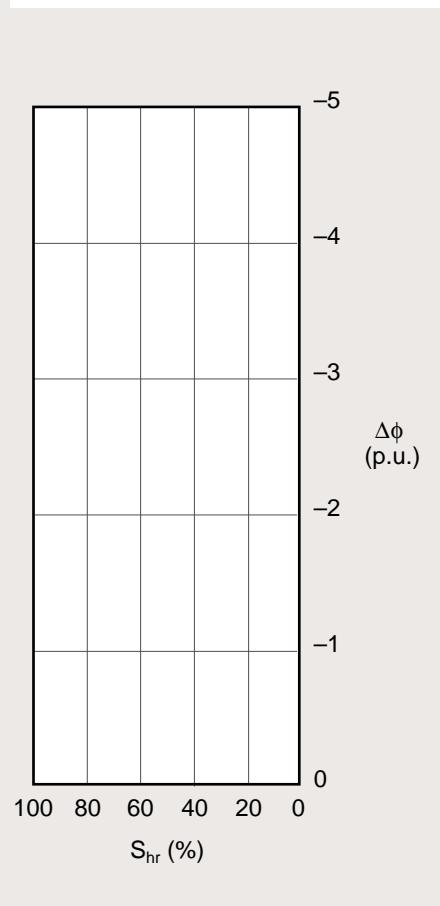

CP-9

This nomograph estimates porosity in hydrocarbon-bearing formations using neutron, density and  $R_{xo}$  logs. The neutron and density logs must be corrected for environmental effects and lithology prior to entry into the nomograph. The chart includes an approximate correction for excavation effect, but if  $\rho_h < 0.25$  (gases), the chart may not be accurate in some extreme cases: very high values of porosity ( $> 35$  p.u.) coupled with medium to high values of  $S_{hr}$ , and for  $S_{hr} \approx 100\%$  for medium to high values of porosity.

To use, connect the apparent neutron porosity point on the appropriate neutron stem with the apparent density porosity on the density stem with a straight line. From the intersection of this line with the porosity,  $\phi_1$ , stem, draw a line to the origin of the  $S_{hr}$  versus  $\Delta\phi$  chart. Entering this chart with the hydrocarbon saturation,  $S_{hr}$ , ( $S_{hr} = 1 - S_{xo}$ ) defines a porosity correction factor  $\Delta\phi$ . This correction factor algebraically added to porosity,  $\phi_1$ , gives the true porosity.

**Example:**  $\phi_{CNLcor} = 12$  p.u. giving  $\phi_1 = 32.2$  p.u.  
 $\phi_{Dcor} = 38$  p.u. and  $\Delta\phi = -1.6$  p.u.  
 $S_{hr} = 50\%$  Therefore,  $\phi = 32.2 - 1.6 = 30.6$  p.u.

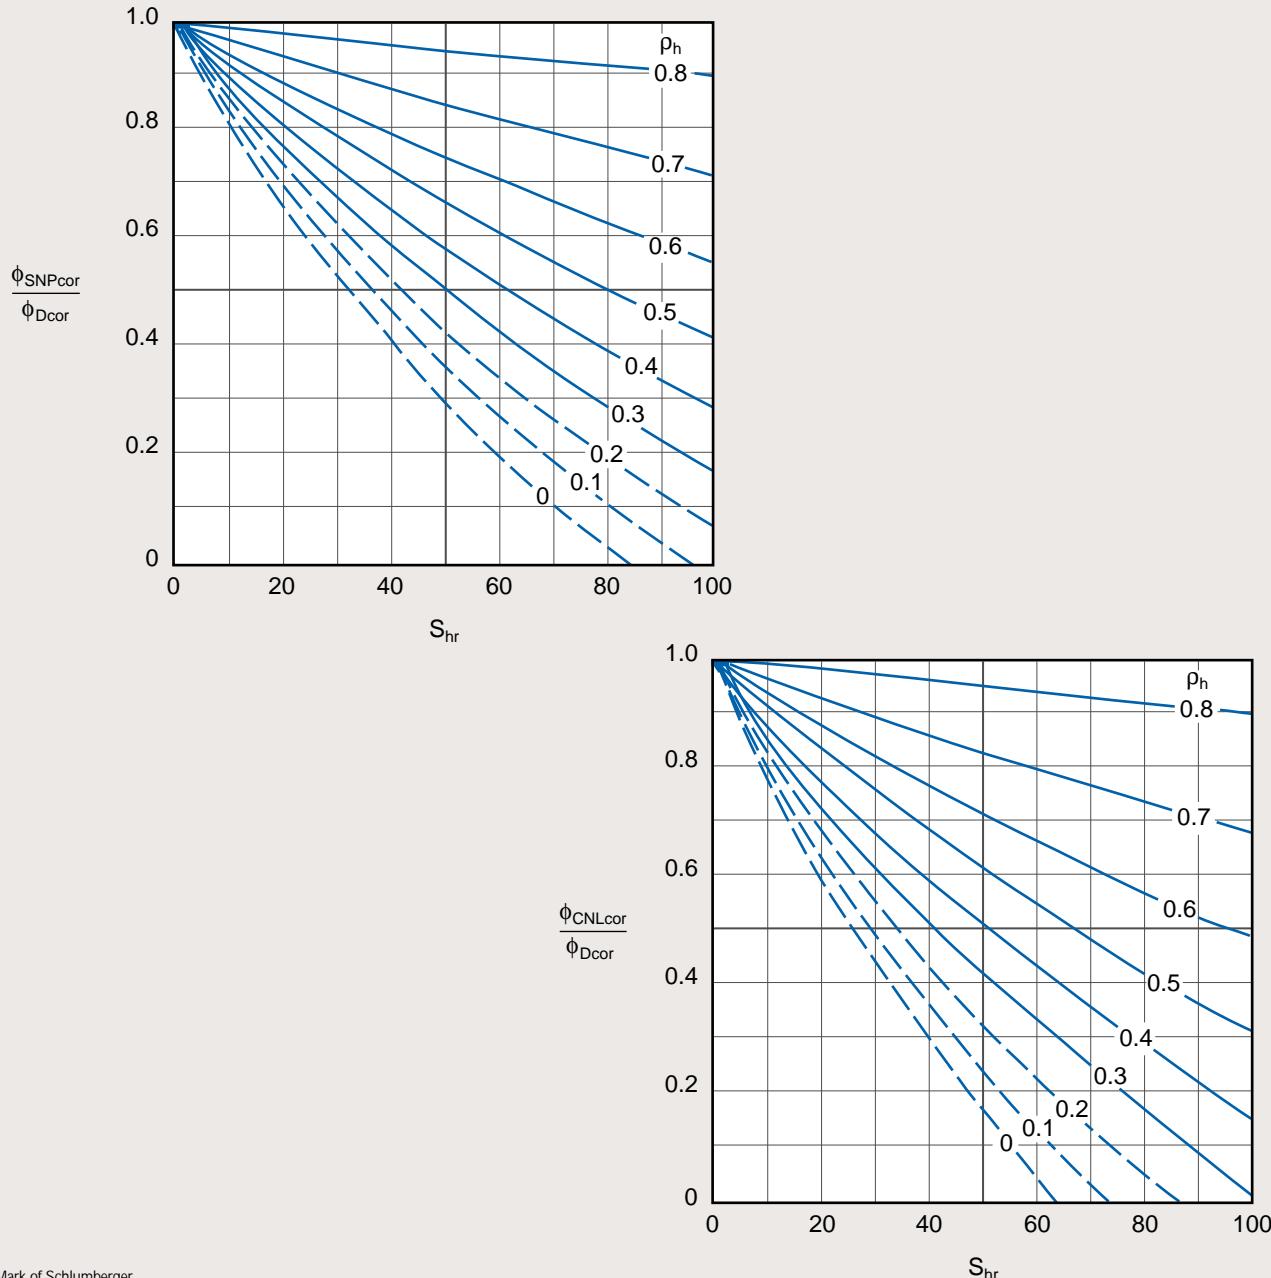

## Estimation of Hydrocarbon Density

From neutron and density logs

CP-10

CP

\*Mark of Schlumberger  
© Schlumberger

These charts estimate the density of the saturating hydrocarbon from a comparison of neutron and density measurements, and the hydrocarbon saturation in the portion of the rock investigated by the neutron and density logs (invaded or flushed zone). The neutron log (either CNL\* or SNP log) and the density log must be corrected for environmental effect and lithology before entry into the charts.

To use, enter the appropriate chart with the ratio of neutron porosity to density porosity, and the hydrocarbon saturation. The intersection defines the hydrocarbon density in g/cm<sup>3</sup>.

*Example:*  $\phi_{CNLcor} = 15$  p.u.

$\phi_{Dcor} = 25$  p.u.

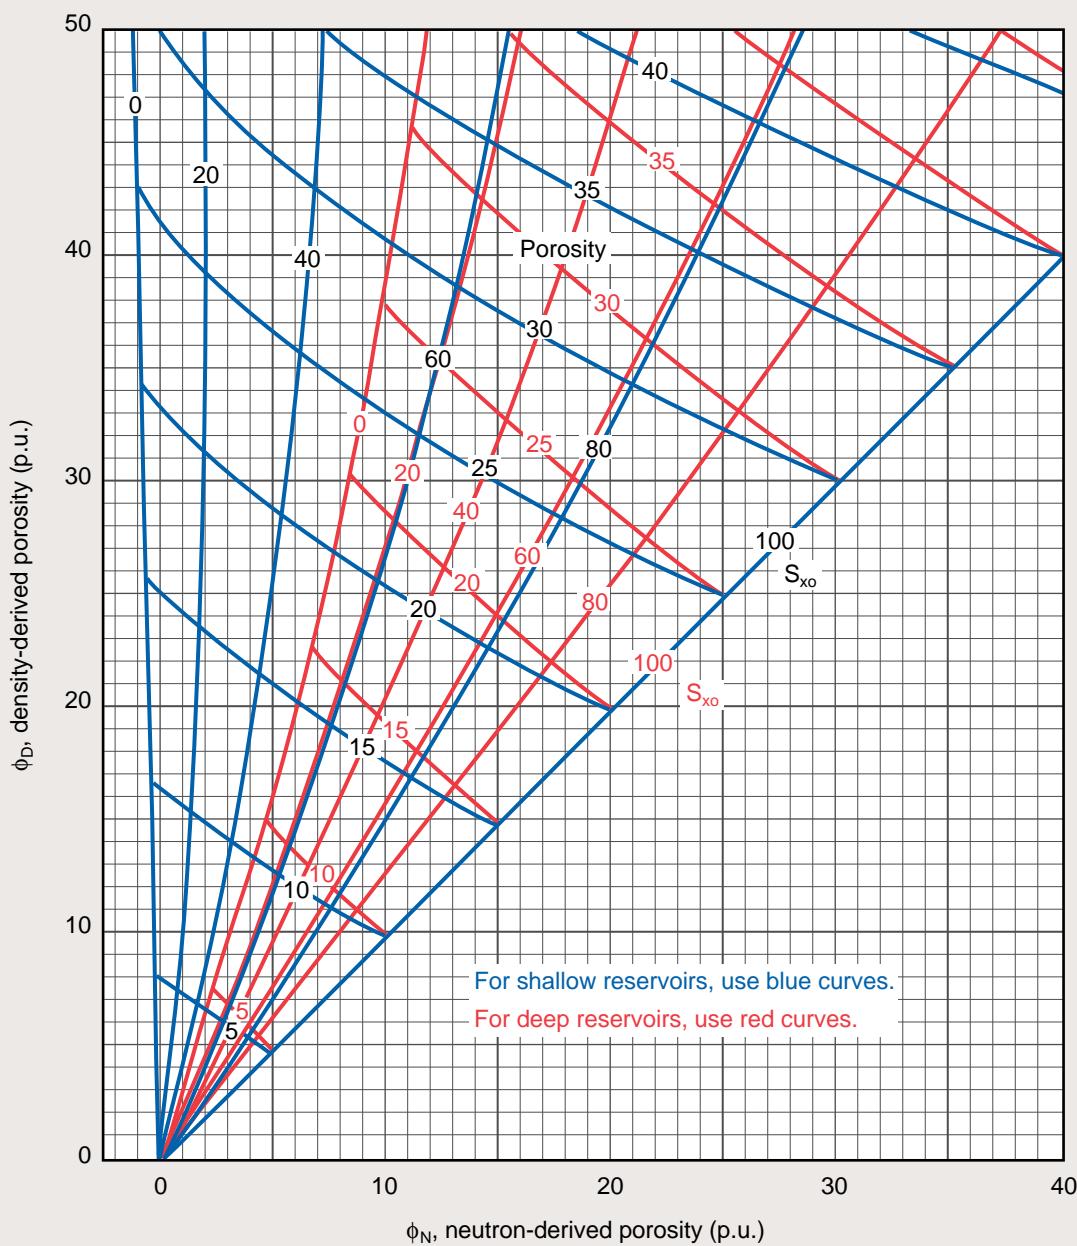

and  $S_{hr} = 30\%$

Therefore,  $\rho_h = 0.28$  g/cm<sup>3</sup>

Charts CP-9 and CP-10 have not been updated for CNL logs run after 1986 or labeled TNPH; approximations may therefore be greater with more recent logs. For approximate results with APLC porosity (from IPL\* logs), use Charts CP-9 and CP-10 for SNP logs.

## Gas-Bearing Formations— Porosity from Density and Neutron Logs

CP-5

© Schlumberger

Based on reservoir depth and conditions, enter the appropriate chart with matrix-corrected porosity values. Average water saturation in the flushed zone, S<sub>xo</sub>, and porosity are derived. This chart assumes fresh water and gas of composition C<sub>1.1</sub>H<sub>4.2</sub>, and it includes correction of the neutron log for “excavation effect.”

For more information see Reference 6.

The conditions represented by the curves are listed in the table below.

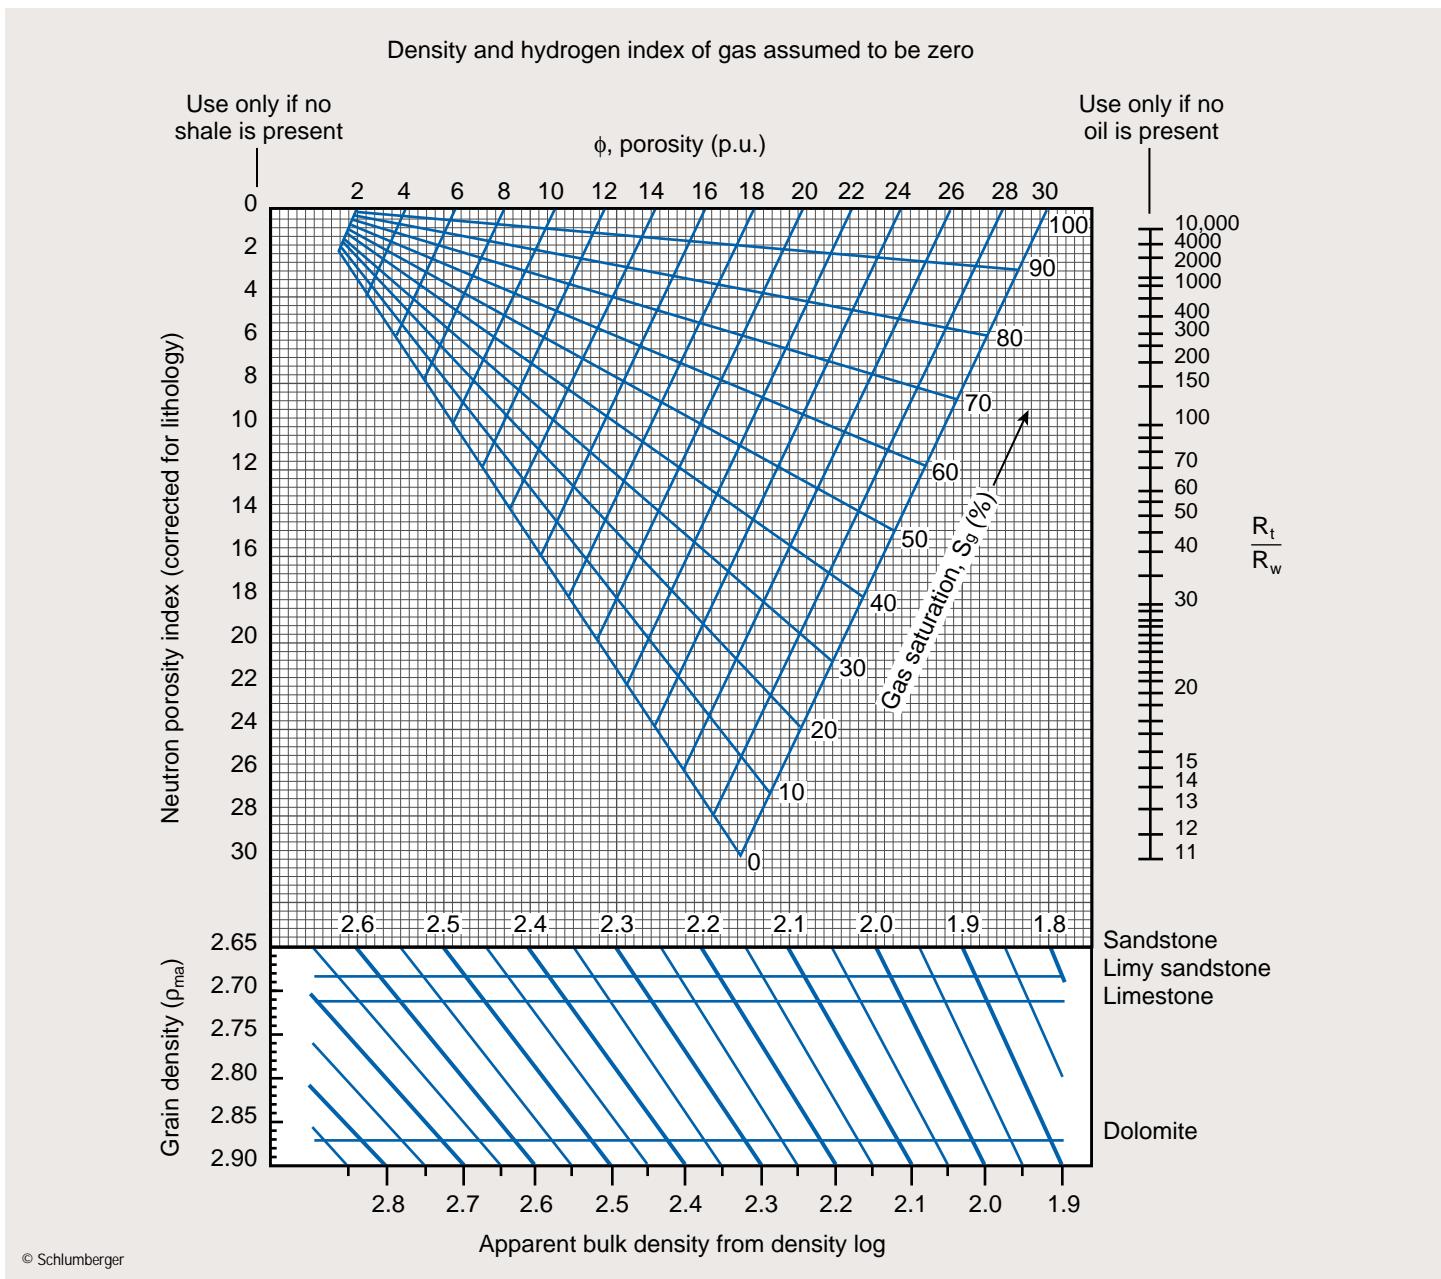

*Example:* φ<sub>D</sub> reads 25%, and φ<sub>N</sub> reads 10% in a low-pressure, shallow (4000-ft) reservoir.

Therefore, φ = 20%, and S<sub>xo</sub> = 62%.

Depth	Pressure	Temperature	P <sub>w</sub>	I <sub>Hw</sub>	P <sub>g</sub>	I <sub>Hg</sub>
Shallow reservoirs (blue)	~2000 psi [~14,000 kPa]	~120°F [~50°C]	1.00	1.00	0	0
Deep reservoirs (red)	~7000 psi [~48,000 kPa]	~240°F [~120°C]	1.00	1.00	0.25	0.54

## Porosity and Gas Saturation in Empty Holes

Sw-11

Porosity,  $\phi$ , and gas saturation,  $S_g$ , can be determined from this chart using either the combination of density-neutron measurements or density-resistivity measurements. To use, enter the chart vertically from the intersection of the apparent bulk density and appropriate grain density values. The intersection of this line with either the neutron porosity (corrected for lithology) or the  $R_t/R_w$  ratio (true resistivity/connate water resistivity) defines actual porosity and gas saturation.

With all three measurements (density, neutron and resistivity), oil saturation can be determined as well. To do so, enter the chart with apparent bulk density and neutron porosity (as described above) to define porosity and gas saturation. Moving along the defined porosity to its intersection with the  $R_t/R_w$  ratio gives the

total hydrocarbon saturation. For more information see Reference 14.

**Example:** In a limy sandstone ( $\rho_{ma} = 2.68$ )

$$\rho_b = 2.44 \text{ g/cm}^3$$

$$\phi_N = 9 \text{ p.u.}$$

$$R_t = 74$$

$$R_w = 0.1$$

$$\text{Therefore, } R_t/R_w = 740$$

$$\text{and } \phi = 12 \text{ p.u.}$$

$$S_g = 25\%$$

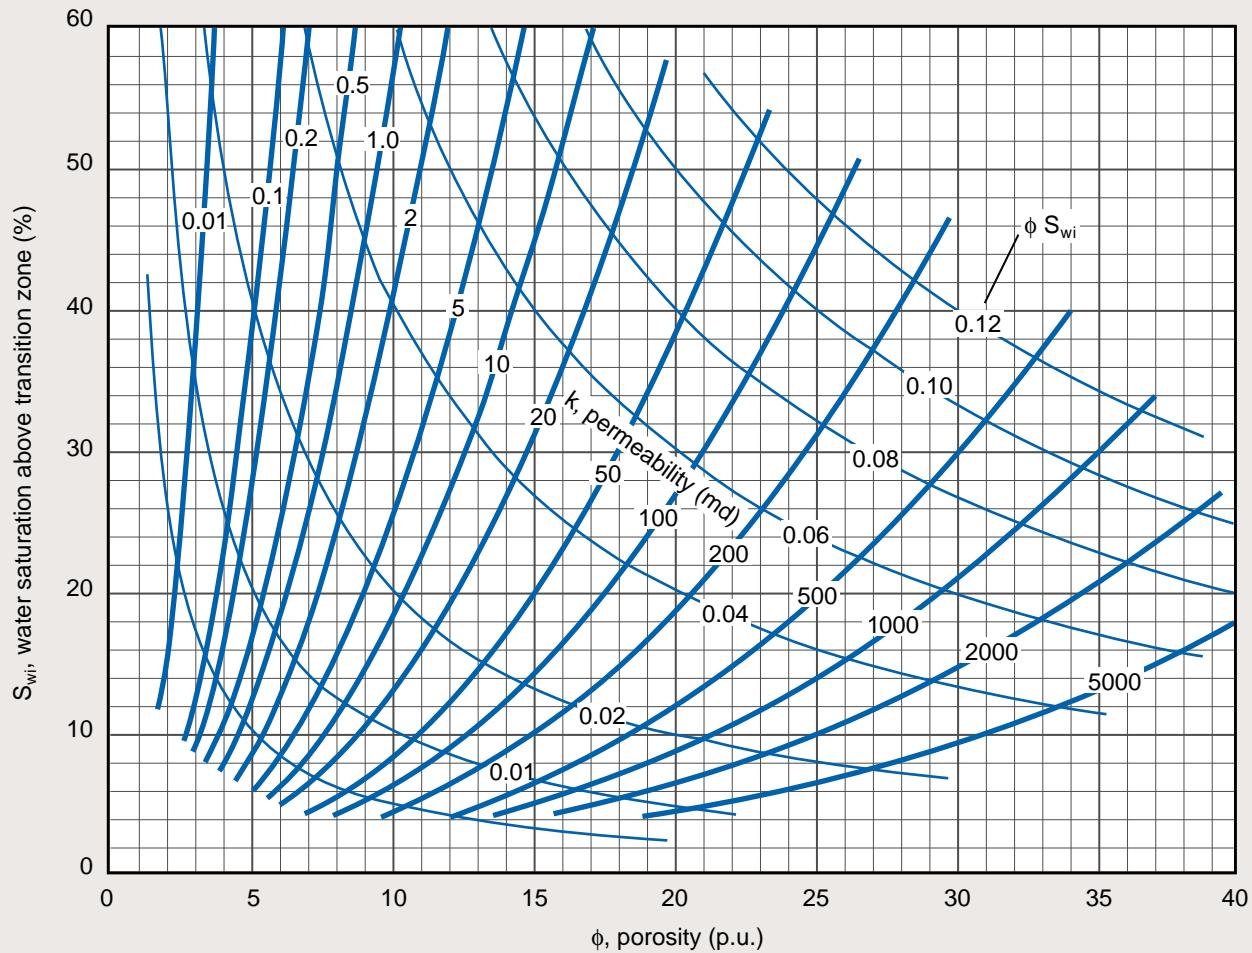

$$S_h = 70\% \text{ (total hydrocarbon saturation)}$$

$$S_o = 70 - 25 = 45\%$$

$$S_w = 100 - 70 = 30\%$$

## Permeability from Porosity and Water Saturation

K-3

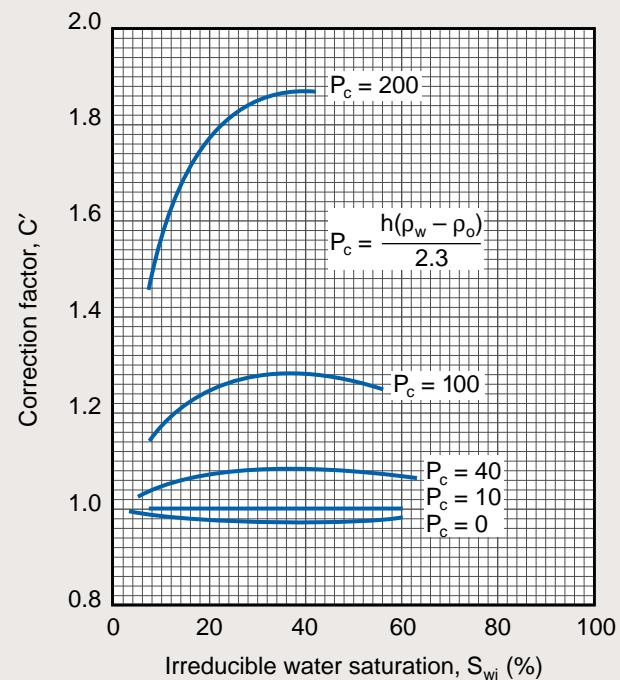

© Schlumberger

Charts K-3 and K-4 provide an estimate of permeability for sands, shaly sands or other hydrocarbon-saturated intergranular rocks at irreducible water saturation,  $S_{wi}$ . Both charts are based on empirical observations and are similar in form to a general expression proposed by Wyllie and Rose (1950):  $k^{1/2} = (c\phi/S_{wi}) + C'$ .

Chart K-3 presents the results of one study; the relationship observed was  $k^{1/2} = 100 \phi^{2.25}/S_{wi}$ . Chart K-4 presents the results of another study; the relationship observed was  $k^{1/2} = 70 \phi_e^2[(1 - S_{wi})/S_{wi}]$ . Both charts are valid only for zones at irreducible water saturation.

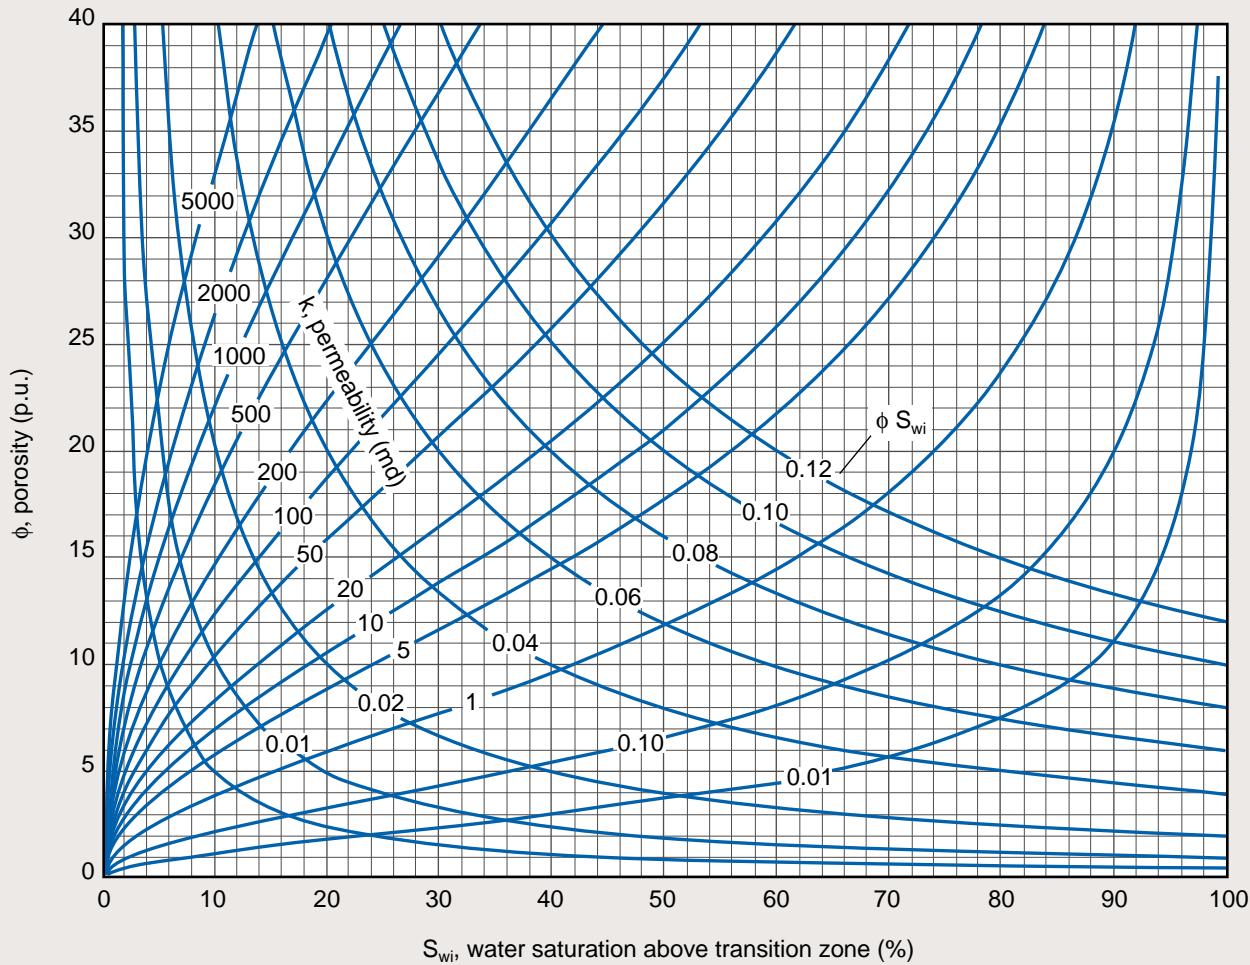

To use, porosity,  $\phi$ , and irreducible water saturation,  $S_{wi}$ , are entered. Their intersection defines the intrinsic (absolute) rock

*Continued on next page*

## Permeability from Porosity and Water Saturation

K-4

© Schlumberger

permeability. A medium-gravity oil is assumed. If the saturating hydrocarbon is other than a medium-gravity oil, a correction factor based upon fluid densities,  $\rho_w$  and  $\rho_h$ , and elevation above the free water level,  $h$ , should be applied to the irreducible water saturation prior to entry into Chart K-3 or K-4. The inset figure provides this correction factor.

*Example:*  $\phi = 23\%$

$S_{wi} = 30\%$

Gas saturation ( $\rho_h = 0.3 \text{ g/cm}^3$ ,  $\rho_w = 1.1 \text{ g/cm}^3$ )

$h$  (elevation above water)  $\approx 120 \text{ ft}$

$$\text{Therefore, } P_c = \frac{h(\rho_w - \rho_h)}{2.3} = \frac{120(1.1 - 0.3)}{2.3} = 42$$

$C'$  correction factor = 1.08

Corrected  $S'_{wi}$  for chart entry = 1.08 (30) = 32.4%

giving  $k \approx 130 \text{ md}$  (Chart K-3)

or  $k \approx 65 \text{ md}$  (Chart K-4)

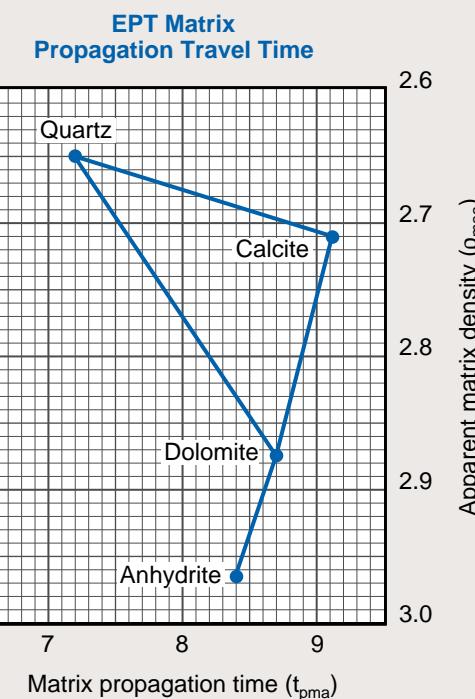

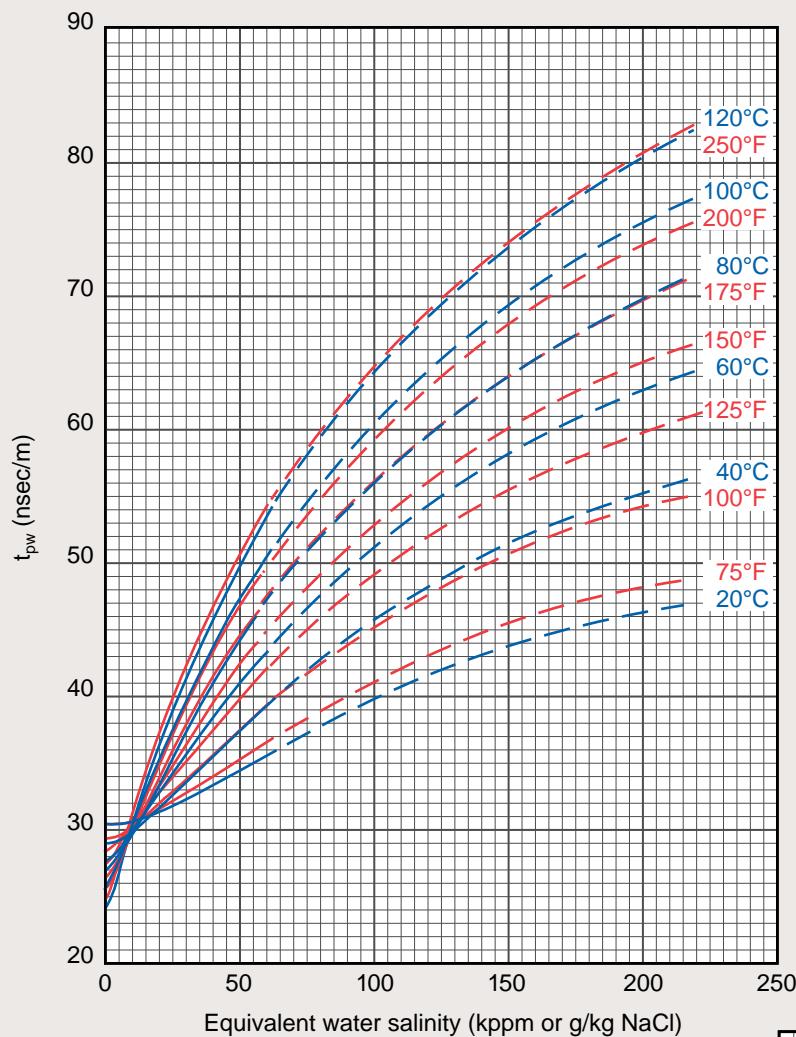

These charts can also be used to recognize zones at irreducible water saturation. Over intervals at irreducible water saturation, the product of porosity and water saturation is generally a constant; thus, data points from levels at irreducible water saturation should plot in a fairly coherent pattern on or parallel to one of the  $\phi \cdot S_w$  lines.

For more information see References 16, 17, 21 and 22.

K

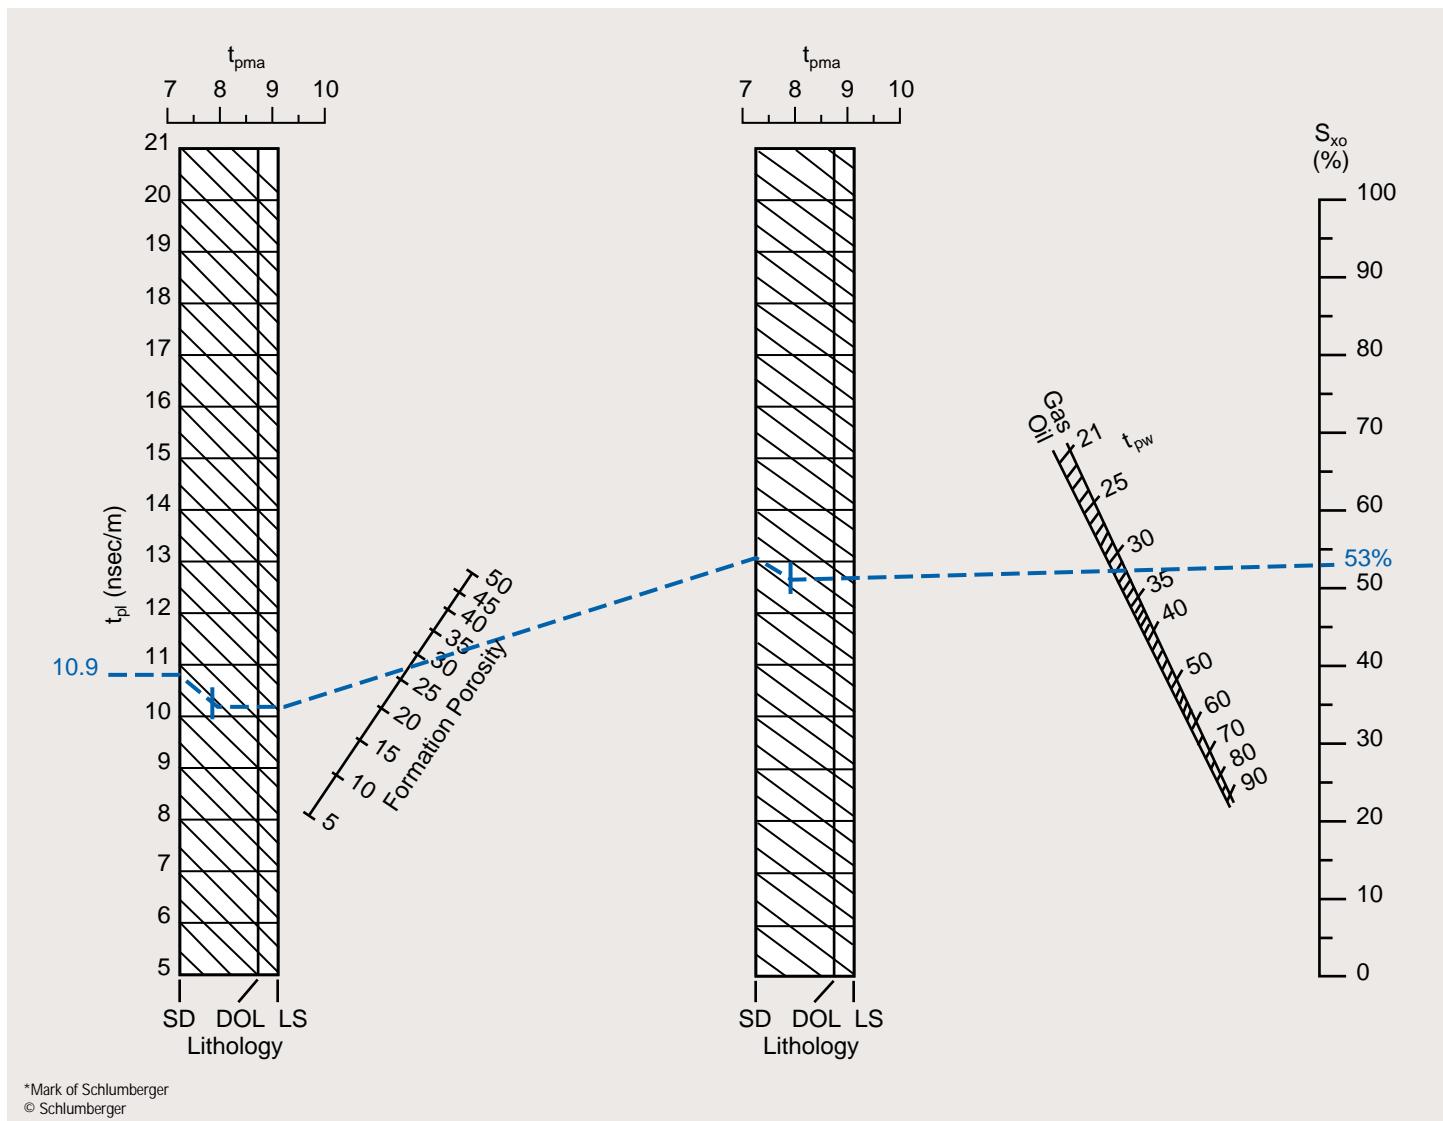

## EPT\* Propagation Time for NaCl Solutions

EPTcor-1

## Flushed Zone Saturation from EPT\* Propagation Time

Sxo-1

\*Mark of Schlumberger  
© Schlumberger

This nomograph defines water saturation in the rock immediately adjacent to the borehole,  $S_{xo}$ , using the EPT\* propagation time measurement,  $t_{pl}$ . It requires knowledge of reservoir lithology or matrix propagation time ( $t_{pma}$ ), the saturating water propagation time ( $t_{pw}$ ), porosity and the expected hydrocarbon type.

Water propagation time,  $t_{pw}$ , can be estimated from the appropriate chart on the previous page as a function of equivalent water salinity and formation temperature. Rock lithology must be known from other sources. For rock mixtures the chart on the previous page can be used to estimate matrix propagation time,  $t_{pma}$ , when the apparent matrix density,  $\rho_{maa}$ , is known. The estimation requires some knowledge of the expected mineral mixture.

To use the nomograph,  $t_{pl}$  is entered on the left grid; follow the diagonal lines to the appropriate  $t_{pma}$  value, then horizontal to the right edge of the grid. From this point, a straight line is extended through the porosity to the center grid; again follow

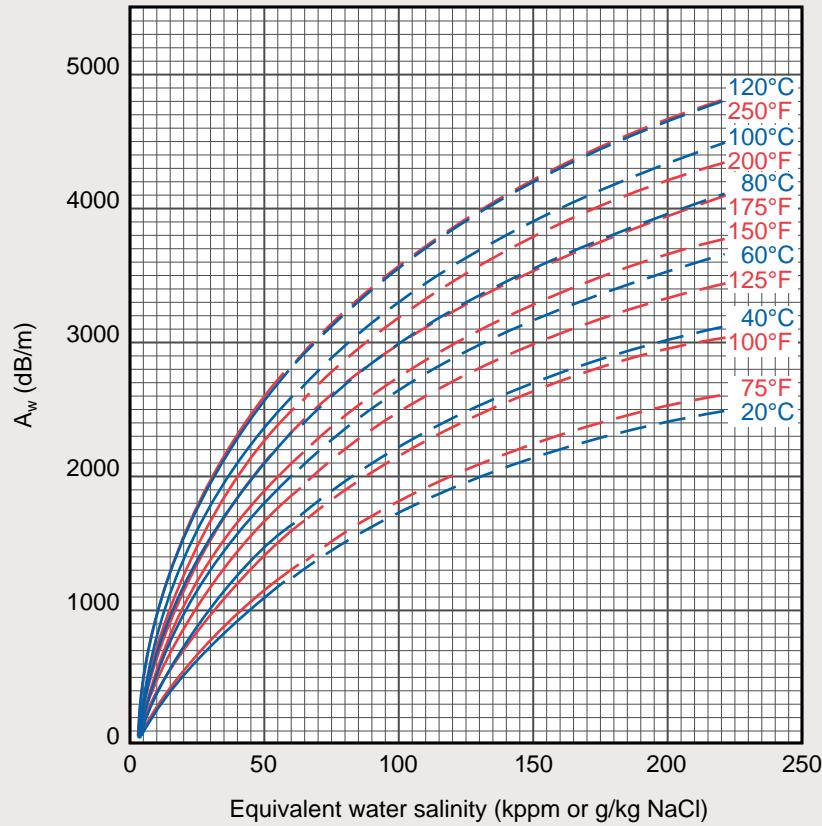

the diagonal lines to the appropriate  $t_{pma}$  value, then horizontal to the right edge of the grid. From this point, extend a straight line through the intersection of  $t_{pw}$  and hydrocarbon type point to the  $S_{xo}$  axis.

For more information see Reference 25.

**Example:**  $t_{pl} = 10.9$  nsec/m  
 $\phi = 28\%$   
 Limy sandstone with  $\rho_{maa} = 2.67$  g/cm<sup>3</sup>  
 Water salinity  $\approx 20$  kppm  
 $BHT = 150^{\circ}\text{F}$   
 Gas saturation expected  
 giving  $t_{pma} = 7.8$  nsec/m (sand-lime mixture)  
 $t_{pw} = 32$  nsec/m  
 and  $S_{xo} = 53\%$

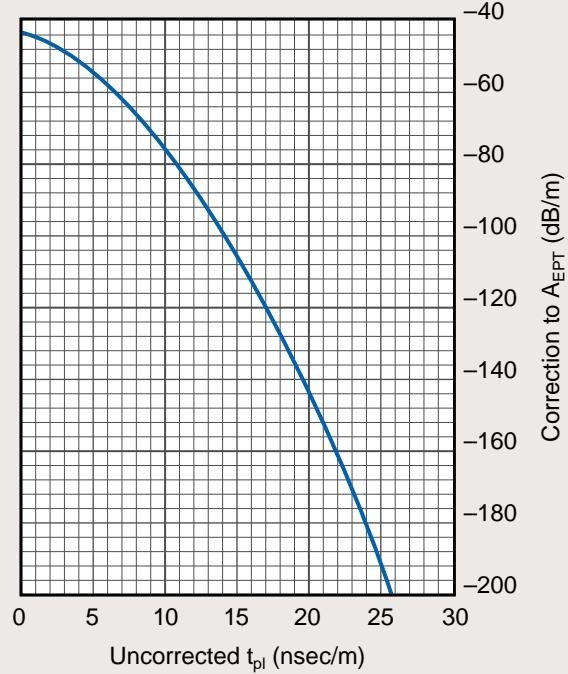

## EPT\* Attenuation for NaCl Solutions

EPTcor-2

EPT

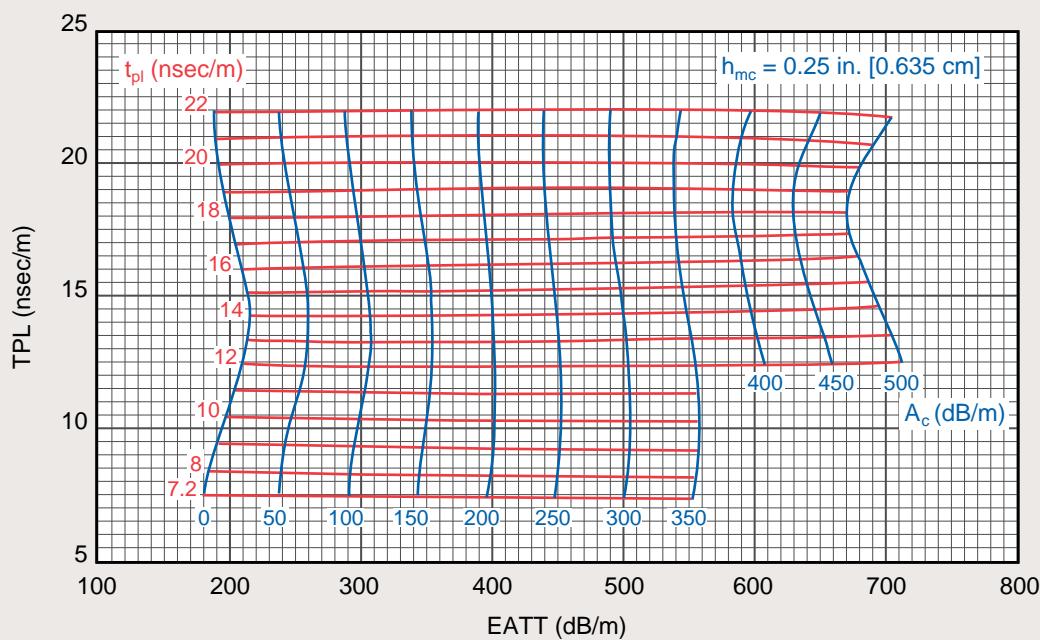

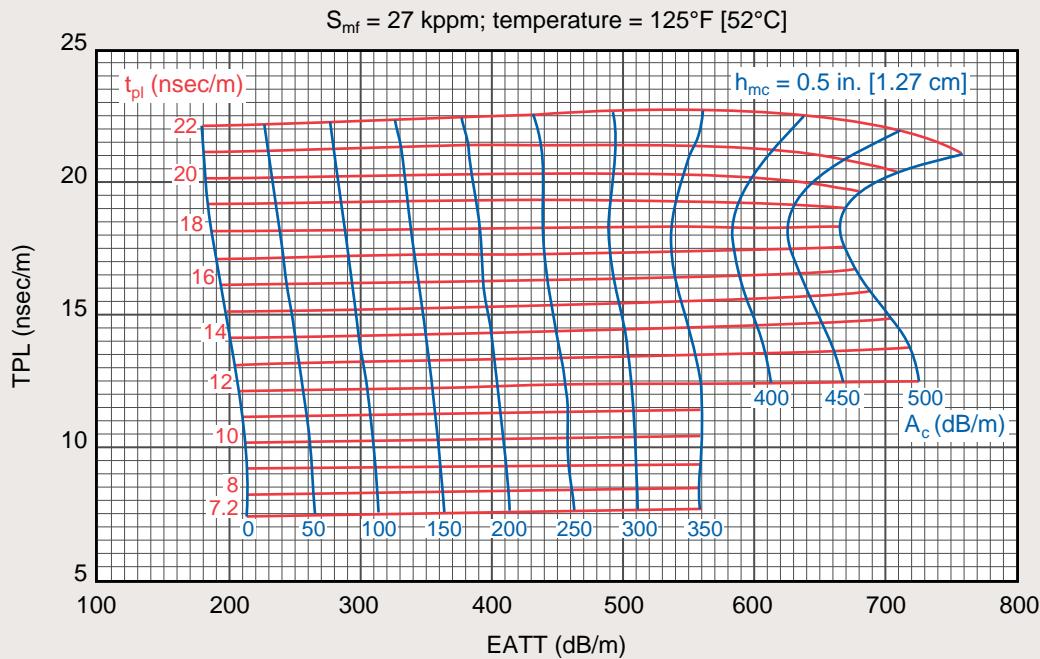

## EPT-D Spreading Loss

## EPT-G Mudcake Correction Charts for Water-Base Mud

EMD-L (endfire array)

EPTcor-3a

© Schlumberger

The EPT-G mudcake charts are used to correct the raw log travel times (TPL) and log attenuations (EATT) for the effects of mudcakes on the tool responses. (Caution: Do not use TPPW and EAPW as inputs into these charts.) The charts also correct the log attenuations for spreading losses so that no further corrections are required. The chart outputs are the true formation travel

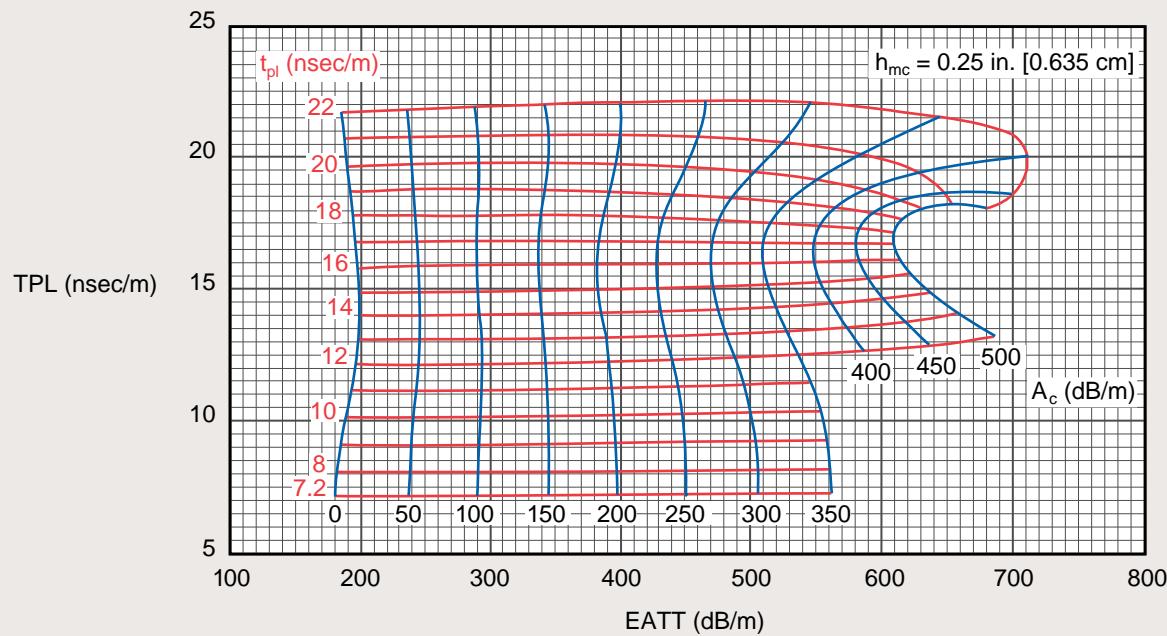

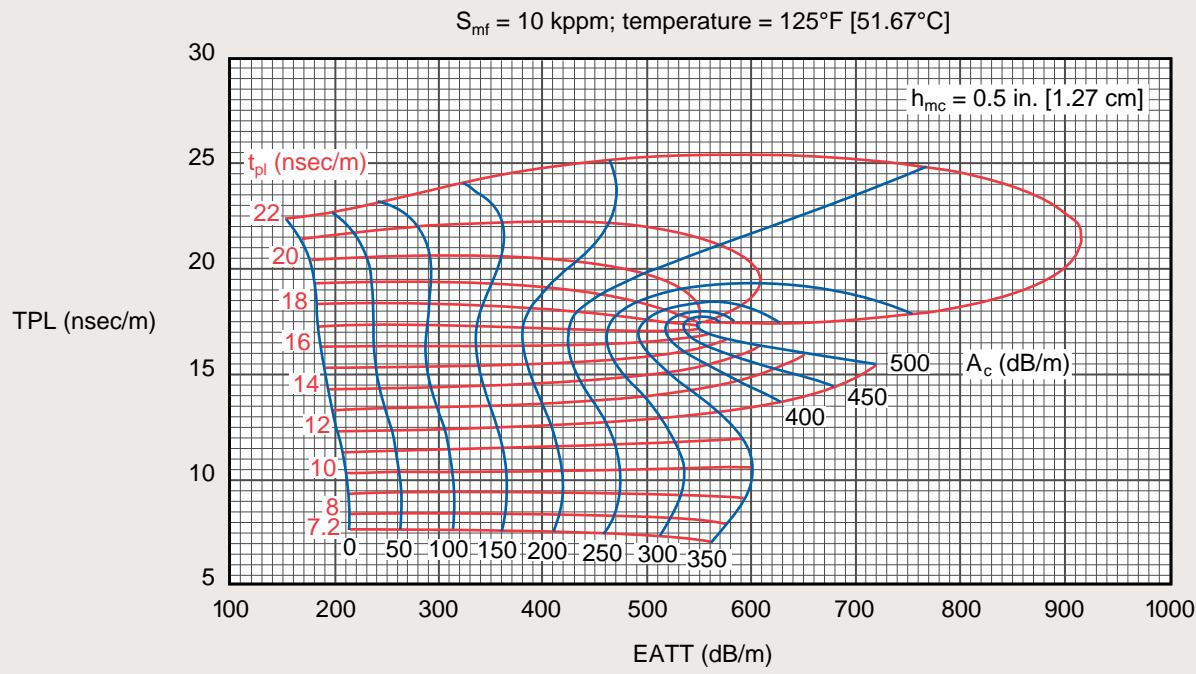

times ( $t_{pl}$ ) and attenuations ( $A_c$ ), which are used to evaluate the flushed zone. For example, these latter quantities are the inputs to petrophysical models such as the Complex Refractive Index Method (CRIM).

*Continued on next page*

## EPT-G Mudcake Correction Charts for Water-Base Mud

EMD-L (endfire array)

EPTcor-3b

© Schlumberger

The true travel times,  $t_{pl}$ , can also be used in nomograms such as Sxo-1 to determine flushed-zone water saturations,  $S_{xo}$ . The charts displayed here are for water-base muds and are applicable, as indicated, for the EMD-L and BMD-S arrays. The charts are valid for the indicated mudcake thicknesses ( $h_{mc}$ ), borehole

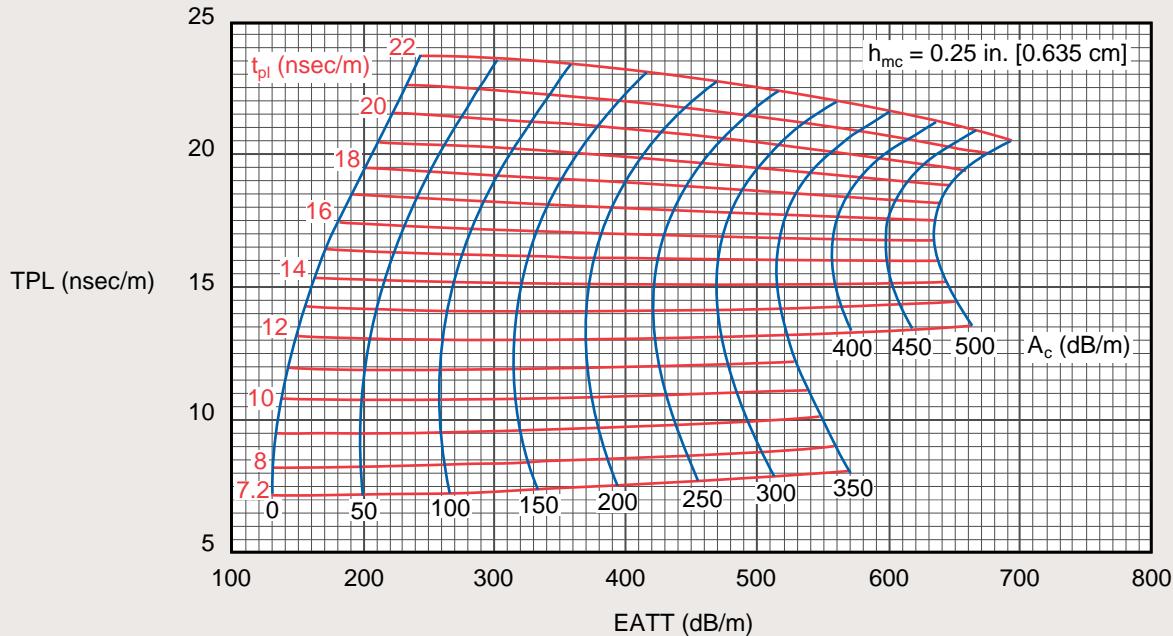

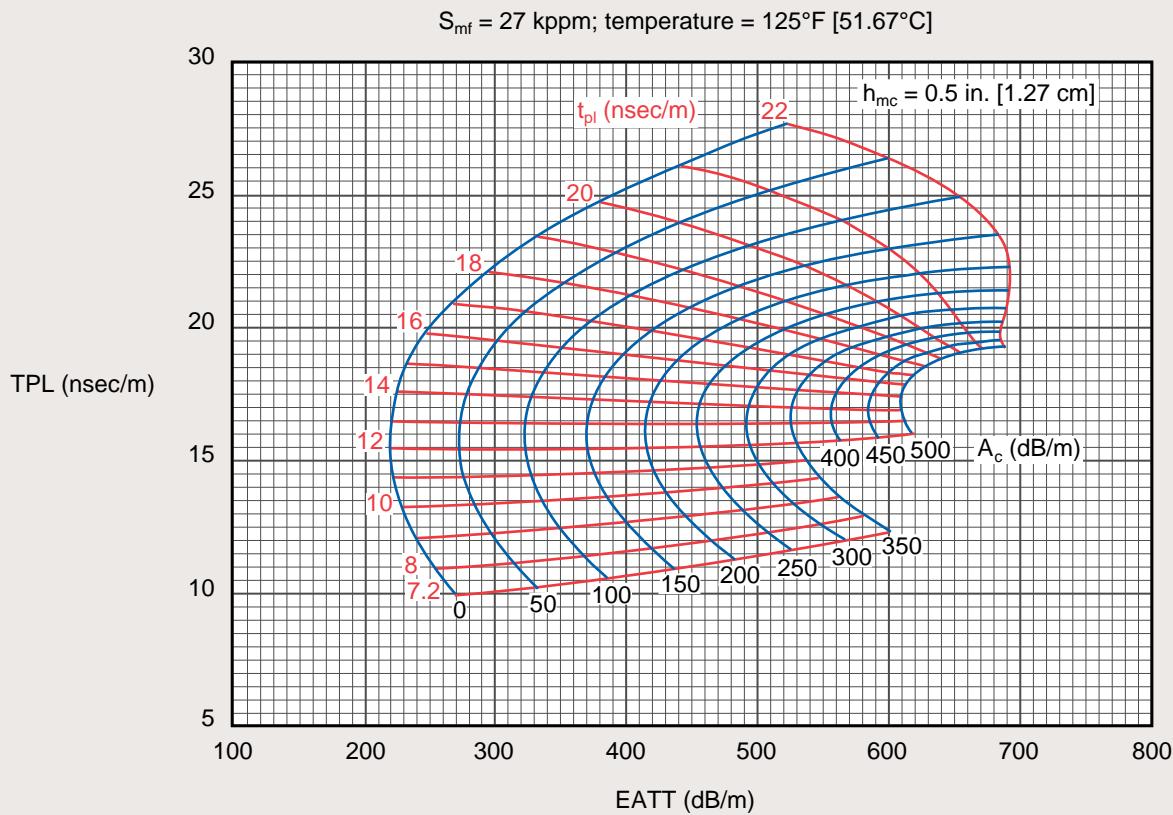

temperatures and mud-filtrate salinities in kppm by weight NaCl ( $S_{mf}$ ). The mudcake effects depend on  $h_{mc}$  and the contrast between the mudcake and formation dielectric properties.

*Continued on next page*

## EPT-G Mudcake Correction Charts for Water-Base Mud

BMD-S (broadside array)

EPTcor-4a

© Schlumberger

In general, low-conductivity muds produce the largest effects so that increases in temperature, mudcake porosity and salinity generally reduce the mudcake effects. The charts displayed here assume a mudcake porosity of 40 p.u. (For more information see

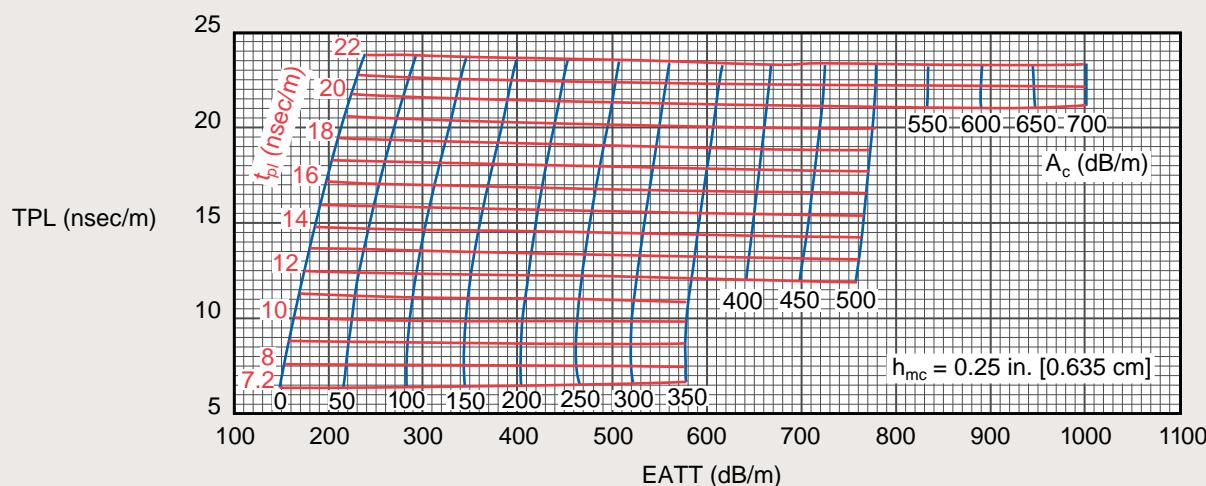

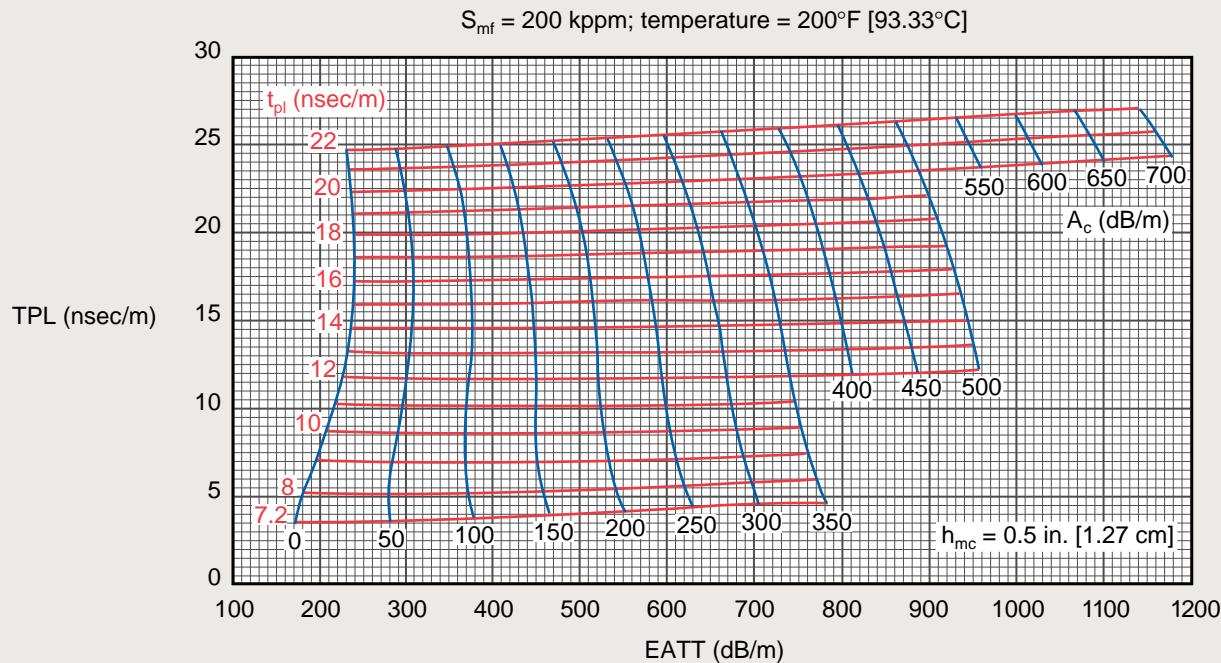

Reference 31.) The mudcake thicknesses are estimated from a caliper or a Microlog using Chart Rxo-1.

*Continued on next page*

## EPT-G Mudcake Correction Charts for Water-Base Mud

BMD-S (broadside array)

EPTcor-4b

© Schlumberger

**Example:** EMD-L array $h_{mc} = 0.5 \text{ in.}$  (estimated from bit size and caliper)Borehole temperature =  $125^\circ\text{F}$ 

Mud filtrate salinity = 27,000 ppm NaCl

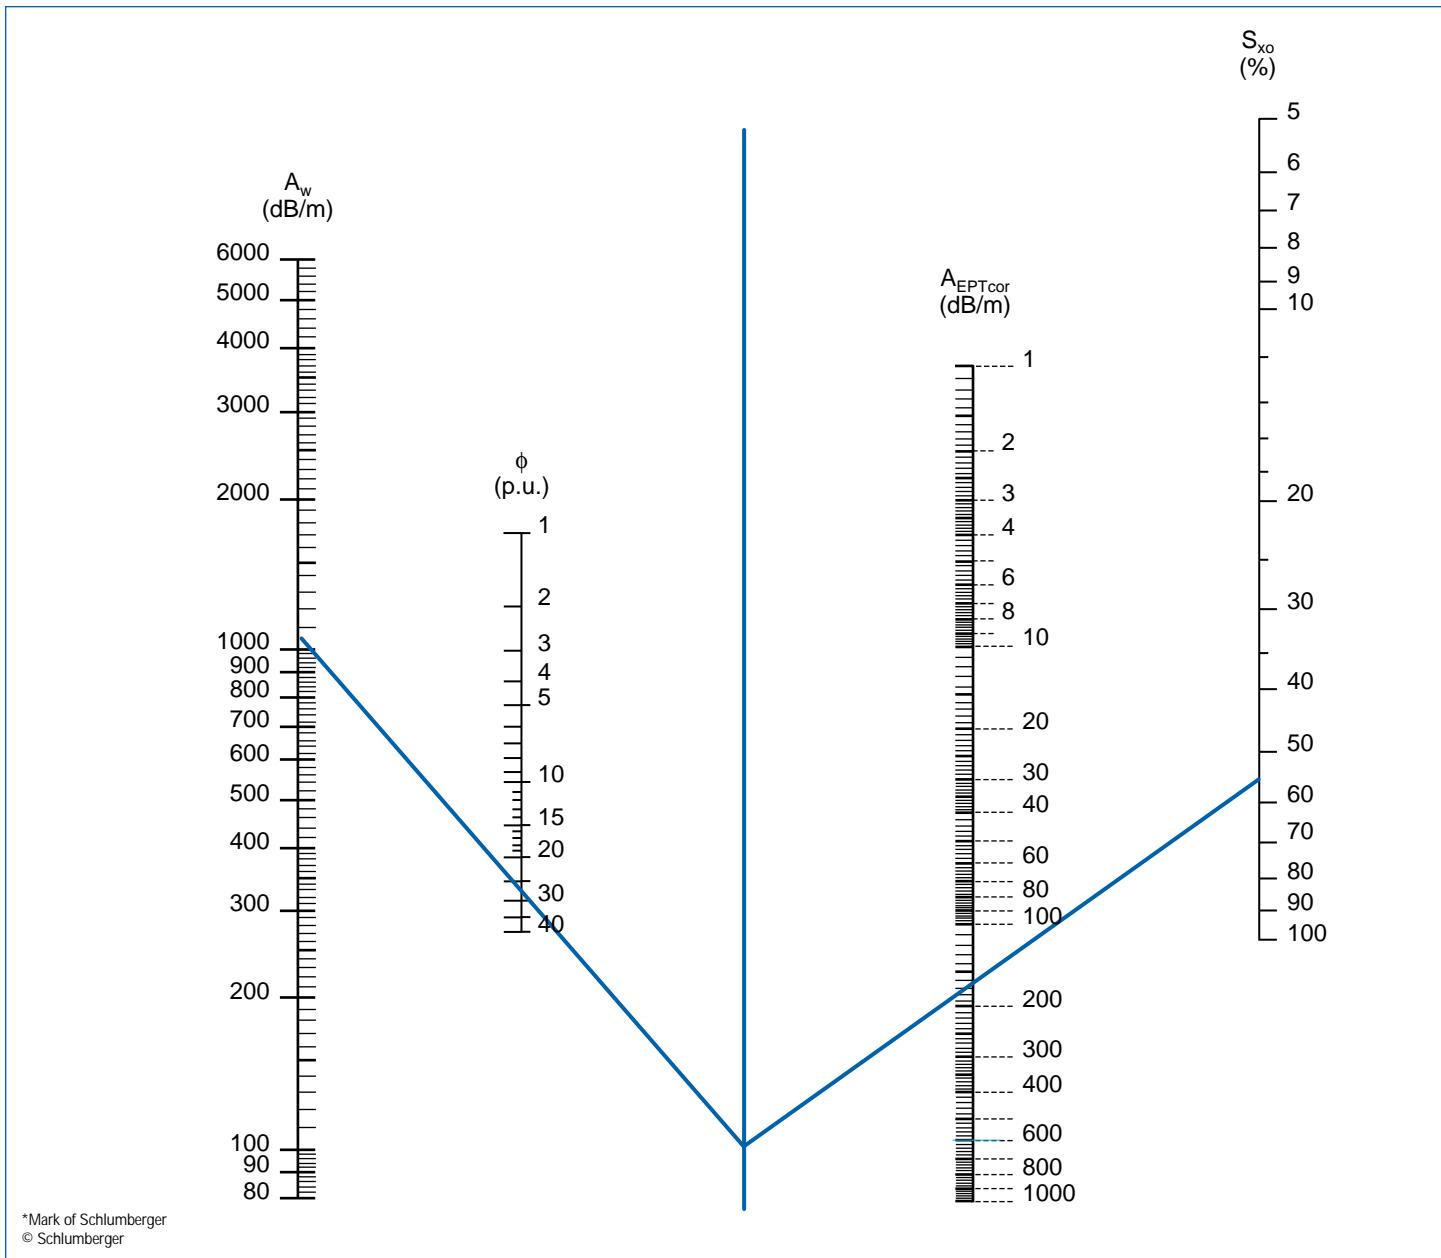

Log TPL = 20 nsec/m

Log EATT = 500 dB/m

Entering Chart EPTcor-3a with the above log values, one reads a true formation travel time,  $t_{pl} = 19.7 \text{ nsec/m}$ , and true formation attenuation,  $A_c = 307 \text{ dB/m}$ .

## Flushed Zone Saturation from EPT\* Attenuation

Sxo-2

The nomograph defines water saturation in the rock immediately adjacent to the borehole,  $S_{xo}$ , using the EPT attenuation measurement. It requires knowledge of saturating fluid (usually mud filtrate) attenuation ( $A_w$ ), porosity and the EPT attenuation ( $A_{EPTcor}$ ) corrected for spreading loss.

Fluid attenuation ( $A_w$ ) can be estimated from Chart EPTcor-2 by knowing the equivalent water salinity and formation temperature. EPT-D spreading loss is also determined from Chart EPTcor-2 based on the uncorrected EPT  $t_{pl}$  measurement. The spreading loss correction algebraically added to the EPT-D attenuation measurement gives the corrected EPT attenuation,  $A_{EPTcor}$ .

These values, together with porosity, inserted into the nomograph lead to the flushed zone water saturation,  $S_{xo}$ .

*Example:*  $A_{EPT} = 250$  dB/m

$$t_{pl} = 10.9 \text{ nsec/m}$$

$$\phi = 28\%$$

$$\text{Water salinity} = 20 \text{ kppm}$$

$$\text{BHT} = 150^\circ\text{F}$$

$$\text{giving Spreading loss} = -82 \text{ dB/m}$$

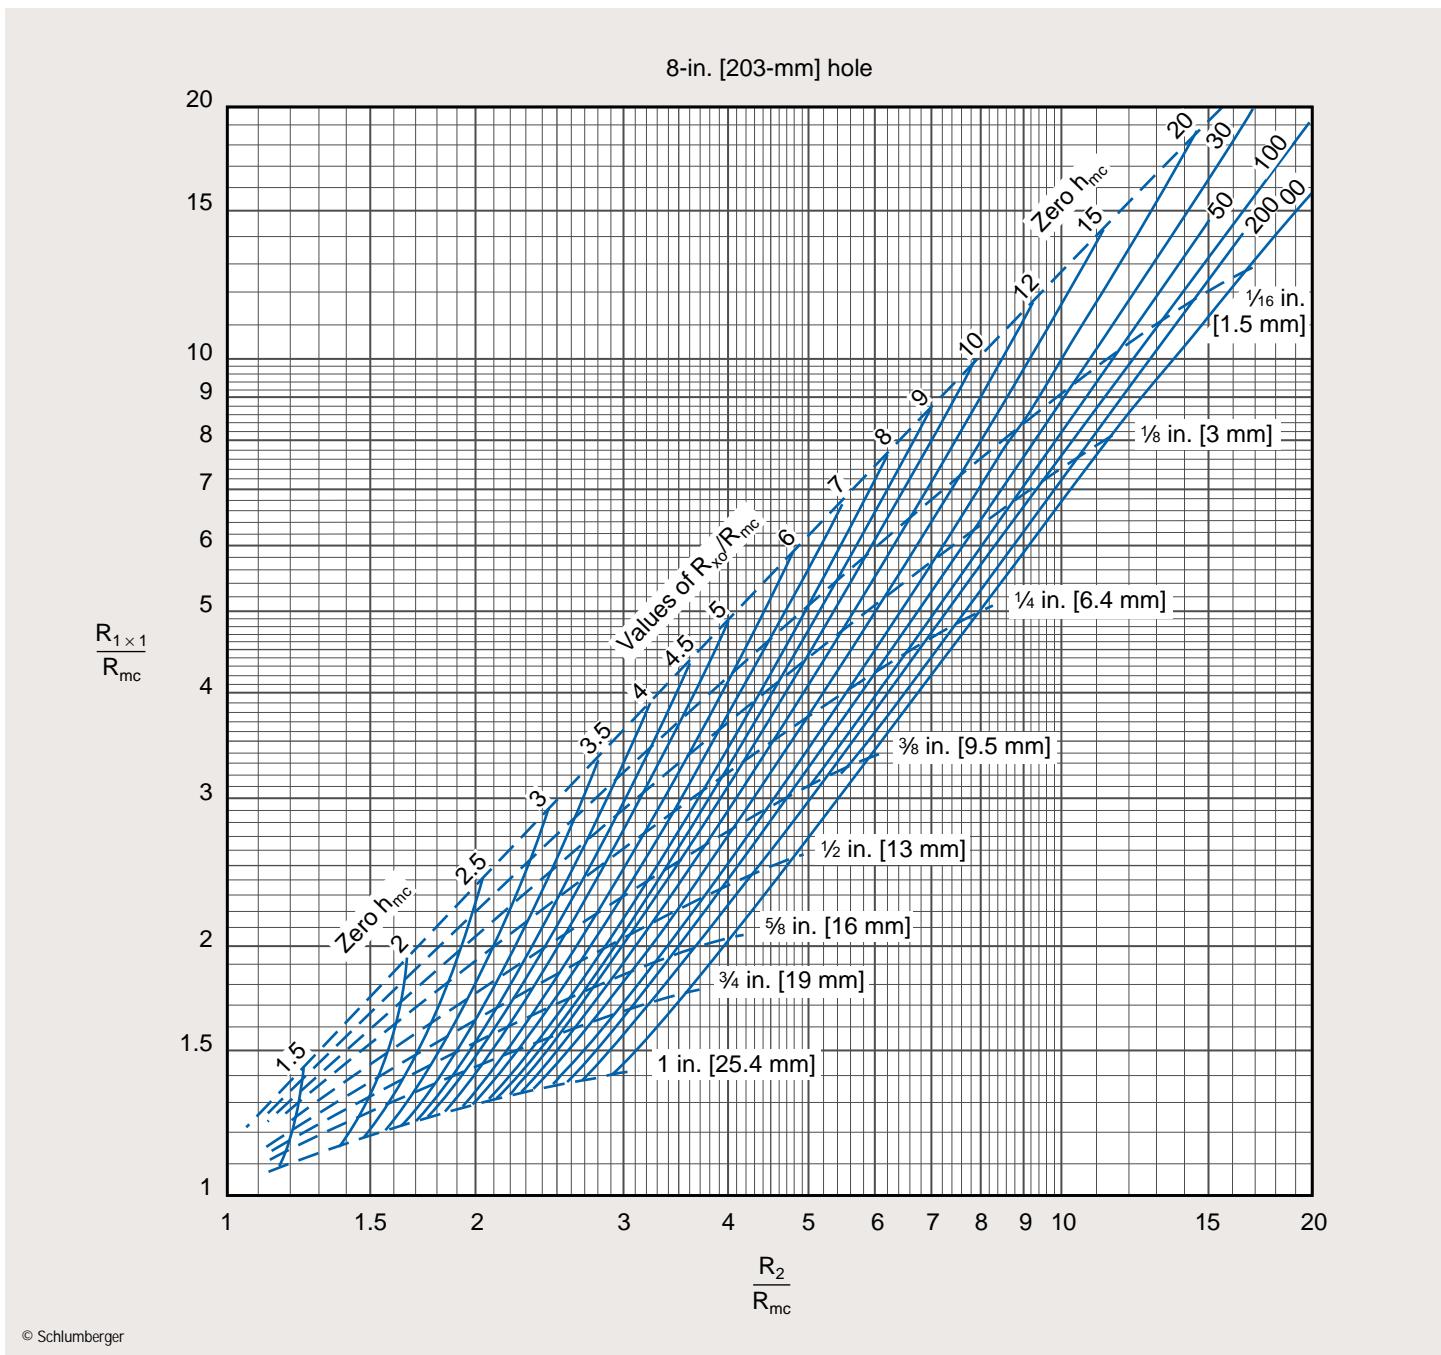

$$A_{EPT} = 250 - 82 = 168 \text{ dB/m}$$

$$A_w = 1100 \text{ dB/m}$$

$$\text{and } S_{xo} = 56\%$$

## Microlog Interpretation Chart

Rxo-1

Enter the chart with the ratios  $R_{1x1}/R_{mc}$  and  $R_2/R_{mc}$ . The point of intersection defines the  $R_{xo}/R_{mc}$  ratio and the mudcake thickness,  $h_{mc}$ . Knowing  $R_{mc}$ ,  $R_{xo}$  can be calculated.

For hole sizes other than 8 in. [203 mm], multiply  $R_{1x1}/R_{mc}$  by the following factors before entering the chart: 1.15 for 4 3/4-in. [120-mm] hole, 1.05 for 6-in. [152-mm] hole, and 0.93 for 10-in. [254-mm] hole.

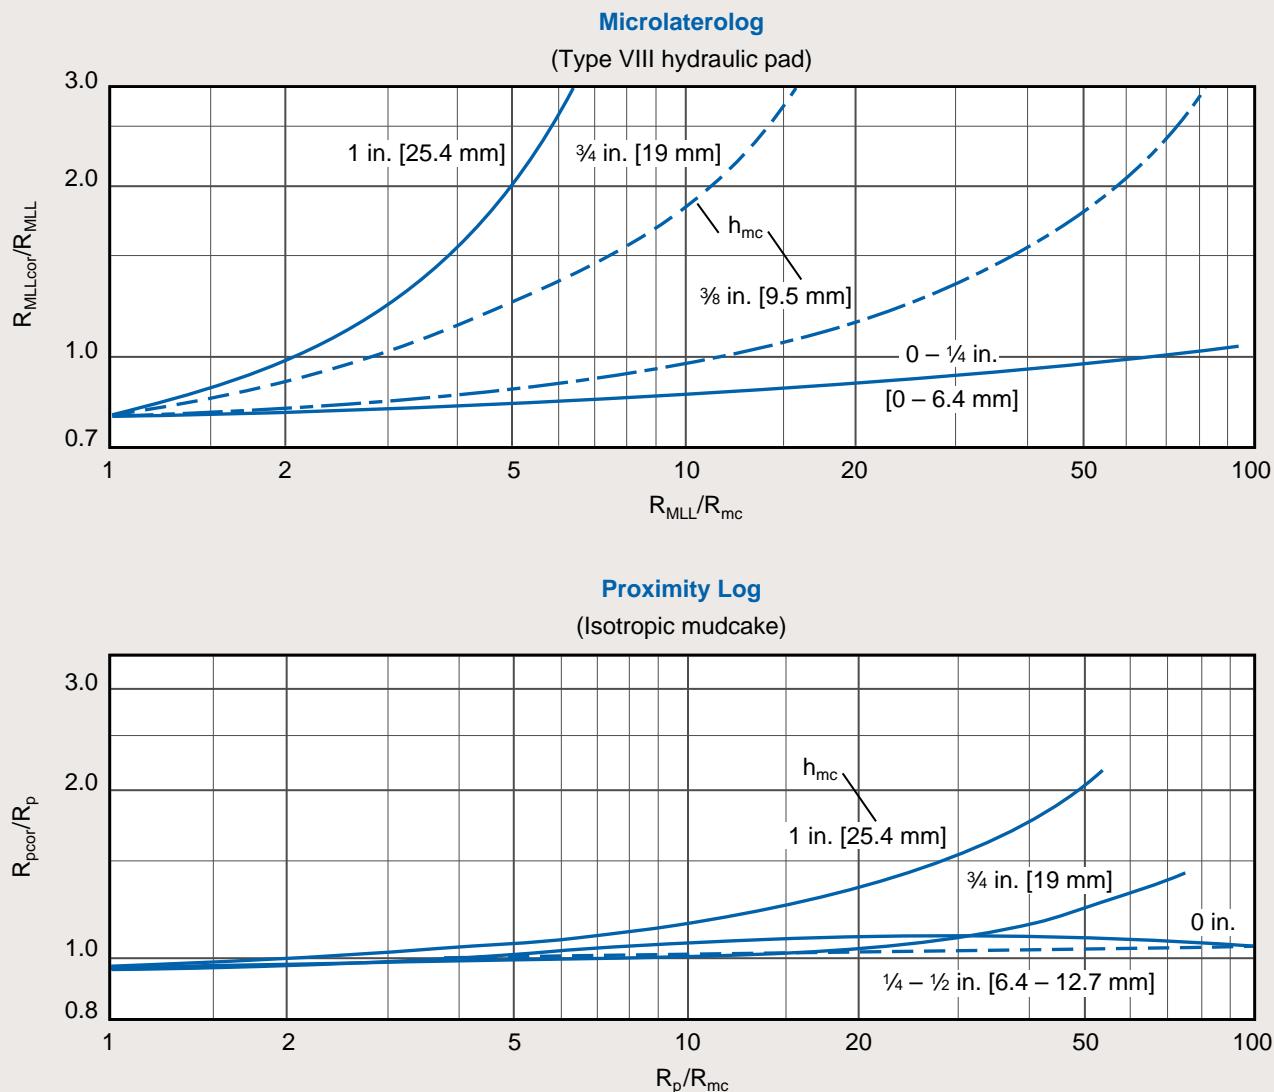

**Note:** An incorrect  $R_{mc}$  will displace the points in the chart along a 45° line. In certain cases this can be recognized when

the mudcake thickness is different from direct measurement by the microcaliper. To correct, move the plotted point at 45° to intersect the known  $h_{mc}$ . For this new point, read  $R_{xo}/R_{mc}$  from the chart and  $R_2/R_{mc}$  from the bottom scale of the chart.

$$R_{xo} = R_2 \left( \frac{R_{xo}/R_{mc}}{R_2/R_{mc}} \right)$$

## Microlaterolog and Proximity Log Mudcake Correction

Rxo-2

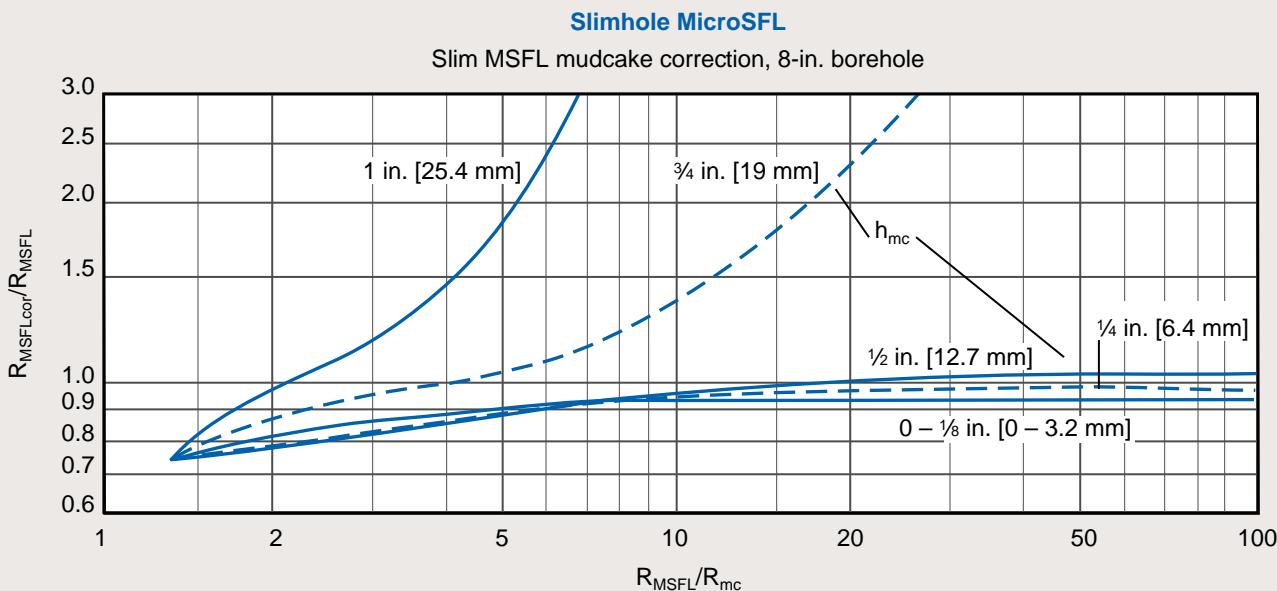

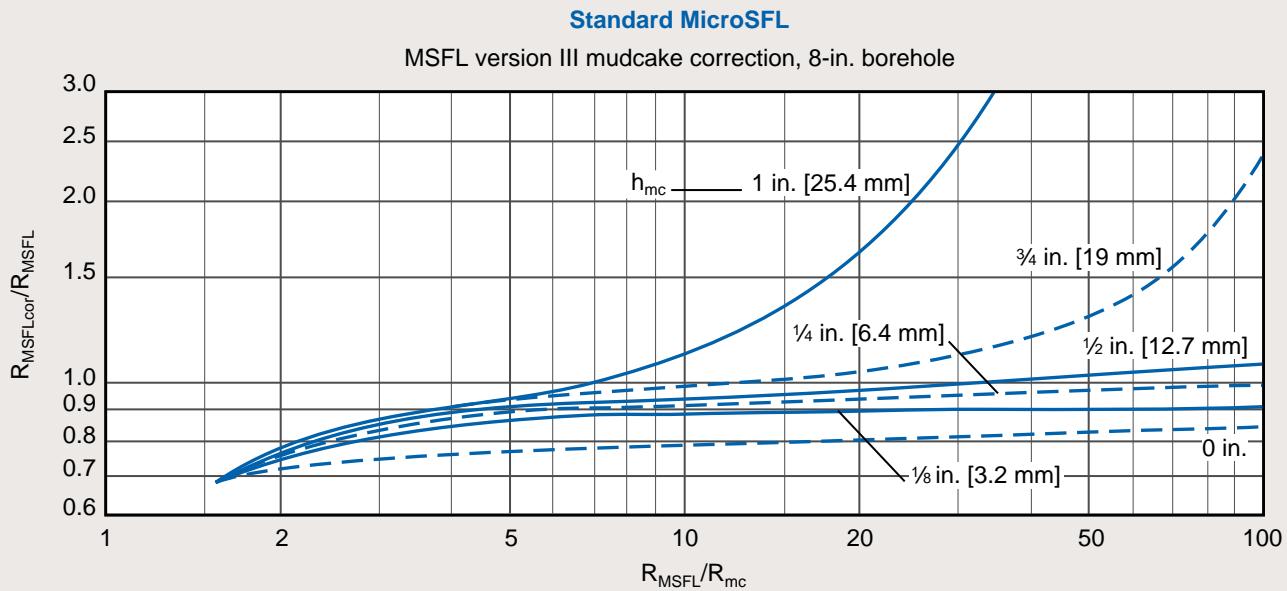

Charts Rxo-2 and Rxo-3 correct microresistivity measurements for mudcake effect. To use, enter the ratio of the microresistivity log reading divided by the mudcake resistivity into the abscissa of the appropriate chart. Go vertically to the mudcake thickness;

the ratio of the corrected microresistivity value to the microresistivity log reading is then given on the ordinate. Multiplication of this ratio by the microresistivity log reading yields the corrected microresistivity.

*Continued on next page*

## MicroSFL® Mudcake Correction

Rxo-3

\*Mark of Schlumberger  
© Schlumberger

*Example:*  $R_{MLL} = 9.0 \text{ ohm-m}$

$R_{mc} = 0.15 \text{ ohm-m}$  at formation temperature

$h_{mc} = 9.5 \text{ mm}$

giving  $R_{MLL}/R_{mc} = 9.0/0.15 = 60$

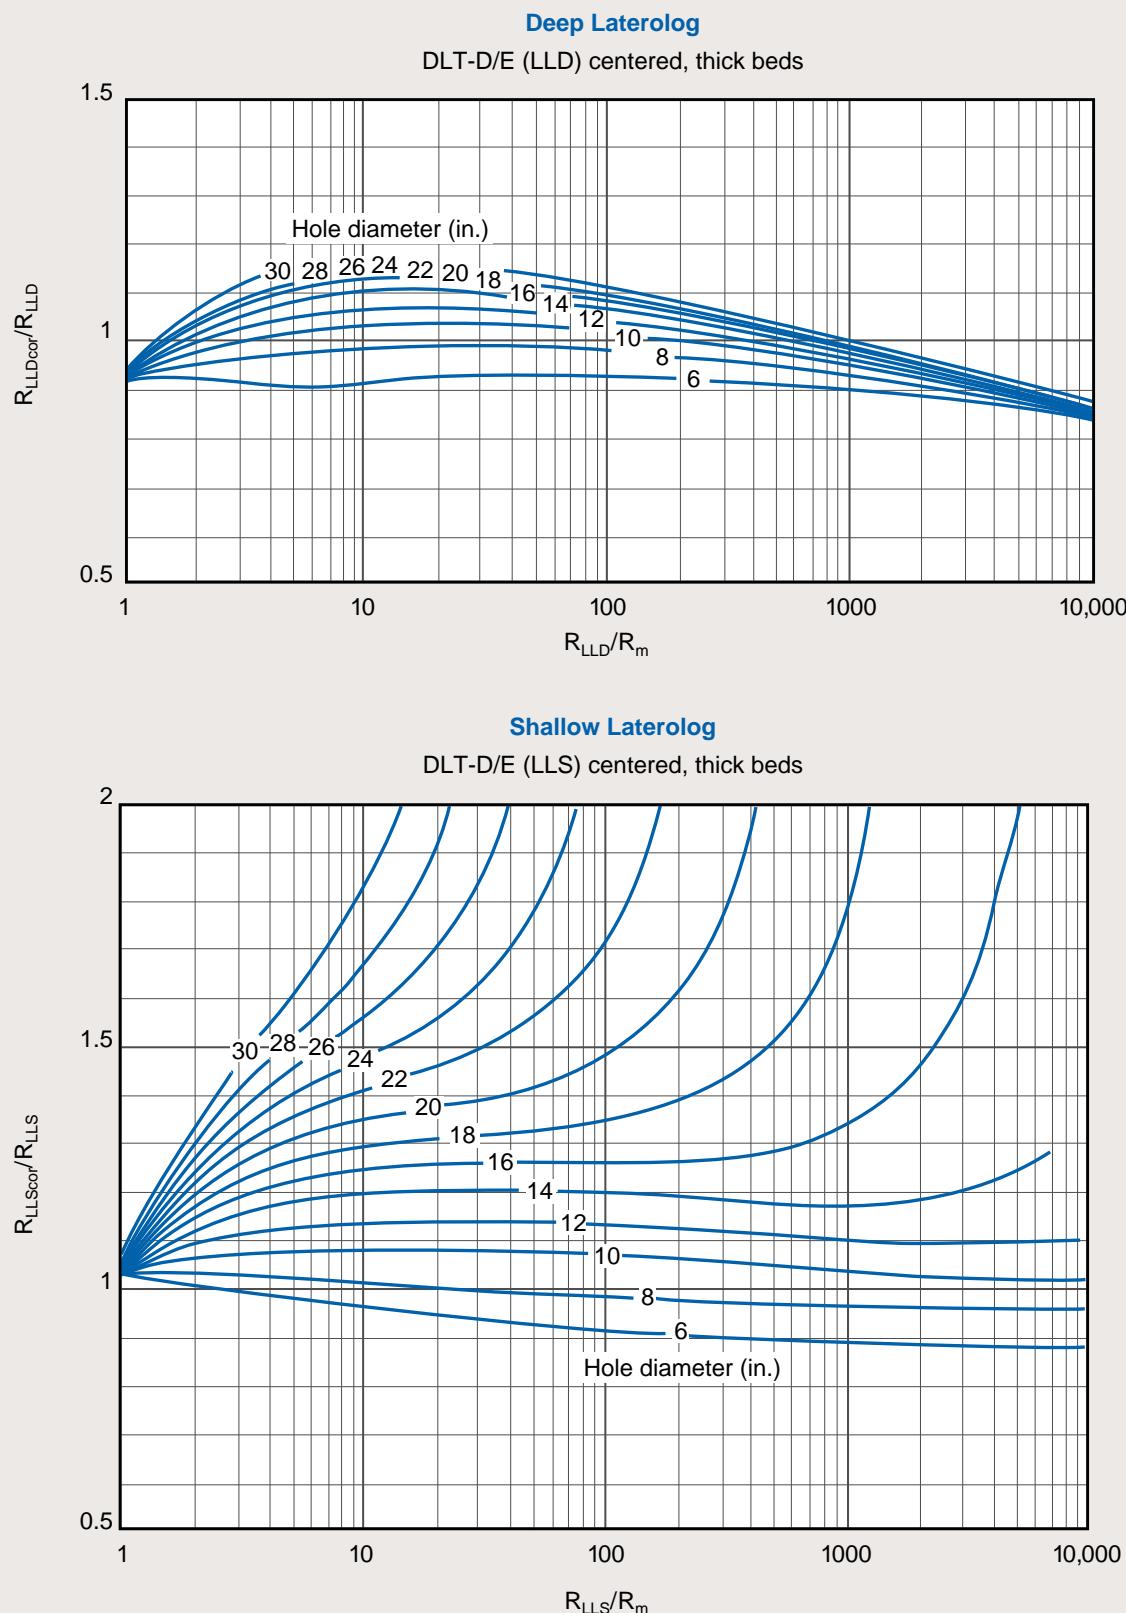

Therefore,  $R_{MLLcor}/R_{MLL} = 2$

and  $R_{MLLcor} = 2(9.0) = 18 \text{ ohm-m}$

Rxo

Rcor-2b

## Dual Laterolog (D/E) Borehole Correction

Rcor-2c

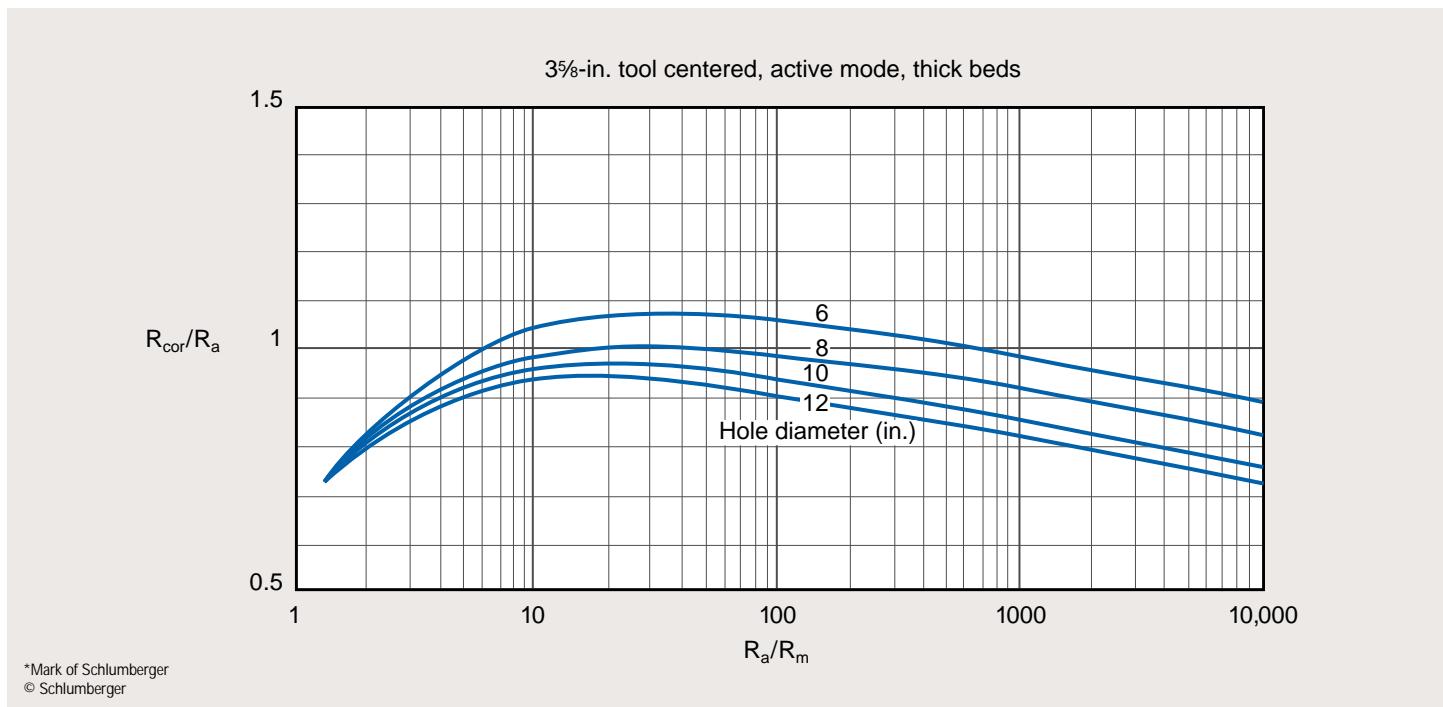

© Schlumberger

## ARI\* Azimuthal Resistivity Imager Borehole Correction

For high-resolution LLhr curve

Rcor-14

The high-resolution deep resistivity curve available from the ARI Azimuthal Resistivity Imager log is subject to borehole effects like any other laterolog measurement. Borehole correction is performed using Chart Rcor-14 in the same way as the deep and shallow laterolog borehole corrections and the microlog and MicroSFL\* mudcake corrections (see Charts Rxo-2 and Rxo-3 for an explanation and illustration).

LLD and LLS curves recorded with the ARI tool are identical to the curves recorded with a standard dual laterolog tool (type D or E) and may be corrected for borehole effects using Chart Rcor-2b or Rcor-2c.

Rcor

## Dual Laterolog (D/E) Bed-Thickness Corrections

Chart Rcor-10 corrects the Dual Laterolog (LLD and LLS) for bed thickness.

To use, laterolog readings should first be corrected for borehole effects (see Charts Rcor-2b and -2c). Then, enter Chart Rcor-10 with the bed thickness and proceed upward to the proper  $R_{LL}/R_s$  ratio (apparent laterolog reading corrected for borehole/adjacent-bed resistivity) curve. Read the ratio of the corrected laterolog value ( $R_{LLcor}$ ) to the apparent laterolog value ( $R_{LL}$ ) in ordinate.

*Example:*  $R_{LLD} = 4.2 \text{ ohm-m}$

$$R_{LLS} = 3.0 \text{ ohm-m}$$

$$R_s \approx 30 \text{ ohm-m}$$

$$\text{Bed thickness} = 6 \text{ ft}$$

Given  $\frac{R_{LLD}}{R_s} = \frac{4.2}{30} = 0.14$

$$\frac{R_{LLS}}{R_s} = \frac{3.0}{30} = 0.10$$

Therefore,  $\frac{R_{LLDcor}}{R_{LLD}} = 0.88$

$$\frac{R_{LLScor}}{R_{LLS}} = 0.80$$

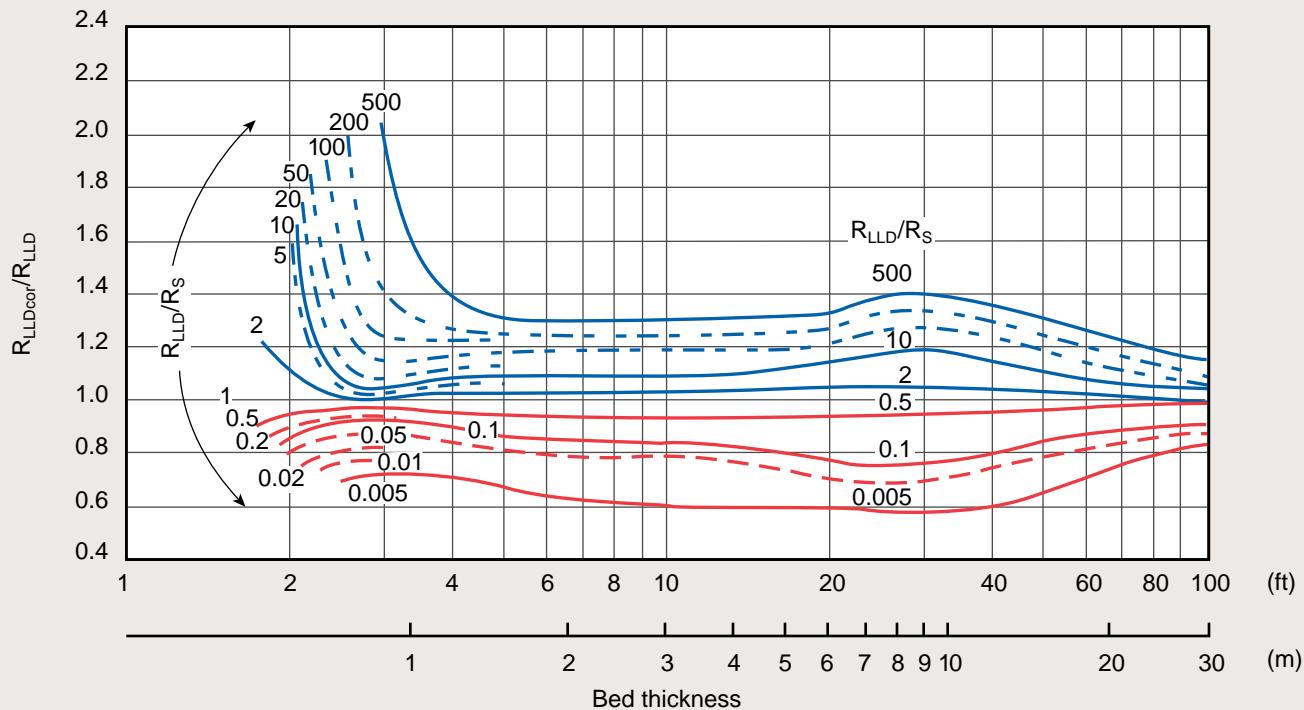

and  $R_{LLDcor} = 3.7 \text{ ohm-m}$   
 $R_{LLScor} = 2.4 \text{ ohm-m}$

## Dual Laterolog (D/E) Bed-Thickness Corrections

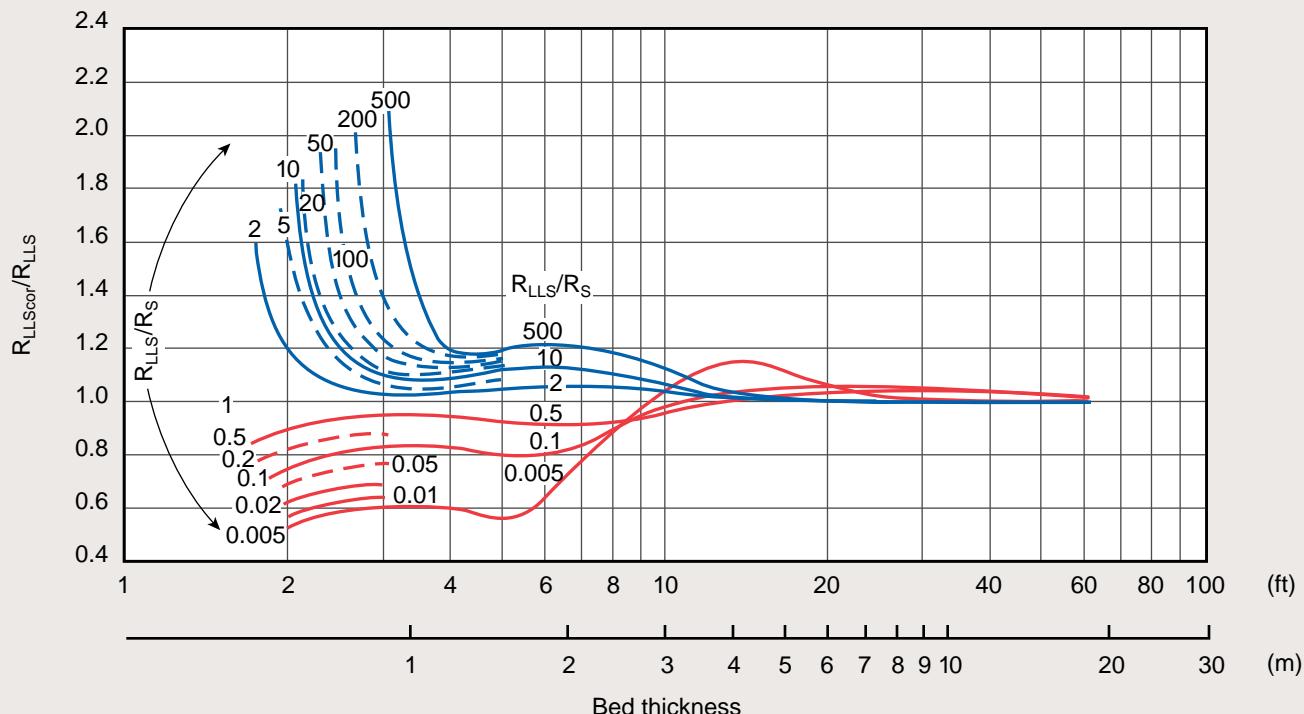

DLS-D/E

Rcor-10

## Deep Laterolog

No invasion, semi-infinite shoulder, 8-in. [203-mm] borehole, squeeze:  $R_t/R_m \approx 30$ , antisqueeze:  $R_s/R_m \approx 30$ 

## Shallow Laterolog

No invasion, semi-infinite shoulder, 8-in. [203-mm] borehole, squeeze:  $R_t/R_m \approx 30$ , antisqueeze:  $R_s/R_m \approx 30$ 

## Invasion Correction Charts

Rint-1

The invasion correction charts, sometimes referred to as “tornado” or “butterfly” charts, of the next several pages (labeled Rint-) are used to define the depth of invasion  $d_i$ , the  $R_{xo}/R_t$  ratio and the true resistivity  $R_t$ . All assume a step-contact profile of invasion and that all resistivity measurements have been corrected, where necessary, for borehole effect and bed thickness using the appropriate Rcor- chart, prior to entry.

To use any of these charts, enter the abscissa and ordinate with the required resistivity ratios. The point of intersection defines  $d_i$ ,  $R_{xo}/R_t$  and  $R_t$  as a function of one resistivity measurement.

### Saturation determination in clean formations

Either of the chart-derived values of  $R_t$  and  $R_{xo}/R_t$  can be used to find values for  $S_w$ . One value, which is designated as  $S_{wA}$  ( $S_w$ -Archie), is found using the Archie saturation formula (or Chart Sw-1) with the  $R_t$  value and known values of  $F_R$  and  $R_w$ .

An alternate  $S_w$  value, designated as  $S_{wR}$  ( $S_w$ -Ratio), is found using  $R_{xo}/R_t$  with  $R_{mf}/R_w$  as in Chart Sw-2.

If  $S_{wA}$  and  $S_{wR}$  are equal, the assumption of a step-contact invasion profile is indicated to be correct, and all values found ( $S_w$ ,  $R_t$ ,  $R_{xo}$ ,  $d_i$ ) are considered good.

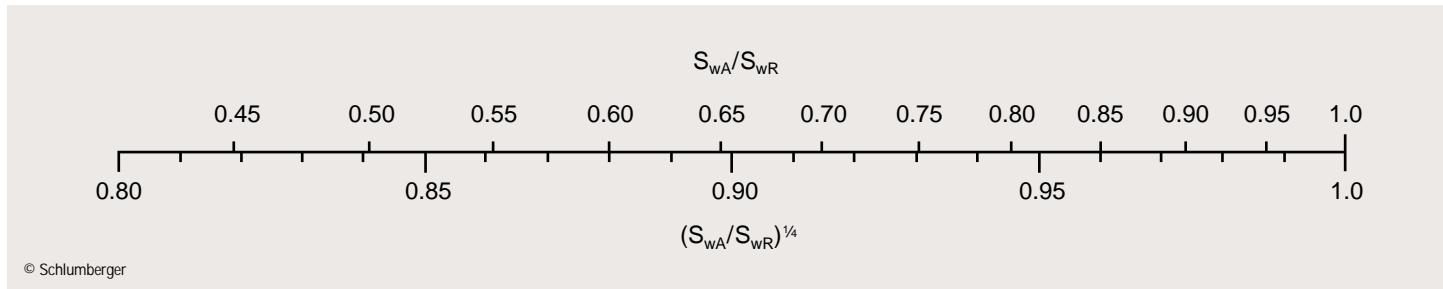

If  $S_{wA} > S_{wR}$ , either invasion is very shallow or a transition type of invasion profile is indicated, and  $S_{wA}$  is considered a good value for  $S_w$ .

If  $S_{wA} < S_{wR}$ , an annulus-type invasion profile may be indicated. In this case a more accurate value of water saturation may be estimated using the relation:

$$S_{wcor} = S_{wA} \left( \frac{S_{wA}}{S_{wR}} \right)^{\frac{1}{4}}$$

The correction factor  $(S_{wA}/S_{wR})^{1/4}$  can be found from the scale below.

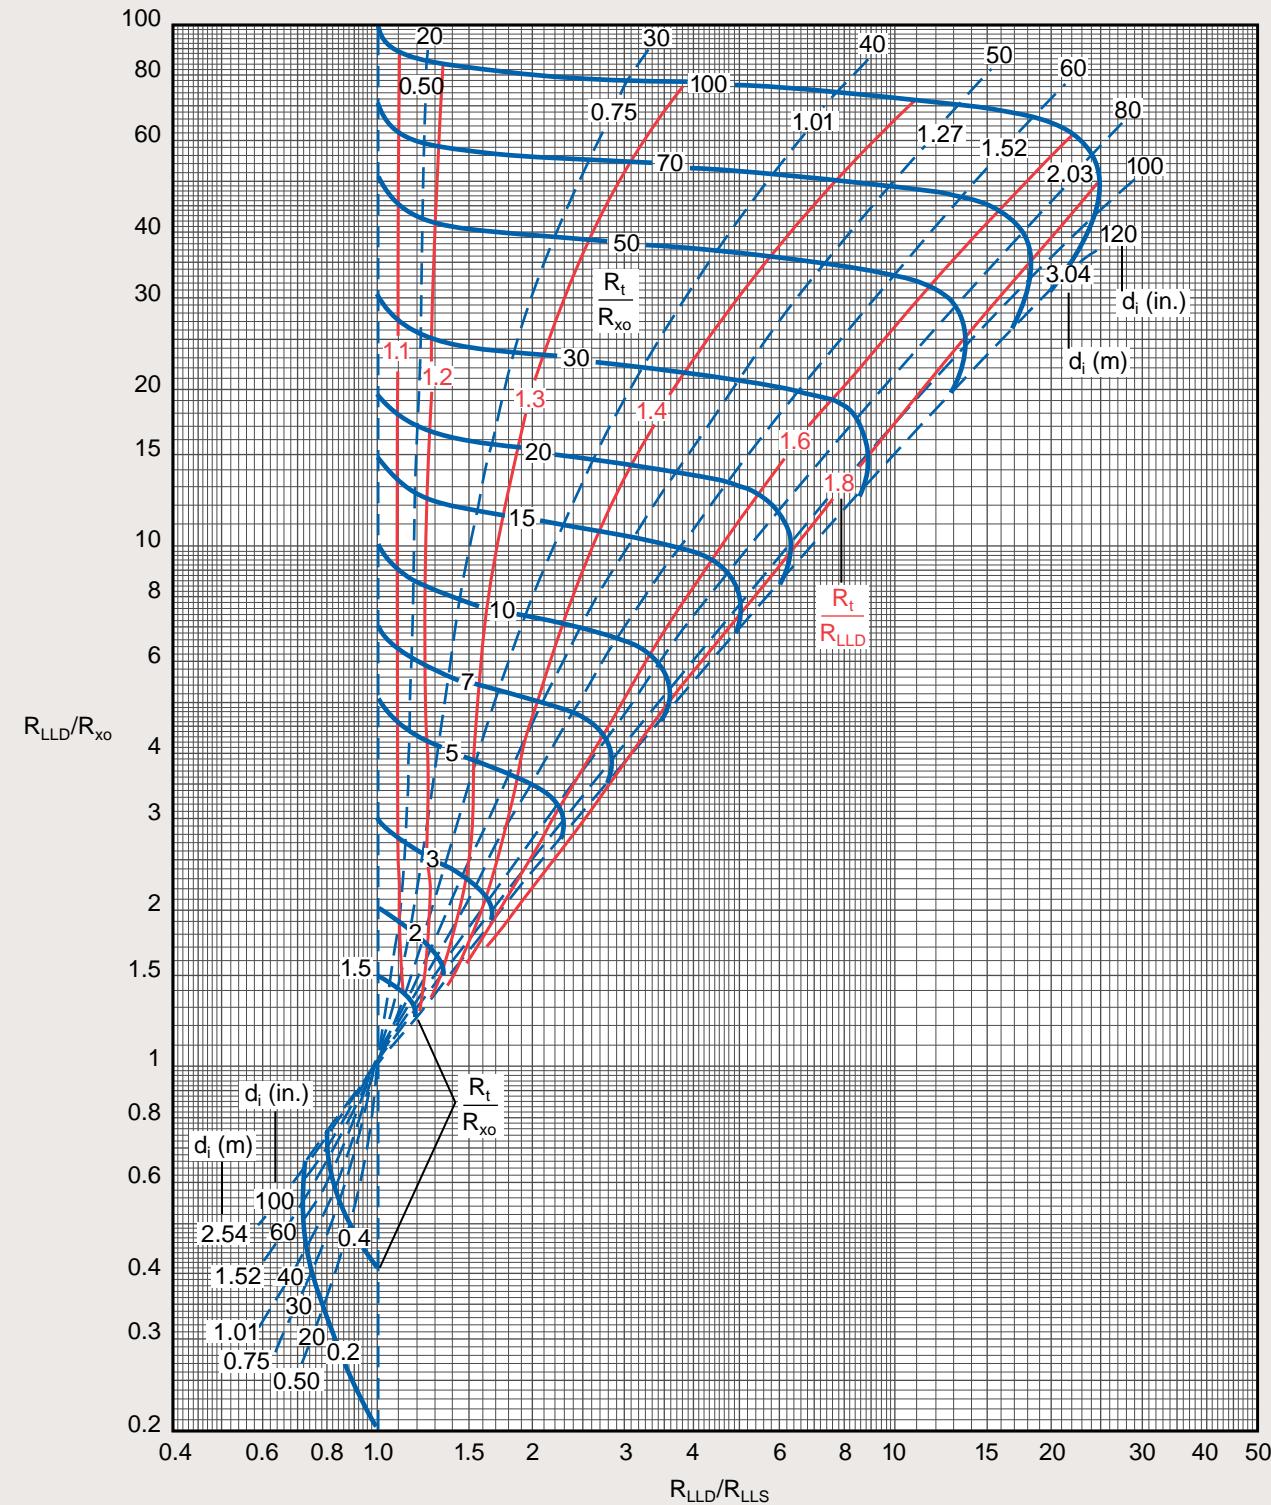

For more information see Reference 9.

## Borehole Correction for 16-in. Normal

Recorded with induction-electrical log

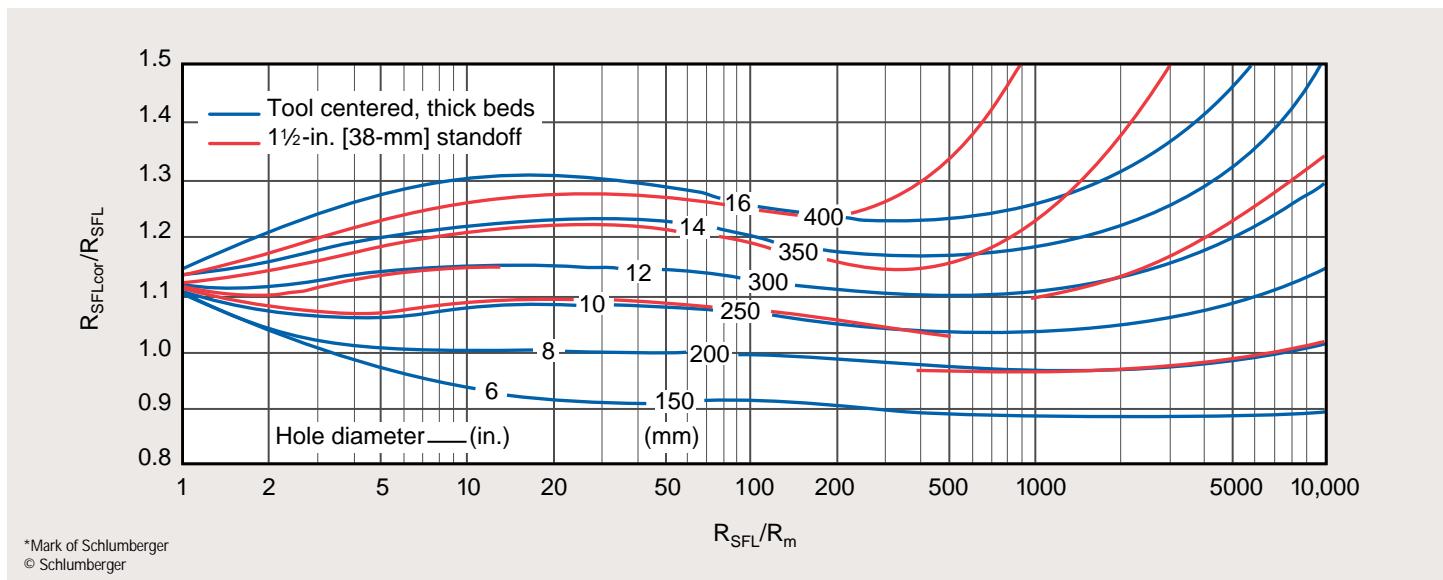

Rcor-8

## SFL\* Spherically Focused Resistivity Borehole Correction

Recorded with DIS-DB, EA or equivalent

Rcor-1

\*Mark of Schlumberger  
© Schlumberger

Most resistivity measurements should be corrected for borehole effect. Charts Rcor-1 and Rcor-8 provide the borehole correction for the 16-in. Normal and the SFL measurements.

To use, the ratio of the resistivity measurement divided by the mud resistivity,  $R_m$ , is entered in abscissa. Proceed to the

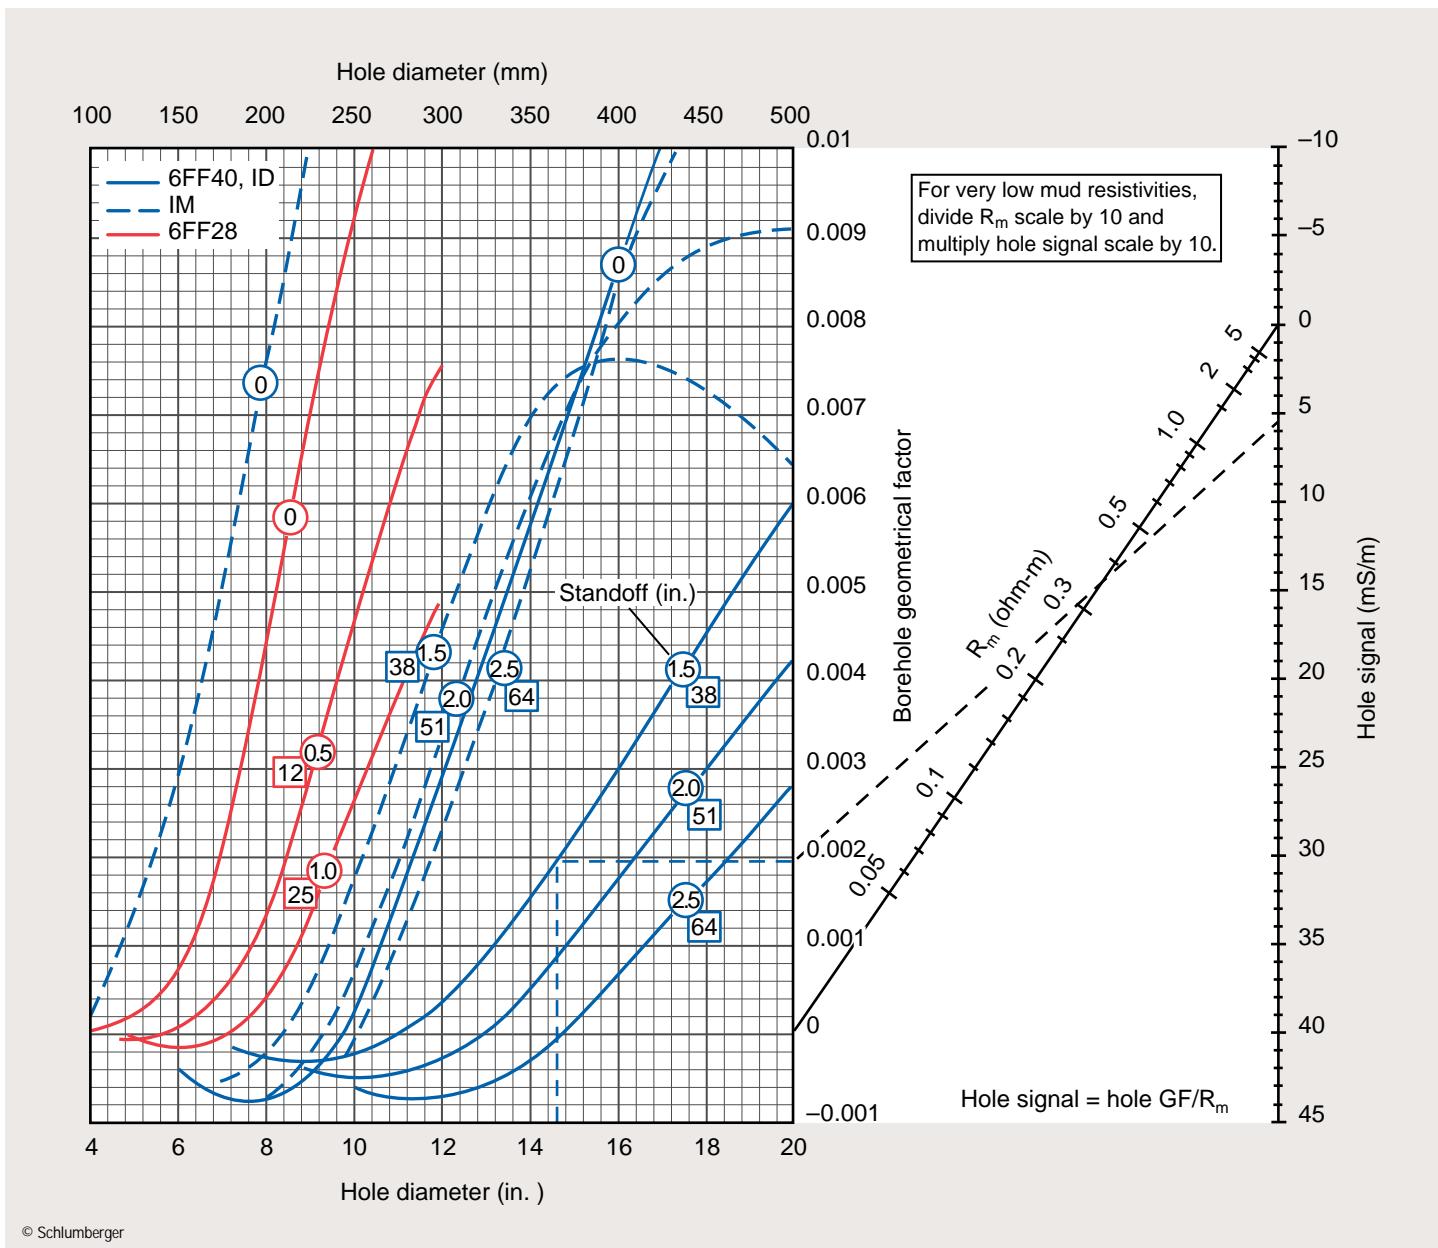

proper borehole diameter, and read the correction factor from the ordinate.

The chart contains curves for a centered tool and for a tool with 1½-in. standoff.

Rcor

## Induction Log Borehole Correction

Rcor-4a

The hole-conductivity signal is to be subtracted, where necessary, from the induction log conductivity reading before other corrections are made.<sup>†</sup> This correction applies to all zones (including shoulder beds) having the same hole size and mud resistivity.

<sup>†</sup> Some induction logs, especially in salty muds, are adjusted so that the hole signal for the nominal hole size is already subtracted out of the recorded curve. Refer to the log heading.

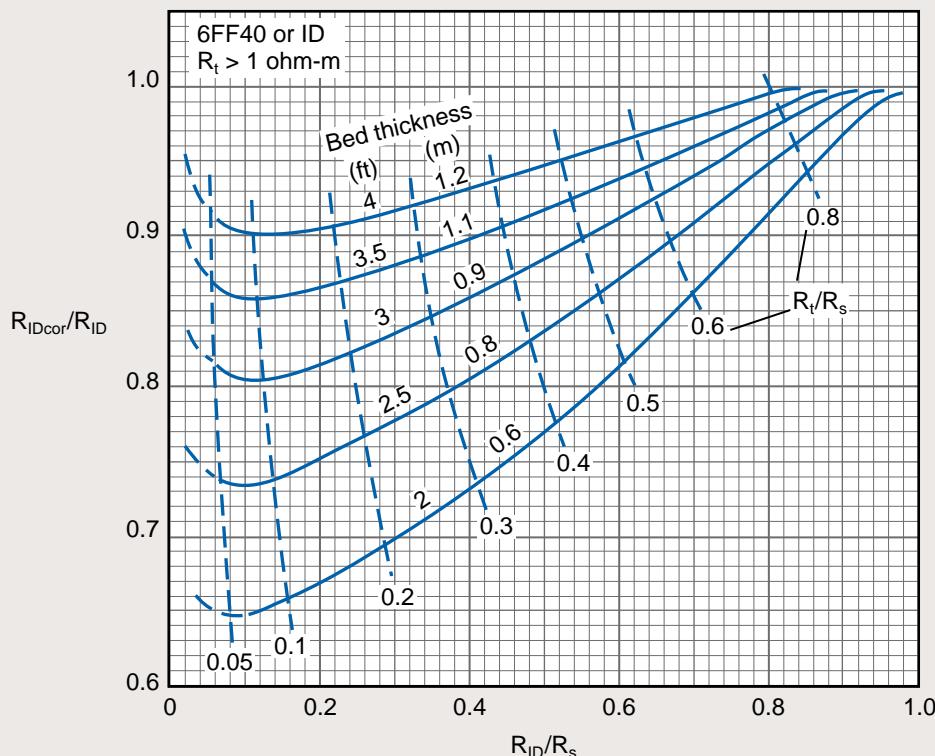

Rcor-4 gives corrections for 6FF40 or ID, IM and 6FF28 for various wall standoffs. Dashed lines illustrate the use of the chart for a 6FF40 sonde with a 1.5-in. standoff in a 14.6-in. borehole, and  $R_m = 0.35 \text{ ohm-m}$ . The hole signal is found to be 5.5 mS/m. If the log reads  $R_I = 20 \text{ ohm-m}$ ,  $C_I$  (conductivity) = 50 mS/m. The corrected  $C_I$  is then  $(50 - 5.5) = 44.5 \text{ mS/m}$ .  $R_I = 1000/44.5 = 22.4 \text{ ohm-m}$ .

## Induction Log Correction for Thin Conductive Beds

6FF40, ID, 6FF28

Rcor-7

Computed for a shoulder-bed resistivity (SBR)  
setting of 1 ohm-m (refer to log heading)

© Schlumberger

Charts Rcor-5, Rcor-6 and Rcor-7 correct the induction logs (6FF40, ID, 6FF28 and IM) for bed thickness. A skin-effect correction is included in these charts.

To use, select the chart appropriate for the tool type and for the adjacent bed resistivity ( $R_s$ ). For Charts Rcor-5 and Rcor-6, enter the bed thickness and proceed upward to the proper  $R_a$  curve. Read the corrected resistivity value ( $R_t$ ) in ordinate.

For Chart Rcor-7, enter the chart with the  $R_{ID}/R_s$  ratio (apparent ID reading/adjacent bed resistivity) and go upward to the bed thickness. Read the correction factor ( $R_{IDcor}/R_{ID}$ ) in ordinate.

*Example:*  $R_{ID} = 4.2 \text{ ohm-m}$

$$R_{IM} = 6.0 \text{ ohm-m}$$

$$R_s = 2.0 \text{ ohm-m}$$

$$\text{Bed thickness} = 3 \text{ m}$$

giving, from the  $R_s = 2 \text{ ohm-m}$  charts,

$$R_{IDcor} = 4.5 \text{ ohm-m}$$

$$R_{IMcor} = 6.2 \text{ ohm-m}$$

For the small-diameter 6FF28, multiply the bed thickness by 1.43 before entering these correction charts. For example, in a 7-ft bed, the bed thickness used in correcting the 6FF28 reading is 10 ft ( $7 \times 1.43 = 10$ ).

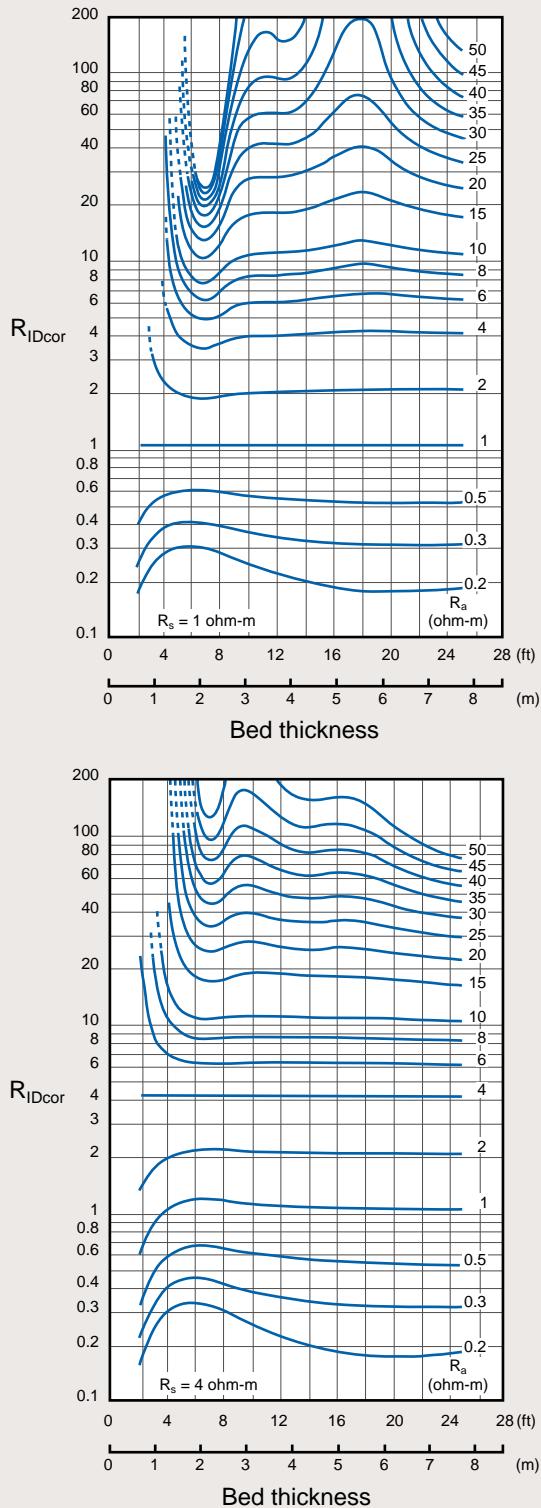

Rcor

## Induction Log Bed-Thickness Correction

6FF40 (ID) and 6FF28

## Invasion Correction Charts

Rint-1a

The invasion correction charts, sometimes referred to as “tornado” or “butterfly” charts, of the next several pages (labeled Rint-) are used to define the depth of invasion  $d_i$ , the  $R_{xo}/R_t$  ratio and the true resistivity  $R_t$ . All assume a step-contact profile of invasion and that all resistivity measurements have been corrected, where necessary, for borehole effect and bed thickness using the appropriate  $R_{cor}$ -chart, prior to entry.

To use any of these charts, enter the abscissa and ordinate with the required resistivity ratios. The point of intersection defines  $d_i$ ,  $R_{xo}/R_t$  and  $R_t$  as a function of one resistivity measurement.

*Example:*  $R_{SFL} = 25 \text{ ohm-m}$   
 $R_{IM} = 5.9 \text{ ohm-m}$   
 $R_{ID} = 4.8 \text{ ohm-m}$   
 $R_m = 0.5 \text{ ohm-m}$

After correction  
for borehole effect  
and bed thickness

Entering the  $R_{xo}/R_m \approx 100$  chart (Chart Rint-2c) with

$$R_{SFL}/R_{ID} = 25/4.8 = 5.2$$

$$R_{IM}/R_{ID} = 5.9/4.8 = 1.2$$

yields  $R_{xo}/R_t = 8$

$$d_i = 39 \text{ in. or } 1 \text{ m}$$

$$R_t/R_{ID} = 0.97$$

Therefore,  $R_t = R_{ID} (R_t/R_{ID}) = 4.8 \times 0.97 = 4.7 \text{ ohm-m}$

$$R_{xo} = R_t (R_{xo}/R_t) = 4.7 \times 8 = 37.6 \text{ ohm-m}$$

Use of Chart Rint-2c is confirmed since  $R_{xo}/R_m = 75$   
(i.e.,  $R_{xo}/R_m \approx 100$ ).

### Saturation determination in clean formations

Either of the chart-derived values of  $R_t$  and  $R_{xo}/R_t$  can be used to find values for  $S_w$ . One value, which is designated as  $S_{wA}$  ( $S_w$ -Archie), is found using the Archie saturation formula (or Chart Sw-1) with the  $R_t$  value and known values of  $F_R$  and  $R_w$ . An alternate  $S_w$  value, designated as  $S_{wR}$  ( $S_w$ -Ratio), is found using  $R_{xo}/R_t$  with  $R_{mf}/R_w$ , as in Chart Sw-2.

If  $S_{wA} = S_{wR}$ , the assumption of a step-contact invasion profile is indicated as correct, and all values found ( $S_w$ ,  $R_t$ ,  $R_{xo}$  and  $d_i$ ) are considered good.

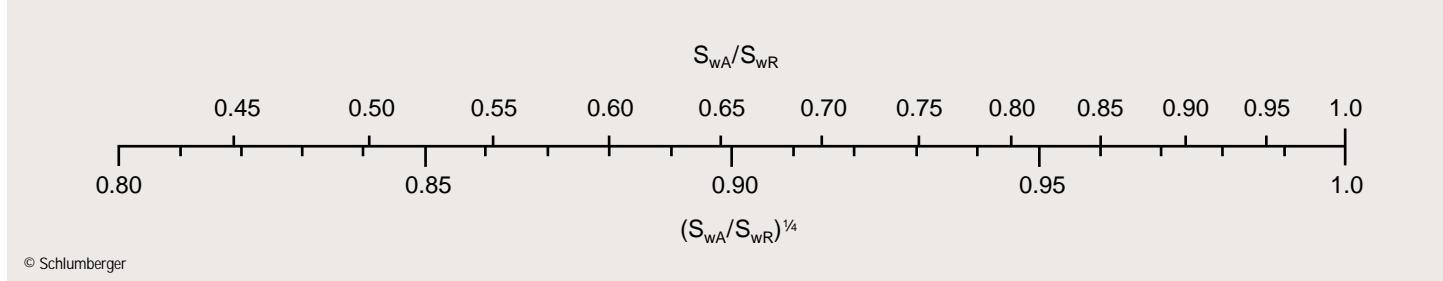

If  $S_{wA} > S_{wR}$ , either invasion is very shallow or a transition-type invasion profile is indicated, and  $S_{wA}$  is considered a good value for  $S_w$ .

If  $S_{wA} < S_{wR}$ , an annulus-type invasion profile may be indicated. In this case a more accurate value of water saturation may be estimated using the relation:

$$S_{wcor} = S_{wA} \left( \frac{S_{wA}}{S_{wR}} \right)^{\frac{1}{4}}$$

The correction factor  $(S_{wA}/S_{wR})^{1/4}$  can be found from the scale below.

## Phasor\* Induction Borehole Correction

Borehole corrections can now be based on exact modeling as well as on traditional experiments. Borehole correction requires four inputs: borehole conductivity ( $C_B$ ), formation conductivity ( $C_f$ ), borehole diameter (D) and standoff (S). For smooth round holes, correction of Phasor Induction logs may be based on Charts Rcor-4b and Rcor-4c. For cases when  $R_t/R_m > 100$ , Chart Rcor-4b is used alone. For cases when  $R_t/R_m < 100$ , both Charts Rcor-4b and Rcor-4c are needed. Each chart gives the borehole geometrical factor ( $G_B$ ) as a function of borehole diameter and standoff.  $G_B$  is used to get from apparent conductivity ( $C_a$ ) to corrected conductivity ( $C_{cor}$ ) through the correction formula

$$C_{cor} = \frac{C_a - C_B G_B}{1 - G_B} \quad (1)$$

$G_B$  is obtained from the charts for the appropriate borehole and standoff. All conductivities are expressed in mS/m and are calculated through the formula

$$C = \frac{1000}{R} \quad (2)$$

where R is the resistivity in ohm-m.

When the formation-to-borehole contrast is low and the boreholes are large enough to warrant correction, the following formula for interpolation between charts gives the approximate borehole geometrical factor:

$$G_{B_{IM}} = A_M G_{B_{M4c}} + (1 - A_M) G_{B_{M4b}} \quad (3)$$

$$G_{B_{ID}} = A_D G_{B_{D4c}} + (1 - A_D) G_{B_{D4b}} \quad (4)$$

where  $G_{BD4b}$  is the ID GF from Chart Rcor-4b and  $G_{BD4c}$  is from Chart Rcor-4c (D refers to ID and M refers to IM). The parameter  $A_M$  is derived from the formation and mud conductivities through the formula

$$A_M = -2.58414 + 3.59087F - 1.49684F^2 \quad (5)$$

and

$$A_D = 0.994584 - 1.59245F + 0.663813F^2 \quad (6)$$

where

$$F = \frac{C_B - C_f}{C_B + C_f} \quad (7)$$

Since  $C_f$  represents the formation conductivity just inside the borehole, SFL is the best estimator of this conductivity. The interpolated borehole geometrical factor is used in Eq. 1.

**Note:** All resistivity logs are limited near 2000 ohm-m. Borehole conditions can cause legitimate negative conductivity readings in conditions such as very resistive formations. The conductivity channels CIDP and CIMP are not limited and are better choices for borehole correction.

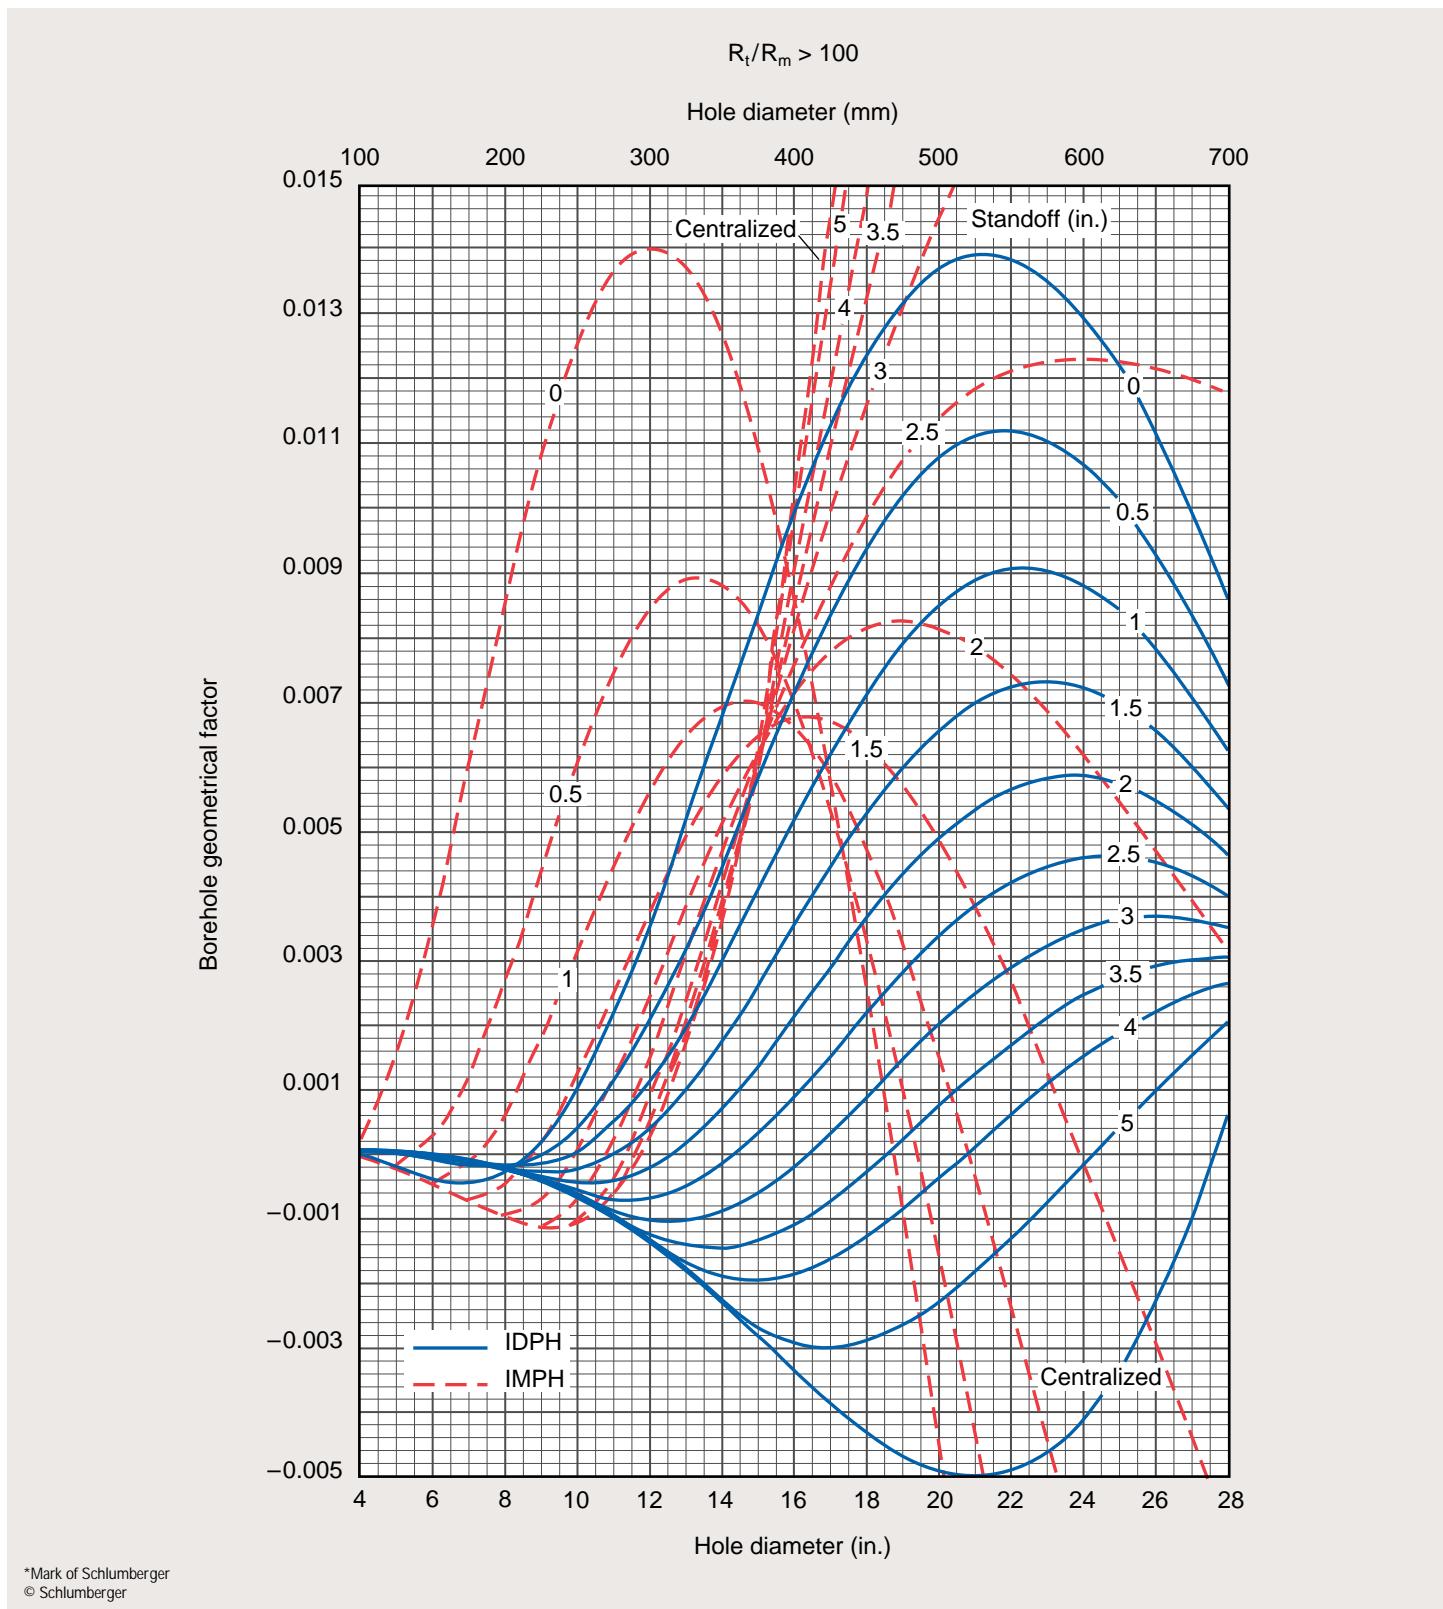

All Phasor Induction borehole corrections are applicable to ERL\* Enhanced Resolution Logging and ERA\* Enhanced Resolution Analysis presentations.

Borehole corrections for the Phasor Induction tool are usually made in real time. These charts provide only approximate corrections for specific cases of  $R_t/R_m$  and unique hole diameters. Any discrepancy between real-time (or Data Services Center) and manual chart-based corrections should normally be resolved in favor of the real-time corrections.

\*Mark of Schlumberger

## Phasor\* Induction Borehole Correction

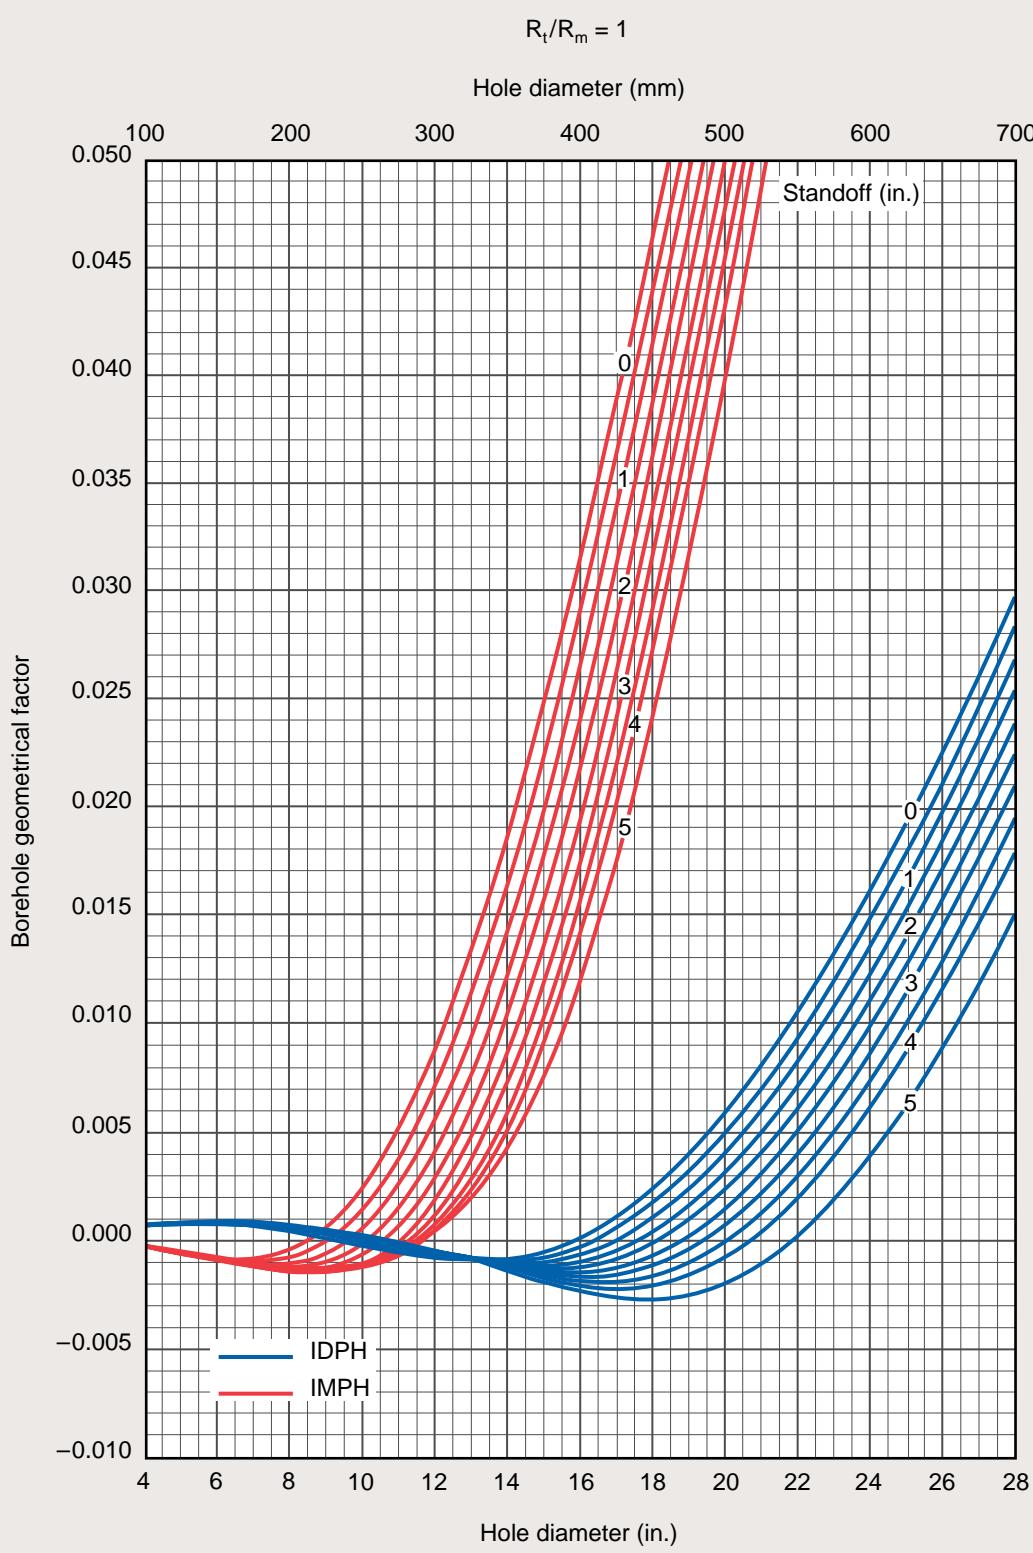

Rcor-4b

The borehole geometrical factor obtained from this chart or Chart Rcor-4c can be inserted into Nomograph Rcor-4a with the mud resistivity ( $R_m$ ) to determine the hole signal (in mS/m).

## Phasor\* Induction Borehole Correction

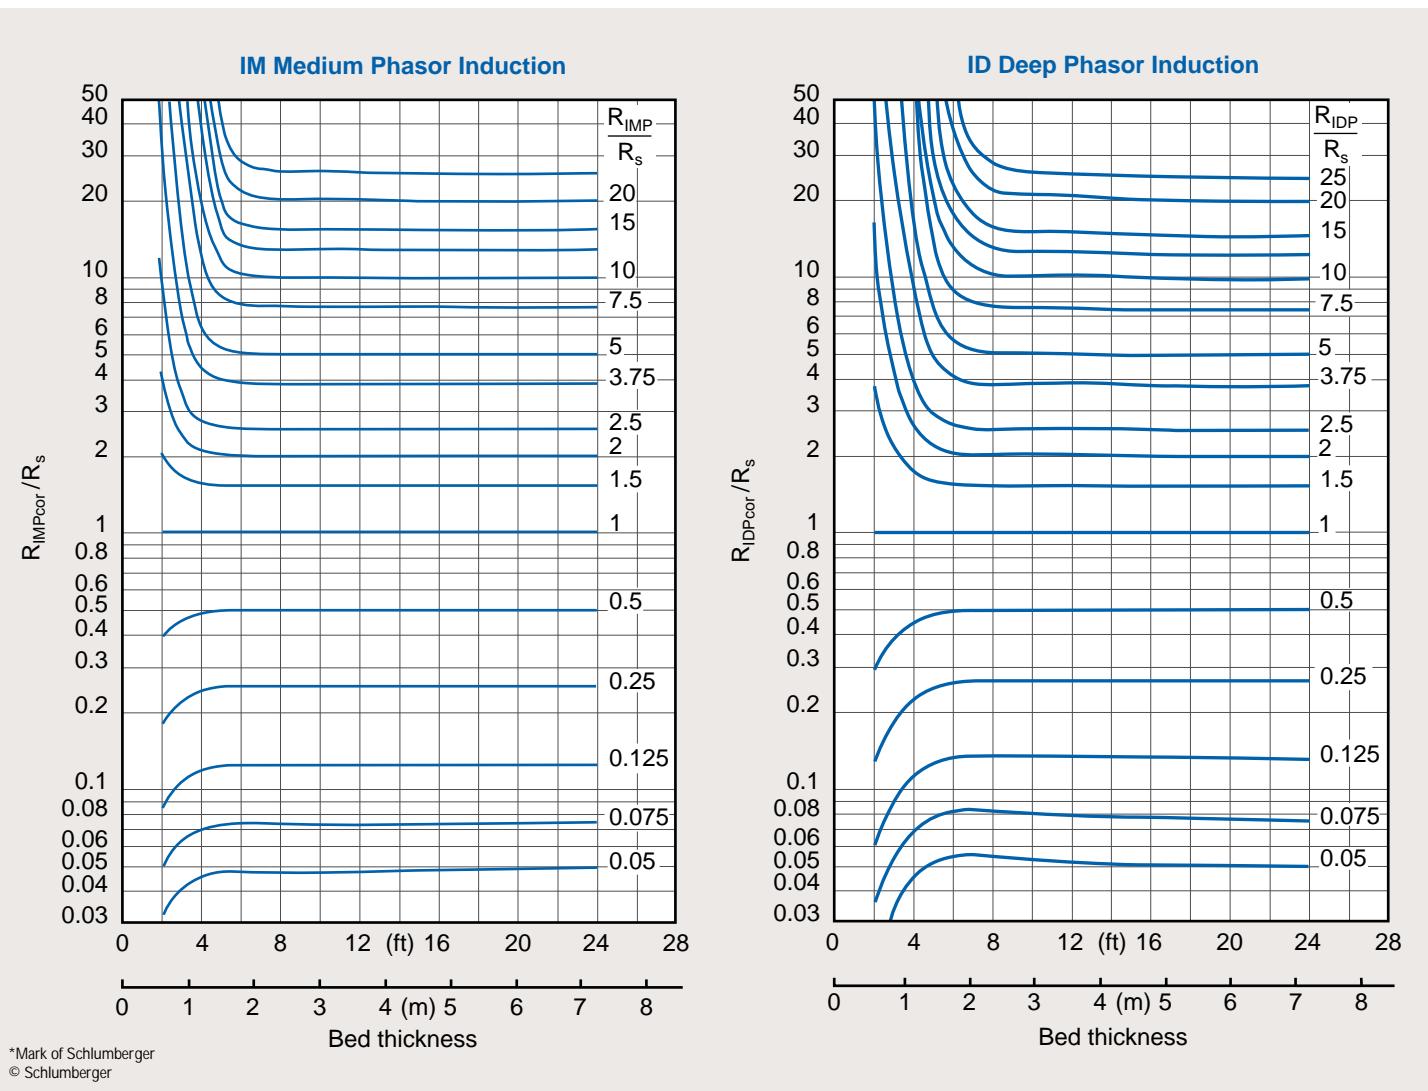

Rcor-4c

## Phasor\* Induction Bed-Thickness Correction

DIT-E Phasor Dual Induction-SFL

Rcor-9

These charts (Rcor-9) correct the DIT-E Phasor Induction (IM and ID) measurements for bed thickness.

To use, enter the appropriate chart with the ratio of the apparent resistivity ( $R_{IMP}$  or  $R_{IDP}$ ) divided by the adjacent bed resistivity ( $R_s$ ) and the bed thickness. At this resulting intersection, the ratio of the corrected resistivity to the adjacent bed resistivity is read on the ordinate.

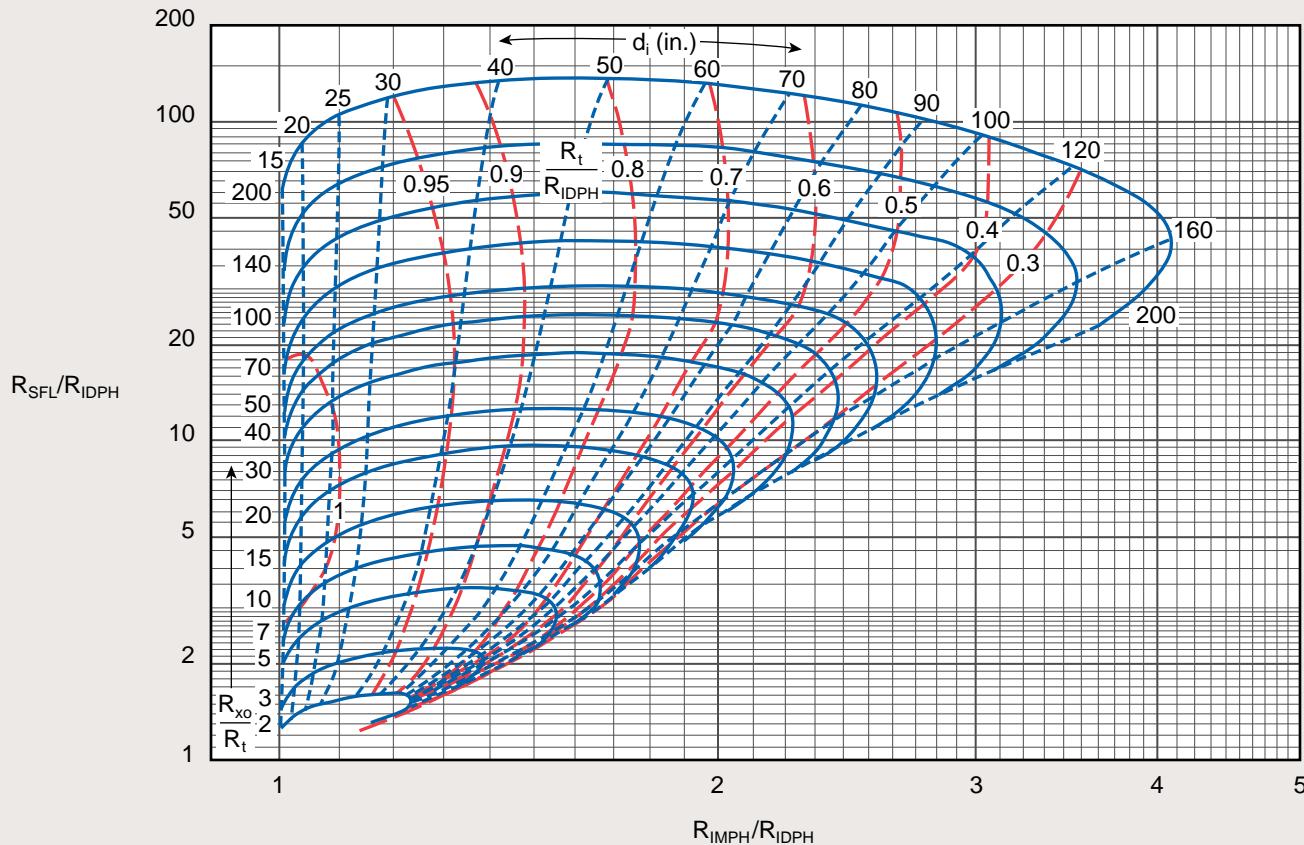

*Example:*  $R_{IDP} = 7.5 \text{ ohm-m}$   
 $R_{IMP} = 6 \text{ ohm-m}$   
 $R_s = 2 \text{ ohm-m}$   
 $\text{Bed thickness} = 6 \text{ ft}$   
giving  $R_{IDP}/R_s = 7.5/2 = 3.75$   
 $R_{IMP}/R_s = 6/2 = 3$   
Therefore,  $R_{IDPcor}/R_s = 4$   
 $R_{IMPcor}/R_s = 3.1$   
and  $R_{IDPcor} = 8 \text{ ohm-m}$   
 $R_{IMPcor} = 6 \text{ ohm-m}$

 $R_{IDP} < 10 \text{ ohm-m}$ , DIT-E or equivalent, frequency = 20 kHz

\*Mark of Schlumberger  
 © Schlumberger

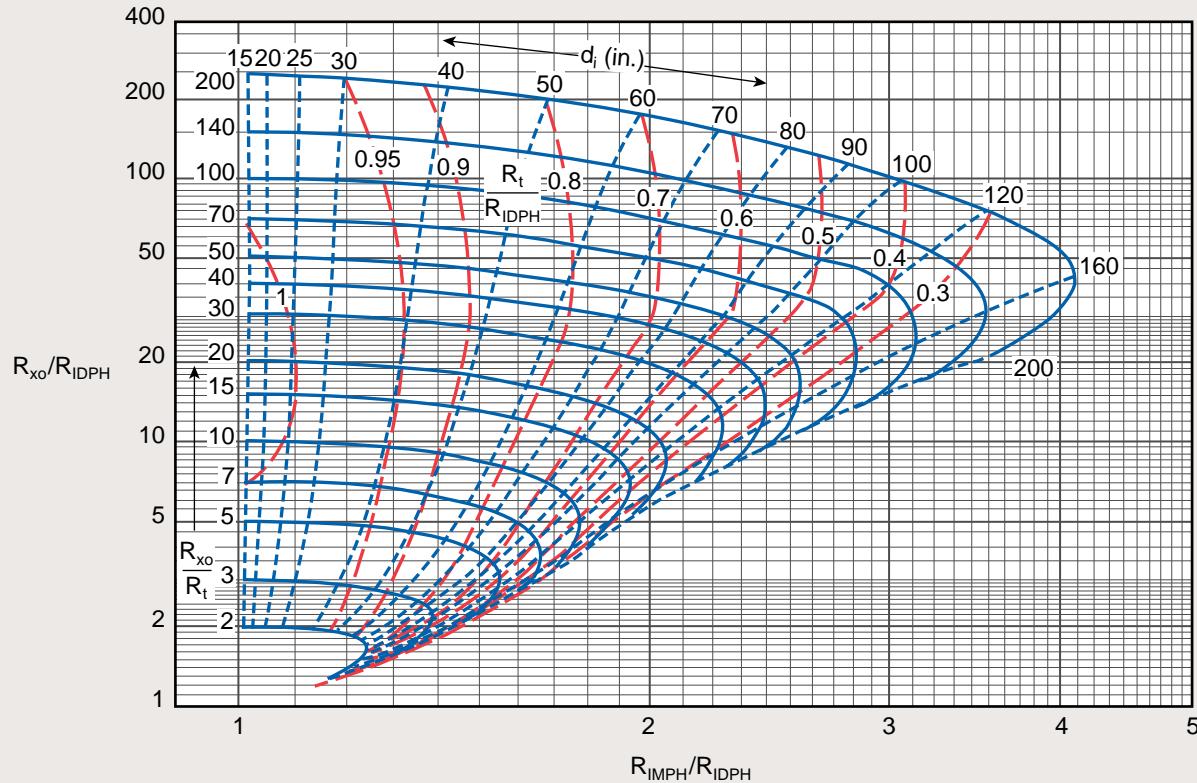

This chart uses the raw, unboosted induction signals and the ID Phasor value to define the invasion profile in a rock drilled with oil-base mud. To use the chart, the ratio of the raw, unboosted medium induction signal (IIM) and the deep Phasor induction (IDP) is entered in abscissa. The ratio of the raw, unboosted deep induction signal (IID) and the deep Phasor induction (IDP) is entered in ordinate. Their intersection defines  $d_i$ ,  $R_{xo}/R_t$  and  $R_t/R_{IDP}$ .

*Example:*  $R_{IDP} = 1.6 \text{ ohm-m}$   
 $R_{IID} = 2.4 \text{ ohm-m}$   
 $R_{IIM} = 2.4 \text{ ohm-m}$   
 giving  $R_{IID}/R_{IDP} = 2.4/1.6 = 1.5$   
 $R_{IIM}/R_{IDP} = 2.4/1.6 = 1.5$   
 Therefore,  $d_i = 50 \text{ in.}$   
 $R_{xo}/R_t = 15$   
 $R_t/R_{IDP} = 0.94$   
 $R_t = 0.94 (1.6) = 1.5 \text{ ohm-m}$

## Rcor

Chart Rcor-15 demonstrates the relative size of the borehole corrections for RAB measurements as a function of mud resistivity. This chart is for illustration purposes only. Borehole corrections

are dependant upon the bottomhole assembly and are normally applied in the software. This example was generated for a RAB tool running behind a 12-in. bit.

## Saturation Determination

Sw-1

© Schlumberger

This nomograph solves the Archie water saturation equation

$$S_w = \sqrt{\frac{R_0}{R_t}} = \sqrt{\frac{F_R R_w}{R_t}}$$

It should be used in clean (nonshaly) formations only. If  $R_0$  (resistivity when 100% water saturated) is known, a straight line from the known  $R_0$  value through the measured  $R_t$  value gives water saturation,  $S_w$ . If  $R_0$  is unknown, it may be determined by

connecting the formation water resistivity,  $R_w$ , with the formation resistivity factor,  $F_R$ , or porosity,  $\phi$ .

**Example:**  $R_w = 0.05$  ohm-m at formation temperature  
 $\phi = 20\%$  ( $F_R = 25$ )

$$R_t = 10 \text{ ohm-m}$$

$$\text{Therefore, } S_w = 35\%$$

For other  $\phi/F$  relations, the porosity scale should be changed according to Chart Por-1.

## Saturation Determination

Ratio method

Chart Sw-2 (next page) is used to determine water saturation in shaly or clean formations when knowledge of porosity is unavailable. It may also be used to verify the water saturation determination from another interpretation method. The main chart assumes

$$S_{xo} = \sqrt[5]{S_w}$$

however, the small chart to the right provides an  $S_{xo}$  correction when  $S_{xo}$  is known. Note, too, that the SP portion of the chart does not provide for any water activity (Chart SP-2) correction.

For clean sands, plot the ratio  $R_{xo}/R_t$  against  $R_{mf}/R_w$  to find water saturation at average residual oil saturation. If  $R_{mf}/R_w$  is unknown, the chart may be entered with the SP value and the formation temperature. If  $S_{xo}$  is known, proceed diagonally upward, parallel to the constant  $S_{wa}$  lines, to the edge of the chart. Then, go horizontally to the known  $S_{xo}$  (or  $S_{or}$ ) value to obtain the corrected water saturation  $S_w$ .

*Example:*  $R_{xo} = 12 \text{ ohm-m}$

$R_t = 2 \text{ ohm-m}$

$R_{mf}/R_w = 20$

$S_{or} = 20\%$

Therefore,  $S_w = 43\%$  (after ROS correction)

In shaly sands, plot  $R_{xo}/R_t$  against  $E_{pSP}$  (the SP in the shaly sand). This point gives an apparent water saturation. Draw a line from the chart's origin (the small circle located at  $R_{xo}/R_t = R_{mf}/R_m = 1$ ) through this point. Extend this line to intersect with the value of  $E_{SSP}$  to obtain a value of  $R_{xo}/R_t$  corrected for shaliness. Plot this value of  $R_{xo}/R_t$  versus  $R_{mf}/R_w$  to find  $S_w$ . If  $R_{mf}/R_w$  is unknown, the point defined by  $R_{xo}/R_t$  and  $E_{SSP}$  is a reasonable approximation of  $S_w$ . Use the diagram at right to further refine  $S_w$  if  $S_{or}$  is known.

*Example:*  $R_{xo}/R_t = 2.8$

$R_{mf}/R_w = 25$

$E_{pSP} = -75 \text{ mV}$

$E_{SSP} = -120 \text{ mV}$

$K = 80$  (formation temperature = 150°F)

Therefore,  $S_w = 38\%$

(If  $S_{or}$  were known to be 10%,  $S_w = 40\%$ )

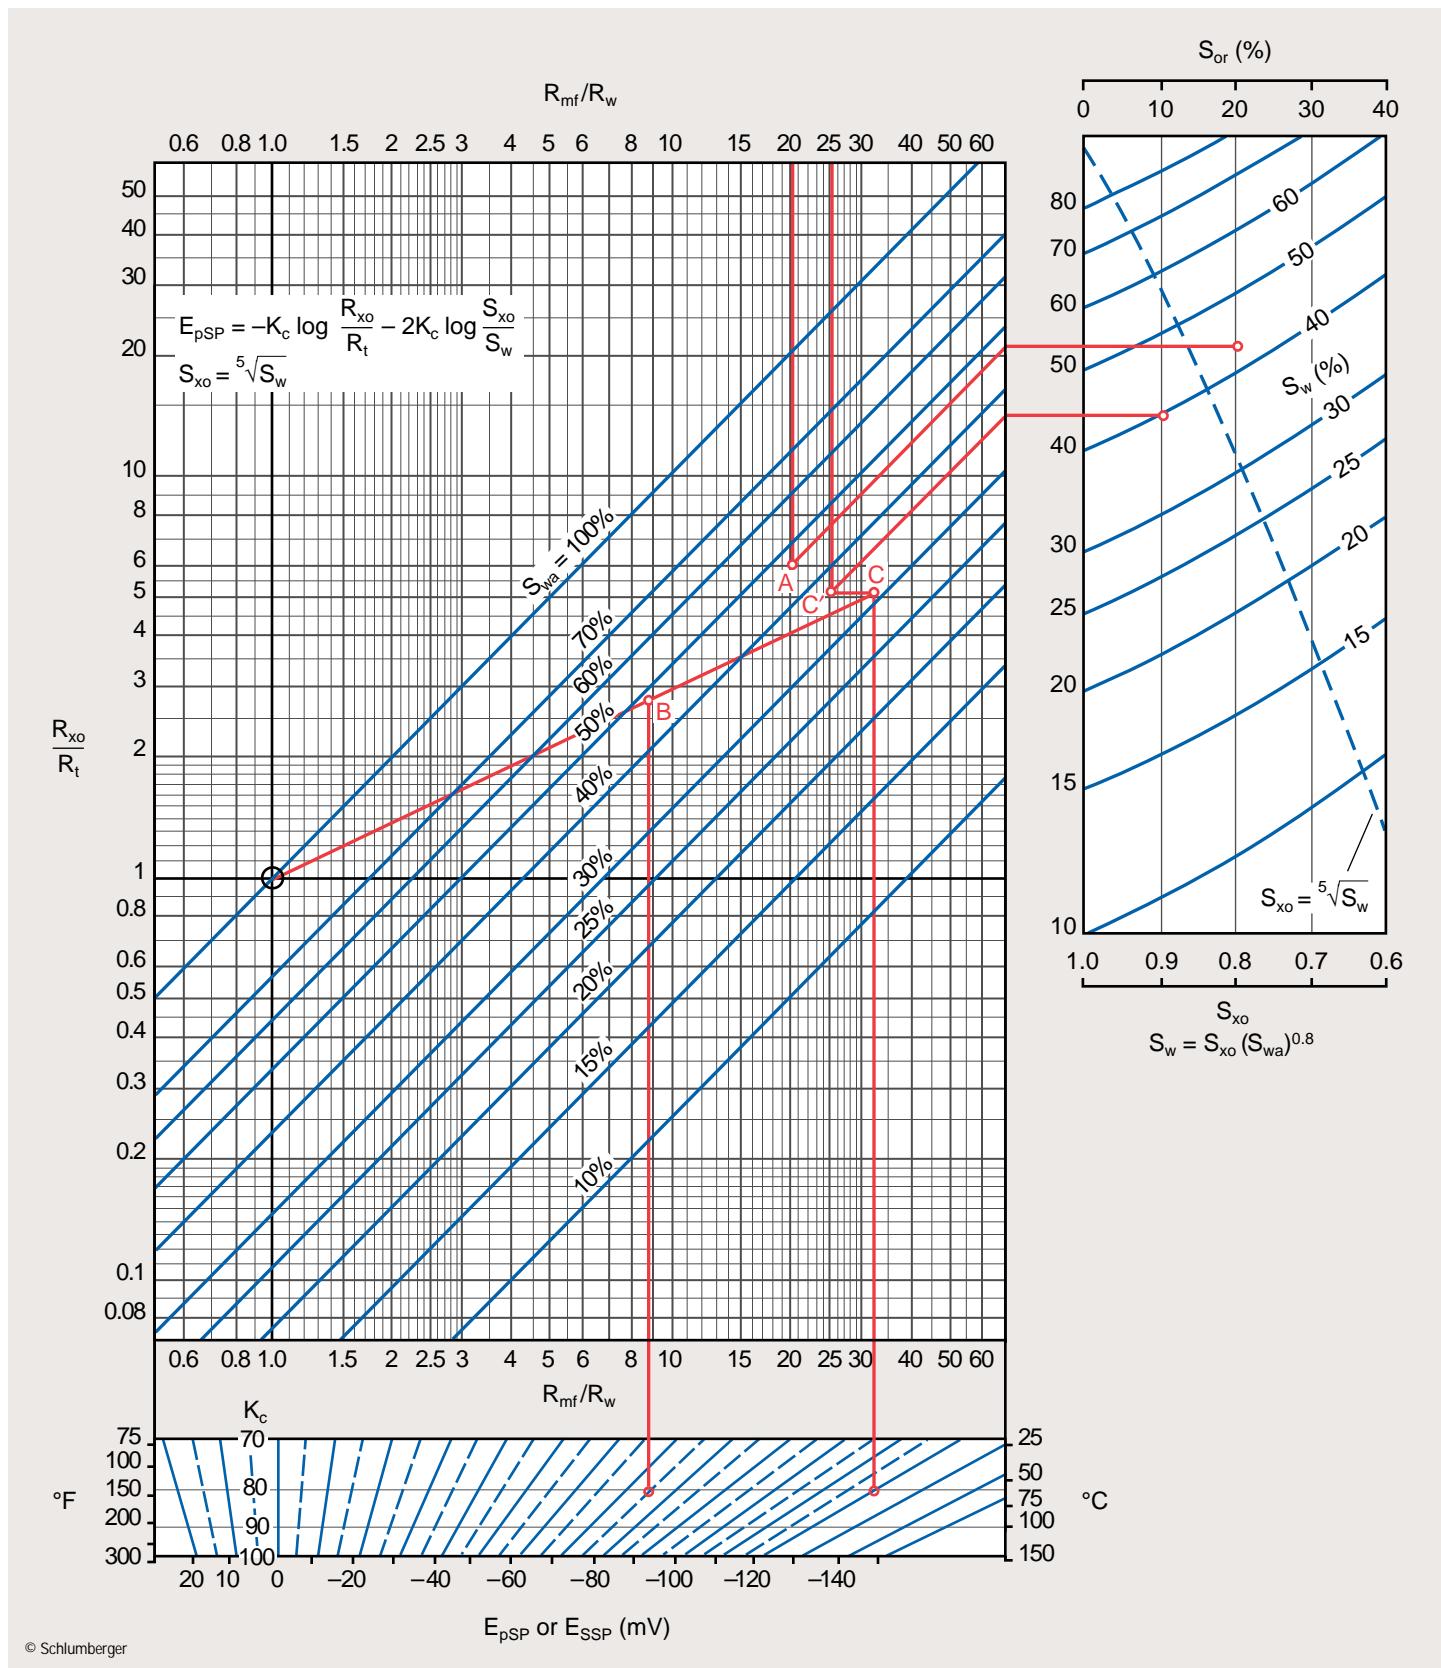

For more information see Reference 12.

Given: A reservoir section at 90°C temperature and 25-MPa pressure contains water of 175,000-ppm (NaCl) salinity, 30° API oil with a gas/oil ratio of 2000 ft<sup>3</sup>/bbl and methane gas.

Results:  $\Sigma_w = 87$  c.u.

$$\Sigma_o = 19 \text{ c.u.}$$

$$\Sigma_g = 6.9 \text{ c.u.}$$

Tcor

## Saturation Determination from TDT\* Thermal Decay Time Logs

Neutron capture cross section,  $\Sigma$ , is expressed in capture units (c.u.).  $\Sigma$  is related to thermal decay time,  $\tau$  (in  $\mu$ sec), by the formula  $\Sigma = 4550/\tau$ . A capture unit is equivalent to one-thousandth of a reciprocal centimeter ( $\text{cm}^{-1}$ ).

Matrix capture cross section,  $\Sigma_{\text{ma}}$ , varies over a small range for each lithology. Practical values, empirically determined, are somewhat larger than those calculated for the pure rock minerals. Average values commonly used are sandstone, 8 c.u.; dolomite, 9 c.u.; and limestone, 11 to 12 c.u.

$\Sigma_w$ , the capture cross section of the formation water, depends on the type and abundance of the elements in solution. The value of  $\Sigma_w$  corresponding to the NaCl concentration can be considered a minimum value; traces of certain elements in the water can increase  $\Sigma_w$  beyond the value indicated by the chemically equivalent concentration of NaCl.

For more information see Reference 11.

### Description and use of Chart Sw-12

If  $\Sigma_{\text{ma}}$ ,  $\Sigma_w$  and porosity are known, Chart Sw-12 may be used to determine water saturation. It may be used in shaly formations if porosity,  $\phi$ , and the fraction of shale in the formation,  $V_{\text{sh}}$ , are known.

### Clean formations

#### Information required:

$\Sigma_{\text{ma}}$	Matrix capture cross section, based on lithology
$\phi$	Porosity
$\Sigma_w$	From NaCl salinity; see Tcor-2a or Tcor-2b
$\Sigma_h$	See Tcor-1

#### Procedure:

Enter the value of  $\Sigma_{\text{ma}}$  on Bar **B**; draw Matrix Line **a** from  $\Sigma_{\text{ma}}$  to Pivot Point **B**. Enter  $\Sigma_{\text{LOG}}$  on Bar **B**; draw Line **b** through the intersection of Line **a** and the value of  $\phi$  to  $\Sigma_f$  on Bar **C**. Draw Line **5** from  $\Sigma_f$  through the intersection of  $\Sigma_h$  and  $\Sigma_w$  to the value of  $S_w$ .

#### Example:

Given:  $\Sigma_{\text{LOG}} = 20$  c.u.

$\Sigma_{\text{ma}} = 8$  c.u. (sandstone)

$\Sigma_h = 21$  c.u. (oil)

$\Sigma_w = 80$  c.u. (150,000 ppm or mg/kg)

$\phi = 30$  p.u.

Solution:  $S_w = 43\%$

### Shaly formations

#### Information required:

$\Sigma_{\text{ma}}$	Based on lithology
$\Sigma_{\text{sh}}$	Read from TDT log in adjacent shale
$\Sigma_w$	From NaCl salinity; see Tcor-2a or Tcor-2b
$\Sigma_h$	See Tcor-1
$V_{\text{sh}}$	From porosity-log crossplot or gamma ray
$\phi_{\text{sh}}$	Read from porosity log in adjacent shale
$\phi$	From porosity log, corrected for shaliness; for neutron and density logs in liquid-filled formations, $\phi = \phi_{\text{LOG}} - V_{\text{sh}} \phi_{\text{sh}}$

#### Procedure:

Enter the value of  $\Sigma_{\text{ma}}$  on Bar **B**; connect with Pivot Point **A** (Line 1). From the value of  $\Sigma_{\text{sh}}$  on Bar **A**, draw Line 2 through the intersection of Line 1 and  $V_{\text{sh}}$  to determine  $\Sigma_{\text{cor}}$ . Draw Line 3 from  $\Sigma_{\text{cor}}$  to the value of  $\Sigma_{\text{ma}}$  on the scale at left of Bar **C**. Enter  $\Sigma_{\text{LOG}}$  on Bar **B**; draw Line 4 through the intersection of Line 3 and  $\phi$  to  $\Sigma_f$ . From  $\Sigma_f$  draw Line 5 through  $\Sigma_h$  and  $\Sigma_w$  to  $S_w$ .

#### Example:

Given:  $\Sigma_{\text{LOG}} = 25$  c.u.

$\Sigma_{\text{ma}} = 8$  c.u.

$\Sigma_h = 21$  c.u.

$\Sigma_w = 80$  c.u.

$\Sigma_{\text{sh}} = 45$  c.u.

$\text{LOG} = 33$  p.u.

$\phi_{\text{sh}} = 45$  p.u.

$V_{\text{sh}} = 20\%$

$\phi = \phi_{\text{LOG}} - V_{\text{sh}} \phi_{\text{sh}}$

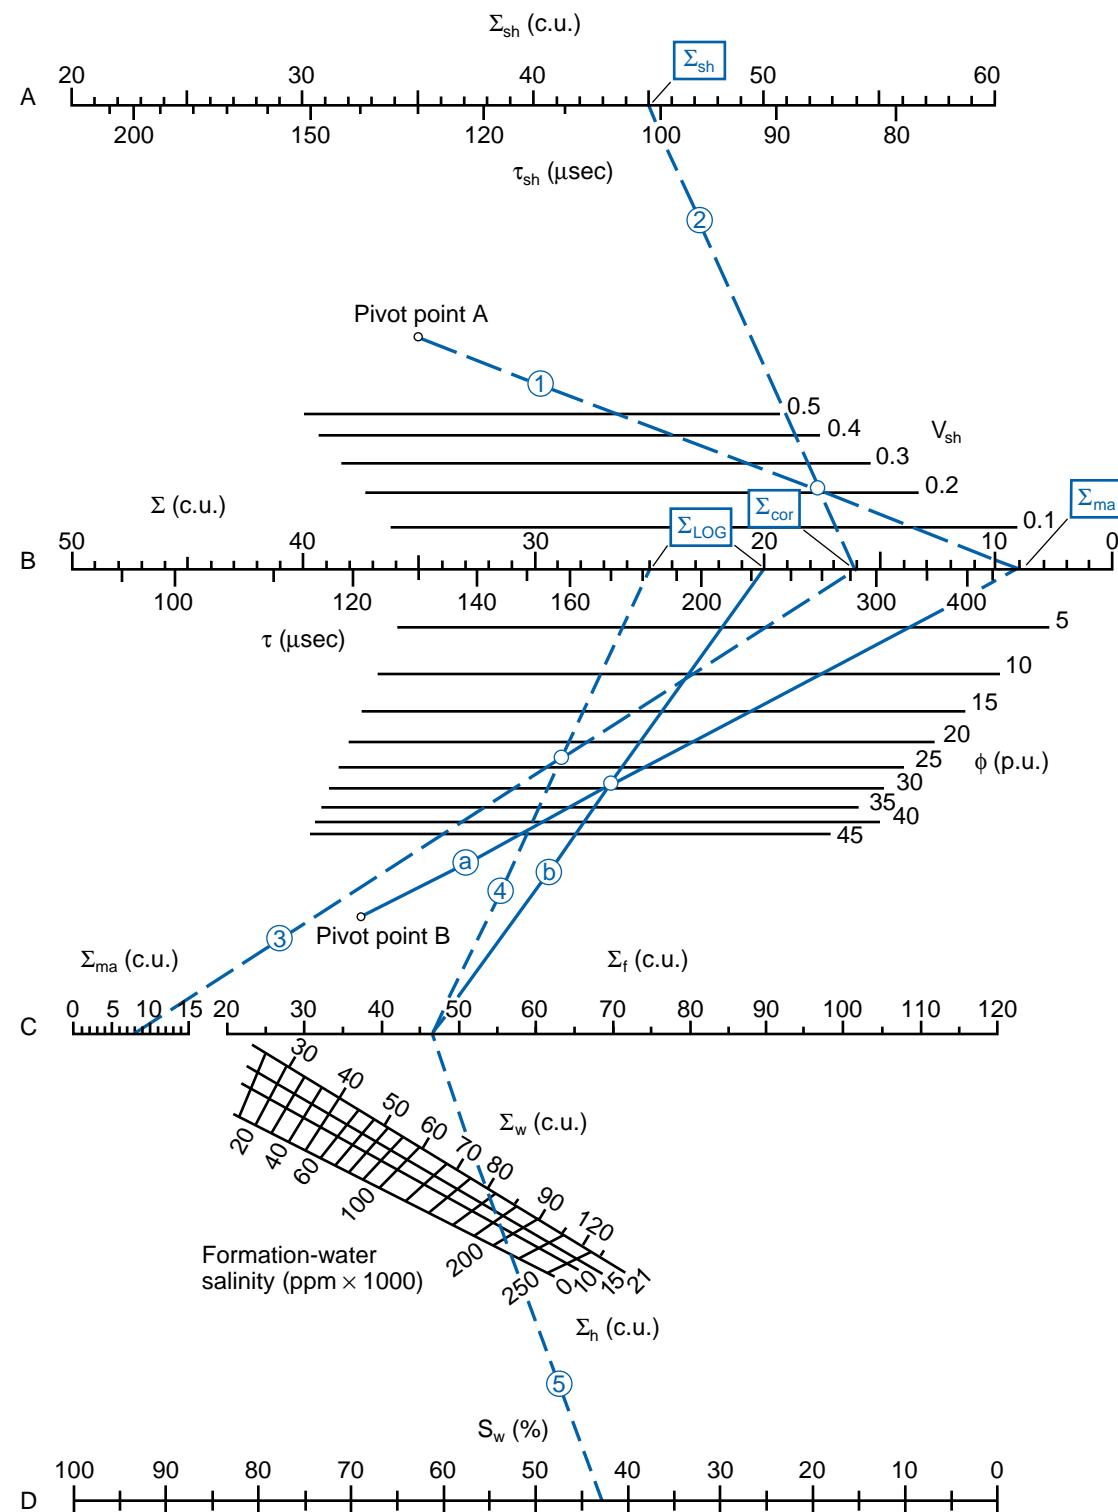

$\phi = 24$  p.u.

Solution:  $S_w = 43\%$

# $S_w$ Determination from TDT\* Thermal Decay Time Log

Sw-12

## Graphical Determination of Total Water Saturation ( $S_{wt}$ ) from TDT\* Thermal Decay Time Data

Grid Sw-17 can be used for graphical interpretation of the TDT Thermal Decay Time log. In one technique, applicable in shaly as well as clean sands, apparent water capture cross section,  $\Sigma_{wa}$ , is plotted versus bound water saturation on a specially constructed grid.

To construct this grid, refer to the chart on this page. Three fluid points must be located: a free water point, a hydrocarbon point and a bound water point. The free (or connate/formation) water point is located on the left edge of the grid and can be obtained from measurement of a formation water sample, from Chart Tcor-2 if water salinity is known, or from the TDT log in a clean water-bearing sand using the following equation:

$$\Sigma_{wa} = \frac{\Sigma_{log} - \Sigma_{ma}}{\phi} + \Sigma_{ma}. \quad (1)$$

The hydrocarbon point is also located on the left edge of the grid. It can be determined from Chart Tcor-1 based upon the known or expected hydrocarbon type.

The bound water point,  $\Sigma_{wb}$ , can be obtained from the TDT log in shale intervals using Eq. 1 above. It is located on the right edge of the grid.

The distance between the free water and hydrocarbon points is linearly divided into constant water saturation lines drawn parallel to a straight line connecting the free water and bound water points. The  $S_{wt} = 0\%$  line originates from the hydrocarbon point, and the  $S_{wt} = 100\%$  line originates from the free water point.

Apparent water capture cross section,  $\Sigma_{wa}$ , from Eq. 1, is then plotted versus bound water saturation,  $S_{wb}$ , to give the total water saturation. Bound water saturation can be estimated from the gamma ray or other bound water saturation estimator.

Knowing the total water saturation and the bound water saturation, the effective water saturation (water saturation of reservoir rock exclusive of shale) can be determined using Chart Sw-14.

### *Example (see chart on this page):*

Free water point = 61 c.u.

(from TDT log in a water-bearing clean sand—Eq. 1, Chart Tcor-2 or measurement of a water sample)

Hydrocarbon point = 21 c.u.

(medium-gravity oil with modest gas/oil ratio—Chart Tcor-1)

Bound water point = 76 c.u.

(from TDT log in a shale interval—Eq. 1)

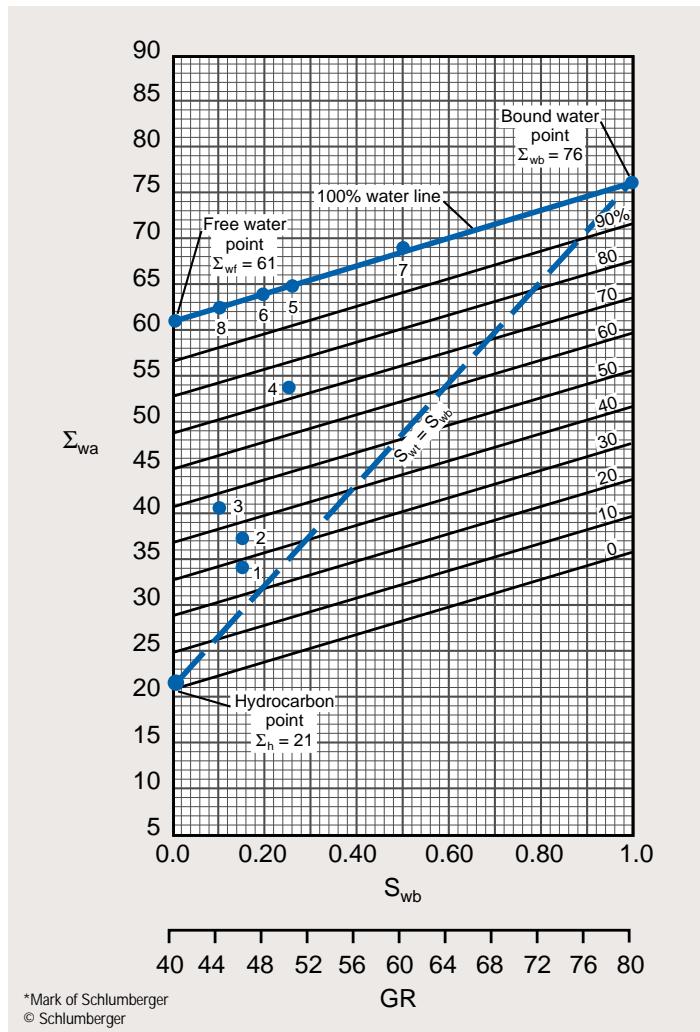

### Analysis of Point 4:

$\Sigma_{wa} = 54$  c.u. (from Eq. 1)

$S_{wb} = 25\%$  (from gamma ray)

Therefore,  $S_{wt} = 72\%$

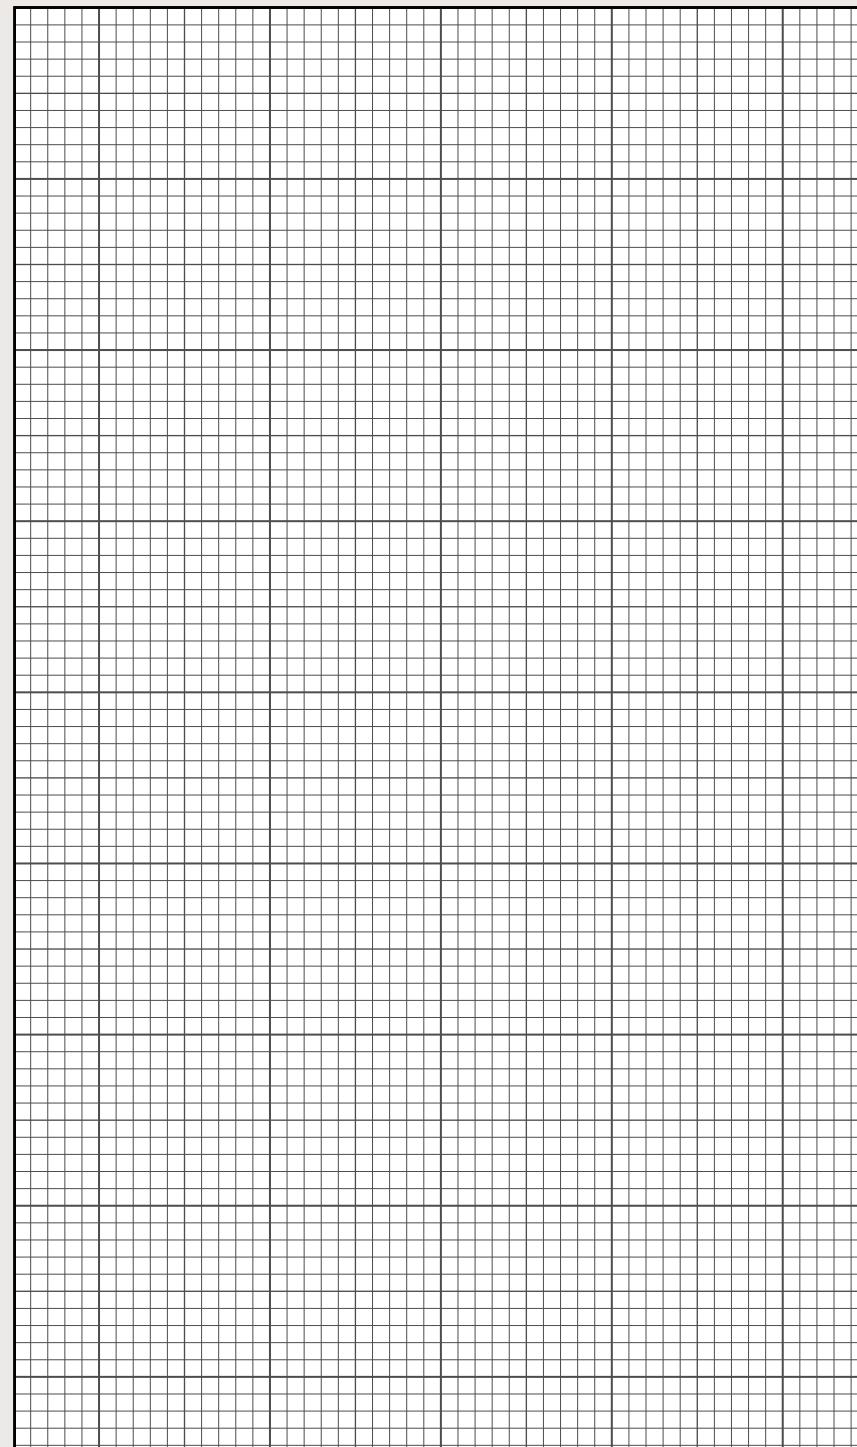

and  $S_w = 63\%$  (from Chart Sw-14)

The grid can also be used to graphically determine water saturation,  $S_w$ , in clean formations by crossplotting  $\Sigma_{LOG}$  in ordinate versus porosity,  $\phi$ , in abscissa. The matrix capture cross section,  $\Sigma_{ma}$ , and the formation water capture cross section,  $\Sigma_w$ , need not be known but must be constant over the interval studied. There must be some points from 100% water zones, and there must be a good variation in porosity. These water points define the  $S_w = 100\%$  line; when extrapolated, this line intersects the zero-porosity axis at  $\Sigma_{ma}$ . The  $S_w = 0\%$  line is drawn from  $\Sigma_{ma}$  at  $\phi = 0$  p.u. to  $\Sigma = \Sigma_h$  at  $\phi = 100$  p.u. [or  $\Sigma = \frac{1}{2}(\Sigma_{ma} + \Sigma_h)$  at  $\phi = 50$  p.u.]. The vertical distance from  $S_w = 0\%$  to  $S_w = 100\%$  is divided linearly to define lines of constant water saturation. The water saturation of any plotted point can thereby be determined.

## Saturation Determination from GST\* Induced Gamma Ray Spectrometry Log

GST-1

8-in. borehole, 5½-in. water-filled casing

\*Mark of Schlumberger  
© Schlumberger

These charts permit the determination of water saturation from carbon/oxygen (C/O) ratio measurements made with the GST Induced Gamma Ray Spectrometry Tool in inelastic mode operation.

To use, the C/O ratio and the porosity,  $\phi$ , are entered in

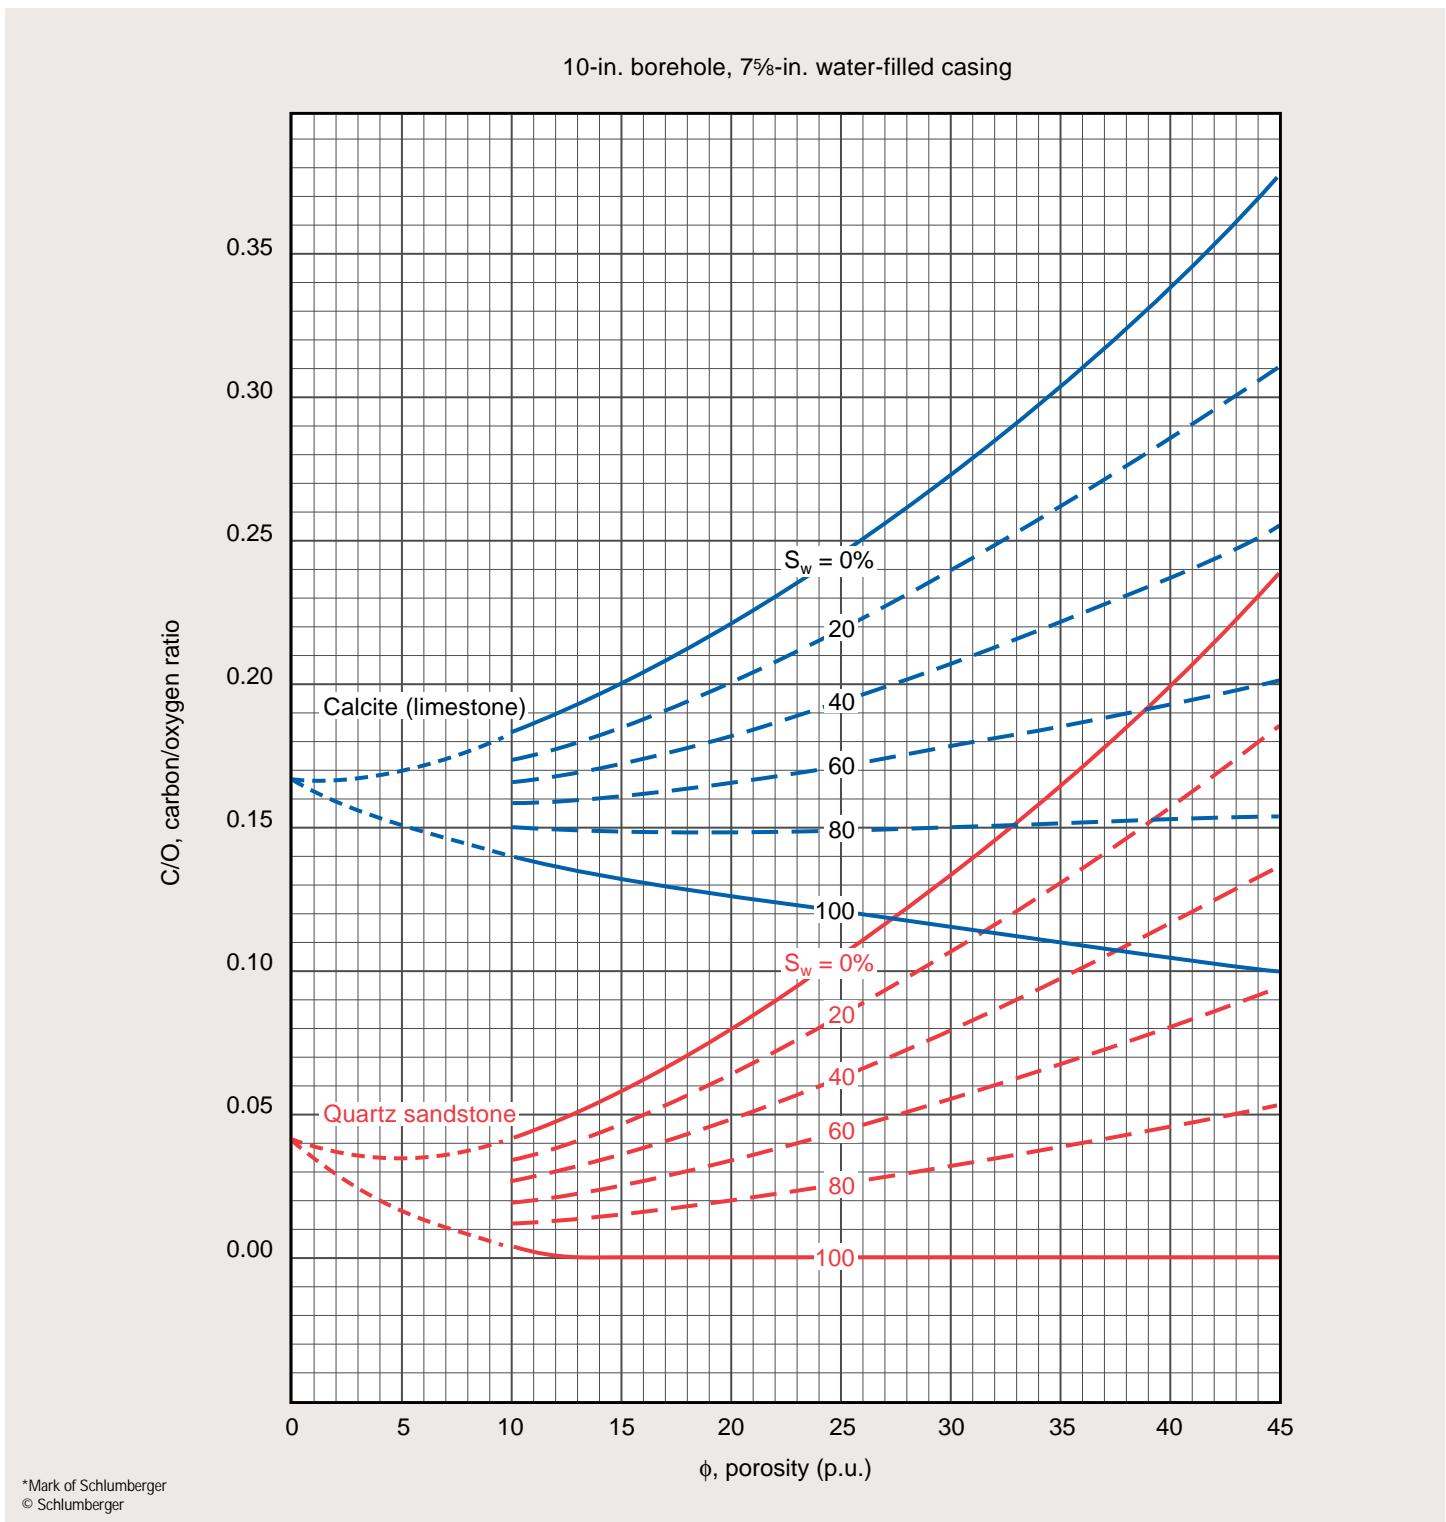

ordinate and abscissa, respectively, on the appropriate chart (dependent upon borehole and casing size). Water saturation is defined by the location of the plotted point within the appropriate matrix "fan chart."

*Continued on next page*

GST

# Saturation Determination from GST\* Induced Gamma Ray Spectrometry Log

GST-2

*Example:* 5 $\frac{1}{2}$ -in. water-filled casing cemented in 7 $\frac{1}{8}$ -in. borehole (use Chart GST-1)

Therefore,  $S_w = 30\%$

$C/O$  ratio = 0.10

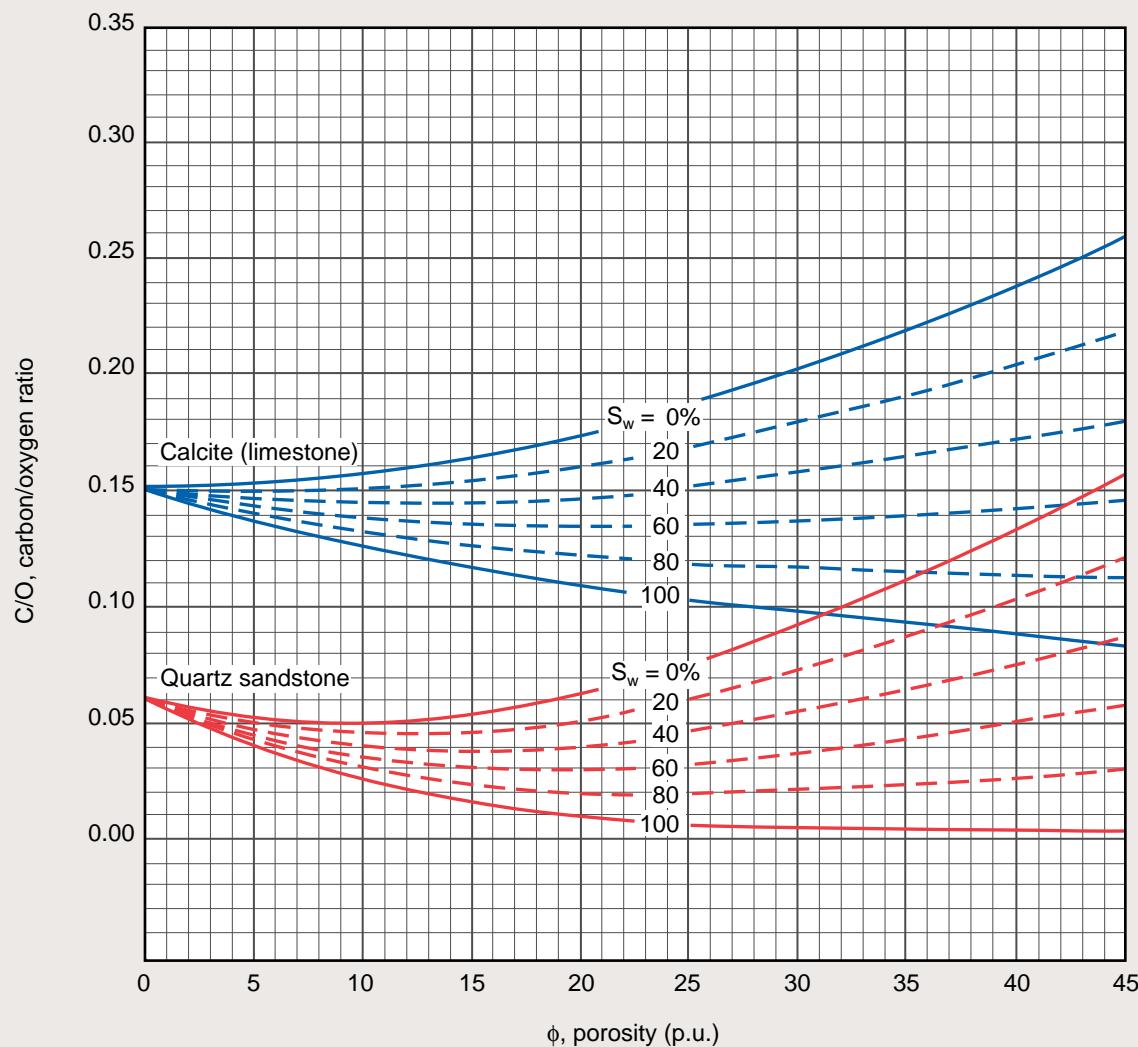

$\phi = 28$  p.u.

Lithology is quartz sandstone

# Saturation Determination from GST\* Induced Gamma Ray Spectrometry Log

GST-5

GST

# Apparent Water Salinity Determination from GST\* Induced Gamma Ray Spectrometry Log

GST-3

Inelastic mode

Charts GST-3 and GST-4 permit the determination of an apparent water salinity from the chlorine-hydrogen ratio (Cl/H) as recorded with the GST Induced Gamma Ray Spectrometry Tool. Two sets of charts are presented. Chart GST-3 applies when the GST tool is operated in inelastic mode; Chart GST-4 applies when the tool is operated in capture-tau mode.

To use, enter the chlorine-hydrogen (Cl/H) ratio into the chart that most nearly matches the borehole and casing size conditions and matches the tool operating mode. Proceed upward to the appropriate combination of borehole fluid salinity and formation porosity conditions. Interpolation between curves may be necessary. The apparent water salinity is given in ordinate.

The apparent water salinity value can then be compared to the known connate water salinity to provide water saturation in clean formations.

*Example:* Cl/H ratio = 5

$$\phi = 30\%$$

Borehole fluid salinity  $\approx 25,000$  ppm

5 ½-in. casing in a 7 5/8-in. borehole

Tool operating in capture-tau mode

From Chart GST-4,

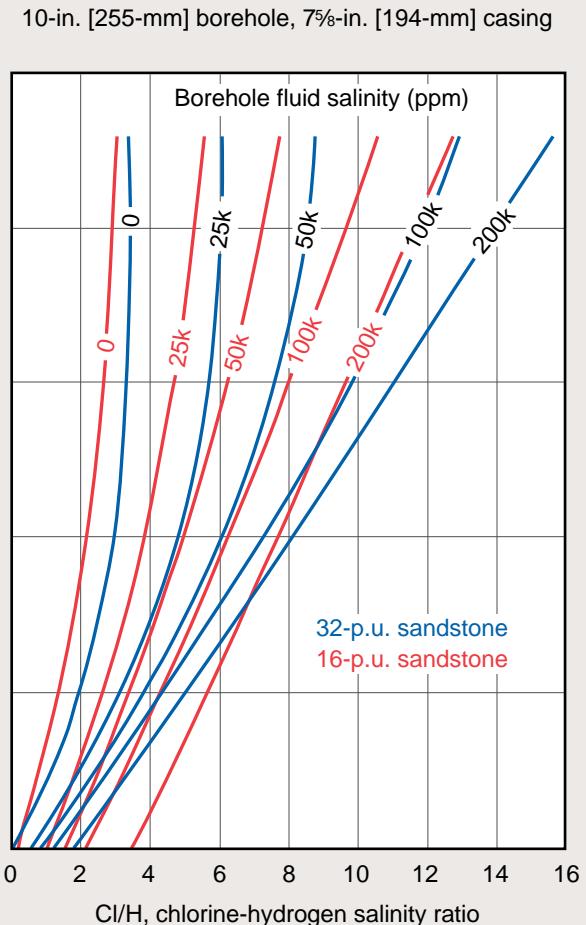

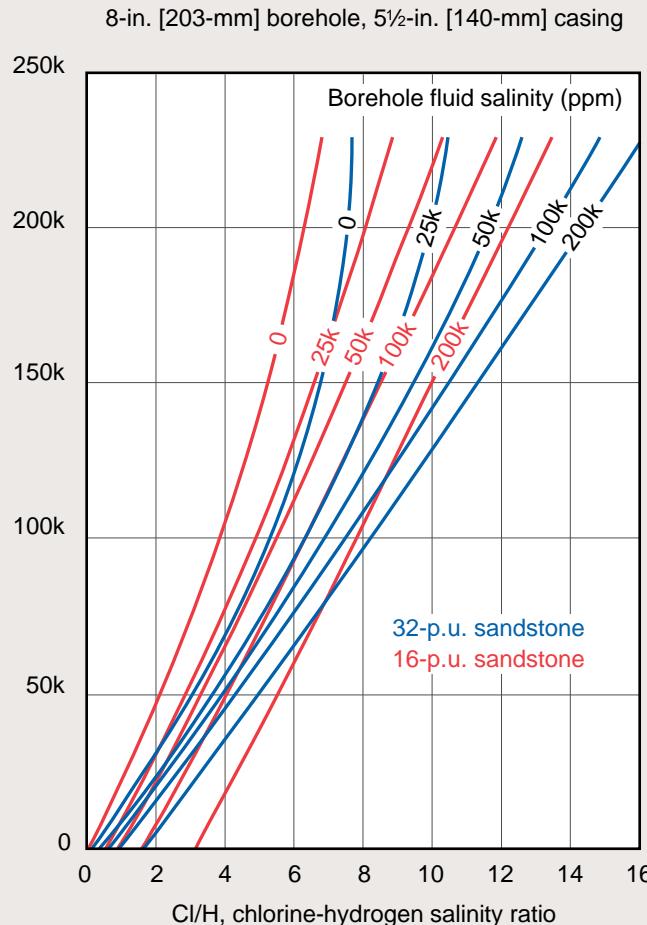

$$\text{Apparent water salinity} = 80,000 \text{ ppm}$$

If the connate water salinity were 200,000 ppm, water saturation would be 40% ( $S_w = 80,000/200,000$ ).

WW: water in borehole, water in formation  
OW: oil in borehole, water in formation  
OO: oil in borehole, oil in formation  
WO: water in borehole, oil in formation

\*Mark of Schlumberger  
© Schlumberger

Charts RST-1, -2 and -3, drawn for specific cased hole and openhole cases, help to ensure that the measured near-detector and far-detector carbon/oxygen ratio data are consistent with the interpretation model. Known formation and borehole data define the expected values of carbon/oxygen ratio for each detector using water saturation and borehole holdup values ranging from 0 to 1. All log data for levels with porosity greater than 10 p.u. should lie within the trapezoidal area bounded by the limits on oil saturation, S<sub>o</sub>, and oil holdup, y<sub>o</sub>. If data fall consistently outside the trapezoid, the interpretation model may require revision.

Each set of near-detector and far-detector carbon/oxygen ratios represents a formation oil saturation and a borehole oil holdup. Oil saturation and oil holdup can be estimated for each level by interpolation within the trapezoid.

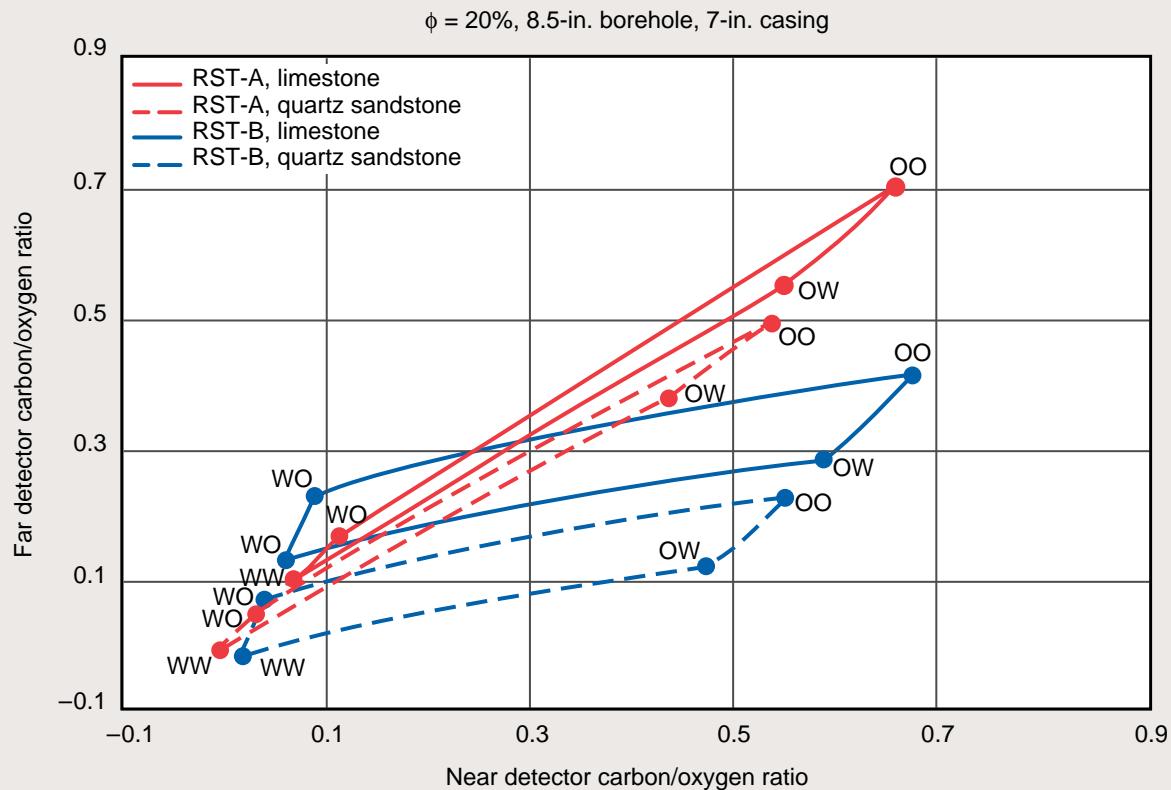

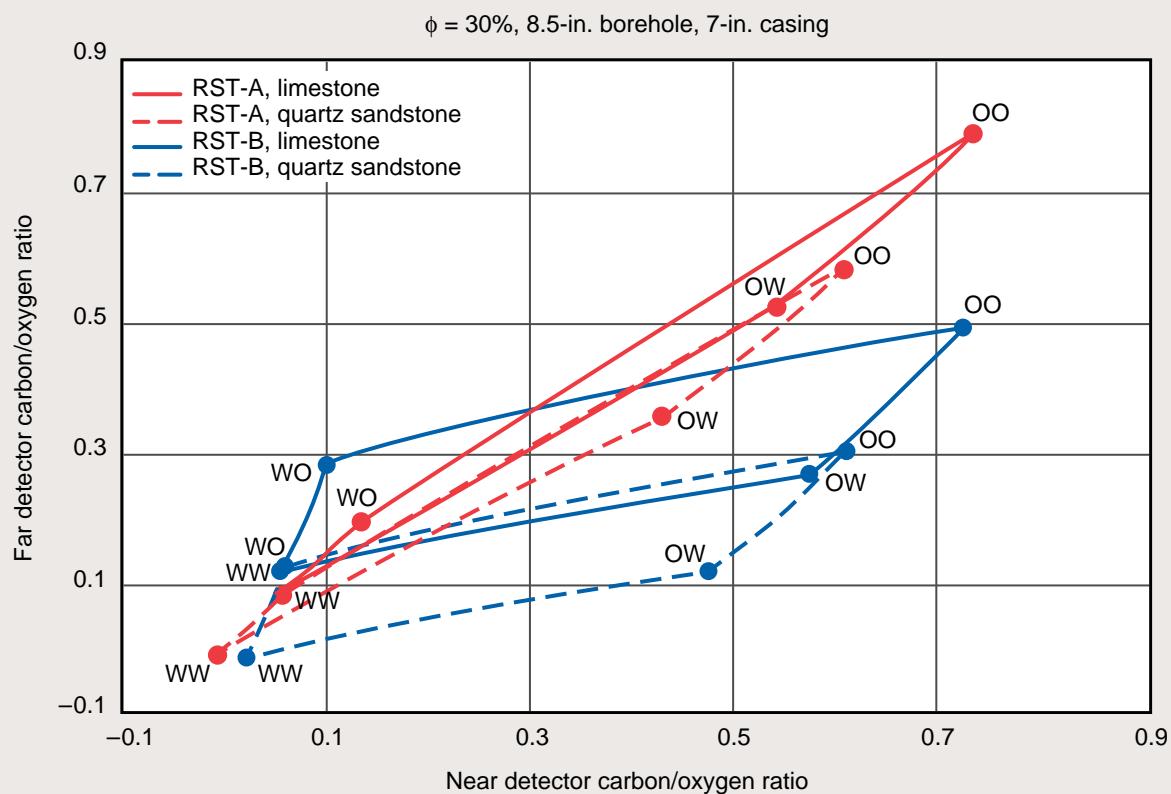

Additional trapezoid charts can be constructed for alternative casing and borehole sizes.

## CBL Interpretation—Casing Data

The compressive strength of bonded cement (either standard or foamed) can be estimated from the CBL amplitude recording using Chart M-1.

Enter the nomograph with the CBL amplitude in mV; then follow diagonal lines to the appropriate casing size. This defines signal attenuation. Connect this value with the casing thickness to estimate the compressive strength of the cement.

*Example:* CBL amplitude = 3.5 mV

Casing size = 7 in.

Casing thickness = 0.41 in. (7 in. 29 lbm)

Cement is standard

Therefore, Signal attenuation = 8.9 dB/ft or 29.2 dB/m  
and Compressive strength = 2100 psi or 14.5 mPa

<sup>†</sup> One atmosphere (standard) = 76 cm of mercury at 0°C

<sup>‡</sup> Bar

<sup>§</sup> To convert height  $h$  of a column of mercury at  $t^\circ\text{C}$  to the equivalent height  $h_0$  at 0°C, use  $h_0 = h \{1 - [(m - l)t / 1 + mt]\}$ , where  $m = 0.0001818$  and  $l = 18.4 \times 10^{-6}$  if the scale is engraved on brass;  $l = 8.5 \times 10^{-6}$  if on glass. This assumes the scale is correct at 0°C; for other cases (any liquid) see *International Critical Tables*, Vol. 1, 68.

<sup>††</sup> 1 gram per square centimeter = 10 kilograms per square meter

<sup>†††</sup> psi = MPa  $\times 145.038$   
psi/ft =  $0.433 \times \text{g/cm}^3 = \text{lb/ft}^3/144 = \text{lb/gal}/19.27$

b Reserve symbols are to be used only if conflict arises between standard symbols used in the same paper.

These unit abbreviations, which have been adopted by the Society for Petroleum Engineers (SPE), are appropriate for most publications. However, an accepted industry standard may be used instead. For instance, in the drilling field, *ppg* may be more common than *lbm/gal* when referring to pounds per gallon.

Unit abbreviations are followed by a period only when the abbreviation forms a word (for example, *in.* for *inch*).

acre .....	spell out
acre-foot .....	acre-ft
alternating-current (adj.) .....	AC
ampere.....	A
ampere-hour.....	amp-hr
angstrom unit ( $10^{-8}$ cm).....	A
