Minerals Yearbook

1976

Volume I

METALS, MINERALS, AND FUELS

Prepared by staff of the

BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR • Cecil D. Andrus, Secretary

BUREAU OF MINES • Roger A. Markle, Director

As the Nation's principal conservation agency, the Department of the Interior has basic responsibilities to protect and conserve our land and water, energy and minerals, fish and wildlife, and park and recreation areas, and for the wise use of all those resources. The Department also has a major responsibility for American Indian reservation communities and for the people who live in Island Territories under U.S. administration.

Foreword

The Federal Government, through the Minerals Yearbook and its predecessor volumes, has reported annually on mineral industry activities for 95 years. This edition discusses the performance of the worldwide mineral industry during 1976. In addition to statistical data, the volumes provide background information to assist in interpreting the year's developments. Content of the individual volumes follows:

Volume I, Metals, Minerals, and Fuels, contains chapters on virtually all metallic, nonmetallic, and mineral fuel commodities important to the domestic economy. In addition, it includes a general review chapter on the mineral industries, a chapter on mining and quarrying trends, and a statistical summary.

Volume II, Area Reports: Domestic, contains chapters on the mineral industry of each of the 50 States, the U.S. island possessions in the Pacific Ocean and the Caribbean Sea, and the Commonwealth of Puerto Rico. This volume also has a statistical summary, identical to that in Volume I.

Volume III, Area Reports: International, contains the latest available mineral data on more than 130 foreign countries and discusses the importance of minerals to the economies of these nations. A separate chapter reviews the international minerals industry in general and its relationship to the world economy.

The Bureau of Mines continually strives to improve the value of its publications to its users. Therefore, the constructive comments and suggestions of readers of the Yearbook will be welcomed.

Roger A. Markle, Director

Acknowledgments

Volume I, Metals, Minerals, and Fuels, of the Minerals Yearbook presents data on more than 90 mineral commodities that was obtained as a result of the mineral information gathering activities of the Associate Directorate—Mineral and Materials Supply/Demand Analysis.

The collection, compilation, and analysis of data on the domestic minerals and mineral fuel industries were performed by the staffs of the Divisions of Ferrous Metals, Nonferrous Metals, and Nonmetallic Minerals, Assistant Directorate—Metals, Minerals and Materials; the Divisions of Coal, Petroleum and Natural Gas, and Fuels Data, Assistant Directorate—Fuels (now in the Department of Energy); and the Division of Economic Analysis, Assistant Directorate—Interindustry and Economic Analysis. Statistical data were compiled from information supplied by mineral producers, processors, and users in response to production and consumption canvasses, and their voluntary response is gratefully appreciated. The information obtained from individual firms by means of confidential surveys has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonconfidential sources or when permission of the companies has been granted. Other material appearing in this volume was obtained from the trade and technical press, industry contacts, and numerous other sources.

Statistics on U.S. imports and exports, world production, and foreign country trade were compiled in the Office of Technical Data Services. U.S. foreign trade data were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. World production and international trade data came from numerous sources, including reports from the Foreign Service, U.S. Department of State.

The Office of Technical Data Services also provided general guidance on the preparation and coordination of the chapters in this volume and reviewed the manuscripts to insure statistical consistency among the tables, figures, and text, between this volume and other volumes, and between this edition and those of former years.

Acknowledgment is also particularly made of the splendid cooperation of the business press, trade associations, scientific journals, international organizations, and other Federal agencies that supplied information.

The Bureau of Mines has been assisted in collecting mine production data and supporting information by numerous cooperating State agencies. These organizations are listed in the acknowledgments to Volume II.

Albert E. Schreck, *Editor-in-Chief*

Review of the Mineral Industries

By Barry W. Klein,[1] David C. Huttenlock,[1] Mary Ann Good,[2] and Kenneth P. Hanks[1]

The U.S. economy was considerably stronger in 1976 than in 1974 or 1975. Real gross national product (GNP) rose sharply in the first quarter of 1976 and then increased at a more moderate rate for the remainder of the year. The unemployment rate fell until June and then increased for most of the remainder of the year, finishing at the same rate as it had started the year. The inflation rate continued to decline in 1976. Reasons for the relatively low rate (compared with those of 1974 and 1975) included small increases in food prices and only moderate increases in energy prices.

Total U.S. output measured in terms of GNP increased 11.6% in 1976. Real GNP in 1972 constant dollars rose 6.2%. Inflation as measured by the implicit price deflator increased 5.1%. In real terms, gross private domestic investment for residential structures rose 22.7% in 1976 after declining 14.7% in 1975; State and local Government expenditures increased 1.4% in 1976; and personal consumption expenditures for services rose 4.5%. The Federal Reserve Board (FRB) index of industrial production increased 10.2%.

In 1976 the unemployment rate dropped to 7.7%, declining from a 34-year high in 1975 of 8.5%. The number of people employed rose during the year at a greater rate than the increase in the total labor force, causing the fall in unemployment. The unemployment rate began and ended the year at 7.8%, declining to a low of 7.3% in May.

The consumer price index (CPI) rose 5.8% in 1976, much less than in 1974 or 1975. Contributing to the small increase in the CPI relative to proceeding years was the decline in food prices in the first part of 1976, and an increase of only 3.1% for the year as a whole. Energy prices also dropped in the first part of 1976, largely as a result of removal of the tariff on oil and the initial price rollback stipulations of the Energy Policy and Conservation Act. All nonfood commodities rose 5.0% for the year. The wholesale price index rose at the moderate rate of 4.6% in 1976. Farm products and processed foods and feed declined 0.6% (farm products by themselves rose 2.4%), and industrial commodities increased 6.3%. As noted above, the implicit price deflator rose 5.1% in 1976.

U.S. monetary policy in 1976 changed little from that in 1975. Faced with continuing high unemployment and relatively high inflation, the FRB sought to help create financial conditions that would facilitate a sustainable economic recovery while at the same time tending to lower inflation. The money supply M1, defined as currency plus demand deposits, grew 5.8% in 1976 up from 4.1% in 1975. M2, defined as M1 plus time and savings deposits, rose 11.3% in 1976 as compared with 8.5% in 1975.

Fiscal policy in 1976 attempted to maintain the same amount of stimulus as in 1975 for a moderate, sustained expansion of the economy. However, fiscal policy unintentionally became less expansionary in the first half of 1976, when expenditures were less than expected while receipts remained near predicted levels. The deceleration in Federal expenditures, which continued the shift away from defense and toward domestic programs in 1976, was primarily a result of much smaller increases in transfer payments to individuals and grants-in-aid to State and local Governments.

U.S. imports were estimated to be $14.2

---

[1]Economist, Division of Economic Analysis.
[2]Statistical assistant, Division of Economic Analysis.

billion higher than exports in 1976. Imports exceeded exports for fuels by an estimated $29.1 billion and for minerals and metals by $4.4 billion. Exports of manufactured products and agricultural products were an estimated $16 billion and $12.5 billion greater than imports, respectively.

Federal activities in areas that affected the mineral industries in 1976 included both continuing and special actions. The Federal Government enacted legislation making the first major revision of the tax code in 7 years and continued to take actions to fight inflation. The subjects of mineral-related laws passed in 1976 included energy, the environment, water, public lands, health and safety, taxes, tariffs, and transportation. Energy legislation was aimed, among other things, at increasing U.S. energy supplies and conserving oil and gas.

Bureau of Mines research programs in 1976 continued to be directed toward improving mineral technology leading to more efficient, less costly extraction; improving the health and safety of miners; increasing the recovery of secondary resources; and minimizing environmental degradation.

Total energy use in the United States rose 4.8% in 1976, in contrast to decreases in 1974 and 1975. As a result of increased economic activity and colder weather, consumption increased for all energy sources except hydropower, which declined due to the Western drought. The household and commercial sector showed the greatest increase of all major consuming sectors. Petroleum (including natural gas liquids) continued to be the Nation's largest energy source, accounting for 47.2% of consumption.

In 1976, the mining industry continued to face environmental regulation problems and higher employment, capital, and operating costs. Cost increases, in some cases, have not been as high as in previous years. Also, firms tried to reduce adverse effects through improved operating methods and better cost controls, and less frequently by curtailing operations. Certain industries, such as lead and aluminum, showed considerable market strength, while others, including zinc and copper, were weak.

The world economy continued to recover in 1976 from the 1974-75 recession, which had been the worst downturn in the post-World War II era. The recovery was largely a result of economic expansions in the United States, West Germany, and Japan. Inflation rates remained high in the face of considerable excess productive capacity and stable or, in some cases, increasing unemployment rates; inflation was, however, somewhat below that of 1974 and 1975.

SOURCES AND USES

ALL MINERALS

Production.—Domestic crude mineral production in 1976 was valued at $69.2 billion, an increase of 11% compared with 1975. Metals production rose 17%, nonmetals increased 11%, and mineral fuels advanced 10%. In constant 1967 dollars total crude mineral output increased just under 1% to $24.8 billion; metals increased 8.3%, and nonmetals rose 5.4%, but mineral fuels declined 1.6%. Shifting back to current dollars, exports of mineral raw materials declined 8.5% to $4.3 billion, and crude mineral imports, over 90% of which consisted of fuels, increased 34.2% to $30.5 billion in 1976.

The FRB index of industrial production (1967=100) for all industries rose 9.8% in 1976 to 129.4 index points. The average for all mining increased 1.2% to 114.1 index points. The average index of production for metal, stone, and earth minerals rose 9.3% to 120.1 index points. The metal index rose 6% and the stone and earth minerals index increased 10.6%. The average index of production for coal, oil, and gas increased 6.6% to 112.8 index points. Individual fuel indexes changed in a mixed pattern: Coal rose 3%, crude oil declined 3%, and natural gas decreased 1.6%.

In the manufacturing sector, production of metals and nonmetals, as shown by the FRB index, rose significantly in 1976. The primary metals index rose 12%, the iron and steel index rose 9%, and the nonferrous metals and products and clay, glass, and stone products indexes both increased more than 15%.

The FRB monthly index for all mining during January was 113.6 index points, a 6% increase over the previous month in 1975. The all mining index decreased to a low of 112.5 index points in July, then

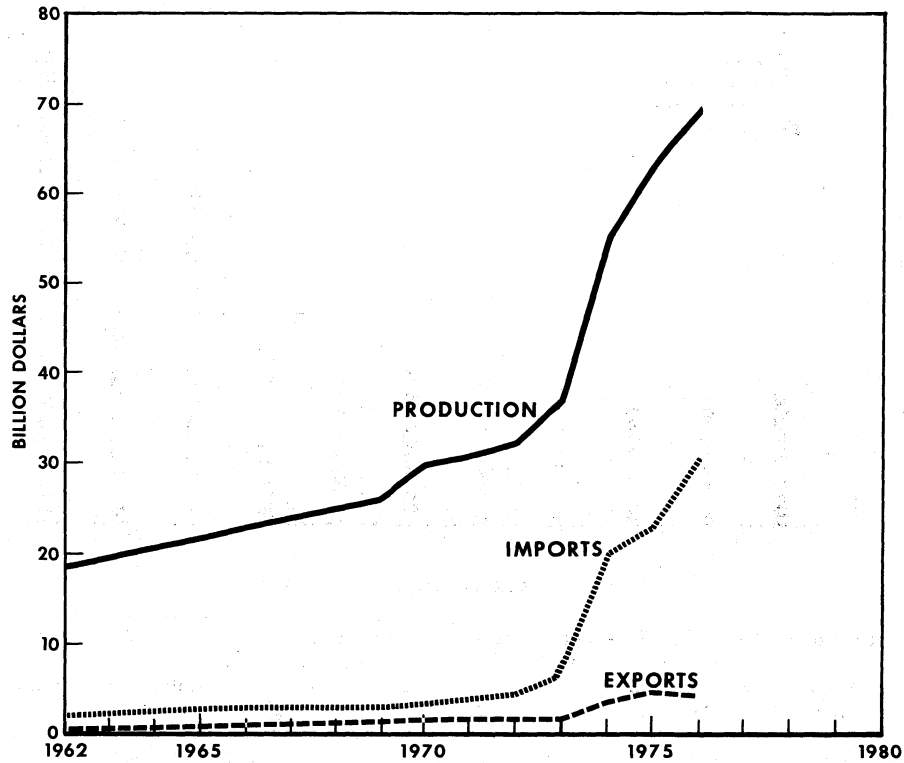

Figure 1.—Value of raw mineral production, exports, and imports.

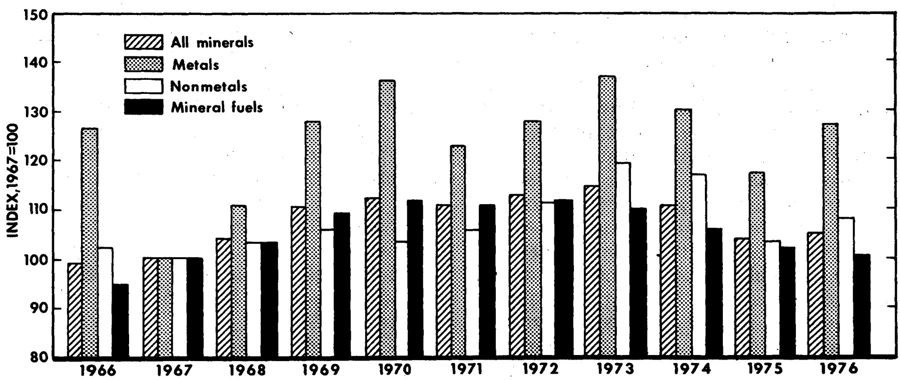

Figure 2.—Indexes of physical volume of mineral production in the United States, by group.

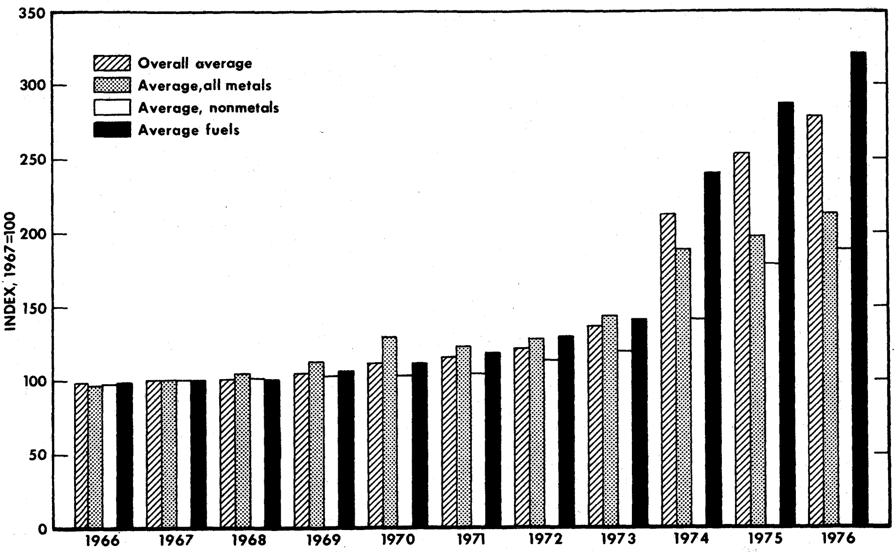

Figure 3.—Indexes of implicit unit value.

increased to 114.4 points in August. There was a continued increase for the remainder of the year finishing at 116.2 index points in December. The coal, oil, and gas index followed the same general trend; coal, although it vacillated due to strikes in the middle of the year, increased 13% over the 12-month period, ending the year at 125.9 index points in December. The oil and gas extraction total index followed the general trend of all mining while the crude oil index started at 94.8 index points in January and decreased to 91.5 index points by December. The metal, stone, and earth minerals and the metal mining index declined in the first half of the year, the lowest point being reached during June after which the index recovered to have an overall increase for the year. Metal mining increased a total of 7% for the year while stone and earth minerals increased by 0.7% for the year.

The net supply of most principal nonfuel minerals increased in 1976. The net supply pattern was mixed for the ferrous metals category. The largest increase within this category was 77% for cobalt followed by 20% for molybdenum, and the largest decline was 12% for tungsten. Iron ore fell 1.4%, but pig iron increased 9.3%, and steel ingot increased 9.8%. Nickel rose 1.8%, chromite declined 2.6%, and manganese declined 7.1%. The net supply of all nonferrous metals, except for tin and ilmenite and slag, increased (excluding metals for which data were not available). Cadmium increased 100% and uranium concentrate rose 54%, but both of these high percentage increases reflect relatively low base figures. Platinum-group metals increased 45.1% and zinc rose 30%. Copper, antimony, and mercury showed increases in the range of 16.7% to 22.4%. Aluminum increased 14% and lead rose 11.5%. Tin declined 3.6% and ilmenite and slag declined 3.2%. The net supply of all but three nonmetals increased. Asbestos increased 20.6%, followed by potash at 20.3%, and gypsum at 14.3%. Sand and gravel, common salt, and crude barite increased in the range of 9.6% to 12.1%. Bromine and clays increased 7.9% and 7.7% respectively. Phosphate rock and talc and allied minerals rose 6.5% and 4.7%, respectively. Sulfur increased 1.6%, mica experienced no change, crushed stone declined a negligible amount, and finished fluorspar showed the only significant decline at 9.3%.

Stocks and Government Stockpiles.—Stocks of crude nonfuel minerals at primary producers at yearend as shown by Bureau of Mines indexes (1967=100), increased for all but one category in 1976. The total index rose 11.9%, the crude metals index increased 12.1%, and the crude nonmetals index increased 11.7%. Within the metals sector, the iron ore index rose 13.7%, the other ferrous index declined 13.5%, and the nonferrous index showed the largest increase of any category at 29.1%. Stocks at mineral manufacturer, consumer, and dealer locations as illustrated by Bureau indexes, unlike those stocks held by primary producers, declined for all categories except one in 1976. The overall index dropped less than 1%, the metals index declined 1.5%, and the nonmetals index decreased 7.7%. Within the metals sector, the iron stock index increased 8.6%, base nonferrous declined less than 1%, other nonferrous fell 4.5%, and other ferrous showed the largest decline at 15.9%.

Producer stocks of bituminous coal and lignite increased 5.2% during 1976; coke increased 29.8%, the largest increase for the reported 1976 stocks. Natural gasoline, plant condensates, and isopentane stocks increased by 10.1%, and crude petroleum, by 5.2%. Other physical stocks that increased in 1976 were special naphthas at 1.5% and the other products category, under crude petroleum and petroleum products, at 2.7%. The overall category of crude petroleum and petroleum products decreased 1.9% and within this category petroleum asphalt had the greatest decline at 15.0% followed by the distillate fuel oil stock down 10.9%; liquefied gases decreased 7.1%; residual fuel oil down 2.4%; and the motor gasoline stock down 1.5%. Also down for 1976 were the carbon black stocks at 7.8% and the natural gas category at 3.7%. The overall trend showed coal and related products with increased physical stocks and the petroleum and related products, in general, with decreased stocks.

The seasonally adjusted book value of product inventories increased for all selected mineral processing industries during 1976. Petroleum and coal products rose by 9.3% to $5,148 million as of December 1976. Stone, clay, and glass products increased by 9% to $4,194 million. Inventories of total primary metals rose 11.6% to $17,329 million. Blast furnace and steel mill inventories rose by 20% to $10,179 million, the largest increase of any category. All other primary metals increased 1.5% to $7,150 million. The total seasonally adjusted book value of inventories for selected mineral processing industries rose 10.7% to $26,671 million during 1976.

The U.S. stockpile of strategic and critical materials continued to represent a significant portion of the Nation's mineral supply in 1976. Minerals in the stockpile as of yearend 1976 that had high total values included antimony, bauxite, chromium, cobalt, industrial diamond, fluorspar, lead, manganese, platinum-group metals, silver, tin, tungsten, and zinc.

Exports.—The total value of selected minerals and mineral products exported in 1976 decreased 7%. Exports in all but two sectors declined. Exports of crude nonmetallic minerals fell 11.2%; those of crude and scrap metals decreased 5.3%; mineral energy resources and related products declined 5.9%; and manufactured metals dropped 18.1%. Iron or steel tubes, pipes, fittings, the largest export value in the manufactured metals category, declined 45%. Those sectors that showed higher export values in 1976 included chemicals which increased 17.5% and manufactured nonmetallic minerals which rose 10.6%.

The geographical distribution pattern, based on value, for most selected mineral exports was similar in 1976 to that in 1975. There were, however, some important exceptions. In the case of nonferrous metal scrap, the share of exports to noncentrally planned Europe, declined from 49% in 1975 to 37% in 1976 while that of noncentrally planned Asia rose from 34% to 47%. The distribution of exports of uranium and thorium ores and concentrates shifted slightly away from noncentrally planned Europe, which dropped from 100% to 86%, and to North America, which rose from zero to 14%. The share of iron and steel hoop and strip exports to North America decreased from 43% to 32% and those to noncentrally planned Europe rose from 29% to 48%. The distribution of silver, platinum, and platinum-group metals exports shifted away from noncentrally planned Europe which declined from 63% to 29% and to noncentrally planned Asia which increased from 15% to 51%. The change in the pattern of lead and lead alloys exports was a shift away from noncentrally planned Europe, which decreased from 65% to 19%, and to both North America, which rose from 13% to 48%, and noncentrally planned Asia, which increased from 7% to 17%. The distribution of exports of uranium and thorium and their alloys shifted away from noncentrally planned Asia, which declined from 34% to 4%, and to North America, which rose from 26% to 59%.

Imports.—The total value of selected minerals and mineral products imported in

1976 increased 24.5%. Imports increased in all sectors: Crude nonmetallic minerals rose 5.4%; crude and scrap metals increased 14.6%; and mineral energy resources and related products increased 28.5%. Imports of chemicals increased 53.9% and within this category radioactive and associated materials except uranium and thorium increased 237.2%. Both manufactured nonmetallic minerals and manufactured metals increased 10%.

The geographical distribution pattern, based on value, for almost all selected mineral imports in 1976 was similar to that in 1975, though there were several significant exceptions. The share of imports of mica, including scrap, supplied by North America decreased from 16% to zero and that supplied by noncentrally planned Asia decreased from 72% to 51%, while that from South America rose from 6% to 31%. The distribution of crude barite imports from North America and South America declined from 27% to 15% and from 33% to 20%, respectively, and that from noncentrally planned Europe increased from 24% to 45%. Imports of columbium ores and concentrates from South America declined from 60% to 39%, from noncentrally planned Asia declined from 22% to 4%, and from North America increased from 1% to 32%. The distribution of lead waste and scrap imports shifted away from North America, which supplied 37% of U.S. imports in 1976 compared with 98% in 1975, and to South America, which supplied 44% in 1976 compared with nothing in 1975.

Consumption.—In 1976 consumption of most major mineral products increased and the few that declined, fell by small amounts with one exception. Most ferrous metals showed significant increases. Iron ore and raw steel consumption each rose 9.9%. Metallurgical-, refractory-, and chemical-grade chromite ores gained 12.2%, 10.4%, and 24.7%, respectively, the last gain being the largest increase of any ferrous metal. Tungsten consumption increased 15%, molybdenum decreased 2.5%, and manganese declined 12%. Consumption of all major nonferrous metals increased. Apparent consumption of aluminum rose 31.1%, refined copper consumption increased 29.8%, and primary mercury showed the largest increase of all major mineral products at 40.5%. All classes of zinc rose more than 25%, followed by platinum-group metals at 22.5%, ilmenite and titanium slag at 19.7%, and primary antimony at 18.1%. Primary and secondary lead consumption rose 14.9%; estimated purchases of uranium by private industry, 12%; and silver for industry and the arts, 8.2%. Consumption of all nonmetallic minerals increased except for crushed stone which declined a negligible amount. Within the nonmetallics sector apparent consumption of potash showed the largest increase at 20.3%, followed by asbestos at 19.4%. Sand and gravel consumption rose 12.2%, salt increased 10.8%, and that of clays gained 7.7%. Lime and cement each increased 5.7%, all forms of sulfur rose 1.6%, and phosphate rock increased a negligible amount.

Total energy resource inputs in terms of British thermal units (Btu) rose 4.9% in 1976. Consumption of bituminous coal and petroleum including natural gas liquids increased significantly while natural gas increased slightly and anthracite remained unchanged. Total net electricity generation increased and within the utilities sector, nuclear showed the largest increase followed by conventional fuel-burning plants; hydropower declined. Generation of industrial electricity increased slightly.

ENERGY

Energy use rose in the United States in 1976, reversing a 2-year decline. The 4.9% increase compared with 1975 was largely attributable to a higher level of economic activity and colder weather. Net imports of all fuels rose 24.3% compared with 1975; net imports of crude petroleum and petroleum products increased 21.4% over 1975, accounting for 40.6% of the estimated 1976 petroleum demand. Consumption on a Btu basis rose in 1976 for all fossil fuels, but declined for hydropower because of the Western drought. Per capita energy use increased 4.1% compared with 1975. The ratio of energy consumption to GNP in 1976 continued to follow the decline that began in 1971. This decreasing ratio indicates that the U.S. economy is using energy in a more efficient way to create GNP.

Production.—Total energy equivalent in Btu's obtained from mineral energy resources produced and from hydroelectric and nuclear power continued to decline slightly in 1976. The total was nearly 60,000 trillion Btu. Energy obtained from bituminous coal and nuclear power increased while that obtained from petroleum, hydroelectric power, and natural gas decreased. Natural gas continued to be our largest source of energy, accounting for 36% of the total.

Consumption.—U.S. energy consumption in 1976 increased 5% to 74,000 trillion Btu, nearly reaching the 1973 level. This increase came mainly from the use of bituminous coal and petroleum products. Natural gas, the other large source of energy consumption, increased only slightly.

The consumption of energy resources in 1976 by sector was 29% by the industrial sector, 26% by transportation, 25% by household and commercial, and 19% by electric utilities. Petroleum, the major source (47%) of all energy, accounted for nearly all of the energy in the transportation sector, 29% in industrial, 34% in household and commercial, and 24% in electric utilities.

Coal.—The domestic supply of bituminous coal and lignite in 1976 increased 7.4% to 597 million tons; that of anthracite decreased 1.3% to 5.0 million tons. Exports of bituminous coal declined 9.5% to 59 million tons and those of anthracite rose 8.5%. Imports of bituminous coal increased 28% but remained small when compared to exports. Electric utilities were responsible for three-fourths of bituminous coal consumption, and industrial uses accounted for most of the remainder. The household and commercial sector accounted for 40% of anthracite consumption; industrial uses accounted for 33%; and electric utilities, 27%.

Natural gas.—The domestic supply of natural gas increased 2% in 1976 to 19,800 trillion cubic feet or 20,200 trillion Btu. Production continued to decline somewhat as did exports. Imports accounted for 5% of total supply and increased very slightly. Demand for natural gas increased in the industrial sector to 43% of total demand and the household and commercial sector increased to 38% of demand.

Petroleum.—The domestic crude oil supply increased 8.1% to 4,910 million barrels in 1976. Domestic production continued to fall, declining 2.6% to 2,976 million barrels. Imports, which rose 29.2% to a record 1,935 million barrels, were responsible for the increased supply. Exports and stocks increased, but both remained negligible. The domestic supply of refined petroleum products rose 7.2% to 6,384 million barrels. The demand for petroleum increased for all consuming sectors except the miscellaneous category. Transportation continued to be the largest consuming sector, accounting for 61.2% of all petroleum consumed.

Nuclear Energy.—Nuclear energy consumption in 1976 rose 10.8% compared with that in 1975. On a Btu basis it accounted for 2.8% of total energy consumption in 1976, up from 2.6% in 1975.

Hydropower.—In 1976 electricity from hydropower declined for the second year in a row, decreasing 4.8% compared with that in 1975. Hydropower was responsible for 4.1% of total energy consumption in 1976, falling from 4.6% in 1975.

Other Energy.—Work continued in 1976 on development of alternate sources of energy such as geothermal, oil shale, solar, nuclear fusion, wind, tidal, and biological

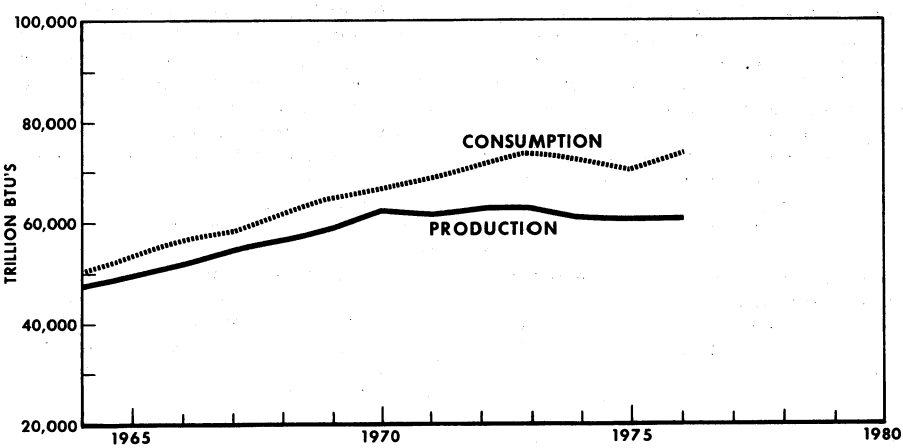

Figure 4.—Production and calculated gross consumption of mineral energy resources and electricity from hydropower and nuclear power.

(from organic wastes). Of these energy sources, geothermal remained the only one that has reached commercial development to any significant extent. Solar energy systems were approaching the commercial stage at some geographic locations. Oil shale development advanced in an effort to overcome problems of high costs and environmental concerns. Several projects were underway to produce energy from waste. Among the technologies being advanced are the production of methane from sewage sludge and the organic portion of urban refuse, the use of combustible portions of urban refuse (such as paper, plastics, wood, and rubber) as fuel for powerplants, and the production of oil from wood waste. Research continued on wind power and energy from fusion, the latter being theoretical at the present time, but offering great promise in the long term.

EMPLOYMENT AND PRODUCTIVITY

Employment.—Employment in selected mineral industries increased for all mining industries, except copper and nonmetal mining and quarrying, and half the selected manufacturing industries in 1976. Total mining employment increased 5.1%, and within this category metal mining employment rose less than 1%, nonmetal mining and quarrying remained unchanged, and fuels extraction increased 6.9%. Within the metal mining group, iron ore employment rose 2.4% and copper ores declined 4.3%. In the fuels group, crude petroleum and natural gas fields employment increased 3.4%, bituminous coal increased 6.2%, and oil and gas field services rose 10.8%.

Total selected manufacturing employment declined less than 1% in 1976, and within this category nonfuel mineral manufacturing remained virtually unchanged and fuel manufacturing increased 2.7%. Within the nonfuel mineral manufacturing group, employment declined less than 1% for fertilizers, 2.3% for hydraulic cement, and less than 0.5% for blast furnaces, steelworks, and rolling mills; nonferrous smelting and refining employment increased 2.6%. Within the fuel manufacturing group, petroleum refining rose 1.9%, and other petroleum and coal products rose 6%.

Hours and Earnings.—Average hourly earnings in the extractive industries during 1976 increased 10.5% to $5.99 for nonfuels, and 8.5% to $6.66 for fuels. Also, hours worked rose 1.2% in both the nonfuels and fuels industries resulting in increases in weekly earnings of 12.1% and 9.8%, respectively. Within the nonfuels industry average hourly earnings increased 9.8% for metal mining and 10.9% for nonmetallic mining and quarrying, though the latter continued to pay the lowest hourly wages in the extractive sector. Hours worked rose 1.7% for the former, and about 1% for the latter which also had the longest workweek of any extractive sector. Weekly earnings rose about 12% for both industries. Within the metal mining sector, both hourly and weekly earnings for the iron ore industry increased almost 12%. Copper ores average hourly earnings rose 10.6% and average weekly hours rose 2.3%, resulting in an increase in average weekly earnings of 13.1%.

The bituminous coal industry continued to pay the highest hourly wages and have the shortest workweek of all extractive industries with $7.91 and 39.5 hours, respectively, representing increases of 9.4% for wages and almost 1% for hours. Crude petroleum and natural gas average hourly earnings increased 8.9% and average weekly hours rose 1.5%, resulting in an increase in average weekly earnings of 9.6%.

The average hourly earnings for total selected manufacturing rose 7.5% to $7.21; average weekly hours decreased 1.5%; and resultant weekly earnings were 9% higher in 1976. The blast furnaces, steel and rolling mills industry continued to pay the highest hourly wages and have the shortest workweek of all manufacturing industries considered, with $7.86 and 39.8 hours, respectively, representing increases of 10.5% for wages and 1.5% for hours. The opposite was true of the fertilizer industry (complete and mixing) which paid the lowest hourly wages at $4.88 and had the longest workweek at 43.1 hours in the manufacturing sector, representing increases of 10% and 1%, respectively. Hydraulic cement experienced the largest percentage increase in average hourly earnings of any industry at 14.7% and, coupled with an increase in weekly hours of under 1%, also showed the largest weekly earnings increase of 15.5%. Average hourly earnings for nonferrous smelting and refining rose 10.7%, average weekly hours rose 2%, and weekly earnings increased 12.9%. For petroleum refining and related products, average hourly earnings rose 11.2%, hours worked increased 1.4%, and resultant weekly earnings rose 12.8%.

Wages and Salaries.—In 1976, total wages and salaries for all industries rose substantially to $891.8 billion, an increase of 10.7%. Total wages and salaries in both the mining and manufacturing sectors rose nearly 13% to $12.2 billion and $238.2 billion, respectively. Average yearly earnings per full-time employee in all industries rose 7.2% to $11,623. Mining sector employees earned an average of $16,089 in 1976, a gain of 8.9% compared with 1975. Manufacturing sector employee earnings rose 8.3% to $12,888.

Labor Turnover Rates.— The accession rate (hires and rehires) for most industries generally increased after a 2-year overall decline. In the manufacturing sector the accession rate increased 5% over that of 1975. The greatest overall increase occurred in the nonfuel mineral industry sector; this was attributed to the copper ore sector with a 68% increase and the nonferrous smelting and refining sector with a 44% increase. Within the selected fuel industries, all sectors increased with the exception of the coal industry which decreased 13% overall. The separation rate declined for all of the selected industries with the exception of the fuel-related industries. In the manufacturing and copper ore sectors, the decrease was 9%; metal mining decreased 6% while both blast furnaces, steel and rolling mills, and the nonferrous smelting and refining sectors each decreased 26%. Iron ore changed the least by decreasing 3% and the cement, hydraulic sector separation rate decreased 31%. Petroleum refining and related industries increased 5%, petroleum refining alone increased 16%, and the separation rate for the coal mining sector increased 28%, the greatest increase for the fuel-related sectors. The layoff rate decreased for all nonfuel mineral sectors while the rate for fuel-related sectors increased. The greatest layoff decline was for nonferrous smelting and refining at 70% and cement, hydraulic was next with a decrease of 45%. The manufacturing sectors decreased 38% and the blast furnaces, steel and rolling mills followed, decreasing 36%. Metal mining decreased 20%, iron ore decreased 23% and copper ore at 15% decreased the least within the nonfuels sector. Petroleum refining and related industries remained constant relative to 1975 while the petroleum refining layoff rate increased by two-thirds; coal mining increased by one-half. The last two rates reflect low base figures.

Productivity.—Indexes of labor productivity for selected minerals in 1975 (latest data available) were mixed. All indexes for copper increased while those for iron and bituminous coal and lignite declined. Indexes of copper ore output per employee, production worker, and production worker man-hour rose about 2%, 5%, and 10%, respectively. For recoverable copper metal, the corresponding indexes increased 0.4%, 3.4%, and 8.2%, respectively. The indexes of iron ore output per employee and per production worker each decreased about 3%, and the per production worker man-hour index dropped 1.3%. Indexes of usable iron ore mined per employee, production worker, and production worker man-hour declined 7.5%, 6.9%, and 5.5%, respectively. For bituminous coal and lignite, the indexes of output per employee and per production worker each declined about 8% and the per production worker man-hour index declined 10.2%. Indexes for refined petroleum were mixed, with output per employee and per production worker each declining 1% and the per production worker man-hour index increasing 1%.

PRICES AND COSTS

Index of Average Unit Mine Value.—The index of average unit mine value (1967=100) is designed to reflect unit values of mine production. It showed unit mine values for all but two mineral categories increasing in 1976. The overall index of average unit mine value rose 10.4% to 279.4 index points. The total metals index increased 9%, the ferrous metal index increased 13.7%, and the nonferrous metal index rose 3.9%. Within the nonferrous metal category, the base metal index increased 5.5%, the monetary metal index showed a substantial decline of 14.5%, and the other nonferrous metals index increased by the largest percentage of any mineral category at 16%. The total nonmetals index rose 5.5%, with the construction index increasing 8.4%, the chemical index decreasing 3.5%, and the other nonmetals index rising 11.9%. The fuels index increased 11.5%, and within this category the coal index rose 4.2% and the crude oil and natural gas index increased 13.3%.

Index of Implicit Unit Value.—The index of implicit unit value (1967=100) is designed to reflect unit values of the minerals included in the index of physical volume of mineral production. For 1976 it shows the same pattern of price changes as the index of average unit mine value discussed above. The implicit unit value indexes increased for all but two mineral sectors. The overall index of implicit unit value increased slightly over 10% to 278.2 index points. The index for all metals rose 8.2%, the ferrous metal index grew 13.7%, and the nonferrous metal index increased 5.2%. Within the nonferrous metal category, the base metal index rose 6%, the monetary metal index declined 12.4%, and the other nonferrous metals index increased the most of all mineral sectors at 14.5%. The total nonmetal index increased 5.2%, with the construction index advancing 8.5%, the chemical index falling 4%, and the other nonmetals index increasing 12.5%. The fuels index rose 12.3%, and within this category the coal index increased 4.2% and the crude oil and natural gas index increased slightly over 14%.

Prices.—The wholesale price indexes for selected metals, minerals, and fuels increased in general for 1976. The index for all commodities increased 4.6% to 183.0 index points, while all commodities other than farm and food increased 6.4% to 182.4 index points. Metals and metal products increased 5.5% to 195.9 index points; selected commodities within this grouping that reflected the extremes of the reported price index changes were as follows: Nonferrous scrap increased 21.1%, foundry and forge shop products increased 12.5%, iron ore increased 10.8%, and aluminum, primary, buyers increased 10.6%. Most other commodities that are listed within this grouping increased at a rate above the 5.5% group average, with the exception of zinc, slab, prime western which had decreased 3.4%.

Nonmetallic mineral products increased 7.0% to 186.3 index points. The greatest increases occurred for building lime, which increased 10.3%, and concrete ingredients and insulation materials, both increased 8.4%. The greatest decreases were as follows: Phosphates down 20.5%, fertilizer materials down 17.7%, and nitrogenates down 15.4%.

Fuels and related products and power increased 8.4% to 265.6 index points. Within this group of commodities, gas fuels increased the most, at 32.3%, followed by petroleum products, refined and electric power with increases of 7.4% and 7.3%, respectively; coal declined 4.4%.

Prices of most mineral energy commodities increased in 1976. The average price of bituminous coal at merchant coke ovens rose 4.3% to $54.90 per short ton. Average sales realization prices for anthracite ranged between $29.11 and $47.13 per ton, with a decrease of less than 1% for one size of anthracite and an increase of 5.4% for another size. All petroleum and petroleum products increased in price with the exceptions of Bunker C residual fuel oil at all gulf ports and No. 6 residual fuel, maximum 1% sulfur, at Philadelphia, which declined almost 3% to $9.03 per barrel and 2% to $12.05 per barrel, respectively. The average price of No. 6 residual fuel, maximum 0.3% sulfur, at Philadelphia, rose almost 1% to $13.28 per barrel. The average price of crude petroleum at the well increased 7.7%, and the average dealers' price of gasoline rose 9%. Prices of No. 2 distillate fuel oil rose 8% at Philadelphia and 5% at all gulf ports. The average value of natural gas at the well rose 30.3% to 58 cents per thousand cubic feet and it was unavailable at the point of consumption.

In the year 1975 (latest data available), the average cost of electricity increased at the same rate as in the past few years. Different from previous years, New England and Middle Atlantic regions had the highest costs, reflective of the high cost of petroleum on the spot market. The Tennessee Valley Authority charged rates in the East South-Central States that permitted this region to continue to have the lowest average cost of electricity for the United States. The average cost of electricity in the residential market increased 0.4 cent to 3.2 cents per kilowatt-hour. All other geographic regions had increases averaging 0.4 cent per kilowatt-hour. In the commercial and industrial sectors the average increase in 1975 was 0.4 cent per kilowatt-hour. The only decline in rates occurred in Alaska and Hawaii, where the residential rate decreased 0.1 cent per kilowatt-hour.

Principal Metal Mining Expenses.—The index of principal metal mining expenses (1967=100), following the price trend for the economy as a whole, rose 5.3% to 199 index points in 1976. The fuel component increased 8.5%, the largest percentage increase of any component, reaching 266 index points, and the electrical energy component was next, rising 7.8% to 208 index points. The supplies component increased 6.2% to 188 index points and labor, with a gain of 4.2% to 198 index points, was the only component rising less than the overall price index.

Costs.—In 1976, indexes of relative costs and productivity (1967=100) generally increased with a few exceptions. For iron ore, all three indexes increased—the index of labor costs per unit of output and the index of value of product per production-worker-period both increased moderately as the index of labor costs per dollar of product rose slightly. The copper indexes showed mixed changes—the index of labor costs per unit of output declined slightly, the index of value of product per production-worker-period increased by more than one-fourth, and the index of labor costs per dollar of product declined moderately. For bituminous coal, the index of labor costs per unit of output rose moderately, the index of value of product per production-worker-period declined slightly, and the index of labor costs per dollar of product rose moderately. In 1974 (latest data available) the petroleum indexes of labor costs per unit of output and the value of product per production-worker-period both increased and the index of labor costs per dollar of product declined as reported in 1973.

Price indexes for mining construction and material handling machinery and equipment (1967=100) increased only moderately in 1976 compared with large increases in 1975. The index for portable air compressors showed the smallest increase at 2%, followed by mixers, pavers, spreaders, etc., at 5% and construction machinery and equipment at 7%. The indexes for specialized construction machinery, scrapers and graders, and tractors other than farm, all increased about 8%. The index for power cranes, excavators, and equipment rose 9%, the oilfield machinery and tools index rose 11%, and the largest price index increase was again for mining machinery and equipment which rose 15%.

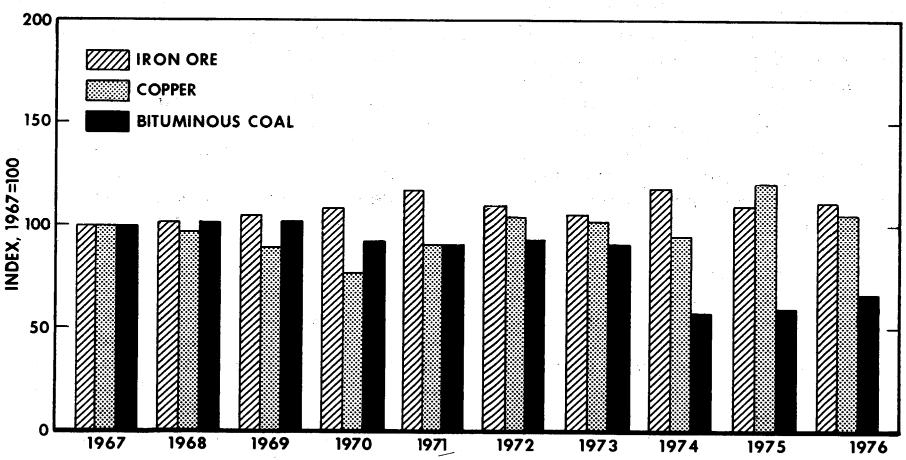

Figure 5.—Index of labor costs per dollar of product.

INCOME AND INVESTMENT

National Income Generated.—National income originating in all industries in 1976 increased 12.2% to $1,399 billion. Income in the mining sector rose to $19.4 billion, an increase of 7.8%. Oil and gas extraction accounted for the largest share within the mining sector at $8.8 billion and also showed the greatest percentage increase in mining at 12.9%. Coal mining contributed the next largest share, rising 3.4% to $6.6 billion. Nonmetallic minerals, excluding fuels, increased 3.1% to $2.3 billion and metal mining rose 7.2% to $1.8 billion. Manufacturing increased 17.2% in 1976 to $365.0

billion. Within this category, petroleum and coal products showed the largest percentage increase, up 25% to $15.5 billion. Stone, clay, and glass products had the second largest increase at 19.5%, rising to $11.8 billion. The primary metal industries generated $26.6 billion in income, a gain of 8.4% and chemicals and allied products accounted for $27.1 billion, an increase of 13.6%.

Profits and Dividends.—The average annual profit rate on shareholders' equity in all manufacturing industries rose by more than two percentage points in 1976 to 14%. All but two of the selected mineral manufacturing industries showed increasing profit rates. The profit rate for primary metals declined a negligible amount to 8.3% and that for iron and steel decreased by almost two percentage points to 9%. Nonferrous metals increased more than one-third to a profit rate of 6.8%; stone, clay, and glass products rose almost four percentage points to 11.9%; chemicals and allied products increased a negligible amount to 15.5%; and petroleum and coal products rose almost two percentage points to 14.4%.

Total dividends for all manufacturing increased 13.8% to $22,716 million in 1976. Dividends rose for all but one of the selected mineral manufacturing industries. For primary metals, they increased 1% to $1,200 million, which was a result of iron and steel increasing 3.6% to $773 million and nonferrous metals declining 3.8% to $425 million. Dividends for stone, clay, and glass products increased 6.5% to $440 million; for chemicals and allied products the increase was 13% to $3,128 million; and for petroleum and coal products the increase was 4% to $4,414 million.

The total number of industrial and commercial failures and their current liabilities declined rather substantially in 1976. The number of failures decreased 15.8% to 9,628 and their liabilities dropped to slightly over $3 billion, a decline of more than 31%. Mining failures rose to 37 in 1976, 11 more than in 1975. The current liabilities of mining firms that failed were almost $106 million, more than 10 times those of 1975. The manufacturing sector showed a decline of 18.3% in the number of failures, but their liabilities increased by a negligible amount.

New Plant and Equipment.—Expenditures for new plant and equipment increased for mining (including fuels) and for all but one of the selected mineral manufacturing industries in 1976. Expenditures by mining industry companies rose 5.5% to $4.0 billion; those by all manufacturing increased 9.4% to $52.48 billion. Primary nonferrous metals industry expenditures showed the only decline of the selected mineral manufacturing industries, decreasing by 5.3% to $2.16 billion. Expenditures by the primary iron and steel industry increased by 2.7% to $3.81 billion and those by chemicals and allied products increased by 6.9% to $6.68 billion. Petroleum industry expenditures increased 10.6% to $11.62 billion, and stone, clay, and glass products industry expenditures showed the largest percentage increase, a rise of 21.1% to $1.72 billion.

Plant and equipment expenditures of foreign affiliates of U.S. mining companies in mining and smelting declined by 21.9% to $916 million in 1976. Canada showed a decrease of 8.2%, Latin America showed a decrease of 39.4%, and the all other areas category fell 30%. Expenditures in petroleum rose almost 3% to $9,757 million. Canada showed an increase of 5.2%, expenditures for Latin America declined 15.8%, those for Europe increased 9.8%, and all other areas remained at virtually the same level as in 1975. Plant and equipment expenditures in manufacturing rose 2%, with Latin America increasing 19.1% and the all other areas category falling 11.8%.

Issues of Mining Securities.—Estimated gross proceeds of new securities offered by extractive industries totaled $1.77 billion in 1976, an increase of 8.6% from that of 1975. As a departure from previous years, bonds accounted for 57.8% of the proceeds in 1976, while common stock's share was only 34.3% and preferred stock was responsible for 7.9% of the proceeds.

Foreign Investment.—Direct private investment by U.S. companies abroad increased 12% to $133.2 billion in 1975 (latest data available). The increase in the petroleum sector was 15.3%. The share of petroleum investments received by developing countries continued to be greater than the share of total investments they received. Developed countries received $20.3 billion of the petroleum industry investment, while developing countries received $11.1 billion. The value of petroleum investment in European affiliates increased 14.3% to $11.4 billion and that in Canadian affiliates increased 8.3% to $6.2 billion. Petroleum investments were up sharply in two developing areas: The Middle East increased 127.7% to $3.7 billion and the Other Asia and Pacific category rose 59.5% to $2.8 billion.

U.S. direct investments in foreign mining increased 7% in 1975 (latest data available) to $6.6 billion. The developed countries received two-thirds of these investments or $4.4 billion. Canada received the largest share, or 69.4% of mining investments in developed countries. Latin American Republics continued to account for almost half of mining investments in developing countries which totaled $2.1 billion.

The value of foreign direct investments in the United States in 1975 (latest data available) was $26.7 billion, an increase of 19.3%. Investments in the petroleum sector increased 37% to $8.2 billion, which was 30.6% of the total foreign direct investments in the United States.

TRANSPORTATION

The total quantity of major minerals and mineral energy products transported by railroad and water continued to decrease in 1975 (latest data available), declining by 95.4 million short tons to 1,642 million short tons. Total mineral products accounted for 62% of all products carried by rail and 82% of all commodities transported by water. The former represented a small increase over that of 1974. Almost 65% of minerals, excluding fuels, were transported by rail. Slightly over 55% of fuels and related energy products were transported by water.

In the minerals, excluding fuels, category the quantity of commodities transported by rail decreased 15.9% to 406.6 million short tons. Of this total 61.9% consisted of five commodities: Iron ores and concentrates, phosphate rock, steelworks and rolling mill products, sand and gravel, and crushed stone. All commodities decreased in 1975 except for nonferrous metal scrap, which increased 365%, and phosphate rock, which rose less than 1%.

Water transportation of minerals, excluding fuels, declined almost 13% to 220.4 million short tons. Three commodities—iron ores and concentrates, sand and gravel, and limestone flux— accounted for 75.5% of this tonnage. All commodities decreased with the exceptions of phosphate rock, which increased 10%, and other ores, which increased 6%.

In the fuels and related energy products category, the quantity of commodities carried by rail rose 2.1% to 456.2 million short tons in 1975. Bituminous coal and lignite continued to be responsible for the major share, accounting for 89.3% of this tonnage. All fuel products declined in 1975 except for coal, which increased 4.3%, and crude petroleum and natural gas, which rose 5.6%.

Fuels and related products transported by water increased less than 1% to 559.2 million short tons. Coal continued to account for the largest share of fuels shipped by water at 27.3%. Others responsible for significant shares included residual fuel oil at 20%, gasoline, jet fuel, kerosine at 19%, distillate fuel at 16%, and crude petroleum and natural gas at 14%. The largest percentage increase was for liquefied petroleum gas and coal gas which rose 21.4%.

A total of 987,700 miles (preliminary) of gas pipelines existed in 1976. This represents an increase of less than 1% from the 980,000 miles of pipelines that existed in 1975. Total petroleum pipeline mileage in 1974 (latest data available) as previously reported was 222,000 miles. It was distributed among the following components: Crude gathering systems in field operations with a 31% share, large-size crude trunklines accounting for 34%, and petroleum product pipelines that extend from refineries to extraction terminals with 35%.

RESEARCH ACTIVITIES

U.S. total research and development expenditures in 1975 (latest data available) were $23.5 billion, an increase of more than 5% compared with that of 1974. The shares spent by the private sector and the Federal Government were 62.8% and 37.2%, respectively, the same percentages as in 1974. Research and development expenditures in the petroleum refining and extractive industries increased 17%, reaching $700 million in 1975. Almost 96% of these expenditures were financed by private industry, and Federal Government funds supplied the remaining 4%. Research expenditures for chemicals and allied products increased over 12% to $2,650 million. Private industry financed 91% of this total.

Bureau of Mines funding obligations for mining and mineral research and development were $131.3 million in fiscal year

1976, an increase of 29% compared with 1975. Funds for applied research increased more than 42% to $72.5 million. Basic research funds continued to drop, declining 58.7% to $0.8 million. Funds for development rose 19% to $58 million. Funding obligations for fiscal year 1977 were estimated at $153.7 million, 17% higher than for 1976. Fiscal year 1977 funds were estimated to increase 8.8% to $78.9 million for applied research, to remain the same for basic research, and to increase 12.7% to $65.4 million for development.

Bureau of Mines funding obligations for total research rose 38.5% to $73.3 million for fiscal year 1976. Funds for engineering sciences increased 41.5% to $67.5 million; physical sciences funds declined 5.6% to $1.8 million; mathematical sciences rose 24.5% to $1.6 million; and environmental sciences increased 18% to $2.4 million. Obligations for total research during fiscal year 1977 were estimated to increase 8.7% to $79.7 million. Funds for engineering sciences were estimated to increase 9.3%; for physical sciences they were estimated to rise 5.6%; and for both mathematical and environmental sciences they were estimated to remain the same. Highlights of Bureau research programs, including work in progress, follow.

Mining.—The Bureau continued to make field studies with shallow seismic reflection methods for mapping coal seams and underground geologic features in coal mines in 1976. Only recently has this technique been applied to shallow investigations. The application is similar in effect to the deeper methods already utilized; however, shallow reflection methods require modified procedures. Some of these are to minimize surface noise, select optimum detector spacing, generate high-frequency source signals, and use improved data collection and data processing technology. The seismic method was proving useful for locating geologic features at moderate cost and with better definition than available with drilling programs alone.

The Bureau developed a first-generation roof bolter inserter (R.B.I.) and flex drill system. The R.B.I. is designed to bend and insert longer than seam height bolts without the need to manually bend and straighten the bolts. It removes the miner from the hazardous bolting area to improve safety. This is done by moving the operator's controls to the back of the bolter and moving the operator away from the bolter altogether and controlling its operations remotely. Completion of the R.B.I. has led to the next step of drilling longer than seam height. Five flexible drill contracts investigated different methods of achieving the goal of longer than seam height drilling.

The Bureau of Mines embarked on a contract research effort to develop a fast, reliable, accurate, and effective reconnaissance system to gather and quantify data on stability of mine waste embankments. After investigating a number of systems involving conventional surveying, telemetry, remote sensing, and innovative techniques, the airborne photogrammetry system was selected as the one that best combines accuracy, rapidity, and reliability with reasonable cost.

Photogrammetry is both fast and accurate; embankments can be photographed in a fraction of the time required for onsite visual inspection and surveying. Additional benefits are that site mapping is facilitated, embankment volume can be measured, and a permanent, reliable record of the life of the embankment results.

The deep, steeply dipping narrow veins of the Coeur d'Alene mining district are mined by overhand horizontal cut-and-fill methods. High ground stresses and hard brittle rock can result in conditions conducive to rockbursts. Experience has shown that many of the damaging rockbursts occur during development of the stope first level and later during mining of the remaining stope sill pillar. Finite element studies showed that if the rock in this area of the mine could be made less brittle during development mining, the potential for rockbursts would be greatly reduced. A cooperative research program was planned between the Bureau of Mines and a mining company to test this theory.

A Bureau program was generated for the development of potential recommended guidelines for underground mining in close proximity to bodies of water. The objective was subject to the constraint of maximum efficient utilization of underground coal resources consistent with minimizing inundation hazards. Several consulting firms were contracted to gather and provide background data from worldwide sources on the application and the case histories of previous inundations to develop recommended guidelines for underground coal mining near bodies of water.

These recommended guidelines cover total extraction by longwall or pillar robbing, partial extraction by room-and-pillar, partial extraction by panel mining, and a combination of these methods.

The Bureau of Mines continued to conduct projects involving the development and in-mine testing of rugged, reasonably priced, mine shaft fire and smoke protection systems. A second-generation system, developed and installed in a mine near Bishop, Calif., was tested in 1976. The system's hardware consists of smoke, CO, and heat sensors, remotely controlled smoke doors, remotely controlled sprinkler systems in the shaft/shaft station area, underground control units, and a master control unit at the surface. After 8 months of in-mine evaluation, the second-generation prototype system was subjected to fire testing. Test fires were lit at two levels of the mine. Each test fire was automatically sensed by the systems; the remotely controlled smoke doors were activated and the remotely controlled sprinklers successfully extinguished the fires via commands from the surface.

Bureau research is concerned with several aspects of circuit protection for mine power systems, ranging from circuit breaker reliability to development of more sensitive and trouble-free devices for detection of ground faults. In one study, existing circuit breakers are being replaced by matching units which are equipped with monitoring devices to provide data on occurrences of circuit current surges and the related circuit interruption performance of the breaker. The old breakers are examined for wear and failure characteristics, as will be the new units when finally removed. Aside from reliability and maintenance scheduling information, the investigation will probably also result in suggestions for circuit breaker improvement and for proper application of the devices.

A "synthetic fault" test apparatus had been developed for in-mine testing and verification of operational readiness of ac circuit breakers.

A second circuit breaker tester was being developed; this one for calibrating dc trolley system circuit breakers.

An experimental model of a dc circuit breaker which almost instantaneously interrupts large fault currents with no arcing across the contacts had been fabricated and was undergoing tests.

The detection of incendive ground fault currents on the order of 10 amperes in trolley line systems, where normal currents may be in excess of 3,500 amperes, is accomplished by means of a "discriminating circuit breaker system." The method by which the system distinguishes a dangerous ground fault from a low resistance normal load involves injection of a 3,000-hertz audio signal into the system and the sensing of current flow at that frequency. All legitimate loads such as pumps, jeeps, and locomotives operating on the line must be equipped with filters to block the flow of 3,000-hertz current, whereas the current will flow freely through a genuine ground fault and cause a relay to trip the circuit breaker. In the present experimental installations, all of the mine vehicles are not equipped with blocking filters; hence, the system cannot be connected so as to actually interrupt the trolley line current; however, 3 years of observation have proven that a fully installed system would be essentially free from nuisance interruptions. Further in-mine evaluation is underway.

The Bureau of Mines in its concern for mine safety has responded by performing research in all areas related to improving the safety of coal mines during the mining operation. Of particular concern are programs to improve the interface of the machine operator and the machine.

Several programs were initiated to achieve this goal; these programs examined innovative machine designs and modification of existing equipment. The innovative machine design program involved complete redesign of equipment, employing human factors engineering in the new designs. The program for modification of existing equipment was broken down into several projects. These projects have been directed toward standardization of controls, panic bar installations, development of low coal canopies, and a survey of available canopies.

Other examples of noncompliance with human engineering principles are the widespread use of identical black, round control knobs (regardless of the function being performed) and frequent inappropriate location, spacing, and labeling of controls. Any or all of these factors may place the operator in a "negative transfer" situation, which means that control manipulations appropriate for one type of machine are different from (or even in the reverse of) the control movements required to produce the same effect of other machine types. The goal of this project was to develop and evaluate criteria for standardized controls for underground electric face equipment.

Several projects were initiated under the protective canopy program to develop protective canopies that were easily retrofitted to existing equipment used in various seam heights. The results of these projects have been combined into one study that applies human engineering principles in conjunction with these past research programs to develop optimized operator compartments. Three projects were initiated under the optimized operator compartment program. These projects were similar with the objective of fabricating operator compartments that were easily retrofittable to existing equipment and included the results of the standardization of controls project, the panic bar project, and the various canopy projects.

One of the optimized operator compartment projects has been completed on an Elkhorn scoop and a pair of National Mine Service shuttle cars. The two shuttle cars were sold to a mining company for use in its mine; the company agreed to accept the cars with optimized operator compartments and evaluate them in normal operation during the months of March and April 1976. The compartment was very well received by the drivers and other mine personnel.

A coal company agreed to cooperate in finding a maintenance shop to modify its Elkhorn Scoop compartment to the optimized operator compartment configuration and to participate in the in-mine evaluation of the scoop. The modifications to the scoop compartment were completed in January 1976. The scoop compartment was then evaluated by the scoop operators, while performing their normal duties, during the months of February and March 1976.

The broad objective of the Bureau's mine machinery equipment training program is to improve the safety and productivity of new operators of underground mine machinery by the systematic and disciplined development of equipment training systems. The present scope, as determined by historic accident and hazard analyses, includes the development, implementation, and validation of miner, roof bolter, and hoist equipment operator training systems.

In providing detailed information concerning equipment operation, a shuttle car training system was developed under contract by Doron Precision Systems. The trainer concepts evolving from the training system analysis have included the development of classroom material, a dynamic concepts trainer, and a reaction trainer. The reaction trainer was designed to teach and provide drill and practice in hazard recognition and avoidance. As such, the reaction trainer is designed to partially simulate the shuttle car and working section with a sufficient degree of fidelity to realistically present many of the hazards a shuttle car operator may encounter. Efforts were underway to adapt this training system to the development of training packages for roof bolter, continuous miner, and hoist equipment operators.

While the machinery trainers address an important area, another technique with broader applicability in terms of general training and testing is the Lincoln Training System (LTS), which is a self-paced, interactive, audiovisual trainer. All information (audio, visual, and control information) is contained on low-cost microfiche. Prototype systems have been evaluated at coal mine training sites with excellent acceptance.

Health-related research is focusing on such problems as respirable coal dust, radioactive gas, noise, toxic mine gases, and on solutions involving both protection of miners and control of the mine environment through engineering advances.

Projects were underway to prevent and control dust generation, improve face ventilation, and develop personal protective devices. Research continued on the radiation hazard which continues to be a major health concern in uranium mines. The major objectives are to improve techniques to inhibit or control radon emanation into the mine air and to develop measurement instrumentation such as a viable personal dosimetry system for measuring miner exposure to specific types of radiation.

Research continued on noise abatement in order to achieve acceptable levels of noise exposure for personnel engaged in coal and noncoal mining activities, both underground and surface. Noise instrumentation was being improved to meet continuing demand for more accurate assessments of noise levels. An industrial hygiene program was aimed at rapidly measuring/monitoring toxic gases such as CO, NO, and NO_2 through the development of low-cost, reliable measuring instrumentation. Thus, the quality of ventilating air in a mine can be quantified and the miners' accumulative exposure can be measured.

A Bureau of Mines research contract developed methods to increase significantly the amount of fresh air that reaches the front of a continuous mining machine. The contract emphasis was on removing methane buildups that occur at the cutter head.

The key to providing more air at the face is to enhance and move forward the "natural" airflow pattern. Devices designed to enhance and move forward this natural pattern always swept away methane better than those that ignored this simple principle.

One way to move forward the natural pattern is with proper placement of a low volume diffuser fan. A twin nozzle diffuser fan placed on the intake side of the machine works best. One disadvantage of this kind of diffuser system was that it required a second, identical system on the other side of the machine to make the air go the other way when the brattice was moved to the other rib.

Another simple and effective air mover is the conventional water spray. It was discovered that if all the water sprays on the machine were realined to take advantage of their air-moving abilities, then the natural airflow pattern was enhanced even more than with a diffuser fan.

While some care in the selection and placement of spray nozzles is necessary, conventional nozzles work as well in this application as specially designed "air-mover" venturi sprays. These "air-mover" sprays move air through a small diameter short tube that surrounds the spray nozzle. However, this Bureau-sponsored research has shown that the key to better face ventilation is recognizing that the space between the machine and the roof or rib is also a "tube," a far larger tube than could ever be tucked away inside the machine. The solution to more air at the face is a more effective use of this tube that has been there all the time.

In an attempt to reduce both the material costs and the man-hours needed to maintain stoppings in working areas of hardrock mines, the Bureau of Mines developed a new type of stopping, called the quick-fix blowout stopping. This is a variation of the parachute stopping developed earlier by the Bureau. Unlike conventional stoppings constructed in working areas, the stopping is not designed to resist blast forces. Rather, it is designed to be easily blown out by blast forces and then to be quickly and easily reinstalled; in contrast, a conventional timber stopping or bulkhead may require an entire shift to replace. Furthermore, restoring conventional wood or brattice stoppings almost always entails the use of new materials, whereas the quick-fix blowout stopping can be used again and again.

A new, self-sealing brattice developed by the Bureau of Mines offers distinct advantages over conventional brattice as to both weight and tightness. Its main feature is that the fabric is sewn into a hemispherical shape rather than a flat sheet-like conventional brattice. The perimeter of the hemisphere is made larger than the airway perimeter, so that the differential air pressure will balloon out the fabric, forcing it against the mine surface and providing an automatic seal that reduces both leakage and the number of attachment points needed. It should be noted that the Bureau of Mines considers this concept still in the developmental stage. Although it has been shown that this type of stopping can be successfully employed underground, it has never been tested in an emergency situation.

The Bureau of Mines developed a mechanically driven sequential sampler that can automatically take air, gas, or liquid samples in underground mines for periods of 1 to 8 days. The new sampler is basically an Archimedes screw—a spiral of plastic tubing wound around a cylinder, which is tilted so that one end of the tube is submerged in a pan of water. The other end of the cylinder is connected to a spring-wound motor that can rotate the cylinder, one revolution per sample, at set intervals ranging from once a minute to once an hour. As the cylinder turns, the low end of the tubing comes out of the water for half a revolution of the cylinder. As the end of the tube submerges again, a plug of air is trapped in the tube between two plugs of water, and successive air samples are automatically spiraled upward in the tubing as the cylinder rotates.

In 1976 the Bureau continued to explore possible ways of reducing the level of airborne respirable coal dust through improvement in coal mining machines, methods, and systems. The objective of a Bureau contract was to design, construct, and test a full-scale continuous coal miner for the purpose of quantifying the relationships between cutterhead's rotational speed and the depth of cut by the bits into the coal face as related to the generation of airborne respirable dust. The results showed that airborne respirable dust was reduced by greater than 60% in the air return when the depth of cut was increased from 1 to 2 inches. Rotational speed had only a slight effect in the return, but at the operator's station, a reduction of 77% could be realized by slowing the head from 51 to 18 revolutions per minute. The contract has been completed and the machine was being demonstrated under a cooperative agreement with a coal company. The purpose of this demonstration is to show that a drum-type continuous coal miner can operate in a much cleaner mode and yet can maintain or increase production.

More than 90% of the coal in underground mines is hauled by various types of shuttle cars from the mining face to the secondary haulage system. Approximately 72% of the cars are electric powered through a trailing cable. All of the remaining cars are powered by lead acid batteries with the exception of a small number that are powered with diesel engines.

Continuous face haulage systems transport 8% of the underground coal and their application is expected to grow. However, shuttle car haulage will continue to be the predominant face haulage method during the foreseeable future. Shuttle cars, in general, have the relative advantages of low capital cost and high reliability. In the case of the electric trailing cable powered shuttle car, it is a simple and easily maintained vehicle. The principal disadvantages of this kind of vehicle are limited coal capacity and various problems related to the trailing cable. Battery-powered vehicles have the flexibility to travel various paths and eliminate the fire hazard and failure problems associated with the trailing cable. The major problems with battery-powered equipment are limited operating time per charging cycle and downtime due to battery replacement. Diesel-powered shuttle cars have the advantages of battery-powered vehicles and, in addition, have a higher operating time and lower operating cost. The critical problems of diesel-powered shuttle cars are the health hazard of the engine exhaust emissions and noise. In 1976, research was being conducted on all of the problems cited above with the objective of reducing or eliminating them.

A contract was awarded to a firm to maximize the coal carrying capacity and to improve or, at a minimum, retain the existing maintainability and reliability standards of shuttle cars without increasing the outside dimensions. An evaluation was made of all currently used shuttle cars and relevant technology to identify those features and components that could be combined to meet contract requirements. The evaluation has been completed and a shuttle car design is nearly completed that will have a capacity more than 25% greater than existing shuttle cars of equivalent overall dimensions.

Under a contract, an iron-nickel high performance battery for coal haulage vehicles and a more efficient battery charging system was being developed. The iron-nickel battery will have sufficient energy to last a full shift and can be charged and ready for use in less than 3 hours.

Also through a contract, the closed Rankine cycle steam engine that was developed for automotive propulsion has been modified for use in underground coal mine vehicles. The steam powerplant potentially offers significant advantages over existing diesel-powered (internal combustion) vehicles. Emission levels for oxides of nitrogen and carbon monoxide from the steam engine system are anticipated to be approximately less than 10% and 40%, respectively, of those obtained from diesel systems presently in use underground.

Significant advances have been made recently in flywheel materials and technology. Shuttle cars appear to be uniquely suited to the application of flywheel technology. The distance of travel is typically short and the cycle frequency is high. Conceptually, the shuttle car flywheel would be rapidly recharged in fresh mine air while the car is being unloaded at the transfer point. A contract has been awarded to assess existing flywheel technology and its practical application to underground coal mine shuttle cars. The evaluation includes flywheel size and material, methods of charging, recovering, and transmitting flywheel energy, and safety, and cost-effectiveness.

Studies, research, and development are currently underway by the National Aeronautics and Space Administration/ Marshall Space Flight Center for the

Bureau of Mines to develop the coal interface detectors and associated control systems required for the automation of a longwall shearing machine. The specific goal is to define, test, and recommend practical low-cost guidance and control systems and detectors required for the development of an automated bidirectional double-drum arranging shearer/loader.

To date, the following four sensor types have survived the feasibility tests and are being developed further by laboratory and field testing: (1) Nucleonic, which employs back-scattering gamma rays to measure the thickness of coal left on the roof or floor after cutting; (2) radar, which employs an FM or CW single-antenna radar to measure depths of coal and/or strata in roof or floor after cutting (discrimination depends on differences in the dielectric constant of the materials); (3) sensitized pick, which uses a strain-gaged pick block to measure force on cutting bit and discriminates between hard and soft materials; and (4) penetrometer/reflectometer, which is a dual sensor which measures the impact hardness and color of material left exposed on roof or floor. A fifth sensor is being developed for the Bureau that is based on an analysis of the vibration spectrum of the coal-cutting operations.

Concurrent with the detector development work, concepts for shearer guidance and control systems, utilizing one or a suite of detectors, were being evaluated. This evaluation includes mathematical simulation of the control system, identification of hardware design approaches, and the definition of the system requirements.

In addition, studies were being conducted on methods for measuring the alinement of the longwall coal face with respect to established mine reference locations. Measuring instruments that can measure the path of the face conveyor (yaw) have been developed and were undergoing laboratory evaluation. Instruments also have been identified for measuring the shearer tilt (roll attitude).

The choice of detectors will depend ultimately on the physical properties of the roof, coalbed, and floor; the mining strategy (how much coal to leave, how much roof or floor to cut, etc.); and the accuracy of the fully developed sensors.

Because of new impetus on coal to satisfy U.S. energy demands, the Bureau of Mines had a program for improving underground coal production. Part of this effort is the "Automated Continuous Roof Support" subprogram for developing and demonstrating equipment that will increase production and lower coal costs.

An approach to increasing room-and-pillar production is to provide more operating time for high-capacity continuous miners. By installing supports during the mining operation, the separate steps required for mining and supporting can be eliminated. Eliminating separate mining and bolting operations with equipment that can simultaneously mine coal and install roof supports would then enable a miner/bolter to produce 750 tons of coal per shift—a considerable improvement over today's 350-ton rate. The Bureau has contracts to design, fabricate, assemble, and test equipment that combines the bolting and mining functions.

The Bureau of Mines is conducting research to help apply the potential benefits of mining uranium by in situ leaching. In situ leaching presently provides only a small fraction of the Nation's uranium production. There are certain problems to be overcome before in situ leaching will contribute large amounts of uranium. One of these problems is optimizing the type and concentration of chemical lixiviant for the particular ore being leached. A second problem is optimizing the construction of injection wells so as to minimize clogging; in certain types of deposits, organic drilling fluids have caused clogging. A description of the preferred method of making injection wells was being prepared for publication.

The third problem is limiting the lixiviant to the uranium-bearing zones, especially when there are several layers of ore. With conventional methods of placing screens, the barren zones between the uranium-bearing zones are exposed to the lixiviant. An alternative method is to case and grout the well all the way to the bottom of the lowest uranium-bearing zone, then perforate the casing and grout at the desired levels. The Bureau of Mines has developed an excellent technique for making the required perforations by using a high-pressure water jet. The water jet makes smaller, more regular holes than mechanical perforations, and so provides better sand control. The water jet not only can be used to make original perforations, but also can make new holes in a clogged screen. Both applications were tested successfully in

Texas. By such research, the Bureau is attempting to improve the efficiency of in situ uranium leaching so that lower grade and smaller deposits can contribute to the Nation's energy supply.

Explosive fracturing of copper ore bodies in preparation for in situ leaching is a new technology with a high potential for developing low-grade deposits. The Bureau initiated field research to assist mining companies in developing this technology. The Bureau and a mining company conducted a cooperative in situ leaching research program at a mine near Kingman, Ariz. The objective was to develop in situ leaching methods for 200,000 tons of ore exposed in the pit bottom and also 3 million tons of ore under 200 feet of overburden adjacent to the pit. The grade of the ore remaining at the mine had became marginal, and it was no longer economical to continue open pit operations.

In another cooperative research program the Bureau and another mining company began investigating the in situ leaching potential of copper ore along the fringes of an open pit mine near Benson, Ariz. This fringe ore is beyond the projected pit limits and if an in situ leaching system is successful, the life of this mine would be extended and the total copper production would be increased.

The techniques demonstrated by these Government-industry cooperative efforts can be of significant industrial value to any company that is considering the use of in situ leaching.

For over 5 years, the Bureau has sponsored research for the development of a conical reamer for hard rock. This device attacks the hole bottom at an angle, which decreases the force on individual cutter elements to be spaced further apart than is possible with a tricone bit. As a result, this geometry leaves more room for cutter bearings and, consequently, has the potential for longer bit life.

The Bureau, with the cooperation of two firms mining taconite, conducted an extensive field test of the conical reamer blasthole bit on the Minnesota Mesabi Iron Range in 1976. Taconite rock is extremely hard (50,000 to 75,000 pounds per square inch), so these tests enabled the Bureau to evaluate performance under very severe conditions. The tests were considered a technical success, but the economic analysis indicated that for drilling in taconite, the conical reamer bit is more expensive than using a standard bit. The technology has been transferred to industry. A manufacturer recently began marketing the bit and apparently the bit is performing very well in softer formations.

To encourage improved production and work efficiency, the Bureau contracted research for the design, fabrication, and field testing in a vein mine of an improved portable man-rated service hoisting system for transporting men, supplies, and equipment into stopes. The following general requirements were designed into the hoisting system: (1) Capable of operating at a speed of 50 feet per minute under normal 2,000-pound man-rated load; (2) capable of serving a 3,000-foot raise; (3) capable of operating with a 4,000-pound payload of equipment; and (4) capable of being moved and reinstalled quickly and easily in other stopes in the mine. The system was field tested for a 6-week period at a mine in Colorado. Minor modifications and additional in-mine testing and demonstration are planned.

The Bureau of Mines has a contract to develop a remote controlled, mechanized shotcrete placement system for raise drilled shafts. This is to eliminate the major deterrent of the current lining process, which is slow, costly, and dangerous owing to the need for men in the shaft. On a single shift basis, this shotcrete system could conservatively place 30 feet per day figuring 50% of an 8-hour shift to be operating time. By adding two more shifts, this rate could conceivably be increased to 90 feet per day. Based on a conservative analysis, the economics of the system look extremely attractive. Excluding research and development costs, an estimated $9.00 per foot cost saving was realized on the demonstration shaft. Not figured into the cost analysis were such factors as the benefits gained by faster development and the loss of fewer raises due to collapse. The system is undergoing a refinement phase to correct shortcomings noted on mine equipment trials. Subsequently, the system will be demonstrated in a deeper shaft.

The underground auger has the potential advantages of low capital and operating costs, and high tons per manshift output. With a Bureau contract, a project was successfully constructed, demonstrating peak production rates reaching 130 tons per shift or about 25 tons per manshift. An extension to the contract to gather more field data and improve the machine has been granted. Under an in-house project, several high recovery auger mining (Hiream) systems were developed. The first involves drilling square holes with or without temporary support for a potential recovery of 75%. The second system uses a backreaming tool that allows holes to be drilled closer together with or without temporary support for a potential recovery of 72%. During fiscal year 1976, prototype equipment was developed and tested for the square hole drilling system, the circular backreaming system, and the temporary support system, all of which appeared feasible.

Environmental restrictions imposed on contour mining in steep slope areas of Appalachia have prompted the development of new mining techniques, such as the haulback or blockcut method, which permit controlled placement of overburden and eliminate spoiling on the outslopes. The major disadvantage associated with these methods is that production is lowered mainly because of time delays caused by equipment cycling and interference between coal mining and overburden handling equipment causes congestion in the pit area.

The feasibility of portable belt conveyors for handling of overburden either along the lowwall or highwall is being examined under a Bureau contract. These conveyor haulage systems alleviate the pit congestion and production hinderances associated with truck haulage of overburden through the active pit area in haulback and blockcut mining methods.

Two systems each using portable belt conveyors have been developed. In the lowwall concept, the conveyor units are placed along the lowwall side of the pit. A front-end loader places the overburden into a hopper, to screen oversize material, which feeds the belt conveyors. The conveyors transport the material through the pit to the reclamation site. Here a reclamation stacker is used to deposit the overburden for final grading by dozers. In the highwall concept, similar equipment is utilized; however, the conveyor units run along the highwall. A single lift elevator lifts the overburden from the bench to the top of the highwall where it is deposited onto the conveyor units. The conveyors run along the top of the highwall and feed into a highwall reclamation stacker, which deposits the overburden into the pit for final grading.

Evaluations indicate that conveyor haulage of overburden offers numerous advantages over trucks such as potentially higher production rates, additional coal recovery, improved reclamation due to concurrent backfilling, improved spoil placement, and reduced pit congestion. Of the two concepts developed, the lowwall system has the most promise.

Only a small portion of the vast reserves of oil shale can be mined by conventional surface or underground techniques. To recover the remainder of this fuel, a modified in situ technique will be required. Through a contract, the Bureau assessed the technical and economic feasibility of a modified in situ process. In the modified technique, upper and lower development levels are advanced by standard mining methods. Compared to conventional mining methods, the modified in situ method will minimize surface disposal problems, increase resource recovery in thick beds, reduce surface disturbance, and reduce capital plant costs.

Areas of investigation important to the development of a modified in situ operation are the geology and mineralogy of the tract to be mined, rock mechanics for mine design, access mining systems, ventilation requirements, rubblization technique, in situ retorting parameters, safety considerations, and environmental impact.

The feasibility study indicated that modified in situ oil shale mining is a technically feasible, environmentally acceptable, and economically competitive energy alternative. A typical retorting facility producing 50,000 barrels per day from 20-gallon-per-ton shale, utilizing 230-foot-high retorts under 1,000 feet of overburden will produce kerogen for $8.75 per barrel (January 1975 dollars). Various other combinations of parameters yielded costs varying from $7.70 to $15.50 per barrel. Additional economy and resource utilization can be attained by surface retorting of the development material.

The Bureau's environmental efforts are directed to the correction of adverse effects of past mining and mineral processing and to the development of new environmentally acceptable technology for methods of mining and processing in the future.

Most of the current mined-area restoration efforts are in the Appalachian region. Considerable progress has been made in techniques of back-filling mine voids to prevent surface subsidence in urban areas. Surface reclamation projects have demonstrated procedures and costs for converting strip-mined land to such public uses as schools, shopping and residential areas, and recreation.

Results of these research/demonstration projects are applied in the Bureau's administration of the Mining Area Restoration Section of the Appalachian Regional Development Act in which the improvement of environmental quality and protection of public health and safety are major concerns. A demonstration of subsidence control is underway for two residential areas in western Illinois. In the anthracite region of Pennsylvania, the recovery of low-sulfur fuel from mine refuse is receiving major attention. Bureau research into technology for future mining emphasizes surface effects resulting from both underground and surface mining, with special attention to integrated reclamation practices and to prevention of uncontrolled future subsidence.

Reclamation research workshops were held in eight States during the period from December 12, 1975, through June 25, 1976, under a Bureau of Mines contract with the University of Missouri-Rolla. The workshops were designed to help define the Bureau's research and development priorities. At each workshop a summary of current Bureau mine reclamation research was presented, which was followed by identification of problems associated with mine land reclamation in the State where the meeting was being held. Discussions included the seriousness of problems locally and how the Bureau could best undertake research to assist in developing the technology for solving the problems identified. Participants included representatives of State agencies, educational institutions, and companies involved in surface mining.

The Bureau of Mines principal activity in the area of subsidence control has been the development of an improved method for backfilling abandoned mine workings particularly in urban areas. During 1976, surface stabilization was needed in an area in Jessup, Pa., where subsidence had already started. Because caving of the workings would limit the lateral migration of slurry underground, a pumped-slurry demonstration project was tailored to fit the site conditions. Experience was gained in backfilling areas where the uppermost mined coalbed was close to the surface. Problems of fracturing or flooding basements of houses, or disturbing masses of caved material within the mines, were avoided by careful control of pumping pressures. Throughout 1976, the Bureau experimented with the pumped-slurry backfilling process to expedite the procedure and minimize costs.

The Bureau of Mines has been asked by the Congress to direct its technical efforts toward resolving problems associated with the nonutilization of recoverable low-sulfur coal from refuse in the northern anthracite region of Pennsylvania. As a result the Bureau is in the initial stage of evaluating proposals to cooperate in the design, construction, and operation of an anthracite refuse preparation plant. The objective of this project will be to increase the supply of anthracite through actual recovery of coal from anthracite refuse sources located in northeastern Pennsylvania. In addition, it is hoped that the demonstration of a feasible system for reclaiming coal from anthracite refuse and the resulting economics will lead to production of anthracite at a reduced cost, thereby showing how coal from mine refuse can produce a low cost/high quality fuel.

Abandoned coal mines and oil and gas wells in some areas leak large amounts of water containing acid and other pollutants into surface waters. Fires in abandoned underground mines, coal outcrops, and refuse piles can be a source of air pollution to neighboring residents as well as threaten surface improvements and adjacent coal deposits. Mined-area restoration projects undertake to alleviate these problems. They include projects funded on 75% Federal, 25% State basis by the Appalachian Regional Commission, in-house research and demonstration projects that are funded entirely by the Bureau, and cooperative projects with the Commonwealth of Pennsylvania. The Bureau has been involved with mine water problems through monitoring, deep mine pumping, surface water diversion, water treatment methods, and oil and gas well sealing projects.

Various methods have been developed for dealing with fire problems. Outcrop fires are sometimes smothered and sometimes excavated and extinguished; underground fires in abandoned mines are controlled by placement of noncombustible and airproof barriers. A special "ponding" method has proved successful in extinguishing burning refuse banks while reducing temporary pollution problems that accompany other methods.

Several years ago the Bureau of Mines conducted a mined land survey to determine how much land was used, and reclaimed, by the mining industry during the period 1930-71, inclusive. More recently the Bureau undertook a similar survey, the results of which will be used to update data previously obtained. Unlike the earlier study, which covered land used in the production of all commodities during a 41-year period, this study focused on acquiring data on land utilized by the bituminous coal and lignite industry for 1975. Information was sought from the coal industry itself, including corroborative data from Federal and State agencies, and mining and trade associations. State agencies were also canvassed for 1975 data on administration and enforcement of surface mining regulatory procedures. Results of the survey will be disseminated through published Bureau reports.

During 1976, the Bureau held four open industry briefings under the Technology Transfer program, attracting over 500 people from the mining industry and allied fields. Technology transfer seminars are used to introduce and stimulate the transfer of specific technologic "packages," or groups of transferrable results from single research areas or combinations of related areas. During 1976, a seminar on respirable dust control was held in Pittsburgh, Pa., and Denver, Colo., in September. Exhibits and displays are widely used at major industry conferences and trade shows as another means of keeping industry abreast of ongoing research programs and accomplishments. Audiovisual presentations and hardware displays and demonstrations are employed in the technology transfer exhibit. In 1976, the exhibit was used at six such meetings, attracting estimated audiences totaling 5,500.

In-mine demonstrations and field trials are frequently important elements of the technology transfer process and are aimed at demonstrating the usefulness and applicability of new technology. Significant demonstrations and field trials completed, or ongoing, during 1976 included shallow seismic geophysical technique for detection of coal seam disturbances, prototype roof bolting machine with flexible drill and bolt bender, automatic fire detection and suppression system for mine shafts, and shield-type supports on longwall faces in Utah, New Mexico, and Illinois.

Technology News bulletins were used throughout the year to report research results ready for use by the industry. Eleven issues published during 1976 reached over 3,000 subscribers in the mining industry and related fields.

Other special publications used by the Bureau to inform industry of mining research developments include Mining Technology Research, an annual description of program funding and goals, and Mining Research Review, an annual review of selected activities and accomplishments. These are augmented by the Bureau's regular publication series, technical papers in the trade press, and presentations at major industry meetings.

The Bureau film "Safer Coal Mining Equipment," which describes the Inherently Safe Mining Systems program, was released and by the end of the year had been seen by an estimated 3,000 individuals in industry, government, and academia. The film is first in a new series of technology transfer films now being produced by the Bureau of Mines.

The licensing of technology contained in Government-owned patents provides another mechanism for technology transfer. During 1976, the Bureau's Mining Research activities were responsible for the issuance of 26 U.S. patents to the Department of the Interior. Seventeen of these inventions resulted from contracts and grants with commercial organizations and universities. Licenses to practice the technology are available to qualified parties from the Solicitor, Department of the Interior.

The major coal-producing nations of the world conduct substantial research towards improving coal mining techniques and equipment and developing more positive means to protect the miners from health and safety hazards. Of the 38 countries mining coal, 19 are known to sponsor national research and development programs. A remarkable aspect of this statistic is that about 98% of the world's coal miners are covered by the work of these research organizations.

An important international organization is the International Committee for Coal Research. The concept of this group was proposed in May 1973 by Carl E. Bagge, president of the National Coal Association at the annual meeting of the European Coal Association. Mr. Bagge's proposal resulted in an agreement to jointly sponsor a committee to seek coordination of the coal technology research efforts of the European community and the United States. The organizing committee adopted the name International Committee for Coal Research (ICCR) and agreed to sponsor the third international conference in Sidney, Australia, in October 1976.

The Bureau of Mines has been an active supporter of ICCR since its creation, and the goals of the organization reflect the mission of the Bureau to increase the production and use of coal consistent with maximum protection to the miner and the environment.

The world's major coal producers support a significant research and development program in coal mining. Collectively, this effort has resulted in substantial progress in mechanization and improved safety. With the increase in collaboration and cooperation on an international basis, even greater progress should take place at an accelerated pace. Towards this goal, the United States is committed to expand and strengthen its research and development ties with other coal-producing nations.

Metallurgy.—The general objective of the Metallurgy program is to assure a supply of mineral raw materials, essential to the Nation's security and full employment, by improving minerals and metals processing technology. Research and development is carried out to develop new technology or improve existing processes to permit the utilization of domestic low-grade ores, to develop substitute sources of raw materials, to augment the resource base through recovering byproducts now bypassed by current technology, to reduce the usage of critical materials by developing substitute materials or materials having longer life, and to improve recovery from wastes and secondary sources. Primary concerns include the development and improvement of metallurgical operations to avoid environmental degradation, to minimize energy use, and to secure the health and safety of workers and the general populace.

The Bureau's miniplant for testing and evaluating processes for recovering alumina from domestic nonbauxitic resources continued to operate at Boulder City, Nev. This cooperative project, with the support and advice of the alumina consuming industry, considered six potential processes. These included nitric acid, hydrochloric acid (both the evaporative and sparging crystallization options), and sulfurous acid processes for the extraction of alumina from clay and processes for treating anorthosite, alunite, and dawsonite. A firm under Bureau of Mines contract was to evaluate the major processes for commercial feasibility studies, make a preliminary pilot plant design for the process selected for further development.

Curtailment of natural gas deliveries to taconite pelletizing plants of the Lake Superior region was the stimulus for Bureau of Mines investigations of the induration of iron ore pellets using substitute fuels. A variety of low-rank coals were being tested using a cyclone burner to remove the coal ash as a slag externally and thereby prevent contact of the ash with the pellets. A californium-252 source/gamma ray analyzer was being used for continuous monitor flotation pilot plant slurries during a series of beneficiation tests on Mesabi taconite at the Bureau Twin Cities Metallurgy Research Center. The californium-252 system was found to be accurate enough to be used for the direct determination of iron analyses and has shown potential for use as a process control device.

With the depletion of sulfide ores, laterite oxide deposits are being increasingly utilized as a source of nickel. Under a Bureau of Mines contract, Phase I of a study was completed to determine the technical and economic feasibility of the Bureau's extraction process utilizing low-grade domestic western laterite ores. The study, based on a 5,000- ton-per-day commercial scale plant for extracting nickel, cobalt, and copper, found that the process was technically feasible and, depending upon financing structure, could provide a modest return on equity. The report, (OFR 65-76) is available for inspection at the Bureau's Metallurgy Research Centers, and is available from the National Technical Information Service (PB 256 574/AS).

A recent development by the Bureau of Mines was an improvement on established cyanide-leaching procedures for gold- and silver-bearing ores. A solution of ethyl alcohol and alkaline cyanide is used to strip loaded carbon, thereby reducing the time required for this key step without reducing effectiveness. Procedures were developed for separating smaller amounts of silver from gold-laden solutions. A portable carbon stripping unit for gold-silver recovery from activated carbon was being field tested.

The Bureau of Mines was supporting research to apply recent developments in membrane technology to the liquid-liquid extraction and separation of metals from solution. Laboratory research, conducted under a Bureau contract, demonstrated that copper can be concentrated from ore leach liquor using active transport through specially prepared membranes. The special microporous membranes employed were fabricated to contain a water-immiscible extractant system in the pores. The complexing agent in the organic phase was selected to specifically extract copper ions; it served as a "shuttle" to transport metal ions across the membrane in one direction and hydrogen ions in the opposite direction. The counterflow of hydrogen ions is the driving force to separate and concentrate the metal ions in the second (aqueous) phase on the other side of the membrane. A bench-scale unit was under construction to permit evaluation of potential scale-up problems, including possible membrance fouling and reagent loss. Laboratory studies were underway to select and optimize the extractant systems in the membranes for extracting nickel and uranium.

Viburnam Trend lead ores contain 4,500 tons of cobalt and nickel which is discarded annually with mill tailings and smelter residues. Bureau of Mines beneficiation studies were developing procedures to concentrate the cobalt and nickel, which is contained in the mineral siegenite, in one of the byproducts and to extract and win these critical metals from the byproduct.

The Bureau of Mines was planning to accelerate development of an electrolytic procedure for recovering lead from galena under a cooperative agreement with major lead producers. The new procedure, which has already shown promise in the laboratory, is to be explored using continuous process development facilities. In the procedure, galena is leached with a hot solution of ferric chloride and sodium chloride. Elemental sulfur is recovered and lead chloride crystals are dried, melted, and electrolyzed to produce molten lead and chlorine gas. The chlorine gas can be recycled to make more ferric chloride for further leaching.

Recent advances in the development of electroslag melting have stimulated interest in the process among metal producers. Bureau of Mines Bulletin 669, "The Electroslag Melting Process," is a timely review of this technology, including choice of fluxes and applications to reactive metals, base metals, ferrous alloys, superalloys, and refractory metals. Important basic mechanisms such as electrochemistry, thermochemistry, and heat transport are also described.

After intensive testing of the potash flotation system developed by the Bureau, the system was incorporated into the operations of a firm near the Great Salt Lake. Formerly the firm was able to use only the high-grade salts deposited as a result of solar evaporation of Great Salt Lake brine for processing into fertilizer. The Bureau's method converts nonfloatable kainite ($KCl \cdot MgSO_4 \cdot 3H_2O$) to a salt which can be floated using fatty acids. The new plant treats evaporites averaging 6% K_2O to recover 80% of the potash in concentrates assaying more than 14% K_2O. In a related development a procedure was found for recovering much of the saturated potash brine that has been lost with the slime during the beneficiation of potash ores.

The Bureau developed a new method for preparing molds for casting titanium that reduces cost and uses less energy. Because of titanium's chemical reactivity at liquid metal temperatures, there are few candidates for titanium molding materials: Graphite, high-cost ceramics, or refractory metals. The Bureau of Mines developed low-reactivity zircon molds with silicate binders; the sand may be reused through many cycles. Curing schedules are low (250° C) compared with those of industry (950° C), reflecting an important energy saving. The surfaces of the titanium castings produced by the Bureau method are similar to other metal castings used for utility hardware, such as pipefittings and pump housings.

Secondary Resources Recovery and Pollution Abatement.—Waste glass from the Bureau's College Park Raw Refuse Pilot Plant was incorporated into two 5-foot sections of glass-polymer-composite sewer pipe by the Brookhaven National Laboratory. In December 1975 these sections were installed in the sewer system of an industrial area of Newark, N.J., containing high-acid waste water. In September 1976, an inspection by remote television camera showed no evidence of pipe distortion or failure, infiltration through joints or pipe wall, and no deposits. Periodic inspections are to continue. This study was part of an effort to develop a market for products of municipal refuse plants.

Bureau of Mines Report of Investigations 8123 describes a new method for processing lead battery scrap that eliminates nearly all of the sulfur dioxide emission produced when normal reverberatory or blast furnace methods are used. The patented method employs a hydrometallurgical step to convert lead sulfate to lead oxide and calcium sulfate. The lead oxide is then reduced by carbon, and the calcium sulfate removed with a flux. This promising nonpolluting method for recycling battery scrap has lead recoveries as high as 97%.

Pilot plant tests of the citrate process for recovering of sulfur from smelter waste gases were concluded at a lead smelter in Kellogg, Idaho. The plant, which treated 1,000 to 1,200 standard cubic feet per minute or a gas stream containing 0.3% to 0.5% SO_2, provided engineering data on gas conditioning, SO_2 absorption, sulfur precipitation, sulfur recovery, and H_2S generation. Consistent SO_2 removal efficiencies in excess of 98% were achieved. A $12.7 million cost-sharing agreement was signed by the Bureau of Mines and St. Joe Minerals Corp. to demonstrate the Bureau's Citrate Process for scrubbing the air pollutant, sulfur dioxide (SO_2), out of powerplant flue gas. The agreement will test the Bureau's process for removing SO_2 in flue gas from a 50-megawatt coal-fired boiler at St. Joe's George F. Weaton powerplant in Monaca, Pa.

Under a cooperative program with the Florida phosphate mining industry, the Bureau was investigating methods for dewatering and stabilizing waste slimes from processed ores before impoundment of the slimes. The most promising result to date stems from a Bureau-developed flocculating-dewatering technique: A polymer of polyethylene oxide used as the flocculant and a special mechanical handling system dewatered slimes at a rapid rate. Whereas years are required to thicken the slime using the conventional storage system, only minutes are needed with the new scheme. This relatively simple system, which can be adapted for in-line processing, requires mixing the slime with the flocculant and conveying the slurry through a rotating trommel-like, wire mesh screen to remove water and discharge a thick, solid mass. In small-scale, continuous tests, retention periods of about 5 minutes yielded 25% to 35% solid products from feeds containing only 2% to 5% solids.

As a means of avoiding the slime disposal problem inherent in the present method for treating Florida land-pebble phosphate matrix and to recover phosphate now lost in beneficiation to slimes, the Bureau of Mines has been studying the direct sulfuric acid digestion of the phosphate matrix. Tests showed that about 90% of the P_2O_5 could be extracted to form sandy filter cakes, comprised mostly of quartz and gypsum, which appear suitable for backfilling. Unfortunately, the product acid produced by direct digestion sometimes contains high levels of aluminum and iron. Procedures are being worked out for reducing the levels of these contaminants to enhance acid stability during storage and transportation.

The Bureau of Mines constructed and operated a miniplant to test its laboratory-developed technology for recovering aluminum metal and aluminum oxide from the salt slag generated during treatment of aluminum dross by the secondary aluminum industry. The Bureau procedure combines leaching, screening, and filtering to separate the slag into an aluminum-rich fraction, an aluminum oxide fraction, and brine solution. The fluxing salts (NaCl-KCl) are recovered from the brine by submerged combustion evaporation. The salts and the recovered metal can then be recycled to an aluminum dross treatment furnace.

Preliminary evaluation of the durability and stiffness of sulfur-asphalt-concrete mixtures developed by the Bureau suggest that they may be able to last at least 15 years under heavy traffic conditions. The sulfur-bearing material can be formulated to have twice the dynamic stiffness of conventional paving thereby permitting placement of thinner road sections with a corresponding savings in raw materials. Sulfur-substituted asphalt paving was found in Bureau studies to be less susceptible to attack by gasoline, jet fuels, and diesel oil than is conventional bituminous concrete. Long-term wear and weathering tests were underway at a number of heavily trafficked road and airport locations.

The loss of critical metal values in stainless steel wastes and ferroalloy fumes prompted Bureau of Mines research to develop technology for recycling these wastes. In the Bureau-developed procedure the various stainless steel wastes are pelletized with 10% coke breeze and 5% portland cement. The pellets are reduced in an electric-arc furnace using a second stage ferrosilicon addition which is required to complete the reduction of chromium.

Approximately 1% to 2% of the charge in electric furnace steelmaking comes off as particulates. This flue dust is a rich source of zinc (values are substantially higher than in ore), but although there are several processes for recovering the metal, none are considered economic in the United States. Bureau of Mines Report of Investigations 8209, "Electric Furnace Steelmaking Dusts—A Zinc Raw Material" reviews extraction technology and presents results of Bureau of Mines reduction-volatilization tests on pelletized electric furnace dusts that achieved high recoveries of zinc. The data are sufficiently encouraging to warrant consideration of electric furnace dusts as raw material for zinc smelters.

Microscopic mineral particles were studied using specialized scientific disciplines that can clearly identify such potentially harmful substances as asbestos and distinguish them from thousands of other mineral particles. These studies were being performed by the Particulate Mineralogy Unit established in 1976 at the College Park (Maryland) Metallurgy Research Center of the Bureau of Mines. The new research unit utilizes the Bureau's recognized expertise in particulate mineralogy to eliminate lack of precision with which the term "asbestos" is used, a situation having environmental and health implications. The objective of this unit is to develop a solid scientific basis for research into particle-related pollution problems and to provide technically sound information on the identification of particulates involved in regulatory and research activities of Federal, State, and local agencies. The unit has been working toward the development of new and improved analytical methods for positively identifying small particles. As part of its activities, the unit has been preparing, precisely identifying, and characterizing various fibrous minerals which are then supplied to the National Institute of Environmental Health Sciences for medical investigation. The unit itself performs no medical studies.

The Imperial Valley of California contains several large geothermal reservoirs with potentially valuable resources, the recovery of which is seriously hindered by corrosion and scaling problems. In cooperation with the Energy Research and Development Administration, Bureau researchers erected mobile laboratory facilities at the Salton Sea geothermal field near Niland, Calif. In 1976 the Salton Sea facility tested 6,400 samples for general corrosion, stress corrosion cracking, corrosion fatigue failure, and electrochemical properties. Also the solubilities of hydrogen sulfide, oxygen, carbon dioxide, and methane in geothermal brines was determined, and the role of these gases in corrosion, scaling, and mineral-recovery processes evaluated.

Economic Analysis.—The Bureau's economic research program in 1976 continued to focus on economic factors that affect the minerals sector as well as on how the mineral industries affect and are affected by conditions prevalent in the national and international economies. The purpose of this research was to provide decisionmakers with accurate, up-to-date information and analysis to use in choosing among alternative courses of action. The economic analysis program attempted to develop the general methodology necessary for such analysis, as well as information relevant to problem solving in the field of mineral economics. Major long-term research projects included the study and forecasting of demand, supply, and productivity; commodity action analyses; mineral taxation; financial analysis; mineral transportation; international trade; ocean mining; input-output analysis; mining and land use; waste recycling; measures of the role of minerals in the U.S. economy; a weekly price report on fuels and minerals; and a monthly report on major minerals. Short-term projects undertaken in 1976 included: A second round study of the methodology for determining strategic stockpile levels, analysis of the Bureau of Mines information system, a mathematical model to determine an optimal stockpile to counteract foreign-induced commodity actions, an examination of the relationship of the percentage depletion allowance to nonfuel mineral supplies, development of a computer system to estimate aluminum old scrap recovery in the United States, examination of the Federal Helium Program operating within the Bureau of Mines, consultations with officials in two States on regional economic impacts from future mining, study of a tax incentive for recycling, cost-benefit analyses, 20-year time-trend projections for domestic production of commodities, and material for the annual report of the Secretary of the Interior.

Helium.—The Bureau of Mines conducts a helium program under the Helium Act of 1960 to foster individual enterprise in production and distribution; encourage conservation; and to continue research on all phases of production, transportation, and use.

The atmosphere contains an inexhaustible supply of helium, but recovery is now economically feasible only from natural gas, primarily fuel gas. The Bureau annually extracts about 350 million cubic feet of helium from natural gas at its Keyes, Okla., plant. Unsold helium is transported by pipeline to underground storage at the Bureau's Cliffside field near Amarillo, Tex. In 1976, the Cliffside field contained about 42,000 million cubic feet of helium. Mixtures of stored helium and native gas produced from Cliffside are transported by pipeline to the Bureau's Exell, Tex., plant for processing. The Bureau has contracts with eight firms for which it stores and redelivers privately produced helium.

LEGISLATION AND GOVERNMENT PROGRAMS

Economic growth in the United States continued at a steady rate in spite of the slowdown that occurred in the second half of 1976. With the assistance of the monetary and fiscal policies established during the year, real GNP rose at an average rate of about 5-3/4%.

Tax legislation in 1976 made the first extensive changes in the tax code since 1969; in spite of this, fundamental reform and simplification of the tax code were not achieved.

Energy price increases were slowed significantly during the year; this resulted partially from the Energy Policy and Conservation Act that became effective in February 1976. Energy consumption had increased owing to the economic recovery in 1976. However, higher prices held the consumption below previously established levels. The mining industry continued to meet with environmental regulation problems resulting from legislation enacted to conserve natural resources. This includes the regulation of mining activity within the National Park System.

Legislation approved during the 94th Congress covered many areas affecting the minerals sector of industry in the United States. Summarized below are some of the more important laws enacted. Amending the Mineral Leasing Act of 1920, Public Law (P.L.) 94-377 was implemented to provide diligent development and continuous operation of coal leases on Federal lands. Public Law 94-332 and Public Law 94-385 extended the authority and funding for the Federal Energy Administration during 1976 and extended their authority into the next fiscal year. Public Law 94-493 provided a renewal and extension of the interstate compact to conserve oil and gas to prevent physical waste of this natural resource. Public Law 94-586 is designed to help alleviate the natural gas shortage in the contiguous States of the United States by transporting natural gas from Alaska. In the environmental area, Public Law 94-580 amends the Solid Waste Disposal Act to promote the protection of health and the environment and to conserve valuable material and energy resources. Public Law 94-429 provides for the regulation of mining activity within, and repeals application of mining laws to, areas of the National Park System. In establishing a public land policy, Public Law 94-579, the Bureau of Land Management Organic Act, was enacted. Public Law 94-469 requires testing and necessary use restriction on certain chemical substances under the title, "Toxic Substances Control Act." Public Law 94-455, the Tax Reform Act of 1976, has included with other sections, an amendment to the rules pertaining to limitations on percentage depletion in the case of oil and gas wells. Public Law 94-409, the "Government in the Sunshine Act," provides that meetings of Government agencies shall be open to the public. A listing of mineral-related Federal legislation signed into law during 1976 follows:

Public Law (P.L.)	Description	Signed into Law
Energy:		
94-258	Establish national petroleum reserves on public lands.	Apr. 5
94-332	Extend FEA expiration date.	June 30
94-355	Public works in Water and Power Development and Energy Research Appropriations Act.	July 12
94-370	Improve coastal zone management for energy development.	July 26
94-377	Federal Coal Leasing Amendment Act.	Aug. 4
94-385	Extend Federal Engery Administration Act of 1974.	Aug. 4
94-422	Monies paid to any State involving oil shale in public lands may be used by such State.	Sept. 28
94-493	Extend interstate compact to conserve oil and gas.	Oct. 14
94-586	Expedite decision on delivery of Alaskan natural gas.	Oct. 22

Public Law (P.L.)	Description	Signed into Law
Environmental Quality:		
94-326	Extend Marine Protection, Research, and Sanctuaries Act 2 years.	June 30
94-558	Loan guarantees for construction of treatment works under Federal Water Pollution Control Act.	Oct. 19
94-580	Provide technical and financial assistance under Resource Conservation and Recovery Act of 1976.	Oct. 21
Water Resources:		
94-228	Authorize and modify various Federal reclamation programs.	Mar. 11
94-316	Appropriation for Saline Water Conversion Program.	June 22
94-423	Appropriation for Federal reclamation programs.	Sept. 28
Public Lands:		
94-429	Regulate mining activity within National Park Service.	Sept. 28
94-456	Withdrawal of lands under Alaska Native Claims Settlement Act.	Oct. 4
94-458	Provide improved administration of National Park Service.	Oct. 7
94-486	Amend Wild and Scenic Rivers Act.	Oct. 12
94-565	Provide payments to local Governments based on boundaries on public lands.	Oct. 20
94-567	Designate certain National Park Service lands as wilderness.	Oct. 20
94-579	Establish policy under Federal Land Policy Management. Act of 1976.	Oct. 21
Health and Safety:		
94-469	Toxic substances control.	Oct. 11
94-477	Amend Natural Gas Pipeline Safety Act of 1968.	Oct. 11
94-504	Qualified individuals to hear and determine claims under Title IV of Federal Coal Mine Health and Safety Act of 1969.	Oct. 15
Taxes:		
94-455	Tax reform, 1976.	Sept. 28
Tariff and Duties:		
94-560	Continue suspension of duties on Mn ore and related products through June 30, 1979.	Oct. 19

Public Law (P.L.)	Description	Signed into Law
Transportation:		
94-280	Appropriation for highway construction.	May 5
Miscellaneous:		
94-373	Appropriation for Interior and related agencies.	July 31
94-409	Government in the Sunshine Act, meetings of Government agencies to be open to public.	Sept. 13

The acquisition cost of strategic and critical materials in the national stockpile as of December 31, 1976, was $2.5 billion having a market value of $6.0 billion. The supplemental stockpile acquisition cost was $1.1 billion with a market value of $1.9 billion and corresponding Defense Production Act stockpile figures were $0.3 billion and $0.2 billion, respectively. The total acquisition cost of these materials was $3.9 billion having a market value of $8.2 billion. In 1976, disposals from the national and supplemental stockpiles totaled $90.1 million, a decline of 16.5% from that of 1975. Including the Defense Production Act inventory and other inventory disposals, the grand total of sales commitments for mineral commodities was $102.3 million. Commodities with largest sales value were tin with $26.3 million, cobalt with $20.8 million, tungsten ores and concentrates with $14.5 million, and aluminum with $8.0 million.

In 1975-76, a major interagency review of the strategic and critical material stockpile was conducted and in August 1976 the President approved new national stockpile policies on advice from the National Security Council. A set of long-range goals for acquisition and disposal of materials to plan for the first 3 years of an emergency, as opposed to the earlier policy of 1 year, was announced on October 1, 1976.

WORLD REVIEW

World Economy.—In 1976, six major industrialized countries—Canada, France, Italy, Japan, the United Kingdom, and West Germany—showed economic turnarounds compared with 1975. All six countries experienced slowdowns in their economies to varying degrees in the second half of the year compared with the first 6 months. Some progress was made in fighting inflation in 1976, though the problem was still far from being solved. Unemployment rates in most countries remained high despite improved levels of industrial production. However, as economic activity increased, the volume of trade worldwide also rose. The volume of trade increased an estimated 11% in 1976 compared to a decline of 6% to 7% in 1975.

Real GNP growth rates for 1976 were estimated at 5.9% in Japan, 5.6% in West

Germany, 4.8% in both Canada and France, 4.5% in Italy, and 0.9% in the United Kingdom. Inventory buildups contributed to improving economic conditions in these countries, but as inventory accumulation was completed, consumer spending declined and plant and equipment expenditures were less than expected.

World oil prices continued to increase in 1976, though at a more gradual rate than the rapid rise of 1973-74. These higher fuel costs have caused continuing economic structural adjustments and led to added demands for scarce capital resources because of the need to develop alternative energy sources.

World Production.—The United Nations (UN) indexes of world mineral industry production (1970=100) for the extractive industries increased 6 index points to 121 in 1976. Within the extractive industry, the metal mining index rose 3 index points to 106, the coal index increased 1 point to 100, and the crude petroleum and natural gas index increased 9 points to 130. The mineral processing industries indexes showed increases of 9 points to 121 for base metals, 9 points to 135 for nonmetallic mineral products, and 14 points to 146 for chemicals, petroleum, and coal products. Overall industrial production as measured by the UN index rose 11 points to 136 in 1976.

World Trade.—The value of world export trade grew 4.7% to $872.5 billion in 1975 (latest data available). The value of mineral commodities entering world trade declined 3% to $253.6 billion. Internationally traded metals decreased 9.8% in value to $78.8 billion, and within this group iron and steel declined 1.3% to $45.8 billion, nonferrous metals dropped 27.7% to $18.2 billion, and all ores, concentrates, and scrap fell 6.4% to $14.7 billion. Crude nonmetal exports increased 6.8% in value to $6.3 billion. The value of mineral fuels rose by a negligible amount in 1975 to $168.6 billion.

World Prices.—(Note that all export price data, with the exception of the all crude minerals index, is for the first three quarters of the year only, because the United Nations discontinued publishing the data that would provide the series for the remainder of the year.) In 1976 mineral commodity export price indexes (1970=100) increased slightly for all crude minerals and appeared to have risen for the metal ores and fuels sectors. All crude minerals increased 16 index points to 510, and metal ores and fuels averaged 210 points and 616 points, respectively, for the first three quarters. Based on data through third quarter 1976, export prices for total minerals remained nearly constant in developed areas and averaged 595 index points in developing areas. Nonferrous base metals showed gains in both developed and developing areas, averaging 136 points and 123 points, respectively, based on the first three quarters of 1976.

Table 6.—Net supply of principal minerals by component

(Thousand short tons of mineral content, unless otherwise stated)

Commodity	Total net supply		Percent change	Components as percentage of gross supply[1]						Exports as percentage of gross supply	
				Primary shipments		Old scrap		Imports			
	1975	1976		1975	1976	1975	1976	1975	1976	1975	1976
FERROUS METALS											
Iron ore ---- thousand long tons	119,901	118,174	-1.4	62	63	--	--	38	37	2	2
Pig iron	79,658	87,079	+9.3	99	99	--	--	1	1	([2])	([2])
Steel ingot	125,155	137,425	+9.8	90	91	--	--	10	9	3	3
Chromite (Cr_2O_3)	420	409	-2.6	--	--	--	--	100	100	[e]9	23
Cobalt ---- thousand pounds	17,627	31,218	+77.1	66	50	--	--	34	50	9	5
Manganese	561	521	-7.1	--	--	--	--	100	100	27	20
Molybdenum (ore and concentrate) ---- thousand pounds	45,126	54,146	+20.0	98	98	--	--	2	2	58	54
Nickel	166	169	+1.8	[r]9	7	[r]9	6	[3]82	87	[r]15	22
Tungsten ---- thousand pounds	10,742	9,441	-12.1	46	53	--	--	54	47	11	15
OTHER METALS											
Aluminum	4,327	4,931	+14.0	81	79	[r]7	8	12	14	[r]9	9
Antimony	36	42	+16.7	2	1	[e]46	[e]47	52	52	1	1
Cadmium	3	6	+100.0	24	43	--	--	76	57	6	4
Copper	2,037	2,472	+21.4	[r]69	64	[r]18	17	[3]13	19	1	1
Lead	1,403	1,564	+11.5	44	39	46	46	10	15	1	([2])
Mercury ---- 76-pound flasks	58,789	69,957	+19.0	12	33	14	5	74	62	1	1
Platinum group ---- thousand troy ounces	2,739	3,973	+45.1	39	36	8	5	53	59	19	11
Tin ---- thousand long tons	56	54	-3.6	--	--	27	20	73	80	7	4
Titanium concentrate (TiO_2):											
Ilmenite and slag	739	715	-3.2	55	52	--	--	45	48	--	--
Uranium concentrate (U_3O_8)	13	20	+53.8	92	70	--	--	8	30	([2])	--
Zinc	1,044	1,357	+30.0	45	36	[r]6	5	50	60	1	([2])
NONMETALS											
Asbestos	602	726	+20.6	16	15	--	--	84	85	6	6
Barite, crude	1,952	2,139	+9.6	[r]68	58	--	--	[r]32	42	--	--
Bromine ---- thousand pounds	403,577	435,445	+7.9	100	100	--	--	([2])	([2])	1	1
Clays	47,111	50,733	+7.7	100	100	--	--	([2])	([2])	5	5
Fluorspar, finished	1,189	1,078	-9.3	12	17	--	--	88	83	([2])	([2])
Gypsum	20,961	23,967	+14.3	74	74	--	--	26	26	([2])	1
Mica (excluding scrap)	117	117	--	93	96	--	--	7	4	5	6
Phosphate rock (P_2O_5)	11,110	11,837	+6.5	100	100	--	--	([2])	([2])	26	22
Potash (K_2O equivalent)	5,112	6,149	+20.3	36	35	--	--	64	65	13	13
Salt, common	42,913	47,536	+10.8	93	91	--	--	7	9	3	2
Sand and gravel ---- million tons	787	882	+12.1	100	100	--	--	([2])	([2])	([2])	([2])

Stone, crushed ---- do----	900	899	-.1	100	100	--	--	(2)	(2)	(2)	(2)
Sulfur, all forms ---- thousand long tons--	10,603	10,768	+1.6	84	86	--	--	16	14	11	11
Talc and allied minerals ----	830	869	+4.7	98	98	--	--	2	2	16	20

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Net supply is sum of primary shipments, old scrap, and imports minus exports. Stockpile disposals are included in primary shipments. Gross supply is the total before subtraction of exports.
[2]Less than 1/2 unit.
[3]Erroneously reported in previous year.

Table 7.—Shipments, net new orders, and yearend unfilled orders for selected mineral processing industries

(Million dollars)

Year and month	Shipments			Net new orders[1]			Unfilled orders at end of period[1]

Table 9.—Physical stocks of mineral energy resources and related products at yearend

(Producers' stocks, unless otherwise indicated)

Fuel	1972	1973	1974	1975	1976[p]
Coal and related products:					
Bituminous coal and lignite[1] short tons	116,500,000	103,022,000	95,528,000	127,115,000	133,673,000
Coke do	2,941,000	1,184,000	935,000	4,996,000	6,487,000
Petroleum and related products:					
Carbon black thousand pounds	237,695	230,325	293,903	231,695	213,594
Natural gasoline, plant condensates, isopentane thousand barrels	6,075	7,835	7,550	7,382	8,128
Crude petroleum and petroleum products[2] do	[3]958,979	[3]1,008,307	[3]1,073,646	[3]1,132,955	1,111,810
Crude petroleum do	246,395	[3]242,478	265,020	271,354	285,471
Motor gasoline do	[3]212,894	[3]209,478	[3]218,410	[3]234,978	231,432
Special naphthas do	5,232	[3]4,521	[3]5,720	[3]4,377	4,441
Liquefied gases[3] do	85,717	[3]98,641	[3]112,542	[3]125,148	116,295
Distillate fuel oil do	154,319	[3]196,461	[3]200,068	[3]208,833	185,986
Residual fuel oil do	55,216	53,480	59,694	74,126	72,344
Petroleum asphalt do	[3]21,638	15,024	21,370	22,794	19,375
Other products do	[3]177,568	[3]188,224	[3]190,822	[3]191,345	196,466
Natural gas[4] billion cubic feet	3,523	3,906	3,969	[5]4,400	4,239

[p]Preliminary.
[1]Industrial consumers and retail yards.
[2]Includes natural gas liquids and products at bulk terminals and in pipelines.
[3]Incorrectly reported in previous year.
[4]Includes ethane.
[5]Adjusted upward by 123 billion cubic feet to conform to new data source.

Table 10.—Seasonally adjusted book value of product inventories for selected mineral processing industries

(Million dollars)

End of year or month	Petroleum and coal products	Stone, clay, glass products	Primary metals: Blast furnaces and steel mills	Primary metals: All other primary metals[1]	Primary metals: Total
1972: December	2,300	2,463	5,268	4,390	9,658

Table 11.—Value of selected minerals and mineral products imported and exported by the United States in 1976, by commodity group and commodity[1]

(Thousand dollars)

SITC code[2]	Commodity	Exports	Imports
	Minerals, nonmetallic (crude):		
271	Fertilizers, crude	329,160	12,674
273	Stone, sand and gravel	46,550	28,935
274	Sulfur and unroasted iron pyrites	60,351	59,619
275	Natural abrasives (including industrial diamonds)	62,700	63,034
276	Other crude minerals	293,299	301,930
	Total[3]	792,060	466,194
	Metals (crude and scrap):		
281	Iron ore and concentrates	82,192	980,347
282	Iron and steel scrap	634,476	42,757
283	Ores and concentrates of nonferrous base metals	260,034	892,550
284	Nonferrous metal scrap	238,898	221,185
285	Silver, platinum, platinum-group metal ores and concentrates	44,471	109,109
286	Uranium and thorium ores and concentrates	24,432	430
	Total[3]	1,284,503	2,246,381
	Mineral energy resources and related products:		
321	Coal, coke, briquets (including peat)	2,988,232	158,731
331	Petroleum, crude and partly refined	27,129	26,346,781
332	Petroleum products, except chemicals	970,811	5,408,528
341	Gas, natural and manufactured	239,937	2,014,679
	Total[3]	4,226,109	33,928,720
	Chemicals:		
	Inorganic chemicals:		
513	Elements, oxides, halogen salts	643,887	804,419
514	Other inorganic chemicals	365,711	128,704
515	Radioactive and associated materials except uranium and thorium	466,679	659,053
521	Mineral tar and crude chemicals from coal, petroleum, natural gas	74,819	11,403
	Total[3]	1,551,096	1,603,579
	Minerals, nonmetallic (manufactured):		
661	Lime, cement, fabricated building material, except glass and clay	54,684	113,865
662	Clay and refractory construction materials	138,283	81,573
663	Mineral manufactures, not elsewhere specified	203,024	97,431
	Total	395,991	292,869
	Metals (manufactured):		
671	Pig iron, spiegeleisen, sponge iron, iron and steel powder and shot, ferroalloys	73,182	535,659
672	Iron or steel ingots and other primary forms	46,610	52,812
673	Iron or steel bars, rods, angles, shapes, sections	153,227	863,580
674	Iron or steel universals, plates, sheets	337,538	1,915,102
675	Iron or steel hoops and strips	100,799	72,409
676	Iron or steel rails and railway track construction materials	61,579	18,989
677	Iron or steel wire (excluding wire rod)	36,191	214,061
678	Iron or steel tubes, pipes, fittings	776,541	819,821
679	Iron or steel castings and forgings, unworked	318,492	20,990
681	Silver, platinum, platinum-group metals	96,710	559,498
682	Copper and copper alloys	281,672	776,792
683	Nickel and nickel alloys	158,078	526,302
684	Aluminum and aluminum alloys	466,386	549,854
685	Lead and lead alloys	5,321	63,495
686	Zinc and zinc alloys	11,199	502,869
687	Tin and tin alloys	4,629	329,689
688	Uranium and thorium metals and alloys	146	117
689	Miscellaneous nonferrous base metals	158,533	185,518
	Total[3]	3,086,833	8,007,563
	Grand total	11,336,592	46,545,306

[1]Data in this table are for the indicated SITC numbers only, and therefore may not correspond to the figures classified by commodity in the "Statistical Summary" chapter of this volume.
[2]Standard International Trade Classification.
[3]Import data may not add to totals shown because of independent rounding.

Table 14.—Consumption of major mineral products, mineral fuels, and electricity, and projections

Commodity and unit	1975	1976	2000
MINERAL PRODUCTS			
Ferrous metals:			
Iron ore ---- thousand long tons--	114,126	125,424	NA
Iron content[e] ---- thousand short tons--	79,250	87,095	129,000
Raw steel (production) ---- do----	116,642	128,000	237,000
Chromite ores (gross weight):			
Metallurgical grade ---- do----	532	597	
Refractory grade ---- do----	183	202	1,200
Chemical grade ---- do----	166	207	
Manganese ore (35% or more Mn) ---- do----	1,819	1,601	3,900
Molybdenum (Mo content) ---- thousand pounds--	51,743	50,448	188,000
Tungsten (W content) ---- do----	14,012	16,107	76,400
Nonferrous metals:			
Aluminum (apparent consumption) ---- thousand short tons--	3,903	5,118	28,400
Antimony, primary ---- short tons--	12,987	15,337	48,000
Copper, refined ---- thousand short tons--	1,535	1,992	7,100
Lead, primary and secondary ---- do----	1,297	1,490	2,730
Mercury, primary ---- 76-pound flasks--	48,649	68,371	102,000
Platinum-group metals ---- thousand troy ounces--	1,309	1,603	3,157
Silver (industrial and the arts) ---- do----	157,650	170,559	420,000
Ilmenite and titanium slag (estimated TiO_2 content) - short tons--	536,994	642,519	1,840,000
Uranium (U_3O_8, estimated purchases by private industry) do----	12,500	14,000	73,113
Nonmetals:			
Asbestos (apparent consumption) ---- thousand short tons--	608	726	2,430
Cement (apparent consumption) ---- million short tons--	70	74	220
Clays (apparent consumption) ---- thousand short tons--	49,388	53,181	174,000
Lime (sold or used) ---- do----	19,133	20,229	43,300
Phosphate rock (P_2O_5 content, apparent consumption) -- do----	10,315	10,345	57,000
Potash (K_2O content, apparent consumption) ---- do----	5,112	6,149	14,455
Salt (apparent consumption) ---- do----	42,913	47,536	136,400
Sand and gravel ---- million short tons--	789	885	3,200
Stone, crushed (sold or used) ---- do----	901	900	3,400
Sulfur, all forms (apparent consumption) - thousand long tons--	10,603	10,768	30,000
MINERAL ENERGY RESOURCES AND ELECTRICITY			
Energy resources:			
Bituminous coal ---- million short tons--	556	597	1,000
Coal carbonized for coke[1] ---- do----	(83)	(84)	(115)
Anthracite ---- do----	5	5	2
Petroleum production and natural gas liquids - million barrels--	5,958	6,384	14,500
Natural gas, dry[2] ---- million cubic feet--	19,538	[e]19,813	49,000
Electricity generation, net ---- million kilowatt hours--	2,002,983	2,123,422	NA
Utilities ---- do----	1,917,619	2,036,503	[3]8,650,000
Hydropower[4] ---- do----	306,253	292,318	[3] [5]605,000
Nuclear power ---- do----	172,506	191,111	[3]5,085,000
Conventional fuel-burning plants ---- do----	1,445,048	1,561,685	[3]2,960,000
Industrial ---- do----	85,364	86,919	NA
Total energy resources inputs ---- trillion Btu--	70,576	74,025	[3]163,430

[e]Estimate. NA Not available.
[1]Figures in parentheses are not added to totals.
[2]Residual gas excludes extraction loss but includes transmission loss.
[3]Dupree, W. G., Jr., and J. S. Corsentino. U.S. Energy Through Year 2000 (revised). U.S. Bureau of Mines. December 1975, tables 1 and 15.
[4]Net generations adjusted for net imports or exports. The bulk of net trade is hydropower with an undetermined amount of steam plant power.
[5]Includes power produced at geothermal plants.

Table 15.—Energy equivalent in British thermal units (Btu) obtained from mineral energy resources produced and from hydroelectric and nuclear power produced

(Trillion Btu)

	1972	1973	1974	1975	1976[p]
Anthracite	181	174	168	158	158
Bituminous coal and lignite	14,319	14,208	14,319	15,044	15,610
Crude petroleum	20,041	19,493	18,575	17,729	17,262
Hydroelectric power	2,866	2,860	3,177	3,155	2,974
Natural gas	24,792	24,764	23,689	22,022	21,831
Nuclear power	576	888	1,211	1,832	2,037
Total	62,775	62,387	61,139	59,940	59,872

[p]Preliminary.

Table 16.—Energy consumed in British thermal units (Btu) as equivalent to consumption of mineral energy resources, and hydroelectric and nuclear power

(Trillion Btu)

	1972	1973	1974	1975	1976	Percent (1976)
Anthracite	150	144	138	130	128	1
Bituminous coal and lignite	12,273	13,150	12,751	12,684	13,443	18
Hydroelectric power	2,946	3,009	3,309	3,219	3,064	4
Natural gas	22,698	22,512	21,733	19,948	20,209	27
Natural gas liquids	2,584	2,576	2,479	2,382	2,350	3
Nuclear power	576	888	1,211	1,839	2,037	3
Petroleum products, except natural gas liquids	30,382	32,276	30,988	30,360	32,794	44
Total energy consumed	71,609	74,555	72,609	70,562	74,025	100

Table 17.—Consumption of energy resources, by consuming sector

(Trillion Btu)

Final consuming sector and resource	1972	1973	1974	1975	1976	Percent (1976)
Industrial:

[p]Preliminary. NA Not available.
[1]Includes use by producers for power and heat.
[2]Includes shipments to U.S. Armed Forces in West Germany.
[3]Except for small quantities used as raw material for coal chemicals, all anthracite is used for fuel and power.
[4]Data represent "retail deliveries to other consumers." These are mainly household and commercial users, with some unknown portion of use by small industries.
[5]Includes consumption by coke plants, steel and rolling mills, and other industrial uses. Adjusted to exclude coal equivalent of raw material uses.
[6]Figures in parentheses are not added into totals.
[7]Includes bunkers and military transportation.
[8]Coal equivalent based on British thermal unit value of raw material consumption of coal chemicals listed.

[p]Preliminary.
[1]Supply and demand for crude oil and petroleum products. Petroleum products include products refined and processed from crude oil, including still gas and liquefied refinery gas; also natural gas liquids transferred from natural gas.
[2]Btu values for natural gas liquids for each year shown are implicitly derived from weighted averages of major natural gas liquids, with natural gasoline and other products at 110,000 Btu per gallon, liquefied petroleum gases at 95,500 Btu per gallon, ethane at 73,390 Btu per gallon, and plant condensate at 129,000 Btu per gallon.
[3]Btu values for imported and exported refined products for each year shown are totals of the Btu values of the respective products imported and exported.
[4]Includes natural gas liquids other than those channeled into refinery input as follows: Petrochemical feedstocks, direct uses for fuel and power, and other uses.
[5]Includes bunkers and military fuel uses.
[6]Includes some fuel and power use by raw materials industries.

[P]Preliminary.
[1]Includes liquefied refinery gas and natural gas liquids.
[2]Includes bunkers, military transportation, and all military use of distillate and residual fuel oils.
[3]Includes secondary recovery of petroleum and agriculture uses.
[4]Kerosine-type jet fuel sold for use as kerosine totaled 1,763,000 barrels in 1975 and 651,000 barrels in 1976.
[5]Includes some fuel and power used by raw materials industries.
[6]Lubricants are distributed on basis of data from Bureau of the Census.
[7]Includes portions of petroleum coke estimated to be consumed in nonfuel uses.
[8]Includes ethane.
[9]Includes liquefied petroleum gas for synthetic rubber.

Weekly earnings	$185.40	$198.56	$241.43	$271.35	$303.73
Weekly hours	41.2	42.7	43.5	42.8	42.9
Hourly earnings	$4.50	$4.65	$5.55	$6.34	$7.08
Copper ores:					
Weekly earnings	$192.19	$206.52	$226.46	$248.14	$280.70
Weekly hours	41.6	42.3	41.1	39.2	40.1
Hourly earnings	$4.62	$4.88	$5.51	$6.33	$7.00
All metal mining:[1]					
Weekly earnings	$185.51	$200.40	$226.97	$250.72	$280.80
Weekly hours	41.5	42.1	41.8	40.9	41.6
Hourly earnings	$4.47	$4.76	$5.43	$6.13	$6.75
Nonmetallic mining and quarrying:					
Weekly earnings	$176.96	$196.88	$209.28	$210.98	$236.72
Weekly hours	44.8	47.1	46.3	43.5	44.0
Hourly earnings	$3.95	$4.18	$4.52	$4.85	$5.38
All mining (excluding fuels):[2]					
Weekly earnings	$180.61	$195.90	$213.09	$228.55	$256.16
Weekly hours	43.4	44.0	43.5	42.4	42.9
Hourly earnings	$4.17	$4.47	$4.91	$5.42	$5.99
Fuels:					
All coal mining:					
Weekly earnings	$215.83	$226.86	$236.84	$283.35	$312.44
Weekly hours	[3]41.0	39.9	38.2	[3]39.3	[3]39.5
Hourly earnings	[3]$5.30	[3]$5.69	$6.20	[3]$7.21	[3]$7.88
Bituminous coal:					
Weekly earnings	$217.46	$228.45	$238.37	$284.53	$313.24
Weekly hours	[3]41.0	39.8	38.2	[3]39.2	[3]39.5
Hourly earnings	[3]$5.34	[3]$5.74	$6.24	[3]$7.23	[3]$7.91
Crude petroleum and natural gas:					
Weekly earnings	$169.92	$191.82	$223.86	$248.84	$272.83
Weekly hours	42.8	40.9	42.0	40.8	41.4
Hourly earnings	$3.97	$4.69	$5.33	$6.05	$6.59
All fuels:[2]					
Weekly earnings	$191.27	$201.43	$224.08	$256.86	$282.16
Weekly hours	41.8	40.8	41.9	42.2	42.7
Hourly earnings	$4.53	$4.90	$5.39	$6.14	$6.66
MANUFACTURING					
Fertilizers, complete and mixing only:					
Weekly earnings	$143.14	$155.66	$172.40	$188.72	$210.33
Weekly hours	42.6	43.0	43.1	42.6	43.1
Hourly earnings	$3.36	$3.62	$4.00	$4.43	$4.88
Cement, hydraulic:					
Weekly earnings	$215.37	$233.20	$247.97	$262.06	$302.74
Weekly hours	42.0	42.4	42.1	41.4	41.7
Hourly earnings	$5.12	$5.50	$5.89	$6.33	$7.26
Blast furnaces, steel and rolling mills:					
Weekly earnings	$210.12	$230.74	$263.49	$278.71	$312.38
Weekly hours	40.8	41.8	41.3	39.2	39.8
Hourly earnings	$5.15	$5.56	$6.38	$7.11	$7.86
Nonferrous smelting and refining:					
Weekly earnings	$185.59	$203.46	$227.46	$243.76	$275.22
Weekly hours	41.8	42.3	42.2	40.9	41.7
Hourly earnings	$4.44	$4.81	$5.39	$5.96	$6.60
Petroleum refining and related industries:					
Weekly earnings	$208.89	$220.28	$238.71	$267.07	$301.31
Weekly hours	42.2	42.2	42.4	41.6	42.2
Hourly earnings	$4.95	$5.22	$5.63	$6.42	$7.14
Petroleum refining:					
Weekly earnings	$219.45	$231.02	$250.92	$283.87	$324.73
Weekly hours	41.8	41.7	42.1	41.2	41.9
Hourly earnings	$5.25	$5.54	$5.96	$6.89	$7.75
Other petroleum and coal products:					
Weekly earnings	$175.34	$187.91	$199.67	$215.28	$231.66
Weekly hours	43.4	43.7	43.5	42.8	42.9
Hourly earnings	$4.04	$4.30	$4.59	$5.03	$5.40
Total selected manufacturing:[2]					
Weekly earnings	$206.52	$224.92	$250.99	$268.58	$292.76
Weekly hours	41.1	41.7	41.7	40.1	39.5
Hourly earnings	$5.02	$5.41	$6.08	$6.71	$7.21

[1]Indexes constructed using the following weights derived from the 1967 Census of Mineral Industries: Labor, 50.04; explosives, 3.18; steel mill shapes and forms, 7.32; all other supplies, 26.89; fuels, 5.88; electric energy, 6.69; and data from U.S. Department of Labor, Bureau of Labor Statistics, Wholesale Prices and Price Indexes. The index is computed for iron and copper ores only because sufficient data are not available for other mining sectors.

Table 35.—Index of major input expenses for bituminous coal and crude petroleum and natural gas mining[1]

(1967=100)

Year	Bituminous coal	Crude petroleum and natural gas
1972	141	122
1973	155	136
1974	175	167
1975	222	NA
1976p	248	NA

pPreliminary. NA Not available.

[1]Indexes constructed by using data from the U.S. Department of Labor Statistics, Wholesale Prices and Price Indexes, annual and monthly and weights derived from data shown in the 1967 Census of Mineral Industries, U.S. Department of Commerce, Bureau of the Census. Weights used are as follows: Bituminous coal—labor, 61.55; explosives, 2.70; steel mill shapes and forms, 5.08; all other supplies, 24.58; fuels, 1.74; electric energy, 4.35; crude petroleum and natural gas—labor, 44.65; supplies, 48.79; fuel, 2.07; and electric energy, 4.49.

Table 36.—Indexes of relative costs and productivity for iron ore, copper, bituminous coal, and petroleum mining[1]

(1967=100)

Year	Iron ore[2]	Copper[2]	Bituminous coal	Petroleum
INDEX OF LABOR COSTS PER UNIT OF OUTPUT

pPreliminary. rRevised. NA Not available.

[1]Index of labor costs per unit of output: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based upon net tons per man per day (see chapter on Bituminous Coal) and index of average earnings derived from Bureau of Labor Statistics data on hourly earnings; petroleum index based on barrels per year (see chapter on Petroleum) and Bureau of Employment Security data on total wages in petroleum production.

Index of value of product per production-worker period: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on net tons per man per day and mine value of production; petroleum index based on average employment and total value of production.

Index of labor costs per dollar of product: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on index of value per man per day and index of average earnings; petroleum index based on total value of production and total wages.

[2]Indexes are for recoverable metal.

Table 37.—Price indexes for selected cost items in minerals and mineral fuels production

(1967=100)

Commodity	1976		Percent change from January	Annual average		Percent change from 1975
	January	December		1975	1976	
Coal	370.3	373.9	+1.0	385.8	368.8	-4.4
Coke	331.1	363.4	+9.8	330.8	346.8	+4.8
Gas fuels	244.0	337.6	+38.4	216.7	286.8	+32.3
Petroleum products, refined	273.1	287.1	+5.1	257.5	276.4	+7.3

Total	3,852,308,400	8,160,423,800
Total inventories reserved for goals and uncommitted excess inventories	NA	6,410,079,700

NA Not available
[1]Market values are computed from prices at which similar materials are being traded; or in the absence of current trading, at an estimate of the price that would prevail in commercial markets. Prices used are unadjusted for normal premiums and discounts relating to contained qualities, or for inherent materials-handling allowances. Market values do not necessarily reflect the amount that would be realized at time of sale. The uncommitted excess excludes the unshipped sales; the inventories in storage include quantities that have been sold but not shipped.

[r]Revised.

[1]Data presented are for selected major commodity groups of the Standard International Trade Classification—Revised (SITC-R), and as such exclude some mineral commodities classified in that data array together with other (nonmetal) commodities. SITC-R categories, included are as follows: Ores, concentrates, and scrap—SITC Division 28; iron and steel—SITC Division 67; nonferrous metals—SITC Division 68; nonmetals (crude only)—SITC Division 27; mineral fuels—SITC Division 3. Major items not included are the metals, metalloids, and metal oxides of SITC Division 52; mineral tar and crude chemicals from coal, petroleum and natural gas of SITC Division 52; manufactured fertilizers of SITC Division 56; and nonmetallic mineral manufactures of SITC Divisions 661,662, 663, and 667. Data includes special category exports, ship's stores and bunkers and other exports of minor importance, and excludes the inter-trade of the centrally planned economies of Asia and trade between West Germany and East Germany.

Mining and Quarrying Trends in the Metal and Nonmetal Industries

By T. A. Johnson[1]

Recovering from low demand in 1975, raw mineral production in the United States maintained a steady climb in value and quantity throughout 1976, keeping pace with the gross national product (GNP), which increased 11.5% compared with that of 1975. The minerals industry, in the past, has met ever-increasing demand while keeping production costs to a minimum. To maintain this capability, technological research and development of more efficient processing methods must continue.

The role of Government and its increasing involvement in minerals industry actions received unfavorable comment from various segments of the industry in 1976. Government pricing controls were of concern to most industrial firms marketing like products. Public land withdrawals in large blocks were of concern to the mineral industry.

The large amounts of capital and the length of time required to bring a new facility into production were also of concern. For the latter, estimates from conception to realization were as much as 15 years. Capital outlay for the mineral industry in the past few years has increased from $25-$30 to $75-$90 per ton of output.

In underground mining, raise- and shaft-boring methods have been perfected and 1,000-foot borings are common. Because Federal regulations require better air quality, mine operators throughout the United States are engaged in improving mine ventilation systems. The safer and more rapid completion of 7-foot-diameter shafts at lower costs, compared with the more conventional shaft-sinking methods, have contributed toward the use of raise-boring for constructing mine ventilation shafts. Longer cutter life has also advanced this method; often 3,000 to 5,000 feet of boring can be completed before cutters must be replaced. The trend in boring is toward larger diameters, with 15-foot diameter shafts being the next size in certain rock formations. The largest and longest raise bored, to date, is the 2,300-foot-long, 12-foot-diameter shaft at the Cargill salt mine in New York State.

Roof control in underground mining remains a problem, owing to the increased depth of mines. The Bureau of Mines, in cooperation with the mining industry, has researched methods to monitor and predict roof falls. Utilizing a computer, the Bureau constructed and installed an instrumentation system whereby up to 400 underground locations were monitored simultaneously. The computer automatically plotted load, deformation, stresses, and closures as desired. Additional support was installed in suspected unsafe locations.

Research and development of more efficient underground drilling equipment continued. Interest in the all-hydraulic drill, which has only one moving part and provides the capability for drilling larger diameter holes, has increased. The percussive drills presently used are limited to 2 to 2 1/2-inch-diameter holes, because larger holes would require much bulkier machines, commensurately larger rods, and greater compressor capacity. In addition, research was being directed toward radical-

[1]Mining engineer, Division of Ferrous Metals.

ly different drilling techniques, such as laser-assisted drilling and high-pressure, jet-assisted mechanical drilling. In the former, the laser beam performs the "kerfing" at the same time as the conventional drill bit cuts the hole gauge. In the latter, the high-pressure water jet is placed slightly ahead of the rotary bit to increase the penetration rate.

Advances in blasting technology were oriented toward pattern selection rather than explosive development. The trend at present is also toward higher benches, larger diameter holes, and delay blasting. Metallized slurries, however, will increasingly be used in underground blasting in the future because of higher blasting efficiency.

The mining industry has continued to adopt new methods for underground loading and haulage, as evidenced by the increasing use of trackless haulage and the development of conveyor technology. It is estimated that 5,000 to 6,000 diesel load-haul-dump (LHD) units are presently in use in the hard-rock sector. These units are characterized by their high productivity, flexibility, and low initial cost. The design trends for the LHD's are toward lower profiles, power-shift transmissions, articulated steering, and fast-reversing units. Environmental constraints have led to the development of more effective exhaust systems and electrically powered units.

Environmental constraints have influenced the search for future uses of mined out areas. One such area has been converted into an industrial park with warehouses, factories, and offices. In the past, mined out areas have been used for oil and water storage and as nurseries for seedling pine trees. Often, possible future uses for the mined space are taken into consideration in the planning stages of mine design. Storage and waste disposal areas are of primary interest.

Companies engaged in surface mining and processing are experimenting with new methods for increased and more efficient production. Computer systems for the evaluation of deposits and the design of open pits are being used by an increasing number of companies. Equipment changes in open pit mining have not been drastic, although most taconite companies have changed from jet-piercers to large rotary drills for blastholes. For haulage, the average operation utilizes 50- to 170-ton trucks. In the smaller open pit operations, the trend is toward the use of front-end-loaders rather than power shovels. Where shovels are used, the shift is to hydraulic machines. The main advantages of the hydraulic shovels are lower overall weight and the fact that the bucket may be loaded by rotation rather than by being drawn through the bank. The bucket-wheel excavator, in conjunction with a conveyor system is finding favor where material to be stripped is relatively soft and needs to be transported long distances. Use of bucket-wheel excavators for reclaiming stockpiled material such as iron ore is also increasing. However, where flexibility is needed, truck transport is still the preferred method.

In the processing sector, computer control is becoming more common. Advantages cited include better recoveries, increased throughput, and improved grade. Use of autogenous grinding and high-intensity magnetic separation is increasing. Plant design trends for processing equipment are toward larger machines owing to reduced total capital outlays for equipment, foundations, buildings, piping, and instrumentation.

The Bureau of Mines continued its pilot plant research of Western Mesabi Range nonmagnetic taconites, using processes such as reduction roasting, high-intensity magnetic separation, selective flocculation, desliming, and cationic flotation. From a 34% iron feed, a concentrate containing 63% iron, and less than 5.5% silica was produced with an iron recovery of about 75%. The results obtained indicate that these taconites may be a future source of iron ore on the Mesabi Range. Investigations by the Bureau of Mines were also continuing on the use of various coals as substitutes for gas or oil for pellet induration.

Mineral processing will be faced with greater restraints on water pollution and noise pollution in the future. Many plants are installing water treatment facilities. To comply with the maximum daily noise emission levels as recommended by the U.S. Mining Enforcement and Safety Administration, rubber liners in grinding mills and rubber screen cloths on screens will be used. In addition dumps and mined out areas will be reclaimed for industrial or residential development.

Magnitude of the Mining Industry.—The number of metal and nonmetal mines increased from 15,014 in 1975 to 15,279 in 1976; of the 265 additional mines, 15, were metal and 250 were nonmetal.

In 1976, the number of mines that produced more than 10 million tons of crude ore totaled 25, the same as in 1975. The increase of one mine in the metal mines category was offset by the decrease by one in the number of nonmetal mines. The principal commodities produced in these mines were copper (10 mines), and gold (5), phosphate rock (5), and sand and gravel (2).

Crude ore output in 1976 totaled 2.7 billion tons, an increase of 5% compared with that of 1975. Total material handled was 4.4 billion tons, an increase of 5% compared with that of 1975.

Output of crude ore from the 25 leading metal mines totaled 437 million short tons, an increase of 8.4% compared with that of 1975. Output of crude ore from the 25 leading nonmetal mines totaled 200 million short tons, a decrease of 5.7% compared with that of 1975.

The Minntac iron ore mine of the United States Steel Corp., the Erie Commercial iron ore mine of Pickands Mather & Co., and the Sierrita copper mine of Duval Sierrita Corp. headed the list of metal mines in output of crude ore. Three phosphate mines—Swift Creek mine of the Occidental Chemical Corp. and the Kingsford and Noralyn mines of the International Minerals & Chemical Corp.—were the leading producers of crude nonmetal ore.

The Utah Copper mine of Kennecott Copper Corp. regained its position as the leading metal mine in total material handled, followed by the Tyrone mine of Phelps Dodge Corp. The Kingsford and Noralyn phosphate mines, both owned by International Minerals & Chemical Corp., were the leading nonmetal mines in total material handled.

The 25 leading metal mines handled a total of 1,263 million short tons of material in 1976, an increase of 3.5% over that of 1975. The 25 leading nonmetal mines handled a total of 432 million short tons of material in 1976, an increase of 6.3% over that of 1975.

In metal mining, copper mines (14) and iron ore mines (9) made up the majority of the 25 leading producers of crude ore, while phosphate rock (14) and stone (9) operations comprised the majority of the 25 largest nonmetal crude ore producers. Copper mines (14), iron ore mines (5), and uranium mines (4), comprised the majority of the 25 leading metal mines in terms of material handled. Phosphate (18) and stone (4) made up the majority of the 25 leading nonmetal mines in total material handled.

Crude ore production of 21 States came entirely from surface mines.

Materials Handled.—The U.S. mineral-producing industry, excluding fuels, handled 4.4 billion tons of crude ore and waste in 1976, an increase of 5% compared with that of 1975. Of the total material handled, crude ore comprised 62%. In 1976, materials handled increased 120 million tons for metal and 100 million tons for nonmetal mines, compared with those of 1975. The largest increase in metals occurred in uranium mining; in nonmetal mining, the largest increase was in sand and gravel.

The amount of waste handled in 1976 totaled 1,660 million tons, a 6% increase compared with that of 1975. This compares with 1,011 million tons of waste handled in 1966 and 1,410 million tons handled in 1970.

Crude ore output at metal mines increased 6% in 1976 over that of 1975; in nonmetal mines crude ore output increased 5%.

Copper, iron ore, uranium, and titanium mines accounted for 89% of the crude ore produced and 93% of the total material handled in metal mining. Phosphate rock, sand and gravel, and crushed stone operations accounted for 94% of the crude ore produced and 92% of the total materials handled in the nonmetals sector.

In 1976, more than 10 million tons of material was handled in each of 10 States, compared with 11 States in 1975. Arizona was the leading State followed by Florida and Minnesota. These three States handled 31% of the U.S. total, and were also the leaders in total crude ore produced.

Value of Principal Mineral Products.—The values shown in table 4 represent crude ore treated or, in the case of some nonmetals, crude ore shipped.

The average value for all commodities increased 8% compared with that of 1975. Of the metal commodities, approximately 55% showed an increase in value and the average value increased 11%. The metal commodities showing the greatest increases were mercury, gold, bauxite, and uranium with silver showing the greatest decrease. For the nonmetal commodities, 78% showed an increase in average value. The overall average value of the nonmetals increased 5% compared with that of 1975. Among the nonmetals, mica, barite, and feldspar showed the largest increases in average value, with diatomite showing the largest decrease.

Byproducts were responsible for increasing the average value of all but three of the metal mine products and all but eight of the nonmetal products, as shown in table 4. The largest additions to average values by byproducts occurred in ores of lead (36%), bauxite (57%), silver (19%), zinc (18%), feldspar (37%), fluorspar (14%), and salt (16%).

In the metal commodities, byproduct values accounted for 17% of the total for underground mines while in the surface mines they accounted for 6% of the average value. In the nonmetal minerals, byproducts from both surface and underground mining contributed about 1% to the average value.

Excluding stone and sand and gravel, average value for nonmetals was 7% higher in 1976 than in 1975, and, for metals and nonmetals combined, the average value was 10% higher.

Ratio of Treated to Marketable Product.—The number of tons of crude ore treated to obtain a unit of marketable product in the metals, varied from a high of 737 for uranium to a low of 0.2 for silver. For most nonmetals, the ratio is generally 1:1. As the higher grade ores approach depletion, the ratio increases. When mining by underground methods, it is essential to keep the ratio as low as possible to maintain minimum costs. In surface mining, the lowest possible ratio is also desirable; however, it is not usually as critical as in underground mining, because labor costs, material-handling costs, and production costs escalate much more rapidly in underground mining than in surface mining.

Comparison of Production From Surface and Underground Mines.—As in previous years, there was little change in the percentages of crude ore mined and total material handled by surface and underground mines. In 1976, surface mines accounted for 94% of the crude ore produced and 96% of the total material handled, the same as in 1975. Crude ore production and total material handled at surface metal mines in 1967 accounted for 83% and 93% of the respective aggregate totals; in 1976, they accounted for 89% of the total crude ore produced and 95% of the total material handled.

Crude iron ore (25%) and copper ore (51%) accounted for more than 75% of the crude ore produced and total material handled by metal mines in 1976.

In the nonmetals sector, surface mines accounted for 96% of the crude ore produced and 96% of the total material handled. Phosphate rock (17%), sand and gravel (36%), and crushed and broken stone (39%), accounted for more than 90% of all crude ore produced and material handled in 1976.

Crude ore production of 10 metals and 22 nonmetals came entirely from surface mines. Underground mines accounted for all production of primary lead, potassium salts, and sodium carbonate.

Exploration and Development.—Development footage increased 14% while exploration footage decreased 41% in 1976, compared with that of 1975. Metal mine exploration work decreased 44% while nonmetal exploration work increased 57%.

Metal mining accounted for 65% of the development footage and 94% of the exploration footage. The major portion of the metals development footage was in uranium, copper, and zinc, accounting for 71% of the total metals development footage. The majority of the nonmetals footage was in phosphate rock and fluorspar ores.

Exploration drilling and trenching for uranium, gold, and copper accounted for 90% of the metals exploration footage. Drilling and trenching for phosphate rock and fluorspar accounted for 72% of the total nonmetals exploration footage.

South Dakota, Wyoming, New Mexico, and Colorado all had over 1 million feet of combined development and exploration activity during 1976. Of the total combined footage of 14.5 million feet, the percentages were: South Dakota, 24%; Wyoming, 20%; New Mexico, 18%; and Colorado 11%. Utah, Missouri, and Montana also had considerable exploration and development footage.

Of the 2.58 million short tons of development material produced, 95% came from stripping. Of this total, Wyoming (40%), New Mexico (22%), and Texas (18%) accounted for most of the material handled. Stripping to uncover uranium, copper, and iron ore produced most of the metals development material; while phosphate rock and gypsum accounted for most of the nonmetallic minerals tonnage. Wyoming had the most footage for drifting, crosscutting, and tunneling development, and Utah had the most raising, and shaft- and winze-sinking development footage.

Explosives.—Continuing the trend of recent years, the apparent U.S. consumption of industrial explosives in 1976 increased 7% compared with that of 1975 to a total of 3,329 million pounds. Coal mining consumed 54% of the total industrial explosives and blasting agents; metal mining and quarrying each consumed 15%. The remaining 16% was consumed in construction and exploration.

Coal mining continued to be the leading consumer of permissible explosives (97% of the total), cylindrically packaged blasting agents (80%), and other processed blasting agents and unprocessed ammonium nitrate (72%). As in previous years, the leading consumer of high explosives was quarrying (53%), and the leading consumer of water gels and slurries was metal mining (66%). Of the 2.78 million pounds of explosives consumed by the minerals industry, coal mining consumed 65%; metal and nonmetal mining consumed 17%, and quarrying, 18%. Each type of mining increased its usage of explosives. The leading consumers of explosives in coal mining by State continued to be Kentucky, Pennsylvania, and Alabama, accounting for 57% of the total. Arizona and Minnesota were the leaders in metal mining (53%), and Pennsylvania, Illinois, and Ohio accounted for 22% of the explosives used in quarrying.

More detailed explosives information may be found in the Annual Explosive issue of Mineral Industry Surveys, prepared by the Division of Nonmetallic Minerals, Minerals Supply/Demand Analysis, Bureau of Mines.

[e]Estimate. W Withheld to avoid disclosing individual company confidential data.
[1]Excludes material from wells, ponds, or pumping operations.
[2]Data may not add to totals shown because of independent rounding.
[3]Less than 1/2 unit.
[4]Antimony, beryllium, manganiferous ore, molybdenum, nickel, platinum-group metals, rare-earth metals, tin, vanadium, and quantity of metal items indicated by symbol W.
[5]Abrasive stone, emery, garnet, and tripoli.
[6]Aplite, boron minerals, graphite, greensand marl, iron oxide pigments (crude), kyanite, lithium minerals, magnesite, millstones, olivine, tube-mill liners, vermiculite, wollastonite, and quantity of nonmetal items indicated by symbol W.

Statistical Summary

By Staff, Office of Technical Data Services

This chapter summarizes data on crude mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Included also are tables that show the principal mineral commodities exported from and imported into the United States and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual commodity chapters of volume I and in the State chapters of volume II of this edition of the Minerals Yearbook.

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of measurement used in this chapter is what is normally termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the production of auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. In the cases of gold, silver, copper, lead, zinc, and tin, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not on the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustment made to compensate for changes in the purchasing power of the dollar.

Table 1.—Value of crude mineral production[1] in the United States, by mineral group

(Million dollars)

Year	Mineral fuels	Nonmetals except fuels	Metals	Total
1972	22,061	6,482	3,642	32,185

[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

[2] Includes a small quantity of anthracite mined in States other than Pennsylvania.

[3] Grindstones, pulpstones, grinding pebbles, sharpening stones, and tube mill liners.

[4] Excludes abrasive stone, bituminous limestone, bituminous sandstone, and soapstone, all included elsewhere in table.

Table 3.—Minerals produced in the United States and principal producing States in 1976

Mineral	Principal producing States, in order of quantity	Other producing States
Antimony ore and concentrate	Mont. and Idaho.	
Aplite	Va.	
Asbestos	Calif., Vt., Ariz., N.C.	
Asphalt (native)	Tex., Utah, Ala., Mo.	
Barite	Nev., Mo., Ark., Ga	Idaho, Ill., Mont., Tenn.
Bauxite	Ark., Ala., Ga.	
Beryllium concentrate	Utah	Ariz. and S. Dak.
Boron minerals	Calif.	
Bromine	Ark. and Mich.	
Calcium-chloride	Mich. and Calif.	
Carbon dioxide (natural)	N. Mex., Colo., Calif., Utah.	
Cement	Calif., Tex., Pa., Mich.	Ala., Ariz., Ark., Colo., Fla., Ga., Hawaii, Idaho, Ill., Ind., Iowa, Kans., Ky., La., Maine, Md., Miss., Mo., Mont., Nebr., Nev., N. Mex., N.Y., N.C., Ohio, Okla., Oreg., S.C., S. Dak., Tenn., Utah, Va., Wash., W. Va., Wis., Wyo.
Clays	Ga., Ohio, Tex., N.C	All other States except Alaska, R.I., Vt.
Coal	Ky., W. Va., Pa., Ill	Ala., Alaska, Ariz., Ark., Colo., Ga., Ind., Iowa, Kans., Md., Mo., Mont., N. Mex., N. Dak., Ohio, Okla., Tenn., Tex., Utah, Va., Wash., Wyo.
Copper (mine)	Ariz., Utah, N. Mex., Mont	Calif., Colo., Idaho, Maine, Mich., Mo., Nev., Pa., Tenn., Wash.
Diatomite	Calif., Nev., Wash	Kans. and Oreg.
Emery	N.Y.	
Feldspar	N.C., Conn., Ga., Calif	Ariz., Colo., Maine, Okla., S. Dak., Wyo.
Fluorspar	Ill., Ky., Tex., Nev	Ariz., Mont., Utah.
Garnet, abrasive	Idaho and N.Y.	
Gold (mine)	S. Dak., Nev., Utah, Ariz	Alaska, Calif., Colo., Idaho, Mont., N. Mex., Oreg., Tenn., Wash.
Graphite	Tex.	
Gypsum	Mich., Calif., Tex., Iowa	Ariz., Ark., Colo., Idaho, Ind., Kans., La., Mont., Nev., N. Mex., N.Y., Ohio, Okla., S. Dak., Utah, Va., Wash., Wyo.
Helium	Kans., Okla., Tex	Ariz. and N. Mex.
Iodine	Mich.	
Iron ore	Minn., Mich., Calif., Wyo	Ariz., Colo., Ga., Mo., Mont., Nev., N.Y., Pa., S. Dak., Tex., Utah, Wis.
Kyanite	Va. and Ga.	
Lead (mine)	Mo., Idaho, Colo., Utah	Alaska, Ariz., Calif., Ill., Maine, Mont., Nev., N. Mex., N.Y., Okla., Va., Wash., Wis.
Lime	Ohio, Pa., Mo., Mich	Ala., Ariz., Ark., Calif., Colo., Conn., Fla., Hawaii, Idaho, Ill., Ind., Iowa, Kans., Ky., La., Md., Mass., Minn., Miss., Mont., Nebr., Nev., N.J., N. Mex., N.Y., N. Dak., Okla., Oreg., S. Dak., Tenn., Tex., Utah, Va., Wash., W. Va., Wis., Wyo.
Lithium minerals	N.C., Nev., Calif.	
Magnesite	Nev.	
Magnesium chloride	Tex.	
Magnesium compounds	Mich, Calif., N.J., Fla	Del., Miss., Tex., Utah.
Manganiferous ore	Minn., N. Mex., S.C.	
Manganiferous residuum	N.J.	
Marl, greensand	N.J.	
Mercury	Nev. and Calif.	
Mica, scrap	N.C., Ala., N. Mex., Ga	Ariz., Conn., Pa., S.C.
Molybdenum	Colo., Ariz., N. Mex., Utah	Calif. and Nev.
Natural gas	Tex., La., Okla., N. Mex	Ala., Alaska, Ariz., Ark., Calif., Colo., Fla., Ill., Ind., Kans., Ky., Md., Mich., Miss., Mo., Mont., Nebr., N.Y., N. Dak., Ohio, Pa., Tenn., Utah, Va., W. Va., Wyo.
Natural gas liquids	Tex., La., Okla., N. Mex	Ala., Alaska, Ark., Calif., Colo., Fla., Ill., Kans., Ky., Mich., Miss., Mont., Nebr., N. Dak., Pa., S. Dak., Utah, W. Va., Wyo.
Nickel	Oreg.	
Olivine	N.C. and Wash.	
Peat	Mich., Ind., Pa., Ill	Calif., Colo., Fla., Ga., Iowa, Maine, Md., Mass., Minn., Mont., N.J., N.Y., N. Dak., Ohio, S.C., Wash., Wis.
Perlite	N. Mex., Ariz., Calif., Idaho	Colo. and Nev.

Table 3.—Minerals produced in the United States and principal producing States in 1976 —Continued

Mineral	Principal producing States, in order of quantity	Other producing States
Petroleum, crude	Tex., La., Calif., Okla	Ala., Alaska, Ariz., Ark., Colo., Fla., Ill., Ind., Kans., Ky., Mich., Miss., Mo., Mont., Nebr., Nev., N. Mex., N.Y., N. Dak., Ohio, Pa., S. Dak., Tenn., Utah, Va., W. Va., Wyo.
Phosphate rock	Fla., Idaho, N.C., Tenn	Ark., Calif., Mo., Mont., Utah, Wyo.
Platinum-group metals	Alaska.	
Potassium salts	N. Mex., Utah, Calif.	
Pumice	Oreg., Ariz., Calif., N. Mex	Colo., Hawaii, Idaho, Mont., Nev., Okla., Utah.
Pyrites ore and concentrate	Tenn., Colo., Ariz.	
Rare-earth metal concentrate	Calif. and Fla.	
Salt	La., Tex., N.Y., Ohio	Ala., Ariz., Calif., Colo., Kans., Mich., Nev., N. Mex., N. Dak., Okla., Utah, W. Va.

Silver (mine)	Idaho, Ariz., Colo., Mont	Alaska, Calif., Ill., Maine, Mich., Mo., Nev., N. Mex., N.Y., S. Dak., Tenn., Utah, Va., Wash.
Sodium carbonate (natural)	Wyo. and Calif.	
Sodium sulfate (natural)	Calif., Tex., Utah.	
Staurolite	Fla.	
Stone	Pa., Ill., Tex., Mo	All other States except Del. and N. Dak.
Sulfur (Frasch)	Tex. and La.	
Talc, soapstone, pyrophyllite	Vt., Mont., N.Y., Tex	Ark., Calif., Ga., Nev., N.C., Oreg., Va., Wash.
Tin	Colo. and N. Mex.	
Titanium concentrate	Fla., N.J., N.Y.	
Tripoli	Ill., Okla., Ark., Pa.	
Tungsten concentrate	Calif., Colo., Nev	Ariz., Idaho, Mont., Oreg., Utah, Wash.
Uranium	N. Mex., Wyo., Utah, Colo	Tex. and Wash.
Vanadium	Ark., Colo., Idaho, Utah	N. Mex.
Vermiculite	Mont. and S.C.	
Wollastonite	N.Y.	
Zinc (mine)	Mo., Tenn., N.Y., Colo	Alaska, Ariz., Calif., Idaho, Ill., Ky., Maine, Mont., Nev., N.J., N. Mex., Okla., Pa., Utah, Va., Wash., Wis.
Zircon concentrate	Fla.	

Table 4.—Value of mineral production in the United States and principal minerals produced in 1976

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	$1,029,536	20	1.49	Coal, petroleum, cement, stone.
Alaska	625,188	23	.90	Petroleum, sand and gravel, natural gas, stone.
Arizona	1,726,621	10	2.50	Copper, molybdenum, sand and gravel, cement.
Arkansas	535,448	25	.77	Petroleum, bromine, natural gas, cement.
California	3,483,373	4	5.04	Petroleum, natural gas, cement, sand and gravel.
Colorado	1,110,166	18	1.60	Petroleum, molybdenum, coal, natural gas.
Connecticut	34,318	47	.05	Stone, sand and gravel, feldspar, lime.
Delaware	[1]1,837	50	([2])	Sand and gravel, magnesium compounds, clays, gem stones.
Florida	1,652,232	11	2.39	Phosphate rock, petroleum, cement, stone.
Georgia	428,479	28	.62	Clays, stone, cement, sand and gravel.
Hawaii	42,252	44	.06	Stone, cement, sand and gravel, pumice.
Idaho	210,246	33	.30	Silver, phosphate rock, zinc, lead.
Illinois	1,581,165	12	2.29	Coal, petroleum, stone, sand and gravel.
Indiana	607,321	24	.88	Coal, cement, stone, petroleum.
Iowa	216,027	32	.31	Cement, stone, sand and gravel, coal.
Kansas	1,213,853	16	1.75	Petroleum, natural gas, natural gas liquids, stone.
Kentucky	3,114,589	5	4.50	Coal, petroleum, stone, natural gas.
Louisiana	8,652,107	2	12.51	Petroleum, natural gas, natural gas liquids, sulfur.
Maine	40,364	45	.06	Sand and gravel, cement, zinc, stone.
Maryland	184,918	36	.27	Coal, stone, cement, sand and gravel.
Massachusetts	69,850	43	.10	Stone, sand and gravel, lime, clays.
Michigan	1,543,516	13	2.23	Iron ore, petroleum, cement, natural gas.
Minnesota	1,218,030	15	1.76	Iron ore, sand and gravel, stone, lime.
Mississippi	449,862	26	.65	Petroleum, natural gas, cement, sand and gravel.
Missouri	785,160	21	1.13	Lead, cement, stone, iron ore.
Montana	636,289	22	.92	Petroleum, coal, copper, cement.
Nebraska	123,365	39	.18	Petroleum, cement, sand and gravel, stone.
Nevada	233,683	31	.34	Copper, gold, sand and gravel, barite.
New Hampshire	17,579	48	.03	Sand and gravel, stone, clays, gem stones.
New Jersey	119,886	40	.17	Sand and gravel, stone, zinc, titanium concentrate.
New Mexico	2,510,127	8	3.63	Petroleum, natural gas, copper, natural gas liquids.
New York	427,964	29	.62	Cement, stone, salt, sand and gravel.
North Carolina	203,339	34	.29	Stone, phosphate rock, sand and gravel, lithium minerals.
North Dakota	244,105	30	.35	Petroleum, coal, natural gas, natural gas liquids.
Ohio	1,435,896	14	2.08	Coal, petroleum, lime, stone.
Oklahoma	2,789,974	7	4.03	Petroleum, natural gas, natural gas liquids, coal.
Oregon	112,566	41	.16	Stone, sand and gravel, cement, nickel.
Pennsylvania	3,041,186	6	4.40	Coal, cement, stone, lime.
Rhode Island	6,400	49	.01	Sand and gravel, stone, gem stones.
South Carolina	125,455	38	.18	Cement, stone, clays, sand and gravel.
South Dakota	101,530	42	.15	Gold, cement, stone, sand and gravel.
Tennessee	439,714	27	.64	Coal, stone, zinc, cement.
Texas	18,143,204	1	26.23	Petroleum, natural gas, natural gas liquids, cement.
Utah	1,043,981	19	1.51	Petroleum, copper, coal, uranium.
Vermont	35,097	46	.05	Stone, asbestos, sand and gravel, talc.
Virginia	1,160,645	17	1.68	Coal, stone, cement, lime.
Washington	187,222	35	.27	Cement, coal, sand and gravel, stone.
West Virginia	3,498,001	3	5.06	Coal, natural gas, petroleum, natural gas liquids.
Wisconsin	132,453	37	.19	Sand and gravel, stone, iron ore, cement.
Wyoming	1,851,599	9	2.68	Petroleum, sodium compounds, coal, natural gas.
Total	69,178,000	--	100.00	

[1]Incomplete total.
[2]Less than 1/2 unit.

Table 5.—Value of mineral production per capita and per square mile in 1976, by State

State	Area (square miles)	1976 population (thousands)	Value of mineral production: Total (thousands)	Per square mile: Dollars	Per square mile: Rank	Per capita: Dollars	Per capita: Rank

XX Not applicable.
[1]Incomplete total.
[2]Excludes Washington, D.C., with an area of 67 square miles and a population of 702,000 (which had no mineral production).

Bauxite, including bauxite concentrates thousand long tons	19	1,651	15	1,297
Beryllium pounds	37,336	1,152	114,143	1,756
Bismuth, metals and alloys do	[1]128,893	[1]636	[1]68,488	[1]514
Cadmium thousand pounds	396	589	504	713
Calcium:				
Carbonate short tons	4,640	705	3,411	735
Chloride do	28,359	2,314	33,533	2,578
Dicalcium phosphate do	21,053	6,270	32,302	7,612
Chrome:				
Ore and concentrates:				
Exports thousand short tons	139	6,896	124	5,609
Reexports do	45	2,111	85	5,475
Ferrochrome do	13	9,075	14	8,785
Cobalt thousand pounds	4,237	14,881	3,892	12,427
Columbium metals, alloys, other forms do	53	787	67	778
Copper:				
Ore, concentrate, composition metal, and unrefined (copper content) short tons	16,451	14,454	22,689	19,769
Scrap do	45,002	40,793	37,473	37,079
Refined copper and semimanufactures do	258,165	465,553	176,877	313,377
Other copper manufactures do	9,518	14,158	4,923	8,435
Copper sulfate or blue vitriol do	1,248	2,067	2,071	2,935
Copper-base alloys do	130,254	179,838	110,665	177,270
Ferroalloys:				
Ferrosilicon do	39,712	15,732	12,416	7,449
Ferrophosphorus do	437	57	1,636	153
Gold:				
Ore and base bullion troy ounces	393,970	63,654	337,517	41,624
Bullion, refined do	3,101,812	429,278	3,193,248	333,424
Iron ore thousand long tons	2,537	60,071	2,913	82,192
Iron and steel:				
Pig iron short tons	59,596	4,636	57,480	5,408
Iron and steel products (major):				
Semimanufactures do	1,690,956	633,502	1,856,573	592,126
Manufactures and steel mill products do	2,284,043	2,336,341	1,814,776	1,870,281
Iron and steel scrap: Ferrous scrap, including rerolling materials thousand short tons	9,642	780,984	8,168	636,758
Slag short tons	139,516	5,506	38,718	1,264
Lead:				
Pigs, bars, anodes, sheets, etc short tons	21,256	12,041	5,877	5,320
Scrap do	49,951	10,063	46,883	11,539
Magnesium, metal and alloys, scrap, semimanufactured forms, n.e.c. do	32,591	48,191	13,444	26,902
Manganese:				
Ore and concentrate do	204,523	13,886	127,971	7,510
Ferromanganese do	[r]32,487	[r]10,743	6,789	3,462
Metal do	3,256	3,318	4,654	3,434
Mercury:				
Exports 76-pound flasks	339	152	501	306
Reexports do	155	68	12	6
Molybdenum:				
Ore and concentrates (molybdenum content) thousand pounds	62,611	159,592	62,474	183,536
Metals and alloys, crude and scrap do	317	858	223	390
Wire do	270	2,863	343	3,672
Semimanufactured forms, n.e.c do	312	1,790	184	1,584
Powder do	60	296	25	136
Ferromolybdenum do	2,241	4,798	3,596	9,447
Nickel:				
Alloys and scrap (including Monel metal), ingots, bars, sheets, etc short tons	23,118	102,400	38,143	141,724
Catalysts do	3,536	13,713	4,442	16,282
Nickel-chrome electric resistance wire do	679	4,769	769	5,253
Semifabricated forms, n.e.c do	2,788	20,420	4,207	30,736
Platinum:				
Ore, concentrate, metal and alloys in ingots, bars, sheets, anodes, other forms, including scrap troy ounces	376,450	56,412	325,805	37,868
Palladium, rhodium, iridium, osmiridium, ruthenium, and osmium (metal and alloys including scrap) do	283,435	31,102	186,602	14,885

See footnotes at end of table.

Table 9.—U.S. exports of principal minerals and products —Continued

Mineral	1975 Quantity	1975 Value (thousands)	1976 Quantity	1976 Value (thousands)
METALS —Continued				
Platinum —Continued				
Platinum-group manufactures, except jewelry	NA	$3,246	NA	$2,977
Rare earths:				
Cerium ore, metal, alloys lighter flints pounds	100,279	300	119,792	335
Silicon:				
Ferrosilicon short tons	[r]39,712	[r]15,732	12,416	7,449
Silicon carbide, crude and in grains do	12,970	6,839	10,106	6,174
Silver:				
Ore, concentrates, waste, sweepings thousand troy ounces	10,005	43,481	7,000	28,849
Bullion, refined do	22,621	104,086	7,596	32,586
Tantalum:				
Ore, metal, other forms thousand pounds	531	5,545	213	6,711
Powder do	161	5,974	110	7,982
Tin:				
Ingots, pigs, bars, etc.:				
Exports metric tons	[r]1,444	10,457	540	2,998
Reexports do	[r]2,152	15,531	1,798	13,967
Tin scrap and other tin-bearing material except tinplate scrap do	5,062	4,343	6,927	7,391
Titanium:				
Ore and concentrate short tons	3,147	505	4,802	477
Sponge (including iodide titanium and scrap) do	4,326	7,630	6,144	8,547
Intermediate mill shapes and mill products, n.e.c. do	1,900	24,726	1,065	15,039
Dioxide and pigments do	15,807	12,110	20,580	16,229
Tungsten, ore and concentrates:				
Exports thousand pounds	1,316	8,082	1,729	11,189
Reexports do	316	930	887	1,903
Uranium:				
Ores and concentrates (U_3O_8 content) pounds	122,663	1,840	1,495,130	24,432
Metal do	14,840	203	7,108	146
Compounds do	3,837,266	52,040	369,036	7,232
Isotopes (stable) and their compounds	NA	2,679	NA	2,103
Radioactive materials thousand curies	37,850,386	20,088	31,474,488	25,905
Special nuclear materials	NA	236,849	NA	426,423
Vanadium:				
Ore and concentrate, pentoxide, etc. (vanadium content) pounds	430,592	1,628	197,035	742
Ferrovanadium do	2,035,851	7,952	2,421,776	9,180
Zinc:				
Slabs, pigs, or blocks short tons	6,897	5,870	3,513	2,306
Sheets, plates, strips, other forms n.e.c do	1,629	2,086	2,271	2,817
Waste, scrap, and dust (zinc content) do	5,051	2,448	8,945	3,535
Semifabricated forms, n.e.c do	14,196	9,379	9,320	6,076
Zirconium:				
Ore and concentrate pounds	37,531,345	4,787	18,855,595	2,784
Metals, alloys, other forms do	2,649,694	[r]25,828	2,304,202	43,809
NONMETALS				
Abrasives:				
Dust and powder of precious or semiprecious stones, including diamond dust and powder thousand carats	12,802	32,088	14,155	35,450
Crushing bort do	3	12	77	182
Industrial diamonds do	950	5,948	639	3,677
Diamond grinding wheels do	684	4,933	730	4,911
Other natural and artificial metallic abrasives and products	NA	59,868	NA	68,979
Asbestos:				
Exports:				
Unmanufactured short tons	34,921	10,059	46,317	12,640
Products do	NA	60,556	NA	60,276
Reexports:				
Unmanufactured do	1,526	608	606	151
Products do	NA	220	NA	296
Barite:				
Natural barium sulfate do	57,386	1,868	41,063	2,871
Lithopone do	1,833	1,060	779	937
Boron:				
Boric acid do	33,697	11,532	36,492	12,363
Sodium borates, refined do	212,266	42,486	211,362	49,156
Cement do	494,132	28,409	466,055	26,601
Clays:				
Kaolin or china clay do	878,619	47,905	839,230	57,649
Fire clay do	219,431	7,191	296,016	12,895

See footnotes at end of table.

Table 9.—U.S. exports of principal minerals and products —Continued

Mineral	1975 Quantity	1975 Value (thousands)	1976 Quantity	1976 Value (thousands)
NONMETALS —Continued				
Clays —Continued				
Other clays ---- short tons	1,216,088	$65,202	1,351,953	$81,409
Feldspar, leucite nepheline syenite - thousand pounds	19,087	507	12,289	352
Fluorspar ---- short tons	1,355	194	4,923	764
Gem stones:				
Diamonds ---- thousand carats	265	236,988	313	306,098
Pearls	NA	413	NA	581
Other	NA	25,480	NA	30,896
Graphite ---- short tons	10,586	1,890	79,098	6,753
Gypsum:				
Crude, crushed or calcined -- thousand short tons	75	4,505	284	6,739
Manufactures, n.e.c	NA	5,976	NA	25,855
Lithium hydroxide ---- thousand pounds	1,226	1,593	534	674
Kyanite and allied minerals ---- short tons	150,369	9,355	63,329	4,942
Lime ---- do	53,853	2,746	55,852	2,981
Magnesium compounds:				
Magnesite, dead-burned ---- thousand pounds	165,309	14,146	142,745	13,466
Magnesite, crude, caustic calcined, lump or ground -- do	18,195	4,538	20,242	5,422
Mica sheet, waste and scrap, and ground ---- pounds	10,977,353	3,154	14,449,150	3,477
Mica, manufactured ---- do	1,132,301	3,950	2,481,151	3,776
Mineral-earth pigments, iron oxide, natural and manufactured ---- short tons	13,231	7,710	11,867	11,387
Nitrogen compounds (major) --- thousand short tons	[r]4,736	[r]860,110	4,714	449,147
Phosphate rock ---- do	12,606	461,553	11,019	327,410
Phosphatic fertilizers:				
Superphosphates ---- do	[r]1,166	[r]192,898	1,334	110,835
Ammonium phosphates ---- do	2,422	532,274	2,406	269,855
Elemental phosphorus ---- short tons	35,845	36,659	29,038	30,387
Mixed chemical fertilizers -- thousand short tons	324	40,695	42	30,284
Pigments and compounds (lead and zinc):				
Lead oxides:				
Pigment grade ---- short tons	1,695	901	2,620	1,661
Other grade ---- do	580	490	345	438
Zinc oxides:				
Pigment grade ---- do	2,389	1,867	4,261	2,587
Other grade ---- do	715	496	577	524
Zinc compounds ---- do	917	1,060	779	937
Potash:				
Fertilizer ---- do	1,419,317	[1]92,701	1,669,691	91,887
Chemical ---- do	104,497	18,949	60,025	19,422
Pumice and pumicite ---- thousand pounds	2,504	1,027	2,022	271
Quartz, natural, quartzite, cryolite, chiolite short tons	1,767	1,106	--	--
Salt:				
Crude and refined ---- thousand short tons	1,332	9,070	1,007	10,326
Shipments to noncontiguous territories --- do	20	2,304	18	2,230
Sand and gravel:				
Sand:				
Construction ---- short tons	510,859	1,111	558,733	1,337
Industrial ---- do	2,171,109	13,071	2,553,475	17,080
Gravel ---- do	537,290	864	579,359	1,099
Sodium and sodium compounds:				
Sodium sulfate ---- do	77	6,144	57	3,636
Sodium carbonate ---- do	529	45,822	645	49,781
Stone:				
Dolomite, block ---- do	49	1,464	63	1,486
Limestone, crushed, ground, broken ---- do	3,386	9,993	3,191	10,537
Marble and other building and monumental do	NA	2,449	NA	2,596
Stone, crushed, ground, broken thousand short tons	896	5,843	866	7,073
Manufactures of stone ---- do	NA	2,376	NA	2,273
Sulfur:				
Crude ---- thousand long tons	1,288	69,553	1,183	60,226
Crushed, ground flowers of ---- do	7	2,248	15	3,358
Talc, crude and ground ---- short tons	157,681	6,338	212,344	9,034
MINERAL FUELS				
Carbon black ---- thousand pounds	87,947	15,474	110,760	27,231
Coal:				
Anthracite ---- thousand short tons	640	25,801	615	24,008
Bituminous ---- do	65,669	3,232,893	59,406	2,886,467
Briquets ---- do	90	9,566	87	10,998
Coke ---- do	1,273	74,732	1,315	66,726
Natural gas ---- thousand cubic feet	105,879,552	114,275	95,866,953	140,854
Petroleum:				
Crude ---- thousand barrels	19	187	2,227	27,129
Gasoline ---- do	185	3,103	266	5,592
Jet fuel ---- do	326	3,459	348	3,404
Naphtha ---- do	1,168	27,271	2,608	37,045
Kerosine ---- do	28	437	33	504
Distillate oil ---- do	92	1,156	97	1,333

See footnotes at end of table.

Table 10.—U.S. imports for consumption of principal minerals and products

Mineral	1975 Quantity	1975 Value (thousands)	1976 Quantity	1976 Value (thousands)
METALS				
Aluminum:				
Metal ---- short tons	434,119	$316,873	575,350	$439,570
Scrap ---- do	54,806	27,586	85,714	46,166
Plates, sheets, bars, etc ---- do	61,354	65,079	87,560	96,312
Aluminum oxide (alumina) ---- do	3,507,415	370,039	3,624,367	404,478
Anitimony:				
Ore (antimony content) ---- do	8,320	14,535	10,023	16,911
Needle or liquated ---- do	74	255	41	129
Metal ---- do	2,112	5,677	2,083	4,986
Oxide ---- do	9,908	12,588	11,611	17,029
Arsenic:				
White (As_2O_3 content) ---- do	12,013	4,426	4,262	1,528
Metallic ---- do	483	2,716	288	1,735
Bauxite, crude ---- thousand long tons	[r]11,529	NA	12,548	NA
Beryllium ore ---- short tons	[1]1,479	[1]468	1,058	380
Bismuth ---- pounds	1,331,173	9,442	2,328,051	14,154
Cadmium:				
Metal ---- short tons	2,618	13,902	3,411	14,511
Flue dust (cadmium content) ---- do	346	1,489	246	536
Calcium:				
Metal ---- pounds	70,128	78	461,965	475
Chloride ---- short tons	12,021	598	16,046	480
Chrome:				
Ore and concentrates (Cr_2O_3 content) thousand short tons	559	60,651	533	70,075
Ferrochrome ---- do	198	190,630	150	124,819
Metal ---- do	2	6,630	2	9,142
Cobalt:				
Metal ---- thousand pounds	6,092	25,611	15,129	66,299
Oxide (gross weight) ---- do	233	779	138	573
Salts and compounds (gross weight) ---- do	41	74	235	365
Columbium ore ---- do	1,542	2,012	3,968	5,737
Copper (copper content):				
Ore and concentrates ---- short tons	29,301	35,649	35,197	49,861
Regulus, black, coarse ---- do	5,675	20,560	14,097	54,878
Unrefined, black, blister ---- do	78,969	90,846	19,388	22,144
Refined in ingots, etc ---- do	142,945	166,159	381,343	453,279
Old and scrap ---- do	14,399	14,459	19,735	19,231
Ferroalloys, n.e.c ---- do	[r]61,946	[r]35,556	99,905	47,430
Gallium ---- kilograms	6,830	3,555	4,920	2,326
Gold (general imports):				
Ore and base bullion ---- troy ounces	313,038	50,055	166,312	20,007
Bullion ---- do	2,348,936	406,583	2,489,679	311,011
Indium ---- do	113,800	629	290,139	1,802
Iron ore ---- thousand long tons	46,743	860,496	44,390	980,348
Iron and steel:				
Pig iron ---- short tons	478,106	69,316	444,282	51,142
Iron and steel products (major):				
Iron products ---- do	47,535	32,299	44,877	32,002
Steel products ---- do	12,440,326	4,475,191	13,051,471	4,479,191
Scrap ---- do	293,082	24,464	495,584	34,524
Tinplate ---- do	12,277	786	11,581	596
Lead:				
Ore, flue dust, matte (lead content) ---- do	45,024	12,329	88,988	29,492
Base bullion (lead content) ---- do	462	183	2,334	955
Pigs and bars (lead content) ---- do	99,054	46,703	141,980	60,245
Reclaimed scrap, etc. (lead content) ---- do	1,741	617	2,644	1,022
Sheet, pipe, shot ---- do	147	99	294	495
Magnesium:				
Metallic and scrap ---- do	6,787	9,299	13,066	19,020
Alloys (magnesium content) ---- do	1,111	2,215	1,820	3,604
Sheets, tubing, ribbons, wire, other forms (magnesium content) ---- do	5	33	21	38
Manganese:				
Ore (35% or more contained manganese) ---- do	765,530	77,103	649,245	73,627
Ferromanganese (manganese content) ---- do	306,650	128,381	417,433	164,698
Metal ---- do	4,378	4,041	7,082	5,258
Mercury:				
Compounds ---- pounds	[r]6,112	[r]42	35,536	90
Metal ---- 76-pound flasks	43,865	7,599	44,415	4,325
Minor metals: Selenium and salts ---- pounds	889,320	10,265	811,257	12,118
Molybdenum:				
Ore (content) ---- do	2,556,680	5,916	2,092,623	4,850
Waste and scrap ---- do	44,672	101	297,554	1,183
Metal ---- do	38,926	434	63,500	705,274
Compounds ---- do	682,039	745	679,289	690
Nickel:				
Pigs, ingots, shot, cathodes ---- short tons	107,084	406,894	111,255	456,398
Plates, bars, etc ---- do	[r]1,752	11,118	3,223	20,348
Slurry ---- do	23,991	63,522	33,280	98,178
Scrap ---- do	2,353	5,864	2,359	4,827
Powder and flakes ---- do	9,772	39,413	10,181	45,267
Ferronickel ---- do	65,046	67,818	55,721	72,161
Oxide ---- do	5,063	15,172	5,932	21,948

See footnotes at end of table.

Table 10.—U.S. imports for consumption of principal minerals and products —Continued

Mineral	1975 Quantity	1975 Value (thousands)	1976 Quantity	1976 Value (thousands)
METALS —Continued				
Platinum-group metals:				
Unwrought:				
Grains and nuggets (platinum) troy ounces	19,253	$2,941	596	$88
Sponge (platinum) do	567,466	91,567	904,048	139,378
Sweepings, waste, scrap do	116,523	14,278	146,773	20,080
Iridium do	14,419	6,892	18,179	5,045
Palladium do	409,862	33,863	994,360	48,535
Rhodium do	80,197	34,400	62,260	18,342
Ruthenium do	16,535	926	75,673	3,580
Other platinum-group metals do	234,757	37,055	224,560	32,195
Semimanufactured:				
Platinum do	96,630	15,337	95,653	15,623
Palladium do	144,240	15,163	128,951	6,325
Rhodium do	1,832	675	1,864	382
Other platinum-group metals do	118,570	19,726	14,142	1,963
Radium: Radioactive substitutes	NA	8,297	NA	12,200
Rare-earth metals, ferrocerium, other cerium alloys pounds	33,852	187	40,259	167
Silicon (silicon content):				
Metal short tons	3,852	6,591	[2]1,359	[2]6,170
Ferrosilicon do	47,365	41,950	64,124	39,808
Silver (general imports):				
Ore and base bullion thousand troy ounces	21,197	87,755	16,717	70,206
Bullion do	61,629	274,254	67,187	289,032
Sweepings, waste, dore do	7,596	32,527	4,454	18,823
Tantalum ore thousand pounds	[r]1,753	[r]7,794	2,557	15,124
Tin:				
Ore (tin content) metric tons	[r]6,415	44,114	5,733	38,529
Blocks, pigs, grains, etc do	[r]44,366	312,346	45,055	325,453
Dross, skimmings, scrap, residue, and tin alloys, n.s.p.f do	[r]2,468	2,452	2,666	3,550
Tinfoil, powder, flitters, etc	NA	7,257	NA	8,148
Titanium:				
Ilmenite[3] short tons	334,692	15,903	431,717	18,715
Rutile do	224,499	46,362	281,712	54,849
Metal pounds	10,549,619	18,332	7,922,050	12,690
Ferrotitanium do	1,071,048	1,125	1,798,936	1,438
Compounds and mixtures do	53,964,945	19,654	140,795,246	53,806
Tungsten (tungsten content):				
Ore and concentrate thousand pounds	6,570	31,665	5,301	28,320
Waste and scrap do	71	317	170	694
Other alloys do	1,898	11,104	2,473	14,255
Ferrotungsten do	418	2,542	844	5,451
Uranium and other uranium-bearing and nuclear materials:				
Oxide U_3O_8 do	2,451,538	24,481	11,074,298	203,926
Compounds, n.e.c do	19,226,578	161,507	33,876,908	441,603
Isotopes (stable) and their compounds	NA	957	NA	1,067
Radio isotopes, elements, etc thousand curies	35,346,036	8,297	60,302,966	12,200
Vanadium (content):				
Ferrovanadium thousand pounds	273	1,435	518	2,448
Vanadium-bearing materials (vanadium pentoxide content) do	8,185	7,075	10,702	7,721
Zinc:				
Ore (zinc content) short tons	428,544	108,822	155,803	50,553
Blocks, pigs, slabs do	374,922	273,636	695,131	482,265
Sheets, etc do	236	507	209	329
Old, dross, skimmings do	3,158	1,238	12,445	4,884
Dust, powder, flakes do	5,739	5,744	6,009	5,134
Manufactures	NA	79	NA	96
Zirconium:				
Ore, including zirconium sand short tons	40,205	8,874	64,643	13,733
Unwrought, scrap, and compounds do	2,013	5,991	914	1,153
NONMETALS				
Abrasives:				
Diamonds (industrial) thousand carats	14,291	53,383	17,047	61,102
Other abrasives	NA	[r]68,480	NA	96,130
Asbestos short tons	538,553	111,011	657,851	142,145
Barite:				
Crude and ground do	672,528	9,264	917,812	17,829
Witherite do	85	44	278	56
Chemicals do	10,937	4,443	16,913	5,095
Boron:				
Carbide pounds	137,572	[r]645	30,232	240
Boric acid do	345,237	[r]59	112,870	14
Calcium borate, crude do	55,282,329	[r]1,560	60,493,065	1,953
Cement thousand short tons	3,702	70,620	3,107	67,085
Clays:				
Raw short tons	33,851	1,644	34,359	1,207
Manufactured do	4,143	303	4,309	607
Cryolite do	22,120	9,058	11,325	4,329

See footnotes at end of table.

Table 10.—U.S. imports for consumption of principal minerals and products —Continued

Mineral	1975 Quantity	1975 Value (thousands)	1976 Quantity	1976 Value (thousands)
NONMETALS —Continued				
Feldspar:				
Crude ---- short tons	[1]209	$17	93	$17,614
Ground and crushed ---- do	81	6	--	--
Fluorspar ---- do	1,050,448	61,059	895,254	56,580
Gem stones:				
Diamond ---- thousand carats	4,577	722,119	6,716	1,011,839
Emeralds ---- do	806	40,348	1,165	55,286
Other	NA	87,963	NA	112,241
Graphite ---- short tons	65,663	5,698	79,098	6,753
Gypsum:				
Crude, ground, calcined ---- thousand short tons	5,450	16,193	6,253	18,285
Manufactures	NA	3,617	NA	3,468
Iodine, crude ---- thousand pounds	5,309	11,721	6,482	13,824
Kyanite ---- short tons	65	3	110	12
Lime:				
Hydrated ---- do	44,637	1,392	48,461	1,814
Other ---- do	214,311	4,867	316,442	8,816
Lithium:				
Ore ---- do	4,548	538	68	1
Compounds ---- do	11	107	48	621
Magnesium compounds:				
Crude magnesite ---- do	10	1	18	2
Lump, ground, caustic-calcined magnesia ---- do	5,716	502	8,194	808
Refractory magnesia, dead-burned, fused magnesite, dead-burned dolomite ---- do	156,332	24,668	88,035	14,518
Compounds ---- do	36,572	1,796	27,039	2,267
Mica:				
Uncut sheet and punch ---- thousand pounds	904	696	1,654	941
Scrap ---- do	10,672	356	4,210	202
Manufactures ---- do	5,075	2,935	3,328	3,193
Mineral-earth pigments, iron oxide pigments:				
Ocher, crude and refined ---- short tons	20	3	50	11
Siennas, crude and refined ---- do	521	107	624	122
Umber, crude and refined ---- do	4,251	350	6,908	561
Vandyke brown ---- do	319	57	739	147
Natural, other ---- do	1,001	223	1,231	190
Synthetic ---- do	21,867	8,444	40,547	15,523
Nepheline syenite:				
Crude ---- do	6,275	98	2,112	38
Ground, crushed, etc ---- do	424,838	6,869	499,135	8,785
Nitrogen compounds (major), including urea ---- thousand short tons	3,113	415,534	3,467	296,814
Phosphate, crude ---- do	37	1,604	51	2,234
Phosphatic fertilizers ---- do	147	26,970	47	6,631
Pigments and salts:				
Lead pigments and compounds ---- short tons	15,337	7,470	17,836	9,462
Zinc pigments and compounds ---- do	18,447	10,746	27,969	15,557
Potash ---- do	6,292,329	285,272	7,595,246	360,756
Pumice:				
Crude or unmanufactured ---- do	3,260	77	3,344	148
Wholly or partly manufactured ---- do	142,120	380	78,057	350
Manufactures, n.s.p.f	NA	76	NA	70
Quartz crystal (Brazilian pebble) ---- pounds	1,487,272	931	1,148,801	368
Salt ---- thousand short tons	3,215	15,272	4,352	23,476
Sand and gravel:				
Glass sand ---- do	45	475	61	484
Other sand and gravel ---- do	329	301	292	425
Sodium sulfate ---- do	285	12,624	316	16,111
Stone and whiting	NA	[r]46,137	NA	46,211
Strontium:				
Mineral ---- short tons	21,613	826	35,711	1,486
Compounds ---- do	3,100	1,261	5,370	2,334
Sulfur and compounds, sulfur ore and other forms, n.e.s. ---- thousand long tons	1,897	70,848	1,727	59,494
Talc, unmanufactured ---- short tons	23,378	1,471	20,071	1,861
MINERAL FUELS				
Carbon black:				
Acetylene ---- pounds	5,839,266	2,578	8,294,902	4,366
Gas black and carbon black ---- do	33,034,187	4,284	44,120,742	7,016
Coal:				
Bituminous, slack, culm, lignite ---- short tons	939,721	21,682	1,203,076	17,739
Briquets ---- do	16,367	270	18,829	434
Coke ---- do	1,818,981	156,488	1,311,472	111,066
Natural gas, ethane, methane, and mixtures thereof ---- thousand cubic feet	944,352,390	1,070,539	943,432,188	1,611,644
Peat:				
Fertilizer grade ---- short tons	283,732	23,371	332,433	28,939
Poultry and stable grade ---- do	6,626	488	5,618	553
Petroleum:				
Crude petroleum ---- thousand barrels	1,581,129	18,290,012	2,051,307	25,456,155
Distillate ---- do	39,420	489,351	22,023	270,707

See footnotes at end of table.

Table 10.—U.S. imports for consumption of principal minerals and products —Continued

Mineral	1975 Quantity	1975 Value (thousands)	1976 Quantity	1976 Value (thousands)
MINERAL FUELS —Continued				
Petroleum —Continued				
Residual ____ thousand barrels	362,084	$3,958,178	405,833	$4,372,317
Unfinished oils ____ do	1,514	18,042	5,686	74,934
Gasoline ____ do	22,740	314,971	8,073	130,373
Jet fuel ____ do	44,368	619,102	26,056	373,450
Motor fuels, n.e.s ____ do	666	8,799	1,019	12,178
Kerosine ____ do	46	511	(4)	2
Lubricants ____ do	130	4,159	547	5,491
Wax ____ do	157	6,128	164	5,212
Naphtha ____ do	64,654	782,485	51,112	702,583
Liquefied petroleum gases ____ do	41,171	354,947	47,528	396,035
Asphalt ____ do	4,835	52,274	4,388	46,022
Miscellaneous ____ do	21,285	248,453	18,372	256,230
Total ____	XX	r38,847,295	XX	48,718,321

rRevised. NA Not available. XX Not applicable.
1Adjusted by the Bureau of Mines.
2Does not include silicon metal more than 96% but less than 99% silicon.
3Includes titanium slag averaging about 70% TiO_2, for detail see Titanium chapter.
4Less than 1/2 unit.

Table 11.—Comparison of world and U. S. production of principal mineral commodities

(Thousand short tons unless otherwise specified)

Minerals	1975			1976[p]		
	World production[1]	U.S. production	U.S. percent of world production	World production[1]	U.S. production	U.S. percent of world production
MINERAL FUELS						
Carbon black ---- million pounds	6,937	2,742	40	7,726	3,004	39
Coal:						
Bituminous	[2]1,976,155	628,619	32	[2]2,018,657	653,055	32
Lignite	944,677	19,819	2	985,178	25,630	3
Pennsylvania anthracite	196,301	6,203	3	196,769	6,228	3
Coke (excluding breeze):

Table 11.—Comparison of world and U. S. production of principal mineral commodities —Continued

(Thousand short tons unless otherwise specified)

Minerals	1975 World production[1]	1975 U.S. production	1975 U.S. percent of world production	1976[p] World production[1]	1976[p] U.S. production	1976[p] U.S. percent of world production
METALS, SMELTER BASIS						
Aluminum	13,352	3,879	29	13,774	4,251	31
Cadmium ____ short tons	16,925	[12]2,193	13	18,892	[12]2,256	12
Copper	7,793	[13]1,447	19	8,164	[13]1,535	19
Iron, pig	528,861	79,721	15	549,298	86,848	16
Lead	3,656	[14]636	17	3,788	[14]653	17
Magnesium	138	W	NA	148	W	NA
Selenium[8] ____ thousand pounds	2,561	358	14	2,773	401	14
Steel ingots and castings	712,556	[15]116,642	16	748,492	[15]128,000	17
Tellurium[8] ____ thousand pounds	315	131	42	NA	W	NA
Tin ____ metric tons	230,596	[16]6,500	3	228,856	[16]5,700	2
Zinc	5,592	438	8	5,978	499	8

[p]Preliminary. NA Not available. W Withheld to avoid to disclosing individual company confidential data.
[1]May not represent total world production because confidential U.S. data are excluded for some commodities. World totals include reported figures and reasonable estimates; however, for some commodities where data were not available, no reasonable estimates could be made and none have been included.
[2]Includes small quantities of lignite for People's Republic of China and Pakistan, and anthracite for Colombia.
[3]Includes low- and medium-temperature and gashouse coke.
[4]Less than 1/2 unit.
[5]Includes Puerto Rico.
[6]Kaolin sold or used by producers.
[7]Year ended June 30 of year stated (United Nations).
[8]World total exclusive of the U.S.S.R.
[9]Dry bauxite, equivalent of crude ore.
[10]Recoverable.
[11]Includes byproduct ore.
[12]Includes secondary.
[13]Smelter output from domestic and foreign ores, exclusive of scrap.
[14]Lead refined from domestic and foreign ores; excludes lead refined from imported base bullion.
[15]Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingot.
[16]Includes tin content of alloys made directly from ore.

Abrasive Materials

By W. T. Adams[1]

The production of natural abrasives varied in quantity and value compared with 1975. Output of tripoli-type materials and garnet increased in both quantity and value; special silica stone products decreased in quantity and increased in value; the production of emery decreased.

The production and value of manufactured abrasive materials increased for all types.

Imports for consumption (value) do	$106,512	$136,655	$142,974	r$121,863	$157,232

rRevised. W Withheld to avoid disclosing individual company confidential data.
[1]Includes grinding pebbles, grindstones, oilstones, tube-mill liners, and whetstones.
[2]Production of silicon carbide and aluminum oxide (the United States and Canada); shipments of metallic abrasives (the United States).
[3]Includes production of aluminum zirconium oxide (the United States and Canada).

FOREIGN TRADE

Imports of abrasive materials were 29% greater in value than in 1975, and exports plus reexports increased 9% in value. Net imports, the excess of imports over exports and reexports, were $14.7 million. The volume and value of all abrasive materials exported varied.

Industrial diamond imports totaled 17.0 million carats of loose material valued at $61.1 million, reflecting increases of 19% in quantity and 14% in value from those of 1975. Exports of loose industrial diamond were 14.9 million carats, an increase of 8%, and the value was $39.3 million, an increase of 3%. Reexports of similar industrial diamond were 3.1 million carats, a decrease of 4%, and the value was $28.9 million, an increase of 2%. The diamond content in diamond wheels, exported and reexported, was 749,000 carats, an increase of 8%, and

[1]Physical scientist, Division of Nonmetallic Minerals.

the declared value was $5.0 million, for no change in value. The imports of diamond wheels are listed by number and value; the value in 1976 increased to $1,302,000 from $896,000 in 1975.

The 1976 imports of industrial diamond from Ireland were 5.9 million carats valued at $13.9 million, reflecting increases of 31% in quantity and 33% in value from those of 1975. The share of imports from Ireland was 35% of the total quantity and 23% of the value. Of the industrial imported bort, powder, and dust, synthetic diamond was 4.5 million carats valued at $9.0 million and natural diamond was 6.9 million carats valued at $15.1 million.

TRIPOLI

Fine-grained, porous, silica materials are grouped together because they have similar properties and end uses. Production of crude tripoli increased 54% in quantity and 38% in value. Processed tripoli sold or used increased 67% in quantity and 62% in value. The uses for processed tripoli in 1976 were 60% for abrasives and 35% for fillers, compared with 57% and 41% respectively in 1975.

Tripoli producers in 1976 were Malvern Minerals Co., Garland County, Ark., which produced crude and finished material, Midwestern Minerals Corp., Ottawa County, Okla., which produced crude and finished material, and American Tripoli Co., Division of The Carborundum Co., which produced crude in Ottawa County, Okla., and finished material in Newton County, Mo. Illinois Minerals Co. and Tammsco, Inc., both in Alexander County, Ill., produced amorphous silica. Keystone Filler and Manufacturing Co., Northumberland County, Pa., mined and processed rottenstone. Prices quoted in Engineering and Mining Journal, December 1976, for tripoli and amorphous silica follow:

Tripoli, paper bags, carload lots, f.o.b., in cents per pound:	
White, Elco, Ill.: Air floated through 200 mesh ----------	1.6
Rose and cream, Seneca, Mo. and Rogers, Ark.:	
Once ground ----------	2.90
Double ground ----------	2.90
Air float ----------	3.15
Amorphous silica, bags, f.o.b., in dollars per ton:	
Elco, Ill:	
Through 200 mesh, 90% to 95% -----	$31
Through 200 mesh, 96% to 99% -----	32
Through 325 mesh, 96% to 98% -----	37
Through 325 mesh, 98% to 99.4% ----	35.50
Through 325 mesh, 99.5% ----------	51.50

SPECIAL SILICA STONE PRODUCTS

Special silica stone products produced in 1976 included oil stones from Arkansas, whetstones from Arkansas and Indiana, grindstones from Ohio, grinding pebbles and deburring media from Minnesota and Wisconsin, and tube-mill liners from Minnesota. Output decreased 9%.

Producers of oilstones and whetstones in Garland County, Ark., were John O. Glassford; Hiram A. Smith, Inc.; Arkansas Abrasives, Inc.; and Norton Pike Division of Norton Co. Whetstones were produced by Milroy and Smith in Hot Springs County, Ark., and by K & K Mines, Inc., in Pike County, Ark. Hindostan Whetstone Co. operated a plant in Lawrence County, Ind., to finish stone obtained from a quarry in Orange County, Ind. Cleveland Quarries Co., produced grindstones at its Amherst quarry, Lorain County, Ohio. Jasper Stones Co. produced grinding media, rough and rounded, from its quarry in Rock County, Minn., and Baraboo Quartzite Co., Inc., produced deburring media at its quarry in Sauk County, Wis.

NATURAL SILICATE ABRASIVES

Garnet.—Sales of domestic garnet increased 43% in quantity and 62% in value from those of 1975. Three producers were active in 1976—two in Idaho and one in New York. Barton Mines Corp., Warren County, N.Y. sold garnet for use in coated abrasives, glass grinding and polishing, and metal lapping. Emerald Creek Garnet Milling Co. and Idaho Garnet Abrasive Co., both in Benewah County, Idaho, reported their garnet was used in sandblasting, water filtration, as a filler in rubber products, and as an additive in decorations.

NATURAL ALUMINA ABRASIVES

Corundum.—No domestic corundum was produced in 1976. Requirements for domestic consumption were met by imports, mainly from the Republic of South Africa. Total imports were 3,074 tons at a declared value of $229,987.

Prices quoted in Engineering and Mining Journal, December 1976, for crystal corundum, per short ton of crude, c.i.f., U.S. ports, were $150 to $160.

Emery.—Two producers of emery were active in 1976: De Luca Emery Mine, Inc., and Emeri Crete, Inc., both near Peekskill in Westchester County, N.Y. Domestic emery was used mostly in aggregates as a nonslip additive for floors, pavements, and stair treads. The minor use for domestic emery was in abrasive materials for coated abrasives and tumbling or deburring media.

World production data for emery are principally for Greece and Turkey. In 1975, production of emery in Greece was estimated to be 7,700 short tons. Production of emery in Turkey in 1975 was reported as 70,670 short tons. No value was reported on either Greek or Turkish production.

Prices quoted in Industrial Minerals, No. 99, December 1976, for emery, per metric ton, c.i.f., main European port were $127 to $136 for coarse grain and $136 to $153 for medium and fine grain.

Table 8.—Natural corundum: World production, by country

(Short tons)

Country[1]	1974	1975	1976[p]
India	360	337	582
South Africa, Republic of	278	266	157
U.S.S.R.[e]	7,700	8,300	8,300
Uruguay	366	460	420
Total	8,704	9,363	9,459

[e]Estimate. [p]Preliminary.

[1]In addition to the countries listed, Southern Rhodesia presumably continued to produce natural corundum at a significant level (several thousand tons annually), and both Argentina and Kenya may have produced minor quantities of this commodity, but output is not reported and available information is inadequate for the formulation of reliable estimates of output levels.

INDUSTRIAL DIAMOND

Domestic production of synthetic industrial diamond in 1976 was estimated to be 25.3 million carats, an increase of 6.3 million carats from above of 1975. Secondary production, comprising salvage from used diamond tools and from wet and dry diamond-containing wastes, was estimated to be 2.7 million carats from a consumption canvass by the Department of Commerce.

The Government stockpile inventory as of December 31, 1976, was 31.0 million carats of crushing bort and 20.0 million carats of stones. The goal for crushing bort was 15.0 million carats and 5.6 million for stones. Available for disposal from prior enabling legislation were 9.9 million carats of bort.

Diamonds in a serpentinized garnet peridotite nodule from diotreme-pipe in southern Wyoming were the first known North American occurrence in an upper-mantle peridotite xenolith from a kimberlite intrusion, as well as the second authenticated North American occurrence of diamond from kimberlite pipes.[2]

Exports and reexports of industrial diamond dust and powder, which included synthetics, were 14.5 million carats valued at $36.2 million. Crushing bort, except dust and powder, exported was 433,000 carats valued at $2.3 million. Exports and reexports of stones were 3.1 million carats valued at $29.7 million. The total of exports and reexports of dust and powder, bort, and stones was 18.0 million carats valued at $68.2 million.

[2]McCallum, M. E. Diamonds in an Upper Mantle Peridotite Nodule From Kimberlite in Southern Wyoming. Science, v. 192, No. 4236, pp. 253-256.

WORLD REVIEW

Australia.—An exploration consortium confirmed that diamond was found in the Kimberly Region of Western Australia. Systematic sampling yielded some 160 stones of approximately 7 carats total weight. There has been no announcement as to whether kimberlite pipes have been found.[3]

Botswana.—At the Orapa mine 3,428,985 tons were processed in 1976, compared with 3,048,020 tons in 1975. Diamond production was 2,360,945 carats in 1976, compared with 2,397,245 carats in 1975. The Mopipi Dam provided all water requirements for Orapa in 1976. Construction work is in progress at the Orapa mine to increase capacity from 2.3 million carats to 4.5 million carats per year. A new kimberlite pipe was discovered in southern Botswana; accurate assessment of its potential will require a detailed underground sampling program, which will take about 4 years to complete.[4]

Ghana.—Consolidated Diamond Ltd. has estimated remaining diamond deposits along the lower Birim River to yield about 50 million carats. The deposits will be mined at a rate of 2 million carats per year. Ghana has begun to exploit this new deposit because the traditional diamond area at Akwatia in Akyem Abuakwa is expected to be phased out by 1980. Two other small firms, Cayo Ltd. and Dunkwa Goldfields Ltd., are no longer active.[5]

Lesotho.—The Letseng-La-Terai diamond mine is on schedule and was in production in 1976. Overlying soft, weathered kimberlite was mined and stockpiled with the object of exposing harder kimberlite at depth. Mining and recovery operations have been geared to winning larger stones, with primary sorting and washing done when the ore is still at a fairly large size to prevent crushing such stones.[6]

South Africa, Republic of.—Record diamond sales of $1,555 million, 46% higher than in 1975, has caused De Beers Consolidated Mines Ltd. to draw on stockpiles. Sales of industrial diamond, both natural and synthetic, reached a record high in 1976. Total diamond production fell from 10,760,118 carats to 10,523,267 carats. No breakdown was given for sales of either gem stones or industrial diamond. Production is being increased to 1.4 million carats per year at the Namaqualand mine to decrease reliance on the mines in the Territory of South-West Africa.[7]

TECHNOLOGY

Synthesis of cubic boron nitride using high-pressure, high-temperature technology was announced by De Beers Industrial Diamond Div., Ltd. The grit obtained by the De Beers process is from 80 to 230 U.S. mesh in size and comprises clear, amber-colored crystals of high purity. The shapes are described as irregular with smooth crystal faces or irregular fracture surfaces.[8]

Megadiamond Corp., Provo, Utah, produced a fiber spinnert for the synthetic fiber industry from sintered polycrystalline diamond material.[9]

National Research Co. added the processing of copper- and nickel-coated natural and synthetic diamond to its diamond and carbide recovery operations.[10]

De Beers Diamond Research Center in Johannesburg, Republic of South Africa, reported progress on a number of projects, among which were the following:[11]

A new diamond-crushing system was installed for processing smaller diamond grit sizes. Results indicate a high yield of blocky grit particles with sharp well-defined edges that are suited for stone-sawing and glass-grinding operations.

Carbide Diamond Abrasive (CDA) was synthesized especially for use in the grinding of tungsten carbide. The particles have a polycrystalline mosaic structure and break away in very small chips. New sharp cutting edges are constantly generated.

Precise monitoring of the absorbed radiation dose is essential during treatment of cancer by radiotherapy. Diamond can contribute toward accurate medical dosimetry and successful radiotherapy. Properties that make diamond attractive for this use are low conductivity, low trapping rate, and high carrier mobility.[12]

Successful tests demonstrate the effectiveness of X-ray topographic maps. In-

^eEstimate. ^pPreliminary. ^rRevised.

[1]Total (gem plus industrial) diamond output for each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of every country except Lesotho (1974-75), Liberia (1974), Venezuela (all years), and Zaire (1974-75) where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2]Exports of diamond originating in Lesotho; excludes stone imported for cutting and subsequently reexported.

[3]Exports.

[4]Partial figure; January 1 through December 15 only.

[5]All company output from the Republic of South Africa except for that credited to the Premier mine; also excludes company output from the Territory of South-West Africa and Botswana.

ternal crystal lattice defects act as fingerprints that unambiguously identify a given cut gem with its parent rough stone or identify the gem even though it may have been recut.[13]

Boron is the dopant responsible for the acceptor center in semiconducting diamond. Other potential donors and acceptors are discussed. At normal temperatures, conduction occurs in the valence bond. At low temperatures, and particularly in heavily boron-doped synthetic diamond, an impurity bond is formed, and conduction takes place through variable range hopping. Limited success has been achieved by ion implantation of boron.[14]

Abstracts relative to properties of diamond-hard materials, machines, and patents were published monthly in the Industrial Diamond Review. Each issue, January to December 1976, contained from 14 to 18 pages of abstracts and patent information.

ARTIFICIAL ABRASIVES

Five firms produced crude fused aluminum oxide in the United States and Canada in 1976. Operators of plants in both countries were The Carborundum Co., Norton Co., and General Abrasive Co., Div. of U.S. Industries. The Exolon Co. and Simonds Canada Abrasive Co., Ltd., operated plants in Canada. The production of white, high-purity material was 30,279 tons, and pro-

[13]Lang, A. R., and G. S. Woods. Fingerprinting Diamonds by X-Ray Topography. Industrial Diamond Review, March 1976, pp. 96-103.

[14]Bourgoin, J. D., and J. Walker. Electrical Conduction in Diamond. Industrial Diamond Review, October 1977, pp. 362-367.

duction of regular grade was 160,512 tons. Of the combined output of white and regular, 12% was used for nonabrasive applications, principally in the manufacture of refractories. The production was 62% of the rated capacity of the furnaces assigned to fused aluminum oxide production. Yearend stocks were reported as 11,935 tons.

One firm, General Abrasive Co., Div. of U.S. Industries, produced fused-alumina zirconia abrasive in the United States and in Canada; and three firms, The Carborundum Co., Norton Co., and Exolon Co., operated plants in Canada. All production was reportedly used for abrasive applications. The output was 58% of the capacity of the furnaces assigned to the production of fused-alumina zirconia. Yearend stocks were reported as 1,259 tons.

Six firms in the United States and in Canada produced silicon carbide in 1976. The Carborundum Co. operated plants in both countries. Electro-Refractories & Abrasives Canada, Ltd., Exolon Co., Norton Co., and General Abrasive Co., Div. of U.S. Industries, operated in Canada. These five companies produced crude for abrasive uses and for refractory and other nonabrasive uses. Satellite Alloy Corp. operated in the United States and produced crude for nonabrasive applications. Production by the six firms was 81% of capacity, and 37% was reportedly used for abrasive applications. Nonabrasive use was 63% of the output and was mostly for refractory and metallurgical applications. Yearend stocks were reported as 11,326 tons.

In the Stockpile Report to the Congress by the General Services Administration, the inventory of crude fused aluminum oxide in calendar 1976 was reduced to 249,009 tons, with 77,229 tons uncommitted excess; the stock of aluminum oxide grain was unchanged at 50,905 tons, with the goal increased to 75,000 tons; and the stock of silicon carbide crude was 80,619 tons, with the goal increased to 306,628 tons.

Metallic abrasives were produced by 13 firms in the United States in 1976. Steel shot and grit comprised 77% of the total quantity sold or used; chilled iron shot and grit, 14%; and annealed iron shot and grit, 9%. The amounts from Ohio were 25% of the total sold or used, the highest of the producing States. Michigan, Indiana, Pennsylvania, Alabama, New York, and Connecticut followed in quantity sold or used. Three companies recycled material: Copperweld Steel Co., Glassport, Pa.; Industeel Corp., Pittsburgh, Pa; and Kohler Co., Sheboygan, Wis.

TECHNOLOGY

Ceramics are prone to surface damage caused by grinding, cutting, thermal shocking, impacting, and even handling. The resulting flaws cause a decrease in the actual strength of ceramics. Thermally shocked alumina regains its strength when annealed. Cracks appear to heal via the disappearance of void space between the grains. The major event during healing involves pore evolution.[15]

Submicrometer-sized high-purity powders were offered by Aremco Products, Inc., Ossining, N.Y. These powders include aluminum, aluminum carbide, barium titanate, boron carbide, cobalt oxide, hafnium boride, manganese, silicon, silicon nitride, tantalum oxide, titanium nitride, tungsten diboride, vanadium diboride, and zirconium carbide.[16]

Coated-abrasives manufacturers introduced specialized products characterized by high-tensile, low-stretch, tear-resistant polyester cloth backing, an improved phenolic resin-modified bond system, and sharp shape classified aluminum oxide grain. The new abrasives are beginning to make significant inroads into paperbacked products for metalworking.[17]

Zirconia alumina abrasives have had great impact on metal and woodworking industries. Used in grinding wheels and coated abrasives they have provided 50% to 250% increases in productivity.[18]

Escalating production costs, new technologies, tightening air-pollution regulations, and changing market conditions are forcing changes in the U. S. abrasives industry. Abrasive makers are moving away from direct competition in several market areas; each firm is concentrating on those segments of the market in which it holds strong technological or marketing advantages.[19]

The Carborundum Co. completed a new electric furnace for the production of fused

aluminum oxide. The furnace has a capacity of 50,000 tons per year and uses less electric power per ton of output. Ferrosilicon is bottom-tapped from the furnace.[20]

Advanced ceramics are being used in industrial applications. Manufacturers of industrial and aircraft gas turbine engines are giving serious consideration to commercial applications as design factors are more well known. Advanced ceramics have high strength at temperatures of 2,500°F and higher. They are extremely resistant to oxidation and corrosion at high temperatures. They have very low coefficients of thermal expansion. These materials resist mechanical and thermal shock almost as well as most superalloys and are 60% lighter. Special cooling is not required to maintain high-temperature strength.[21] [22]

Airless blast cleaning gives processors low-cost, environmentally clean options for a systems approach to surface preparation. White or near-white clean metal surfaces are being increasingly specified by designers, engineers, and architects. A single blast wheel powered by 25 to 30 horsepower will clean 15 square feet or more per minute.[23]

Aluminum

By John W. Stamper[1] and Christine M. Monroe[2]

World primary aluminum production increased about 3% during 1976 as producers restarted potlines idled in 1975. Stocks of primary aluminum held by members of the International Primary Aluminum Institute (IPAI), which represents the bulk of inventories held outside the centrally controlled economies, decreased about 25% during 1976.

U.S. aluminum demand, as measured by net shipments of aluminum ingot and mill products to domestic industry, increased 31% compared with the 1975 level. Total metal inventories held by the domestic industry at yearend 1976 were 6% lower than at the beginning of the year.

Primary aluminum production capacity increased during the year in 16 countries, including Brazil, Ghana, India, Japan, New Zealand, and Taiwan. Additional production capacity was under consideration in Brazil, Indonesia, Mexico, Trinidad, and the U.S.S.R.

[1]To domestic industry.
[2]Not comparable to previous years. See table 6 for derivation.

Legislation and Government Programs.—The shipment of 9,181 tons of primary aluminum from government inventories during 1976 under the aluminum disposal program that became effective November 23, 1965, brought the total shipped under the program to almost 1.9 million tons. From December 1, 1965 to December 31, 1976, shipments of primary aluminum by the General Services Administration were as follows, in short tons:

1965	9,374
1966	325,925
1967	61,599
1968	56,554
1969	139,635
1970	24,261
1971	21
1972	6,125
1973	730,249
1974	510,741
1975	2,486
1976	9,181
Total	1,876,151

[1]Physical scientist, Division of Nonferrous Metals.
[2]Mineral specialist, Division of Nonferrous Metals.

DOMESTIC PRODUCTION

Primary.—Primary aluminum production increased about 10% during 1976 to 4,251,395 tons, compared with 3,879,146 tons in 1975. Primary producers restarted potlines idled in 1975 due to decreased demand and by yearend 1976 smelters were operating at 90% of rated capacity compared with 74% at yearend 1975.

Domestic primary aluminum production capacity increased slightly from that of 1975 to 5,193,000 tons per year. The Aluminum Company of America (Alcoa) began production at its 15,000-ton-per-year Palestine, Tex., facility. The smelter used an experimental process based on the electrolysis of aluminum chloride and reportedly used 4.2 kilowatt-hours per pound of aluminum produced, compared with 6.0-7.0 kilowatt-hours per pound of aluminum produced in the most efficient Hall-type cells, and with an industry average of about 8 kilowatt-hours per pound.

Noranda Aluminum, Inc., a subsidiary of Noranda Mines, Ltd., completed the expansion of its New Madrid, Mo., smelter to 140,000 tons per year.

Alcoa announced that it was studying the feasibility of an additional potline at its Alcoa, Tenn., smelter. The issuance of revenue bonds to finance pollution control equipment for the expansion was authorized by the Blount County Industrial Development Board.

Alcoa agreed to supply Texas Power & Light Co. with lignite for a generating plant that the power company will build to supply power to Alcoa's 285,000-ton-per-year smelter at Rockdale, Tex.

Anaconda Aluminum Co. was licensed to use the Alcoa dry-scrubbing process for control of fluoride emissions at Anaconda's Columbia Falls, Mont., smelter.

Kaiser Aluminum & Chemical Corp. signed contracts with Devon Corp. and Eason Oil Co. to determine the extent of gas reserves in the vicinity of Kaiser's 163,000-ton-per-year primary smelter at Ravenswood, W.Va. The smelter could be expanded by 50,000 tons per year if long-term power were available.

Martin Marietta Aluminum Inc. began modernization and technological improvement at its Goldendale, Wash., and The Dalles, Oreg., smelters. Emission controls and solid-state electric power rectification equipment were installed to increase operating efficiency of the plants.

The Bonneville Power Administration (BPA) sent notices of insufficiency to its industrial users stating that there would not be enough generating capacity to meet projected demand by the early 1980's. If this occurs electric power from BPA reportedly would not be able to provide sufficient power to aluminum producers after their current contracts expire. The contracts of the six primary aluminum producers in the Pacific Northwest expire between 1984 and 1988.

Secondary.—Recovery of secondary aluminum-base scrap, calculated from reports to the Bureau of Mines, was 1,155,018 tons, 18% higher than the quantity recovered in 1975. Calculated recovery of all metallic constituents from aluminum-base scrap in 1976 increased 18% compared with the 1975 level.

The Bureau estimated that full coverage of the industry would indicate a total scrap consumption of 1,741,000 tons in 1976. On this basis, aluminum recovery would total 1,371,000 tons and total metallic recovery would be 1,471,000 tons.

Hall Aluminum Co. installed a 150,000-pound capacity aluminum refining furnace at its Chicago Heights, Ill. smelter, increasing the facility's aluminum-melting capacity to 40,000 tons per year. Keystone Georgia Metal Co. began production at its Greensboro, Ga., secondary aluminum smelter which was converted from a copper-scrap-processing plant. Texas Reduction Corp. reportedly began production at its new secondary aluminum smelter in Houston, Tex. The $1.7 million plant had a capacity of 22,000 tons per year. Alcan Aluminium Ltd. purchased 50% interest in International Alloys, Inc., which operated a 14,000-ton-per-year secondary smelter in Joliet, Ill. Alcoa began operations at its 4,200-ton-per-year recycling facility for aluminum cans in Houston, Tex. American Can Co. announced that its subsidiary, U.S. Reduction Co., planned to build a $2 million plant in Anniston, Ala., to recover aluminum from scrapped automobiles.

A municipal-waste-processing plant began operations in New Orleans, La. Monthly output of the facility reportedly would be 1,200 tons of steel and glass, 520 tons of copper, 94 tons of aluminum, and other metals such as brass, tin, zinc, and copper. At full capacity the $6.5 million recovery plant was expected to process 650 tons of waste per day at a projected cost of $11 per ton.

Table 2.—Consumption of and recovery from purchased new and old aluminum scrap in 1976[1]

Grand total	980,340	1,155,018			

[1]Aluminum alloys recovered from aluminum-base scrap in 1975, including all constituents, were 742,993 tons from new scrap and 305,882 tons from old scrap and sweated pig, a total of 1,048,875 tons.
[2]Aluminum alloys recovered from aluminum-base scrap in 1976, including all constituents, were 868,301 tons from new scrap and 370,113 tons from old scrap and sweated pig, a total of 1,238,414 tons.
[3]Includes recovery in deoxidizing ingot assuming 85% aluminum content in such ingot.

Table 4.—Stocks, receipts, and consumption of purchased new and old aluminum scrap and sweated pig in the United States in 1976[1]

(Short tons)

r Revised. W Withheld to avoid disclosing individual company confidential data; included in the "Miscellaneous," and "Other" categories.

[1]Gross weight, including copper, silicon, and other alloying elements. Secondary smelters used 16,902 and 20,700 tons of primary aluminum in 1975 and 1976, respectively, in producing secondary aluminum-base alloys.

[2]No allowance was made for consumption or receipts by producing plants.

[3]Includes data withheld.

CONSUMPTION

The Bureau of Mines estimate of apparent aluminum consumption in end products such as automobiles, cans, air-conditioning equipment, and residential siding, as shown in table 6, increased 31% compared with that of 1975.

Domestic consumption as measured by net shipments of aluminum ingot and mill products to domestic industry also was 31% higher than the 1975 level. Shipments to the building and construction industry, the largest user of aluminum, increased 31% from the 1975 level. The containers and packaging industry was the second largest user of aluminum, with shipments totaling 1,285,000 tons, 28% higher than the 1975 level. Transportation applications increased 44% and shipments to electrical markets increased 9% compared with those of 1975.

The average quantity of aluminum used in 1976 model automobiles was about 87 pounds per unit compared with 84.2 pounds per unit in 1975. Estimates indicated that approximately 100 pounds would be required per unit in 1977 models.

Shipments of aluminum sheet to can producers increased during the year and aluminum was reportedly used for about 28% of the metal cans produced in 1976, compared with about 25% of the market in 1975.

Table 6.—Apparent aluminum supply and consumption in the United States

(Thousand short tons)

	1972	1973	1974	1975	1976
Primary production	4,122	4,529	4,903	3,879	4,251
Change in stocks:[1]					
Aluminum industry	+83	+248	-395	-421	+184
Government	+6	+730	+511	+2	+9
Imports	794	614	629	550	749
Secondary recovery:[2]					
New scrap	876	977	978	905	1,062
Old scrap	250	265	304	334	409
Total supply	6,131	7,363	6,930	5,249	6,664
Less total exports	329	561	524	440	484
Apparent aluminum supply available for domestic manufacturing	5,802	6,802	6,406	4,809	6,180
Apparent consumption [3]	4,926	5,825	5,428	3,904	5,118

[1]Positive figure indicates a decrease in stocks, negative figure indicates an increase in stocks.
[2]Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.
[3]Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

STOCKS

Metal inventories held at reduction and other processing plants as reported by the U.S. Department of Commerce, Bureau of Domestic Commerce (BDC), decreased 6% from 2,999,354 tons (revised) at yearend 1975 to 2,815,324 tons at yearend 1976.

PRICES

The price of 99.5% pure aluminum ingot as quoted by the American Metal Market increased from 41.0 cents per pound at the beginning of 1976 to 44.0 cents per pound on June 1. The price increased an additional 4.0 cents per pound to 48.0 cents per pound on August 13, and remained at that level through yearend.

Prices quoted by the American Metal Market for smelters' secondary aluminum alloys increased from a range of 40.5 to 50.0 cents per pound at the beginning of 1976 to 51.0 to 59.0 cents per pound at yearend.

Prices quoted by the American Metal Market for smelters' scrap aluminum increased from a range of 12.0 to 20.0 cents per pound on January 2 to a range of 22.0 to 30.0 cents per pound on December 30.

FOREIGN TRADE

Exports of crude and semicrude aluminum metal including scrap increased 10% compared with the 1975 level. Exports of aluminum ingot decreased during the year but were offset by a marked increase in exports of scrap. The People's Republic of China received 27%, or 41,170 short tons, of aluminum ingot. Other major recipients of ingot included Japan, Canada, Mexico, and Taiwan. Japan received 60% of the scrap exports during the year.

U.S. imports for consumption of crude and semicrude aluminum including scrap increased 36% to 748,624 short tons compared with 550,279 tons in 1975. Canada supplied 66% of crude metal and alloys and Ghana supplied 16%. Imports of scrap increased sharply during the year; the major sources of scrap were Canada (47%) and the U.S.S.R. (38%).

WORLD REVIEW

World primary aluminum production in 1976 increased 3% compared with the 1975 level as primary smelters restarted potlines that had been shut down in 1975 due to decreased demand. Stocks held by primary producers decreased steadily during the year.

Expansions of production capacity were completed in Brazil, Ghana, India, Japan, New Zealand, and Taiwan. Construction of additional smelting capacity was underway in Australia, Norway, Spain, Venezuela, and Yugoslavia. Plans for new primary aluminum reduction facilities were under consideration in Algeria, Brazil, Costa Rica, Dubai, Guyana, Iceland, Indonesia, Libya, Mexico, Paraguay, Saudi Arabia, Trinidad, and the U.S.S.R. Some projects in Australia, India, and Japan were postponed indefinitely.

Algeria.—The Soviet Union agreed to help finance the 154,000-ton-per-year primary aluminum smelter to be built near M'sila. Production at the $400 million facility was scheduled to begin in 1982. A 600-megawatt power station, technical assistance, and port improvements at Bejaia were included in the agreement. Alumina would be imported from Guinea and Jamaica.

Australia.—Comalco Ltd. postponed indefinitely plans for a 353,000-ton-per-year smelter at Gladstone, Queensland due to decreased demand and high construction costs. The company resumed work on a new potline at its Bell Bay, Tasmania smelter. Upon its scheduled completion in 1977, capacity of the facility would be 126,000 tons per year.

Bahrain.—Western Metals Corp. and Amalgamated Metals Corp. sold their share in Aluminium Bahrain Ltd., which operated a 132,000-ton-per-year smelter. Ownership of the facility at yearend included the Government of Bahrain (78%), Kaiser Aluminum & Chemical Corp. (17%), and Breton Investments (5%).

Brazil.—Cia. Vale do Rio Doce (CVRD) and the Light Metal Smelters Association (LMSA) announced an agreement to build a 350,000-ton-per-year primary aluminum smelter at Belem. The facility, which would be based on bauxite from the Trombetas project, would use hydroelectric power from the Tocantinas River. Japanese members of the consortium agreed to supply about $600 million of the estimated $1.3 billion cost of the project.

Reynolds International, Inc. and CVRD formed a new aluminum company, Vale do Sul Aluminio, S. A. (Valesul), to build an 88,000-ton-per-year smelter at Sepetiba Bay near Rio de Janeiro. The $250 million project was scheduled to begin production in 1979. Alumina would be supplied by Reynolds until the Alunorte bauxite-alumina project was completed.

Alcan Alumínio do Brasil, S.A. announced plans to expand its 35,000-ton-per-year smelter at Saramenha to 66,000 tons per year by 1980. Companhia Mineira de Alumínio doubled the capacity at Poços de Caldas to 66,000 tons per year and announced plans to further expand the plant to 99,000 tons per year. Alumínio do Brasil Nordeste, S.A., completed the expansion of its Aratü smelter to 31,000 tons per year.

Cameroon.—The Government of Cameroon announced that within the next 5 years development of bauxite deposits would start, the construction of an alumina refinery would be underway, and the tripling of the 61,000-ton-per-year primary aluminum smelter at Edea would be completed.

Canada.—Alcan Aluminium Ltd. primary aluminum smelters at Arvida, Quebec; Isle Maligne, Quebec; Beauharnois, Quebec; and Kitimat, British Columbia; were closed on June 3, 1976, due to a strike, and metal froze in the pots at the three Quebec smelters. Production was resumed later in the month at the Kitimat facility. A settlement between the company and the Federation des Syndicats du Secteur Aluminium (FSSA) in Quebec was reached November 14. Full production at the smelters was not expected until early 1977.

A strike occurred at the Alcan smelter at Shawinigan Falls, Quebec, in November, closing that plant through yearend.

Alcan announced plans to build a 200,000-ton-per-year smelter at Port Alfred, Quebec, where a 2,500-acre site was purchased in 1975. Design and engineering work was underway.

The Quebec Government announced plans to increase the fee charged private firms for use of public water resources used to generate hydroelectric power.

Costa Rica.—The National Aluminum Commission sought partners for a 100,000-

to 300,000-ton-per-year aluminum smelter to be built in Boruca. The project included a hydroelectric plant as well as the related infrastructure. Alcan, Kaiser, Alumax, Inc., and Martin Marietta Aluminum, Inc., have reportedly expressed interest in the $1.2 billion project.

Dubai.—The Government of Dubai and an international group of banks arranged a $200 million loan to help finance a proposed 132,000-ton-per-year smelter at Jebel Ali. British Smelter Construction would build the facility. Initial production was scheduled for 1979 with full capacity production scheduled for 1981. Southwire Corp. and Nissho Iwai Co. signed 12-year contracts to buy 80% of the aluminum production. Ownership of the facility consisted of the Government of Dubai (80%), Southwire Corp. (7.5%), Nissho Iwai (7.5%), and local interests (5%).

France.—The Government of France lifted price controls on domestic primary aluminum ingot at the beginning of May. Pechiney Ugine Kuhlmann increased the price of 99.5% purity ingot from 43.4 cents per pound to 45.6 cents per pound, and in July increased the price to 48.7 cents per pound, where it remained at yearend.

Germany, West.—Hamburger Aluminium-Werke G.m.b.H. announced that its 110,000-ton-per-year aluminum reduction facility in Hamburg operated at 100% of its rated capacity during the year. The smelter had operated at two-thirds of capacity since startup in 1973 due to various court actions involving environmental issues.

Swiss Aluminium Ltd. (Alusuisse) purchased the remaining 50% equity share in Leichtmetall G.m.b.H. from Metallgesellschaft A.G. Leichtmetall operated a 143,000-ton-per-year smelter at Essen.

Ghana.—Volta Aluminium Co. Ltd. completed expansion of the Tema smelter to 220,000 tons per year. Kaiser owned 90% of the facility, and Reynolds owned 10%.

Guyana.—Plans for a 165,000- to 240,000-ton-per-year smelter were under consideration. Power for the facility would be supplied by a 600- to 1,000- megawatt hydroelectric project on the Upper Mazaruni River. Production was scheduled for 1982.

Hungary.—The primary aluminum smelter and alumina refinery at Ajka were scheduled to be modernized between 1976 and 1980.

Iceland.—The Government of Iceland and Norsk Hydro A/S announced that preliminary studies were underway for a 110,000-ton-per-year smelter to be located in Eyjafjordur. The facility, to be based on geothermal power, was scheduled to come onstream in 1982.

India.—The ban on exports of primary aluminum was lifted due to decreased domestic consumption. During the fiscal year 1975-76, 15,000 tons of commercial grade metal were exported.

Bharat Aluminium Co. completed the expansion program at its Korba, Madhya Pradesh smelter, increasing the capacity of the facility to 55,000 tons per year. Power availability will determine whether expansion of the plant to 110,000 tons per year is feasible.

Indian Aluminium Co. Ltd. (Indal) increased the capacity of its Belgaum smelter to 83,000 tons per year. However, power shortages at yearend forced a 50% decrease in the plant's operating rate. The Indal smelter at Hirakud also experienced power shortages.

Hindustan Aluminium Co. announced plans to expand its primary smelter at Renukoot, Uttar Pradesh, by 27,000 tons per year.

The Indian Planning Commission postponed indefinitely plans for the 55,000-ton-per-year aluminum reduction facility at Ratnigiri, Maharashtra.

Indonesia.—The Governments of Indonesia and Japan agreed to lend Indonesia Asahan Aluminium Co. $87.5 million for equipment for the Asahan aluminum project. Production was scheduled for 1981 with an initial capacity of 83,000 tons per year. Expansion to 250,000 tons per year was planned.

Iran.—A second primary aluminum smelter to be built in conjunction with India and the U.S.S.R. was under consideration.

Italy.—The State corporation Ente Partecipazione Finanziamento Industria Manifattura (EFIM) announced that Alumetal S.p.A. would gradually phase out production at its primary smelters in Mori and Bolzano. Planned expansion of Alumetal's Fusina smelter was expected to compensate for the phased-out production capacity. Societá Alluminio Veneto per Azioni (SAVA) reportedly would phase out its smelter at Porto Marghera.

Japan.—Sumikei Aluminium Co. completed construction of a 50,000-ton-per-year primary aluminum smelter in Sakata, but production startup was postponed indefinitely. The facility is owned 45% by

Sumitomo Light Metal Industries, 20% each by Sumitomo Metal Industries, Ltd., and Sumitomo Chemical Co. Ltd., and 5% each by Sumitomo Bank, Sumitomo Shintaku, and Sumitomo Shoji Co.

Mitsui Aluminium Co. Ltd. brought its 23,000-ton-per-year expansion at Omuta, Miike onstream at yearend. Furukawa Aluminium Co. Ltd. postponed indefinitely plans for a 77,000-ton-per-year primary aluminum smelter in Mikuni, Fukui Prefecture. Mitsubishi Chemical Industries, Ltd. formed a new group, Mitsubishi Light Metal Industry, to handle primary aluminum production and sales.

Showa Light Metal Co., which was owned 50% by Showa Denko K.K. and 50% by the Fuyo group, took over management of the Chiba smelter in October and reportedly was to begin management of the Omachi and Kitikata aluminum reduction facilities in early 1977.

Libya.—The Government of Libya continued to discuss plans for an aluminum smelter with the Government of Yugoslavia which would have a 30% to 40% equity share in the project.

Mexico.—Alcan Project Services signed an agreement with Jalumex S.A. de C.V. to undertake a feasibility study for a 165,000-ton-per-year primary smelter. Alumina would be supplied from a planned alumina refinery at Manchester, Jamaica.

Netherlands.—Billiton N.V. withdrew from Holland Aluminium N.V., which operated a 106,000-ton-per-year smelter at Delfzijl.

New Zealand.—New Zealand Aluminium Smelters Ltd. began production in its new 42,000-ton-per-year potline at the Bluff smelter. Total capacity of the plant was 165,000 tons per year.

Norway.—Expansion of the Lista Aluminiumverk A/S (Elkem) primary aluminum plant at Lista to 90,000 tons was completed. A/S Ardal og Sunndal Verk (ASV) announced plans to complete expansion of its Ardal smelter to 203,000 tons per year by 1978. ASV also planned to build an aluminum foundry at the Hoyanger aluminum facilities with startup scheduled for 1979.

Paraguay.—Reynolds Metals Co. announced that it was considering participation in a 110,000-ton-per-year primary aluminum smelter. The $500 million project would use power from the Itaipu hydroelectric project and Reynolds would supply alumina.

Saudi Arabia.—Plans for a 220,000-ton-per-year smelter to be built at either Yambo or Jubail were included in the next 5-year plan.

Spain.—Alumínio de Galicia, S.A. (Alugasa), announced plans to expand primary aluminum production capacity at its La Coruña facility to 105,000 tons per year.

Construction of the San Cipriano aluminum smelter continued and Aluminium Pechiney signed agreements with Aluminio Español, S.A. to provide technical assistance for the project. Production at the 176,000-ton-per-year facility was scheduled to start in 1979.

Sweden.—The Ministry of Industry decided not to participate with Granges Aluminium A/B in the planned expansion of the Sundsvall smelter, resulting in postponement of the project.

Taiwan.—Taiwan Aluminium Corp. completed the expansion program at its Kaohsiung facility. The complex was expected to reach full capacity production of 75,000 tons per year by yearend.

Trinidad.—The Governments of Trinidad, Jamaica, and Guyana awarded Kaiser Aluminum & Chemical Corp. a contract to undertake a feasibility study for an 83,000-ton-per-year smelter in Trinidad. Jamaica and Guyana would each own 33% of the $165 million facility and would supply bauxite for the alumina refinery. Trinidad would own the remaining 34% and would supply natural gas. Plans called for eventual expansion to 193,000-ton-per-year capacity.

Turkey.—The U.S.S.R. undertook a feasibility study for the expansion of the Seydiseher aluminum complex. In addition to supplying technical assistance, the U.S.S.R. earmarked $50 million of a $1.2 billion loan to the Turkish Government for the expansion project.

U.S.S.R.—Pechiney Ugine Kuhlmann signed an agreement with the Soviet Union to build a 1.1 million ton-per-year alumina refinery in Siberia and also reached agreement to negotiate terms for a 550,000-ton-per-year smelter in Sayona-Sushenskaya.

Gerald Metals and Derby & Co. of the United Kingdom signed agreements with the Soviet Union to purchase about 30,000 tons each of primary aluminum ingot.

United Kingdom.—Kaiser Aluminum & Chemical Corp. announced plans to expand the Anglesey Aluminium Ltd. smelter at Holyhead by 55,000 tons per year.

The British Aluminium Co. smelter at Invergordon lost 6,000 to 8,000 tons of primary aluminum production due to a fire in the electrical rectifier.

Venezuela.—New Venalum, comprised of Corporacion Venezolana de Guayana (80%) and a Japanese consortium consisting of Sumitomo Metal Mining Co. Ltd., Mitsubishi Metal Corp., Kobe Steel Co., Marubeni Corp., and Showa Denko K.K., contracted to purchase 1 million tons of alumina over the next 5 years from Surinam through Montanore BV and from Jamaica through Reynolds Metals Co. The alumina would supply the 77,000-ton-per-year New Venalum smelter which was under construction at San Felix.

Yugoslavia.—The U.S.S.R. was awarded a contract to supply equipment and materials for the expansion of the Titograd smelter to 110,000 tons per year. Banque de Paris et des Pays-Bas agreed to provide the financing and Pechiney Ugine Kuhlmann would provide technical assistance.

The Tvornica Lakih Metals Boris Kidric smelter at Sibenik was under expansion to 110,000 tons per year to be completed in 1977. Construction started on the 94,000-ton-per-year smelter at Mostar.

An aluminum-waste-processing plant was under construction at Lozovac, the site of a phased-out primary smelter.

[1]Detailed information on the individual aluminum reduction plants is available in a 2-part report which can be obtained from Chief, Division of Finance, Bureau of Mines Bldg. 20, Federal Center, Denver, Colo. 80225. Part One of "Primary Alumimum Plants, Worldwide," which costs $9.70 details location, ownership, and production capacity for 1976-83, and sources of energy and aluminum raw materials for foreign and domestic primary aluminum plants, including those in centrally planned economies. Part Two, which costs $2.55, summarizes production capacities for 1976-83, by smelter and country.

TECHNOLOGY

Conservation of energy and minimizing the impact of environmental standards and costs continued to be major research objectives of the aluminum industry. Results of recent studies presented at the Aluminum Association Energy Conservation Workshop were published.[3] Spurred by increasing energy costs, aluminum producers, fabricators, finishers, and end-product manufacturers have undertaken extensive investigations to reduce overall energy requirements. Much of the research centered around conservation of energy through recuperation of heat energy evolved from a processing step, such as melting or annealing, and returning it to the process to preheat the air and fuel used, or the metal itself.

A heat-wheel recuperator made of ceramic material for use at temperatures up to

[3]Light Metal Age. Aluminum Industry Conservation Workshop, Part 1. V. 34, No. 5-6, June 1976, pp. 5-16.

———. Aluminum Industry Conservation Workshop, Part 2. V. 34, No. 7-8, August 1976, pp. 5-15.

1,600°F reportedly was gaining acceptance in the aluminum industry. The heat wheel involves the passing of hot exhaust gases through one side of a slowly rotating wheel, absorbing the heat, while cold air is heated by passing it through the other side of the wheel in the opposite direction. The heated air can then be fed directly to a combustion furnace or used to preheat the metal directly. Alternating the direction of the air flow helps prevent buildup and subsequent plugging of the openings in the wheel by particulate matter. Efficiencies of the heat wheel approach 70%. At one aluminum billet heating furnace facility, installation of ceramic heat wheels reportedly reduced fuel consumption from 1.7 cubic feet of natural gas per pound of aluminum to 0.65 cubic foot per pound. Preheating of combustion air by a ceramic heat wheel in another facility reportedly saved 60% of the fuel used per heating cycle and shortened the cycle by about 25%.

Under a Bureau of Mines contract, Battelle Columbus Laboratories reviewed and assessed the development of alternative aluminum production processes that might conserve energy.[4] A 20% energy savings was believed possible by replacing the conventional Hall-Heroult process for producing primary aluminum which is based on the electrolysis of aluminum oxide by the Alcoa process. The Alcoa process is based on electrolysis of aluminum chloride. However, direct operating costs of the Alcoa process were estimated to be about 10% higher than the Hall-Heroult process. Other processes evaluated used more energy. In another study the energy savings of the Alcoa process were estimated to be 30% in comparison with the Hall-Heroult process and production costs of the two processes were almost the same.[5]

Background information on the impact of air pollution control standards on the primary aluminum industry was summarized in a report.[6] The report stated that, based on an economic analysis and other available information, the following conclusions could be drawn (cost data are in 1975 constant dollars):

(1) Growth in total domestic primary aluminum capacity and supplies will not be adversely affected by the promulgated standards.

(2) The promulgated standards will accelerate the current industry trend to prebake cells and away from Soderberg cells.

(3) The standards are expected to result in an investment cost increase at new primary aluminum plants of approximately $95 per ton of capacity (first quarter of 1975) or approximately 8% of the cost of a new uncontrolled plant.

(4) Existing control levels are estimated to require average investment costs of approximately $65 per ton of aluminum capacity. Viewed as an incremental cost, the promulgated standards would require an investment cost increase over the current industry average of $30 per ton of capacity.

(5) The standards are expected to result in an annual cost increase at new primary aluminum plants of approximately $16 per ton, or 0.82 cent per pound of aluminum produced (assuming no existing State control requirements would apply). A total annual cost increase of approximately $31 million in the fifth year is expected to result from the imposition of the standards (making the same assumption). If the entire cost increase were passed on to consumers, it would amount to a price increase of 2.1% of current prices. Allowing a pretax return on the pollution control capital of 20% would result in a total price increase of approximately 1.8 cents per pound of aluminum, or 4.6% of current prices.

(6) The level of cost for control of fluoride emissions to the air currently being incurred by the industry averages approximately $14 per ton of aluminum, or 0.7 cent per pound.

(7) The standards would result in the reduction of fluoride emissions to the air of approximately 48 pounds of fluoride per ton of aluminum produced (96%) in the case of an uncontrolled plant and 11 pounds per ton of aluminum produced (85%) in the case of a plant employing the industry's current average level of control.

(8) No plant closings or production curtailments are expected to result from the imposition of the standards.

(9) The energy requirements for air pollution control systems currently in use at existing primary aluminum plants and the

energy requirements to meet the 1983 Environmental Protection Agency effluent guidelines at these plants have been estimated to total 285 kilowatt-hours per ton of aluminum produced (industry-wide average). The energy requirements for air pollution control for a new prebake plant (only prebake plants are expected to be built) have been estimated at 211 kilowatt-hours per ton of aluminum produced.

In another study of the energy used for pollution controls and the environmental impact of production of primary and secondary aluminum metal, the total cost of pollution controls (1975 basis) was estimated at $10.16 to $13.59 per metric ton of primary aluminum and $4.98 to $10.10 per metric ton for secondary.[7]

Information on pollution control performance standards for primary[8] and secondary[9] sources of aluminum was published.

In a patented process, developed by the Bureau of Mines,[10] aluminum metal is recovered from processed wastes such as dross and beverage-can scrap without use of a flux. Aluminum is recovered by heating the wastes to a temperature above the melting point of aluminum (about 660°C) but below about 800°C while maintaining the wastes under a protective gaseous atmosphere which is substantially inert to molten aluminum. Argon is preferred as the protective atmosphere. After the aluminum-contained in the wastes has been melted, the heated material is agitated gently to agglomerate the molten aluminum and to cause it to settle and collect in the bottom of the containment vessel. Molten aluminum is then removed from the vessel leaving a substantially inert residue.

Antimony

By John A. Rathjen[1]

The U.S. antimony industry during 1976 registered increases in all phases of activity with the exception of domestic mine production. Consumption rose to 15,337 tons, reflecting increased demand in the chemical area, particularly as a flame retardant. Smelter and secondary production and imports rose, but exports were virtually unchanged. Industry stocks also rose slightly, increasing above the record high level established in 1975.

Domestic mine production dropped sharply as a result of a strike at the Sunshine mine in Idaho. The strike began in March and was in effect for the remainder of the year.

The generally increased level of business activity during the first half of the year precipitated a price rise in September to $1.79 per pound from $1.60 per pound, which had prevailed since June 1975.

Legislation and Government Programs.—Government stocks of antimony remained at 40,700 tons. On October 1, 1976, the Federal Preparedness Agency (FPA), a part of the General Services Administration (GSA), established a new goal for antimony of 20,130 tons. This action created a surplus of 20,570 tons, but Congressional approval is required for disposal. Antimony remained on the list of commodities eligible for exploration assistance under the program administered by the Office of Minerals Exploration (OME). However, funds for exploration projects have not been requested from Congress since fiscal year 1974.

Federal income tax laws under the Tax Reform Act of 1969 provided a percentage depletion allowance of 22% for domestic production and 14% for U.S. production from foreign sources.

DOMESTIC PRODUCTION

Mine Production

Domestic mine production from two mines totaled 283 tons during 1976, a decrease of 68% from that of 1975. A number of companies were involved in feasibility studies and development programs in Nevada and Alaska. The Sunshine mine, operated by the Sunshine Mining Co. in the Coeur d'Alene district of Idaho, contributed 133 tons to the total U.S. output. Low production was the result of a prolonged strike which began March 11 and continued throughout the year. Antimony was produced at the Sunshine mine from the treatment of tetrahedrite, a complex silver-copper-antimony sulfide mineral, one of the principal metal-bearing ores in the Kellog area.

Production at the Babbitt mine-mill-smelter complex operated by the U.S. Antimony Corp. at Thompson Falls, Mont., dropped considerably to 150 tons of antimony in 1976, as compared with 273 tons in 1975. This decline was primarily attributed to the continuing development of the mine and a change in the end product mix. Stibnite, the most common of the antimony minerals, is the primary source of antimony at this operation.

Byproduct antimonial lead, produced in the refining of primary lead from domestic ores, increased 32% to 355 tons in 1976 compared with 268 tons in 1975.

Table 2.—Antimony mine production and shipments in the United States

(Short tons)

1972	2,072	489	547
1973	2,468	545	494
1974	3,217	661	593
1975	4,505	886	966
1976	1,111	283	310

Smelter Production

Primary.—The total production of primary antimony products in 1976 was 14,618 tons, an increase of about 20% compared with output in 1975. Virtually all of the increase was reflected in increased production of oxide, which was 2,738 tons higher than production of 7,890 tons in 1975. Metal production decreased 5% to 3,102 tons during 1976 compared with 3,254 tons produced in 1975.

The major producers of antimony oxide were Harshaw Chemical Co., Gloucester City, N.J.; Chemetron Corp., Cuyahoga Heights, Ohio; M&T Chemicals Inc., Baltimore, Md.; and ASARCO Inc., Perth Amboy, N.J. During 1976 McGean Chemical Co. Inc., Cleveland, Ohio, resumed commercial activity in the antimony oxide marketplace. Producers of antimony metal included NL Industries, Inc., Laredo, Tex.; U.S. Antimony Corp., Thompson Falls, Mont.; and Sunshine Mining Co., Kellog, Idaho. During 1976 ASARCO continued planning and engineering studies for the antimony refinery to be built at El Paso, Tex. It was expected that operating plans would be announced during 1977.

Table 3.—Primary antimony produced in the United States

(Short tons, antimony content)

[1]Includes primary residues and a small quantity of antimony ore.
[2]Includes foreign base bullion and small quantities of foreign antimony ore.

Secondary.—Production of antimony from secondary sources increased slightly to 19,799 tons, an increase of 1,835 tons above that of 1975. Of this, 16,498 tons, or 83% of the total metal, was recovered by treating battery scrap. It is expected that this source of antimony will increase over the next 3 years as the automotive battery industry changes over to new antimony-free and low-antimony grid systems. Additional quantities of antimony are recovered by processing various secondary materials such as type metal, old bearings, drosses, cable sheathing, and other items.

Table 5.—Secondary antimony produced in the United States, by kind of scrap and form of recovery

(Short tons, antimony content)

Grand total	17,964	19,799			

[1]Includes 117 tons of antimony recovered in antimonial lead from secondary sources at primary plants in 1975 and 33 tons in 1976.

CONSUMPTION AND USES

Domestic consumption of primary antimony in 1976 increased by 2,350 tons to 15,337 tons. A loss of 747 tons in the metal products category was more than offset by gains in nonmetal and flame retardant applications, which combined was 10,437 tons, an increase of 42% over that of 1975. The decline in the use of primary antimony metal products was attributed mainly to the changeover in automotive battery grid systems. The adoption of calcium-tin and low-antimony alloys reduced the demand for primary metal, because recovery from secondary smelting was more than adequate to meet requirements.

Use of antimony trioxide as a flame retardant increased by 1,753 tons to a total of 5,552 tons in 1976, establishing a record high for this application. Use of primary antimony in nonmetal products increased 38% to 4,885 tons.

[1]Flameproofing chemicals and compounds shown separately by use starting 1974.

STOCKS

Industry stocks of antimony climbed for the fourth consecutive year to a record total of 15,070 tons at the end of 1976. There was a decline in stocks of antimony contained in ores and concentrates. However, this was offset by gains in metal and oxide holdings which climbed 282 and 674 tons, respectively. This change in inventory mix is expected to continue as more countries initiate value added programs, wherein they upgrade raw materials to realize higher return on investment.

Table 8.—Industry stocks of primary antimony in the United States, December 31

(Short tons, antimony content)

PRICES

The New York price for RMM brand 99.5% antimony metal was quoted at $1.60 per pound through September 16, at which time NL Industries increased its quotation to $1.75 per pound f.o.b. Laredo, Tex. The effective freight differential was increased from 2 cents to 3 cents per pound f.o.b. New York for RMM metal. This remained in effect through the end of the year. Antimony trioxide followed metal pricing very closely beginning the year at $1.65 per pound and increasing on October 1 to $1.80 per pound. The New York dealer price for foreign metal, which was quoted in a range of $1.35 to $1.45 per pound in January, rose to $1.70 to $1.80 per pound in August, but fell late in the year to $1.35 to $1.40 per pound. The European market quotation for lump ore, on a 60% antimony basis increased during 1976 from a low of $20 to $22 per metric ton unit, c.i.f. to $25.50 to $27.50, at yearend.

Table 9.—Antimony price ranges in 1976

Type of antimony	Price per pound
Domestic metal[1]	$1.58-$1.75
Foreign metal[2]	1.35- 1.80
Antimony trioxide[3]	1.65- 1.80

[2]Duty-paid delivery, New York.
[3]Quoted in Metals Week.

FOREIGN TRADE

Exports of antimony ore, metal, alloys, and scrap totaled 341 tons in 1976, virtually unchanged from those of 1975. Canada received 30% of the shipments; Poland and Japan, 16% each. The balance was shipped in small parcels to 17 additional countries. Exports of antimony oxide rose to 324 tons, an increase of 36 tons from that of 1975. Canada received 43% of the total, and the remainder was distributed among 17 other countries.

Imports of antimony in all forms totaled 21,770 tons (metal content), an increase of 16% over the 1975 total. Antimony ore receipts increased 20% to 10,023 tons. Antimony oxide receipts, which totaled 11,611 tons, increased 17% above that of 1975. Imports of both antimony metal and liquated material declined from the 1975 level.

Four countries supplied over 89% of antimony oxide imports during 1976: The Republic of South Africa, 6,005 tons; the United Kingdom, 1,623 tons; France, 1,464 tons; and the People's Republic of China, 1,288 tons. Both France and the People's Republic of China more than doubled their shipments of oxide in 1976, compared with those of 1975, indicating a continuing effort by the producing countries to upgrade the value of their production. Receipts of antimony in ores and concentrates increased by 1,703 tons in 1976 to a total of 10,023 tons. A sharp drop in shipments from Mexico and Guatemala was more than offset by increased tonnage from the Republic of South Africa and Canada. Imports of refined metal decreased slightly to 2,083 tons, a loss of 29 tons from the 1975 total; however, the pattern of imports changed considerably from that of 1975. Belgium-Luxembourg, the People's Republic of China, Italy, and Japan, which cumulatively shipped 1,144 tons in 1975, supplied only 649 tons in 1976. This 495-ton decline was essentially offset by the increased tonnage from Bolivia and Yugoslavia, which together shipped 558 tons above their combined 1975 total.

WORLD REVIEW

World mine production of antimony in 1976, 76,286 tons, showed a nominal decline of 414 tons from that of 1975. The Republic of South Africa reported a major drop in production to 11,890 tons, a loss of 5,663 tons from that of 1975. This decline was balanced by increased production in Bolivia, Thailand, the Republic of Korea, Morocco, Peru, and Guatemala, which collectively increased production by 5,814 tons. Bolivia was the world's largest producer with 16,873 tons, an increase of 3,737 tons.

Australia.—Antimony production in Australia declined in 1976 to 1,818 tons, a drop of 14% from that of 1975. The decrease was attributed mainly to curtailed production by Australian Antimony Corp. NL at its new mine near Dorrigo on the north coast of New South Wales. The mine was closed for economic reasons, but it was being maintained on a standby basis.

The closedown at Dorrigo was partially offset by startup of the Blue Spec antimony-gold mine near Nullagine in Western Australia. The Blue Spec mine, which is operated as a joint venture by Metramor Minerals Ltd., and Australian Anglo-American Ltd., is expected to produce about 1,400 tons of antimony per year.

Bolivia.—During 1976, Bolivia emerged as the world's largest producer of antimony, passing the Republic of South Africa which had previously been the leader. A combined total of 16,873 tons of antimony (metal content), was produced in Bolivia at a new smelter. The smelter, which was completed in December 1975, is located at Vinto, near the city of Oruro, and is operated by Empresa Nacional de Fundiciones (ENAF). The plant had been scheduled for full production in 1976, but startup problems prevented maximum utilization through most of the year. The design capacity of the smelter provides for treatment of 10,300 tons of high-grade concentrates containing 63.2% antimony, which will yield approximately 4,700 tons of antimony metal, and 1,100 tons each of antimony alloys and antimony trioxide.

Since Bolivian mine production exceeds smelter capacity it is expected that Bolivia will continue to sell antimony ore and concentrate throughout the world.

Canada.—Antimony metal was produced in Canada as a byproduct of lead smelting and refining. It was recovered chiefly in the form of antimonial lead by Cominco Ltd. at its smelter and refinery at Trail, British Columbia, and Brunswick Mining and Smelting Corp., which operated a lead smelter at Belledune, New Brunswick.

Consolidated Durham Mines and Resources Ltd. operated Canada's only antimony mine. The Lake George property near Fredrickton, New Brunswick, has a mill capacity of 400 tons per day. Concentrates average slightly over 65% antimony, and are shipped mainly to Europe, with small quantities going to the United States and Japan.

Con-Am Resources announced a preliminary feasibility study of its Carbon Hill antimony property near Whitehorse, Yukon Territory. Work carried out on the property from 1964-67 by Yukon Antimony outlined a possible reserve of 140,000 tons of ore grading 4% antimony. If the reserves are confirmed, the company plans to install a 200-ton-per-day plant.

China, People's Republic of.—Estimated production of 13,000 tons of antimony established the People's Republic of China as the world's second largest producer. The bulk of Chinese antimony was produced in

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Estimated on the basis of value of production.
[2]Antimony content of ores for export plus antimony content of antimonial lead and other smelter products produced.
[3]Production by COMIBOL plus exports by medium and small mines and so-called other producers.
[4]Total national production.
[5]Antimony content of antimony concentrates, lead concentrates, and zinc concentrates.

southwestern Hunan Province, with the largest output from the Hsikwangshan mine. This mine has been estimated to contain reserves in excess of 1.5 million tons of antimony. Antimony ore is also mined in Kwangtun Province. Material produced in the People's Republic of China is smelted and refined near the city of Changshan in Hunan Province.

South Africa, Republic of.—Consolidated Murchison Ltd. continued as the single significant producer of antimony in South Africa with a total output of 11,890 tons, 32% below the output in 1975. The decline was attributed to lower ore grades at the mill, and production of high-arsenic material, which has been set aside for future processing. Mining operations were conducted in the Letaba district of the Transvaal. Most of the production was in the form of concentrates; however, there was a substantial amount of cobbed ore which was recovered and shipped as a direct smelting material. During 1976 there was a considerable drop in production to 10,625 tons of antimony contained in combined concentrate and cobbed ore compared with 15,048 tons produced in 1975. Total shipments, however, were up in 1976 to 13,725 tons of contained antimony, an increase of 1,124 tons over that of 1975, reflecting a draw down on raw material inventories, which had become large.

Thailand.—Production of antimony increased 17% to 8,637 tons of concentrates. About 480 tons of refined metal was also produced during the year. A portion of the increase was attributed to the reopening of the Phahad mine in Phrae Province. The mine, which had been shut down in 1970, was modernized and became the first mechanized underground antimony operation in Thailand. Planned capacity was established at 150 tons per month of hand-cobbed ore and gravity concentrates. Phluang Thong Thai Co. (PTT), a consortium of local interests and the Hochschild group, was the owner-operator.

The Hibino Metal Industrial Corp. of Japan reported that it would begin operating a new property near Chiang Mai. Planned production would be 100 tons per month of 60% concentrate.

Yugoslavia.—A new mine began production of antimony concentrate at Kopanik-Raiceyoj Gori in Serbia. The mine is operated by the mining and metallurgical enterprise Aajaca Rudarsko—Topionicarski Basen (Aajaca). Initial annual production rate was approximately 45,000 tons of ore, yielding about 1,500 tons of concentrate. It is planned to expand production eventually to about 300,000 tons of ore per year, a move that will add significantly to the world mine capacity of antimony and will place Yugoslavia among the world's major producers.

Asbestos

By R. A. Clifton[1]

Shipments of asbestos (mostly chrysotile) in 1976 from mines in the United States increased 16% over those in 1975. With the continued high demand for domestic asbestos, all previously operating mines, plus the newly reopened Calaveras (Pacific) mine, were producing at capacity. Imports were 22% higher than those in 1975 because of recovery from the Canadian strike, but demand may still be depressed owing to the economic recession and/or environmental factors.

Canadian production in 1976 was 47% more than that for 1975, and shipments from Canada to the United States were 23% more than those in 1975. Imports from the U.S.S.R. were nearly 2% of total U.S. imports, and those from the Republic of South Africa accounted for 3%.

Table 1.—Salient asbestos statistics

1Measured by quantity produced, plus imports, plus stockpile releases, minus exports.

Legislation and Government Programs.—As of December 31, 1976, the Occupational Safety and Health Administration (OSHA) had not yet set a date for the mandatory public hearing on its proposed revision of the asbestos standard for manufacturing. The regulated allowable exposure to asbestos had been lowered on July 1 from 5.0 to 2.0 fibres per cubic centimeters (f/cm^3); the OSHA proposal was for a permissible-exposure level of 0.5 f/cm^3. However, the National Institute of Occupational Safety and Health (NIOSH) recommended a still lower level. In a December 15, 1976 letter to OSHA, the Director of NIOSH recommended a level of 0.1f/cm^3. Thus, during 1976, changes made and proposed represent a fiftyfold reduction in the regulated allowable exposure to asbestos in the manufacturing workplace.

The President signed the Toxic Substances Control Act into law on October 11, 1976, too late to allow meaningful evaluation of its impact on the asbestos industry.

[1]Physical scientist, Division of Nonmetallic Minerals.

New stockpile goals were announced by the Federal Preparedness Agency (General Services Administration) in a press release dated November 24, 1976. The announced stockpile goal for chrysotile was zero; and for amosite, the goal was 26,291 short tons. Crocidolite was not named as a strategic material. As shown in table 2, there were few asbestos sales from the national stockpile in 1976.

Table 2.—Stockpile goals and Government inventories as of December 31

(Short tons)

	Stock-pile goals	Total inventories 1975[r]	Total inventories 1976	Sales of excesses, 1976

Chrysotile	None	10,956	[1]10,955	--
Crocidolite	None	2,478	[1]2,474	--
Total	--	58,727	56,052	2,670

[r]Revised.
[1]Adjusted figure, Federal Preparedness Agency.

Environmental Impact.—Disruptions in the marketplace in 1976 left consumption of asbestos by U.S. industry at 82% of the 1973 alltime high. These disruptions cannot be blamed entirely on either the economy or environmental factors. With the possible exception of the textile portion of the industry, much of the decline in consumption can be argued to have come from recession-related factors. The decrease in exports of asbestos-textile products and the increase in imports lend validity to this position. UNIROYAL Inc., announced that its Fiber and Textile Div. would no longer be manufacturing asbestos-containing textiles after July 1, 1976, because of marginal profitability and the cost of full compliance with OSHA regulations.

The costs of environmental compliance to asbestos producers, however, have readily been absorbed by consumers. The Vermont Asbestos Group announced that the purchase costs of their Lowell mine, formerly a GAF Corp. property, had been recouped in less than 2 years. The management of Calaveras Asbestos Corp. stated that the firm was profitable after 1 year of operation.

DOMESTIC PRODUCTION

Mines in the United States shipped 16% more asbestos in 1976 than in 1975. Value was 67% higher than in 1975. Three States produced asbestos; California, was the leader, with 68%, followed by Vermont and Arizona. There was a possibility of some production from North Carolina. Total output was 114,842 tons valued at $23,693,000.

California led the increase in production. Reopening of the Calaveras Asbestos Corp. mine (formerly Pacific Asbestos Corp.) led to a production increase 39% above the 1975 State total. The value increased 160% over the 1975 value of the fiber. By yearend, Calaveras Asbestos Corp. was in full operation. At yearend mines were also active on the Joaquin Ridge near Coalinga. Atlas Asbestos Corp. worked its Santa Cruz mine in Fresno County and Union Carbide Corp. operated its Santa Rita mine in San Benito County.

The Vermont Asbestos Group mine in Orleans County, Vt., remained the mine with the highest production of asbestos in the United States. Its output decreased slightly from that in 1975. This mine is owned and operated by an employee group, which has been highly successful in its operation.

Arizona production in 1976 was below the 1975 level. The Jaquays Mining Corp., in Gila County, had the only active asbestos mine in the State.

Powhatan Mining Co.'s mine in North Carolina was inactive, but about 878 tons of anthophyllite were mined and shipped from North Carolina in 1976. U.S. asbestos producers and mine sites follow:

State and company[1]	County	Name of mine	Type of asbestos
Arizona: Jaquays Mining Corp	Gila	Chrysotile	Chrysotile.
California:			
Atlas Asbestos Corp	Fresno	Santa Cruz	Do.
Calaveras Asbestos Corp	Calaveras	Copperopolis	Do.
Union Carbide Corp	San Benito	Santa Rita	Do.
Vermont: Vermont Asbestos Group	Orleans	Lowell	Do.

[1]In addition to the States listed, some anthophyllite was mined and shipped from North Carolina, but information on firm and location was not available.

CONSUMPTION AND USES

In a year of partial recovery from the effects of the recession and of the Canadian strike, enduse data for 1976 are difficult to analyze. Asbestos used in asbestos-cement pipe decreased 9%. Further decreases were asbestos cement sheet, 48%; flooring products, 16%; and paper, 53%. Asbestos used in friction products remained about the same, but that used in roofing products increased a surprising 447%, as reported by consumers.

Roofing products accounted for 35% of the asbestos consumed, and was the largest user. Asbestos-cement pipe was next with 19%, followed by flooring products with 16%. When the 3% used in making asbestos-cement sheet is added to the preceding three categories, products used in the construction industry accounted for nearly three-fourths of the asbestos consumed in 1976.

Other major asbestos-using end products were friction materials, 9%; paper, 4%; coatings and compounds, packing and gaskets, and plastics, 3% each; and textiles and insulation (thermal), 1% each.

PRICES

Quoted prices for Quebec asbestos, all chrysotile, were not raised during 1976. The last rise was effective on December 1, 1975. Effective December 1, 1976, British Columbia asbestos chrysotile prices rose 15%.

Prices for Vermont chrysotile asbestos rose 13% on January 1, 1976. Arizona prices rose twice during 1976, the latest on July 1. Quotations, f.o.b. Globe, follow:

Grade	Description	Per short ton
Group 1	Crude	$3,000
Group 2	do	1,800
AAA		1,300
Group 3	Nonferrous filtering and spinning	$750-840
Group 4	Nonferrous plastic and filtering	750-840
Group 7	White shorts	100-200

As of January 1, 1976, Vermont chrysotile asbestos, f.o.b. Morrisville, was priced as follows:

Grade	Description	Per short ton
4T	Fiber	$418
5D through 5R	do	$275-324
6D	Waste	200
7D through 7T	Shorts	83-160
7TF	Floats (shorts)	72
8S	Shorts	54
Hooker No. 1	Packaged in 50-pound woven polyvinyl bags	970
Hooker No. 2	Packaged in 100-pound woven polyvinyl bags	485

Other	--	300	800	2,500	4,400	14,700	--	22,700	--	1,200	--	23,900
Total	1,700	14,900	102,400	72,800	52,900	454,000	200	698,900	21,400	4,500	1,500	726,300

Quotations for Canadian (Quebec) chrysotile, f.o.b. mine, as of December 1, 1976, follow:

Grade	Description	Per short ton
Group 1	Crude	Can $3,496
Group 2	do	1,879
Group 3	Spinning fiber	Can $891-1,463
Group 4	Asbestos-cement fiber	492- 829
Group 5	Paper fiber	278- 392
Group 6	Waste, stucco, or plaster	236- 244
Group 7	Refuse or shorts	89- 198

Prices for chrysotile asbestos from British Columbia and Yukon Territory, Canada, effective December 1, 1976, f.o.b. Vancouver, follow:

Grade	Description	Per short ton
	CASSIAR MINE	
C-1	Crude	Can $3,261
AAA	Nonferrous spinning fiber	2,093
AA	do	1,664
A	do	1,267
AC	do	913
AK	Asbestos-cement fiber	651
AS	do	563
AX	do	516
AY	do	362
AZ	do	268
	CLINTON MINE	
CP	Asbestos-cement fiber	Can $611
CT	do	553
CY	do	362
CZ	do	268

African asbestos producers privately negotiate sales, thereby ruling out market quotations. The following tabulation shows the average value per short ton, regardless of grade, of South African imports, calculated from U.S. Department of Commerce data:

Type	1972	1973	1974	1975	1976
Amosite	$187	$188	$228	$395	$461
Crocidolite	211	213	251	427	518
Chrysotile	202	234	282	940	235

The increased demand for and the shortage of all types of asbestos, plus increased mining costs, resulted in price increases in almost all categories. Other price rises were expected early in 1977.

The unit value of 1 ton of Canadian chrysotile has more than doubled in the past 4 years from $Can 122 in 1972 to Can $261 in 1976.

FOREIGN TRADE

No real change occurred from 1975 to 1976 in the value of exports of asbestos products manufactured in the United States. The number of articles exported increased slightly.

Major groupings of exported products and their share of the total value were textiles and yarns, 22%; friction products, 18%; packing and gaskets, 16%; asbestos-cement products, 14%; and insulation products, 7% (table 4).

Table 4.—Countries importing U.S. asbestos products in 1976, by type

(Thousand dollars)

	Canada	Mexico	Germany, West	United Kingdom	Australia	Other	Total

Figure 1.—Major international asbestos mining groups.

In 1976, 52% of the cost of imported asbestos was recovered by exporting and reexporting fibers and products.

In 1976, the United States imported 91% of its asbestos consumption. This was above the 1975 percentage. Canada provided more than 93% of the imports, the Republic of South Africa provided 3%, the U.S.S.R. provided 2%, and six other countries provided the remainder. Chrysotile, with 96%, dominated the imported types. The dollar value of imported fibers was 28% higher than that in 1975.

The larger international asbestos groups and their affiliations are depicted in figure 1, taken from a recent Canadian Government publication.[2]

[1]Less than 1/2 unit.

WORLD REVIEW

An in-depth article in a Canadian mining paper,[3] described activities in world and Canadian asbestos markets in 1976. The strength of the Canadian industry, a long time major supplier to the world market, was demonstrated by its rebound in output from the low level experienced in 1975. A fire, landslide, and strike in 1975, resulted in output being reduced to the levels of 1960 and 1961, thereby tightening an already tight supply situation. Many producing companies had to allocate available supplies to their customers. The article also cited statements of Asbestos Corp., Ltd. officials that indicated the asbestos fiber market remained bouyant. Saturation of the markets in Western Europe and the United States, was compensated for by increased demand in Eastern Europe and Middle East and African countries. The firms' inventories of Groups 4, 5, and 6 fibers were expected to stay at minimum levels and those of Groups 3 and 7 to increase slowly. It was anticipated that any excess in Group 3 spinning fibers would be absorbed by the market in the second half of 1977. Only the market for Group 7 appeared to be weak.

Algeria.—Scheduled for June 1976 startup were three identical asbestos-cement-product plants. These plants, designed and built by Belgian companies, will have a combined capacity of 150,000 tons of finished product. The new markets for asbestos fiber to feed these and similar plants being built throughout Mediterranean Africa and Asia are helping keep demand very strong.

Australia.—Woodsreef mine borrowed $A1.5 million to increase its annual capacity to 105,000 tons. Estimates of reserves at both contiguous ore bodies have been revised upward and the company has discovered a promising new ore body near Baryulgil in northern New South Wales. Exploration continued in that Province. Woodsreef acquired 95% of 10 asbestos claims in Western Australia.

Brazil.—The chrysotile mine at Cana Brava operated by S.A. Mineração de Amianto (SAMA) has a projected 1979 production of 115,000 tons, all for domestic consumption. Reserves were estimated at 3.5 million tons of fiber. In 1976 there were

[3]Northern Miner. V. 62, No. 37, Nov. 5, 1976, p. C-10.

900 employees at the site, which is 160 miles northwest of Brasilia.

Canada.—Canadian asbestos production rebounded sharply from the problems of 1975. Total production in 1976 (all chrysotile) was nearly 47% above that of 1975, but still only 92% of the 1973 record.

Abitibi Asbestos Mining Co.'s deposit in northwestern Quebec is 55% owned by Brinco Ltd. At yearend discussions were underway with ASARCO, Inc., owner of Lake Asbestos of Quebec Ltd., as to ways to finance, operate, and market fibers from the proposed $292 million facility. A 220,000-ton-per-year capacity is proposed.

United Asbestos, Inc. was operating its mine at Midlothian Township in Ontario at yearend after having been closed during the spring by Ontario's environmental authorities.

Canadian Johns-Manville Corp. announced a $77-million capital investment program to improve its Jeffrey mine at Asbestos, Quebec. It is a 5-year program, and initial expenditures will be for acquiring property surrounding the mine, repairs, and new facilities. The mine produces 45% of Canada's asbestos and 15% of the world's production.

A possibly important new find in northern Ontario was announced by Talisman Mines, Ltd. and Shield Development Co., Ltd. The find, in Newtown Township, showed asbestos mineralization over 3 miles long and indicated that some fibers may be 1-1/2 inches long and of spinning quality.

China, People's Republic of.—Export data from China for the 1957-74 period reveal that asbestos is not a major export item, either in quantity or value. In 1974, the year of highest export, only 2,400 short tons worth $0.5 million were exported. A number of textile products from China are available on the world market.

Colombia.—Minera Las Brisas, S. A. announced completion of feasibility studies of its asbestos property in the Antioquia Province. Indications are that the deposit has 9.3 million short tons of ore capable of producing 390,000 tons of chrysotile asbestos. Production at a 20,000-ton annual rate is planned to begin in 1979.

France.—French imports of asbestos in 1975 were less than 80% of those in 1974, with the Canadian strike clearly responsible. In 1974, a typical year, the suppliers of asbestos to France were Canada, with 48% of the market; the U.S.S.R., with 31%; the Republic of South Africa, 11%; and Italy, 10%.

Japan.—The large market in Japan for asbestos also declined significantly in 1975. The 29% drop in imports from 1974 cannot be explained by the Canadian strike alone, because other vendors' sales were also down. In 1974 Australia had 5% of the market, Canada, 39%, the Republic of South Africa, 35%, the U.S.S.R., 18%, the United States, 2%, and other, 1%.

Oman.—The Sultanate of Oman, in announcing newly found mineral deposits in the northern part of the country, included asbestos among the minerals to be developed for use in domestic industry.

South Africa, Republic of.—The Republic of South Africa's asbestos producers enjoyed what that nation's press called "spectacular" pre-tax gains from 1975 sales. World market price increases and the heightened demand brought on by the Canadian strike were the main reasons. Inventories were depleted as exports totaled an estimated 150% of production. Amosite production declined 6%, while local sales and exports increased by 136% and 92%, respectively. Chrysotile production was up 21%, and local sales and exports were up 14% and 57%, respectively. Crocidolite production was also up 6%, but local sales and exports rose 73% and 62%, respectively.

Sudan.—Gulf International (Sudan) and Johns-Manville Corp. were conducting a test drilling program on asbestos deposits in the Ingessana Hills of southeastern Sudan near the crossing of the Ethiopian border by the Blue Nile. Indications were favorable for a 100,000-ton-per-year fiber plant which would cost an estimated $115 million.

Turkey.—Among the minerals announced to be found in Eskisehir Province was 500,000 tons of asbestos.

United Kingdom.—Turner Asbestos Fibers Ltd. ordered 880 short tons of Soviet asbestos to replace some of the declining supply from Cassiar's Clinton Mine in the Canadian Yukon.

U.S.S.R.—A Soviet periodical[4] described the Kiyenbai asbestos deposit on the eastern slope of the southern Urals. Ore in the deposit contains 4% asbestos, and by 1979, it is anticipated that a quarter of a million tons will be produced. Output reportedly will increase to 500,000 tons by 1982. To achieve this ore output some 14 million cubic yards of earth and rock will be moved. A new town, Yasny, has been established and in a few years will attain a population of 50,000.

---

TECHNOLOGY

In 1976, as in previous years, much of the research on asbestos concerned the problems arising from alleged health effects and regulations (both current and proposed) to minimize the hazards. By the July 1, 1976 changeover date to the 2-f/cm^3 level, the asbestos-containing product industry and the domestic-asbestos-producing industry were generally in compliance, but engineering research aimed at further reduction of dust-exposure levels continued.

The NIOSH method of monitoring the workplace and identifying asbestos continued to be a matter of controversy. At least two separate actions took place late in 1976 because of this controversy:

The National Bureau of Standards agreed to determine the asbestos content of a series of talc samples for OSHA, using the NIOSH method (as given in 29 CFR 1910.1001) and OSHA's "Asbestos Fiber in Air" Method (No. P & CAM239, dated Mar. 30, 1976).

The Bureau of Mines has established a Particulate Mineralogy Unit at its College Park, Md., Metallurgy Research Center. In the announcement made November 15, 1976, the Director of the Bureau stated, "Its job is to develop a solid scientific basis for research into particle-related pollution problems and for the process of decision-making by regulatory bodies." A major activity of the Particulate Mineralogy Unit will be characterizing morphological, compositional, and structural distinctions between asbestos and nonasbestos particles. The new unit also will work to develop new and improved methods for positively identifying small particles.

The National Institute of Environmental Health Science's animal-feeding study to determine if ingested asbestos is carcinogenic was proceeding on schedule, but no results were reported in 1976.

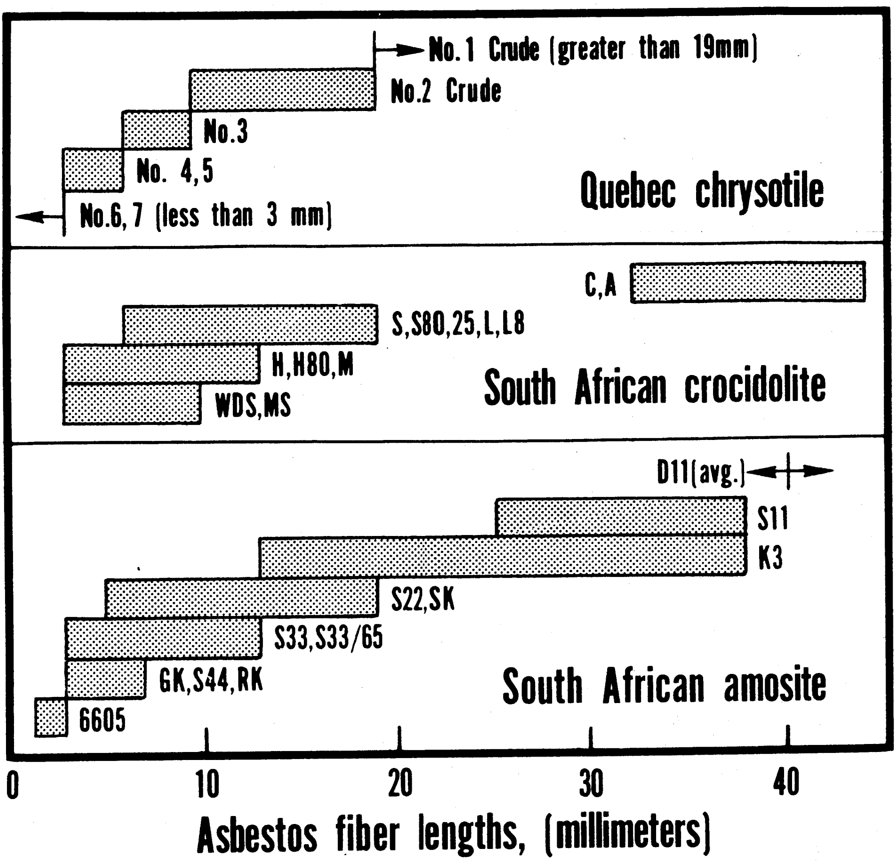

Figure 2.—Asbestos fiber lengths (millimeters).

The International Agency for Research on Cancer (IARC) of Lyon, France, initiated a three-pronged study into carcinogenic activity of man-made mineral fibers used as asbestos substitutes. The European glass-fiber and textile industries asked IARC to carry out epidemiological studies in 70 factories and 15 countries, laboratory studies on animals, and fiber-dust measurements in factories using these materials.

The search for asbestos substitutes continued. One product now available commercially in the United States and Europe that could affect the future of the asbestos industry is glass-reinforced cement. The glass used is a high-zirconia, alkali-resistant fiber developed by the United Kingdom's Building Research Station. However, several drawbacks to the product were reported: The glass fibers have inferior drainage characteristics; they require a costly spray-suction forming process; the strength gradually fails with time; and the fibers currently cost about four times as much as the equivalent asbestos.[5]

Asbestos shortages and projected demands indicated serious depletion of reserves by the end of the century. Accelerated research seems needed to find substitute fibers that will have at least some of the desirable asbestos characteristics of strength, chemical inertness, heat resistance, and economy in the same fiber.

Figure 2 provides the metric equivalent of fiber descriptions in the English system or Quebec Standard Classification.

Barite

By Stanley K. Haines[1]

Domestic production of barite decreased 6% from 1.32 million tons in 1975 to 1.23 million tons in 1976. Nevada continued as the leading producing State with 73% of the total production of primary barite; however, production in Nevada declined 5% below 1975 levels. Imports of crude barite increased 43% to 905,000 tons. All major end-uses of ground barite increased compared with 1975 levels, for a total consumption of 2.2 million tons. The oil- and gas-well drilling industries were the leading consumers of ground domestic and imported barite with 90% of the total.

Total[2]	r1,318	r21,200	1,234	28,689

rRevised. W Withheld to avoid disclosing individual company confidential data, included with "Other States."
[1]Including Arkansas, Georgia, Idaho, Illinois, Montana, Tennessee, and States indicated by symbol W.
[2]Data may not add to totals shown because of independent rounding.

DOMESTIC PRODUCTION

Producers sold or used 1,234,000 tons of primary barite in 1976. Primary barite is the first marketable product and includes crude or run-of-mine barite, flotation con-

[1]Physical scientist, Division of Nonmetallic Minerals.

centrates, and other beneficiated material such as washer, jig, or magnetic separation concentrates.

Barite was produced at 36 mines: 17 in Nevada, 10 in Missouri, 3 in Arkansas, 2 in Georgia, and 1 each in Idaho, Illinois, Montana, and Tennessee. Nevada remained the leading producing State with 73% of the total quantity and 64% of the total value. The other producing States were, in descending order of production, Missouri, Arkansas, Georgia, Tennessee, Montana, Idaho, and Illinois.

Run-of-mine barite sold or used by producers represented 48% of total production, other beneficiated material, 44%; and flotation concentrate, 8%.

The leading producers of domestic barite for use in well drilling were (in alphabetical order) Baroid Div., NL Industries, Inc., with mines in Arkansas, Missouri, and Nevada; Dresser Minerals Div., Dresser Industries, Inc., with mines in Missouri and Nevada; and Minerals Div., Milchem, Inc., with mines in Missouri and Nevada.

Barite for chemical, glass, and filler uses was sold by C. R. Wood Co., Inc.; Dresser Minerals Div., Dresser Industries, Inc.; Industrial Chemical Div., FMC Corp.; IMCO Services Div., Halliburton Co.; Milwhite Co., Inc.; New Riverside Ochre Co.; De Lore Products, Industrial Chemicals Div., NL Industries, Inc.; Paga Mining Co.; Minerals, Pigments, and Metals Div., Pfizer, Inc.; and Standard Slag, Inc.

Imported and/or domestic barite was ground at 44 plants in 12 States. Texas with nine plants and Louisiana with seven had the heaviest concentration of grinding plants, due to the availability of port facilities for imported barite and the close proximity to areas of high drilling activity. Other States with grinding plants were Missouri, with six operations; Nevada and Utah, five each; California, four; Arkansas and Georgia, two each; and Alaska, Illinois, Montana, and Tennessee, one each.

CONSUMPTION AND USES

Barite for use as a weighting agent in oil- and gas-well drilling fluids represented the dominant end-use of crushed and ground barite in 1976. Total quantity consumed for this use increased 21% to 1,986,000 tons in 1976 owing to increased drilling activity; total footage drilled increased from 178.5 million feet in 1975 to 181.7 million feet. Barite for use in the manufacture of barium chemicals and paint increased 9% and 43%, respectively. Other uses declined 11%, and included filler in rubber and plastics; flux, oxidizer, and decolorizer in glass manufacture; and miscellaneous uses, including ballast for ships, heavy concrete aggregate, and unspecified industrial uses.

The data in table 3 are mainly for ground barite, but they also include the relatively small quantity of crushed barite used primarily in the barium-chemical industry.

Barite is the principal raw material used in the production of barium chemicals. Producers of barium chemicals in 1976 were J. T. Baker Chemical Co., Phillipsburg, N. J.; Chemical Products Corp., Cartersville, Ga.; Industrial Chemical Div., FMC Corp., Modesto, Calif.; Mallinckrodt, Inc., St. Louis, Mo.; and Chemical Div., Sherwin-Williams

Table 3.—Crushed and ground barite sold, by use[1]

Use[2]	1975		1976

Well drilling	1,638,370	90	1,985,966	90
Other uses	85,221	4	75,908	3
Total	1,830,196	100	2,204,317	100

W Withheld to avoid disclosing individual company confidential data, included with "Other uses."
[1]Includes imported barite.
[2]Uses reported by producers of ground and crushed barite, except for barium chemicals.
[3]Quantities reported by consumers.

Co., Coffeyville, Kans. Sherwin-Williams also produced lithopone.

IMCO Services Div., Halliburton, Inc. finished construction of a jig, table, and flotation plant at Mountain Springs, Nev. The capacity of the facility is about 150,000 tons per year. IMCO also installed a second mill at Battle Mountain, Nev., and a jig plant at its Norris (Clipper) mine in Lander County, Nev.

The Mining and Minerals Div. of Chromalloy has begun construction of a heavy-media concentrating plant at Castle Island, Alaska, to produce barite for the Alaska drilling market. Chromalloy has also installed a jig plant near Marion, Ky.

Milchem, Inc., began exploratory drilling and quality testing on the Fancy Hill barite property in Montgomery County, Ark.[2]

Sales of barium carbonate increased 25% from 28,018 short tons in 1975 to 34,991 short tons in 1976. Total production increased 37%. Barium carbonate is used in the manufacture of television picture tubes (for screen control), in brick and tile, in barium-ferrite manufacture, and for many other purposes.

Table 4.—Barium chemicals produced and sold by producers in the United States in 1976[1]

Barium chemical	Plants	Production (short tons)	Sold by producers	
			Quantity (short tons)	Value
Barium carbonate	4	35,488	34,991	$4,857,355
Barium chloride	3	W	W	W
Barium hydroxide	3	W	W	W
Black ash	2	W	W	W
Blanc fixe	1	W	W	W
Other barium chemicals	4	24,825	17,107	7,531,596
Total	[2]6	60,313	52,098	12,388,951

W Withheld to avoid disclosing individual company confidential data; included with "Other barium chemicals."
[1]Only data reported by barium-chemical plants that consume barite are included.
[2]A plant producing more than one product is counted only once.

PRICES

Prices for chemical, filler, and glass grades of barite increased while those for drilling-mud grade remained constant, according to the Engineering and Mining Journal. The prices listed in table 5 are from trade publications; they serve as a general guide but do not necessarily reflect actual transactions.

The average value per ton of crude barite was $23.25, a 44% increase over the 1975 value of $16.08. The average value per ton of crushed and ground barite increased to $42.56 in 1976, from $40.44 in 1975.

[2]Stevens, R. M., Barite. Mining Engineering. V. 29, No. 3, March 1977, pp. 53-54.

Table 5.—Barite price quotations in 1976

Item	Price per short ton
Barite:[1]	
Chemical, filler, glass grades, f.o.b. shipping point, carload lots:	
Handpicked, 95% $BaSO_4$, not over 1% Fe	$42.50- $50.00
Magnetic or flotation, 96% $BaSO_4$, not over 0.5% Fe	60.00- 70.00
Water-ground, 99.5% $BaSO_4$, 325 mesh, 50-pound bags	60.00- 80.00
Drilling-mud grade:	
Ground, 83%-93% $BaSO_4$, 3%-12% Fe, specific gravity 4.20-4.30, f.o.b. shipping point, carload lots	71.00- 78.00
Crude, imported, specific gravity 4.20-4.30, c.i.f. gulf ports	19.00- 28.00
Barium chemicals:[2]	
Barium carbonate:	
Precip., bulk, c.l., freight equalized (ton)	250.00- 275.00
Electronics grade, bags, same basis	255.00
Barium chloride:	
Purified Fe cryst., 400 pound drums, at works	1.24
Technical cryst., bags, c.l. works (ton)	300.00
Anhydrous, bags, c.l., same basis (ton)	400.00
Barium sulfate:	
USP X-ray diagnosis grade, powder, 250 pound drums, 1,250 pound lots	.25
Barium sulfide (black ash) drums, c.l., works (ton)	115.00- 150.00

FOREIGN TRADE

Exports of barite declined 28% from 57,386 tons in 1975 to 41,063 tons in 1976. Canada replaced Japan as the leading recipient of these exports. Barite, primarily ground material, was shipped principally from the following customs districts: Seat-

tle, Wash. (37%), Houston, Tex. (23%), New Orleans, La. (15%), Detroit, Mich. (8%), and Great Falls, Mont. (6%).

Imports of crude barite increased 43% to 904,500 short tons valued at $17,677,000 in 1976. This increase resulted from a combination of a decline in domestic production and an increase in drilling activity. The principal source countries were Peru, Ireland, and Turkey. Declared values per short ton of crude barite for these countries averaged as follows: Peru, $15.46; Ireland, $11.70; and Turkey, $28.00.

Most of the crude barite imported was drilling-mud grade and entered the United States through the following customs districts: New Orleans, La. (41%), Houston, Tex. (21%), Laredo, Tex. (15%), Port Authur, Tex. (12%), Galveston, Tex. (11%), and a small quantity through El Paso, Tex., and New York, N.Y.

Imports of ground barite decreased 66% to 13,288 tons valued at $151,687. Mexico, the leading source country, reportedly exported 6 short tons of crude witherite (natural barium carbonate) to the United States, and West Germany reportedly exported 278 short tons of ground witherite to the United States. These data are open to question since there has been no reported production of witherite since the Settlingstone mine in northern England was closed in 1969. A recent inquiry by the Bureau of Mines to officials in West Germany brought a reply that stated that there was no production of natural witherite in 1976. Imports into West Germany of crude witherite of unknown origin were 7,718 short tons, but there was no breakdown between natural and manmade. The imports of the United States from West Germany were probably precipitated (manmade) barium carbonate.

Imports of barium chemicals increased 55% compared with those in 1975. The following categories showed significant increases in quantity imported: Lithopone (360%), precipitated barium carbonate (255%), barium chloride (186%), and blanc fixe (46%). Imports of barium hydroxide, barium nitrate, and other barium compounds declined.

WORLD REVIEW

World barite production for 1976 was estimated to be 5.5 million short tons; United States production was 23% of the world total.

Canada.—A final feasibility study concerning the TEA barite deposit in the Yukon Territory was slated for completion in July 1976. The deposit was discovered by Welcome North Mines in 1975. Initial plans call for production of 15,000 to 20,000 tons per year of drilling-mud grade barite. The deposit is a high-quality, bedded barite for which only minimal processing will be necessary before grinding. Reserves are estimated to be more than 1 million tons. The principal market will be the oil- and gas-well drilling operations in the Arctic.[3]

Mexico.—Producers of drilling-mud grade barite have indicated displeasure with the Government's ceiling on prices that the State-owned petroleum company may pay for the barite. The current price is $12 per ton in Mexico. The producers believe that they have the capacity to supply both the domestic and export markets if the price were allowed to rise. If there is no change in the pricing structure, producers have threatened to suspend operations.[4]

Pakistan.—On September 27, 1976, the first shipment of barite moved from the Goonga deposits near Khuzdar to the Meyel oilfields. Reserves at these deposits are estimated at 1.2 million tons. First-year production is expected to be about 15,000 tons, with an expected increase to 60,000 tons in 5 years. The barite will be used for local drilling and export.[5]

Other Countries.—Atlantic Products Corp., a Colombian barite producer, was purchased by Baroid Div., NL Industries, Inc. Construction of or modification to beneficiation and grinding plants were reported in Algeria, the Netherlands, Mexico, and Saudi Arabia. Milchem, Inc. is planning to reopen a barite mine at Clontakilty, County Corke, Ireland. The mine which was closed in 1922, is expected to begin production in 1978.

Bauxite and Alumina

By Horace F. Kurtz[1]

World bauxite and alumina production increased in 1976 but remained below the record high levels set in 1974. Both the decline in production in 1975 and the partial recovery in 1976 resulted from recession-caused changes in demand for aluminum, the principal end use of bauxite and alumina.

World bauxite production increased 2% to 76.3 million long tons in 1976. Output of alumina, the intermediate product between bauxite and aluminum production, rose 3% to about 29.6 million short tons. Australia replaced the United States as the world's leading producer of alumina.

U.S. bauxite and alumina production increased 11% and 13%, respectively. Imports provided about 36% of the new supply of alumina and 87% of the bauxite used by domestic alumina producers.

Legislation and Government Programs.—The Federal Preparedness Agency, General Services Administration, on October 1 proposed new Government stockpile goals which would greatly reduce existing stockpiles of metal-grade bauxite and establish a new stockpile of about 11.5 million short tons of alumina. Stocks of refractory-grade bauxite would be increased to over 2 million long calcined tons.

DOMESTIC PRODUCTION

The production of bauxite in the United States increased 11% to 1.96 million long tons (dry equivalent) in 1976. Production in both Arkansas and Georgia increased, but output in Alabama declined. Arkansas produced 85% of the total. All of the bauxite mines were open pit operations except for the Mars Hill underground mine of Reynolds Mining Corp. in Saline County, Ark.

In Arkansas, Aluminum Co. of America (Alcoa), American Cyanamid Co., and Reynolds produced bauxite in Saline County. Reynolds also mined in Pulaski County. Both Alcoa and Reynolds delivered crude bauxite to their own alumina plants nearby. Plants producing calcined bauxite or activated bauxite were operated by American Cyanamid, Porocel Corp., and Stauffer Chemical Co.

In Alabama, bauxite was mined in the Eufaula district, Barbour and Henry Counties, by Abbeville Lime Co., A. P. Green Refractories Co., Harbison-Walker Refractories Co. (Division of Dresser Indus-

[1]Industry economist, Division of Nonferrous Metals.

tries, Inc.), and Wilson-Snead Mining Co. Drying or calcining plants were operated by A. P. Green, Harbison-Walker, and Wilson-Snead.

American Cyanamid and Mullite Co. of America mined bauxite in Sumter County, Ga., and operated processing plants at Andersonville, Ga.

Production at alumina plants, which had been reduced in 1975 because of lower demand for aluminum, was partially restored in 1976. Production of alumina and aluminum oxide products (excluding aluminates) at the eight alumina plants in the United States and the one plant in the U.S. Virgin Islands increased 13% to an estimated 6.6 million short tons (6.4 million tons calcined alumina equivalent). The total production included an estimated 5.9 million tons of calcined alumina, 600,000 tons of commercial alumina trihydrate, and 100,000 tons of tabular, activated, and other alumina.

Alumina shipments by producers totaled 6.6 million tons (6.4 million tons calcined equivalent) and were valued at $880 million. Calcined alumina shipments to primary aluminum plants totaled 5.7 million tons, or 89% of the calcined equivalent of total shipments. The chemical industry, including producers of aluminum fluoride fluxes for aluminum plants, received over half of the remaining tonnage, largely as hydrate. Other shipments of alumina went mainly to producers of abrasives, ceramics, and refractories.

[1]Capacity may vary depending upon the bauxite used.

CONSUMPTION AND USES

Bauxite consumption in the United States (including the U.S. Virgin Islands) gained 12% or about 1.4 million long dry tons. Despite the increase, consumption remained below the annual rates of 1966-74. About 87% of the bauxite consumed during 1976 came from foreign countries.

Bauxite consumed in the production of alumina increased 12% and comprised 93% of the total bauxite consumed. An estimated average of 2.02 long tons (dry basis) of bauxite was used to produce 1 short ton (calcined basis) of alumina. The two alumina plants in Arkansas used mainly bauxite mined in Arkansas, and the other seven alumina plants used only imported ore.

Bauxite use by the refractory industry declined 2% to 401,000 tons (dry weight basis). Nearly all of this bauxite was used in the calcined form, which weighs about 65%

of the dry equivalent weight. Imports comprised 78% of the bauxite used in refractories. Refractory producers reported receipts of about 90,000 tons (dry basis) of domestic bauxite and 430,000 tons of imported ore. An estimated 93% of the foreign bauxite came from Guyana, and most of the remainder came from Surinam.

Five companies consumed calcined bauxite in the manufacture of artificial abrasives. Over half of the bauxite received by these companies came from Surinam. Australia and the People's Republic of China provided most of the remainder. Total consumption by the abrasives industry increased 35% in 1976. The Carborundum Co. announced the installation of a new furnace to produce aluminum oxide abrasive material at its facilities in Niagara Falls, Canada.[2] Data on consumption by the abrasives industry include bauxite fused and crushed in Canada because much of the fused product is made into abrasive wheels and coated products in the United States. About 10% to 15% of this material is used for nonabrasive applications, principally refractories.

Bauxite consumption in the chemicals industry decreased 17% from 221,000 tons (revised) in 1975 to 184,000 tons in 1976. Guyana and the United States were the principal sources of bauxite for this industry. The production of commercial aluminum sulfate in the United States, according to the Bureau of the Census,[3] decreased from 1.16 million short tons (revised) in 1975 to 1.09 million tons in 1976.

Other consumers of bauxite, in descending order of magnitude, included the cement, oil and gas, and steel and ferroalloys industries, and municipal waterworks.

Thirty-one U.S. primary aluminum plants consumed 8,117,000 short tons of calcined alumina, 8% more than the 7,508,000 tons consumed in 1975. Alumina consumption data for other uses were not available. A significant quantity was used to make aluminum fluoride and synthetic cryolite, which is also used in the production of primary aluminum.

STOCKS

Total inventories of bauxite in the United States declined 2% to 20.4 million long dry tons during 1976. The overall decrease was largely the result of a reduction in stocks at alumina plants. Abrasives producers rebuilt inventories, which had been reduced significantly in 1975. Government stockpiles of bauxite were unchanged.

The Government stockpile at the end of 1976 was composed of 8,859,000 tons of Jamaica-type bauxite, 5,937,000 tons of Surinam-type bauxite, and 175,000 tons (270,000 tons, dry basis) of calcined refractory-grade bauxite. About 637,000 tons of the Surinam-type bauxite had been sold but not removed from the stockpiles.

Inventories of alumina and related products at plants producing alumina and primary aluminum declined to an estimated 1.3 million short tons. The Government held no stocks of alumina except in the form of abrasive grain and crude fused aluminum oxide. These stockpiles were reduced 5% to 322,000 short tons.

In October the Federal Preparedness Agency proposed new government stockpile goals which would replace the previously established stockpile objectives for various strategic materials. The following were included in the proposed new goals:

Bauxite:		
Metal grade:		
Jamaica type	long dry tons	523,000
Surinam type	do	--
Refractory grade	long calcined tons	2,083,000
Alumina	short tons	11,532,000
Aluminum	do	--

PRICES

Prices on most of the bauxite and alumina produced throughout the world are not quoted because the large tonnages used by the aluminum industry are usually obtained from affiliated companies or purchased under long-term negotiated contracts.

Bureau of Mines estimates of the value of domestic production were based on incomplete data supplied by producers. The Bureau's estimated average value of crude domestic bauxite shipments in 1976, f.o.b. mine or plant, was $11.30 per long ton. The average value of shipments of domestic calcined bauxite was estimated at $67 per ton. Bauxite values among producers varied widely because of differences in grade.

The value of imported bauxite consumed at alumina plants in the United States was believed to have increased in 1976, but sufficient company data were not available to determine an average value. Prices published by Engineering and Mining Journal for supercalcined refractory-grade bauxite from Guyana, car lots, f.o.b. Baltimore, Md., or Mobile, Ala., increased about $12 per ton to $119.16 per long ton in January 1976 and remained at that level throughout the year.

The estimated average value of domestic calcined alumina shipments was $132 per short ton. Shipments of alumina trihydrate also averaged $132 per ton. The average value of imported alumina (including small quantities of hydrate), as reported by the Bureau of the Census, was $111.60 per ton at port of shipment and $119 per ton at U.S. ports (c.i.f.). Exports of alumina from the United States and the Virgin Islands averaged $138.10 per ton.

FOREIGN TRADE

U.S. exports classified as "bauxite and concentrates of aluminum excluding alumina" totaled 15,000 long tons in 1976 and were valued at $1.3 million. Canada received 91% of the total and the United Kingdom about 7%.

Exports of alumina, including 35,000 short tons of aluminum hydroxide, increased 13% to 1,158,000 tons. The total included shipments of 272,000 tons to the U.S.S.R. and 37,000 tons to Venezuela from the alumina plant in the U.S. Virgin Islands. Most of the remaining exports were shipments from domestic alumina plants on the Gulf Coast to affiliated aluminum plants in Canada, Ghana, Mexico, and Norway.

Aluminum sulfate exports increased for the fourth successive year and totaled 51,000 short tons at a reported value of $1.6 million. About 33,000 tons was shipped to Brazil, 8,000 tons to Venezuela, and 6,000 tons to Canada. Exports of artificial corundum or fused aluminum oxide decreased 19% to 22,000 tons, valued at $14.8 million. Canada, the largest recipient among 55 countries, received 8,000 tons. Exports classified as "other aluminum compounds" declined slightly to 41,000 tons, valued at $21 million. Much of the tonnage in this category was believed to be aluminum fluoride and synthetic cryolite shipped to other countries for use as a flux in making primary aluminum. About 12,000 tons was shipped to Canada, 9,000 tons to Ghana, and 6,000 tons to Surinam.

The United States imposed no duties on imports of bauxite, alumina, or aluminum hydroxide in 1976. All duties on these commodities were suspended in 1971.

Imports of crude, partially dried, and dried bauxite into the United States and the U.S. Virgin Islands increased 9% to 12.5 million long tons from 11.5 million tons (revised) in 1975. The increase was attributed to a partial recovery in demand for aluminum, which resulted in the reactivation of some of the domestic aluminum and alumina facilities shut down in 1975. Receipts increased from all major import sources except Surinam and the Dominican Republic. Jamaica provided about half of the total, and Guinea provided nearly one-quarter. Receipts from Surinam were 12% of the total, down from about 20% in 1973 and 30% in 1966. Guyana and Haiti each provided 5% of the 1976 total, and the Dominican Republic supplied 4%.

Calcined bauxite imports dropped 11% to 309,000 long calcined tons. Most of these imports were refractory-grade bauxite from Guyana. Additional calcined bauxite was imported into Canada from Surinam and Australia for manufacture into crude fused aluminum oxide, much of which was subse-

quently used in abrasive and refractory products in the United States.

Alumina imports, including small quantities of aluminum hydroxide, rose 3% to 3.6 million short tons. Shipments from Australia, largely to aluminum plants in the Pacific Northwest, increased 28% and provided 76% of the total imports. Receipts from the other two principal suppliers, Jamaica and Surinam, declined.

WORLD REVIEW

World production of bauxite increased an estimated 2% in 1976. The largest increases occurred in Australia and Guinea. Australia, the largest producer, accounted for 31% of the world total, and Guinea and Jamaica accounted for 14% and 13%, respectively. Of the countries showing lower production in 1976, Jamaica, Guyana, and Greece registered the largest declines.

World alumina production increased 3% during 1976. Australia became the world's largest producer as its output surpassed that of the United States. Australia and the United States had the largest increases in alumina production, and together the two countries produced 45% of the world total. The countries showing the largest declines were Canada and Jamaica.

Studies continued on the proposed bauxite-alumina-aluminum joint venture of the Caricom countries, Jamaica, Guyana, and Trinidad and Tobago. In this venture, bauxite and alumina would be supplied by Jamaica and Guyana, and a primary aluminum plant based on natural gas or oil would be constructed at Point Lisas, Trinidad. A second phase of the project would include an aluminum plant in Guyana based on hydroelectric power.

Australia.—Three companies, Alcoa of Australia (W.A.) Ltd., Comalco Ltd., and Nabalco Pty. Ltd., accounted for all of the bauxite production in Australia, the world's largest producing country. Alumina was produced at four plants, two of which were operated by Alcoa, one by Queensland Alumina Ltd., an affiliate of Comalco, and one by Nabalco.

Alcoa of Australia was owned by Aluminum Co. of America (51%), Western Mining Corp. Ltd. (20%), Broken Hill South Ltd. (16.6%), North Broken Hill Ltd. (12%), and two other companies (0.4%). Alcoa's alumina plants were located in Western Australia and supplied with bauxite from the Darling Range. The alumina plant at Kwinana received bauxite from mines near Jarrahdale, and the Pinjarra refinery was supplied by the Del Park and Huntly mines north of Dwellingup.

Comalco, owned by Kaiser Aluminum & Chemical Corp. (45%), Conzinc Riotinto of Australia, Ltd. (45%), and the public (10%), produced bauxite in the Weipa area of Cape York Peninsula, Queensland. Output increased about 1% to a record 9.5 million long tons in 1976. Shipments declined slightly to 8.9 million tons, of which 53% went to the Queensland Alumina refinery at Gladstone, 16% to Japan, and 31% to Europe and other areas. Comalco also produced calcined bauxite and reported that production and sales of this product were at record levels.

Production of alumina by Queensland Alumina totaled 2.27 million short tons, an increase over that of 1975, despite a strike which halted production for 1 week. Queensland Alumina was owned by Kaiser (32.3%), Alcan Aluminium Ltd. (21.4%), Pechiney Ugine Kuhlmann Group (PUK) (20%), Comalco (13.8%), and Conzinc Riotinto of Australia (12.5%). A tentative agreement was reached by Comalco's major stockholders to rearrange the ownership of Queensland Alumina. If the necessary approvals are obtained, Comalco will purchase all of Conzinc Riotinto's interest in Queensland Alumina and a 4% interest from Kaiser.

Nabalco, owned by Swiss Aluminium Ltd. (Alusuisse) (70%) and Gove Alumina Ltd. (30%), produced bauxite and alumina near Gove, Northern Territory. Bauxite production in 1976 totaled about 4.4 million long tons, and alumina output reportedly reached 1,135,000 short tons, exceeding the rated annual plant capacity.

Plans to construct a large new alumina plant at Wagerup, Western Australia, about 75 miles south of Perth, were announced in December. A preliminary understanding was reached by the prospective participants, which included Reynolds Metals Co., Alcoa of Australia, and Alwest Pty., Ltd., a joint venture of News Ltd. and Dampier Mining Co. Ltd. Other companies were to be invited to participate in the consortium.

Brazil.—Mineração Rio do Norte S.A. signed a contract in January with Construtora Andrade Gutierrez for construction of Rio do Norte's bauxite project on the Trombetas River in the Amazon Basin. The construction, which will include a 19-mile railroad, ore treatment and shipping facilities, a town, and other infrastructure, was expected to be completed within 3 years at a cost of about $300 million. The project will have an initial bauxite production capacity of 3.3 million long tons. Reserves have been reported at 500 million tons, averaging, on a washed basis, about 56% Al_2O_3 and 5% SiO_2, plus an additional 100 million tons of slightly lower grade bauxite. Rio do Norte was a consortium consisting of the Brazilian Government's Cia. Vale do Rio Doce (CVRD), 41%; Alcan Aluminium Ltd., 19%; Cia. Brasileira de Aluminio S.A., 10%; Reynolds Metals Co., 5%, and five European companies, 25%.

Total bauxite reserves in the Trombetas area, including the concessions of Rio do Norte and subsidiaries of Alcoa and National Bulk Carriers, have been estimated at 2 billion tons. Alcoa, operating through its subsidiary, Cia. de Mineração Santarem S.A. (COMISA), continued to evaluate its concessions west of the Rio do Norte project and submitted feasibility studies to the Government. Reynolds was active in exploration of its concessions on the south bank of the Amazon west of Santarem.

In the Paragominas area south of Belém, Mineração Vera Cruz Ltda., a subsidiary of Rio Tinto Zinc (RTZ), and CVRD were conducting exploration on separate concessions. RTZ completed construction of a pilot plant for crushing and washing bulk samples and was preparing a feasibility study, which was scheduled for completion by the end of 1977. It was reported that CVRD may join with RTZ in developing the RTZ deposit to supply a proposed alumina plant near Belém.

An agreement was reached between CVRD and Japanese interests to construct an alumina plant (the Alunorte project) and an aluminum smelter (the Albras project) near Belém based on the use of hydroelectric power from the Tocantins River. The joint venture was to be owned 51% by CVRD and 49% by 32 private Japanese companies. The alumina plant would have an annual capacity of 880,000 short tons and would cost an estimated $409 million.

Alcan obtained approval to expand the facilities of its subsidiary, Alcan Aluminio do Brazil S.A., at Saramenha in Minas Gerais. The capacity of the alumina plant will be increased by 33,000 tons to 133,000 tons, and construction was expected to begin in 1977.

Canada.—Alumina production at Alcan's plant in Quebec Province declined over 50% in 1976, largely because of strikes at the company's alumina and aluminum plants.

Greece.—Bauxite production in Greece declined 15% to 2.7 million long tons in 1976. Greek bauxite was used to supply the alumina plant of Aluminium de Grece S.A. at Distomon, and most of the remaining output was exported. Total licensed exports for 1977 were reduced 28% to 2,264,000 tons, with the largest allocations going to the European Economic Community, the U.S.S.R., and Romania.

Bauxites Parnasse Mining S.A., the largest bauxite producer in Greece, was undergoing a $10 million investment program to increase annual production capacity at its Parnassos-Ghiona mines in central Greece from 2 million tons to 3.5 million tons. The program will include an expansion of underground facilities from about 500,000 tons to 1.5 million tons annual capacity by 1982. Bauxite Parnasse is the principal Greek partner in a planned 660,000 short-ton-per-year alumina plant to be constructed near Itea on the Gulf of Corinth.

The second largest bauxite producer, Eleusis Bauxite Mines, Inc. (Scalistiri group), was reported to have an annual bauxite mining capacity of 720,000 tons, including 200,000 tons from Aluminium de Grece's Delphi Bauxites S.A. mines, which were operated by Eleusis. Barlos Bauxite Hellas S.A. was reported to be producing at a level of about 200,000 tons in 1976. Both Eleusis and Barlos were increasing production capacity during the year. Other bauxite producers included Distomon Hellenic Bauxites, controlled by Aluminium de Grece, with an annual production of 270,000 tons, and Elikon Bauxites-G. Barlos S.A., with an annual capacity of 200,000 tons.

Guinea.—Guinea Bauxite Co. (CBG), owned by Halco (51%) and the Government of Guinea (49%), was the largest of three bauxite producers in Guinea and produced a reported 6.4 million long tons in 1976. Halco was a consortium of aluminum producers consisting of Alcoa (27%), Alcan (27%), Martin Marietta Aluminum, Inc. (20%), PUK (10%), Vereinigte Aluminium-Werke AG (VAW) (10%), and Alumetal S.p.A. (6%). The bauxite was mined at Sangaredi, shipped by rail to the treatment plant and port at Kamsar, and exported largely to members of Halco. Bauxite exported by CBG averaged over 59% Al_2O_3 (less than 3% monohydrate) and about 1% SiO_2.

Kindia Bauxite Office (OBK), owned by the Government of Guinea and operated with U.S.S.R. assistance, produced about 2.4 million tons of bauxite, averaging 46% to 48% Al_2O_3 and 2% SiO_2. The ore is mined at Débélé in the Kindia region, shipped by rail to Conakry, and exported to the U.S.S.R. [4]

The third bauxite producer, Friguia, also operated the only alumina plant in Africa. Friguia was owned by Frialco (51%) and the Government (49%); Frialco was a consortium consisting of Noranda Mines Ltd. (38.5%), PUK (36.5%), British Aluminium

[4]Wyllie, R. J. M. OBK, Guinea's National Bauxite Company, Operates 2,500,000 Ton Mine and Railroad. World Mining, v. 29, No. 4, April 1976, pp. 72-75.

Co., Ltd. (10%), Alusuisse (10%), and VAW (5%). Bauxite production by Friguia totaled 1.8 million tons during the year, and alumina production declined 13% to 617,000 short tons.

The Governments of Guinea, Egypt, Iraq, Kuwait, Libya, Saudi Arabia, and the United Arab Emirates have agreed to a joint venture to build a large bauxite-alumina complex to exploit the bauxite deposits at Ayékoyé near the CBG concession. The project will cost an estimated $1 billion. Reportedly Alusuisse has agreed to conduct feasibility studies and preliminary design for the venture.

Guyana.—Bauxite was produced by two government-owned companies, Guyana Bauxite Co. (Guybau) and Berbice Mines (Bermine). In addition to the production of metal-grade bauxite, Guyana continued to be the world's largest supplier of high-grade calcined bauxite for refractory uses. Guyana also produced alumina. Production of both grades of bauxite and alumina decreased in 1976 because of heavy rains early in the year, strikes at yearend, and depressed markets for alumina. Shipments of metal-grade bauxite to the United States increased, reflecting a reported contract with Reynolds for 300,000 to 400,000 tons.

It was reported that Guybau will replace the rotary-kiln facilities at its alumina plant with fluidized-bed calciners, which were expected to reduce energy requirements by 30% to 40%. The new facilities were to be built by the West German company Lurgi Chemie und Huettentechnik and completed by 1978.

Haiti.—The Haitian Government and Reynolds Haitian Mines, Inc., reached an agreement covering bauxite taxes and export quotas for the 5-year period 1977-81.

Hungary.—A new bauxite mine, Iza-II, near Tapolca in western Hungary, was reported to have begun production at an annual rate of over 400,000 tons.

India.—The Government continued its program of exploration and evaluation of bauxite deposits in the east coast States of Orissa and Andhra Pradesh. The bauxite belt being investigated was said to extend about 185 miles in a northeast-southwest direction and to be 25 to 60 miles wide. Much of the bauxite was reported to be in deposits ranging from 20 feet to over 100 feet thick, with little overburden. Preliminary estimates of reserves in this area were about 1 billion tons. Reportedly, the bauxite has a high iron content (19% to 26%) but is low in silica (2% to 4%). The Government company Bharat Aluminium Co. was expected to be granted mining leases for these deposits. Proposals to construct alumina plants based on this bauxite were being considered.

Jamaica.—It was reported that the Jamaica Bauxite Institute, an agency of the Government of Jamaica, had reestimated total bauxite reserves on the island at 2 billion tons.

Bauxite and alumina were produced by affiliates of five North American aluminum companies. In addition to the bauxite produced to supply the four alumina plants operated during the year, Jamaican bauxite was exported to U.S. alumina plants by Kaiser Bauxite Co., Reynolds Jamaica Mines Ltd., and Alcoa Minerals of Jamaica, Inc. Exports of bauxite increased 15% to 6.2 million long tons (dry basis) in 1976, while exports of alumina decreased 32% to 1.8 million short tons.

The levy on bauxite production was increased by the Government from 7.5% to 8.0% of the price realized on primary aluminum ingot. Assuming a realized aluminum price of 42 cents per pound, the new production levy would amount to $15.62 per long dry-ton of bauxite. Any increase in the price received for primary aluminum above 42 cents per pound would increase the bauxite levy proportionately. Reportedly, a levy rate of less than 8% will apply under agreements reached with several producers.

In October, Alcoa and the Government of Jamaica agreed to form a joint bauxite and alumina venture to be known as Jamalco. Under the 40-year agreement, Alcoa will sell the Government a 6% interest in its mining and refining assets and all of its mining and nonoperating lands. Alcoa will receive a reduced bauxite levy rate for the first 8 years of the agreement and will continue to manage the alumina plant.

Alcoa's alumina plant was shut down for two 3-month periods during 1976. Labor disputes caused Alcoa to suspend operations from mid-February to early May. Two months later an explosion of a pressure vessel forced a second plant closure. The plant was reopened in October and operated at half capacity the remainder of the year.

Total production of alumina at the two plants owned by Alcan Jamaica Ltd. was down 19% to 841,000 short tons. The decline was attributed to both lower demand and a strike at one of the plants. Talks between the Government and Alcan regarding such questions as the ownership of bauxite reserves and government participation in the company's equity were conducted during the year.

The alumina plant and mines of Revere Jamaica Alumina, Ltd., were closed down in August 1975 and remained closed throughout 1976. Revere initiated a suit against the Government challenging the validity of the bauxite production levy as applied to Revere and seeking confirmation that its mining lease remained valid. Revere also filed a claim with the Overseas Private Investment Corp. (OPIC), a U.S. Government insurance agency, under the expropriation provisions of its policy with OPIC. Neither of these actions was resolved at yearend.

Japan.—Japan continued to rely on imports for virtually all of its aluminum raw materials. Bauxite imports in 1976 totaled 4.2 million long tons, of which 2,674,000 tons came from Australia, 952,000 tons from Indonesia, 504,000 tons from Malaysia, and 80,000 tons from other sources, largely Guyana. An additional 682,000 short tons of alumina, all from Australia, was imported for use in making aluminum. Mitsui Alumina Corp. completed installation of new facilities which doubled the alumina production capacity at its Wakamatsu plant.

Sierra Leone.—Sierra Leone Ore and Metal Co., a wholly owned subsidiary of Alusuisse, operated the only bauxite mine in Sierra Leone at Mokanje. Alusuisse was reported to be considering the opening of a new bauxite mine in the Port Loko area and the possibility of constructing an alumina plant. If plans for the new mine materialize, Alusuisse may be joined in the venture by the Norwegian aluminum producers, A/S Ardal og Sunndal Verk and Norsk Hydro A/S. The Government reached agreement with Alusuisse and passed legislation in 1976 to increase its total bauxite revenues accruing from royalties, mining leases, and income tax.

South Africa, Republic of.—A discovery of large low-grade bauxite deposits in the Midlands and Zululand of Natal was reported.

Spain.—An 880,000-ton-per-year-capacity alumina plant was under construction at San Cipriano in 1976. The plant will be owned by the Spanish aluminum companies Empresa Nacional del Aluminio, S.A., 55%, and Aluminio de Galicia, S.A., 45%, and was scheduled to begin production in 1979.

Surinam.—Metallurgical and special grades of bauxite were mined by Surinam Aluminum Co. (Suralco), an Alcoa subsidiary, in the Moengo area of eastern Surinam and by Suralco and N.V. Billiton Mij. Suriname in the Paranam area. Billiton's bauxite mining operations were described.[5] Suralco also produced alumina and aluminum and converted bauxite to alumina for Billiton. Total exports of bauxite, most of which was shipped to the United States, decreased 13% to just under 2 million long tons in 1976. Exports of alumina declined slightly to 1.2 million short tons, as reduced shipments by Suralco offset an increase by Billiton.

The Government of Surinam and Suralco reached an agreement on the payment of bauxite production levies over the 3-year period ending December 31, 1978. The tax will be based, as it had been since 1974, on a rate of 6% of the price Alcoa receives on unalloyed primary metal. It was reported that the company also agreed to produce a minimum of about 8.2 million long tons of bauxite during the 3-year period.

Grasshopper Aluminium Co. Ltd. (Grassalco), a Government-owned company, was developing plans to mine lateritic-type bauxite in the Bakhuis Mountains of western Surinam. A prefeasibility study of two areas in the Bakhuis Mountains was conducted for Grassalco by Billiton in 1976, and Grassalco reported reserves totaling over 50 million tons of bauxite containing at least 42% available alumina. A 44-mile railroad will be built from the deposits to Apoera on the Corantijn River bordering Guyana, and a $60 million contract for its construction was awarded to a joint venture sponsored by Morrison-Knudsen International Co. Shipments of bauxite from these deposits were scheduled to begin in 1979. The feasibility of constructing an alumina plant at Apoera was also being studied.

U.S.S.R.—The bauxite and other aluminum resources of the U.S.S.R., a history of their use, and the trend toward the U.S.S.R. dependence on imported aluminum raw materials were described.[6]

Venezuela.—It was reported that Alusuisse and Corporación Venezolana de Guay-

[5] Argall, G. O., Jr. Bucket Wheels, Dredges, Draglines Strip and Mine at Billiton Suriname. Min. World, v. 29, No. 3, March 1976, pp. 46-51.

[6] Shabad, T. Raw Material Problems of the Soviet Aluminum Industry. Resources Policy, v. 2, No. 4, December 1976, pp. 222-234.

ana (CVG) would form a joint venture to produce alumina in Venezuela. The venture would be named Interamericana de Alúmina C.A. (INTER-ALUMINA) and would be owned by Alusuisse (20%) and CVG (80%). The proposed alumina plant would have an annual capacity of 1 million tons, would cost an estimated $550 to $600 million, and would be located in the Guayana region of Venezuela. The plant would provide 800,000 tons of alumina per year to supply the Venalum and Alcasa primary aluminum plants and 200,000 tons for export by Alusuisse. Production would be based on imported bauxite, and natural gas available in the area would provide the required energy.

Yugoslavia.—Expansion of bauxite and alumina production facilities continued in Yugoslavia. A new alumina plant at Obrovac, Croatia, was reported to be producing at yearend at the rate of 110,000 short tons per year. The plant eventually will have a capacity of 330,000 tons. Another new alumina plant was under construction at Zvornik, Bosnia-Hercegovina, for Energoinvest. The Zvornik plant will have an annual capacity of 660,000 tons, half of which was expected to come onstream in 1977. It was also announced that the alumina plant at Titograd, Montenegro, would be expanded from 220,000 tons to 310,000 tons.

TECHNOLOGY

Research and development of processes to use nonbauxitic aluminum resources was continued in countries with insufficient bauxite resources by both government and private organizations.[7]

The Federal Bureau of Mines continued its research program on the recovery of alumina from clay, anorthosite, and other raw materials abundant in the United States. The most promising technologies for extracting alumina were being tested and developed in small pilot plants, or miniplants, at the Bureau's Boulder City (Nevada) Metallurgy Engineering Laboratory. Additional research in support of this effort was being conducted at other Bureau research centers.[8] The miniplant program was initiated to evaluate the various processes on a comparative basis and to obtain cost and engineering data for the design and operation of large-scale demonstration plants. Nine companies were participating with the Bureau in the miniplant project on a cooperative cost-sharing basis.

In 1976 the major emphasis of the miniplant program was on the hydrochloric acid process for recovering alumina from clay, and test runs of several sections of this miniplant were completed. The clay-nitric acid miniplant was placed on standby status, and the design was completed and equipment was ordered for facilities to recover alumina from anorthosite using a lime-sinter process. At yearend the Bureau awarded a $1.6 million contract to Kaiser Engineers to evaluate several of the alumina processes being tested by the Bureau and, subsequently, to design a larger pilot plant based on a process which will be selected by the Bureau.

The Bureau reported on its investigations of the potential for recovering aluminum from copper-dump leach liquors by the use of single-contact ion-exchange technology.[9]

Dawsonite, an aluminum mineral occurring in the oil shales of the Piceance Creek Basin in Colorado, has been of interest as a potential source of alumina should the shales be mined to recover oil. The Bureau placed on open file reports which explore the technical and economic feasibility of three different methods of developing these oil shale deposits.[10] Another process to recover oil, alumina, nahcolite, and soda ash was under investigation by Superior Oil Co.[11]

A joint venture of Earth Sciences, Inc., National Steel Corp., and Southwire Co. continued its research and planning for the production of alumina and fertilizer byproducts using alunite deposits in southwestern Utah. A pilot plant program and preliminary engineering and cost analysis were reported to be near completion at yearend. An environmental impact statement for the project, which would produce 500,000 tons per year of alumina, was being prepared.

Iran and the U.S.S.R. were reported to have signed an agreement to build a plant near Tehran to produce alumina from alunite deposits in Iran using Russian technology. The plant would have a capacity of 550,000 tons per year and cost an estimated $600 million.

Aluminium Pechiney and Alcan completed construction of a pilot plant near Marseilles, France, in September. The plant will test the H-Plus process, which uses both sulfuric acid and hydrochloric acid to recover high-purity alumina from shale, clay, and other low-grade aluminous materials. The plant was designed to produce 20 tons of alumina per day.

A/S Ardal og Sunndal Verk and Elkem Spigerverket, two Norwegian aluminum companies, were reported to have constructed a pilot plant for testing a new process for extracting alumina from anorthosite. The two firms have acquired rights to large anorthosite deposits containing about 30% Al_2O_3 in western Norway.

Beryllium

By Benjamin Petkof[1]

Bertrandite was the major commercial beryllium mineral produced in the United States, and it contributed a significant proportion of the world beryllium mineral supply. A small quantity of beryl was also produced domestically. Ore consumption and imports declined, but exports of beryllium materials increased.

Legislation and Government Programs.—On October 1, 1976, the Federal Preparedness Agency of the General Services Administration, issued new goals for beryllium materials in the strategic stockpile: Beryl, 0; beryllium-copper master alloy, 16,710 short tons; and beryllium metal, 895 tons. No beryl was released from the strategic stockpile during the year.

Table 1.—Salient beryllium mineral statistics

	1972	1973	1974	1975	1976
United States:

Price, approximate, per unit BeO, imported cobbed beryl at port of exportation	$30	$30	$30	$30	$33
Bertrandite ore: Utah, low-grade, shipped from mines short tons	W	W	W	W	W
World production of beryl do	4,330	3,963	r3,469	r3,608	3,035

rRevised. W Withheld to avoid disclosing individual company confidential data.
[1]Includes bertrandite ore which was calculated as equivalent to beryl containing 11% BeO.

DOMESTIC PRODUCTION

Bertrandite was the Nation's major source of beryllium ore during the year. Brush Wellman, Inc. (Brush) produced the bertrandite ore at its Spor Mountain mine in Millard County, Utah. A small quantity of beryl production was also reported in South Dakota and Arizona.

Brush converted its ore to beryllium hydroxide at a facility north of Delta, Utah, and then shipped the hydroxide to its Elmore, Ohio, facility for conversion to beryllium oxide, metal, and copper alloys.

Kawecki-Berylco Industries, Inc. (KBI) produced beryllium materials principally from imported beryl. KBI processed beryllium hydroxide at its plants in Hazelton and Reading, Pa., into beryllium metal, alloys, and oxide.

In December 1976, Brush announced plans to build a beryl ore processing facility at its bertrandite processing plant in Utah. The company planned to spend an estimated $4.5 million on the new plant. Upon completion, this will be the only plant capable of processing any commercial beryllium ore to beryllium hydroxide. Brush planned to close its beryl processing facility at Elmore, Ohio, in 1977.

Domestic production of beryllium metal declined in 1976, but production of beryllium containing alloys and beryllium oxide

[1]Physical scientist, Division of Nonferrous Metals.

increased. Improvement in metal production is expected to occur with the inception of new space and nuclear energy programs that specify the use of beryllium metal.

CONSUMPTION AND USES

The domestic beryllium industry consumed beryllium ore equivalent to 3,740 tons of beryl containing a nominal 11% BeO, a decline of 23% from that of 1975.

Beryllium metal, with its high stiffness-to-weight ratio, continued to be used primarily in defense and aerospace applications. The metal was used in the manufacture of commercial and military navigational systems, satellite structures, space vehicle instrumentation and optics, X-ray transmission windows, aircraft brakes and structures, and missile parts.

Products utilizing beryllium-copper alloys accounted for the greatest quantity of beryllium consumption. These alloys were used by the business machine, appliance, transportation, and communications industries. Beryllium-copper alloys were also widely used in electrical and electronic systems for connectors, sockets, switches, and temperature- and pressure-sensing devices to provide reliability and long service life.

Beryllium oxide ceramics were used in lasers, microwave tubes, and semiconductors, primarily for heat dissipation in these devices. In addition, beryllia was used as a substrate in various electronic devices and equipment.

STOCKS

Consumer stocks of beryllium minerals totaled 3,957 tons at yearend 1976, a 12% increase above those of 1975. Dealers' stocks of beryl were not reported.

PRICES AND SPECIFICATIONS

There were no known price quotations for the small quantities of domestically produced beryl. The price of any available domestic beryl was negotiated between buyer and seller. At the beginning of the year, Metals Week quoted the price of imported beryl at $30 per short-ton unit of contained BeO. As of February 12, 1976, to the end of the year, Metals Week quoted the price at $40 to $42 per short-ton unit. At yearend, American Metal Market quoted the following prices for beryllium materials: Vacuum cast ingot, $75 per pound; metal bead (97% purity and 10,000-pound lots), $61 per pound; metal powder (20,000-pound lots), $56 to $63 per pound; metal rod, $125.55 per pound; beryllium-copper master alloy, $59 per pound of contained beryllium; beryllium-copper casting alloy, $2.05 to $2.86 per pound; beryllium-copper in strip, rod, bar, and wire, $4 per pound; beryllium-aluminum alloy ingot, $72 per pound; and beryllium oxide powder, $26 per pound.

FOREIGN TRADE

Exports of wrought, and unwrought beryllium alloys and of waste and scrap increased threefold in quantity over those of 1975 but did not reach the level of 1974. Total value of exports increased 52%, although average value of exports declined from $30.85 per pound to $15.38 per pound, still above the average value of $7.71 for 1974. In terms of quantity, 65% of the total material exported went to Mexico, 11% to Japan, 8% to the United Kingdom, and 4% to France.

Beryl ore imports decreased 28% in quantity and 19% in value from those of 1975. The average value of imported material was $359 per ton in 1976 compared with $316 per ton in 1975. Forty-eight percent of U.S. imports came from Brazil, 11% from India, 10% each from France, and Australia, and 9% from the Republic of South Africa. In addition, 1,492 pounds of wrought and unwrought, waste and scrap beryllium metal valued at $3,117 were imported.

Table 2.—U.S. exports of beryllium alloys, wrought or unwrought, and waste and scrap[1]

WORLD REVIEW

Total world production of beryl declined below that of 1975. Beryl competes with the nonpegmatite mineral bertrandite as a commercial source of beryllium.

The capability of mining and processing Utah bertrandite ore that has been developed during the past 10 to 15 years has made the United States a significant world source of commercial beryllium minerals. Any future increase in U.S. bertrandite mining and processing capability could displace additional world beryl output that is recovered by hand mining and sorting.

[1]In addition to the countries listed, the Territory of South-West Africa may also have produced beryl, but available information is inadequate to formulate reliable estimates of output levels.

TECHNOLOGY

A report provided guidelines for determining beryllium emission rates from stationary sources. The report included guidelines on good operating practices, assessment of performance and qualification of data, identification of trouble and improvement of data quality, and design of auditing activities.[2]

A report assessed the potential use of beryllium in the construction of controlled nuclear reactors.[3]

Bismuth

By John A. Rathjen[1]

Domestic consumption and imports of bismuth in 1976 increased sharply over the totals reported in 1975, while both domestic production and exports declined during the year. Consumption rose to 2.4 million pounds, an increase of 71% above that of 1975. With the exception of other alloys, consumption in all categories increased and cumulatively was over 1 million pounds higher than that of 1975. Imports of bismuth were up 75% to 2.3 million pounds. Exports dropped to 68,488 pounds, a reduction of 60,405 pounds from those of 1975. This was attributed to reduced demand and low prices in the European market. The domestic price remained at $7.50 per pound throughout the year despite the apparent increase in demand in the United States. World bismuth mine production increased 5% to 9.26 million pounds. The general pattern of production was unchanged from the previous year.

Legislation and Government Programs.—Government stocks of bismuth remained at 2,081,298 pounds. Broken down, the total included 567,186 pounds in the national stockpile and 1,514,112 pounds in the supplemental stockpile. On October 1, 1976, the Federal Preparedness Agency (FPA) set a new goal for bismuth of 771,000 pounds. This resulted in a surplus of 1,310,298 pounds, which would require congressional authorization for disposal. Bismuth remained on the list of commodities eligible for exploration assistance under the program administered by the Office of Minerals Exploration (OME). However, no funds were available in 1976 for exploration projects, and none have been requested since fiscal year 1974. The Tax Reform Act of 1969 provides a percentage depletion allowance of 22% for domestic production and 14% for U.S. companies producing from foreign sources.

[1]Mineral specialist, Division of Nonferrous Metals.

DOMESTIC PRODUCTION

Bismuth was produced almost entirely from the treatment of lead ores and bullion of both foreign and domestic origin. A single primary refinery operated by ASARCO, Inc. at Omaha, Nebr., accounted for some 99% of the primary U.S. production. A final shipment was made of primary metal from the lead refinery of UV Industries, Inc., at East Chicago, Ind. A small quantity of bismuth was also recovered by recycling secondary material at the United Refining and Smelting Co., Franklin Park, Ill. U.S. refinery production statistics are withheld to avoid disclosing company confidential data.

CONSUMPTION AND USES

Consumption of bismuth in the United States during 1976 was 2.4 million pounds, a rise of 1 million pounds over the quantity consumed in 1975. All consumption categories, with the exception of other alloys, showed increases. The largest increase occurred in the pharmaceutical sector, which consumed almost 1.4 million pounds, a gain of some 840,000 pounds compared with that of 1975. The major part of this growth was attributed to the use of bismuth in the industrial chemical area, where it functions as a catalyst in the manufacture of acrylonitrile. Use of bismuth in the metallurgical area also rose significantly, reflecting a general rise in the domestic economy. Bismuth consumption in cosmetics remained steady.

Table 2.—Bismuth metal consumed in the United States, by use

(Pounds)

Use	1975	1976
Fusible alloys	401,932	518,648
Metallurgical additives	416,200	455,940
Other alloys	26,007	20,263

Other uses	7,856	15,314
Total	1,406,021	2,410,584

[1]Includes industrial and laboratory chemicals and cosmetics.

STOCKS

Consumer stocks at yearend were 483,810 pounds, a rise of 32,560 pounds during the year. No data are available on producer or dealer stocks.

PRICES

The domestic producer price for refined bismuth was $7.50 per pound throughout the year. Dealer quotations rose to a range of $6.50-$6.80 per pound at the end of the first quarter but declined during the year, closing in December at $4.50-$4.80 per pound.

FOREIGN TRADE

Exports of bismuth in all forms dropped sharply for the second consecutive year to 68,488 pounds, a decline of 60,405 pounds from that of 1975. During 1976, bismuth was exported to 17 countries, of which 7 accounted for about 95% of total shipments. The principal countries receiving U.S. exports, in order of declining quantity, were

Italy 21,075 pounds, 31%; Canada, 16,503 pounds, 24%; the Netherlands, 8,722 pounds, 13%; the United Kingdom, 6,712 pounds, 10%; Spain, 5,758 pounds, 8%; Ireland, 3,348 pounds, 5%; and Belgium-Luxembourg, 2,754 pounds, 4%.

General imports of metallic bismuth in 1976 increased by about 997,000 pounds to 2.3 million pounds as compared with that of 1975. This large increase was attributed primarily to the general uptrend of the economy and reflected the very strong demand in the category of industrial chemicals. A total of 12 countries supplied the U.S. import requirements; 9 of these accounted for about 96% of the total. The principal suppliers were Peru, 24%; the United Kingdom, 13%; West Germany and Japan, 12% each; Mexico, 11%; the Republic of Korea, 8%; Belgium-Luxembourg, 7%; Chile (Bolivia) 5%; and Canada, 4%. Chile does not produce bismuth in any form; however, Bolivia has no seaport and Bolivian materials shipped to the United States via a Chilean port show the intermediate country as a port of origin.

WORLD REVIEW

Although U.S. consumption recovered substantially during 1976, world production increased only slightly. This was attributed primarily to the decreased use for pharmaceuticals in France and the generally slow recovery of the European economy from the recession of 1975. All of the producing countries produced at levels similar to those in 1975.

Australia.—Mine production of bismuth in Australia rose nominally from 1.8 million pounds in 1975 to an estimated 1.9 million pounds in 1976. Production continued to be somewhat curtailed since copper mining by Peko-Wallsend Ltd. at Tennant Creek in the Northern Territory remained dormant. The main source of bismuth from Australia in 1976 was a gold-bismuth bullion which was shipped through northern Europe for gold recovery, with residue moved forward to the United Kingdom for bismuth recovery and refining. Minor amounts of bismuth were also shipped from Australia as byproducts in lead ores and concentrates; however, the bismuth assays were too low to be accountable for production purposes.

Bolivia.—Bolivia became the world's leading producer of refined bismuth in March with the inauguration of the new Corporación Minera de Bolivia (COMIBOL) refinery at Quechisla, Potosi. The refinery, with an annual estimated capacity of 13 million pounds, was built at a cost of $500,000 by the Belgian firm Sidech. Metal of 99.99% purity was shipped during the year. Bismuth is also shipped in the form of ores and concentrates by COMIBOL as well as by independent medium and small miners. Bolivia is one of the few countries in which bismuth is mined directly rather than as a byproduct.

Canada.—Bismuth metal was produced by two companies in Canada. The smelting division of Brunswick Mining & Smelting Corp. Ltd. produced metal at its Belledune plant near Bathurst, New Brunswick. The other principal metal producer was Cominco Ltd. at its lead-zinc plant in Trail, British Columbia. Most of the metal produced in Canada came from ores mined within the country, although small quantities were recovered from imported ores. Recent exploration in Charlotte County, New Brunswick, established a large reserve of a complex tungsten-bismuth-molybdenum ore. In some areas the bismuth assays have been established at 0.11% to 0.15% and could provide a considerable increase to world production.

Japan.—Production of bismuth metal in Japan during 1976 continued at about the same level as in 1975 totaling 1.5 million pounds at yearend.

Mexico.—Production of bismuth in Mexico during 1976 was about 1.3 million pounds, a substantial recovery from the relatively low 981,000 pounds in 1975. Two companies; Industrial Minera Mexico, S.A., and Met Mex Peñoles, S.A., continued as the producers of metal and bullion at their refineries, both of which are located in Monterrey, in the State of Nuevo Léon.

Peru.—Bismuth production in Peru continued at a steady level, totaling 1.4 million pounds during 1976. Metal was produced at the Oroya works, managed by Centromin-Peru, and marketed on a worldwide basis by Minero Peru Comercial.

Boron

By J. W. Pressler[1]

In 1976, U.S. production and consumption of boron minerals increased somewhat compared with that of 1975, however the total value of sales and captive uses increased to $185 million, the largest amount in history. Exports of boric acid increased slightly in 1976, while exports of refined sodium borate were unchanged. Production was maintained at near peak levels, and the three major producers had a steadily increasing market demand during the year.

Insulation fiberglass, textile fiberglass, and borosilicate glass products continued to be the principal uses for borate minerals and chemicals in the United States, consuming more than 50% of the total supply. During the year, a constantly increasing market for thermal insulation caused increased demands on borate minerals and chemicals in insulation fiberglass (glass wool) and on boric acid in the production of cellulosic insulation (paper wool).

California provided the entire U.S. output of boron minerals, mostly as sodium borates and boric acid but more recently with some calcium borates. Imports of calcium borate (colemanite) from Turkey in 1976 increased slightly over those of 1975.

Table 1.—Salient boron minerals and compounds in the United States

DOMESTIC PRODUCTION

Domestic production and sales of boron minerals increased 4% in 1976, compared with that of 1975. Most of the output continued to come from Kern County, Calif., and to a smaller extent from San Bernardino and Inyo Counties, Calif.

At Boron, in Kern County, the large open pit mine and refining plant belonging to U.S. Borax & Chemical Corp., a member of Rio Tinto-Zinc Corp., Ltd., of London, England, continued to be the world's chief source of boron, although Turkish tincal, colemanite, and refined products are rapidly becoming of great importance in world trade. U.S. Borax now processes over 10,000 tons of ore per day, producing principally crude sodium borate, refined sodium borate, and their anhydrous varieties at the Boron mine site. During the year, the $54 million expansion project at Boron continued on schedule; a major portion of the new capacity was to be onstream by 1977. This project will provide a 25% to 30% increase in the output of U.S. Borax's primary products,

[1]Physical scientist, Division of Nonmetallic Minerals.

pentahydrate and decahydrate borax. Considerable "debottlenecking" of the facilities was accomplished during the year, and design of additional facilities to further expand capacity was in progress. The company's chemical plant at Wilmington, Calif., produced a variety of high-quality specialty borate products and had a secondary function of serving as an overseas shipping point for bulk shipments. The rated capacity of the boric acid plant at Wilmington was increased 25% in 1976, and the spray-dry plant's capacity was tripled. The company's total production increased slightly during 1976. Demand for all industrial borax products increased steadily during the year. Economic recovery started later than might have been expected by reference to 1975, but by the latter part of 1976 sales were again at a very satisfactory level.

Boric acid was projected to have a strong growth rate for a large variety of end uses, including cellulose insulation and fire-resistant cotton batting, textile fiberglass, and heat-resistant glass, and U.S. Borax was giving serious consideration to additional boric acid capacity at yearend. At Burlington, Iowa, U.S. Borax has a plant and warehousing facility for compounding, packaging, and distributing household soaps and other consumer products to the Eastern and Midwestern United States. These combined operations of U.S. Borax in the United States had an annual capacity of more than 600,000 short tons of boric oxide (B_2O_3) equivalent (or about 190,000 tons of contained boron) in 1976 and will be 25% to 30% greater when the planned expansions are completed in 1977.

Crude commercial-grade sodium borates, known as Rasorite 46 (pentahydrate borax) and Rasorite 65, the anhydrous equivalent, represent almost one-half of U.S. Borax's output in tonnage and about one-half of the value. In addition to the Rasorite 46 and 65 production, refined borax pentahydrate and decahydrate represent over one-third of the output tonnage.

U.S. Borax maintains a warehouse and distribution facility at Botlek, Netherlands, from which borax and boron chemicals are shipped to other parts of Europe.

At Searles Lake, Kerr-McGee Corp. operated the Trona and Westend plants, with combined capacities of approximately 130,000 tons of B_2O_3 equivalent per year. Borates were produced along with potassium compounds, lithium carbonate, soda ash, and salt cake from the mineral-rich brines. The Westend plant had a capacity of 25,000 tons per year of B_2O_3 equivalent, principally as anhydrous borax. The flowsheet was based upon the carbonation process. At the nearby Trona plant, Kerr-McGee utilized the carbonation process and a differential evaporative process with a combined capacity of 100,000 equivalent tons of B_2O_3 per year to produce borax pentahydrate and decahydrate, boric acid, and anhydrous borax. Boric acid was also produced from weak brines by liquid-liquid extraction. A major new soda ash plant is being constructed adjacent to these existing facilities for completion by yearend 1977, but a borate cycle apparently is being deferred until the recovery economics are feasible.

In 1976, Tenneco Oil Co., the third U.S. producer, significantly increased production of colemanite and ulexite from its Ryan mine near Death Valley, Inyo County, Calif. The colemanite (calcium borate) is processed at a plant at Lathrop Wells, Nev., utilizing calcination and screening, principally for the fiberglass market. The ulexite (calcium-sodium borate) is trucked to a plant at Dunn, Calif., where it is prepared for the market by grinding to minus 200 mesh. Its principal use is in the manufacture of glass wool insulation and fire-retardant chemicals.

Tenneco had increased its reserves as a result of exploration and development and had approved a plan to double production within 3 years with a capital investment of $20 million. In October, however, Tenneco sold its total boron mining and marketing assets to the American Borate Corp., which will continue the present operations. This action followed the passage by Congress of Public Law 94-429 to regulate and constrain all mining activities within the National Park system. The law, which repealed the mineral entry provision for certain units, also applied to Death Valley National Monument, which is currently the sole commercial source of colemanite and ulexite in the United States.

CONSUMPTION AND USES

About 50% of the U.S. output of boron minerals and compounds was exported in 1976, while the balance was consumed domestically. Official U.S. trade statistics report only the export of refined boron chemical products; the export of crude sodium borate, equivalent to a commercial grade of 98% to 99% purity, is proprietary information. So-called "crude" product exports have never been reported by the Bureau of the Census, but probably will be, effective January 1, 1978. With these total figures, an accurate consumption figure will be available each year.

Measured in terms of boron content, U.S. consumption was probably about 112,000 short tons in 1976, compared with possibly 98,000 tons in 1975 and 110,000 tons in 1974. Insulating fiberglass, textile fiberglass, and borosilicate glasses were the major consuming uses for boron minerals and compounds in the United States in 1976, approaching 50% of the total end use. Spectacular growth for thermal insulation was reflected in increased demand for borates in insulation fiberglass manufacturing and in the production of cellulosic insulation. The production of "paper wool" from shredded scrap newsprint and boric acid created an unusually heavy demand for boric acid by yearend and may continue unabated for the near term.

About 80% of home insulation materials in 1976 was accounted for by glass fiber, produced by three companies in the United States. Dominant in the industry were Owens-Corning Fiberglas Corp. with about 50% of the market, and Johns-Manville Corp. and CertainTeed Corp., sharing the other 50%. However, 1976 saw the emergence and strong competition of cellulosic insulation, especially that produced by shredded newsprint with the addition of about 20% to 25% boric acid and borax for flame and fire retardancy. Small plants were promoted and financed by the Small Business Administration, surmounting the traditional industry entrance barriers of high capital cost, competitive technology, and industry expertise. By yearend, shortages of boric acid had developed which caused sales allocations and black market activities.

Up to 11,000 tons of boron content was used in 1976 in the rapidly growing cellulosic insulation business, consuming up to 25% of the weight of the insulation in formulations of boric acid and sodium borate and other chemicals. A recent survey of this market indicated a growth rate of 34% for the next 3 years.

In addition to the thermal insulation markets, applications for borates currently experiencing significant growth included the treatment of mattresses and upholstery with boric acid for fire retardance and the incorporation of borate compounds in plastics for similar purposes.

U.S. consumption in 1976 of borate compounds in cleaning and bleaching was about 17,000 tons of boron content, including about 6,000 tons in sodium perborate detergents for higher temperature washing. Perborates were also used as a bleaching agent or as a source of active oxygen in laundry products. In addition, chemical derivatives require at least another 10,000 tons per year of boron content. Borohydrides have a growing use as chemical reductants in such important industrial processes as regenerating sodium hydrosulfite in reductive pulp bleaching. Borax and boric acid uses in the cleansing field included toothpaste, mouthwash, and eyewash. Approximately 8,000 tons of boron yearly was used in the manufacture of biological and growth-control chemicals for use in algicides and water treatment, fertilizers, herbicides, and insecticides.

Two minor but important uses, as corrosion inhibitors in antifreeze and as fire retardants, consumed as much as 5,000 tons of boron content per year. The use of fire-retardant chemicals such as zinc borate in the plastics industry enjoyed a very rapid growth in this market.

The list of miscellaneous uses is very diverse: Borates as fluxing material and as shielding slag in the nonferrous metallurgical industry; borate compounds as components in plating baths in the electroplating industry; ferroboron in small amounts in specialty steels; boron in nonferrous alloys such as surfacing metal that are subject to heavy wear; boron nitride compounds as abrasives; boric acid as a catalyst in air oxidation of hydrocarbons to key nylon intermediates, in the oxidation of paraffins to higher alcohols used as intermediates for surfactants, and as a conditioning agent in the manufacture of ammonium nitrate; and various boron products used in pharmaceuticals, paper, textile, leather, nuclear shielding, photography, paints and varnishes, adhesives, and pyrotechnics, and in a few commercial automotive fuels as boron esters to inhibit surface ignition and spark plug fouling.

U.S. demand for boron minerals and compounds is expected to increase substantially in view of the strong growth projected for a large variety of end uses, including textile fiberglass, heat-resistant glass, cellulosic insulation, and fire-resistant cotton batting.

PRICES

U.S. boron mineral and chemical prices, which were unchanged in 1975, were raised at least 12% (depending upon the product) at the beginning of 1976. The average value of 1976 borate mineral shipments was $293 per ton of B_2O_3, compared with $268 in 1975. As a result of general inflationary pressure plus the continued sharply rising cost of energy for industrial purposes in California, a further rise of around 7% was announced at yearend to take effect in early 1977. The rounded dollar figures quoted in table 2 are for U.S. f.o.b. plant prices per short ton of product.

Table 2.—Borate prices per short ton, 1976[1]

Product	Dec. 31, 1976
Borax, technical, anhydrous, 99%, bulk, works	$203-$248
Borax, technical, pentahydrate, 99-1/2%, bulk, works	105- 110
Borax, technical, decahydrate, 99-1/2%, bulk, works	82- 91
Boric acid, technical, 99.9%, bulk, works	202- 227
Boric acid, anhydrous, 96.0% B_2O_3, bulk, works	[2]538
Colemanite, American Borate Corp., calcined and screened, minus 70 mesh, 47% B_2O_3, f.o.b. railcars, Dunn, Calif.	[3]184
Colemanite, Turkish, 42% B_2O_3, crude, lump, f.o.b. railcars, U.S. east coast port	[4]134

FOREIGN TRADE

U.S. exports of boric acid increased to 36,492 tons valued at $12.4 million in 1976, compared with 33,697 tons valued at $11.5 million in 1975. Exports of refined sodium borate showed a small decrease—to 211,362 tons valued at $49.2 million in 1976, from 212,266 tons valued at $42.5 million in 1975. In addition, a large amount of crude sodium borate (mostly Rasorite 46 with a B_2O_3 content of 48%) was exported and not reported in U.S. trade statistics. However, beginning in 1978, it will be reported as part of the official U.S. trade statistics. Exports of crude sodium borates remained the same compared with 1975.

A detailed breakdown of reported exports in 1975 is shown in table 3. Within this table, data for all countries outside Western Europe are fairly accurate. The aberration of high exports of refined sodium borates to the Netherlands continued in 1976, explained by the fact that the Netherlands is a major transshipment point rather than the final destination. A more meaningful tabulation of consuming nations, including the exports of crude borates, would show that West Germany, France, the United Kingdom, Belgium, and Italy were ahead of the Netherlands in that order.

In 1976, the United States imported 30,247 short tons of commercial-grade colemanite (calcium borate) valued at $1,953,000, all from Turkey. It was used principally for insulation fiberglass manufacturing. This compared with 27,641 short tons valued at $1,560,000 in 1975. Enamels and cleaning compounds were the principal borate markets in Europe. Sodium perborate was very effective as a detergent and bleaching agent because of the higher washing temperatures commonly used. This end use accounted for almost one-third of the total European borate consumption, but only about 5% of U.S. consumption.

Table 3.—U.S. exports of boric acid and sodium borates, in 1976

Destination	Boric acid (H_3BO_3 content) Quantity (short tons)	Boric acid (H_3BO_3 content) Value (thousands)	Sodium borates (refined) Quantity (short tons)	Sodium borates (refined) Value (thousands)

WORLD REVIEW

Argentina.—Argentina remained the only known producer of boron minerals in South America in 1976, maintaining a borate minerals output of 86,000 short tons. Boroquimica, an RTZ Borax Ltd. subsidiary, produced the major portion of the output from its Tincalayu mine in the Salar del Hombre Muerto basin in the Salta region of northwest Argentina. A small production also came from the Compañía Productora de Boratos. Most of the output was consumed domestically, with some exports to other countries in the Latin America Free Trade Area. In 1976, 24,208 short tons of sodium and calcium borates was reportedly exported to Brazil. The production and export of calcium borate in this case indicated that the Salar de Pastos Grandes deposit near the Tincalayu mine may also be in operation.[2]

Bolivia.—Although there was no current production, it was known that there were large deposits of sodium carbonate, ulexite, and borax associated with the Salara de Uyuni and Coipasa as well as other smaller saltpans on the Altiplano. The most important deposit appeared to be located just south of the Salara de Uyuni.[3]

[2]Bank of London and South America Review. March 1977, p. 136
Kistler, R. B., and W. C. Smith. Boron and Borates. Ch. in Industrial Minerals and Rocks, 4th ed., A.I.M.E., New York, 1975. p. 487.
[3]U.S. Embassy, La Paz, Bolivia. State Department Airgram A-38, Apr. 29, 1977, p. 61.

Chile.—Production of ulexite from Ascotan and boric acid from the refinery at Coya Sur was being phased out. In 1974 there was a small production of 1,100 tons, and no production was reported in 1975. In 1976, it was reported that only 3.5 short tons of ulexite with a 31% B_2O_3 content was produced.[4]

China, People's Republic of.—The People's Republic of China produced a sufficient but relatively unknown amount of borate minerals, and little is known about the industry. A decade ago, it was reported that a borax plant with hundreds of furnaces was built at Iksaydam, which is a 15-square-mile salt lake near Chaha in Tsinghai Province in northwest China at an elevation of over 10,000 feet. This lake is also a major salt producer, and the borax is a byproduct of the brine refining.[5]

A comprehensive survey in 1976 by Chinese scientific workers on the Chinghai-Tibet plateau established that Tibet had almost 1,000 lakes, most of which are brackish or salt, and with abundant borax content in many of the lakes in northern Tibet.[6]

Small shipments of approximately 430 short tons of borate minerals were exported to Japan in 1976, while 100 tons of refined products, mostly borates and perborates, were imported from Japan.

France and Spain.—Increased boric acid refining capacity was completed during 1976 at the plants of RTZ Borax Ltd. in France and Spain, and the new installations were reported as operating satisfactorily.[7]

Germany, East.—Small quantities of borates were recovered during potash mining and processing operations in the Strassfurt area. It is estimated that 4,200 tons of processed borax decahydrate was produced in 1976 and similar amounts in 1974 and 1975.

Other South America.—There are over 40 borate deposits in the high Andes along a 550-mile stretch of the common borders of Argentina, Bolivia, Chile, and Peru. This tectonic-volcanic belt has many closed basins with playas or salt flats, called salares. Resources are large, but any figures lack supporting data. Prior to 1950, Chile was an important producer of ulexite for the world market, and Peru exported ulexite from 1894 until the 1920's. Almost all production from South America at present is from the Salta Province of Argentina.[8]

Turkey.—The Turkish third 5-year plan (1973-77) and other programs have emphasized the importance of the mining sector to the growth of the Turkish economy. This is true even though mineral production accounts for only about 1.5% of the gross national product and for about 8% of the combined value-added in manufacturing and mining. Mineral exports, led by chromite, borates, and magnesite, contributed $130 million, or 6.5% of overall export earnings, in 1976. A continuing recommendation of the 1977 Annual Program, released by the Government on December 1, 1976, was the nationalization of boron minerals, effectively limiting exploitation to the public sector. Pragmatically, this was already a fait accompli, as Etibank apparently controlled 98.5% of the reserves and produced over 60% of the 1976 production.[9]

Production of borate minerals in Turkey in 1976 was 1,005,000 short tons of 27% to 46% B_2O_3 content, as provisionally reported by the Turkish State Institute of Statistics, Mineral Division. This was about 5% less compared with 1975. The boron mineral industry, dominated by the mines, washing concentrators, and refineries of Etibank (the Turkish Government mining corporation responsible for all State mining activities), continued its production at about the same rate in 1976 as 1975. Sales were not as high as expected, but towards yearend new orders increased rapidly.

Installation of the new 110,000-ton-per-year boric acid plant at the port city of Bandirma was proceeding on schedule. Tenders for equipment went out at yearend, and completion was scheduled for 1979. Total investment cost was estimated at approximately $19 million, with escalation considerations.[10]

Etibank's large boron chemical complex planned for the Kirka area has been plagued with delays and cost increases. The facilities, with a planned capacity of over 284,000 tons of boron products per year, were originally scheduled for completion in 1973 at a cost of $2 million. In 1976, completion was scheduled for 1979 at a cost of $69 million.[11]

U.S.S.R.—In 1976, Japan reported imports of 4,079 short tons of crude borates from the U.S.S.R., 2,686 short tons of boric acid, 29 short tons of boric oxide, and 440 short tons of other sodium borates. These were increases compared with those of 1975. Only minor amounts of Japanese borate chemical exports to the U.S.S.R. were noted.

TECHNOLOGY

In one important area of research U.S. Borax & Chemical Corp. received a British patent (No. 1,465,299) on the froth flotation recovery of clean crystalline boric acid from a hot slurry obtained by treating borate minerals or compounds with sulfuric acid. By this patented process, the warm-to-hot acid slurry is treated with a salt of a polymeric carboxylic acid as a crystal modifier and with an anionic silicone as a froth modifier. The treated slurry is then cooled, and subjected to flotation to obtain a froth concentrate of crystalline boric acid containing substantially no clay slime or sodium sulfate. The industry awaited the commercial feasibility of this technique, which holds considerable promise for the treatment of low-grade and off-grade ores.

Fiberglass-reinforced plastic storage tanks developed into one of the fastest growing tank materials for the storage of petroleum and chemical products. Corrosion resistance and lightweight characteristics made installation faster, easier, and more economical.

The use of alkali-resistant glass-fiber-reinforced cement for cladding panels, retaining walls, and acoustical hoods resulted in a new construction material which is strong, relatively lightweight, and very versatile. It is also noncombustible and flexible and has a high impact resistance.[12]

Bromine

By Russell J. Foster[1]

The amount of elemental bromine sold or used by domestic producers in 1976 increased 8% to an alltime high of nearly 440 million pounds owing to greater demand for ethylene dibromide and flame-retardant compounds. The total value of bromine and bromine compounds sold by producers was $206 million.

Arkansas continued as the dominant site of the industry. During the year four bromine producers located in Arkansas either expanded capacity or were constructing new facilities for the manufacture of bromine-related products. Another producer announced plans to shift bromine operations from Michigan to its plant in Arkansas within 2 years.

The authority of the Environmental Protection Agency (EPA) to regulate the lead content of gasoline was upheld by the courts, signaling what should be reduced demand in the future for ethylene dibromide as an additive for leaded gasoline. EPA also questioned the use of ethylene dibromide as a pesticide. The possibility of harmful effects on those exposed to high concentrations of the flame-retardant polybrominated biphenyl was being evaluated in Michigan. Another flame-retardant, tris(2,3-dibromopropyl)phosphate, was named as a possible carcinogen.

DOMESTIC PRODUCTION

The quantity of domestic elemental bromine sold or used increased 8% in 1976 to a record level of 439,538,000 pounds. Sales of bromine compounds by producers climbed 7%. After 2 years of decline, ethylene dibromide sales showed an 8% gain in 1976. The amount of methyl bromide sold rose less than 1%, but other bromine compounds sales, including flame-retardants, increased 6%. The total value of bromine compounds and elemental bromine rose nearly $5.8 million. This can be attributed solely to greater production, because the unit value of elemental bromine and the average price of manufactured compounds both declined.

There were nine bromine-producing plants operated in two States by six companies. Three of these companies combined produced 83% of the U.S. output. The State of Arkansas maintained its position as the Nation's principal source of bromine, but, the State-appointed Brine Study Commission continued to evaluate problems related to health, the environment, and royalty payments to local landowners.

The Great Lakes Chemical Corp. brought a new bromine plant onstream at Marysville, Ark., in February 1976. The cost of the facility was more than $10 million.[2] Great Lakes and Produits Chimiques Ugine Kuhlmann of France agreed to form a jointly owned company, Forex Chemical Corp., in the United States to manufacture and market brominated fire-extinguishing compounds.[3]

Michigan Chemical Corp. announced plans to phase out the operations of its St. Louis, Mich., plant during the next 2 years. By September 1978, bromine-based operations will be shifted to the El Dorado, Ark. plant, where construction was begun on a

$9 million, multimillion pound, flame-retardant-products complex. Completion of the unit was scheduled for early 1977.[4] Michigan Chemical and Velsicol Chemical Corp., both subsidiaries of Northwest Industries, Inc., agreed to a merger effective January 1, 1977.[5]

The Dow Chemical Co. revealed a plan to quadruple production capacity for calcium bromide at its Midland, Mich., plant by 1977.[6] Dow closed its ethylene dibromide unit at Midland in July 1976, diverting the bromine to the manufacture of other bromine compounds.[7] The company continued ethylene dibromide production at its plant in Magnolia, Ark., where bromine capacity was increased in 1976.

Ethyl Corp. initiated a $15 million expansion of its plant at Magnolia, Ark. The first of two new units was completed in the fall of 1976 for the manufacture of an agricultural chemical intermediate. The second facility, slated for startup in early 1977, will produce alkyldimethylamines. Both operations will utilize bromine chemistry for the production of these materials.[8]

CONSUMPTION AND USES

Demand for ethylene dibromide as a lead-scavenging additive in leaded gasoline increased in conjunction with higher gasoline consumption in 1976. Due to greater production of other bromine compounds, ethylene dibromide's share of bromine sold or used by producers remained at 56%.

The lengthy court battle over the EPA phasedown of lead in gasoline reached a conclusion. The suit brought by Ethyl Corp. and others against EPA initially received a favorable decision in December 1974 when a U.S. Court of Appeals ruled that EPA failed to prove its contention that lead emissions from auto exhausts were a significant health hazard. In March 1976, the same court vacated that judgment, permitting EPA to proceed with the phasedown. In June, the U.S. Supreme Court refused to hear the industry appeal, and EPA announced that enforcement would begin October 1, 1976. However, in late September, EPA delayed full implementation of the regulations. The 1976 and 1977 standards of 1.4 grams per gallon and 1.0 grams per gallon respectively, were deleted, and the 0.8 gram per gallon level effective January 1, 1978, would be suspended if the individual refining company could show that it had taken action toward procuring and installing the equipment needed to insure achievement of the final 0.5 gram per gallon standard by October 1, 1979. EPA felt that the original timetable would have imposed lead limits before refiners could install the equipment necessary to reach them, thus causing possible gasoline shortages in the summers of 1977 and 1978. A smaller, secondary use for ethylene dibromide, that of soil and space fumigation, was threatened when EPA listed it among pesticides that may be too dangerous to use.[9]

Consumption of methyl bromide, also used as an agricultural fumigant, was up only slightly in 1976 after a sharp increase in demand during 1975. Methyl bromide accounted for less than 5% of bromine sold or used.

Increased demand for other bromine compounds, which consumed 22% of the bromine sold or used, was paced by flame-retardants. The market for these chemicals has expanded dramatically owing to government flammability legislation.[10]

In March 1976, the Environmental Defense Fund claimed that tris(2,3-dibromopropyl)phosphate, a flame-retardant used in textiles including children's sleepwear, may cause cancer.[11] Results of extensive, long-term feeding studies with rats and mice at the National Cancer Institute were expected in early 1977. Tris was shown to be mutagenic by the Ames test, which has demonstrated a high correlation between mutagenicity and carcinogenic potential.[12]

A medical team from New York investigated the health of more than 1,000 people who had been exposed to high levels of polybrominated biphenyl in Michigan.[13] In 1973, this fire retardant was inadvertently substituted for a magnesium-oxide animal-feed supplement in Michigan, and thus was introduced into the food chain. Preliminary findings showed that approximately one-third of the group examined have suffered some ill effects, presumably caused by the chemical.[14]

The amount of elemental bromine sold as such to nonproducers declined 3% and accounted for nearly 13% of total bromine sold or used. Elemental bromine was utilized in water treatment, oxidation, and in the manufacture of bromine compounds.

PRICES

The average price, f.o.b. plant, of bulk elemental bromine as reported by producers in 1976 was 23.72 cents per pound, down 14% from the 1975 average price of 27.65 cents per pound. Quoted prices for bromine and selected compounds remained unchanged during 1976.

Product	Value per pound (cents)
Bromine, purified:	
Carlots, truckloads, delivered	75
Drums, carlots, truckloads, delivered east of the Rocky Mountains	55-62
Zone I:[1] Bulk tank car, tank trucks (45,000-pound minimum), delivered	25-30
Ammonium bromide, national formulary (N.F.), granular, drums, carlots, truckload, freight equalized	74
Bromochloromethane, drums, carlots, freight equalized	73
Tanks, same basis	71
Ethyl bromide, technical, 98%, drums, carlots, freight allowed, East	61.5
Ethylene dibromide, drums, carlots, freight equalized	37
Methyl bromide, distilled, tanks, 140,000-pound minimum, freight allowed	41
Potassium bromate, granular, powdered, 200-pound drums, carlots, f.o.b.	106
Potassium bromide, N.F., granular, drums, carlots, f.o.b.	67
Sodium bromide, 99% granular, 400-pound drums, freight, f.o.b.	65

[1]Delivered prices for drums and bulk shipped west of the Rockies, 1 cent per pound higher. Bulk truck prices 1 cent per pound higher for 30,000-pound minimum and 2 cents per pound higher for 15,000-pound minimum. Price f.o.b. Midland and Ludington, Mich., freight equalized, 1 cent per pound lower.

FOREIGN TRADE

Exports of elemental bromine and bromine contained in compounds increased 3% in 1976 to 67 million pounds and represented 15% of domestic bromine production. The amount of exported bromine compounds increased 2% while elemental bromine exports rose 22%. The value of total bromine exports increased 13%.

Imports of bromine amounted to less than 0.1% of domestic consumption. Approximately 73% of the bromine imported by the United States came from Israel.

Table 4.—U.S. exports of bromine and bromine compounds

(Thousand pounds and thousand dollars)

Year	Elemental bromine		Bromine compounds		
	Quantity	Value	Gross weight	Contained bromine	Value
1974	918	260	82,082	68,427	24,195
1975	3,635	1,037	72,395	61,598	25,791
1976	4,435	944	74,063	62,589	29,244

WORLD REVIEW

Israel.—Dead Sea Bromine Co., Ltd., announced plans to construct a 7,500-ton-per-year bromine-derivatives plant at Terneuzen in the Netherlands at a cost of $12 million. An Israeli trade agreement with the European Economic Community included reduction and eventual elimination of certain tariffs.[15] The company also planned to increase bromine production capacity to 55,000 tons per year by yearend 1978. The Biersheeba-based Bromine Compounds,[16] a sister company of Dead Sea Bromine Co.,

[15]Industrial Minerals. Bromine and Phosphate for Europe. No. 102, March 1976, p. 10.

[16]U.S. Embassy, Tel Aviv, Israel. State Department Airgram, A-192, Sept. 24, 1976, 6 pp., enclosure.

Ltd., was constructing a new plant at Ramat Hovev to process 44,000 tons per year of bromine.

Japan.—Toyo Soda Manufacturing Co. completed a 660-ton-per-year unit at its Nanyo plant for production of decabromodiphenyl ether, a flame-retardant additive for plastics. The expansion was facilitated by partial modification of an existing bromine-based agricultural chemical unit. Demand for the product increased due to more stringent U.S. flammability regulations concerning plastics used in electric household appliances.[17]

Asahi Glass Co. started up a plant to produce 500 tons per year of bromine-based flame-retardants at Kita-Kyushu.[18]

Poland.—The Geological Institute of Warsaw has established that the bromine content of underground waters in the Lower Silesia and the Wielhopolska areas is 36 million tons.[19]

United Kingdom.—The bromine flame-retardants section of Steetley Co.'s Stratford plant in London was closed. Expected legislation covering the flammability of certain materials had not yet been introduced in Parliament.[20]

Table 5.—Bromine: World production, by country

(Thousand pounds)

[e]Estimate. [p]Preliminary. [r]Revised.
[1]In addition to the countries listed, several other nations produce bromine, but output data are not reported, and available general information is inadequate for formulation of reliable estimates of output levels.

TECHNOLOGY

Gould, Inc., of Chicago and the Electronic Power Research Institute, Palo Alto, Calif., signed an 18-month, $274,000 contract to develop and assess the economic and technical feasibility of using a zinc-bromine storage battery to serve as an electric utility load-leveling device. Load levelers are used to store power generated during early morning hours for use during peak demand periods later in the day.[21]

Calcium bromide gained increased acceptance as a completion fluid in high-pressure oil and gas wells. Production capacity of the high-density, solids-free solutions expanded dramatically in 1976.[22]

Bromine chloride for cooling water treatment in power generation facilities was undergoing advanced field evaluation.[23]

Cadmium

By Ronald J. DeFilippo[1]

In 1976 cadmium metal production in the United States declined for the fourth consecutive year as output fell to the lowest level since 1936. Apparent consumption returned to a median level from the low level of 1975. Imported cadmium metal, not including the cadmium content of imported flue dusts and zinc concentrates, provided 42% of the total U.S. supply, compared with 41% in 1975.

Seven plants and six companies accounted for the total domestic primary production. Canada was the major source of zinc concentrates from which cadmium was extracted as a byproduct. The producer price increased from $2 per pound at the beginning of the year to $3 at yearend.

Legislation and Government Programs.—In March, 63 tons of cadmium metal was sold by the General Services Administration (GSA) from national stockpile excesses. On October 1 the Federal Preparedness Agency recommended a new stockpile goal of 12,351 tons. The yearend uncommitted inventory of cadmium was 3,164 tons.

The Office of Minerals Exploration is authorized to loan up to 50% of approved exploration costs for cadmium. However, no new funds were available in 1976 for exploration contracts. Depletion allowances were 22% for domestic mines and 14% for mines in foreign countries.

The National Institute for Occupational Safety and Health (NIOSH) was developing new criteria for cadmium exposure in the workplace. Previous standards limited dust exposure to 200 micrograms per cubic meter and fume exposure to 100 micrograms over an 8-hour day. The new recommended standard proposed in August 1976 was that workers should not be exposed to more than 40 micrograms of cadmium per cubic meter on a time-weighted average up to a 10-hour day, 40-hour week, or to more than 200 micrograms per cubic meter for any 15-minute sampling period.

Late in the year, the Environmental Protection Agency (EPA) suspended its plating effluent regulations, which required that platers meet best practical technology

standards by July 1977. Most platers were already covered by discharge permits that allowed them to exceed the standards while treatment facilities were being designed and installed. EPA expected to have new, less stringent regulations by mid-1977.

DOMESTIC PRODUCTION

Domestic cadmium metal production was 439 tons in the first quarter, decreased to 434 tons in the second quarter, peaked at 491 tons in the third quarter, and then declined in the fourth quarter to 470 tons. Total cadmium metal production for the year was 2,256 tons, up 3% from that of 1975. The New Jersey Zinc Co. cadmium plant was producing only part of the year, and production of cadmium began at midyear from National Zinc Co.'s new plant. Metal shipments were 40% greater than metal production and were over three times greater than those of 1975.

Smelter production of cadmium metal in the United States averaged about 7 pounds of cadmium per ton of slab zinc produced, compared with 10 pounds in 1975, 12 pounds in 1974, and 13 pounds in 1973. In prior years the pounds of cadmium per ton of zinc ranged between 10 and 12. In recent years, primary producers have been making more compounds at the expense of metal.

Cadmium sulfide production (including cadmium sulfoselenide and lithopone) declined 18% from that of 1975, slightly more than the rate of decline for metal production.

Cadmium oxide was produced at two of the seven primary-metal-producing plants. One plant reported secondary production, which was remelted metal or refined cadmium. Data on cadmium oxide production are not published to avoid disclosing individual company confidential data.

Table 2.— Primary cadmium producers in the United States in 1976

Company	Plant location
AMAX Zinc Co. Inc	Sauget, Ill.
ASARCO, Inc	Corpus Christi, Tex.
Do	Denver, Colo.
Bunker Hill Co	Kellogg, Idaho
National Zinc Co	Bartlesville, Okla.
New Jersey Zinc Co	Palmerton, Pa.
St. Joe Minerals Corp	Monaca, Pa.

Table 3.—Cadmium sulfide produced in the United States

(Short tons)

1972	1,357
1973	1,412
1974	1,085
1975	987
1976	804

[1]Includes cadmium lithopone and cadmium sulfoselenide.

CONSUMPTION AND USES

Actual consumption data are not gathered by the Bureau of Mines. The apparent consumption of cadmium, 5,932 tons, was 76% above that of 1975. Metal used for electroplating hardware used in transportation vehicles and stationary mechanical and electrical equipment was estimated to account for slightly less than half of the total U.S. cadmium consumption. Cadmium compounds used for red, orange, and yellow pigments and other compounds used as plastics stabilizers accounted for an additional one-third of U.S. consumption. The remainder of U.S. consumption was accounted for by cadmium metal and compounds used in alloys, nickel-cadmium batteries, and specialized electronic devices.

STOCKS

Stocks of cadmium metal held by metal producers at the end of 1976 decreased 34% to 1,369 tons. The metal stocks of compound manufacturers increased 23%, and metal stocks of distributors increased 31%.

Table 5.—Industry stocks, December 31

(Short tons)

	1975		1976	
	Cadmium metal	Cadmium in compounds	Cadmium metal	Cadmium in compounds

Distributors	213	34	279	29
Total	2,419	422	1,811	576

W Withheld to avoid disclosing individual company confidential data; included with "Compound manufacturers."

PRICES

Producers, all beset by large inventories, began the year with cadmium priced at $2 per pound. Late in February, increased European prices put upward pressure on domestic prices. ASARCO, Inc. raised its cadmium quote to $2.50 per pound on March 8, and by March 10 all U.S. producers quoted the same price. Also on March 10 GSA raised the price for cadmium to $2.42. On April 5 ASARCO raised its price to $2.75 per pound, and National Zinc Co. and Bunker Hill Co. followed closely. By April 29, the other three producers raised their prices to the same level. Bunker Hill raised its quote to $3 per pound on August 5, and by August 31 all other U.S. producers had followed. The producer price for cadmium remained at $3 through yearend. Dealer prices were generally the same as producer prices with some discounting at the beginning and end of the year.

Table 6.—Cadmium prices, 1976

(Dollars per pound)

Date	Producer price (1- to 5-ton lots)
Jan. 1 to Mar. 8	2.00

Apr. 5 to Apr. 29	2.50–2.75
Apr. 29 to Aug. 13	2.75
Aug. 13 to Aug. 31	2.75–3.00
Aug. 31 to Dec. 31	3.00

FOREIGN TRADE

Exports of cadmium metal and scrap increased from 198 tons in 1975 to 252 tons in 1976. The principal recipient countries were Belgium-Luxembourg, 51%; the Netherlands, 30%; and France 13%.

Imports of cadmium metal increased 30% over those of 1975. Canada was the largest supplier of metal with 31% of the total, followed by Australia, 12%; Mexico, 12%; Yugoslavia, 9%; Belgium-Luxembourg, 8%; West Germany, 4%; France, 4%; and the Republic of Korea, 3%. The cadmium content of flue dust imported from Mexico decreased 29% from that of 1975.

WORLD REVIEW

World smelter production of cadmium increased 9% over that of 1975. Japan, the U.S.S.R., the United States and West Germany were the largest cadmium producers with 17%, 16%, 10%, and 9%, respectively, of the world total. Apparent U.S. consumption was 30% of world production.

On July 12 the Cadmium Association was formed in London. The Association is operated in conjunction with the Lead and Zinc Development Association and will include cadmium producers outside the United States and Canada. The U.S. counterpart is the Cadmium Council, formed earlier in the year as part of the Zinc Institute, Inc. Both organizations will cooperate in technical publications, development work, and market surveys. The first joint meeting was scheduled to be held at the First International Cadmium Conference in San Francisco, Calif., from January 31 through February 2, 1977.

TECHNOLOGY

Cadmium in the environment and its effects on human health remained an important area of research. An isotope dilution technique was developed in Australia to establish a baseline for other measurements of the environmental levels of cadmium. Sensitivity of the technique was reported as 0.02 to 0.10 microgram per liter.[2] The effects of chronic exposure to cadmium were evaluated including those in glucose homeostasis, the glandular system, and the central nervous system.[3] Cadmium metabolism in animals was the subject of a study that concluded that muscle meat and milk of animals fed a high-cadmium diet were safe for human consumption.[4] The influence of factors such as soil pH, the presence of ammonium nitrate, and soil type on the accumulation of cadmium from superphosphate fertilizers was studied. These fertilizers contain up to 100 parts per million (ppm) cadmium, and uptake by crops has been a cause for concern.[5] The assimilation of cadmium by shellfish was the subject of two investigations. In one study, oysters exposed to seawater containing 0.005 ppm cadmium for 40 weeks were found to have accumulated up to 10.75 ppm cadmium.[6] Another study determined the accumulation of cadmium in various shellfish which were under intensive cultivation using municipal wastes as a nutrient

[e]Estimate. [p]Preliminary. [r]Revised.

[1]This table gives unwrought metal production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovered from scrap) is included or not; where known, this has been indicated by footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, London) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main). Cadmium is produced in ores, concentrates, and/or flue dusts in a number of other countries, but these materials are exported for treatment elsewhere to recover cadmium metal; therefore, such output is not recorded in this table to avoid double counting.

[2]Includes secondary.

[3]Output of Tsumeb Corp. for calendar years.

source.[7] Urine analyses of Australians and Western Europeans indicated a daily cadmium intake of 30 to 50 micrograms.[8] The safety of cadmium pigments was investigated. It was concluded that cadmium pigments in plastics that came in contact with food did not leach intolerable amounts of cadmium.[9]

Comparisons were made between the corrosion resistance of electroplated zinc and cadmium coatings. It was determined that cadmium had a better resistance to marine atmospheric corrosion.[10] A summary of the practical and theoretical aspects of cadmium plating was presented which discussed various alloy systems including zinc-cadmium, cadmium-gold, and cadmium-silver.[11] A tin-10% cadmium alloy solder was found to reduce embrittlement in joining gold-plated components.[12] An outline of the EPA's regulations on plating

effluents was given,[13] and methods and costs were discussed.[14] One plater reported using an evaporator to concentrate its effluents. This not only eliminated cadmium pollution but saved $9,000 worth of chemicals annually.[15]

An investigation was conducted into the mechanism by which cadmium nucleants lower the corrosion rate of lead-4% antimony alloys for batteries. Corrosion rate reductions of 50% were attained by the addition of 0.1% cadmium.[16] A photovoltaic cell using n-type cadmium sulfide or cadmium selenide cells in a sodium hydroxide electrolyte was studied. Power output of 0.14 milliwatt with an efficiency of 1% was attained.[17] A method for extracting cadmium, indium, and zinc from aqueous solutions using a phosphoric acid ester was patented.[18] Special applications of nickel-cadmium batteries were reported including a quartz wristwatch, a light aircraft powered by a bank of 120 cells, a standby lighting source, and a power supply for a deep-sea camera unit.[19]

Developments in cadmium technology are abstracted in Cadmium Abstracts, a bimonthly publication available from the Zinc Institute, Inc., 292 Madison Ave., New York, N.Y. 10017.

Calcium and Calcium Compounds

By J. W. Pressler[1]

Calcium metal was manufactured by one company in Connecticut. Calcium chloride was produced by two companies in California and three companies in Michigan. Synthetic calcium chloride was manufactured by one company in New York and two companies in Washington.

DOMESTIC PRODUCTION

Pfizer Inc. produced calcium metal at Canaan, Conn., by the Pidgeon process, in which quicklime and aluminum powder are heated in vacuum retorts; at a temperature of 1,170° C, calcium vaporizes and is collected at one end of the retort.

National Chloride Co. of America and Leslie Salt Co. produced calcium chloride from wells in San Bernardino County, Calif. Output increased 15%. The Dow Chemical Co., Michigan Chemical Corp., and Wilkinson Chemical Corp. recovered calcium chloride from brine in Gratiot, Lapeer, Mason, and Midland Counties, Mich. Output increased 9%. Total production of natural calcium chloride was 649,000 tons, an increase of 9% compared with 1975 production.

Allied Chemical Corp. recovered synthetic calcium chloride as a byproduct of soda ash at Syracuse, N.Y.; Reichold Chemicals, Inc. recovered synthetic calcium chloride as a byproduct of pentachlorophenol manufacture at Tacoma, Wash.; and Hooker Chemicals & Plastics Corp. manufactured calcium chloride at Tacoma using limestone and hydrochloric acid. Total output of synthetic calcium chloride was 248,000 tons, an increase of 6% compared with that of 1975.

The total value of all calcium chloride sold in 1976 was an alltime record high of $47 million.

CONSUMPTION AND USES

Calcium metal was used as a reducing agent to separate metals such as columbium, tantalum, thorium, titanium, uranium, vanadium, and zirconium from their oxides; to form alloys with aluminum, lead, lithium, magnesium, and silicon; as a scavenger in the steel industry; and in the manufacture of calcium hydride. The use of calcium metal in the new maintenance-free (MF) storage battery increased rapidly in 1976, with two of the largest battery producers reporting threefold increases in the production of Pb-Ca MF batteries. General Motors Corp. was apparently committed to the use of MF batteries in 65% of its cars in 1977 and 100% by 1980.

The principal use of calcium chloride was to melt snow and ice from roads, streets, bridges, and pavements. Calcium chloride is more effective at lower temperatures than rock salt and is mainly used in the northern and eastern States. Because of its considerably higher price, it is used in conjunction with rock salt for maximum effectiveness

[1]Physical scientist, Division of Nonmetallic Minerals.

and economy. It was also used to stabilize the surface of roads and driveways for dust reduction and as a set-accelerator for concrete.

PRICES AND SPECIFICATIONS

The price of calcium metal crowns was maintained at $1.33 per pound through all of 1976; the last increase was March 21, 1975. The price of calcium-silicon alloy decreased from 57 cents per pound to 51 cents on January 21, 1976, and maintained that level throughout the remainder of the year. Published prices and specifications at yearend were as follows:

	Value per pound
Calcium metal, 1-ton lots, 50-pound full crowns, 10 by 18 inches, Ca+Mg 99.5%, Mg 0.7%	$1.33
Calcium-silicon alloy, 32% calcium, carload lots, f.o.b. shipping point	.51

Source: Metals Week. V. 48, No. 1, Jan. 3, 1976, p. 4.

Calcium metal is usually sold in the form of crowns, broken pieces, or billets, shipped in 55-gallon metal containers with a maximum of 300 pounds, and gasketed to provide an airtight condition, with argon atmosphere provided if desired. The U.S. Customs-declared value for calcium metal in 1976 ranged from $0.73 to $1.28 per pound, c.i.f. port of entry into the United States. This did not include the assessed tariff, which varied from 7.5% ad valorem for preferential status, to 25% ad valorem for statutory status.

Calcium chloride is usually sold either as solid flake or pellet averaging about 75% $CaCl_2$, or as a concentrated liquid averaging about 40% $CaCl_2$. The price of calcium chloride maintained its level throughout the year. Published prices and specifications at yearend were as follows:

	Value per ton[1]
Calcium chloride, regular grade, 77% to 80%, flake, bulk, carload, works	$55-$65
Calcium chloride, liquid, 40% to 45%, tankcar or tanktruck, works	22-24

[1]Differences between high and low price are accounted for by differences in quantity, quality, and location.

Source: Chemical Marketing Reporter. V. 211, No. 1, Jan. 3, 1977, p. 52.

As reported by producers on an f.o.b. warehouse basis, with conversions of all products to a 75% $CaCl_2$ basis, the average value in 1976 for natural calcium chloride was $50.68 per ton; the average value for synthetic calcium chloride was $57.92 per ton.

FOREIGN TRADE

Exports of calcium chloride, mainly to Canada and Mexico, were 33,533 tons valued at $2,578,000, compared with 28,400 tons valued at $2,314,000 in 1975. Exports of dicalcium phosphate were 32,302 tons valued at $6,460,000; leading destinations were Canada, Mexico, and Brazil. Exports of precipitated calcium carbonate, mainly to Canada and Mexico, totaled 3,411 tons valued at $735,000.

Total imports of calcium and calcium compounds were 208,000 tons valued at $15,120,000. Imports of calcium metal from Canada, the U.S.S.R., and France were 231 tons valued at $475,000. Imports of calcium chloride, mainly from Canada, were 16,000 tons valued at $480,000. Imports of other calcium compounds, mainly from Turkey, Canada, Norway, the United Kingdom, and France totaled 191,800 tons, valued at $14,160,000.

Imports of other calcium compounds included 63,770 tons of calcium nitrate, mainly from Norway; 37,230 tons of calcium cyanamide, mainly from Canada; 35,920 tons of chalk whiting, mainly from France, Switzerland, the United Kingdom, and Belgium; 30,250 tons of calcium borate from Turkey; 4,500 tons of calcium carbide from Canada and West Germany; 4,350 tons of precipitated calcium carbonate, mainly from Japan, France, Canada, and West Germany; 1,470 tons of calcium cyanide from Canada; 1,030 tons of calcium hypochlorite from Japan and Taiwan; and 6,580 tons of other compounds, mainly from the United Kingdom, Canada, and West Germany.

Table 1.—U.S. imports for consumption of calcium and calcium chloride, by year

Year	Calcium		Calcium chloride	
	Quantity (pounds)	Value	Quantity (short tons)	Value
1972	248,080	$181,437	6,128	$225,463
1973	110,407	77,864	7,357	317,007
1974	109,252	120,883	3,599	155,727

Total	16,046	480,259

[1]Less than 1/2 unit.

WORLD REVIEW

Canada.—Chromasco Corp. Ltd. produced calcium metal at its Haley smelter near Renfrew, Ontario. Canada continued to lead all other countries in the production of calcium metal, producing about 1 million pounds per year, with most of it exported to the United States and European countries. About 165 tons valued at $392,000 was exported to the United States, more than a sixfold increase compared with the 25 tons imported in 1975. Canada was the leading source of U.S. imports of calcium chloride.

France.—Planet Wattohm S.A., a subsidiary of Compagnie de Mokta, produced calcium metal by the Pidgeon process. About 1 ton valued at $8,800 was exported to the United States.

U.S.S.R.—Some calcium metal was produced in the U.S.S.R. Sixty-five tons of Soviet calcium metal valued at $74,297 was exported to the United States.

TECHNOLOGY

The market potential substantially increased for the use of calcium metal in the Pb-Ca and Pb-Ca-Sn MF storage battery. In 1976, battery manufacturers in the United States produced over 3 million units of this new permanent MF battery. Some technical difficulties such as sustained performance for deep-cycle operations remained to be solved, but these are of special application.

Calcium chloride was considered as a potential phase-change heat-storage material by microencapsulation in polyester resin, and small wall, floor, and ceiling panels were successfully tested.[2]

Rapidly increasing worldwide demand in the oil and gas industry for high-density, solids-free completion, packer, and workover fluids necessitated rapid expansion for the production of calcium bromide. Calcium bromide is a superior chemical in producing high-density drilling fluids, and would replace the traditional barite.[3]

Carbon Black

By Herbert L. Franklin[1]

By early 1976 general economic recovery was well underway in the United States, and rubber industry leaders were looking forward to sales levels approximating those in the near-record year of 1972. This meant a good year for carbon black manufacturers since rubber manufacturers accounted for 93% of carbon black sales in 1976. Early optimism for high sales volumes was blunted, however, by the longest rubber workers' strike in history, which kept carbon black demand 7% below 1972 requirements. However, despite the 4-month strike, carbon black sales rose 7.1% above the depressed level of 1975.

Production of gas-based channel black, which has declined steadily for the past 10 years, ended in September when the only remaining channel-black plant was closed. Thermal-black production, which is also dependent on natural gas as a feedstock, reversed its declining trend as output increased almost 27% over 1975 levels.

Raw-material input patterns did not change significantly, although the share of natural gas feedstocks apparently increased slightly over that of 1975. The average unit cost of liquid hydrocarbon inputs, 25.72 cents per gallon in 1976, decreased slightly from that of 1975, but the cost for natural gas, 87.71 cents per thousand cubic feet in 1976, was up sharply.

Use of carbon black as a colorant in foodstuffs and cosmetics was banned by the Food and Drug Administration (FDA) because it was believed to contain a cancer-causing substance, but this action affected only a small portion of carbon black sales. However, a new type of plastic tire has reportedly been developed that could lead to a significant reduction in carbon black sales as a rubber-compounding agent.

Pricing problems continued to plague the industry as demand levels, suppressed by the rubber workers' strike, remained low. Price increases by yearend were considered inadequate to offset rising costs.

DOMESTIC PRODUCTION

Production Trends.—In 1976, carbon black production rebounded from the recessionary levels of 1975 to 3,004 million pounds plus an undisclosed amount of channel black. However, this was substantially lower than early forecasts, which predicted a return to a high level of activity similar to that achieved in 1972. General economic recovery and the resultant increase in demand for rubber products, particularly tires, would have supported early optimistic estimates. However, a 4-month strike by rubber workers suppressed rubber production and hence reduced sales of carbon black, which were about 7% below expected levels.

Production by State.—Texas and Louisiana, with the greatest concentration of carbon black production facilities and proximity to raw materials, comprised the geographic center of national production. Texas was the leading producer with 44% of national output, and Louisiana was second with 34%. The remaining U.S. production took place in Alabama, Arkansas, California, Kansas, Ohio, Oklahoma, and West Virginia.

Production by Grade and Type.—Furnace-combustion processing remained the dominant method of production with 94.9% of reported output; thermal cracking facilities accounted for the remainder. An undisclosed amount of channel black was also produced. Processing methods based on liquid hydrocarbon feedstocks accounted for 84.2% of the reported national output. Products of the liquid hydrocarbon feedstocks included General Purpose Furnace (GPF), Fast Extruding Furnace (FEF), High Abrasion Furnace (HAF), Intermediate Super Abrasion Furnace (ISAF), and Super Abrasion Furnace (SAF). Surprisingly, thermal and Semi-Reinforcing Furnace (SRF) blacks, produced from natural gas feedstocks, increased their combined share of national output from 13.3% in 1975 to 15.8% in 1976.

Number and Capacity of Plants.—Although the total number of carbon black plants in operation at yearend remained at 32 (the same as in 1975), 1 plant ceased operating and another resumed operations during the year. Furnace blacks were produced at all but one of the plants currently in operation, and thermal black was produced at three facilities. In recent years channel black producers have faced rapidly rising feedstock costs and stringent environmental pollution control requirements. The environmental problems associated with channel black production were greater than those involved with the production of fur-

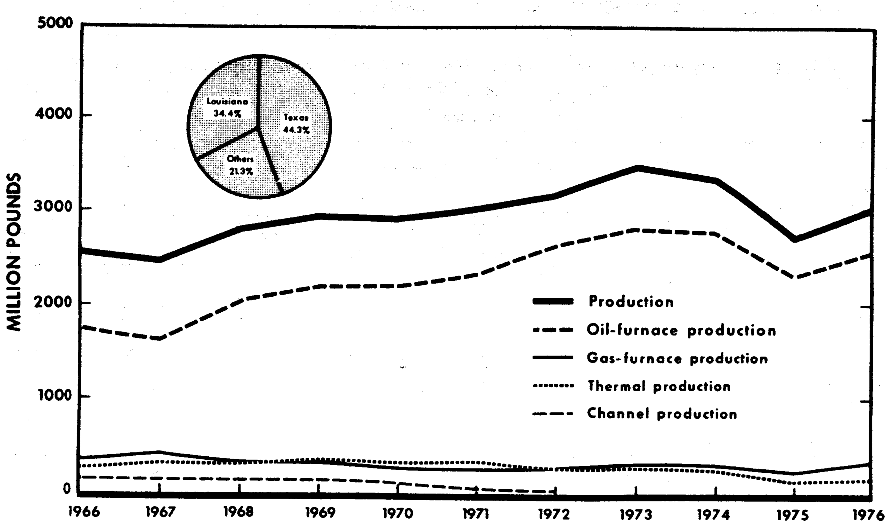

Figure 1.—U.S. production by process and geographic area.

nace blacks. By 1974, only Cities Service Co. continued producing channel black, and in September 1976 that firm closed its channel black plant at Gaines, Tex. ending channel black production in the United States. In December 1976, Continental Carbon Co. reopened its Phenix City, Ala. furnace black plant, which had been closed since late 1973. Even though industry leaders expected a steady long-term growth in demand for carbon black, aggregate daily production capacity dropped for the second straight year, and no new domestic plant developments were reported. Capacity additions to existing facilities were designed mainly to replace older inefficient equipment rather than to increase overall productive capability. The lack of development activity was attributed primarily to unsatisfactory earnings, which failed to generate the capital necessary for large-scale expansion. However, it might also be noted that only 82% of existing capacity (based on 350 days of operation) was utilized.

Materials Used and Yields.—Carbon black production consumed greater amounts of both liquid hydrocarbons and natural gas during 1976 as the industry rebounded from the low output levels of 1975. Liquid hydrocarbons continued their dominance as a feedstock with 561.3 million gallons used to produce 2,859 million pounds of carbon black, or 95.2% of total production. Yields from liquid hydrocarbons increased slightly, from 5.04 pounds per gallon in 1975 to 5.09 pounds per gallon in 1976. Because natural gas data reported encompass both fuel and feedstock use, comparisons with liquid hydrocarbons cannot be made. However, in view of the increased share of natural-gas-based blacks produced, compared with total U.S. output, it can be deduced that natural gas actually increased its significance as a raw material as well as a processing fuel. The unit cost of liquid hydrocarbons used as feedstocks decreased slightly, from 26 cents per gallon in 1975 to 25.72 cents per gallon in 1976, thus interrupting the increasing trend of the past 5 years. Natural gas costs, however, continued their steep ascent with an increase of 26.2% over 1975 costs as the average price rose to 87.71 cents per thousand cubic feet.

CONSUMPTION AND USES

Early in 1976 economic indicators pointed toward a strong recovery in demand for carbon black from the depressed levels of 1975. Greater rubber demand was predicted, primarily on the basis of an upturn in construction activity, extensive bicentennial travel and thus greater tire use, required replacement of tires on the record number of new cars sold in 1973, trends indicating increased sale of new cars, and consumer preference for large cars requiring large tires. Thus it appeared that rubber production, which has traditionally accounted for more than 90% of carbon black use, would boost carbon black sales back to the levels of 1972.

During the first 4 months, shipments exceeded 1972 levels, and early optimistic forecasts appeared valid. However, a 4-month strike by rubber workers caused shipments during May through August to plummet 28% below those of the same period in 1972. Accelerated poststrike activity by the rubber industry stimulated demand for carbon black, thus causing sales to rise 6% above 1972 levels for the final 4 months of the year. However, this final acceleration in demand was not enough to overcome the impact of the strike, and sales totals for the year ended 7% below the 1972 level.

Traditional domestic use patterns changed very little during 1976. Rubber manufacturers consumed 93% of available carbon black with 60% used for tire production and 33% for other rubber products, particularly hoses and belts for vehicles, machinery, and construction equipment. Printing inks used 2.7% of the available product, and other non-rubber industries including paint, paper, chemical, food processing, metallurgy, and plastics used the remaining 4.3%.

Carbon black use in cosmetics and food manufacture was banned by the FDA because there was no reliable test to assure that the colorant is free of a cancer-causing byproduct. The byproduct, produced during manufacture of carbon black, adheres tightly to the surface of the carbon, and extreme heat and special solvents are required for its removal.

If a new type of tire, developed by Polyair, an Austrian plastic machinery maker, can be produced economically and proves to be technically feasible, it will have a major impact on rubber manufacturers and hence on the carbon black industry. The tire is known as a liquid injection molding (LIM) tire and is made of a polyurethane plastic. It has been reported that the tire can get up to 60,000 miles of tread life, is lighter than steel-belted radials, and can run up to 50 miles at 50 miles per hour after being punctured. However, raw material costs are expected to be higher than for the conventional rubber tire. An LIM tire production plant is scheduled to begin operating in Berlin, Germany, during 1977, and a second plant, also in Germany, may startup in 1978.

STOCKS

As of December 31, 1976 producers' stocks were at their lowest level since 1969. A significant drawdown occurred during the first quarter as rubber producers accelerated production in anticipation of a strike. During the subsequent 5 months producer stocks were increased 65.9 million pounds. Immediately following the strike in September, however, heavy demand by rubber manufacturers resulted in a drawdown of 77.6 million pounds. Demand remained strong for the rest of the year, and ending stocks were 8% lower than at the close of 1975.

Drawdowns occurred in all grades of carbon black except SRF and FEF. The greatest depletion took place in thermal blacks for the second straight year, and supplies at yearend were 35.2% less than that of 1975; this drawdown occurred despite a 26.6% increase in thermal black output during the year. Substantial increases in production of SRF and FEF blacks led to increased supplies of both grades at yearend; FEF blacks increased most significantly, rising nearly 55% above the 1975 yearend level. Stocks of the most heavily used blacks, HAF and GPF, decreased 15.7% and 19.1%, respectively.

PRICES

Increasing feedstock and operating costs since early 1974 and slack demand in late 1974 and throughout 1975 created a cost-price dilemma for carbon black producers that extended into 1976.

The cost of raw materials has contributed most heavily to overall production costs because heavy aromatic residual oils, the principal carbon black feedstock, have another use as fuel. As their value in the fuel market increases, carbon black manufacturers are forced to pay high fuel-competitive prices to obtain the feedstocks.

The carbon black industry was optimistic in early 1976 that an emerging healthy demand for its products would permit significant price expansion to offset the constantly increasing production costs. However, early optimism for a return to the sales level of 1972 was blunted by the prolonged strike by rubber workers. Consequently, the average price of a pound of carbon black increased only about 17% above that of 1975 to 13.07 cents per pound.

According to Chemical Marketing Reporter, average yearend prices ranged from 10.13 cents per pound for GPF and SRF grades to 14.88 cents per pound for SAF. The average yearend price difference between bulk and bag quantities was 0.75 cent per pound.

FOREIGN TRADE

Bureau of the Census data show an increase in carbon black exports to about 110.8 million pounds during 1976, nearly 26% above the level of foreign sales during 1975. Nearly 42% of U.S. exports went to Europe, where France, West Germany, and the United Kingdom continued to be the principal recipients. However, shipments to the United Kingdom dropped markedly, while purchases by Belgium-Luxembourg and the Netherlands rebounded strongly from their depressed levels of 1975. North American customers increased their share of purchases from about 25% in 1975 to nearly 28% during 1976, primarily as a result of Mexican purchases, which nearly doubled. The volume of Asian purchases increased slightly, but Asia's share of total purchases from the United States declined from 21% in 1975 to about 17% during 1976. As in 1975 sales to African nations accounted for nearly 9% of U.S. exports, but the South American share of U.S. exports dropped from about 5% in 1975 to approximately 4% in 1976.

Imports of carbon black increased nearly 32% during 1976, totaling approximately 44.2 million pounds. Canada supplied 90% of U.S. foreign purchases, and Indonesia and West Germany were the next two largest suppliers, accounting for 5.3% and 3.2%, respectively. Nearly 45,000 pounds of bone black was also imported, coming mostly from West Germany and France. There were no imports of lamp black reported in 1976.

The average price received from foreign sales of carbon black increased from 16.3 and 17.6 cents per pound in 1974 and 1975, respectively, to 24.6 cents per pound in 1976. In the same time period, U.S. consumers of foreign-produced carbon black paid average prices of 14.6 and 13.0 cents per pound in 1974 and 1975, respectively, and 15.9 cents per pound in 1976.

WORLD REVIEW

During 1976, estimated world production increased 11% over the 1975 level and approached the record high of 1973. The most significant producing areas were North America with nearly 43% of the estimated total output, followed by Western Europe and the Far East with about 29% and 14%, respectively. North American and West European producers rebounded from the recession of 1975 with overall average increases in productivity of about 12%. Production in the Far East increased even more sharply, rising approximately 13%. Although Latin America is not yet one of the leading production areas, it had the largest growth rate during 1976 with an increase in output of nearly 14%. Production in Eastern Europe increased slightly at a rate of about 3%.

Latin America and the Far East remained most active in construction of new plant capacity and expansion of existing capacity. In Latin America a new plant at Capuava, Brazil began production in November 1976; capacity of this facility has not been disclosed. Facilities under construction in Brazil during 1976 included a 33-million-pound-per-year expansion of the Cia. Carbonos Coloidas plant at Candeias and an 11.5-million-pound-per-year addition to the Cia. Petroquimica Brasileira plant at Sao Paulo. Other construction activity in Latin America included a new 40-million-pound-per-year plant at Tampico, Mexico, for Hules Mexicanos S.A., a 7.3-million-pound-per-year expansion to the Petroleos del Peru plant at Talara, Peru, and new plants for United Carbon de Venezuela of 35 million pounds per year at Bachaquero, Venezuela, and 21 million pounds per year at Valencia, Venezuela. In the Far East, a plant of undisclosed capacity was being constructed for Union Carbon Black at Assam, India, a 28-million-pound-per-year plant was under construction for Malaysian Carbon Seniderian Berhad at Port Dickson, Seremban, Malaysia; and a 10-million-pound-per-year plant was being erected for National Refinery, Ltd., at Karachi, Pakistan. In the Near East, a 15-million-pound-per-year plant was being constructed for Petkim Petrokimya, A.S., at Yarimca, Turkey.

TECHNOLOGY

A process for chemically decomposing scrap tires by pyrolysis was being tested by The Oil Shale Corp. (TOSCO) at its test facility near Rocky Flats, Colo. It is believed that an average of nearly 6 pounds of carbon black can be recovered from each tire by the TOSCO process.

The only other significant development reported during 1976 was the introduction of a new product known as Opal Black. This product, developed by Micro Chemical Industries, Inc., is cited as a substitute for thermal black in certain rubber-compounding applications. Opal Black is a fine-particle, high-surface-area, amorphous silica with carbon dispersed within the silica matrix. It is produced by burning rice hulls under special controls and grinding the ash residue into extremely fine particles.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, the People's Republic of China, Norway, Poland, Turkey, and the U.S.S.R. produce carbon black, but production statistics are not reported and available information is inadequate for the formulation of reliable estimates of output levels.

[2]Less than 1/2 unit.

[3]Includes vegetable black, but excludes acetylene and bone black.

Cement

By Norman E. Wingard[1]

Portland cement shipments from plants in the United States and Puerto Rico, including cement imported and distributed by domestic producers, totaled 71,922,000 tons in 1976. This amount was 6.1% higher than was shipped in 1975 but was 9.5% less than in 1974. In 1973, record high cement shipments of 86.6 million tons were recorded, 17% higher than in 1976. The 1976 figure represents a reversal in the 2-year downturn experienced during 1974-75.

Mill value for portland cement increased to $2.4 billion, 16% higher than that of 1975. This reflects an increase in the unit value of $2.77 per ton, or 9%.

The demand for cement during the year increased as the construction industry gained momentum after the recession, particularly in the first half of the year. During the first 6 months of 1976, construction was ahead of 1975. This was followed by 4 months of level activity, and the year ended with more gains in the final 2 months. Residential construction was almost solely responsible for the improvement. The number of housing starts increased from 1.15 million in 1975 to 1.55 million in 1976. In all, the construction industry developed about 75% of the volume reached in the early 1970's, representing a growth of about 8% compared with 1975 levels. The recovery of the construction industry, in fact, proceeded at a slower pace than had been expected, with the typically largest uses of cement, such as highway and industrial building, down from 1975.

Maintenance, repair, fuel, and operating costs were up significantly, especially at older plants. Higher prices, however, generally allowed companies to experience better mill-net profits despite increased production costs.

Little new capacity came onstream in 1976 or was scheduled in the near future; as a result, supply-demand approached a close balance in many market areas. With stable capacity, more plants were producing at near-capacity limits in 1976. Undercapacity within the next few years is a possibility.

Although little new capacity was developed during the year, a number of plant modernization and renovation projects were underway. Primarily aimed at increasing energy efficiency, virtually all major projects involved conversion to dry process with preheaters and the ability to use coal as a principal fuel.

Citadel Cement Corp. received an award from the city of Birmingham, Ala., for environmental improvements as a result of the installation of electrostatic precipitators in 1976. Southwestern Portland Cement Co. of Amarillo, Tex., received the 1976 Citation to Industry award from the Texas Panhandle Audubon Society for its effective reclamation of strip-mined lands. More than 70 acres of land was restored to productive grassland.

The Portland Cement Association (PCA) presented safety trophy awards to 34 plants that had injury-free operations in 1976. Medusa Cement Co. of Manitowoc, Wis., received its 29th reaward for 30 years without a disabling injury. Martin Marietta Corp.'s plants in Atlanta, Ga., and Lyons, Colo., received new trophy awards for an accident-free year. Thousand-day achievement awards were presented to three companies by the PCA: Louisville Cement Co. at Logansport, Ind., received its award for 4,000 consecutive accident-free days; and

[1]Physical scientist, Division of Nonmetallic Minerals.

Ideal Basic Industries, Inc.'s plants at Fort Collins, Colo., and Trident, Mont., each received a 1,000-day citation.

The Atlantic Cement Co., a subsidiary of Newmont Mining Corp., was awarded the Environmental Protection Agency's "Flag of Achievement" for meeting all pollution control regulations.[2] Atlantic was the first portland cement company to receive this award, and represented the only industry selected in 1976.

Again in 1976, energy continued to be a major concern in the cement industry. Major items of planned or actual capital expenditure were the conversion to coal as a primary or backup fuel in plant operations, and conversion from wet- to dry-process operation with the addition of preheaters. Several companies were involved in the development of their own coal reserves and mining facilities.

Some of the tables show statistical data arranged by State or by groups of States which form cement districts. A cement district may represent a group of States, a portion of a State, or in some cases, will correspond to a State. The States of California, New York, and Pennsylvania have been divided to provide additional marketing information. Divisions for these States are as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

California, Southern.—All other counties in California.

New York, Western.—All counties west of a dividing line following the eastern boundaries of St. Lawrence, Lewis, Oneida, Madison, Chenango, and Broome Counties.

New York, Eastern.—All counties east of the above dividing line.

New York, Metropolitan.—The five counties of New York City (Bronx, Kings, New York, Queens, and Richmond) plus Westchester, Rockland, Suffolk, and Nassau Counties.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Potter, Clinton, Centre, Huntingdon, and Franklin Counties.

Pennsylvania, Western.—All other counties in Pennsylvania.

Legislation and Government Programs.—The Housing Authorization Act of 1976 allocated $675 million per year for subsidized housing. Of this amount, $85 million was for new construction or substantial rehabilitation of existing housing.

The President signed a 2-year extension of the Federal highway program for $17.6 billion. Most of this was not expected to be spent in the 2 years, because the funds were tied to State and local matching fund requirements. It was, however, the largest 2-year highway program ever enacted and would allow expenditures on interstate, primary, secondary, and urban roads.

A total of 6,775 Federally aided contracts for highway and bridge construction were awarded by State highway departments during 1976 at a cost of $5.2 billion.

The PCA and a number of cement producers were named in several civil antitrust suits filed by the Attorneys General of California, Arizona, and Colorado. The suits, on behalf of buyers and users of cement and readi-mix concrete, alleged various violations of the Sherman Anti-Trust Act and were seeking treble damages in unspecified amounts. Violations charged include price fixing and conspiracy to eliminate competition in the cement industry. Defendants, in addition to the PCA, included virtually every cement manufacturer that marketed in the States.

The Federal Trade Commission issued an order barring the Martin Marietta Corp., Ideal Basic Industries, Inc., and the OKC Corp. from exchanging price information and from controlling "the place of use" of portland cement. The order also required that the companies offer customers the option of arranging their own transportation for shipments and that they provide mill-price quotations.

---

[r]Revised.
[1]Excludes Puerto Rico.
[2]Portland and masonry cement only.
[3]Includes imported cement shipped by domestic producers.
[4]Value received, f.o.b. mill, excluding cost of containers.
[5]Quantity shipped plus imports minus exports.
[6]Adjusted to eliminate duplication of imported clinker and cement shipped by domestic cement manufacturers.

DOMESTIC PRODUCTION

During 1976, 1 State agency and 57 companies operated 167 plants in 40 States. An additional two companies operated two plants in Puerto Rico, manufacturing one or more kinds of hydraulic cement.

PORTLAND CEMENT

Manufacturers in the United States and Puerto Rico produced 68,579,000 tons of clinker, and imported 962,000 tons of foreign clinker to grind 71,227,000 tons of portland cement. Domestic producers shipped 71,922,000 tons of portland cement, which included 1,201,000 tons of imported cement. Stocks at mills increased by 215,000 tons. An additional 911,000 tons of portland cement was imported and shipped or used by others not producing cement in the United States or Puerto Rico.

Production Capacity.—Multiplant operations were run by 30 companies. No single company, however, provided more than 6.3% of the Nation's total clinker production capacity. The five largest producers provided 25.5% of the total clinker production capacity; the 10 largest provided for a combined 45.3%. The 10 largest companies, in terms of clinker production capacity, were Ideal Basic Industries, Inc.; General Portland, Inc.; Amcord, Inc.; Martin Marietta Cement Corp.; Marquette Cement Manufacturing Co.; Medusa Cement Co.; Lone Star Industries, Inc.; Kaiser Cement & Gypsum Corp.; Huron Cement Div. of National Gypsum Co.; and Universal Atlas Cement Div. of United States Steel Corp.

At yearend, 405 kilns located at 157 plants were being operated by 54 companies and 1 State agency in the United States and Puerto Rico. The estimated 24-hour daily clinker production capacity was 281,000 tons. An average of 61 days downtime was reported for kiln maintenance and replacing refractory brick. Based on 304 days of operation, the annual clinker production capacity of the industry was 85.4 million tons. The industry operated at 80.2% of its apparent capacity, compared to 70% in 1975. Average annual clinker capacity of each kiln in the United States was 211,000 tons, that of each plant was 544,000 tons, and that of each producing company, 1,569,000 tons. There were 163 clinker-producing plants, 7 of which produced white cement. In addition, eight plants operated grinding mills using only imported or purchased clinker, or interplant transfers of clinker. Of these eight, six have for some years operated in this manner, one was a closed clinker-producing plant that ground clinker early in the year to dispose of stocks on hand, and one was a clinker-producing plant whose kilns remained shut down for the year. Of the grinding plants, six produced portland cement only and two ground clinker for both masonry and portland cement. Based on the fineness necessary to grind Types I and II cements and making allowance for downtime required for maintenance, the cement industry in the United States and Puerto Rico had an estimated grinding capacity of 104 million tons of cement annually.

In 1976, clinker was produced by wet-process kilns at 91 plants and by dry-process kilns at 59 plants; 7 additional plants operated both wet and dry kilns. Dry-process kilns with preheaters were replacing many older wet-process facilities and were also being extensively used in plans for new plant construction because of their higher operating efficiency and lower fuel consumption. Flash calciners were being considered for use in conjunction with these systems to further reduce fuel consumption per ton of cement produced. By yearend, 34 suspension and 16 grate preheaters were in operation in 29 plants. During the year, four new suspension preheaters were put into operation, increasing capacity more than 1 million tons per year.

Capacity Changes—New Plant Installations.—No entirely new plants were built in 1976. The latest plant to be completed was Florida Mining & Materials Corp.'s new 564,000-ton-capacity plant, which began production on December 31, 1975, and was the only new plant to be built that year. Kaiser Cement & Gypsum Corp. completed the first full year of operation of its new dry-process kiln at San Antonio, Tex.

Citadel Cement Corp., a subsidiary of Lone Star Industries, Inc., installed a new preheater kiln, two new raw mills, and converted the old raw mills to finish mills at its Roanoke, Va., plant. Capacity was to be increased from 750,000 to 1.2 million tons per year by 1977. The new preheater kiln is an Allis-Chalmers ACL system, similar to the German LEPOL design. It is a traveling-grate preheater with precalcination.

A new dry-process kiln was installed by Northwestern States Portland Cement Co. at its Mason City, Iowa, plant. The new kiln, rated at 1,060 tons per day, should provide an increase in plant capacity of 25%. In addition to the kiln, a new raw mill and finish-grinding mill, each with an output of 100 tons per hour, were added.

National Cement Co., Inc., a subsidiary of Société des Ciments-Vicat of Grenoble, France, completed a $10 million expansion project that included installation of a six-stage suspension preheater with flash calciner. An existing kiln was shortened by 150 feet, to 390 feet. Capacity was increased from 1,200 tons per day from the old kiln to 2,200 tons with the new system. Continuing into 1977, plant expansion was to include a new Loesche roller mill, a vertical-spray chamber to condition bypass gases, and storage and related materials-handling facilities. In 1978, conversion to coal as the primary fuel is planned.

A single-stage, twin-cyclone preheater kiln was installed by Lehigh Portland Cement Co. at Mitchell, Ind. Rated at 250,000 tons per year, this kiln will increase plant output capacity to 750,000 tons per year.

At the Stockertown, Pa., plant of the Hercules Cement Co. of Amcord, Inc., a three-stage suspension preheater was installed, and the existing kiln was shortened. Capacity was increased 15% to 700,000 tons per year.

At Hagerstown, Md., Marquette Cement Manufacturing Co. completed the installation of a new finish-grinding department for masonry cement. The new mill provides grinding capability to use clinker directly in the manufacture of masonry cement, rather than by blending plasticizers into portland cement as done previously. At its Superior, Ohio, plant, Marquette installed a new glass baghouse dust collector for air pollution control.

Planned Expansions and New Plants.—Marquette announced plans to build a 1-million-ton-per-year plant at Cape Girardeau, Mo. The new facility is to replace an existing wet-process plant that the company acquired in 1923. Cost of the new plant is expected to be $70 million to $80 million. Completion was expected to be in 1980. Clinker production capacity will be 950,000 tons per year, with finished cement production totaling 1,090,000 tons.

Centex Corp. announced plans to construct a new single dry-process kiln with suspension preheater near Austin, Tex. Capacity of the facility is to be 470,000 tons per year, replacing the 282,000-ton-per-year Corpus Christi plant. The $32 million plant was scheduled for completion in 1978.

Lehigh Portland Cement Co. announced that it would be increasing the capacity at its Mason City, Iowa, plant 20%, to 750,000 tons per year. Two-thirds of the output would be from new facilities, and one-third, from a kiln in operation since 1958. Six small, 65-year-old kilns capable of producing 365,000 tons of clinker per year would be scrapped. A new single 500,000-ton dry-process kiln, with four-stage preheater and flash calciner, and a new raw-grinding mill would be added by 1978, at an estimated cost of $25 million. Cost savings from the renovation was expected to be $3 million per year.[3]

Lone Star Lafarge Co., a joint venture of Lone Star Industries, Inc., and Lafarge Fondu International, announced plans for a new plant in Chesapeake, Va., to produce

[3]Lehigh Portland Cement Co. 1976 Annual Report. P. 8.

high-purity calcium aluminate cement. Lafarge, the original producer of calcium aluminate cement, has been producing the product for more than 50 years. The intended completion date was late 1977. The former grinding facility at this site was shut down.

Citadel Cement Corp. was working on a $110 million expansion to double capacity to 2.2 million tons per year by mid-1977. This capacity would place Citadel among the 10 largest cement companies in the United States. Citadel was formed in 1974 as a 50-50 joint venture between Lone Star Industries, Inc. and Canada Cement Lafarge Ltd. Two plants, at Demopolis, Ala., and Roanoke Va., and other assets were contributed by Lone Star, while expansion capital was supplied by Lafarge. Plans were developed to increase the capacity of the new Demopolis plant from 280,000 to 750,000 tons per year. A new semiportable crusher and conveying system will supply the plant with raw materials from the massive Selma Chalk. The chalk will be taken to a preblender-stacker-reclaimer at a rate of 1,000 tons per hour. A vertical roller mill will grind and dry preblended material at 176 tons per hour. Homogenized material will then feed into a four-stage preheater kiln, rated at 2,350 tons per day. Two 3,700-horsepower cement mills will grind the clinker. The Roanoke plant underwent extensive expansion.

Lone Star was progressing with the installation of high-ratio dust collectors for two clinker coolers and an 11- by 29-foot, 1,750-horsepower cement grinding mill at its Bonner Springs, Kans., plant. Plans to upgrade and expand the Santa Cruz, Calif., plant would result in replacing the older production units with a single, new 300,000-ton-per-year capacity preheater kiln, a new cooler, and a self-contained roller mill. Two new electrostatic precipitators will be added for environmental control. In addition to use in the preheater, exhaust kiln heat will also be used by the roller mill to dry the raw materials before they enter the preheater. This will eliminate the old raw material driers. The new mill is expected to require little more than half the energy formerly consumed for raw materials preparation. The new plant is intended to produce low-alkali cement for use in the San Francisco Bay area. Completion of the project was scheduled for 1979 at an estimated cost of $38 million.

Bessemer Cement Co., a subsidiary of Louisville Cement Co., announced plans to install a new 10-module Rexnord gravel bed filter system at its Bessemer, Pa., plant. A $25 million program to modernize the Speed, Ind., plant, including installation of a new 670,000-ton-per-year suspension preheater and kiln, was well underway. Production should be increased 16% to 18%, with 20% to 35% greater energy efficiency.

Installation of the largest preheater kiln in the United States was being planned by the oldest cement manufacturer in the country. Coplay Cement Manufacturing Co. designated Kaiser Engineers of Pennsylvania, Inc., to make arrangements for a $50 million modernization program. Included is a 1-million-ton-per-year preheater kiln with planetary cooler, to be supplied by Polysius, A.G., of West Germany. Additional improvements include a Pfeifer/Allis-Chalmers roller mill for raw feed, and a 6,350-horsepower F. L. Smidth & Co. finish mill. The new facilities will replace existing equipment at both the Nazareth and Coplay plants. Controlling interest in Coplay was purchased by Société des Ciments Français, which provided the capital needed to carry out the modernization. Completion was scheduled for 1978.

Ideal Basic Industries, Inc., announced plans to install a grate preheater kiln at its Boettcher, Colo., plant. The company plans to use kerogen-bearing raw materials to reduce energy costs, and increase cement production 135,000 tons per year. Kerogen, present in the limestone to be used, will supply 25% of the energy needed for burning the clinker.

Phase 3 of a 5-year, $49 million modernization by Ideal was underway at Knoxville, Tenn. Four wet units were being replaced by a dry-process kiln and preheater. Capacity will be 583,000 tons per year by early 1979, an increase of 113,000 tons per year.

At its Tijeras, New Mex. plant, Ideal was to bring a new dry-process preheater kiln on stream in 1977. This would increase the plant's capacity by 80,000 tons per year, to 500,000 tons.[4]

Oregon Portland Cement Co. planned to construct a new plant near Durkee, in eastern Oregon. The plant would have a 500,000-ton-per-year capacity, and would replace a 200,000-ton-per-year plant at Lime, Oreg., which is 12 miles from the proposed

---

[4]Portland Cement Association, private communication.

plant site. Completion was projected for early 1979 at a cost of approximately $37 million. A coal-fired, dry-process, four-stage cyclone preheater kiln will be used.

The South Dakota Cement Commission was to have a new preheater kiln operational in 1977, which would increase production capacity 570,000 tons per year.[5]

Plant Closings.—During the year, seven clinker-producing plants and one grinding plant were closed down and several more were partially shut down or scheduled to close. Reasons given as the cause of these closings varied, and included the following: Inefficient old plants were unable to compete with newer, more efficient operations; the cost of obtaining raw materials was too high; many of the plants could not meet environmental emission standards; and the cost of retrofitting older facilities could not be economically justified.

On February 12, 1976, Puerto Rican Cement Co., Inc., announced the closing of its Cataño plant, while continuing to operate its main plant in Ponce. The shutdown was completed in July. The plant, which had been purchased from the Puerto Rican Government in 1950, was built in 1938, and had a capacity of 40,000 bags per day. Prior to closing, it had been operating at only about 50% capacity. Closure was brought on by higher costs, particularly for pollution control, a depressed local housing market, and an increase in production facilities in former export markets.

The directors of Valley Cement Industries, Inc., on July 19, 1976, voted to permanently discontinue cement manufacture at its Redwood, Miss., plant and to dispose of the equipment and property. The kiln was shut down on July 31.

United States Steel Corp. closed its Universal Atlas Cement Div. plant at Duluth, Minn., in January 1976, and announced plans for a possible sale to Intermix Corp. of White Pine, Mich. On September 7, 1976, United States Steel announced the pending shutdown of its Hudson cement plant on the Hudson River at Greenport, N. Y. The property, which included two dry-process kilns, rail transportation connections, and river docking and storage facilities was sold to St. Lawrence Cement Co. of Montreal, Canada.

A slowdown in building construction was cited as the major reason for the Penn-Dixie Industries, Inc., shutdown of its Howes Cave., N. Y., plant. Howes Cave was among Penn-Dixie's oldest and smallest plants, with a rated capacity of 324,000 tons per year. It had operated at less than 50% capacity for 2 years prior to shutting down.

PPG Industries, Inc., closed its underground limestone mine and cement plant near Barberton, Ohio. The operation had become uneconomical because of the high costs of underground mining of the limestone. PPG's other cement operations were sold to Filtrol Corp. in 1973.

The Flintkote Co.'s Diamond-Kosmos Cement Div. phased out the entire Middle Branch, Ohio, operation during the year. As with many other older plants, the capital investment necessary to bring the plant into compliance with air quality standards was not justified by expected returns.

General Portland Inc. permanently shut down one of the kilns at its Trinity Div. plant in Houston, Tex. Under company reorganization, the Houston plant continued limited operations through 1976 under the new Trinity South Div.

Lone Star-Citadel shut down its Norfolk plant at Chesapeake, Va., at yearend. It had previously operated as a grinding plant on imported clinker, but was no longer needed with the expansion of the Roanoke plant.

Corporate Changes.—Marquette Cement Manufacturing Co. became a wholly owned subsidiary of Gulf & Western Industries, Inc., in 1976.

Kaiser Cement & Gypsum Corp. sold its 46% equity interest in Ryukyu Cement Co., Ltd. of Japan to Ube Industries Ltd. of Japan for $6,965,000.

National Gypsum Co. combined its Huron and Allentown Cement Divisions; the respective trade names, however, were retained. The company made plans to move the corporate headquarters to Dallas, Tex., in 1977.

Société des Ciments Français purchased controlling interest in Coplay Cement Manufacturing Co. The merger provided Coplay with funds necessary to carry out plant modernization. Coplay was the first cement manufacturing firm in the United States. It was founded in 1866 by David O. Saylor, who developed and patented the first portland cement in the United States.

Missouri Portland Cement Co. became a wholly owned subsidiary of H. K. Porter Co., Inc.

Universal Atlas Cement Div. of United States Steel Corp. sold its Hudson plant in Greenport, N. Y., to the St. Lawrence Ce-

[5]Work cited in footnote 4.

ment Co. of Montreal, Canada.

Lehigh Portland Cement Co. sold its Miami, Fla., production facilities for $12 million to the Rinker Group of West Palm Beach, Fla., to form the Rinker Portland Cement Corp.

Intermix Corp. was negotiating the purchase of United States Steel's Universal Atlas Cement Div. plant at Duluth, Minn. The plant had been closed since the first of the year, owing to lack of raw materials. Intermix intended to use tailings from the White Pine Copper Co., to be shipped in by rail, and limestone from Michigan's lower peninsula, which would be shipped in by lake vessels.

Table 2.—Portland cement shipped by producers in the United States, by district[1] [2]

(Thousand short tons and thousand dollars)

District	1975			1976

Table 6.—Raw materials used in producing portland cement in the United States[1]

(Thousand short tons)

Raw materials	1975	1976
Calcareous:		
Limestone (includes aragonite)	76,414	[2]81,342
Cement rock (includes marl)	17,869	20,159
Oystershell	3,006	2,390
Argillaceous:		
Clay	6,659	7,009
Shale	3,447	3,655
Other (includes staurolite, bauxite, aluminum dross, pumice, and volcanic material)	208	187
Siliceous:		
Sand	1,813	1,985
Sandstone and quartz	582	707
Ferrous: Iron ore, pyrites, millscale, and other iron-bearing material	772	825
Other:		
Gypsum and anhydrite	3,527	3,658
Blast furnace slag	465	435
Fly ash	180	264
Other, n.e.c	2	8
Total	114,944	122,624

[1]Includes Puerto Rico.
[2]Includes marble.

MASONRY CEMENT

Shipments of masonry cement totaled 3.3 million tons in 1976, an increase of 13.6% compared with those of 1975, but still 20% less than the record shipments of 1973. The average unit price was $42.63 per ton, a 9.6% increase compared with that of 1975. Total value of masonry cement shipments increased to $141 million, nearly 25% above the value of 1975 shipments. By yearend, 111 plants manufactured masonry cement in the United States. Four plants produced masonry cement exclusively, as follows: Cheney Lime & Cement Co., Allgood, Ala.; G. & W. H. Corson, Inc., Plymouth Meeting, Pa.; Campbell-Grove Div. of The Flintkote Co., Frederick, Md.; and Riverton Corp., Riverton, Va. Martin Marietta Corp. ceased production of masonry cement at its North Birmingham, Ala., plant at yearend 1975. Masonry cement was not produced in some parts of the country because many of the masons preferred to use portland cement and add clay or lime to provide the necessary plasticity.

Table 7.—Masonry cement shipped by producers in the United States, by district[1]

(Thousand short tons and thousand dollars)

District	1975 Quantity	1975 Value	1975 Average per ton	1976 Quantity	1976 Value	1976 Average per ton

[1]Includes imported cement.
[2]Less than 500 short tons.
[3]Includes 2,185,000 tons produced from clinker, and 739,000 tons produced from cement (1975); 2,597,000 tons produced from clinker, and 671,000 tons produced from cement (1976).

ALUMINOUS CEMENT

Aluminous cement, also known as calcium aluminate cement, high-alumina cement, and "Ciment Fondu," is a nonportland hydraulic cement. It was produced at the following three plants in the United States: United States Steel Corp., Universal Atlas Cement Div., Buffington, Ind.; Lone Star Lafarge Co. at Chesapeake, Va.; and Aluminum Co. of America at Bauxite, Ark.

As discussed previously, Lone Star Lafarge announced plans to build a new calcium aluminate cement manufacturing plant at its Chesapeake, Va., site. Primary use of the product will be in refractory castables and in metallurgical and petroleum manufacturing operations.

ENERGY

The cement industry has the highest ratio of energy costs to total material costs found in any manufacturing process. The availability of economical and continuing supplies of energy has become one of the cement industry's principal concerns. Rising prices and interruptible supplies of fuels necessitated efforts to increase energy efficiency and convert to available lower cost sources. New technology, which incorporates energy-saving preheater systems, is being used in both new plant installations and modernization projects. The preheater systems are being installed in increasing numbers with precalcining stages that, in addition to heating the raw materials with kiln exhaust gases, actually start the calcining reaction by applying heat to the feed before it enters the kiln. In this way, kiln length can be reduced, with less heat dissipated into the atmosphere.

Conversions to alternate sources of energy from scarce and expensive natural gas generally involved coal or petroleum coke, depending upon availability. Cement plants that converted from gas to coal during 1976 included the following: Martin Marietta Cement Corp. Western Div., Tulsa, Okla.; Ideal Basic Industries, Inc. Cement Div., Ada, Okla.; OKC Corp., Oklahoma Cement Co. Div. at Pryor, Okla.; Kaiser Cement & Gypsum Corp., San Antonio, Tex.; and Centex Corp., Nevada Cement Co., Fernley, Nev. In other changes, San Antonio Portland Cement Co. converted two kilns to petroleum coke at its Cementville, Tex., plant. The Louisiana Cement Co. plant of OKC Corp. at New Orleans, La., and the Santa Cruz plant of Lone Star Industries, Inc., at Davenport, Calif., converted from natural gas to fuel oil as their principal fuel. In another fuel-related change, Florida Mining & Materials Corp. installed a new coal mill at its Tampa, Fla., plant. Several additional companies were considering changeovers to either coal or petroleum coke.

By 1976, a number of cement-producing companies possessed their own coal properties, including Marquette Cement Manufacturing Co., which acquired coal properties in 1974; Medusa Corp., which began strip-mining coal in 1975; National Cement Co., Inc.; Texas Industries, Inc.; United Cement Co.; California Portland Cement Co.; Ideal Basic Industries, Inc., through its subsidiary, Union Pacific Corp.; and Amcord, Inc. Since 1975, Amcord, through its coal operations known as Amcoal with holdings in New Mexico, had been seeking to obtain coal mining operations in Pennsylvania and also looking for deposits in Utah and California.[6]

In 1976, total energy from fossil fuels consumed by the cement industry in clinker manufacture was about 410 trillion Btu, equivalent to 0.6% of the total energy used in the United States. Of this amount, 215 trillion Btu was derived from coal; 136 trillion Btu, from natural gas; 50 trillion Btu, from fuel oil; and 9 trillion Btu, from petroleum coke. Total consumption of coal by the industry was 23% more than it had been in 1975, reflecting the trend to coal as the primary kiln fuel. Consumption by the cement industry of natural gas decreased 27 billion cubic feet, a 17% reduction in usage compared with that of 1975.

Energy from fossil fuels consumed in cement plants to produce clinker averaged 5.8 million Btu per ton in 1976, ranging from 11.7 million to 3.4 million Btu per ton. These figures show only a very slight improvement compared with those of 1975, when the average was 6.05 million Btu per ton, ranging from 11.8 million to 3.5 million Btu per ton.

[6]Amcord, Inc. Summary of the 1976 Annual Meeting. May 11, 1976, 10 pp.

Wet-process plants were the least energy efficient. Average consumption nationwide was 6.4 million Btu per ton, whereas the average for dry-process kilns was 5.2 million Btu per ton. Small wet-process kilns were the most inefficient; however, some of the larger wet-process kilns produced clinker with less energy than at many dry-process plants. There was a less direct relationship between kiln capacity and efficiency among dry-process plants than among wet-process plants. Kilns without preheaters averaged 6.1 million Btu per ton; those with suspension preheaters averaged 4.6 million and those with grate-type preheaters averaged 5.8 million Btu per ton of clinker produced.

Electrical energy consumed in the manufacture of cement totaled 10 billion kilowatt-hours, 9.5 billion of which was purchased commercially and 0.5 billion was generated on site. The average amount of electrical energy used to produce 1 ton of cement was 141.5 kilowatt-hours, 1 kilowatt-hour less than that required in 1975. This energy, used principally for grinding operations, added nearly another 0.5 Btu of energy required to manufacture 1 ton of cement. (This is based on 3,412 Btu per kilowatt-hour instead of 10,660 Btu, as used in the 1975 Minerals Yearbook chapter on Cement). The resulting 1976 total energy requirement, onsite, to produce portland and masonry cement averaged about 6.3 million Btu per ton.

Gains in energy efficiency that have been achieved during the last few years are largely due to reduction in kiln feed moisture content and improved heat transfer in the kiln through installation of chains.[7] In some plants, lowered operating rates, because of poor market conditions, worked to offset these gains.

Another means of conserving energy which has not yet achieved wide use is the incorporation of pozzolanic additives. Several plants have increased the use of fly ash and slag in the production of Type IP, portland-pozzolan cement, and Type IS, portland-blast-furnace-slag cement. However, the proportion of total shipments has remained constant or decreased in the last few years. In 1976, shipments of Type IP and Type IS were 344,000 tons, less than 0.5% of total portland cement shipments. This ratio is virtually the same as in 1975, and only about half of the relative amount shipped in 1974. In 1976, the boom cement year, Types IP and IS commanded 1.2% of the market. It is expected that energy considerations will provide impetus for greater future use of pozzolanic additives.

The use of municipal refuse as a kiln fuel was being investigated and put into practice in Europe. It is not expected to emerge as a significant fuel source in the United States for some time to come, owing to incompatibility with present feed mechanisms, transportation, and storage systems, and possible adverse effect on clinker quality in existing kiln systems.[8]

Studies were being proposed in Canada to investigate replacing conventional fuels for kiln operation with low-Btu substitutes, such as garbage, used oil, lignite, and tar sands.[9]

[1]Includes grinding plants and white cement facilities.
[2]Includes Puerto Rico.
[3]Includes data for grinding plants, seven in 1975; six in 1976.
[4]Data do not add to total shown because of independent rounding.

TRANSPORTATION

Trucks hauled most of the cement delivered to customers in the United States; railroads and barges transported most cement shipments from manufacturing plants to distribution terminals. Trucks hauled 86.5% of the cement shipped to customers, railroads handled 11.5%, and 2% was transported by waterway. This represented very little change from 1975. Compared with those of 1975, barge shipments increased 58%, railroad shipments decreased 3%, and shipments by truck increased 6%.

Table 12.—Shipments of portland cement from mills in the United States, in bulk and in containers, by type of carrier[1]

(Thousand short tons)

Total or average	[4]67,776	[4]2,107,020	31.09	71,922	2,435,395	33.86

[1]Includes Puerto Rico.

[2]Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges to customer, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal if any, less cost of paper bags and pallets.

[3]Includes waterproof cement and low-heat (Type IV) (1975-76) and regulated fast setting (1975).

[4]Data do not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Shipments of cement into various States are considered to be an index of consumption. Portland cement consumption increased 6% above that of 1975. Domestic producers shipped 71.9 million tons of portland cement, which included 1.2 million tons of imported cement. In addition to the imported cement shipped by domestic manufacturers, 911,000 tons of portland cement was imported and shipped or used by others not producing cement in the United States or Puerto Rico.

Consumption increased in all but 11 States, the District of Columbia, and Puerto Rico. The greatest regional reduction in usage was in the New York City metropolitan area, and the State showing the largest drop was Hawaii, where shipments were down 29%. Other large decreases in consumption were in the Northeast United States as follows: District of Columbia, 21%; Massachusetts, 11%; Connecticut, 9%; and New Jersey, 5%. The largest increase in consumption was in Illinois, where shipments were up 479,000 tons, a 15% increase over those of 1975. The second largest increase was in California, where consumption increased 456,000 tons compared with that of 1975. Next in order of increased consumption were Texas and Louisiana, where shipments increased 339,000 and 295,000 tons, respectively. Alabama and Utah each increased consumption by about 230,000 tons.

Ready-mix concrete producers were the primary consumers of portland cement, accounting for 65% of the total quantity shipped by domestic producers. Manufacturers of concrete products used 14% of the cement to make concrete blocks and pipe, precast-prestressed concrete, and other concrete products. Highway contractors and building materials dealers each received 8% of the total cement consumed; other contractors received 4%; and Federal, State, and other government agencies, and other miscellaneous users consumed the remaining 1% to 2%.

PRICES

The average mill value[10] of all types of portland cement was $33.86 per ton in 1976, $2.77 per ton higher than in 1975. The mill values ranged from a low of $27.58 in New York and Maine to highs of $40.94 in Oregon and Nevada, $42.46 in Puerto Rico, and $54.11 in Hawaii.

According to Engineering News-Record, December bulk mill prices ranged from

[10]Mill value is the actual value of sales to customers f.o.b. plant, less all discounts and allowances, less all freight charges to customer, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal if any, less cost of paper bags and pallets.

$28.80 in Louisville, Ky., to $57.60 in Waianae, Hawaii. The highest price in the continental United States was $48.40 per ton at Redding, Calif. Bagged cement prices were $6.00 to $11.00 per ton higher than bulk prices, and all prices were subject to cash discounts. The area price for bulk cement reached a high of $82.20 per ton in Anchorage, Alaska. Base prices for portland cement in carload lots f.o.b. were reported monthly in Engineering News-Record for 20 cities in the United States. The December 1976 average price for bulk cement was $41.06 per ton, compared with $37.50 per ton in December 1975. Bulk prices in the 20 cities ranged from $34.60 in Detroit to $46.80 in Los Angeles.

Table 16.—Average mill value in bulk, of cement in the United States[1]

(Per short ton)

Year	Portland cement	Prepared masonry cement[2]	All classes of cement
1972	$20.31	$26.52	$20.59
1973	21.88	29.43	22.23
1974	26.52	32.93	26.79
1975	31.09	38.90	31.41
1976	33.86	42.63	34.25

[1]Includes Puerto Rico.
[2]Masonry cement made at cement plants only.

FOREIGN TRADE

Hydraulic cement exported from the United States decreased 5.7% in quantity and 6.4% in value from that of 1975. Exported cement was equivalent to 0.7% of domestic shipments by quantity and 1.1% of their value. Six countries—Canada, Mexico, Venezuela, Leeward and Windward Islands, the Dominican Republic, and Ecuador—received nearly 95% of the 466,000 tons of cement valued at $26,601,000, which was exported to 87 countries.

Hydraulic cement and clinker imported into the United States decreased 16% in quantity, while the value decreased only 5% from that of 1975. Imported cement amounted to 4.2% of domestic shipments by weight and 2.7% of the value.

Canada continued to supply the largest amount of imported cement and clinker, providing 58% of the total, followed by the Bahamas and Spain, with 9% each, Norway, 8%; France and Mexico, each 5%.

Clinker comprised 31% of the total imports in 1976, compared with 28% in 1975, 32% in 1974, and 41% in 1973. Two plants operated exclusively on imported clinker, and an additional nine supplemented cement production by grinding imported clinker.

[1]Less than 1/2 unit.

WORLD REVIEW

A number of countries announced long-term cement-industry expansion programs that were to provide future self-sufficiency in cement. These included Algeria, Hungary, Poland, Tunisia, the Dominican Republic, and Yugoslavia. In addition, many oil-rich countries pushed ahead with plans to increase cement production to supply their extensive construction programs. Congestion at ports continued to be a problem, particularly in Iran and Saudi Arabia.

In the Middle East, the chemical-admixture market for cement is growing 35% to 40% per year, according to the British Chemical Development Corp. Lack of potable water and local raw materials with high salt content has caused special problems that are being combated by technology involving a variety of admixtures.

The technology in new plant installations clearly shows the continuing concern for energy efficiency in cement manufacture, with the dominance of dry-process, preheater plants.

World cement production increased to 811.5 million tons, 4.8% more than the 1975 total of 774 million tons. The largest increase in production was in Asia, where overall production averaged 10% above that of 1975. Production changes ranged from a 71% increase in Bangladesh to net reductions in some Middle East countries and Nepal.

Oceania showed an increase of 8% over 1975, solely as a result of Australia's 12% boost.

Western European production was virtually the same as in 1975, whereas Eastern European countries expanded output by 3%, to 206 million tons.

Production in North America increased 6% to 105 million tons, and South American countries increased by 1%, manufacturing 38 million tons of cement.

African countries increased production 3% with 26.6 million tons, compared with 25.7 in 1975.

The 10 leading cement-producing countries, according to Bureau of Mines data, were the U.S.S.R., Japan, the United States, Italy, the People's Republic of China, West Germany, France, Spain, Poland, and India.

NORTH AMERICA

Canada.—Construction expenditures in Canada were up about 12% over those in 1975; however, wages and costs of materials increased at approximately equivalent rates, showing that there was no real growth in the cement industry.[11]

Canada's cement exports to the United States dropped for the third successive year, this time by 6%. The 1975 level was down 14% from that of 1974, which was in turn 10% less than 1973 exports.

Canadian cement-producing capacity reported at yearend 1976 was about 16.5 million tons per year, according to the Canadian Department of Energy, Mines, and Resources. Capacity changes during the year resulted in a net reduction of 84,700 tons.

Cement production in all Canadian Provinces for 1976 totaled 10,858,000 tons, 94% of which was produced in six Provinces, as follows: Ontario, 38%; Quebec, 27%; Alberta, 11%; British Columbia, 9%; Manitoba, 6%; and Saskatchewan, 3%.

Genstar's Ocean Cement Ltd. began construction of a new plant at Vancouver, British Columbia, designed to produce 1.2 million tons per year. The $64 million facility was intended to replace an old plant on Vancouver Island by 1978. Genstar also began planning a two-stage expansion of its Edmonton, Alberta, plant. Inland Cement Industries Ltd. began a $60 million program to increase capacity 75% at its Edmonton plant by the early 1980's. The initial stage will be a $3 million electrostatic precipitator system.

St. Lawrence Cement Co., after almost 2 years of government review, took over Ciment Independant of Montreal for $Can67 million (US$68 million) and 200,000 shares of St. Lawrence stock. St. Marys Cement Ltd. installed a new dry-process, four-stage suspension preheater kiln, increasing capacity 661,000 tons per year at its St. Marys, Ontario, plant. Other expansion plans included doubling the capacity of Canada Cement Lafarge Ltd.'s plant at Brookfield, Nova Scotia.

The cement industry in Canada has set a voluntary goal to reduce energy consumption 9% to 12%, compared with that of 1974, by 1980. In 1976, the Canadian cement industry consumed approximately 62 trillion Btu, or about 4% of the energy used by Canadian industry as a whole.

Costa Rica.—Costa Rica produced 399,000 tons of cement in 1976. Cementos del Pacífico S. A. awarded a $30 million contract to Allis-Chalmers Corp. to build a new plant in Guanacaste, about 108 miles from San José. Total estimated cost for the plant will be $55 million.

Dominican Republic.—The Dominican Republic's expectation of becoming a cement exporter in 1976 did not materialize. Surplus production was, however, expected in 1977. Four cement plants were expected to produce about 42 million bags per year. This, compared to the 1976 domestic consumption of 18 million bags, should provide an exportable surplus.

Cementos Nationales S. A. began operation of a new dry-process plant. Fuller Co. was responsible for the turnkey operation. A capacity of 562,000 tons per year was achieved with a single, four-stage suspension preheater kiln. This plant doubled the

[11]Stonehouse, D. H. Cement preprint chapter. Canadian Minerals Yearbook 1976. Department of Energy, Mines and Resources, Ottawa, Canada, 17 pp.

previous national output and provides cement self-sufficiency for the present.[12] The country's previous cement production came exclusively from Fabrica Dominicana de Cemento. Production in 1976 was 585,000 tons.

El Salvador.—A 1,102-ton-per-day suspension preheater kiln and related plant equipment were contracted to be installed by Allis-Chalmers Corp. for Cemento de El Salvador S. A. Completion is scheduled for 1978. Production totaled 366,000 tons in 1976.

Jamaica.—Construction of a 660,000-short-ton-per-year cement plant was scheduled to begin in late 1976. Located on the western end of Jamaica, the plant is expected to cost $J60 million. (US$66 million). The Jamaican Government will own 85% interest, and the Cavendas Group of Venezuela will hold the remaining 15%. Caribbean Cement Co. increased its price of cement in January by 32 cents (US 35 cents) to $J2.28 (US$2.51) per bag. The purpose of the price increase was to generate reserves for the proposed $J25 million (US$27.5 million) expansion program. Prior to the suspension of the program in midyear, $8 million had already been spent. The intended expansion would double potential output to 800,000 tons per year by 1978. National production was 400,892 long tons for 1976.

Mexico.—Cemento Portland Nacional was building a cement plant at Hermosillo, Sonora. Scheduled for completion in 1977, the plant will have a production capacity of 1,500 tons per day. Construction of another 1,500-ton-per-day plant was being planned at Campeche, on the Yucatán Peninsula. Canteras y Calizas de Campeche signed a contract with Capital Plant International and Fives Lille Cail of the United Kingdom. The plant and associated marine loading facilities were expected to cost about £35 million (US$63 million). The plant is scheduled for completion in early 1979.

Cementos Apasco brought a new plant on stream, increasing capacity to 1.5 million tons per year. It is located about 50 miles north of Mexico City, near the village of Apaxco.[13]

An investigation by the U. S. International Trade Commission concluded that antidumping regulations had not been violated by Mexican cement producers.[14]

Total production of cement in Mexico in 1976 was 13,871,000 tons.

SOUTH AMERICA

Barbados and Guyana.—Technical feasibility studies for a joint project of the Governments of Barbados and Guyana were undertaken by Holderbank Consulting Ltd. of Ontario, Canada. The plant, to be constructed in Barbados, would produce 250,000 tons per year of clinker, 100,000 tons of which would be shipped for final processing to Guyana. The project was scheduled for completion in 1979.

Bolivia.—Sociedad Boliviana de Cemento, S. A., at La Paz announced that it would expand its capacity 551 tons per day by 1978. The turnkey project, to be carried out by F. L. Smidth & Co., comprises a four-stage preheater kiln, planetary clinker cooler, a new raw mill with air separator, an open-circuit finish mill, and new storage facilities.

Although Bolivia experienced a mild recession beginning in late 1975 and continuing through the first half of 1976, a construction boom produced higher cement sales. Because of production problems, domestic cement output declined, requiring the importation of 55,000 tons.

Cement production for Bolivia in 1976 was around 243,000 tons from three plants.

Brazil.—Cement production for 1976 was 18.6 million tons, a decrease of 3% compared with that of 1975.

Companhia Nacional Cimento Portland, a subsidiary of Lone Star Industries, Inc., in Rio de Janeiro, began engineering and feasibility studies for a new cement plant to be built at Cantagalo, about 250 miles from Rio de Janeiro. Construction is to begin in 1978. The new plant, which will have a capacity of between 661,000 and 772,000 tons, will eventually replace the present 496,000-ton plant at Guaxindiba. Sociedad de Empreendimentos Industriais Comerciais e Mineração was setting up a 1-million-ton-per-year cement plant at Vespasiano, Minas Gerais, at a cost of $100 million. Cement production grew nearly 20% during the year to one-third of the national total of cement production.

Cimento Tupi S.A. (Blue Circle Group) began production at its new plant at Pedra do Sino in February 1976. Under con-

[12]Rock Products. Dominican Republic Puts New Cement Plant Into Production. V. 79, No. 8, August 1976, pp. 43-47.

——. V. 41, No. 181, Sept. 16, 1976.

U. S. International Trade Commission. Portland Hydraulic Cement from Mexico. USITC Publication 795, December 1976.

struction since 1973, this 661,000-ton-per-year, dry-process plant was reported to be producing near capacity.[15]

Cimento Santa Rita S.A. at São Paulo reportedly completed a new dry-process, 2,200-ton-per-day plant, supplied largely by Allis-Chalmers Corp. cement and mining systems. Itabira Agro-Industrial S. A. installed a 1,000-ton-per-day, two-kiln plant at Cappao Bonito, equipped by the Czechoslovakian Pragoinvest.[16]

Ecuador.—A new cement plant was being planned, to be located near Latacunga in Cotopaxi Province. Cementos Cotopaxi, C. A., was to provide 30% of the financing, with the remainder to be supplied by a foreign partner. The existing Guapan cement plant in Cañar Province was to be expanded from 200-ton-per-day capacity to 1,000-ton-per-day capacity at a cost of $30 million. Production in Ecuador totaled 679,000 short tons in 1976.

Peru.—Cementos Norte Pacasmayo of Lima planned to triple capacity of its Pacasmayo plant. Fuller Co. was to supply the plant with a complete equipment package for a flash calciner-preheater, dry-process kiln plant, at a cost of $7 million. The plant, scheduled for operation by September 1977, was to have a capacity of 3,000 tons per day.[17] Cementos Lima S. A. contracted with Holderbank Consulting Ltd. of Canada for engineering work on a 3,000-ton-per-day expansion of the Atacongo plant near Lima. The existing plant was completed in 1969 and the new facilities were expected to be operational by 1978. Plans call for a flash precalciner, which, when installed, will be the first such unit in Latin America. Cost of the expansion is $100 million.

Peruvian cement production totaled 2,167,000 tons in 1976.

Uruguay.—Administracion National de Combustibles Alcohol y Portland is expanding its plant in Paysandú from 441 to 992 tons per day with a new four-stage preheater system from Fuller Co.'s South American subsidiary.[18]

Venezuela.—Cementos Caribe C. A. of Caracas contracted with Holderbank Consulting Ltd. of Ontario, Canada, to engineer and manage the construction of a new 3,000-ton-per-day, dry-process plant at Puerto Cumarebo. Additional marine distribution facilities will be built as well. Construction was scheduled to begin in 1977, with completion in 1978.[19]

Venezuelan cement production in 1976 was 3.9 million tons.

EUROPE

According to Cembureau, the European Cement Association, cement production in the nine Eastern European countries (Albania, Bulgaria, Czechoslovakia, East German, Hungary, Poland, Romania, the U.S.S.R., and Yugoslavia) in 1975 was 207 million tons, or 27% of the world total. It was estimated that output would increase by 5% per year from 1976 to 1980.

Orders for new cement mills increased during the year, according to the German firm Polysius, A. G. (Neu Beckum, West Germany), and its six overseas affiliates. Much of the increased demand was for turnkey operations for new plants in developing countries.

Albania.—Production in Albania in 1976 was 882,000 tons, a 23% increase compared with that of 1975. Albania has announced its intention to increase production 55% above the 1975 level by 1980. Two plants were known to be operating in 1976, at Fushë-Frujë and Elbasan.

Germany, East.—East Germany produced 12.5 million tons, a 6.5% increase over 1975 production. Eleven plants were distributed around the country, the largest being the Karsdorf Cement Works near Halle, with a capacity of 4.7 million tons per year. Work was being undertaken to expand the capacity of the plant at Duena, near Erfurt, to 2.8 million tons per year. Plans through 1980 are to increase production 25% through better utilization and expansion of existing facilities.

Hungary.—In Hungary, production was 4.7 million tons in 1976 from six plants. The new works at Hejöcsaba went into production officially in April. This gas-fired, dry-process, 1.8-million-ton-per-year plant went into trial operation in January 1975, and produced 248,000 tons that year. Total cost was $230 million. Another new plant at Belapatfalva was scheduled for 1978. It too will be a two-kiln, dry-process plant. Principal fuels will be oil and gas, and capacity is to be 1.25 million tons. Cost was estimated at $220 million.

Ireland.—Ireland's cement and clinker production in 1976 was estimated at 1.5 million tons. Work was progressing on a

---

[15]Industrial Minerals. No. 111, December 1976, p. 64.

[16]The Associated Portland Cement Manufacturers Ltd. 1976 Reports and Accounts. 1976, p. 10.

[17]Grancher, R. A. International Cement Review. Rock Products, v. 80, No. 4, April 1977, p. 100.

[18]Rock Products. Rock Newscope. V. 79, No. 7, July 1976, p. 18.

[19]Work cited in footnote 18.

1-million-ton expansion of the Platin plant of Cement Ltd. The project, begun in 1974 at an estimated cost of £40 million, was expected to go onstream in October 1977. The expanded facility will provide Cement Ltd. with a clinker capacity of 2.1 million tons.[20]

Norway.—Production of cement and clinker in Norway in 1976 was about 3.0 million tons. Cement sales were down from those of 1975, largely because of reduced deliveries to North Sea activities. To compensate for higher production costs, the Government permitted an increase in the price of cement by an average of NKr26 per ton (US$4.76 per ton).

Romania.—Romania reported production of 14 million tons of cement in 1976, a 9% increase compared with that of 1975. Construction continued on the new Tasca works, begun in 1975. This two-kiln, dry-process plant was scheduled to begin partial production in 1977, and to be fully operational in 1978.

Spain.—Asland S.A. began production from a new, 1-million-ton-per-year plant at Sagunto, near Valencia. This expands Asland's total capacity from its four plants to 5.5 million tons. As of mid-1976, cement consumption was running at about the same level as in 1975, or at an annual figure of about 28 million tons.

Sweden.—As in other parts of the world, energy efficiency considerations in Sweden have resulted in the building of larger plants and wet- to-dry-process conversion. Euroc estimated that by 1980, four cement plants will produce the same amount as seven plants in 1976. Cementa announced the quadrupling of its Slite plant on the Island of Gotland, at a cost of SKr600 million (US$138 million). Since 1976, Cementa has been the only cement manufacturer in Sweden. Swedish consumption declined to 3 million tons, a 10% decline compared with that of 1975. Exports were 110,000 tons, or 25% of the 1975 level.

U.S.S.R.—The Soviet Union has announced the intention of a maximum growth in cement production of 4% per year through 1980. Production by 1980 was expected to be 177 million tons. Production in 1976 was reported as 137 million tons from 115 plants. Ninety of these plants were operated by the U.S.S.R. Ministry of Construction Materials.

United Kingdom.—Demand for cement in the United Kingdom declined 9% during 1976, the third consecutive year of decreasing cement consumption according to Associated Portland Cement Manufacturers Ltd. (APCM), (Blue Circle Group). Domestic shipments dropped 7.4% to 17 million tons, and production of portland cement fell 7.4% during the year. The 1974 shipments were down 12% from 1973 levels, and those of 1975 declined another 4% from 1974. As a result of this depressed construction market, about 2.2 million tons of capacity was lost because of closures. Exports increased only 2.5% to nearly 1.1 million tons, despite increased exports of cement to the Middle East, Nigeria, and Venezuela.

APCM closed down three older plants during the year. This reduced the country's annual production capability 717,000 tons. Despite the closures, Blue Circle was operating at 80% of capacity. In a step toward energy-cost savings, Blue Circle converted two previously oil-fired plants to burn coal. In addition, the Blue Circle Group installed a full-scale refuse preparation plant. The company has been investigating the use of domestic refuse as a replacement fuel in its kilns. Blue Circle hopes eventually to use 66,000 to 88,000 tons of refuse. An advantage in cement manufacturing, the company reports, is that combustion gases from the refuse neutralize some of the alkalies from the kiln. The new plant was scheduled to go onstream in early 1977.

Tunnel Holdings, Ltd. closed its plant at West Thurrock, Essex. This reduced the company's capacity by nearly 1 million tons, or approximately one-third of its total output. During 1976, a new wet-process kiln of 330,000 tons capacity was installed at Clitheroe, near Manchester.

According to Cembureau, a total of 19 kilns were shut down in 1976, with a combined capacity of 2.3 million tons. The outlook for 1977 was for a further 5% to 6% decline in the construction market, but continued export increases were expected to maintain production at the 1976 level.

The Department of the Environment's Building Research Establishment ordered that buildings throughout the country be inspected for potential hazards caused by the use of high-alumina cement in precast concrete structural members. The problem was caused by a conversion and subsequent weakening of the crystalline structure of the cement upon exposure to heat and moisture.

---

[20]The Northern Miner. V. 61, No. 4, Jan. 15, 1976, p. 15.

The price of cement in the United Kingdom increased 6% on November 4, 1976. Further increases were expected to follow in 1977 as a result of continuing increases in the costs of raw materials and labor.

Yugoslavia.—The Partizan Cement Works on the Adriatic Coast requested that Polysius, A.G., deliver a new PREPOL process precalciner kiln, along with quarry machinery, crushers, crushing mill, packaging and loading machinery, and process-automation and electrical equipment. The plant is expected to expand present capacity to 3,500 tons per day. Production for 1976 was 8.4 million tons.

AFRICA

Algeria.—Annual cement capacity for Algeria was rated at about 3.8 million tons. Production for 1976, however, was estimated at less than half of capacity, perhaps 1.5 million tons. Consumption was between 3.5 million and 4 million tons, with the balance being imported. With the 1-million-ton-per-year Al-Asnam plant coming onstream, it was estimated that production will increase at least 25%. Algeria would like to achieve self-sufficiency in construction materials, including the production of cement, by 1980. An average annual growth rate of 13% in cement demand is forecast through 1981. According to World Bank figures for November 1975, Algeria's expansion plans call for increasing national cement production capacity to 8 million tons per year in 1978, with an approximate balance of supply and demand expected by 1979 or 1980. An integral part of this expansion plan is the construction of a 500,000-ton-per-year, dry-process cement plant near Saida, and expansion of distribution facilities nationwide. The Société National des Materiaux de Construction, which dominates the cement market in Algeria, will operate for the Saida plant and all new distribution facilities and equipment. Kawasaki Heavy Industries of Japan will build the turnkey plant.

Kenya.—A new kiln was placed in operation at Bamburi Portland Cement Co. Production was expected to reach 1 million tons per year during 1976.

Libya.—A 3,000-ton-per-day, dry-process cement plant was to be built about 6 miles from the coastal city of Homs. Société Fives-Cail Babcock contracted to supply the turnkey facility at a cost of F700 million (US$146 million). The new system includes a two-stage facility for raw grinding and drying, which uses a 270-ton-per-hour roller mill and is capable of removing moisture up to 12%. The kiln is 17.7 feet in diameter by 290 feet long and uses a four-stage cyclone preheater and a grate-type clinker cooler. Clinker is ground by two closed-circuit ball mills each rated at 100 tons per hour.

Cement produced by Libya in 1976 amounted to 1,653,000 tons valued at £60.3 million.

Morocco.—State-owned Cimenterie de l'Oriental was moving ahead with plans to build a 1.2-million-ton-per-year cement plant near Oujda at a cost of $182 million. Funding was to come from several sources, including the Moroccan Government ($105.5 million), the World Bank ($45 million), the Arab Fund for Economic and Social Development ($24.5 million), and Moroccan commercial banks ($7 million). The project is expected to be completed in 1978. A shortage of cement in Morocco resulted in 740,000 tons being imported in 1976. When in full production, the new plant is expected to save Morocco about $34 million per year in foreign exchange. APCM, which will do the engineering work, will also provide supervisory services for a 1-million-ton-per-year plant at Mediouna, south of Casablanca. Contracts for this plant should be awarded in 1978, with completion scheduled for 4 years from that time.

The new Marrakech cement plant, located 28 miles west of Marrakech, was scheduled to begin production in June 1976. Société des Ciments de Marrakech (Marrakech Cement) was created in December 1972 to finance and develop a project to build the new 550,000-ton-per-year plant. Investors in the $40 million project included the International Finance Corp. and two affiliates of Ciments Lafarge. Planning and construction were supervised by Ciments Lafarge. The new dry-process kiln uses fuel oil.

Ciments Lafarge operated two other cement plants in Morocco—Lafarge Maroc in Casablanca and Société des Ciments Artificiels de Meknes in Meknes. These two plants provided 70% of the country's total cement output.

Nigeria.—Construction began on a new 882,000-ton-per-year cement plant by Ashaka Cement Co. Ltd. Installation of a third kiln was being considered, which would increase annual production capacity to 1.3 million tons. APCM has a 30% interest in Ashaka, which is principally owned by the Nigerian Government.

Nigeria's 1975 cement crisis, in which some 170 cement-laden ships unable to unload lay at anchor at the port of Lagos-Apapay, by mid-1976 resulted in legal actions taken by the United States, the United Kingdom, and West Germany. The suits involve Nigeria's failure to pay heavy demurrage and freight charges incurred when massive congestion developed at the port. The U.S. and German cases involved letters of credit issued by the Bank of Nigeria and its agents; the British suit was directed at the Banco Internacional de Commercio in Madrid, Spain. Out-of-court settlements were reportedly reached by some suppliers, but other cases may yet be brought to court.

The Nigerian National Supply Co. made arrangements to import 3.3 million tons of cement in 1977.

South Africa, Republic of.—Cement production for 1976 was 7.9 million tons, virtually the same as that of 1975. Domestic sales were 1.2% above the 1975 level, and exports dropped in volume by 12.5%. Imports of cement totaled 82,000 tons, a 5% increase compared with those of 1975.

Installed cement production capacity in the Republic of South Africa for 1976 was about 7 million tons per year. An industry goal is to reach 10 million tons capacity by 1980. The Cement Producers Association has indicated that this production is expected to be from new plants with capacities of about 600,000 tons per year each. Single units of less capacity were considered uneconomic in the Republic of South Africa, owing to current construction and operation costs.

Anglo Alpha Cement Ltd. closed its old (1937) plant at Henneman, Orange Free State, owing to high operational costs. To offset that production loss of 100,000 tons per year, Anglo Alpha was scheduling the opening of its new Dudfield plant in 1977. Production capacity of the new plant is expected to be 2.2 million tons per year.

ASIA

Afghanistan.—Three U.S. firms were awarded a contract to build a new cement plant in Afghanistan in the Kandahar region. Oman Construction, Fuller Co., and Fischback & Moore International, Inc. expect to complete the installation in 1979. Capacity will be 1,600 tons per day. The turnkey operation was financed for $50.5 million by the Government of Iran. It was the largest industrial project ever undertaken in Afghanistan.[21]

Bangladesh.—The new Chittagong clinker grinding plant was expected to provide most of the increased cement manufacturing capacity to double the country's production. The new facility supplements the existing Chhatak cement plant. It was expected that the increased production would satisfy 60% of Bangladesh's annual demand of 606,000 tons. Production at the two plants in 1976 was 241,000 tons.

A new 1-million-ton-per-year plant was planned, to be called the Jaipurhat Limestone Mining and Cement Works. This project was estimated to cost around $200 million, and is expected to give the country self-sufficiency in cement or the basis of indigenous resources.

China, People's Republic of.—The number of relatively small vertical-shaft kilns has been increasing very rapidly in China during the last several years. Small cement plants, which are usually located in rural areas and numbered about 200 in 1965, were estimated at 2,800 in 1973. While the overall cement-producing capability of the country has increased, individual plant capacity decreased from an average in 1965 of about 25,500 tons per year to around 7,100 tons per year in 1973. The small vertical-shaft kiln plants can be located in areas with limited transportation and communications facilities, or where raw materials supplies or market demand would preclude establishment of a larger plant. Savings in transportation appears to be a major factor offsetting the economics of scale that would be realized by larger plants in many other parts of the world.

Hong Kong.—National cement production for the year was estimated at around 683,000 tons. Fifty-nine percent of Hong Kong's cement was produced in small plants. Small plant production increased about 7% over that of 1975. Although first quarter cement production was up about 12% in 1976, no yearend national figures were made available by the New China News Agency.

India.—A new cement plant was under construction at Ariyalur, in the Tridhirapalli District for the Government-owned Tamil Nadu Cements Corp. Ltd. of Madras. Research and development programs, under the sponsorship of the Cement Research Institute of India, included studies on the feasibility of cement miniplants for northeastern India (a region that presently has only two cement plants), and an appraisal of vertical-shaft technology.

[21]Work cited in footnote 15.

The amount of cement produced in India in 1976 was 20,392,000 tons.

Indonesia.—In 1976, domestic production of cement was 2 million tons. Extensive expansion of cement-manufacturing capacity was in progress. Plans call for seven cement plant projects, which will increase capacity 6 million tons or more by 1979.

The Indonesian Directorate General of Chemical Industries recommended the construction of 12 new cement plants, each with a capacity of 500,000 tons per year, to meet an estimated market demand of 12 million tons by 1984. Since 1973, cement supply has fallen behind market demand in Malaysia, a principal export market.

Kaiser Cement & Gypsum Corp. was working on an expansion to approximately double the capacity of its Cibinong (Indonesia) plant. Expected completion date was late 1977.

Iran.—Iran plans to increase cement production capability from 6.1 million tons per year in 1976 to 10 million tons in 1977, 16 million tons in 1978, 19 million tons in 1979, and 20 million tons by 1980. All expansion would be by means of large-capacity, dry-process kilns. One plant, the Aria Cement Co., southwest of Isfahan, will use about 1 million tons of slag per year from a nearby steelworks.

Iraq.—Eight new kilns were planned to go into operation in 1977 and 1978, which would increase the 1976 capacity of 3.2 million tons to 7 million tons. Six of the eight new kilns were to use the wet-process. Only two new dry-process kilns were planned—one in 1977 and one in 1978 at the Badoosh plant, Mosul. Each would have a capacity of 0.6 million tons. A 500,000-ton-per-year grinding plant at Umm Qasr was to operate on clinker from the Samawa plant, 186 miles south of Baghdad; a white cement plant with 100,000-tons-per-year capacity was scheduled to be built by 1978.

Israel.—A projected 0.6- to 1-million-ton-per-year capacity plant was planned for the southeastern part of Israel. Currently, three cement plants of the Nesher Co. provide production capacity of approximately 2 million tons per year.

Japan.—In 1976, Japan was the second largest producer of cement in the world. Total cement production in Japan was 75.7 million tons, a 5% increase over 1975.

Kaiser Cement & Gypsum Corp. completed the sale of its 46% equity interest in Ryukyu Cement Co. Ltd. of Okinawa to Ube Industries Ltd. for nearly $7 million.

Japan continued to make significant contributions to cement and concrete research and technology in such areas as alkali-resistant glass fiber for use in concrete reinforcement and the use of steel slag in both cement manufacture and as concrete aggregate.

Japanese exports of cement and clinker were reported up for the year to nearly 6.2 million tons, more than 75% of which went to Southeast Asia, particularly Singapore, Indonesia, Hong Kong, and Malaysia.[22]

Jordan.—Jordan's cement production was 649,000 tons in 1976. A shortage of cement developed during the year as a result of a production breakdown at the Jordan Cement Co. and increased demand owing to a construction boom. Cement can be legally imported into Jordan only by Jordan Cement Co., which is 49.5% Government-owned.

By 1978, one cement plant southwest of Amman will have a capacity of 600,000 tons per year owing to the addition of a 2,000-ton-per-day dry kiln.

Kuwait.—The Kuwait Cement Co. located at Shuwaykh, near Kuwait City, was considering some expansion. In 1976, it was operating a clinker-grinding plant with a capacity of 300,000 tons per year.

Lebanon.—Cimenterie de Sibline planned a new cement plant with a capacity of around 300,000 tons per year. Capacity for 1976 was 2.1 million tons. An increase of 100,000 tons in white cement production was scheduled for 1977.

Malaysia.—Malaysian cement production was expected to increase to about 4 million tons per year by 1980, as a result of planned expansions of the two existing plants and the construction of three new plants by 1979.[23]

Cement production of 1.9 million tons in 1976 was 20% higher than that of 1975.

Oman.—A 350,000-ton-per-year plant was being built at Qurum. It was scheduled for operation in 1978 or 1979.

Pakistan.—The State Cement Corp. of Pakistan owns all of the cement production facilities in the country. Expansion announced for 1976 was expected to increase capacity 2.3 million tons, from 3.5 million tons per year in 1975 to 5.8 million

[22]Harbin, P. The Industrial Minerals of Japan. Industrial Minerals, No. 119, August 1977, pp. 15-39.
[23]Industrial Minerals. No. 110, November 1976, p. 42.

tons. The program included expanding 3 existing works and the erection of 3 new works, bringing the total number of cement plants to 12.

Philippines.—The Philippines exported 779,000 tons of cement during 1976, 12% less than the 884,000 tons exported in 1975. The decline was largely due to decreased sales to Middle East countries, which have been building their own plants to supply extensive on-going building programs.

Domestic production for 1976 was given as 102,607,000 bags (4.8 million tons).

Qatar.—The Qatar National Cement Co. planned to expand its plant at Umm-Bab from 200,000 tons to 300,000 tons per year. Future plans call for further expansion to 900,000 tons per year.

Saudi Arabia.—The 1976 cement-producing capacity of 1.3 million tons per year was expected to increase to 2.2 million tons per year in 1977, 3.1 million tons in 1978, and to 6.9 million tons by the end of the decade. All new capacity will be from dry-process kilns.

El-Kasseim Cement Co. contracted with the KHD Industrieanlagen unit of Humboldt Deutz for a turnkey cement factory valued at 235 million West German marks (US$93 million). It was to be located at Buraydah, 248 miles northwest of Riyadh. Operation was scheduled for 1980, with an annual capacity of 717,000 tons. A Swedish firm, Cementa, was awarded the contract to build a bulk cement terminal at the port of Yanbu. The terminal is to be capable of unloading and packing 700,000 tons per year. Scheduled for completion in 1978, it is intended to help relieve congestion at the port of Jidda. A new company, Saudi Bulkhandling Ltd., consisting of two Saudi Arabian partners and A/S Norcem of Oslo, Norway, planned to import bulk cement by means of two floating silos in the Arabian Gulf.

Syria.—Total Syrian cement capacity in 1976 was 1.7 million tons. This was expected to increase to 2.3 million tons in 1977 and to 4.2 million tons in 1979.

Taiwan.—Cement production in Taiwan totaled 9,644,000 tons in 1976, a 29% increase over the 1975 production figure of 7,491,000 tons. This increase was largely due to the completion during the year of several expansion projects. Domestic demand was expected to have been around 8.5 million tons, leaving an exportable surplus of over 1 million tons. Actual exports reached nearly 600,000 tons, going principally to Hong Kong, Singapore, and Saudi Arabia.

There were 14 plants operating in Taiwan in 1976. The largest producer was Taiwan Cement Corp., which operated four plants with a combined capacity of 4.2 million tons per year.

Thailand.—Several developments improved of the Thai cement industry in 1976. The single most important factor was the investment by the Government of $300 million to improve rural conditions. Other positive factors included the lifting of cement export restrictions, a major construction program announcement by the National Housing Authority, and the Government's raising of price ceilings on domestic sales. Five cement companies had a combined production capacity of 5.6 million tons per year. Production in 1976 was 4.5 million tons, of which 4.3 million tons was domestically consumed and 666,000 tons was exported.

Turkey.—Construction of a new 600,000-ton-per-year cement plant was scheduled to begin at Darende, Malatya, in east central Turkey. The cost of 500 million Turkish lira (US$31 million) was being raised by a new joint stock corporation. Equipment was to be supplied by local manufacturers. The Adana cement plant, Turkey's largest, was to be expanded to a capacity of 1.5 million tons per year by yearend 1977.

United Arab Emirates.—Dubai began work on a 0.5-million-ton-per-year cement plant scheduled to come onstream in early 1978. Abu Dhabi was completing construction of a 250,000-ton-per-year plant, which was to start production in 1976. In Ras al Khaimah, a 250,000-ton-per-year plant was scheduled for completion in 1978, doubling the 1976 capacity of existing works. Sharjah was building a 200,000-ton-per-year-capacity plant to come onstream by 1977.

Vietnam.—A contract for a cement plant valued at 19.57 billion Japanese yen (US$66 million) was awarded to a Japanese-Danish consortium, consisting of the Mitsui Group and F. L. Smidth & Co., by the Vietnamese Techno-Import Agency. The plant is to be located between Hanoi and Haiphong. This was the first major plant contract in Vietnam since unification in April 1976.

Yemen Arab Republic.—According to Cembureau, a cement plant was erected at Bajil, near Hodeida, with a capacity of approximately 200,000 tons per year.

OCEANIA

Australia.—Blue Circle Southern Cement Ltd. announced that it would proceed with the installation of a new, 827,000-ton-per-year, dry-process kiln to replace older units at Berrima, New South Wales. Completion was estimated for late 1978. The project was expected to cost 70 million Australian dollars (US$86 million), and included a 4,500-horsepower cement-grinding mill at Maldon and expanded quarrying and crushing facilities at Marulan. The cement market in New South Wales of about 1.9 million tons per year was being partially supplied by cement from other States. There was virtually no growth in the market in 1975, but it had been increasing at an annual rate of 5% to 6% in previous years. Financing was jointly underwritten by APCM and Broken Hill Portland Ltd.

Blue Circle Southern Cement Ltd. operated four plants in New South Wales and one in Victoria. Total cement production in 1976 was 6.2 million tons.

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Year beginning March 21 of that stated.

TECHNOLOGY

Cement Manufacture.—Research and development efforts focused largely on means of improving energy efficiency in the manufacture of cement and efficient uses of cement in concrete products and structures.

Municipal refuse, mixed with coal, was first used to fire a cement kiln at the APCM plant in Westbury, Wiltshire County, England.[24] The system developed by APCM first pulverizes, then screens the refuse. When blown into the kiln at high velocity, it is completely oxidized. It was anticipated that by adding approximately 6% refuse to coal by weight, a 3% to 4% savings in coal would result. Four to 5 tons of pulverized refuse is calculated to have the same energy content as 1 ton of coal. In addition to the energy recovery potential of the process, alkaline flue emissions normally associated with cement manufacture are to some extent neutralized by acid gases produced by the refuse incineration. The process, reportedly, does not affect product quality.

Humboldt-Wedag Co. of West Germany completed an investigation into a new clinker-grinding system designed to be more energy-efficient than the closed-circuit, two-compartment tube mill. According to Humboldt-Wedag, very fine particles that are returned from the classifier interfere with grinding performance. The new proposed grinding system feeds the product of each compartment of the tube mill into a coarse classifier assigned to that compartment. Each classifier delivers coarse material, free of fines, back to the individual compartments of the mill and routes the fines from each classifier to the next coarse classifier. A final stage of coarse and fine classifiers supplies the finished product.

Dyckerhoff Zementwerke, A.G., of Wiesbaden, West Germany, conducted a study to determine "clinkerability" of cement raw meal. Experiments were conducted controlling temperatures or burning times. "Clinkerability," it was determined, depends on fineness of grind, homogeniety, and lime and silica content, and is influenced by the time-temperature relationship of the burning process.[25]

Dyckerhoff Zementwerke also installed a computer-operated continuous sampling device and control system. Supplied by Polysius, A.G., the system analyzes fluctuations in the raw mix with a computer-calibrated X-ray fluorescence apparatus. The system provided improved homogeniety of the raw-meal composition and allowed more uniform kiln operation.[26]

A precalcining system using pelletized feed, developed by Steven Gottlieb of Australia, had been licensed to Heyl & Patterson of Pittsburgh, Pa., for design, sale, and installation in the Western Hemisphere. The system uses hot kiln gas and supplemental heaters in a precalciner to increase productivity of existing kilns. Alkalies are removed in a high-velocity gas flow and collected by an electrostatic precipitator.[27] No installation had been made or planned in North America.

A new British standard, BS4982, *Standard sizes of refractory bricks for use in rotary cement kilns, Part 2, Fireclay and high alumina refractories,* prescribes sizes of refractory bricks for use in rotary kilns that produce cement clinker. The Cement Makers Federation and British refractory brick producers participated in its preparation. The standard was intended to reduce the number of shapes of refractory brick being produced. Nomograms appended to the standard give the approximate number of bricks needed for different kiln diameters.

Blended Cements.—The use of blended cements containing fly ash and slag received increased attention as part of the push toward energy conservation and as a means of waste product utilization. A program sponsored by the Federal Energy Administration to examine the feasibility of intergrinding fly ash, slag, and kiln dust, was undertaken by the Southwest Research Institute and General Portland Inc.[28] This was reported on at the Fourth International Ash Utilization symposium in March. It was projected that 2 million tons per year of coal and 14,000 tons of raw materials could be saved by 10% fly ash substitution in any Type I cement. A major obstacle to the use

of blended cements was lack of applicable tests and standards.

Researchers at the National Bureau of Standards, under sponsorship of the Energy Research and Development Administration (ERDA), worked toward the development of standards for Type IP and Type IS cements. Bureau of Standards scientists reported that fly ash cement might be an acceptable substitute for any type specified by the American Society for Testing Materials (ASTM) except Type III (high early strength), if restrictive ASTM specifications were modified to conform with new research findings relating to performance of the blended cements.

Opinion was divided among cement producers regarding the economies of fly ash cement. According to Rock Products magazine, 18 States permitted use of Type IP cement for some uses. Several firms used ash as a replacement for shale.

At the National Ash Association, 4th International Ash Utilization Symposium, St. Louis, Mo., March 24-25, 1976, Leon Trief, a Belgian chemist, described a fly ash cement that he had developed. The product, which incorporates 70% fly ash, reportedly requires one-third the capital investment for its manufacture compared with conventional cement. Further, it is claimed that only one-half as much energy is required and that iron and unburned carbon can be profitably recovered. In the process, blended raw materials (fly ash and limestone) are heated to 1,430° C. The resulting slag is quenched by pressurized water to form a granular material which is, in turn, wet ground to a diameter of less than 10 micrometers with a specific surface of greater than 10,000 square centimeters per gram. The product, according to the developer, cures more fully and faster than conventional cement, develops high overall mechanical strength, has high resistance to chemical attack, and low heat of hydration. A pilot plant was being planned to produce 165,000 tons per year at Liège, Belgium.[29]

Direct utilization of ash in concrete production also increased during the year.

Slag cements were produced in the Netherlands, Belgium, and Iran. Nihon Cement Co. in Japan studied plans for new cement and slag aggregate facilities.

The PCA, in continued testing of Type IP cements, determined that, in comparison to Type I, they exhibited similar freeze-thaw resistance and strength development and showed somewhat less drying shrinkage, but were slightly less resistant to deicer scaling.[30]

New Cements.—A quick-setting specialty cement was developed containing powdered wollastonite and buffered phosphoric acid. It sets in less than 30 minutes, is water insoluble, and develops a compressive strength of over 7,500 pounds per square inch within 4 hours. Potential applications include highway patching, cement pipe, sprayable foam insulation, flame-resistant coatings, etc.[31]

A high-strength cement was developed and put to use in the construction of Chicago's Water Tower Place. The 76-story structure incorporated cement capable of strengths up to 8,000 to 10,000 pounds per square inch. Additional new technology was required to proportion cement and lightweight aggregates for use in the upper 25 stories of the building.[32]

A plant to produce cement from the ash of burned rice husks was set up in a village in India. Aau, in the Banda District, has the first facility which makes what is reported as an architecturally attractive and structurally sound cement from this waste product. An advantage to rice husk cement, in addition to low cost, is acid resistance reportedly superior to that of portland cement. The average Indian rice crop supplies enough husk to provide about 2.5 million tons of the cement per year.

Concrete.—Research in improved concrete products included the use of steel fibers to increase shock resistance for pavement resurfacing; and thick, unreinforced concrete in highways. In addition, concrete railroad ties and concrete long-span bridges were tested; more than a dozen such bridges were on the drawing boards as a result of testing of a structural model by the PCA.

A manufacturing-plant package for producing a new fiberglass-reinforced concrete sheet was being offered to manufacturers in the United Kingdom. The package included machinery, installation, training, and start-

up. The reinforced concrete sheets are made from a cement slurry and alkali-resistant fiber that are sprayed onto a moving conveyor. The panels can be curved into three-dimensional shapes, grooved, or provided with openings. The panels can be used for earth-retaining segments, gutters, roofing, walls for swimming pools, and fire-resistant building construction. The alkali-resistant glass fiber was to be marketed in the United Kingdom. The product was to be used in the manufacture of a new fiberglass-reinforced concrete pipe.[33] The United Kingdom has also reported development of a new concrete pump for small users. ACS Engineering developed a unit capable of pumping concrete with 3/4-inch aggregate up to 60 feet vertically and 100 feet horizontally or 250 feet horizontally only.[34]

A joint company, Dytam, formed by Tampimex Oil, a British subsidiary of Ingram Corp. of New Orleans, La., and Dyckerhoff & Widman of Munich, West Germany, announced the design of a concrete ship to carry liquid natural gas (LNG) from Middle Eastern countries and Indonesia to North America, Europe, and Japan. LNG is viewed by some as a major energy resource for the 1980's. Between 60 and 100 new LNG carriers may be needed during the coming decade. The concrete design reportedly has been shown by extensive computer studies to be superior to steel-hulled counterparts in fatigue strength, corrosion resistance, maintenance costs, and ability to withstand the very low temperature of the gas (-160° C), as well as the impact of collision or explosion. Furthermore, the cost of construction should be 15% less than for a steel-hulled ship of the same capacity. The entire hull would be a monolithic construction of prestressed concrete, reinforced longitudinally transversely. Its length is envisioned at 950 feet, with a capacity of 4,507,520 cubic feet of LNG.[35]

A marketing agreement was signed between Giba-Geigy (United Kingdom) and Kao Soap of Japan to market a concrete additive in Europe, Africa, and the Middle East. The additive is to be used in production of flowing and high-strength concretes, fluid mortar, and grouting.[36]

The British Department of Energy announced a 2-year research program testing the use of reinforced and prestressed concrete as a structural material for offshore platforms, particularly in the hostile North Sea environment. Fatigue strength of large prestressed concrete towers under stress by varying sea and wind loads is one of the areas being investigated. Other areas include materials research relating to corrosion and temperature effects on concrete structures exposed to seawater, and investigations of failure modes of concrete platforms.[37]

A new British standard, BS5328, Methods of Specifying Concrete, was issued by the British Standards Institute. The standard distinguishes between performance and prescription specifications.[38]

An increase in the use of manufactured sand (stone sand) in portland cement concrete was reported.[39]

Chromium

By John L. Morning[1]

The year was marked by the first domestic production of chromite since 1961, although the output was small. Demand for chromium alloys increased substantially over that of 1975 but failed to reach the level of 1973-74. Chromite ore prices held their gains of 1975, while those of chromium alloys decreased as increased imports and stocks put pressure on prices. The Republic of South Africa's ferrochromium production capacity continued to grow as a new plant came onstream late in the year, and additional capacity was announced as being under construction. The South African Minerals Bureau estimated that the country's chromite reserves, to a depth of 300 feet, totaled 3.4 billion short tons.

rRevised.

Legislation and Government Programs.—Government chromium material inventories are shown in table 2. Included in the inventories as material sold but unshipped were chemical-grade chromite, 98,000 tons; refractory-grade chromite, 305,000 tons; and metallurgical-grade chromite, 580,000 tons. Deliveries of chromite from prior-year sales of stockpile excesses included the following: Chemical-grade chromite, 22,048 tons; refractory-grade chromite, 180,215 tons; and metallurgical-grade chromite, 109,408 tons.

During the year, no chromium material was available for sale from government stockpile excesses. Congressional authorization was required for disposal of materials.

New stockpile goals for chromium materials, established in October by the Federal Preparedness Agency of the General Services Administration, are shown in table 2. These goals were based on a material stockpile capable of supporting U.S. defense requirements for a major war over a 3-year period.

At yearend 1975, the U.S. Department of the Treasury made a final countervailing determination in the case of ferrochromium from the Republic of South Africa and held that no bounties or grants were being paid on the production or exportation of ferrochromium. However, in January a domestic concern gave notice that it desired to contest the determination before the U.S. Customs Court. No action was taken in 1976.

The U.S. Environmental Protection Agency (EPA) issued the first national standards for Federal air pollution control, covering new and modified ferroalloy

[1]Physical scientist, Division of Ferrous Metals.

production plants. Emission of particulate matter is limited to less than 0.51 pound per megawatt-hour for furnaces producing chromium alloys.

Producers of ferroalloys at a special Trade Policy Staff Committee (Office of Special Representative for Trade Negotiations) hearing urged the restoration of duties on seven ferroalloys classified for the General Systems of Preferences (GSP). Under the GSP, ferrochromium imports from Brazil, Yugoslavia, Taiwan, and Turkey entered duty-free. The GSP went into effect January 1, 1976, and is reviewed annually. No change was made in 1976.

A preliminary report on the demand and supply of nonfuel minerals and materials, including chromium, for the U.S. energy industry, in 1975-90 was published by the U.S. Geological Survey.[2] Policy implications of producer-country supply restrictions on the world chromite market were the subject of a report prepared for the National Bureau of Standards.[3] The report discussed various aspects of chromium, including supply and demand of chromite, supply disruptions, potential adjustments in chromite use, welfare losses and optional policies, and past crises in the chromite market.

Under a contract from the Office of Mineral Policy Development, U.S. Department of the Interior, an econometric model of the world chromite industry was prepared.[4] The specific structure of the model assessed supply and demand on a worldwide basis as well as stocks and prices. According to the report, the basic model can be used to forecast market behavior from 1975 on.

Table 2.—U.S. Government chromium stockpile material inventories and goals

(Thousand short tons)

	Goal	Inventory by program, Dec. 31, 1976			
		National stockpile	Defense Production Act	Supplemental stockpile	Total[1]

Chromium metal	10	--	--	4	4

[1]Data may not add to totals shown because of independent rounding.

DOMESTIC PRODUCTION

Domestic mine production of chromite ceased in 1961 when the last Government Defense Production Act contract was phased out. Production on a small scale was restarted in 1976 when Marmac Resources Co. rehabilitated the Butler Estates mine and mill near Coalinga, Calif. Most of the usable output was exported because of high transportation costs to domestic markets.

Although domestic chromite production was small, the United States continued to be a substantial chromite consumer in producing chromium alloys, refractories, and chemicals. The principal producers of these products follow:

Airco Alloys, a division of Air Reduction Co., Inc., announced a shifting of its emphasis on production of ferroalloys in the United States and Sweden. Additional ferrosilicon capacity came onstream at Niagara Falls, N.Y., during the year, and a 40,000-kilowatt ferrochromium furnace at Charleston, S.C., was upgraded to 60,000 kilowatts. In Sweden, the firm was converting two furnaces from ferromanganese to ferrochromium production. Although ferromanganese output was not reduced in the United States, more emphasis was to be placed on silicon and chromium alloys.

Interlake, Inc., announced that it was entering the blocking-chromium and high-soluble-chromium markets. Two grades of each type of alloy were offered for sale.

Union Carbide Corp. announced that between 60% and 70% of the output of the new Tubatse ferrochromium plant in the Republic of South Africa would be marketed in the United States. When shipments start arriving in 1977, the firm plans to convert one of its two chromium-producing furnaces to ferromanganese production.

Foote Mineral Co. discontinued production of special proprietary chromium alloys because of environmental considerations. Foote planned to stock most of its H.S. Chrome 50 and V-5 Foundry Alloy throughout 1976.

Consolidated Rail Corp. (Conrail) reduced ferroalloy freight rates in November. This reportedly was done to meet competition from highway carriers and enable domestic producers to compete with imported alloys. The rate change amounted to an average reduction of $6 per ton for many source-destination combinations. The new rates applied to chromium, manganese, molybdenum, nickel, and silicon.

Table 3.—Production, shipments, and stocks of chromium ferroalloys and chromium metal

(Short tons)

Alloy	Production: Gross weight	Production: Chromium content	Shipments	Producer stocks, Dec. 31
1975:

[1]Includes chromium briquets, chromium metal, exothermic chromium additives, and other miscellaneous chromium alloys.

CONSUMPTION AND USES

Domestic consumption of 1,006,000 tons of chromite ore and concentrate containing about 289,000 tons of chromium was 14% above that of 1975. Of the total chromite consumed, the metallurgical industry used 59.3%; the refractory industry, 20.1%; and the chemical industry, 20.6%. The metallurgical industry consumed 596,850 tons of chromite containing 177,000 tons of chromium in producing 267,130 tons of chromium alloys and metal. About 52.0% of the metallurgical-grade ore had a chromium-to-iron ratio of 3:1 and over, 17.6% had a ratio between 2:1 and 3:1, and 30.4% had a ratio of less than 2:1.

Chromium has a wide range of applications in the three primary consuming industries. In the metallurgical industry, its principal use was in stainless steel. Of the total chromium alloys consumed, stainless steel accounted for 70%, full-alloy steels for 16%, high-strength low-alloy and electrical steels for 4%, and carbon steels for 1%. Total chromium alloy consumption increased 24% above that of 1975.

The refractory industry utilized chromium in the form of chromite primarily for manufacturing of refractory bricks to line metallurgical furnaces. Consumption of chromite for refractory purposes increased 10% compared with that of 1975.

The chemical industry consumed chromite for manufacturing sodium and potassium bichromate, which are base materials for a wide range of chromium chemicals. Chromite consumption in this industry increased 25% compared with that of 1975.

Table 4.—Consumption of chromite and tenor of ore used by primary consumer groups in the United States

[2]Includes 3,790 tons of chromium metal.
[3]Includes 839 tons of chromium metal.

STOCKS

Although demand for chromium in 1976 was substantially stronger than in 1975, a high level of chromite and ferrochromium imports increased industry stocks. Total industrial chromite stocks increased 6%. Stocks in the metallurgical and chemical industries increased 9% and 14%, respectively, while stocks in the refractory industry decreased 12%, compared with those of 1975. Consumer chromium alloy stocks increased 3%, and producer stocks increased 22%. Combined consumer and producer chromi¨m alloy stocks totaled nearly 175,000 tons at yearend, equivalent to about a 4 months' supply at the 1974 consumption rate. A considerable tonnage of chromium alloys was in the hands of traders at yearend.

Stocks of chromium chemicals (sodium bichromate equivalent) at producer plants increased from 15,205 tons in 1975 to 16,257 tons in 1976.

Table 6.—Consumer stocks of chromite, December 31

(Thousand short tons)

Total	27,422	48,456	53,747	67,820	69,948

[1]Includes chromium briquets, chromium metal, exothermic chromium additives, and other miscellaneous chromium alloys.

PRICES

Published prices of Turkish and Soviet chromite, which more than doubled in 1975, held at the same level throughout 1976. Soviet chromite was quoted at $150 per metric ton, Black Sea ports; Turkish chromite was quoted at $132 to $142 per long ton, Turkish ports. The published price of $37 to $52 per metric ton for South African Transvaal chromite during the second half of 1975 narrowed to $36 to $42 per ton at the beginning of 1976. In August, the price rose to $38 to $46 per metric ton for the balance of the year.

Although demand for chromium alloys increased over that of 1975, the large stock holdings of producers, consumers, and traders lowered prices for chromium alloys. The price of U.S. charge chromium decreased 7 cents per pound of chromium during the year, while the price of imported charge chromium decreased about 11 cents per pound of chromium. The prices of all grades of low-carbon ferrochromium decreased significantly during the year. The price of both types of chromium metal, which began the year at $2.44 per pound, was increased 16 cents per pound in October. Prices of chromium alloys and metal as published in Metals Week follow:

Material	January	December
	Cents per pound of chromium	
U.S. charge chromium	50	43
U.S. high-carbon ferrochromium	54-61	61
Imported charge chromium	44-50	35.5-37
U.S. low-carbon ferrochromium (0.05% carbon)	92-120	85
U.S. low-carbon ferrochromium (0.025% carbon)	97	85
Imported low-carbon ferrochromium (0.05% carbon)	73-83	68-72
Simplex (low-carbon)	92	85
	Cents per pound of product	
Aluminothermic chromium metal	244	263
Electrolytic chromium metal	244	263

FOREIGN TRADE

Exports of chromite decreased 11% and reexports increased 89%, compared with those of 1975. Sweden received 49% of the exports followed by the Netherlands, 28%; Japan, 9%; and Mexico and Canada, 7% each. Three other countries received small quantities. Reexports of chromite totaling nearly 85,000 tons were made primarily to Mexico, 45%; Sweden, 25%; Canada, 17%; and the United Kingdom, 11%. Two other countries received the balance.

Ferrochromium exports totaled 13,563 tons valued at $8.8 million, went to 15 countries, and were about the same as those of 1975. The leading recipients were Canada, 53%; the Netherlands, West Germany, and Italy, 8% each; and Brazil and Sweden, 6% each.

Chromium and chromium alloys (wrought and unwrought) and waste and scrap exports totaled 594 tons valued at $11.9 million. Of the 32 countries receiving shipments, Jamaica accounted for 27%, Canada for 14%, Israel for 11%, and Argentina and France for 7% each.

Exports of pigment-grade chromium chemicals totaled 456 tons valued at $1.1 million. Japan (53%) and Canada (25%) were the principal recipients among the 22 countries receiving shipments. Exports of non-pigment-grade chromium chemicals totaled 3,623 tons, 78% higher than in 1975. Total exports were valued at $5.5 million.

Exports of sodium bichromate were 35% higher than in 1975, totaling 14,280 tons valued at $6.4 million. Canada (40%), the People's Republic of China (12%), Colombia (10%), the Republic of Korea (8%), and Argentina and Japan (7% each) were the leading recipients of the 29 countries receiving shipments.

Imports of chromite increased 2% in quantity and 16% in value compared with 1975 totals. Imports of chromite from Finland and the Republic of South Africa increased significantly, while those from the U.S.S.R., Southern Rhodesia, and the Philippines dropped sharply. Chromite was received from Sweden as a reexport since Sweden does not produce chromite.

Although imports of low-carbon ferrochromium were about the same as in 1975, imports of high-carbon ferrochromium decreased 31%. Imports of the two grades of ferrochromium totaled 243,000 tons valued at $125 million. Japan supplied 45% and the Republic of South Africa 17% of the low-carbon ferrochromium. High-carbon ferrochromium was supplied primarily by the Republic of South Africa (42%), Southern Rhodesia (22%), Brazil (15%), and Yugoslavia (12%).

Ferrochromium-silicon imports increased to 15,725 tons, nearly four times those of 1975, and were valued at $7.6 million. Five countries supplied imports, with Southern Rhodesia accounting for 84% of the total.

Chromium carbide imports from three countries totaled 164 tons valued at $857,000. West Germany supplied 97% of the total.

Imports of chromium metal, wrought and unwrought and waste and scrap, increased to 2,306 tons from 1,629 tons in 1975. Total value increased from $6.6 million to $9.1 million. Of the seven countries supplying imports, the United Kingdom accounted for 59% and Japan for 35%.

Imports of chromium-containing pigments follow: Chrome green, 151 tons; chrome yellow, 2,747 tons; chromium oxide green, 691 tons; molybdenum orange, 333 tons; strontium chromate, 257 tons; and zinc yellow, 1,225 tons. Total value of these products was $10.7 million, 2.5-fold higher than in 1975. Chrome yellow accounted for 51% of total value of these products, followed by zinc yellow with 23%. The leading supplier was Canada, which accounted for 49% of total value.

Sodium chromate and dichromate imports totaled 570 tons valued at $1.1 million. The U.S.S.R. was the sole supplier. Four tons of potassium dichromate valued at $4,600 was imported from Sweden and West Germany.

[1]Not applicable to centrally planned economy countries.
[2]Duty temporarily suspended on waste and scrap.

WORLD REVIEW

Brazil.—Chromite reserves were reported at about 40 million tons, of which only 10 million tons are recoverable by existing technology. Most of the chromite is the high-chromium variety with about 14% of the total designated as high-iron chromite.[5]

The sole chromium alloy producer, Cia. Ferro Ligas da Bahia S.A. (Ferbasa), produced the three chromium alloys, high-carbon, low-carbon, and ferrochromium-silicon. Six furnaces were utilized with a combined capacity of 51 megawatts in 1976.

Reportedly, Kloeckner and Co., the world trading arm of the German steel company Kloeckner-Werke A.G., entered into a joint venture with Ferbasa S.A. to mine chromite in Brazil. The new firm was named Ferklock S.A.

Egypt.—According to Egyptian sources, production of chromite was 812 tons in 1972, 485 tons in 1973, and 295 tons in 1974.

Finland.—Outokumpu Oy, Finland's sole chromite producer, increased mining of chromite and sales of ferrochromium despite a weak market. Excavation of ore increased 24% as sales of crude ore were made to Sweden and the United States. The beneficiating plant produced 158,000 tons of concentrate and nearly 35,000 tons of chromite sands for foundry use. Although chromite pellet production was down 9%, production of ferrochromium increased slightly to over 44,000 tons. A new stainless steel works was completed at Tornio, and the first melting and casting of ingots was performed in May, using the firm's own ferrochromium and nickel.

India.—India's chromite production in 1976 was estimated at 442,000 tons, or 20% less than in 1975. Most of the production came from the State of Orissa, with small quantities reported from the States of Karnataka and Marharashtra. Most chromite mining was by open pit methods, and the industry employed about 6,000 workers.

India's chromite reserves were estimated at over 17 million tons but are assumed to be higher on the basis of exploration drilling to depths of 330 feet. Principal mines are currently being worked to depths of about 100 feet. Twenty-four percent of the reserves are proved, 14% are indicated, and the balance are inferred. Nearly 75% of India's reserves are in the State of Orissa.

Ferrochromium production of 11,164 tons in 1975 increased to 15,724 tons in 1976. The State-owned Mysore Minerals Ltd. reportedly was evaluating a proposal by Japanese interests to establish a 7,000-ton-annual-capacity ferrochromium plant in Karnataka. The Japanese proposal envisages relocating a charge chromium plant, including two furnaces, from the Republic of South Africa to India.

Iran.—During Iran's fiscal year of March 1975 to March 1976, reported chromite production totaled 232,000 tons and graded 46% to 48% Cr_2O_3. Proven reserves totaled 1.5 million tons of 40% to 48% chromite, while probable reserves totaled over 2 million tons.

Japan.—The Japanese Ministry of Finance approved budgetary requests to establish two nonferrous metal stockpiling corporations during Japan's 1976 fiscal year. One corporation would specialize in handling chromium, nickel, cobalt, and tungsten. Initial funding, as a direct subsidy from the Japanese Government, would total $173,000. The remaining funds of $33 million would be collected from more than 20 investing firms. The stockpile corporation anticipates beginning with a 2-week supply and eventually increasing this to a 3-month supply of the various metals. Japan's chief concern with respect to these metals is possible shortages owing to availability from only a few sources.

Malagasy Republic.—The Malagasy Government in December 1975 took 100% ownership of Compagnie Minière d' Andriamenta (COMINA), formerly owned by the Péchiney-Ugine Kuhlmann Group (France). Under the takeover settlement, COMINA retained one-third of future output at a predetermined price and contracted to manage and operate the mine.

Production in 1976 was from two mines located near the mining districts of Andriamena and Befandriana. At the larger of the two mines, near Andriamena, the chromite grades at 38% Cr_2O_3 and was concentrated to 50% before being transported by road and rail to Tamatave. The unconcentrated ore at Befandriana grades at 35% to 40% Cr_2O_3 and was trucked to Analalava.

Ore reserves have been estimated at 2.2 million tons at Andriamena and about 280,000 tons at Befandriana. Exploration

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the countries listed, Bulgaria and North Korea may also produce chromite, but production is not reported and available information is inadequate for formulation of output estimates.
[2]Less than 500 tons.
[3]Salable chromite estimated from run of mine output.

for new deposits was planned by Péchiney-Ugine Kuhlmann and C. Itoh and Co. Ltd. of Japan.

New Caledonia.—Société de la Tiebaghi, a French subsidiary of Inco Ltd., reached agreement with Compagnie Minière Dong-Trieu and two subsidiaries of the Compagnie Financière de Paris et des Pays-Bas group for an exploration program and feasibility study to determine whether a long-closed chromite mine in New Caledonia could be reopened on an economic basis. The mine was purchased by Inco after its closing in 1962. The exploration program and study are expected to take about 2 years and cost about $3 million.

Philippines.—Output of chromite decreased 18% compared with that of 1975; 76% was classified as high aluminum (refractory) chromite and 24% as high-chromium chromite.

In addition to the two traditional chromite producers, Acoje Mining Co. Inc., producing high-chromium chromite, and Consolidated Mines Inc., producing high-aluminum chromite, nine new producers came onstream between 1975 and 1977. Misamis Exploration Corp., Amer-Asia Mining and Development Corp., and Capitol Resources and Development Co., Inc., became high-aluminum chromite producers in 1976, and G. Lluch and Sons, Silverio Eleazar, San Grace Mining Corp., and Velore Mining Corp. became high-chromium chromite producers in 1976. New Frontier Mines and Superior Mines became high-aluminum chromite producers in 1975.

Obit Philippines Consolidated Mines Ltd. produced and sold small tonnages of chromite to Consolidated Mines, which beneficiates and also markets the concentrate. The firm indicated that reserves totaled 2.2 million tons of ore in its claim area, but that no drilling had been performed.

Rhodesia, Southern.—Reportedly, Rhodesian Alloys (Pty) Ltd. at Gwelo may install new furnaces for expansion of charge chromium production. The firm traditionally produces high-carbon ferrochromium, low-carbon ferrochromium, and ferrochromium-silicon.

In March, Mozambique's President declared a state of war against Southern Rhodesia, closed the border, seized all Rhodesian property, and declared that the United Nations sanctions would be applied fully. The action affected the supply of chromite and ferrochromium, which had been shipped through the port of Maputo.

South Africa, Republic of.—Production of ferrochromium in the Republic of South Africa increased 10% during 1976, rising to nearly 263,000 tons. Production was primarily by Ferroalloys Ltd., Southern Cross

Steel (Pty) Ltd., Palmiet Chrome Corp. (Pty) Ltd., and South African Manganese Amcor Ltd. Late in the year, the Tubatse Ferrochrome (Pty) Ltd. facility at Steelpoort, jointly owned by Union Carbide Corp. and General Mining Corp., came onstream.

In late 1975, South African Manganese Amcor Ltd. (SAMANCOR) (formerly South African Manganese Ltd.) acquired all of Amcor Ltd.'s operating subsidiaries. SAMANCOR has a chromite production capability of 200,000 tons annually and planned to increase output to 430,000 tons by 1980. Other plans included increasing ferrochromium production to 165,000 tons annually.

Consolidated Metallurgical Industries Ltd., a member of Johannesburg Consolidated Investment Co. Ltd., was given approval in 1975 to construct a 132,000-ton-per-year ferrochromium plant at Lydenburg. Construction was initiated in 1976. Reportedly, the British Steel Corp. and a Japanese firm will be partners.

South Africa's growing ferroalloy industry, based on proposed new furnace installations, is expected to increase to 1,200 megawatts of transformer capacity in 1981 from about 600 megawatts in 1974, according to a report at a Conference on Energy in Southern Africa.[6] Most of the new capacity is expected to be used for the production of ferrochromium.

In a report by the South African Minerals Bureau, Department of Mines, chromite reserves to a depth of about 1,000 feet were estimated to total 3.4 billion tons, more than double those reported by the U.S. Geological Survey and Bureau of Mines in recent years.

Shipments of chromite for export throughout the year suffered a bottleneck at the port of Maputo, Mozambique. Lack of maintenance and trained manpower reportedly was the cause. Ore carriers often encountered delays of several weeks, resulting in high demurrage costs and unpredictable delivery schedules. At yearend, the chromium and iron ore loading facilities at Maputo were scheduled for maintenance, thereby further restricting shipments of ore. The Republic of South Africa planned contingency steps to make facilities available to back up the shipping facilities at Maputo.

Sudan.—Two Japanese firms, Mitsubishi Corp. and Japan Metals & Chemicals Co., signed a basic agreement for the development of chromite deposits in Sudan. The long-known deposits in the Ingessena Hills region of eastern Sudan have been subjected to exploration drilling in recent years. Reportedly, the project calls for an annual production of 230,000 to 330,000 tons by 1980, if a joint venture is established after a feasibility study.

Sweden.—Avesta Jernwerks A.B. reportedly closed its ferrochromium production operation because it could not meet pollution control restrictions. Avesta had an annual capacity of 25,000 tons of ferrochromium; output was consumed within the company.

U.S.S.R.—The Donskoy mining and concentrating complex at Khrom-Tau in Oktyubinsk Oblast' of Kazakhstan produces over 90% of the Soviet chromite. The Donskoy deposits are selectively mined by open pits. In 1976, 100-ton unit-rig trucks and large bulldozers were used for the first time. During the year, two concentrators were in operation at Khrom-Tau. Crude ore from the Donskoy complex contained 45% chromic oxide, which was upgraded to a 53.9% chromic oxide marketable product.

TECHNOLOGY

A survey of chromium and nickel wastes, and technology presently available to recover these elements, was described by Bureau of Mines researchers.[7] A great variety of industrial wastes containing chromium and nickel values are generated annually which are not recovered. Much of the technology available has been developed in Bureau laboratories. The status of the most promising technology and recommendations for pilot plant or industrial trials were presented.

Thermodynamic properties of chromium fluorides were investigated by the Bureau of Mines as part of a continuing study to provide fundamental data for various phases of metallurgical research.[8] Gibbs

[8]Schaefer, S. C. Free Energies of Formation of Chromous, Chromic, and Chromium (II, III) Fluorides by Electromotive Force Measurements. Bur. Mines Rept. 8172, 1976, 19 pp.

free energies of formation for various chromium fluorides were determined by electromotive force measurements of reversible high-temperature galvanic cells employing calcium fluoride doped with 1 mole-percent yttrium fluoride as the electrolyte.

Bureau of Mines research projects during the year included studies on reclamation of used refractories containing chromium, treatment of metallurgical wastes containing chromium, preparation of low-carbon ferrochromium by carbothermal reduction of chromite, recovery of chromium from domestic chromium-bearing materials, and improved beneficiation of chromium resources.

Tests and plant experience using the COBO (cold bonded) process for chromite in Sweden were described.[9] Production cost, at a capacity of 20 tons per hour, 114 hours per week, was given as $9 (Canadian) per ton. The plant flexibility was reported as very high and easily shiftable from one ore mixture to another. The binder addition was hydrated lime and silica dust recovered from ferrochromium-silicon production. Pellets had a satisfactory strength for transport and were storable for an unlimited time outdoors. Also, compared with costs of other agglomeration methods, the investment and operation costs were low.

The standard free energy of formation of sodium chromate at high temperatures was measured.[10]

A method for recycling spent chromic acid etchant reportedly was developed and put into commercial use by General Motors Corp.[11] The system is based on reoxidation of chromium by electrochemical regeneration of the spent etchant solution. Over 100,000 pounds of chromic acid was expected to be retained and reused in 1976.

Patent activity for chromium during the year concerned removal of chromite impurities from ilmenite;[12] prereduction of the iron content of chromite, magnetic separation of the iron, and reduction of elemental chromium in an electric furnace;[13] refining of ferrochromium to lower sulfur and silicon contents;[14] and production of sodium bichromate.[15]

Clays

By Sarkis G. Ampian[1]

Clays in one or more of the classification categories (kaolin, ball clay, fire clay, bentonite, fuller's earth, or common clay and shale) were produced in 47 States and Puerto Rico. Clay production was not reported in Alaska, the District of Columbia, Rhode Island, or Vermont. The States leading in output were Georgia, 7.5 million tons; Ohio, 4.3 million tons; and Texas, 3.7 million tons; followed in order by North Carolina, Wyoming, Alabama, and Pennsylvania. Georgia also led in total value of clay output with $273.1 million; Wyoming was second with $40.0 million. Compared with 1975 figures, clay production increased in 29 States and value increased in 38 States. Total quantity of clays sold or used by domestic producers in 1976 was 7% higher in tonnage, and rose 25% in total value. The total value of clays produced was an alltime high. Increases in value per ton were reported for all clays in 1976 owing to increased labor, fuel, and material costs. The energy crisis or, more specifically, the increasing shortage and costs of fuels continued to cause considerable concern among clay producers and clay product manufacturers. Industrywide efforts were made to both economize and obtain standby fuels for their requirements. The costs of environmental protection equipment and environmental restrictions, and rising capital costs, combined with the energy crisis, continued to adversely affect production during 1976.

Production of the specialty clays; kaolin, ball clay, fire clay, bentonite, and fuller's earth—and common clay and shale, all increased. A small upturn in construction that increased the demand for building materials (brick, lightweight aggregate, vitrified clay pipe, clay floor and wall tile, etc.) was responsible for the rise in production of common clay and shale. Production of kaolin increased 15%, ball clay and fuller's earth 13% each, bentonite 9%, fire clay 3%, and common clay and shale 5%.

Kaolin in 1976 accounted for only 12% of the total clay production but for 53% of the value.

[1]Supervisory physical scientist, Division of Nonmetallic Minerals.

DOMESTIC PRODUCTION, PRICES, AND FOREIGN TRADE, BY TYPE OF CLAY

KAOLIN

Domestic production of kaolin in 1976 increased 15%, and the value increased 31%. The average unit value for all grades of kaolin in 1976 was $46.17 per ton, $5.64 higher than in 1975. Kaolin was produced at mines in 14 States. Two States, Georgia (80%) and South Carolina (10%), accounted for 90% of the total U.S. production in 1976. Alabama ranked third; California, fourth; and Missouri, fifth. Output in 1976 increased in Alabama, Florida, Georgia, Minnesota, North Carolina, and South Carolina, and declined in Arkansas, California, Idaho, Missouri, Nevada, Pennsylvania, Texas, and Utah. No kaolin production was reported in 1976 for Colorado.

Kaolin is defined as a white, claylike material approximating the mineral kaolinite. It has a specific gravity of 2.6 and a fusion point of 1,785°C. The other kaolin-group minerals, such as halloysite and dickite, are encompassed.

In April 1976, Freeport Kaolin Co., a division of Freeport Minerals Co., which mines and processes kaolin in Georgia, completed a 24-mile slurry pipeline from its new Scott mining complex near Sandersville, in Washington County, to its main processing plant in Gordon. The new Scott complex currently produces 250,000 tons per year, with a capability of 500,000 tons. Engelhard Minerals and Chemicals Corp., also in Georgia, was in the process of expanding calciner capacity and backup facilities at McIntyre to produce a high-brightness specialty pigment. Engelhard also increased capacity for a fluid bed catalyst based on calcined clay. Thiele Kaolin Co. was doubling the capacity of its 60,000-ton-per-year airfloat plant at Reedy Creek, near Wrens, Ga. The enlargement was scheduled for completion in the first half of 1977. Georgia Kaolin Co. ordered a second high-gradient magnetic separator (HGMS) for its Sandersville plant (American Industrial Clays). The production capacity of its Dry Branch plant was scheduled for expansion and startup in 1977. A non-Georgia kaolin clay producer, Harris Mining Co., Spruce Pine, N. C., purchased 4,000 acres of land in Avery and Mitchell Counties. The purchase, contiguous to present holdings, was made to insure a constant supply of the company's products—primary kaolin and muscovite.[2]

Exports of kaolin, as reported by the U.S. Department of Commerce, decreased from 880,000 tons valued at $47.9 million in 1975 to 839,000 tons valued at $57.6 million in 1976. The tonnage of kaolin exported in 1976 decreased 5%, while the value rose 20% over that shipped in 1975. The unit value per ton increased $14.27. This increase in the unit value of kaolin exported was attributed to both the greater percentage of the higher quality paper-coating grades shipped and higher prices.

Kaolin, including calcined, was exported to 67 countries. The major recipients were Japan, 30%; Canada, 18%; Italy, 16%; West Germany, 11%; Mexico, 5%; and the remaining countries, 20%. Exports increased, except for those to Brazil, France, Taiwan, the United Kingdom, and West Germany. Kaolin producers reported the end use for their exports as follows: Paper coating, 33%; paper filling, 25%; refractories, 11%; rubber, 9%; and others, including adhesives, ceramics, paint, and plastics, 22%.

Kaolin imports in 1976 increased slightly from 19,126 tons valued at $773,000 in 1975 to 23,106 tons valued at $836,000. The United Kingdom supplied nearly 98%; Canada, 2%; and four other countries, less than 1%.

Kaolin prices quoted in the trade journals in 1976, except for the formulary grades, all advanced from 1975. Chemical Marketing Reporter, December 27, 1976, quoted prices as follows:

Waterwashed, fully calcined, bulk carload lots, f.o.b. Georgia, per ton	$145.00-$182.50
Paper-grade, uncalcined, same basis, per ton:	
No. 1 coating	61.50
No. 2 coating	47.00
No. 3 coating	43.00- 46.00
Filler, general purpose, same basis, per ton	30.00- 31.00
Delaminated, waterwashed, uncalcined, paint-grade, 1-micrometer average, same basis, per ton	115.00
Dry-ground, air-floated, soft, same basis, per ton	20.00
National formulary, powder, 50-pound bags, 5,000-pound lots, works, per pound	.07
National formulary, colloidal, 150-pound drums, works, per pound	.36

The average unit value reported by domestic kaolin producers was $46.17 per ton, an increase of $5.64 above the 1975 value.

Grand total	546,893	623,222

[1]Includes floor and wall tile; roofing granules; sanitary ware; and miscellaneous.
[2]Includes high alumina refractories; mortar and cement, refractory; grogs and crudes, refractory; and miscellaneous.
[3]Includes common brick; crockery and other earthenware; drilling mud; linoleum; tile, asphalt and roof; and ink.
[4]Includes ceramics; pesticides and related products; plastics (1975); rubber; and miscellaneous.

BALL CLAY

Production and value reported for domestically mined ball clay in 1976 increased 13% and 16%. Tennessee provided 64% of the Nation's output, followed in order by Kentucky, Mississippi, Texas, Maryland, New York,[3] California, and Arizona. Production in Kentucky, Mississippi, New York, and Tennessee increased over that reported in 1975, but Arizona, California, Maryland, and Texas production decreased.

Ball clay is defined as a plastic, white-firing clay used principally for bonding in ceramic ware. The clays are of sedimentary origin and consist mainly of the clay mineral kaolinite and sericite micas.

In 1976, Kentucky-Tennessee Clay Co., Mayfield, Ky., completed an $800,000 expansion at its Gleason, Tenn., operation. American Olean Tile Co., Inc., a division of National Gypsum Co., sold its glazed tile plant in Pomona, Calif., to Pacific Holding Corp. The sale included manufacturing, warehouse, and office buildings, as well as two talc mines. The firm's plant and master distribution center at Roseville, Calif., was unaffected.[4]

The average unit value for ball clay reported by domestic producers rose in 1976 to $19.23 per ton, an increase of $0.45 per ton. Chemical Marketing Reporter, December 27, 1976, listed ball clay prices unchanged from 1975 as follows:

Domestic, air-floated, bags, carload lots, Tennessee, per ton	$18.00-$22.00
Domestic, crushed, moisture-repellent, bulk, carload lots, Tennessee, per ton	8.00- 11.25
Imported, air-floated, bags, carload lots, Atlantic ports, per ton	70.00
Imported, lump, bulk, Great Lakes, per ton	40.50

Ball clay exports in 1976 amounted to 157,000 short tons valued at $3.6 million compared with 156,000 tons worth $3.5 million in 1975. The tonnage exported, value, and unit value ($22.77) compared with 1975

[3]Albany slip clay is included with ball clay solely for statistical convenience.

were essentially unchanged. These shipments were made to 19 countries. The major recipients were Canada, 55% and Mexico, 41%; 17 countries accounted for the remaining 4%.

Ball clay imports, all from the United Kingdom, decreased slightly from 11,903 tons valued at $366,000 in 1975 to 10,644 tons valued at $342,000.

FIRE CLAY

Fire clay sold or used by domestic producers in 1976 was reported at 3,352,250 tons valued at $40.1 million. Fire clay is defined as detrital material, either plastic or rock-like, containing low percentages of iron oxide, lime, magnesia, and alkalies to enable the material to withstand temperatures of 1,500° C or higher. Fire clay is basically kaolinite but usually contains other materials such as diaspore, ball clay, bauxite clay, and shale. Fire clays commonly occur as underclay below coal seams, and thus are generally used for refractories. Some fire clay was previously reported in other end uses.

Fire clay production was reported in 1976 from mines in 18 States. The first four States in rank, Pennsylvania, Missouri, Ohio, and Alabama, accounted for 81% of the total domestic output.

Swank Refractories Co., Johnstown, Pa., acquired the operation of H. K. Porter Co.'s ladle brick division. Porter's primary product is fire clay brick. The acquisition includes four major refractories, manufacturing plants, and a large underground mine.[5] Harbison-Walker Refractories Div. of Dresser Industries, Inc., opened a new high-alumina refractory production line at Clearfield, Pa., No. 3 works. This will be the first time Harbison's new generation, high-alumina refractories are manufactured in the Northeast.[6]

Exports of fire clay increased from 219,000 tons worth $7.2 million in 1975, to 296,000 tons valued at $12.9 million in 1976. Fire clay exports increased over 35% in tonnage and rose 79% in value. The price of exported fire clay rose by $10.73 to $43.57 per ton.

Fire clay was exported to 40 countries,

[6]Iron and Steel Engineer. Industry News—New Harbison-Walker Production Line. V. 53, No. 11, November 1976, p. 106.

with Canada, Mexico, and West Germany receiving 33%, 22%, and 15%. No imports of fire clay were reported during 1976.

There are no price quotations in domestic journals for fire clay, but the per-ton value reported by producers ranged from $3 to about $50. The reported average unit value for fire clay produced in the United States increased 9% from $11.01 per ton in 1975 to $11.97 in 1976.

BENTONITE

Bentonite production in 1976 increased 9% in tonnage and 16% in value over that of 1975. A general increase in domestic consumption, particularly in filtering, decolorizing, waterproofing and sealing, and exports was noted along with a large increase in drilling mud and slight increases in animal feed and pet absorbent.

Bentonite was produced in 15 States. Increased bentonite production was reported for Alabama, Arizona, California, Colorado, Idaho, Kansas, Mississippi, Nevada, Oregon, South Dakota, Tennessee, Utah, and Wyoming. Production decreased in Montana and Texas.

Generally, the high-swelling or sodium bentonites are produced chiefly in Wyoming, Montana, and South Dakota. The calcium or low-swelling bentonites are produced in the other States.

Industrial Mineral Ventures, Inc., reported to have invested up to $12 million in its Amargosa Valley, Nev., sepiolite, saponite, and hectorite mining and milling operations.[7] Industrywide improvements were continuing to be made in environmental controls systems and in automating, bagging, and handling procedures. Some experimental work was also underway exploring the practicality of switching from oil and gas firing in dryers to coal burning.

On December 27, 1976, Chemical Marketing Reporter quoted bentonite prices unchanged. Domestic, 200-mesh, bags, carload lots, f.o.b. mines, was priced from $15.50 to $16.00 per ton; and imported Italian, white, high-gel, bags, 5-ton lots, ex-warehouse, $337.60 ($0.1688 per pound) per ton. The average unit value reported by domestic producers for bentonite sold or used in 1976 was $16.61, an increase of $0.98 from the $15.63 average of 1975. Per-ton values reported in the various producing States ranged from $4 to $41 but, as in 1975, the average value reported by the larger producers was near the Mississippi average figure of $18.05.

Bentonite exports in 1976 increased from 697,000 tons in 1975 to 787,000 tons; value increased from $39.5 million in 1975 to $50.4 million in 1976. Although the tonnage exported increased nearly 13% above that shipped in 1975, the value increased 28%.

[7]Nevada West and Pahrump Times (South Las Vegas, Nev.). V. 6, No. 1, January 1976, pp. 1, 10-11.

The increase in value was the result of increase in the unit value of exported bentonite from $56.60 per ton in 1975 to $64.04 per ton in 1976. This increase in per-ton value was attributed to a large increase in the value of the higher cost drilling mud and foundry-grade bentonites shipped. Exports in previous years consisted of a larger percentage of the lower cost pelletizing grades. Domestic bentonite producers were facing increased competition in foreign markets. Bentonite from the Greek Island of Milos was being blended with the U.S. clay for pelletizing Canadian taconite ores on a large scale.

Bentonite was again exported to 83 countries. The major recipients were Canada, 50%; Japan, 10%; West Germany, 9%; the United Kingdom, 6%; Australia, 4%; and the others, 21%. Domestic bentonite producers reported the end use of their exports were foundry sand, 43%; drilling mud, 33%; iron ore pelletizing, 22%; and others (including medical, pharmaceutical, cosmetic, soil conditioner, and rubber), 2%.

Bentonite imports in 1976, including chemically activated material, totaled 2,945 tons valued at $466,000 compared with 5,219 tons valued at $617,000 in 1975. The 2,849 tons of chemically activated bentonite was imported from seven countries, with Mexico supplying 36%; Canada, 33%; Japan, 29%; and West Germany, France, the Philippines, and the United Kingdom the remaining 2%. Special-purpose Italian bentonite was also imported in 1976.

FULLER'S EARTH

Production of fuller's earth in 1976 increased 13% in quantity and 23% in value. The unit value assigned by domestic producers increased $3.35 in 1976 to $39.09 per ton. This increase in value was due to large increases in unit value by Florida, Georgia, Illinois, Mississippi, and South Carolina producers.

Fuller's earth production was reported from operations in nine States. The two top producing States, Georgia (39%) and Florida (31%), accounted for 70% of the domestic production. The other seven States accounted for the remaining 30%. All States showed slight gains in production. California and Missouri did not report any production in 1976.

Fuller's earth is defined as a nonplastic clay or claylike material, usually high in magnesia, which has adequate decolorizing and purifying properties.

Production from the region that includes Attapulgus (Decatur County), Ga., and Quincy (Gadsden County), Fla., is composed predominantly of the distinct lath-shaped amphibole clay mineral attapulgite. Most of the fuller's earth produced in the other areas of the United States contains varieties of montmorillonite.

Prices for fuller's earth were not publicly quoted in 1976, but the value per ton for attapulgite reported by producers ranged from $25 to over $55; montmorillonite prices ranged from $21 to $46.

The tonnage, value, and unit value of fuller's earth exported to 36 countries were unchanged from 1975. The unit value of exported fuller's earth declined $3.07

to $64.48 per ton. The major recipients were the United Kingdom, 33%; Canada, 21%; the Netherlands, 19%; and other countries, the remaining 27%.

Imports of fuller's earth in 1976 were 22 tons valued at $2,000 all from the United Kingdom.

COMMON CLAY

Domestic production of common clay and shale in 1976 totaled 37.6 million tons valued at $79.8 million. Common clay and shale represented 71% of the quantity and 15% of the value of the total clays in 1976. Puerto Rican production and value of common clay and shale were withheld to avoid disclosing confidential company data. Domestic output in 1976 increased 5% above that reported for 1975.

Common clays and shales are for the most part used by the producer in fabricating or manufacturing products. Less than 10% of the total clay and shale output was sold. The average unit value for all common clay and shale produced in the United States and Puerto Rico in 1976 was $2.12 per short ton, $0.25 more than in 1975. The range in unit value reported for the bulk of the output was from $1 to $5 per ton.

Common clay is defined as a clay or claylike material which is sufficiently plastic to permit ready mold and vitrification below 1,100° C. Shale is consolidated sedimentary rock composed chiefly of clay minerals that has been both laminated and indurated while buried under other sediments. These materials are used in the manufacture of structural clay products, such as brick and drain tile, portland cement clinker, and bloated lightweight aggregate.

In 1976, Dickey Co., Pittsburg, Kans., announced that it and Hepworth Ceramic Holdings, Ltd., had reached an agreement to merge with a U.S. subsidiary of Hepworth. Dickey is a large Midwest manufacturer of large-diameter clay sewer pipe. The output of the energy-intensive common clay and shale industry was hindered again by shortages of fuel and labor. Construction rates increased in 1976. Industry-wide attention was focusing on coal firing as a possible escape from the high cost and shortages of oil and gas.

Exports of common clay and shale are not tallied by the U.S. Department of Commerce. Most countries have local deposits of either clays or shales that are adequate for manufacturing structural clay products, cement clinker, and lightweight aggregates, and thus have no need to import such materials.

Table 19.—Common clay and shale sold or used by producers in the United States, by State[1]

CONSUMPTION AND USES

The manufacture of heavy clay products (building brick, sewer pipe, drain, roofing, structural, terra cotta, and other tile), portland cement and clinker, and lightweight aggregate accounted for 38%, 21%, and 12%, respectively, of the total domestic consumption for 1976. In summary, 71% of all clay produced in 1976 was consumed in the manufacture of these clay- and shale-based construction materials. The foregoing clay tonnage relationships were similar to those reported for 1975. The utilization of clays in 1976 for heavy clay products and portland cement increased 14% and 12%, respectively, over that reported in 1975.

Heavy Clay Products.—The values reported for shipments of heavy clay products in 1976 increased 20% to $784 million from the 1975 value of $656 million. Trends in the various product categories were less consistent. Thousand-unit counts for building or common face brick increased 19% in 1976 from that shipped in 1975; shipments of glazed and unglazed ceramic tile and glazed brick decreased 22%, and clay floor and wall tile increased 10%. The tonnage of unglazed structural tile decreased 19%, and vitrified clay sewer pipe and fittings shipped during the year declined 8%. The value of these shipments increased 29% for building brick and clay and 17% for floor and wall tile. The value declined less than 1% for clay sewer pipe and over 13% for the structural tiles.

Lightweight Aggregate.—Consumption of clay and shale in the making of lightweight aggregate declined in 1976 to 6,180,643 tons. This was a 24% decrease from the 8.1 million tons used in 1975.

The tonnage of raw material mentioned in tables 20 and 23 for lightweight aggregate production refers only to clay and shale and does not include the quantity of slate and blast furnace slag similarly used. In 1976, 523,000 tons of slate was expanded for lightweight aggregate, 3% above the 1975 figure of 510,000 tons. The National Slag Association reported that the amount of slag used for lightweight concrete aggregate and in block manufacture increased 37% from 1,092,000 tons in 1975 to 1,492,000 tons in 1976.

Refractories.—All types of clay were used in manufacturing refractories. Fire clay, kaolin, and bentonites accounted for 59%, 17%, and 13%, respectively, of the total clays used for this purpose. Bentonite was used primarily as a bonding agent in proprietary foundry formulations. Minor tonnages of ball clay (2%), fuller's earth, and common clay and shale (the remaining 9%) were also used, primarily as bonding agents.

The tonnage used for refractories in 1976 increased to slightly more than 9% of the total clays produced. This slight increase in the use of clay-based refractories continued for a fifth year, a reversal in the downward pattern set for a number of years. The increase was due primarily to both the continued expansion in refractory aggregate production and an upsurge in the manufacturing of more conventional brick-type refractories. Refractory aggregates are used mostly in plastic, gunning, ramming, and castable mixes.

Filler.—All clays are used to some extent as fillers in one or more areas of use. Kaolin, fuller's earth, and bentonite are the principal filler clays. Kaolin was used in the manufacture of a large number of products, such as paper, rubber, plastics, paint, and fertilizers. Fuller's earth was used primarily in pesticides and fertilizers. Clays in pesticides and fertilizers are used either as carriers, diluents, or prilling agents. Bentonites were used mainly in animal feed.

Seven percent of the clay produced in 1976 was used in filler applications. Of all the clay used for these purposes, kaolin accounted for 72%, fuller's earth 5%, and bentonite 4%. Ball clay and common clay and shale accounted for the remaining 19%. The total amount of kaolin consumed by this end use category increased 23%. In the individual kaolin categories, increases of over 100% were recorded in animal feeds and medical, pharmaceutical, and cosmetic categories. Other increases were paint (84%), gypsum products (66%), paper filling (51%), plastics (34%), paper coating (9%), and rubber (7%). Total quantity of fuller's earth used in insecticides and fungicides increased 3%.

Absorbent Uses.—Absorbent uses for clays, 1,156,455 tons, consumed 2% of the total 1976 clay production. Demand for absorbents in 1976 increased 53% over that reported for 1975. Fuller's earth was the principal clay used in absorbent applications; 62% of the entire output was consumed for this purpose. Bentonite was used to a lesser degree. Demand for clays in pet absorbent, representing 31% of the 1976 absorbent demand, increased 13% from that reported for 1975. Demand for use in floor absorbents, chiefly to absorb hazardous oily substances, represented the remaining 56% of absorbent demand and increased 25% from the 1975 figure.

Drilling Mud.—Demand for clays in rotary-drilling muds increased 27% in 1976, from 827,962 tons in 1975 to 1,049,745 tons. This increase in demand, mostly in exploratory gas well drilling and to a lesser degree in oil well drilling, was spurred by the deregulation of "new" gas introduced into the interstate market after April 6, 1972. Drilling muds consumed 2% of the entire 1976 clay production. Swelling-type bentonite is the principal clay used in drilling mud mixes, although fuller's earth or nonswelling bentonite is also used to a limited extent. Bentonite and fuller's earth accounted for nearly 100% of the total amount of clay used for this purpose. Small amounts of ball clay, common clay and shale, and koalin were used in specialized formulations.

Floor and Wall Tile.—Common clay and shale, ball clay, koalin, fire clay, and bentonite, in order of demand, were used in manufacturing floor, wall, and quarry tile. This tile end use category accounted for less than 1% of the total clay production in 1976. Demand in 1976, 381,641 tons, decreased 4% from that shown in 1975.

Pelletizing Iron Ore.—Bentonite is used as a binder in forming iron ore pellets. Demand decreased slightly in 1976 to 868,947 tons. This decrease in the use of bentonite for iron ore pelletizing, reflecting a downturn in steel production, was compounded by inroads made by cheaper foreign bentonites into a traditional U.S. clay market. Of the total bentonite produced in 1976, about 30% of the swelling variety was consumed for this purpose. U.S. deposits continued to be the major source for swelling bentonites.

Ceramics.—The total demand for clays in the manufacture of pottery, sanitary ware, china and dinnerware, and related products, excluding clay flower pots, accounted for 2% of the total 1976 clay output. The total clay demand, principally ball and kaolin clays, increased from approximately 616,000 tons in 1975 to approximately 1,052,343 tons in 1976.

NONCLAY REFRACTORIES					
Silica brick and shapes	1,000 9-inch equivalent	37,478	29,376	38,669	35,721
Magnesite and magnesite-chrome brick and shapes.	do	79,245	152,060	85,106	187,135
Chrome and chrome magnesite brick and shapes.	do	13,890	25,148	13,428	29,455
Shaped refractories containing natural graphite.	Short tons	19,196	21,752	19,852	24,236
Other carbon refractories: Forsterite, pyrophyllite, dolomite, dolomite-magnesite, molten-cast,[5] and other brick and shapes.	1,000 9-inch equivalent	21,759	64,710	28,582	84,159
Other mullite, kyanite, sillimanite, or andalusite brick and shapes.	do	4,273	12,642	3,716	12,356
Other extra-high (over 60%) alumina brick and fused bauxite, fused alumina, and dense-sintered alumina shapes.[6]	do	3,738	20,142	4,205	23,797
Silicon carbide brick, shape, and kiln furniture.	do	4,522	24,975	4,639	27,975
Zircon and zirconia brick and shapes	do	2,121	16,736	1,828	13,287
Refractory bonding mortar	Short tons	37,190	9,182	26,994	8,551
Hydraulic-setting nonclay refractory castables.	do	40,071	16,329	45,869	19,836
Plastic refractories and ramming mixes.	do	171,648	43,732	172,510	50,085
Gunning mixes	do	311,366	53,510	325,160	62,237
Dead-burned magnesia or magnesite.[3] [7]	do	551,108	85,211	526,542	78,137
Other nonclay refractory material sold in lump or ground form.[3]	do	432,265	20,359	491,326	25,661
Total nonclay refractories		XX	595,864	XX	682,628
Grand total refractories		XX	1,005,743	XX	1,131,099

NA Not available. XX Not applicable.

[1]Heated short of fusion; volatile materials thus being driven off in the presence of chemical changes, giving more stable material for refractory use.

[2]More or less plastic brick and materials which, after the addition of any water needed, are rammed into place.

[3]Materials for domestic use as finished refractories, and all exported material.

[4]Including calcined clay, ground brick, and siliceous and other gunning mixes.

[5]Molten cast refractories are made by fusing refractory oxides and pouring the molten material into molds to form finished shapes.

[6]Completely melted and cooled, then crushed and graded for use in a refractory.

[7]Includes shipments to refractory producers for reprocessing in the manufacture of other refractories.

WORLD REVIEW

Australia.—The Dressler Ceramic Group of Pulman-Swindell, a division of Pullman, Inc., Pittsburgh, Pa., received a $1.1 million contract from Cragie Clays Pty. Ltd. of Longford, Tasmania. Cragie Clays is a division of Clifton Brick Ltd. The contract covers a tunnel kiln, dryer, and related facilities to manufacture bricks.[8] Another contract was awarded to the same group by Brick and Pipe Industries Ltd. of Melbourne, Australia. This contract covered design, engineering, and construction of a tunnel kiln, dryer, and associated facilities.[9] A consortium of Consolidated Gold Fields Australia, Western Titanium Ltd., and Winjallock Resources Ltd. formed Western Australian Kaolin Co. to exploit high-grade

[8]Iron Age. Industry Briefs—Contracts. V. 218, No. 14, Oct. 4, 1976, p. 27.

kaolin reserves near Gabbin, about 200 miles northeast of Perth, in Western Australia.[10]

Bolivia.—Plans were announced for a bentonite beneficiation plant near Oruro on the Altiplano, to come onstream in early 1977. The new plant was to be built by the Baroid Div. of NL Industries, Inc., in a joint venture with the local Mosamar Co. Deposits of kaolin were also found on the Altiplano as well as in the east, near Santa Cruz.[11]

Brazil.—Laporte Industries Ltd. (United Kingdom) acquired a 40% participation in the major domestic bentonite manufacturer Bentonite Uniao Group (BUN), for an estimated $3 million.[12] Caulim Da Amazonia Ltda. scheduled startup of its 350,000-ton-per-year kaolin operation at Monte Dourado, Munguba, for May of 1977. The beneficiation plant's 220,000-ton-per-year capacity was targeted for the paper industry.[13]

In another kaolin operation, J. M. Huber Corp. and Construtora Mendes Junior S.A. were constructing a kaolin slurry plant to exploit deposits located on the Rio Capim, in the State of Pará.[14]

Burundi.—An open pit kaolin mining operation was being set up in the Kayanza region. The entire 3,000 tons scheduled for production annually was to be used as an inert carrier for domestically produced pesticides.[15]

Canada.—English China Clay Ltd. (ECC) completed a new slurry facility for its imported kaolin at Three Rivers, Quebec.[16]

Guyana.—The Government of Guyana's 16,000-ton-per-year airfloat plant was expanded to about 40,000 tons. The plant, located at San Isidrio in the State of Bolivar, about 225 miles southeast of Porto Ordaz, processes a sandy primary kaolin by a novel dry technique.[17]

India.—Maharaja Cassimbajar China Clay Mines Pvt. Ltd. was in the process of doubling the crude output of its kaolin clay operation in the Singbhum, Bihar area, to 80,000 tons per year. Production of refined levigated kaolin was similarly doubled from 9,000 to 18,000 tons per year. The clay is consumed domestically by paper (30%), ceramics (30%), and textiles (15%), as well as the rubber, refractories, and paint industries.[18]

Iran.—A $2.5 million contract was signed with the Industrial Equipment Div. of F. L. Smidth & Co. and the Danish Leca Co. to supply a complete lightweight expanded clay aggregate plant. Delivery was set for early 1977, and on completion the plant will be the first lightweight aggregate facility in the Middle East.[19]

Mexico.—Construction of a new plant near Puebla for manufacturing split and ornamental tile and glazed and unglazed brick was announced by Industrial Texmelucan Co. The new plant's rated capacity was to be around 230 tons per day.[20]

Philippines.—Filmag Philippines Inc.'s 40,000-ton-per-year bentonite and processing plant at Merida, northwestern Leyte, was to begin operations at yearend. Most of the output was scheduled for export.[21]

South Africa, Republic of.—The bentonite, open pit mine operated by Pratley Perlite Mining Co. Pty. Ltd. at Nxwala, Zululand, was to be onstream at yearend. A beneficiation plant at Krugersdorp was currently under construction.[22]

Turkey.—The reserves of nonmetallic minerals of Eskisehir Province were reported to include over 500,000 tons of kaolin.[23]

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, the People's Republic of China, East Germany, Lebanon, Nigeria, Vietnam, Southern Rhodesia and Yugoslavia also produced kaolin, but information is inadequate to make reliable estimates of output levels. Costa Rica, Guatemala, Morocco, and Mozambique each produced less than 500 tons in each of the years covered by this table.

[2]Kaolin sold or used by producers.

[3]Includes kaolinitic clay.

[4]Excludes unwashed kaolin as follows in thousand short tons: 1974—84; 1975—187; 1976—150 (estimated).

[5]Revised to zero.

[6]Less than 1/2 unit.

[7]Data given are for ceramic and pottery clays.

Total	[r]1,657,780	1,571,627	1,657,444

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Excludes centrally planned economy countries, some of which presumably produce fuller's earth, but for which no information is available.

[2]In addition to the countries listed, France, Iran, Japan, and Turkey have reportedly produced fuller's earth in the past and may continue to do so, but output is not reported, and available information is inadequate to make reliable estimates of output levels.

United Kingdom.—In the past year, ECC has emphasized developing distribution and storage systems (see Canada) and exploitation of overseas deposits. Significant reserves of kaolin have been found in France and acquired with French partners.[24] ECC started up an 84-inch high gradient wet magnetic separator (HGMS) in Cornwall during June and planned to take delivery of a second unit in 1977.[25] These units, similar to the four now operating in Georgia, are used to extract mica and other feebly magnetic contaminants from kaolin. Hemerdon Mining and Smelting Ltd. completed initial exploration drilling on a china clay-tin-tungsten prospect on the edge of the Dartmoor, 7 miles from Plymouth in Devon. Assay results from these holes were unannounced, but further drilling was contemplated.[26] In clay deliveries ECC has chosen a system of flexible intermediate bulk containers termed "MiniBULK."[27] These containers, in suitable ships, could reduce shipment costs by 30%, and waste through damaged sacks to zero.

Yugoslavia.—The bentonite facility at Kriva Polanka, Serbia, was to be augmented with a new 20,000-ton-per-year soda ash-treated bentonite plant. The new plant, costing about $5 million, will boost total production to 40,000 tons. The soda ash-treated bentonite was intended for foundry application.[28]

TECHNOLOGY

The Federal Bureau of Mines and nine companies (one less than in 1975) eight aluminum producers and a refractory manufacturer continued cosponsoring research on extracting alumina from domestic materials that are plentiful which could ease our dependence on imported metallurgical- and refractory-grade bauxite. Using miniplant facilities at the Boulder City (Nev.) Metallurgy Laboratory, and with support from the eight other Bureau Research Centers, researchers were investigating several methods for extracting alumina from clays, anorthosite, alunite, and dawsonite-bearing oil shales. Each participating company was contributing $50,000 annually, with the cost to the Bureau in excess of $500,000 annually.

The clay-nitric acid miniplant, the first acid process studied, using calcined kaolin was successfully completed and placed on a standby basis. The miniplant study showed that with four stages of countercurrent decantation (CCD), over 90% of the alumina was recoverable. Current work was being devoted to the design, construction, and operation of a kaolin clay-hydrochloric acid miniplant. This miniplant has already been operated for two continuous campaigns of the leaching, solvent extraction, and solids-liquid separation sections mainly to optimize alumina recovery from the leach solutions. Preliminary data show that recoveries of over 95% of the acid-soluble alumina during leaching is possible with a CCD circuit.

A complex problem of $AlCl_3.6H_2O$ crystallization in the circulating pump was solved by a redesigned pump, that eliminated salt supersaturation. Another problem area, thermal decomposition of the salt to alumina in the miniplant, was studied in an indirectly heated rotary calciner and a silicon carbide-heated rotary calciner. These simulated studies have achieved over 90% decomposition of the salt with a residual Cl- of about 0.05%.

Miniplant support studies were in the areas of determining the best materials for construction (emphasizing corrosion), analytical methods for low levels of solvent extraction reagents in purified leach liquors and methods for removal, and tests on the sulfurous acid leaching of clays, lime sinter processing of anorthosites, alternate decomposition methods for aluminum chloride, and disposal of processing wastes. Of particular interest are the latter four studies and the two contracts awarded.

Tests on the sulfurous acid leaching of a calcined kaolin showed that long leaching times (up to 20 hours), using a 30% SO_2 solution, at moderate temperatures and pressures leached up to 80% of the alumina. Best results on recovering alumina from a lime-anorthosite "dusted" sinter was nearly 90%. This research also revealed that up to 1% carbon was beneficial in promoting dusting. Promising results on alternate $AlCl_3.6H_2O$ decomposition were shown by fluidized bed decomposition, 92% at below 200° C, and by a two-stage decomposition system using a flowing airstream approach.

[28]Industrial Minerals (London). No. 106, July 1976, p. 51.

The fluidized bed temperature of under 200° C should make selection of construction material easier. The two-stage system produced an alumina product containing less than 0.004% residual Cl-. Disposal of the processing wastes dealt with the silica wastes from the clay-HCl process. Dewatering techniques, vacuum filtration, and addition of polyethylene oxides were currently being pursued with some success. One contract awarded was for delineating the environmental factors involved in recovering alumina from domestic ores.[29] The other contract was for process feasibility and preliminary pilot plant design, and a more detailed evaluation of the clay-HCl and clay-HNO_3 processes.[30]

In other clay work, the Bureau continued to aid State Geological Surveys and other Federal agencies in delineating undeveloped deposits of ceramic raw materials by clay testing and evaluation, and devising flowsheets designed to upgrade marginal materials. A cooperative program evaluated Montana swelling bentonites for their use in drilling fluids, foundry sands, and pelletizing taconites.

Other alternative methods of producing alumina from clays were patented during the year. In one patent, the dehydrated clay or other relatively low-grade aluminiferous material is reacted with molten anhydrous magnesium chloride at about 2,000° C in a magnesia particulate fluidized bed to vaporize aluminum trichloride.[31] The vapor is separated from the entrained magnesia and used either in producing aluminum metal or chemicals. The byproduct is suitable for refractory manufacture. Another patent outlines a sulfuric acid method for recovering the alumina from clays or kyanite.[32] This technique first forms a concentrated acid-clay slurry which is then heated to a hard anhydrous mass containing aluminum sulfate and silica. The mass is then reduced to an alkali-soluble alumina form and subsequently leached and calcined to recover an alumina product. In a second acid-leaching patent, the clay is fed into the top of a leaching tower and hydrochloric acid flowed countercurrently to leach $AlCl_3$ from the descending ore.[33] Values are crystallized from the leach solution and passed through a crystallizer-washer-thermal decomposer to recover $Al(OH)_3$ suitable for calcining to pure alumina.

The details of producing alumina from coal shales and kaolinitic clays by the H+ process was published.[34] This work included not only the flowsheets for these two types of ore but also a general discussion on bauxite reserves, resources, and rates of consumption. The energy consumption in different nonbauxitic processes was also compared with the Bayer process. A brief article was published on the production of alumina from the U.S.S.R. nonbauxitic sources.[35] In producing alumina from nepheline, the complete processing cycle also yields soda, potash, portland cement, and metallic gallium.

A three-part treatise covered ball and plastic clays. The first part dealt with differing ball clay properties required in ceramics-sanitary ware, wall tiles, earthenware, electrical porcelain, stoneware, refractories, and filler-extenders.[36] This portion also discussed production in the United Kingdom, the companies, and mining and processing. A brief mention was also made of the American and other European producers. The second part detailed the materials and manufacturing of pottery and whiteware.[37] This part, again with English

[37] Pages 19-35 of work cited in footnote 27.

examples, discussed body preparation, plastic and nonplastic shaping techniques, drying and firing, and glazes for manufacturing bone china, porcelain, and vitreous china. The third part concerned the raw materials and the United Kingdom pottery and whiteware industry.[38] The use of linear programing to formulate whitewares from a variety of raw materials at minimum cost, while ensuring that product composition remained within specified limits, was described.[39] Forming a product from cheaper substitute raw materials, as opposed to more expensive traditional raw materials, was cited as a practical problem.

The genesis and geology of the Brazilian Felipe kaolin deposits, their mining, and beneficiation for the world paper markets was outlined in a brief work.[40] A European forecast for kaolin and paper based on the technology of filling and coating printing and writing paper was related to economic factors and future international kaolin supplies.[41] A brief article reviewed the magnetic separation of kaolin clays.[42] This high-intensity, HGMS method permits the mining of lower-grade crude kaolin and reduces the consumption of leaching chemicals. The kaolin surface modification techniques—chemical bonding, chemisorbtion, and coating—for this hydrophilic mineral for eventual use in organics such as rubber, nylon, and polypropylene was summarized.[43]

The mining, processing, laboratory, and pilot plant capabilities of selected French clay and chamotte (calcined clays) producers for use in refractories, ceramics, and filler-extender products was briefly reviewed.[44] A three-section article on industrial minerals in Spain included its bentonite, sepiolite, and attapulgite deposits.[45] The first section touches on the geology of the country, with particular reference to industrial minerals. The second section summarizes, with tables, Spanish production and trade in these minerals. In the final section, some of the more important Spanish producers, both large and small, are reviewed with emphasis on their products, production capabilities, and processing generalities.

The phosphate adsorption capacities of three clays—kaolinite, montmorillonite, and illite—were studied at different pH and ionic strengths.[46] The study showed that kaolin and illite, during periods of high runoff and under slightly acidic pH, contain high amounts of phosphate-bound particles. In transport of these clays, however, if leading to a basic environment, the release of the particles would occur. For clays high in calcium, such as montmorillonite, the reverse response to pH was noted. The free metal content of the clay (in particular Fe and Ca) was shown to be of greater importance in phosphate adsorption than the previously thought alumina-to-silica ratio under varying pH conditions. Another research work evaluated the attenuation properties of several clay minerals, a kaolin, a swelling bentonite, and an illite, to determine whether they would be suitable for sanitary land fill liners to prevent or mitigate pollution of ground and surface waters by leachates from municipal solid waste.[47] Swelling bentonites had the highest attenuation capability, followed by illite, and then kaolin. A similar work considered the effect of pH on the ability of clays to attenuate lead.[48] This work, as with the other two, also investigated the mechanisms responsible for attenuation.

Coal—Bituminous and Lignite

By Lawrence H. Frey[1]

Bituminous coal and lignite production increased from 648.4 million tons in 1975 to 678.7 million tons in 1976, an increase of 4.7%. The increase occurred primarily as a result of the increased demand for coal by electric utilities. The total value of production in 1976 was $13.2 billion compared with $12.5 billion in 1975.

In 1976, there were 6,161 bituminous coal and lignite mines operating in 26 States in Appalachia, the Midwest, and the Mountain and Pacific regions. The leading coal-producing States in order of output were Kentucky, West Virginia, Pennsylvania, Illinois, Ohio, and Virginia. Combined they accounted for 71% of total U.S. production. Total underground coal production increased 2.1 million tons in 1976; production from surface mines increased 28.2 million tons.

Prices of coal increased only moderately in 1976. The average mine price of bituminous coal and lignite increased from $19.23 per ton in 1975 to $19.43 per ton in 1976. The average price of coal produced at underground mines increased from $26.28 per ton in 1975 to $26.56 per ton in 1976. The average f.o.b. mine price of coal at surface mines increased from $13.43 per ton to $13.96 per ton. The average rail freight charge on coal increased from $5.23 per ton in 1975 to $5.86 per ton in 1976.

There were approximately 12,400 more workers mining bituminous coal and lignite in 1976 compared with the total for 1975. The total number of production workers increased from 189,880 workers to 202,280. The decline in productivity was less in 1976 than in 1975. Productivity at underground mines declined from 9.54 tons per man per day to 9.10 tons per man per day. Productivity at surface mines declined from 26.69 tons per man per day to 26.40 tons per man per day. The average productivity at all mines declined from 14.74 tons per man per day in 1975 to 14.46 tons in 1976.

In 1976, the U.S. exported 59.4 million tons of bituminous coal, a decrease of 6.3 million tons compared with exports in 1975. Japan maintained its position as the principal U.S. foreign market with 32% of total U.S. coal exports. Other major shipments of coal went to Canada and Europe, which accounted for 28% and 33%, respectively.

There was a 25-million-ton increase in coal shipped from western coal-producing States in 1976. Shipments of higher sulfur coals from Midwestern coal-producing States declined 5 million tons. Shipments of coal from the Appalachian coalfields declined by nearly 2 million tons.

Tables 12 through 14 summarize the shipments of coal and lignite in 1976. Table 15 shows the quantitative changes in total tons, by geographic division and State of destination, from 1972 through 1975. These distribution data are based on reports submitted quarterly to the Bureau of Mines, Department of the Interior by producers, sales agents, distributors, and wholesales, who normally produce or sell 50,000 tons or more annually. To account for total industry shipments, estimates for the remaining shipments are included, based on data from the Federal Power Commission (FPC) and other reliable coal statistical reporting agencies.

The annual mine operation survey includes all bituminous coal produced in the United States except production from mines that produce less than 1,000 tons per year. All quantity figures represent net tons of marketable coal and excludes washery and other refuse. Statistics are final and are based upon detailed annual reports of production and mine operation furnished by producers. For production not directly reported (chiefly that of small mines), accurate data was obtained from the records of State mine departments.

---

[1]Mineral specialist, Division of Fuels Data.

The weekly and monthly estimates of production, summarized in tables 3 and 4, are based upon railroad carloads of coal reported weekly by railroads, river shipments reported by the U.S. Army Corps of Engineers, reports from mining companies, and monthly production statements compiled by local operators associations and State mine departments.

[1]Prior to 1955 the average heat content of the annual output of bituminous coal and lignite was measured at 13,100 Btu per pound. This value was based on an estimate made in 1949 (U.S. Bureau of Mines Information Circular 7538). In recent years this heat value has not been representative of the average unit heat value of the total annual coal supply because of the large annual increases in utilization of coal of lower heat values by the electric utility industry. The annual production values shown in this table are weighted averages of known and estimated Btu values of coal shipments to each major consuming sector. They include, for example, the Btu value of coal consumed at electric utility generating plants as reported to the Federal Power Commission. Currently, electric utility plants account for 75% of total domestic coal consumption. The averages for domestic consumption exclude shipments overseas and to Canada, the preponderance of which is high-Btu metallurgical coal, thus accounting for the difference in values between total production and domestic consumption.

W Withheld to avoid disclosing individual company confidential data.
[1]Includes coal loaded at mines directly into railroad cars or river barges, hauled by trucks to railroad siding, and hauled by trucks to waterways.
[2]Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for other purposes at mine, and shipped by slurry pipeline in Arizona.
[3]Data may not add to totals shown because of independent rounding.
[4]Value received or charged for coal, f.o.b. mine. Includes a value, estimated by producer, for coal not sold.

NA Not available. W Withheld to avoid disclosing individual company confidential data.
[1]Includes coal loaded at mines directly into railroad cars or river barges, hauled by trucks to railroad sidings, and hauled by trucks to waterways.
[2]Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for other purpose at mine, and shipped by slurry pipeline in Arizona.
[3]Data may not add to totals shown because of independent rounding.
[4]Value received or charged for coal, f.o.b. mine. Includes a value, estimated by producer, for coal not sold.
[5]One mine extends into two counties but is counted only in the county where its greater production occurred.

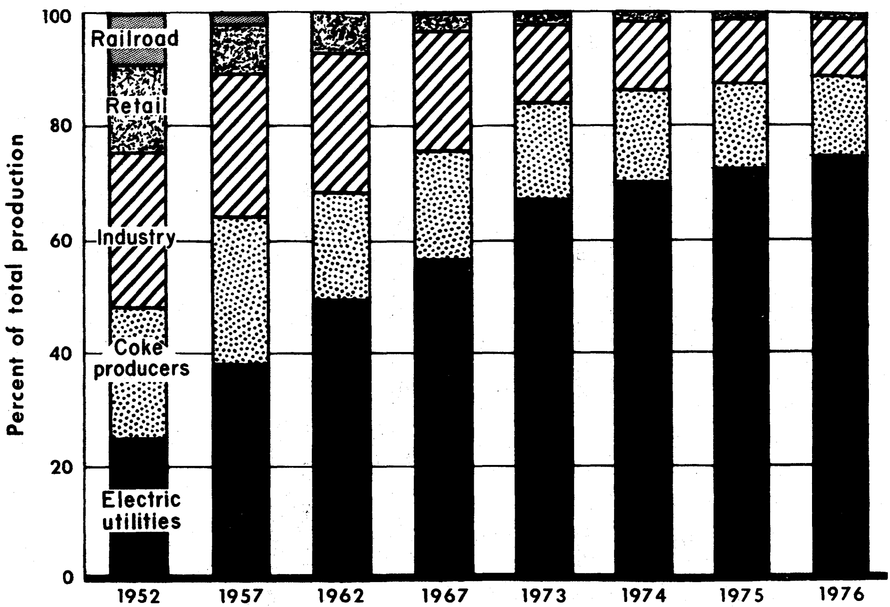

Figure 4.—Percentage of total consumption of bituminous coal and lignite, by consumer class and retail deliveries in the United States.

[r]Revised.
[1]Federal Power Commission.
[2]Bureau of Census, U.S. Department of Commerce, Ore and Coal Exchange.
[3]Estimates based upon reports collected from a selected list of steel and rolling mills.
[4]Estimates based upon reports collected from a selected list of manufacturing plants.
[5]Estimates based upon reports collected from a selected list of retailers. Includes some coal shipped by truck from mine to final destination.
[6]The total of classes shown approximates total consumption. The calculation of consumption from production, imports, exports, and changes in stocks is not as accurate as the "Total of classes shown" because certain significant items of stocks are not included in monthly stocks. These items are stocks on lake and tidewater docks, stocks at other intermediate storage piles between mine and consumer, and coal in transit.

[1]Federal Power Commission.

[2]Days' supply is calculated by dividing the total stocks at the end of the month by the daily average rate of consumption during the same month. By this method, seasonal variation in daily average rate of consumption is not reflected.

Table 12.—Distribution of bituminous coal and lignite, in 1976, by method of movement and consumer use

(Thousand short tons)

Shipments	Electric utilities	Coke and gas plants	Retail dealers	All others	Rail-road fuel	Used at mines and sales to employees

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Ecuador produces coal, but output was less than 500 tons annually in the years covered by this table.

[2]Less than 1/2 unit.

[3]Includes material reported in national sources as brown coal.

[4]Official sources report the aggregate of bituminous coal and anthracite; distribution to these separate grades is estimated from reported total.

[5]Output from Norwegian controlled portion only. Output of that portion of Svalbard controlled by the U.S.S.R. is presumably included in the total output recorded for that country. The U.S.S.R. output in short tons was as follows: 1974, 540,000; 1975, 440,000; 1976, 440,000.

[6]Run-of-mine output.

[7]Includes slurry.

[8]May include a small amount of anthracite.

[9]Sales for year ending August 31 of that stated.

[10]Sales.

[11]Year beginning March 21 of that stated.

[12]Data include low-ranked coals, including some lignite.

[13]Year ending June 30 of that stated.

Coal—Pennsylvania Anthracite

By L. W. Westerstrom[1] and W. M. Watson[2]

All of the reported output of anthracite in 1976 was produced in northeastern Pennsylvania. The anthracite region is divided geologically into four fields: Eastern Middle, Northern, Southern and Western Middle. The area is also grouped into three trade regions: Lehigh, Schuylkill, and Wyoming.

The total production in 1976 was 6.2 million short tons, a 0.4% increase over the amount produced in 1975. Of the total output, 48% was produced at strip pits, 41% was recovered from culm banks, 9% was produced at underground mines, and approximately 2% was recovered from river dredging operations. In comparing 1976 with 1975, there were increases of 17.0% in production from strip mines and 15.8% in the recovery of river coal. There were decreases of 12.5% in culm recovery and 8.9% in production from underground mines.

The total value of the 1976 output was $209.2 million, a 5.4% increase over the 1975 value. The average commercial value, f.o.b. preparation plants for all sizes, increased $1.67 per ton (from $45.04 to $46.71), and the average value of buckwheat No. 1 and smaller sizes increased $1.50 per ton (from $27.61 to $29.11).

Apparent consumption of Pennsylvania anthracite in the United States in 1976, calculated as production minus exports (including that exported to West Germany for use by the U.S. Armed Forces), totaled approximately 5.0 million tons, a decline of 1.3% from the 5.1 million tons consumed in 1975.

Exports of anthracite (as reported to the U.S. Bureau of the Census) totaled 615,167 tons for 1976, a decrease of 3.8% from the amount exported in 1975. However, when the quantity shipped for use by the U.S. Armed Forces in West Germany is added to the tonnage reported by the Bureau of the Census, the actual tonnage exported is 1,188,234 tons, an increase of 8.5% from the comparable amount shipped in 1975.

The Pennsylvania anthracite mining industry worked an average of 235 days in 1976 and employed a work force of 3,686. Of that total, 742 were employed at underground mines, 1,375 at strip operations, 328 in recovering coal from culm banks, 15 in dredging operations, and 1,226 at preparation plants and other surface operations. In operation were 122 underground mines, 112 strip pits, 117 culm banks, 6 dredges, and 91 preparation plants.

Productivity in the anthracite industry declined in 1976. The average output per man per day declined from 7.45 tons in 1975 to 7.19 tons in 1976. There was one fatality in 1975 and one in 1976. Nonfatal injuries increased from 351 in 1975 to 374 in 1976.

Legislation and Government Programs.—State and Federal Government public works-type programs in the environmental area continued throughout 1976 and included control and extinguishment of fires from abandoned underground mines, reclamation of old strip pits and culm banks, and extinguishment of burning coal mine refuse banks. In addition, mine-water control projects were designed to secure the safety and livelihood of mine personnel and to protect anthracite reserves from the hazards of adjoining abandoned mine pools and possible inundatation by surface flood waters.

Hydrologic studies continue to evaluate

[1]Industry economist, Division of Coal.
[2]Statistical assistant, Division of Fuels Data.

mine-water problems. They involve determination of the varying heights of underground mine pools, their hydrostatic pressures, and their possible effect on barrier pillars and mine dams protecting active mining operations, and acid mine-water drainage into surface streams and the unconsolidated valley fill. Under the closely related mine-water control program, a comprehensive series of mine pool monitoring stations have been installed, and additional phases of the project are proceeding in the Western, Middle, and Southern fields.

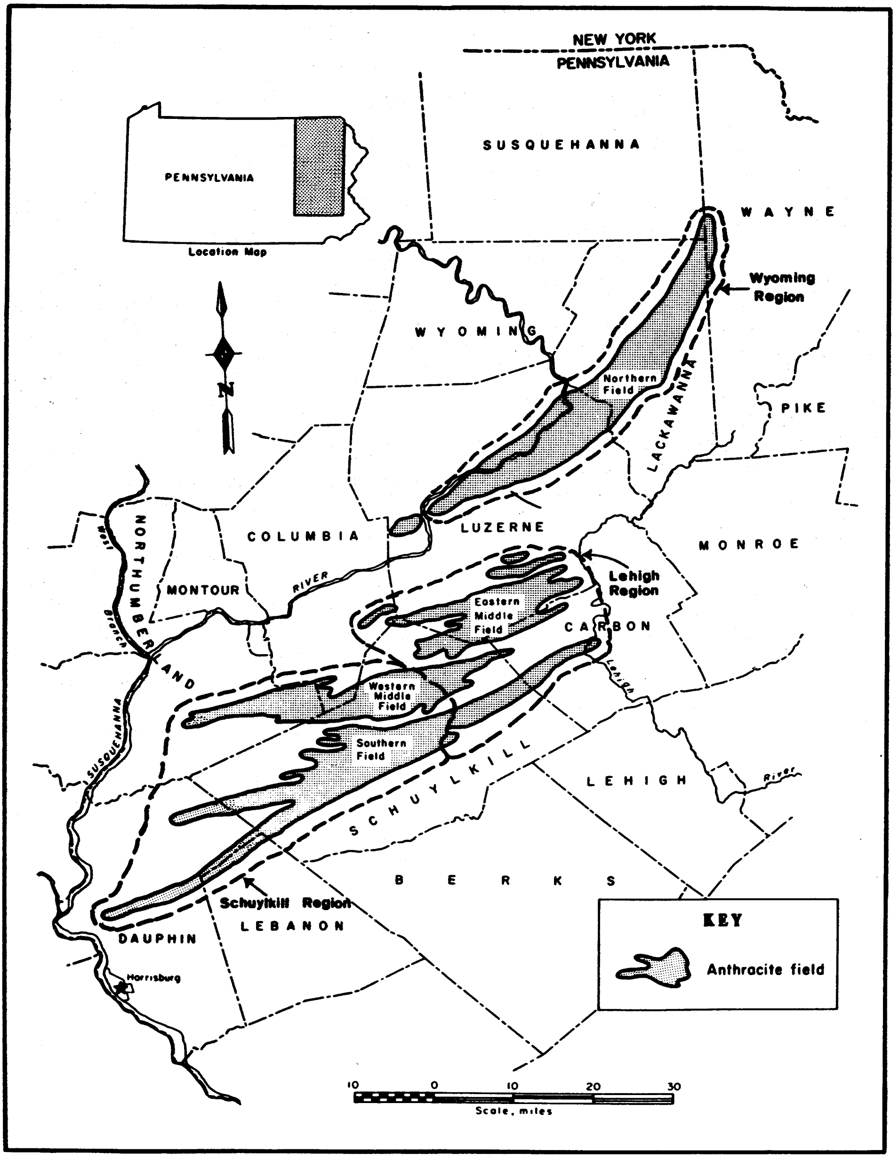

Figure 1.—Coalfields, regions, and counties of the Pennsylvania anthracite area.

FOREIGN TRADE

According to data released by the U.S. Bureau of the Census, 615,167 short tons of Pennsylvania anthracite was exported in 1976, a decrease of 3.8% from that shipped in 1975. Of the total, 72.4% was exported to Canada, a decrease of 18.1% from the amount shipped in 1975; 3.1% to South America; 0.2% to Asia; and the remainder to other countries. The Census Bureau figures do not include anthracite shipped abroad for the use of the U.S. Armed Forces in West Germany; therefore, a more complete measurement of exports can be obtained by adding the military tonnage (573,067) to the tonnage reported by the Bureau of the Census. Consequently, 1,188,234 short tons was exported in 1976.

Table 1.—Salient statistics of the Pennsylvania anthracite industry

	1972	1973	1974	1975	1976
Production:					
Preparation plants short tons	6,618,205	6,377,512	6,454,385	6,117,156	6,127,884
Dredges do	476,792	441,076	150,468	76,142	87,942
Used at collieries for power and heat do	11,298	11,373	12,013	10,012	12,407

Buckwheat No. 5	Through 3/64	NL	NL	--	--	16

NL No limit.
[1]When slate content in sizes from broken to chestnut, inclusive, is less than above standards, bone content may be increased by 1 1/2 times the decrease in slate content under the allowable limits, but slate content specified above shall not be exceeded in any event. A tolerance of 1% is allowed on maximum percentage of undersize and maximum percentage of ash content. Maximum percentage of undersize is applicable only to anthracite as it is produced at preparation plant. Slate is defined as any material that has less than 40% fixed carbon. Bone is defined as any material that has 40% or more, but less than 75%, fixed carbon.
[2]Ash determinations are on a dry basis.

[7]U.S. Department of Commerce. Does not include shipments to the U.S. Military Forces.
[8]Federal Power Commission.
[9]Estimated from reports submitted by a selected list of retail dealers located outside the producing region.
[10]Furnished by the Bureau of Labor Statistics from data obtained from authorized trade publications.

NOTE: According to the Association of American Railroads, 657,052 short tons of anthracite were exported to Europe during 1976, compared with 582,185 short tons for 1975. Of this total 573,586 short tons were consigned to West Germany and the Netherlands, including exports to the U.S. Military Forces. This compares with 510,577 short tons for 1975.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]An unspecified amount of semianthracite is included in figures for some countries.

[2]In addition to the countries listed, Canada, Colombia, and New Zealand, produce anthracite, but the level of production is not recorded and available information is inadequate to make reliable estimates; in Colombia output may total 100,000 tons annually, while in New Zealand output is insignificant.

Cobalt

By Scott F. Sibley[1]

Cobalt demand rebounded in 1976 from the relatively low levels in 1975. The increase followed the general resurgence in industrial activity and the favorable economic situation during the year. Demand for magnetic materials was especially high, while that for superalloys was relatively low. Total reported consumption of cobalt in the United States was 16.5 million pounds, a 29% increase over that of 1975.

A supply bottleneck occurred early in the year after bridges along the Benguela Railway, linking the cobalt-producing regions of Zaire and Zambia with the port of Lobito, Angola, were damaged by rival factions in the Angolan civil disturbances. Informal rationing by suppliers followed. Even though the rail line reportedly was repaired in August, permission for Zaire to use it was delayed. However, a favorable route via the port of East London, the Republic of South Africa, was utilized.

Government deliveries of cobalt sold from strategic stockpile excesses (6.7 million pounds) were a significant source of supply during 1976.

The major dealer for cobalt in the United States, African Metals Corp., notified customers April 6 that it would limit cobalt shipments to each buyer on the basis of average monthly deliveries over the previous 15 months plus 25%. On December 1, African Metals lifted its allocation system because of the return of its stocks to normal levels.

Legislation and Government Programs.—The General Services Administration (GSA) continued to offer for sale during most of 1976 specification-grade cobalt metal in various forms from excesses in the national stockpile. Government sales of cobalt by competitive bidding in 1976 totaled 5,130,696 pounds, compared with 4,896,384 pounds in 1975. Sales were on an unrestricted bid basis except that total sales of specification-grade material were limited to about 1 million pounds per month and 500,000 pounds per bidder per month. On April 6, GSA announced a revision of the cobalt invitation for bid MET-201. The revision provided for (1) a reduction in the total quantity of cobalt available for sale each month during April through September, (2) restriction of sales to domestic use only, and (3) a limitation on the quantity available to any one purchaser to 20% of the quantity offered each month, down from the previous limit of 50%.

On September 7, GSA announced the withdrawal of its Invitation for Bids for Cobalt PMDS-MET-201, following establishment of the Government's new

rRevised.

stockpile policy. From the first bid opening in April 1972, a total of 27,907,371 pounds of cobalt were sold under this invitation. Following this announcement, a government news conference was held October 1, 1976, concerning the U. S. stockpile of strategic and critical materials. A new stockpile goal for cobalt was listed as 85,415,000 pounds. The total inventory of cobalt in the stockpile as of December 31, 1976, excluding material sold but not delivered, was 40,950,635 pounds. Deliveries from the stockpile totaled about 6,698,000 pounds.

DOMESTIC PRODUCTION

There was no domestic mine production of cobalt in 1976. However, AMAX Inc., began significant production at its refinery in Braithwaite, La., and reached greatly improved operating capacity. According to AMAX's 1976 annual report, 363,000 pounds of cobalt were produced during the year; this was about five times that reported for 1975. By yearend, the refinery was operating at about 65% of capacity of 1 million pounds of cobalt per year. Nickel-cobalt and copper-cobalt matte was supplied to the plant from New Caledonia, the Republic of South Africa, and Botswana. Employees at the facility, members of the United Steelworkers of America, Local 8373, accepted a labor agreement at midyear, with a termination date of August 31, 1979. Reportedly, the new wage pact provides for increased wages, including a 90-cent-per-hour across-the-board raise effective September 1, 1976, as well as cost of living protection and other benefits.

Research by the Bureau of Mines to encourage and enable development of low-grade domestic laterites (see Technology section) continued, and the second stage of a feasibility study for a plant to process 5,000 tons per day was completed by contract consultants for the Bureau. Preliminary steps were also taken by the Bureau to evaluate the laterites as to their grade and extent. In addition, some development work was undertaken by AMAX Inc., to develop the Duluth gabbro sulfide deposits. However, environmental obstacles remain to be overcome, and no actual mining is expected before 1983.

CONSUMPTION AND USES

Consumption of cobalt in the United States remained strong throughout 1976, rising 29% over that reported in 1975. Of the cobalt consumed, 71% was as metal, 3% as oxide, 24% as salts and driers, and 2% as purchased scrap. Consumer stocks soared 77% above their 1975 yearend level, reflecting concern over the possibility of disruption of supply from southern Africa.

Major uses in 1976 were transportation (aircraft), 18%; electrical (magnets), 28%; machinery (principally cutting tools), 16%; paints (mainly driers), 15%; ceramics, 12%; chemicals, 9%; and other, 2%. The greatest

Table 2.—Comparison of selected end uses, 1975-76

Use	Percent of total	
	1975	1976
Steel:

Total	14,130	18,741	18,861	12,787	16,482

increases during the year were in magnetic alloys (+73%), pigments (+60%), salts and driers (+39%), catalysts (+30%), and full alloy steel (+28%). Glass decolorizer and tool steel showed significant decreases. Of particular note was the accelerated demand for cobalt in magnetic materials, a reflection of the generally high demand for electric motors, loudspeakers, and various other types of electrical equipment. However, demand for superalloys, traditionally a strong factor in the cobalt market, continued to be relatively sluggish compared with recovery of other end uses. This was primarily caused by low orders for commercial aircraft. For this reason, magnetic materials exceeded superalloys, in terms of percentage of total demand, for the first time in several years. Leading end uses were salts and driers (24%), magnetic alloys (21%), superalloys (17%), cutting and wear-resistant materials (10%), and catalysts (9%). The large increase in pigments and driers may be attributed to increased construction activity and therefore increased demand for paints in 1976 relative to activity in this area in 1975.

PRICES

The producer price of cobalt remained at $4 per pound from January 23, 1975, to April 15, 1976, when it was raised to $4.40 per pound. On September 13, the price was increased to $4.90 per pound, and on December 24, 1977, the price was raised to $5.40 per pound. The first two price rises were reported to be the result of increased producer costs. The last price change was brought about by a realignment of the value of the U.S. dollar with respect to the Belgian franc. Government sales of cobalt on a "sealed bid" basis ranged from $3.55 to $5.63 per pound for specification-grade material. The weighted average price for the year was $4.44 per pound of cobalt. All dealer prices were quoted as f.o.b. New York or Chicago and applied to granules (shot) or broken cathodes in 551-pound (250-kilogram) drums. From January 1973 to January 1977, the price of cobalt rose at an actual annual rate of 21%. In terms of constant 1975 dollars, the price increase averaged 14% per year over the same period. These increases may be compared with average annual increases for a 20-year period (1957-77) of 4.8% and 1.1% for actual and adjusted prices, respectively.

FOREIGN TRADE

Exports of unwrought cobalt metal and alloys and of waste and scrap totaled 3,165,511 pounds, gross weight, having a value of $7,772,413, and went to 22 countries. Japan and West Germany received the greatest part, with 925,509 pounds (gross weight) valued at $1,817,425 and 731,780 pounds (gross weight) valued at $2,249,841, respectively. Exports of wrought cobalt metal and alloys of 726,750 pounds (gross weight), having a value of $4,655,041, went to 23 countries.

Total imports of cobalt (16,487,000 pounds, contained weight) were up 150% from those of 1975. The top five sources of cobalt imports to the United States in 1976 were Zaire (41%), Belgium-Luxembourg (15%), Zambia (10%), Norway (7%), and Botswana (6%). This was the first year since 1972 that Canada was not among the top five and the first year since 1968 that Finland has not been included. Material originating in southern Africa (that imported from Zaire, Zambia, Belgium-Luxembourg, and Botswana) accounted for 73% of total imports. Although imports from Botswana were relatively high, the reported figure was only an estimated cobalt content of the matte received for processing. A percentage of the material was lost in processing at the cobalt-nickel refinery of AMAX Inc., in Braithwaite, La.

WORLD REVIEW

Both mining and refinery operations around the world continued to expand. Except for closure of the Lynn Lake mine of Sherritt Gordon Mines, Ltd., nearly all operations continued production at maximum possible levels in response to a surging world demand which rebounded from its record low in 1975.

International.—At least three international consortia were active in ocean mining development during the year. However, there were no commitments to commercial ventures beyond exploration and/or technology development. Even so, commercial production of metals from the nodules could begin as early as 1982 or 1983, with production of 5 million pounds of cobalt per year by 1985. Several bills were sponsored by members of the U.S. Congress to provide insurance protection to mining companies against loss of their investments if an international authority should preempt their operations. The lending institutions appeared to require this kind of legal and financial protection before large sums of money would be made available to consortia for full-scale operations. However, no relevant legislation was passed in 1976.

Large-scale tests of deep seabed ocean mining systems were scheduled to be made in 1977-79. These would cost the companies $20 to $75 million per operation. Later development of processing systems and infrastructures may cost $300 to $600 million per operation.

The fifth session of the third United Nations Conference on the Law of the Sea, which ended September 17, produced no concrete results. The principal question appeared to be the nature of developing countries' participation in mining of sea floor areas beyond national jurisdiction. Another full conference was scheduled to convene May 23, 1977, in New York City, and an informal session was scheduled for February 28 to March 11, 1977. The topics that were to be considered included (1) establishment of an international agency to supervise the mining operations on the seabed, (2) limiting the rate of mining to the increase in world demand for nickel, and (3) the possibility of developing nations receiving technical aid to start their own mining ventures.

Australia.—Repairs and redesign of ore-processing units at the Greenvale nickel-cobalt metallurgical plant in Queensland, Australia, reportedly brought the operation close to design capacity by yearend. High-silica ore had caused excessive wear in a number of areas. This problem was overcome by selective mining of softer ores. In addition, the installation of mass flow cones to regulate ore feed in the hammer mills alleviated difficulties with bridging and flooding of the 2,000-short-ton capacity bin. Design capacity of the plant is 1,375 short tons per year of cobalt.

The project is a joint venture of Metals Exploration Queensland Pty Ltd., and Freeport Queensland Nickel, Inc. (American owned). The operation posted fiscal losses for the year which were blamed on inflation and increased oil costs. Output of cobalt contained in mixed sulfides was 764,000 pounds, or about 57% of capacity. At last report, these companies were negotiating for replacement of fixed interest and principal payments with a deferral plan, in order to ease the financial burden.

The Greenvale ore body is a laterite deposit with nickel and cobalt occurring in a residual weathering mantle, averaging about 26 feet in thickness. The overburden averages 20 feet. In addition, proven reserves are estimated at 50 million short tons, averaging 0.12% cobalt. Mine life is put at about 20 years. About 220 men are employed at the mine site, which is an opencut operation. Two trains make the run to the Yabulu treatment plant, 140 miles distant, each day. The plant is entirely self-sufficient in terms of electric power, using large amounts of heavy fuel oil from the Persian Gulf. The plant also uses about 5 million gallons of water per day. Throughput of this ammonia leach plant is about 3,025,000 wet short tons per year, with an annual cobalt production of about 1,100 short tons. The nearest port is Townsville, about 15 miles to the south.

A new discovery of manganese nodules on the sea floor southwest of Perth, Western Australia, was announced by the Bureau of Mineral Resources of Australia's Department of National Resources. The nodules reportedly occur at depths of 14,000 to 16,500 feet and have combined cobalt and nickel contents averaging 1.19%. The extent of the field has not yet been determined.

Botswana.—According to reports, in August, Botswana RST Ltd.'s (Botrest) copper-nickel-cobalt smelter at Selebi-Pikwe operated at 7% above the rated capacity of about 3,300 short tons of matte per month. This record production occurred after 2 years of plant production difficulties and was brought about by a new management team. The mining operation continued to face problems; inflated costs partially offset a rise in related metal prices, and Botrest was faced with outstanding claims by Triomf Fertilizer, Ltd. and AMAX Refining, Inc. because of the production delays, which allegedly resulted in nonfulfillment of contract. Bamangwato Concessions, Ltd., a subsidiary of Botrest and operator of Selebi-Pickwe, reported production of 72 million pounds of cobalt-bearing matte in 1976.

The sulfur section at Selebi-Pickwe experienced the most difficulty, and complete rehabilitation of the plant had to be undertaken. In the meantime, until repairs could be made, Triomf reportedly was forced to produce sulfuric acid for the manufacture of phosphoric acid at a greater cost than the contractural one. Despite all these problems, the operation was expected to reach full production levels in 1977. The local smelter provided matte as feedstock to AMAX Inc.'s refinery in Braithwaite, La.

Canada.—Sherritt Gordon Mines, Ltd., closed its Lynn Lake, Manitoba, mine in June after a serious shortfall in production targets. Problems were encountered in recruiting miners for the operation, which used cut-and-fill underground mining method, and in persistently low tonnage and grade. The Lynn Lake mine was the last major Canadian source of feedstock for Sherritt's Fort Saskatchewan refinery. Other sources used by Sherritt on a toll basis were Australia (Western Mining Corp. Ltd., and Freeport Queensland Nickel, Inc., in a joint venture with Metals Exploration Queensland, Pty Ltd.) and the Philippines (Marinduque Mining & Industrial Corp.). The refinery was shut for 2 weeks in May for annual maintenance work and for the purpose of diverting excess anhydrous ammonia to the agricultural market.

The largest producer of byproduct cobalt in Canada was International Nickel of Canada Ltd., (INCO), which recovered a crude oxide at its nickel refineries in Port Colborne, Ontario, and Thompson, Manitoba. Deliveries of cobalt in 1976 were reported as 2,430,000 pounds, up 134% from those of 1975. Cobalt oxides and salts were recovered at the company's nickel refinery in Clydach, Wales. Falconbridge Nickel Mines Ltd., reported deliveries of 2,079,000 pounds, up 52% from those of 1975.

Cuba.—Cuba reportedly planned to raise its output of nickel in sulfide, oxide, and sinter to an annual 102.5 million pounds by 1980 from about 80 million pounds in 1975. If current nickel-to-cobalt production ratios are maintained, this would mean a production of about 4.5 million pounds of cobalt in 1980, versus the current estimate of 3.6

million pounds. Furthermore, if planned expansions are executed, 7.2 million pounds of cobalt would be produced in 1985 and 14.4 million pounds in 1990. There was speculation that some of this material would be made available to Western markets.

Indonesia.—P.T. Pacific Nikkel Indonesia, Ltd., (PNI), made steady progress during the year in the task of assembling financing for its Soroako project on the Island of Sulawesi. The deposit has the potential for production of 100 million pounds per year of nickel and 4 million pounds per year of cobalt in the form of mixed sulfides. PNI reportedly will use a $25 million Australian loan to buy Australian goods and services for the second stage of development. The loan for the $800 million project was arranged by the Australian-supported Export Finance and Insurance Corp. Included in the project plans are an open pit mine, a reduction and smelting plant, and hydroelectric and thermal power generation facilities. Much of the infrastructure will be developed by Australian companies.

India.—Construction of the first Indian nickel-cobalt smelter, to be located at Sukinda in Orissa Province, reportedly will not begin until sometime during the sixth plan (April 1979-March 1984). The project was postponed from a 1976 target date because of a delay in commissioning a pilot plant for the processing of laterite ore in the Kansas area. The plant capacity was to be 210 short tons per year of cobalt.

Japan.—The Nikko Nickel Cobalt Smelting Co., Ltd., a subsidiary of Nippon Mining Co., Ltd., began production of cobalt at its Nitachi plant during the year. Production reached about 51 short tons per month at yearend, and the capacity level of 110 short tons per month was expected to be reached in 1977. The facility was built at a total cost of $14.3 million. Australian feed material (a mixed sulfide containing 15% cobalt and 39% nickel) was delivered to the plant.

Sumitomo Metal Mining Co., Ltd. also began commercial production of metallic cobalt and nickel at its Besshi plant, Ehime Prefecture. Feedstock for the plant was imported from Marinduque Mining & Industrial Corp. in the Philippines. Annual capacity of the plant is 1,760 short tons of cobalt. The facility was completed in September at a cost of $13.3 million and was producing cobalt at the rate of about 70 tons per month by yearend.

Both Nikko Nickel and Sumitomo employed the solvent extraction process for separating cobalt and nickel from mixed sulfides. Nikko Nickel used sulfuric acid as a solvent, while Sumitomo used hydrochloric acid. The two refineries are expected to supply 50% of Japan's refined cobalt requirements.

Philippines.—Marinduque Mining & Industrial Corp. continued to experience technical difficulties at its Nonoc Island nickel-cobalt refinery, which reportedly has an annual production capacity of approximately 3.3 million pounds of cobalt in mixed sulfides. In May, the refinery operated at about 66% of rated capacity, and there was no substantial improvement by yearend. The plant was shut down for 3 weeks in November for annual maintenance and installation of a new gas plant boiler. The main plant operating problems were (1) the reliability of services such as power, steam, and hydrogen and carbon dioxide gases, (2) training of supervisory personnel, (3) roaster availability, (4) parts supply, (5) first-stage-leach-circuit cooling capacity, and (6) excessive ammonia consumption.

Rhodesia, Southern.—Rio Tinto (Rhodesia), Ltd., reportedly was to build a cobalt plant to treat residues from its Empress nickel mines near Gatooma in the Rhodesian midlands. The plant was to be financed by an offer of new shares to existing shareholders and would cost approximately $530,000. According to an official of the company, the plant would start as soon as financing was secured and would be onstream by about January 1977.

Zaire.—A supply shortage occurred early in the year after bridges along the Benguela Railway, linking the mineral-rich regions of Zaire and Zambia with the port of Lobito, Angola, were damaged by rival factions in the Angolan civil disturbance. Informal rationing by suppliers followed. Even though the rail line was repaired in August, Angola reportedly delayed granting Zaire permission to use it. However, Zaire found a favorable route via the port of East London, the Republic of South Africa. Deliveries of cobalt to the United States from July through December continued at a relatively high level, commensurate with demand.

Although Zaire made some use of the port of Matadi on the Atlantic Ocean, the eastern and southern routes carried the greatest portion of cobalt exports. In particular, Zaire made use of the Tazara Railway from Zambia to Dar es Salaam on the Indian

Ocean (the eastern route). Reportedly, however, about one-third of Zairian copper and cobalt moved on the southern route through Rhodesia during the year. Two other less direct routes were also used. One was by rail to Lake Tanganyika, which was crossed by ferry; another rail line through Tanzania completed the route. The other, less-traveled route was by rail to the interior Zairian town of Llebo, where the material was transferred to barges or trucks and shipped to the port of Matadi on the Atlantic Ocean. Reportedly, Zaire made a formal request to Zambia to intercede on Zaire's behalf with the Tazara Railway Authority in Tanzania to obtain formal shipping rights. Meanwhile, guerrilla activity continued in Angola; rebel forces claimed to have blown up sections of the Benguela Railway seven times in the last half of 1976. Prior to 1976, this line was used to transport large quantities of copper and cobalt to the Atlantic. Several alternate routes to ports in Mozambique were blocked when Mozambique closed its border with Rhodesia.

Compounding these transportation problems was Zaire's financial crisis. This was brought about by Zaire's mounting overseas debt, which was estimated at about $1.4 billion at yearend, with interest and principal payments in arrears by about $19 million. Conditions reportedly were set by lending institutions such that if Zaire paid off the amount in arrears in approximately the first 9 months of 1977, a loan of $250 million would be extended. However, tight International Monetary Fund guidelines had to be met.

The proposed $880 million project of Société Minière de Tenke Fungurume (SMTF) remained stalled during the year because of inability to obtain financing. In part, lending institutions were reluctant to extend credit because of the civil strife in neighboring Angola and resultant transportation problems; three additional reasons were spiraling costs, the possibility of mining of cobalt- and copper-bearing manganese nodules from the seabed, and an expected depressed copper market. However, according to officials of Anglo-American Corp. of South Africa Ltd., one of several partners in the project, the proposal may be reworked to encompass a smaller scale operation. According to an official of Charter Consolidated, Ltd., another partner, the project might be reactivated if the price of copper moved into the range of 90 cents to $1 per pound. Prospects for reactivation appeared to be dim at yearend since drilling rigs and other equipment due for shipment to SMTF were sold. About 14 million pounds of cobalt per year was to have been produced. Tied in with suspension of this project are problems with the Shaba power line, which was to have supplied SMTF with its power needs. The 1,500-mile line fell 1 year behind schedule because of payment defaults to Swedish and Italian contractors and withdrawal of an American construction firm.

The plan by Générale des Carrières et des Mines (GÉCAMINES) to expand its operations through a 5-year development plan slowed during the year because of finance problems. However, some progress was made. Tenders for an industrial complex at Luilu in the Shaba region were called for by GÉCAMINES. The complex reportedly will consist of a flash smelting unit and a pyrometallurgical plant using coke and carbon as fuel and lime as a processor. The tender was for construction of the complex, a storage area, and preparation of the fuel and processing units. The construction is part of a plan to produce 40 million pounds of cobalt per year by 1980.

Two additional problems surfaced during the year. The Belgian companies, which had largely returned marketing functions to the Government of Zaire, reportedly were called back to help with technical and marketing matters. An unrelated problem was a shortage of metallurgical coke supplied by Rhodesia. The shortage reportedly was brought on by political sabotage and chronic transportation problems.

Zambia.—As with Zaire, lack of adequate transportation was a major problem during the year. At yearend, there were unconfirmed reports that Zambia was reviewing its border closure with Rhodesia and that there might be a change of policy allowing shipments to cross the border. The Tazara Railway, which runs through Tanzania, accelerated cargo loads from seven to nine per week at midyear in an effort to speed up copper and cobalt exports. Reportedly, the backlog of copper at the terminal port of Dar es Salaam was cleared up at midyear. Zambia's route to Lobito, Angola, was cut off by the Angolan civil war and had not been reopened by yearend. Although landlocked Zambia is independent of Rhodesia's transport system, Zambia's electricity originates in and is controlled by Rhodesia. Electricity is produced at the Kariba South hydroelectric plant, which is jointly controlled by the two countries.

Despite the relatively depressed copper market, Roan Consolidated Mines reportedly planned to expand its Chambishi facilities on the Copperbelt. This would substantially increase Zambia's cobalt production by 1978.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the countries listed, Bulgaria, Cyprus, East Germany, Greece, Poland, Spain, Sweden, and Uganda are known to produce nonferrous ores that contain a recoverable amount of cobalt, but available information is inadequate to permit formulation of reliable estimates of output levels. Other nations may also produce ores containing cobalt as a byproduct component.

[2]In addition to the countries listed, the United Kingdom recovers cobalt metal from intermediate metallurgical products produced in Canada, but data on this output are not reported by the United Kingdom and are inseparable from the total reported by Canadian producers; Czechoslovakia presumably recovers cobalt from material imported from Cuba, but no data are published and available general information is inadequate for formulation of reliable estimates of output levels. Belgium imports substantial quantities of crude materials containing cobalt, but output of metal has not been reported in recent years; production of cobalt metal and/or cobalt compounds, however, has continued.

[3]Sales.

[4]Actual output not reported. Data presented for mine output are total cobalt content of all products, including nickel oxide sinter shipped to the United Kingdom for further processing. Data presented for metal output represent the mine output just described less the cobalt metal output reported for Norway. Thus the metal output data include cobalt content of oxides and other compounds that are not produced as metal and the total cobalt metal output in the United Kingdom from Canadian materials, as well as actual metal output in Canada itself.

[5]Cobalt contained in matte and ferronickel produced; additional cobalt is contained in concentrates exported for further processing, but content of such ores is not reported and available general information is inadequate to permit formulation of reliable estimates of the cobalt content of this material.

[6]Data on domestic mine production, if any, are not available, but if output has continued, a small part of the recorded metal output may be from domestic raw materials, rather than from imported Canadian nickel-copper-cobalt matte.

[7]Revised to zero.

TECHNOLOGY

The Bureau of Mines was actively engaged in research aimed at reducing U.S. import dependence. At the Rolla Metallurgy Research Center, experiments were conducted on recovering cobalt and nickel from Missouri lead ores. The objective of this project is the development of procedures for concentrating, extracting, and recovering cobalt and nickel as byproducts during the concentration and smelting of these ores. The Albany Metallurgy Research Center in Oregon worked on the recovery of cobalt, nickel, and copper from domestic laterites, which occur principally in southwestern Oregon and northern California. Singmaster and Breyer, metallurgical and chemical process engineers, New York, N.Y.,[2] completed the first phase of a government contract to study the technical and economic feasibility of operating a 5,000-ton-per-day commercial-scale plant to extract the metals based on the process developed by the Bureau of Mines.[3]

[3]Siemens, R. E., and J. D. Corrick. Process for Recovery of Nickel, Cobalt, and Copper From Domestic Laterites. Min. Cong. J., v. 63, No. 1, January 1977, pp. 29-34.

The Bureau's Twin Cities, Minn. Metallurgy Research Center conducted research on processing of ores of the Duluth gabbro complex, which extends in a great arc from Duluth to the northeastern point of the State and contains about 0.04% cobalt. An analysis of the composite bulk copper-nickel concentrate produced thus far revealed a range of 0.1% to 0.4% cobalt.[4]

At the Reno Metallurgy Research Center in Nevada, Bureau scientists developed a cobalt rare-earth magnet with an energy product of 9.5 megaoersteds. The magnet contained 35% mischmetal plus other selected elements, which enabled replacement of up to 10 weight-percent cobalt. Based on this research, cheaper high-energy magnets may be made available. A patent on the new magnet was applied for.

A British research firm reportedly produced a cobalt-bearing powdered metal alloy with cutting properties superior to those of high-speed steel. The alloy is made by induction-melting powders containing 45% cobalt, atomizing in an inert gas, and then cold-compacting and sintering to produce preforms with 15% to 20% porosity. The preforms are then forged in a hydraulic press to nearly 100% of theoretical density. Hardness of the finished product reportedly is about Rockwell C 65.[5]

An improved cobalt-base conventional alloy, Capivac IV (Co-25Cr-10Ni-7W-4Ta-0.5Ti-0.62Al), recommended for investment castings, was developed by a major specialty alloy manufacturer. The alloy reportedly overcomes two major problems associated with other cobalt-base turbine alloys. These problems are poor low-temperature ductility and reactivity with mold materials. The latter problem was overcome by eliminating zirconium, which causes surface oxidation of cast parts. Room temperature ductility of the new alloy is two to three times that of zirconium-bearing cobalt-base alloys.[6]

A principal manufacturer of nuclear parts reportedly is using cobalt-base alloy bonnet and seat inserts in valves manufactured for nuclear power stations. The alloy has the trade designation Haynes No. 6PM, and reportedly has been found effective against borated water for both pressurized and boiling water reactors. The seats are shrink-fitted in forged steel valve bodies by chilling the seat rings in liquid nitrogen and heating the valve bodies to about 200°C. The valves are designed to last 40 years and are rated for water, oil, or gas service.[7]

In the general field of superalloys, increasing attention reportedly was being paid to refining current fabrication processes rather than developing new alloys. Working with conventional materials, significantly improved properties are becoming ever harder to achieve. Moreover, increased strength at high temperatures means greater difficulty in hot working the material. Test costs also inhibited development of new alloys, which may possess only marginally improved properties. An example of these new fabrication developments is the significant strides made by industry in directionally solidified eutectics and single crystals for use in jet engine component parts. The purpose of this research is the attainment of higher operating temperatures in jet engines, considered important because engine efficiency is increased at higher temperatures, while pollution is decreased.[8]

The techniques in which major advances were made include hot forging, precision metal working, hot isothermal pressing (HIP) to near net shapes, powder metallurgy, particle metallurgy, and cold pressing. The latter two were used extensively in tool steel fabrication. By use of HIP techniques, the need for recycling large quantities of superalloy scrap generated by machining may be eliminated. One exception to this trend away from new alloy development is the amount of research being conducted in the area of silicon carbide composites, which may eventually result in higher operating temperatures in jet engines than can be reached with alloys currently in use.[9]

The Third International Symposium on Superalloys was held September 12 to 15. Advances in turbine technology and metallurgy of superalloys were reviewed at the conference. Energy system applications for superalloys were considered to have great potential. At an international workshop on rare earth metals at the University of Dayton, cobalt-rare earth magnet applica-

tions were reviewed and regarded as having high potential, particularly in electric motors and automobile accessory devices.

Perhaps the most significant cobalt research in progress during the year was the development of techniques for mining and processing cobalt-bearing manganese nodules from the ocean floor. Many patents have been issued on all phases of the new technology. Nevertheless, there was a debate as to whether hydrometallurgical or pyrometallurgical techniques would be more effective and economical in processing the nodules. The principal factors to be weighed are energy requirements and reagent costs. Pyrometallurgical processes are basically energy intensive. Moreover, the smelting of nodules requires the production of manganese, and because wet, impure 30% Mn nodules are inferior as an ore to 45% to 50% terrestrial material, the smelting method is considered by many not to be economically feasible. In the case of hydrometallurgy, three main processes were being studied. These were sulfuric acid, hydrochloric acid, and ammoniacal leach procedures. For the ammoniacal leach process, investment and reagent costs reportedly are relatively low, while energy requirements are high compared to the sulfuric acid route. However, in comparing the ammoniacal with the sulfuric acid process, high energy costs are more than offset by higher reagent costs of the sulfuric acid process. The HCl process would be more attractive with a higher manganese price. In addition, materials investment costs are high because of the need for materials with high corrosion resistance.[10]

In one patented process, developed by Deepsea Ventures, Inc., a mixture of finely divided manganese ore and at least a stoichiometric amount of a sulfide ore of copper, lead, nickel, or cobalt is contacted in an aqueous slurry with hydrogen chloride, hydrogen bromide, or hydrogen iodide, and the slurry is reacted to dissolve manganese and base metals. Elemental sulfur is also formed, while leaving substantially all of the iron impurity in the solid residue. The leach liquor is treated to crystallize solid manganese halide, the crystalline material is removed, and the low-iron, low-manganese leach liquor is processed for cobalt, nickel and copper and/or recycled.

Several prototypes for mining nodules were being tested, and a decision on commercial mining equipment to be used was expected before July 1978. In one method, a sea floor dredge head is used to gather nodules. The nodules are then cleaned and crushed under water and hydraulically hoisted to the recovery ship. By another method, a series of buckets are mounted on an extremely long loop of cable. The buckets are then dragged along the ocean bottom and hauled to the ship in a continuous operation. Several patents were issued on the lifting technology alone. For example, researchers for INCO (U.S. Patent 3,975,054, dated Aug. 17, 1976, and U.S. Patent 3,973,575, dated Aug. 10, 1976) developed an apparatus and method whereby a towed subsurface vehicle uses a motor-powered water jet to dislodge solids from the sea bottom. These are then collected in a hopper and trough, in which they are sorted and directed to a conduit for delivery to a surface ship.

In the field of laterite and sulfide processing, Freeport Minerals Co. received a patent (U.S. Patent 3,981,968) on recovery of nickel and cobalt values from an ammoniacal ore leach solution. In the process, the solution is contacted with an oxime extractant, and the nickel-enriched extractant phase is separated and stripped with sulfuric acid, first to remove the nickel (at ambient-temperatures), and then to remove cobalt at 170° to 300°F.

In what could be a significant development if cobalt prices continue to rise, Sumitomo Metal Mining Co., Ltd. developed a process (U.S. Patent 3,954,448, dated May 4, 1976) for recovering cobalt and other values from cobaltiferous copper converter slag or matte. The slag or matte is smelted to form a high-cobalt alloy, which is then heated with cupric sulfate and water. The resultant sulfate mixture is calcined to decompose iron sulfate, and the calcine is water-leached to dissolve cobalt sulfate.

Coke and Coal Chemicals

By Staff, Division of Coal

Production of all coal coke in the United States in 1976 was 2% more than in 1975, principally to satisfy an 8.8% increase in production of pig iron and ferroalloys in blast furnaces. Also contributing to the increase were a 15.1% increase in shipments of foundry coke and a 36.9% increase in coke shipped for other industrial plants.

Total coke production remained relatively constant throughout the year and averaged 4.86 million tons per month. The average daily output from all slot-type and beehive plants ranged from a low of 148,000 tons in January to a high of 166,000 tons in June. Average daily total output in 1976 was 160,000 tons.

During the year, the production of coke exceeded demand. Producers' stocks of oven coke, excluding coke breeze, at 6.49 million tons were 1.49 million tons greater at yearend 1976 than yearend 1975.

Blast furnaces continued to use the major portion of the Nation's coke production, receiving 92.5% of the 56.80 million tons of coke distributed by producers. The consumption of coke per ton of hot metal produced at blast furnaces averaged 1,188 pounds, compared with 1,222 pounds in 1975.

The coke equivalent of fuels injected through blast furnace tuyeres amounted to 102.4 pounds of coke equivalent (at 13,000 Btu per pound) per ton of hot metal, compared to 98 pounds of coke equivalent in 1975.

Breeze production in slot ovens averaged 102.4 pounds per ton of coal coked because of reportedly extended coking times and the slightly reduced use of low-volatile coals in the mixtures carbonized. Breeze is unsuitable for almost all metallurgical applications because of its small size and high-volatile and ash contents. The larger part of the breeze production was used by producers for sintering iron-bearing dust and fine ores and for other industrial purposes. However, 42.5% of the output was sold for industrial uses other than as fuel for steam plants or in agglomerating plants. The tonnage of breeze sold was 5.5% less than in 1975 and brought an average of $32.56 per ton, up from $32.21 in 1975.

The average cost of all bituminous coals and anthracite carbonized in slot ovens decreased $0.05 per short ton to $44.16 per short ton. This decrease was reflected in the average value of coal per ton of coke, which decreased $0.52 per short ton to $64.03 per ton. The largest price increases occurred in foundry coke sales. Foundry coke prices, which averaged $114.45 per ton f.o.b. plant, were $7.93 per ton higher than in 1975.

The production of tars was 1.4% less, and that of crude light oil was 1.7% greater, than in 1975. Production of coke-oven gas increased 1.9% compared to that of 1975, and 1.3% more coal was carbonized.

Foreign trade was somewhat greater, with coke exports, at 1.31 million tons, equal to 2.25% of domestic production. About 83% of the exported coke went to Canada, the Netherlands, West Germany, and Mexico. Coke imports were 27.9% less than in 1975, and exports were up 3.3%.

The total value of all coals carbonized was $3,699.1 million, and the total value of all carbonization products was $5,940.7 million. The combined value of coke and breeze, the principal products, accounted for 84.5% of the total value of all products.

Legislation and Government Programs.—The U.S. Department of Labor's Occupational Safety and Health Administration (OSHA) published in the Federal Register of October 22, 1976, a final job standards on exposure to coke oven emissions, to become effective January 20, 1977. In addition to imposing specification and performance standards on coke oven operations, many engineering controls and work practices on oven batteries were required. The standard set 150 micrograms of benzene soluble fraction in the total particulate matter per cubic meter of air, averaged over an 8-hour period, as the maximum employee exposure. All oven batteries producing foundry coke by late 1976 had most of the required engineering controls and all followed most of the required work practices. The coke-oven emissions standards will probably not materially affect oven production, but the costs to the foundry coke producers of complying with the standards will undoubtedly contribute to the spiral of inflation.[1]

The American Iron and Steel Institute (AISI) and the Environmental Protection Agency (EPA) in late 1976 signed contracts totaling $960,000 to cosponsor a study by Battelle Memorial Institute. The study was to develop and demonstrate an improved coke oven door-sealing system. AISI and EPA also sponsored a project, completed at a cost of $1.85 million at Jones & Laughlin Steel Corp., designed to reduce emissions during the charging of coke ovens.[2] OSHA's first Inflation Impact Statement (IIS) stated that imposing coke oven emission standards for particulate emissions would add $2.50 per ton to the price of steel and a negligible 0.01% to the consumer price index. Meeting the limits would require capital expenditures of $451 million by the steel industry and add $173 million to its annual operating costs. The industry would be forced to hire 5,000 new employees.[3]

The Armco Steel Corp's Houston, Tex., coke plant met a court-imposed deadline (July 31, 1976) for the requirement of a larry car for charging the plants 62 ovens without emissions, and a collection shed and electrostatic precipitator for treating the particulate-laden gases emitted during coke discharge. A second phase of the modernization will cost $4 million, for recovering byproducts from about 6 billion cubic feet per year of flared gases or cleaning the gas for use in the plant as fuel. The annual recovery of other products will include 4.5 million gallons of coal tar, 1.4 million gallons of naphthalene-enriched light oil, and 7.5 million pounds of ammonium sulfate.[4]

Armco Steel Corp. received approval in July 1976 for the continued operation of its New Miami, Ohio, coke ovens from Federal and State environmental protection agencies. In return, the company pledged $17.6 million for pollution control measures.[5]

In late September 1976, EPA filed a civil suit against Interlake, Inc., charging the steel producer with violating air pollution standards at its 100-oven coke plant in Chicago, Ill. A company spokesman claimed that EPA refused to approve a pollution control system using untried experimental technology at Interlake's Toledo, Ohio plant.[6]

Problems in reducing coke-oven emissions will cost United States Steel Corp. more than $600 million. In a consent decree issued in October 1976, the firm agreed to close 13 of its Clairton Works coke batteries by 1984, rehabilitate 7 others, and construct 3 new superbatteries using the best available emission control-technology.[7]

The Ohio Environmental Board of Review issued an order delaying the charging of Republic Steel Corp.'s new 51-oven battery until hearings could be held on December 14. The new $35 million facility is one of six operated at the Cleveland, Ohio works, each with an 825-ton-per-day coke capacity. Republic claimed that all necessary equipment had been installed and was ready for operation, except for a $4.7 million pushing control system.[8]

In compliance with a Federal order, United States Steel, shut down three coke-oven batteries at its Gary, Ind. plant, terminating a 3-year dispute with EPA. About 200 workers were laid off at least temporarily. In a confirming statement regarding the shutdown, United States Steel stated that air quality would scarcely, if at all, be improved. The idle oven batteries had provided 2,000 tons of coke and 21.8 million cubic feet of coke oven gas per day.[9]

[r]Revised.
[1]Data do not add to total shown because of independent rounding.

COKE AND BREEZE

DOMESTIC PRODUCTION

An increase in the production of pig iron and ferroalloys in 1976 largely accounted for a 6.2% increase in the demand for blast furnace coke. Output of oven coke plus beehive coke averaged 4.86 million tons per month, with 5.09 million tons produced in March and 5.12 million tons in May. Daily production for the year averaged 160,000 tons, up 1.9% from the average daily output of 1975.

Forty-eight furnace plants produced 92.4% of the slot-oven coke produced. These plants, owned by or financially affiliated with iron and steel companies, were operated mainly to produce coke for iron blast furnaces. The remaining oven coke was produced by 13 merchant plants, who sold blast furnace, foundry, and other grades of coke on the open market.

Coke was produced in 19 States in 1976. The relative amounts of coke produced in the various States have changed little in the past decade. Because coke is used principally as a fuel and reducing agent in blast furnaces, the coke industry is concentrated in the major steel-producing areas of the Eastern and North Central States. The bulk of the 1976 output came from 14 States east of the Mississippi River. Three plants in California, Colorado, and Utah produced 5.6% of the total production. Pennsylvania, the largest producer, accounted for 28% of the output, followed by Ohio and Indiana, these three States accounted for 56.4% of the national output.

An average of 1,384 pounds of breeze-free coke was produced for each ton of coal carbonized in the United States in 1976. The 1976 yield of coke, which averaged 68.92%, has remained nearly constant during the past decade.

The term "coke-breeze" generally refers to a mixture of carbonized bony coal, slaty rock, and coke particles passing through a 1/2-inch-square screen. Approximately 31.4% of the 1976 breeze production was used as fuel in agglomerating plants. The remainder was used in steam plants and in the production of elemental phosphorus from phosphate rock. The amount of breeze sold has increased significantly in recent years; about 42.5% of the 1976 production was sold.

The breeze yield per ton of coal carbonized is influenced by oven-operating practices, the types of coals used, and the extend, of pulverization of coal mixtures carbonized. The lowest yield, 2.99%, was attained in Pennsylvania, while Illinois had the highest yield at 9.74%. The national yield, at 5.12%, has not varied significantly during the past decade.

Oven-coke plants averaged 102.4 pounds of breeze produced per ton of coal carbonized. The yields at beehive coke plants was substantially higher than those of oven plants, but beehive breeze production was negligible because only a few plants had recovery facilities.

According to a Bureau of Mines Special Publication,[10] an expanded program of coke-oven construction in the United States is necessary to avoid a coke shortage in 1985. The author estimated that the probable iron demand of 107 million tons would require 59 million to 62 million tons of coke. Without additional oven construction, the net capacity deficit would range between 5 million and 10 million tons. The report states that currently operating ovens, representing about one-fifth of the theoretical maximum slot-oven coke productive capacity, are more than 30 years old, and an additional 12% are more than 20 years old. The number of domestic coke ovens in late 1976 was 13,324.

Kaufman[11] states that the costs for replacement facilities now under construction exceed $1 billion and that an additional $1 billion for replacement conductive capacity will be needed during the next 10 years.

Rev. William T. Hogan, S. J., Director, Industrial Economics Research Institute, Fordham University, when questioned on emerging shortages of steelmaking raw materials, stated that "there is an even more important area to monitor as steel demand accelerates: Shortages of metallurgical coal and coke could appear. Coke is basic to steelmaking. Two factors at work are the need for more coal mining capacity, and the reductions in coke-making capacity brought on by EPA air pollution control regulations. Some coke-making operations have been slowed down because operating rates have been trimmed back to meet EPA requirements."[12]

According to a Fordham University steel industry specialist, the United States can make 63 to 66 million tons of coke annually. The specialist further stated that "if the U.S. steel industry is going to increase steel capacity, it will also have to increase coke capacity. If the raw steel production is to reach 135 million tons in 1977, some imported coke may be needed."[13]

In mid-May, Armco Steel Corp. filed a breach-of-contract suit against Allied Chemical Corp., seeking $217 million for alleged violations of coke and coke-oven gas agreements. Armco charged that Allied did not comply with EPA and other regulations to repair and maintain No. 3 and No. 4 coke-oven batteries at Allied's Ashland, Ky. plant, and that the firm refused to heed Armco's demands to do so. The suit also charged that Allied's Ironton, Ohio, and Ashland, Ky., plants were permitted to fall into a state of gross disrepair, causing decreased production of coke and recovery of coke-oven gas.[14]

Armco's Steel Corp's new No. 1 battery of 19-feet, Carl Firma Still ovens at Middletown, Ohio, was charged October 27, 1976. A similar new No. 2 battery was scheduled for charging in late December 1976. Both coke batteries will be top charged.[15]

In June 1976 Bethlehem Steel Corp. at its Bethlehem, Pa., plant charged the new 19-foot, 80 McKee-Otto ovens known as battery "A". The initial coking time of 22.9 hours was extended to 32.0 hours in November 1976.[16]

Bethlehem Steel Corp. at its Lackawanna, N.Y., plant in June started up No. 3 coke-oven battery, bringing the number of coke-oven batteries to six out of seven.[17]

Koppers Co., in September 1976, was considering a $30 million to $40 million expansion plant that would increase its total cokemaking capacity about 35%. The plan involved the construction of 100 additional coke ovens at Woodward, Ala., including 1 60-oven battery and 1 40-oven battery. The expansion would result in an 90% increase in cokemaking capacity at Woodward, which currently has 250 ovens in 3 batteries. Koppers said the new ovens could be operated to produce either foundry coke or blast furnace coke as market conditions dictate, and that existing foundations and auxiliary facilities at Woodward would be utilized.[18]

[18]American Metal Market. V. 83, No. 188, Sept. 24, 1976, p. 2.

McLouth Steel Corp., Detroit, Mich., announced on December 22, 1976, that it would purchase the Ironton, Ohio, coke plant of Allied Chemical Corp. The Ironton plant has three oven batteries, one producing foundry coke only, another producing blast furnace coke only, the third, a 24-oven battery provided with pipeline charging, alternately producing both grades of coke.[19]

Mercier Corp., Birmingham, Mich., in early September 1976, announced its intent to purchase the recently closed chemical plant and coke-oven plant of Diamond-Shamrock Corp., Painesville, Ohio. Mercier intended to produce foundry coke for the merchant market. Erie Coke & Chemical Co., a newly formed, wholly owned subsidiary of Mercier, will own and operate the coke facility.[20]

In early May, Republic Steel Corp., Cleveland, Ohio, canceled an $85 million coke-oven order with the Salem Corp. of Pittsburgh, Pa. The coke ovens were originally ordered as part of a $350 million expansion of Republic's Gadsden, Ala., plant; work on the plant was postponed in January 1976.[21]

United States Steel in late 1976, closed the No. 13 coke-oven battery at its Clairton Coke Works as the first step in complying with a consent agreement aimed at reducing air pollution. The closing of the battery caused an immediate loss of 370,000 tons per year of coke and 3.3 billion cubic feet per year of coke-oven gas.[22]

Construction of a new 79-oven coke battery at the Steubenville, Ohio plant of Wheeling-Pittsburgh Steel Corp. was nearing completion with scheduled production starting in the fourth quarter of 1976. The $69 million oven battery, capable of producing 1 million tons of coke annually, is being equipped with proven technology for air and water quality control.[23]

In February 1976, Jones & Laughlin Steel Corp. announced plans for a second 56-oven smokeless coke battery at Aliquippa, Pa., similiar in design to a new $70 million, 56-oven battery that started limited operation in January 1976. The two pipeline-charged batteries will bring coke production at the firm's Aliquippa works back up to 5,700 tons per day.[24]

CONSUMPTION

Apparent consumption of coke (domestic production plus imports, minus exports and changes in stocks) in the United States totaled 56.8 million tons, an increase of 3.15 million tons over that consumed in 1975. The increase was largely attributed to greater demand for blast furnace coke, caused by a 7-million-ton increase in blast furnace pig iron and ferroalloys production.

The amount of breeze-free coke consumed in producing 1 ton of hot metal by blast furnaces decreased from 1,222 pounds in 1975 to 1,188 pounds in 1976.

In 1956, 1,720 pounds of coke was consumed per ton of hot metal produced by blast furnaces. Consumption in 1976 was 532 pounds less than 2 decades ago as a result of the use of increased quantities of iron concentrates, oxygen, and supplemental fuels.

Although a variety of operating practices affect blast furnace coke rates, the 34-pound decrease in the coke rate was accompanied by a 4.4-pound, coke-equivalent increase of supplemental fuels, excluding coal, injected through blast furnace tuyeres per ton of hot metal produced, based on AISI data. The supplemental fuels were principally fuel oil, coal tar and pitch, natural gas, and coke-oven gas. Although the units of measure differ and the quantity of each fuel used varies, the total calorific value of all supplemental fuels consumed in blast furnaces in 1976 was equivalent to 4.46 million of coke. Oxygen consumption in blast furnaces equaled 26,972 million cubic feet, 3.8% more than in 1975. The use of oxygen reduces the blast furnace coke requirement by making available higher temperatures during the reduction of iron ore to pig iron.

Of the 56.8 million tons of oven and beehive coke sold for all purposes, including 2.30 million tons exported, 52.55 million tons went to blast furnaces, 3.01 million tons went to foundries and 1.24 million tons went to other industrial purposes. Steel companies produced 49.15 million tons of blast furnace coke for use in their own blast furnaces. Merchant plants produced 2.80 million tons of blast furnace coke that was sold to blast furnace plants.

Merchant plants produced a total of 4.36

[24]American Metal Market. V. 83, No. 37, Feb. 24, 1976, pp. 3-21.

million tons of coke, equal to 7.6% of the total oven-coke production. Principal markets were blast furnaces not associated with integrated coke-producing facilities, independent gray-iron foundries, nonferrous smelters, and chemical plants and affiliated foundries. All of the coke produced by beehive plants was sold for blast furnace use. Forty-four States received shipments of coke or breeze in 1976. Illinois, Indiana, Michigan, New York, Ohio, and Pennsylvania, which were the major iron- and steel-producing States, received 75.0% of the total coke and 71.5% of the total breeze distributed.

The bulk of the coke distributed was blast furnace grade and was consumed within the producing State, as most blast furnaces were integrated with coke ovens. A few companies shipped coke to affiliated blast furnaces in other States.

About 5% of the breeze-free coke distributed was shipped to foundries. The chief consumers of foundry coke were the automotive, farm machinery, machine tool, heavy machinery, railroad, and electrical equipment industries. Most of these industries were located in the eastern and midwestern States. The combined receipts of Alabama, Illinois, Indiana, Michigan, New York, Ohio, Pennsylvania, and Wisconsin accounted for 76.3% of the foundry coke shipments. Foundry coke was also shipped to 32 other States, and 166,000 tons were exported.

Other industrial coke was used in 35 States for miscellaneous applications. The principal consumers were nonferrous smelters and plants manufacturing sugar, mineral wool, alkalis, calcium carbide, and elemental phosphorus.

Indiana, Idaho, Missouri, Ohio, and Pennsylvania, received 57.1% of the shipments of other industrial coke.

STOCKS

Yearend stocks of slot-oven coke were 29.8% more than at yearend 1975, with the quantity of coke in stock increasing to 6.49 million tons during 1976. Oven-coke plants ended the year with stocks equal to 42.4 days' production at the December 1976 rate. Normally, beehive plants do not stock coke.

The bulk of the stock, 95.1%, was at furnace plants, which roughly had a 43.5 day supply, compared with 28.5-day supply at merchant plants. There were no producers' stocks of beehive coke at yearend 1976.

Stocks of coke breeze at producers' plants increased 9.6% during 1976. Approximately 82.1% of the breeze in stock was at furnace plants.

VALUE AND PRICE

The average value of receipts of all grades of oven coke was $94.35, up $6.71 per ton, 7.7%; beehive coke averaged $72.48, up $7.57 per ton, or 11.2%.

For oven coke, an increase of 7.4% raised the average price of foundry coke sales to $114.45 per ton, and commercial sales to blast furnaces increased an average of 7% to $78.84 per ton. Oven coke used for other industrial purposes increased 3.1% in price to $79.46 per ton.

The differential between the average price of blast furnace and foundry oven coke is attributed to the special specifications for foundry coke, which make it a more costly product, and to its superior properties resulting from long coking times at lower temperatures of coal mixtures containing up to 50 weight-percent low-volatile coal and anthracite, and occasionally petroleum coke, and milled coke dust.

The average price of foundry coke in the United States remained fairly constant throughout much of 1976, with no significant trends. The difference in the average values of oven and beehive cokes is partially due to the additional transportation costs of coal delivered to oven-coke plants, and the substantial investment and maintenance costs of slot-type ovens.

The price of domestic blast furnace coke remained in the range of $78.80 to $85.00 per short ton.

FOREIGN TRADE

Foreign trade in coke was slower than in 1975. Exports, at 1,314,725 tons, were 41,819 tons more than in 1975 and amounted to 2.25% of total production. Of the total coke exported to more than 21 countries, approximately 70.5% went to Canada and the Netherlands at an average price of $47.69 per ton. Exports from Buffalo, N.Y., Detroit, Mich., Norfolk, Va., Philadelphia, Pa., Cleveland, Ohio, Chicago, Ill., and Laredo, Tex., totaled 1,179,428 tons at an average price of $49.68 per ton. Total exports averaged $50.75, per ton, or $7.96 per ton less than in 1975. Canada received 754,433 tons or 57.4% of the total exports. Exports to Canada averaged $48.73 per ton.

Imports of coke totaled 1,311,472 tons and averaged $84.69 per ton, compared with 1,818,981 tons imported in 1975 at $86.03 per ton. Canada, Belgium-Luxembourg, France, and West Germany together shipped 1,250,192 tons at $86.23 per ton to the United States. West Germany alone shipped 891,105 tons averaging $93.61 per ton. Buffalo, N.Y., Detroit, Mich., New Orleans, La., and Chicago, Ill., were the major ports of entry for 1,207,256 tons having an average price of $86.17 per ton.

Despite more-than-adequate inventories, an upturn in world coke trade and price was foreseen because the Government may mandate further coke oven shutdowns in the United States. The prediction was that the U.S. buyers would augment coke supplies by foreign purchases, as a hedge against this possibility.

COKING COALS

QUANTITY AND VALUE OF COAL CARBONIZED

A total of 84.3 million tons of bituminous coal was carbonized at high temperatures for the production of coke in slot-type and beehive ovens. This quantity, equaling 12.4% of the 1976 U.S. bituminous coal production, was the second largest coal market. In addition to bituminous coal, 380,000 tons, or approximately 6.1%, of the U.S. anthracite production was used in the coal blends carbonized. Anthracite was used principally in the production of foundry coke to achieve greater size and density, which are desirable properties during the operation of foundry cupolas.

The average delivered value of all coal and anthracite carbonized by oven-coke plants was $44.16 per ton. The average value of coal carbonized by beehive-coke plants cannot be published because of individual company confidentiality. Transportation costs account for the high value of the coal consumed by oven-coke plants in some States.

The average value per ton of bituminous coal and anthracite carbonized at oven-coke plants was 5 cents per ton less than in 1975. The highest coal price recorded was in Maryland and New York, where the value of coal carbonized averaged $56.65 per ton, or 62 cents less per ton than in 1975.

An overall average of 1.45 tons of coal, valued at $64.03, was required for each ton of oven coke produced. Beehive ovens required an average of 1.57 tons of coal per tons of coke output.

BLENDING

It is difficult to define a "good coking coal." Gradually, the word "good" is being replaced by "satisfactory," which means that a coal or blend of coals produces a coke that permits a blast furnace practice fully competitive in quality, efficiency, and cost. It is only rarely that a single coal is available for making a satisfactory coke; blending of two or more coals having different properties is the rule at the majority of coke plants. While a two-coal blend of high- and low-volatile coals is most common, there are cases in which the use of a third coal or other blending material is advantageous. In certain locations and with similar types of coals, coal tar pitch, petroleum coke, milled coke dust, and other carbonaceous materials have been tried and in some cases have been used commercially with success.

The terms "low-," "medium-," and "high-volatile coking coals" do not designate sharply defined classes. These terms are used by slot-oven operators in a relative sense and the exact meanings intended by the individual operator may vary somewhat with the behavior of the coals with which he is best acquainted, or which are available for his plant.

The term "low-volatile coal" is used in this publication to designate coals of 14% to 22% volatile matter (dry basis), such as the Pocahontas and New River, W. Va., and Somerset County, Pa., type. For byproduct oven use, such coals are mixed with high-volatile coking coals in any proportion up to 60% or more (but usually from 10% to

30%), to increase the size and strength of the coke. This practice increases the coke yield and decreases the byproduct yields. Most slot-oven operators prefer low-volatile coals having a volatile matter content of about 16% to 18% (dry basis), although a considerable quantity of coal that is not within this range is used. Low-volatile coals are not charged in an unmixed condition into slot-ovens because they expand when coked.

The Bureau defines medium-volatile coking coals as those having 22% to 31% volatile matter (dry basis). Such coals have certain coking characteristics that differentiate them from coals having distinctly higher or lower volatile-matter content. The medium-volatile coal, when coked without admixture, nearly always produce large blocky cokes having highly desirable general physical characteristics. Many medium-volatile coals, particularly those having less than 24% to 25% volatile matter, are practically nonshrinking, or even slighty expanding under many operating conditions, in which cases the coke would be difficult or impossible to push from the slot oven.

The largest portion of the tonnage of all coals charged into slot ovens exceeds 31% volatile matter (dry basis), and is designated high-volatile coal by the Bureau. High-volatile coking coal is produced from many seams in many States. Because high-volatile coals, when carbonized alone, produce lower yields of weaker and smaller sized coke, many plants producing blast furnace coke add low- or medium-volatile coals to high-volatile coals to the extent of 10% to 30% of the weight of coal mixtures charged into the slot-type ovens. The use of anthracite imparts increased size and density and the use of tar pitch in the coal mix increases the coke strength.

Blending also permits the use of some high-sulfur-content coals in admixture with low-sulfur coals so that the coke has an acceptable sulfur content.

The overall percentages of high-, medium-, and low-volatile coals in the mixtures carbonized have varied little in the past decade, although there are wide variations in the proportions used by individual plants. Coke plants in West Virginia and the Western States used the largest percentage of high-volatile coals in their blends, while plants in Minnesota and Wisconsin used the largest percentages of low-volatile coals. Compared with furnace plants, some merchant plants used approximately 50% of low-volatile coals with anthracite in mixtures carbonized at lower temperatures during a longer coking time to produce foundry coke.

The types of coals used in each plant are determined by the availability of the desired coal, the moisture content, the content and composition of ash-fusion temperature, volatile matter content, expansive properties, delivered cost, storage characteristics, free-swelling index (FSI), and the physical and chemical properties of the coke product.

SOURCES OF COAL

Of the 26 States that produced bituminous coal in 1976, 14 States shipped coal to coke plants, supplying 84,899 million tons of coals for coking. Of these shipments, 66.1% were high-volatile coals and 13.0% and 120.9% were medium- and low-volatile coals, respectively.

Of the coals received by oven-coke plants, 76.8% were produced in West Virginia, eastern Kentucky, and Pennsylvania; 69.3% were high-volatile coals. West Virginia shipments comprised low-volatile coals from McDowell, Raleigh, and Wyoming Counties and medium-volatile coals from Fayette, Logan, Mingo, and Nicholas Counties. Pennsylvania supplied high-volatile coals from Allegheny, Greene, and Washington Counties and low-volatile coals from Cambria and Somerset Counties. Pennsylvania and West Virginia coals were widely distributed and used in many of the coke-producing States. Eastern Kentucky supplied 13.7% of the shipments to coke plants, all of which were high-volatile coals produced mainly in Floyd, Harlan, Letcher, and Pike Counties.

Illinois produced high-volatile coking coals, principally in Franklin and Jefferson Counties; other States with substantial production were Alabama, Colorado, Utah, and Virginia. Most of the coal produced in these States was used within the State. Colorado, New Mexico, and Utah, however, supplied most of the coals that were carbonized in California.

Inland Steel Co. identified a large deposit of high-volatile coal for possible future deep-mine development near Marshall, Clark County, Ill. Tentative estimates indicate more than 200 million tons of commercially recoverable coal. The discovery was made on lands under lease to an Inland subsidiary, Northern Mining Inc. The tract explored covers 80,000 acres. Additional testing and drilling will be required to determine the quality and confirm the preliminary reserve estimates. Inland also had extensive coking coal reserves at Sesser and McKeansboro in southern Ill.[25]

Wheeling-Pittsburgh Steel Corp. had a 20% participation in the $50 million Scotts Branch mine project in Kentucky, managed by Pickands Mather & Co. By late 1976, coal production had started and the cleaning plant was nearly completed. The facility will have an annual capacity of 1.25 million tons of coking coal.[26]

In November 1976, Wheeling-Pittsburgh Steel Corp. announced plans for a $27 million expansion, to boost by 81% the annual production of high-volatile coking coal at its Omar mine near Charleston, W. Va. The expansion, when completed 3 years later, is expected to increase capacity from 500,000 tons in 1976 to 908,000 tons annually; the productive life of the mining complex will have been increased by at least 21 years. The Omar mine will be a principal source of high-volatile coals needed for the firm's coke batteries at Follansbee, W. Va., where a new $67 million coke battery was scheduled to go into production in early 1977.[27]

Inland Creek Coal Co. reached the Pocahontas No. 3 seam, located 1,350 feet below the surface of Buchanan County, W.Va., after a March 1976 cost sharing agreement with the Nation's largest independent foundry coke producer, Alabama By-Product Corp., (ABC). The mine is expected to produce 1 million tons per year. For its share in the $45 million project, ABC had the right and obligation to take one-third of the mine's production with options for additional tonnage. Presently, ABC gets its low-volatile coal from West Virginia sources. The firm's decision to continue going outside Alabama to assure its future low-volatile coal requirements reflects on the quality of coal expected from deep mines being developed in Alabama.[28]

CAPTIVE COAL

About 53.2% of the coal received by all slot-oven plants was produced by company-owned or affiliated mines. Ordinarily, this captive coal does not enter commercial channels. In 1976, 54.2% of the coal received by furnace-coke plants was captive. Some merchant plants also owned coal mines, but only 38.8% of the coal received was captive production.

STOCKS

Stocks of bituminous coal at slot-oven plants ranged from 7.26 million tons to 11.26 million tons, equal to 32 and 50 days' consumption, respectively, at the yearly daily average of 228,860 tons. Bituminous coal stocks reached their highest yearly level during June when month-end quantities totaled 11.26 million tons. The lowest level, 7.26 million tons, was reported at the end of August.

Bituminous coal stocks at yearend 1976 were 9.8 million tons, compared with 8.67 million tons when the year began. The 9.8 million tons in stock at all slot-oven plants at yearend was equal to a 44-day supply at the December 1976 rate of consumption.

Stocks of anthracite at yearend totaled 98,000 tons, which was equal to a 94-day supply at the 1976 average rate of consumption.

COAL CHEMICALS

The term "coal chemicals" refers to the refined materials recovered from the crude liquids obtained from the gases and vapors released during coal carbonization. Three materials—ammonia, tar, and light oil—are normally recovered at slot-oven plants using condensation and absorption processes. The remaining noncondensible material, which is rich in hydrogen and methane, is called coke-oven gas. Except for ammonia, which is recovered as an aqueous solution, or an ammonium sulfate or phosphate and sold as produced, the materials are in most instances further processed to yield a number of primary organic chemicals or chemical mixtures, the most important of which are benzene, toluene, xylenes, solvent naphtha, crude chemical oil (better known as carbolic oil), and pitch. Although many slot-oven plants in the United States are equipped to process tar and crude light oil, the extent to which such equipment is utilized depends upon economic conditions and tonnage of coal carbonized because

[25] Skillings Mining Review. V. 65, No. 48, Nov. 27, 1976, p. 19.
[26] American Metal Market. V. 82, No. 228, Nov. 23, 1976, p. 2.
[27] Work cited in footnote 26.
[28] Coal Week. April 1976, p. 3.

yields of various chemicals are low.

Yields of chemicals vary with the kinds of coals carbonized, carbonizing temperatures, and operating techniques and equipment. About 315 pounds of coke-oven gas, 76 pounds of tar, 18.7 pounds of crude light oil, and 5 pounds of ammonia were recovered for each short ton of coal carbonized. In standard units of measure, these quantities amount to 11,063 standard cubic feet of coke-oven gas, 7.6 gallons of tar, and 2.55 gallons of crude light oil. Ammonia expressed as ammonium sulfate equivalent was recovered at an average rate of 15.64 pounds per ton of coal carbonized in those 51 plants employing recovery processes.

In terms of calorific value, the products recovered by oven-coke plants (excluding coke) in 1976 totaled 628.4 trillion Btu. This quantity was roughly equivalent to 31.3% of the heating value of the coal carbonized. In deriving the total calorific value of the products recovered, coke-oven gas was based on 550 Btu per standard cubic foot, crude coal tar, 160,000 Btu per gallon; and crude light oil, 125,000 Btu per gallon. Coal as charged to coke ovens was assigned a calorific value of 24 million Btu per ton.

COKE-OVEN AMMONIA

Coal carbonized at high temperatures releases nitrogen and hydrogen parts of which combine to produce ammonia. Ammonia must be removed from coke-oven gas to reduce the subsequent formation of corrosive compounds with oxygen, hydrogen sulfide, and hydrogen cyanide. Coke-plant operators normally recover ammonia as an aqueous solution, or as ammonium sulfate or phosphate. However, 10 plants did not recover ammonia as a salable product in 1976.

Production of ammonia increased 1% although the number of recovery plants decreased by one. The average value of ammonium sulfate decreased from $78.07 per ton in 1975 to $48.72 in 1976, and the value of ammonia liquor increased from $92.75 per ton in 1975 to $93.67. The total value of all sales decreased 11%. Ammonia products sold in 1976 represented 3.2% of the total value of all coal-chemical sales.

The new coke oven plant of Armco Steel Corp., Middletown, Ohio, used a system developed by Firma Carl Still of West Germany to recover hydrogen sulfide from coke-oven gas as a feedstock for sulfuric acid production. Another system, developed by United States Steel Corp., recovers ammonia vapor and converts it to an anhydrous product. In this system, vapors evolved from the ammonia still contain H_2S, NH_3, CO_2 and HCN that, after removal of NH_3 by absorption in cold water, are finally burned in the combustion chamber of the sulfluric acid plant. Armco's Middletown plant will produce about 54 tons per day of 66° Be acid. The heat generated during the conversion steps generates 600-pounds per square inch steam.[29]

COKE-OVEN GAS

The fixed gases resulting from the carbonization of coal have a gross heating value ranging from 520 to 600 Btu per standard cubic foot, and are principally used for heating coke ovens and steel- and allied-plant furnaces. Small volumes were sold for distribution through city mains and for minor industrial uses. Gas yields vary among plants but the average quantity produced for each ton of coal carbonized in all slot ovens was 11,063 cubic feet, compared with the average yield of 10,860 cubic feet for 1975. The total gas production increased 1.90% because 1.55% more coal was carbonized in 1976.

About 39.54% of the coke-oven gas produced was used for heating ovens. Most of the remainder of the production was used by coke producers to fuel boilers or transferred to steel or allied plants to heat open-hearth and other metallurgical furnaces. A small part of the gas produced was flared in situations where production exceeded demand.

Although coke-oven gas was the principal fuel used to heat coke ovens in 1976, some ovens were heated by a mixture of coke-oven and blast furnace gas, or mixtures containing blast furnace and natural gas. A total of 401.6 billion cubic feet of coke-oven gas equivalent was so consumed, of which about 89.8% was coke-oven gas.

Surplus coke-oven gas used and sold in 1976 was valued at $402.120 million, a 37.4% increase from the 1975 value. No value was reported by producers for the coke-oven gas used to heat their ovens, but by applying the average value of $0.747 per thousand cubic feet reported for surplus gas to the gas used for underfiring, the total value of all coke-oven gas used and sold in 1976 would be $671.2 million.

COAL TAR AND DERIVATIVES

All oven-coke plants produced crude tar in quantities ranging between 3.79 and 9.17

[29]Colaianni, L. J. Coke-oven Gas Yield Fuel, Chemical Byproducts. Chem. Eng., v. 83, No. 7, Mar. 29, 1976, pp. 82, 83.

gallons per ton of coal carbonized. Coke plants in California, Colorado, Utah, Ohio, and Pennsylvania had the larger yields of tar, ranging from 9.17 gallons to 7.98 gallons per ton of coal carbonized.

The average tar yield was down 2.9%, and the production was 1.4% less than in 1975.

Coke-plant operators consumed 55.9% of the crude tar produced. Of this quantity, 45.8% was processed (refined or topped) and 52.7% was burned as fuel without any processing. The remaining production, together with withdrawals from stock, was sold to tar-distilling plants for refining into a variety of tar-derived products.

Most of the crude tar that was processed in 1976 was subjected to topping, whereby distillate fractions, consisting mainly of low-boiling tar acids and bases, and naphthalene were obtained. The resulting residue (called soft pitch) was usually used for fuel. Furnace coke plants that were integrated with steel plants in particular benefitted from this situation because they sold the distillate and retained the soft pitch for use as fuel. However, the relative quantities of tar topped, burned, or sold, depend on the availability and current market prices of crude tar, tar distillates, and other substitute fuels. Most of the merchant plant tar production was sold because merchant plants had little demand for pitch, which normally represented 65 to 92 volume-percent of the crude tar feed to the topping stills.

Most of the plants that processed crude tar recovered only crude chemical oil (also known as carbolic oil) and liquid still residues ranging up to soft pitch. Some of the larger plants recovered a number of tar-based products, including cresote oil, cresylic acid, cresols, naphthalene phenols, xylols, pyridine, picoline, quinoline, and medium and hard pitch. Although statistics on many of these tar derivatives are not disclosed in this report because of company confidentiality, the data were transmitted to the U.S. Tariff Commission for publishing with similiar data from tar distillers and petroleum refiners, in monthly and annual reports on synthetic organic chemicals.

CRUDE LIGHT OIL AND DERIVATIVES

Crude light oil is a mixture of aromatic hydrocarbons, thiphene, mercaptans, hydrogen sulfide, and carbon disulfide that are absorbed from the coke-oven gas after tar, ammonia, and in some instances, naphthalene have been removed. Crude tar contains an insignificant content of crude light oil that is seldom recovered at coke plants. Practically all crude light oil produced at coke plants is recovered by absorption, in which the gas is contacted with a high-boiling petroleum oil or a coal-tar-based distillate as the gas passes through absorption equipment. Crude light oil is stripped from the absorption oil by direct steam distillation. About 1.7 to 3.1 gallons (12.5 to 22.7 pounds) of crude light oil was recovered per ton of coal carbonized. Yields vary with the kinds of coal carbonized and with operating conditions. An average of 2.53 gallons per ton of coal carbonized was recovered at 51 plants that extracted light oil in 1976. Yields per ton of coal were about the same as 1976 levels in both merchant and furnace plants. Ten plants left the light oil in the gas to increase its calorific value.

Producers refined 45.4% of their crude light oil output. The increase of crude light oil sales in recent years is attributed to the inability of some plants to produce derivatives meeting the rigid specifications of dependable quality and competitively priced aromatic petrochemicals. Such plants sell crude light oil to petroleum-refining companies for processing with petroleum-derived fractions into benzene, toluene, and a number of other chemical intermediates.

As with other coal-chemical materials, yields of products derived from crude light oil vary, but about 79.1 volume-percent of the crude light oil processed was recovered in 1976 as salable products, comprising 58.8% as benzene, 10.6% as toluene, 1.8% as xylene, and 7.9% as solvent naphtha and other light oil products. All of the benzene production was classed as specification grades. In past years, a large amount of motor-grade benzene was used to increase antiknock properties of gasoline, but current petroleum-refining practices have all but eliminated this use for benzene.

The unit value of light oil derivatives sold in 1976 ranged from $0.794 per gallon for all grades of benzene to $0.398 per gallon average for all crude and refined solvent naphtha. The average value of all light oil products sold increased 1.3% to $0.706 per gallon, compared to $0.698 per gallon in 1975.

WORLD REVIEW

World production of metallurgical coke in 1976 was estimated at 404.7 million short tons. This quantity is 1.1% more than the 1975 output because of increased production in the U.S.S.R., the United States, Poland, Czechoslovakia, and Belgium.

Europe, with 56.2% of the total, led in world production; European production was 1.3% more than in 1975. Asia, with eight producing countries, ranked second in output with 24.9%. North America, with only three producing countries, ranked third with 16.4%.

Australia.—Nippon Steel Corp. and other major Japanese steel mills contracted to import 6,779 million tons of soft coking from six Newcastle coal mines for fiscal 1976 beginning April 1, 1976. The contract included an increase of 15 Australian cents in price plus an escalation clause permitting an increase of up to $1 (Australian) per metric ton.[30]

Utah International was given conditional approval by the Australian Government for a coking-coal project costing more than $200 million, to be located at Norwich Park, Queensland. The projected capacity was set at 4.5 million tons per year.[31]

Australia's coal export levy was reduced in the Government's Federal budget in August 1976, and is to be completely phased out within 3 years. The decision assures that investments totaling $2.5 billion will be made in coal-mining ventures in the next 5 years. The coal export levy was $7.50 per metric ton.[32]

Canada.—During 1975, approximately 8.2 million tons of coking coal was carbonized in 1,066 slot-type coke ovens, which have the capacity to produce 5.8 million tons of coke from 9.44 million tons of coal. About 90% of the coking coal used in Canada was imported from the United States. Three steel companies in Ontario operated coke-oven plants in Hamilton and Sault Ste. Marie. All had captive U.S. mines and long-term contracts. The Sydney Steel Corp. in Nova Scotia used a blend of Nova Scotia, western Canadian, and imported coals to produce coke for its steel mill. The integrated steelmakers accounted for over 90% of the coke production in Canada.[33]

Emkay Canada Natural Resources, Ltd., a subsidiary of Morris Knudsen Co.; sold a 50% interest in its Elk River coking coal properties in British Columbia for about $3.5 million to Elco Mining Ltd. Projected production capacity is 4 million tons of coking coal per year. Production is expected to begin in 1981 and continue for 28 years.[34]

In early September 1976, Denison Mines Ltd., Toronto, agreed to purchase up to 5 million tons of coking coal per year on a long-term basis, from Quinlette Coal Ltd.[35]

During 1975, most industrialized countries experienced downturns in economic activity that affected the demand for both coking coal and thermal coal through reduced demand for steel and reduced industrial need for electric power. This became evident in Canada toward the latter part of the year. Prices increased during the early part of the year, reflecting both the tight market conditions of 1974 and increased costs. By mid-1975, however, spot prices had fallen sharply as stocks of coal and coke were being built up, and by yearend the situation had not improved. Nevertheless, prices on long-term contracts and for top-quality coals remained firm.

Foreign consumers continued to show interest in western Canadian coking coal deposits, with Japanese, West German, Dutch, and Italian interests taking equity partnerships in potential producing properties in British Columbia.

During the year, the Government of each of the three coal-producing Provinces in western Canada, British Columbia, Alberta, and Saskatchewan, continued studies relating to the development of new coal policies. New legislation was expected to be introduced in 1976 in all three provinces.

In 1975, exports of bituminous coal amounted to 12.9 milllion tons, an increase of 8.5% from 11.9 million tons in 1974. Of total exports, about two-thirds originated from mines in British Columbia, with most of the balance from Alberta. Export shipments accounted for approximately 46% of total coal production and nearly three-quarters of bituminous coal production. Japan received nearly 11.9 million tons, or 92% of exports, compared with 11 million tons or 93% in 1974. Since Canada's exports were

mainly coking coal under long-term contracts, Canada's position in international coal trade remained strong even though the international market softened noticeably during the latter part of 1975. In the early part of 1975, Canadian coal producers and their Japanese buyers negotiated new coal prices on the basis of international pricing and abandoned the former basis of "cost plus reasonable profit." The average value of Canadian coking coal exported to Japan in 1975 was $50.00 per long ton, f.o.b. Vancouver.

Germany, West.—A trial production run based on a throughput of 330,000 tons per year of lignite (125,000 tons per year of coke output) was scheduled in August 1976 for the German lignite producer, Rheinische Braunkohlennwerke near Cologne. The lignite degasification was to be done in a hearth-type furnace. The coke product will be used mainly by the German chemical industry as an additive in the processing of lime and phosphate.[36]

Japan.—By late 1976, Mitsui Coke Co., Tokyo, announced its intention to build a 297-short-ton-per-day, semicommercial plant at Omuto, to be completed in October 1979. The plant will employ a new process using asphalt as a solvent for coal dust. The mixture, at 400° to 450°C, yields a pitch that substitutes for hard coking coal. Called Solvolsis, the technique is designed to handle all kinds of Japanese coal dusts, particulary the type produced by the nearby Miike colliery. The plant will also produce about 10,500 thousand cubic feet per day of byproduct gas.[37]

The Pittston Co. concluded the principal elements of a long-term contractual agreement with the six largest Japanese steel producers for purchase of Pittston's medium-volatile, high-fluidity coking coal. The contract will run 12 years, with basic negotiations at 3-year intervals. The quantity of coking coal involved is 10.3 million short tons in fiscal 1977, rising to 10.9 million tons in fiscal 1978 and beyond. Of these quantities, 60% are covered by a basic starting price, $2.05 per short ton more than the current price (not disclosed), plus escalation at agreed-upon intervals. The remaining 40% is subject to price negotiation annually.[38]

Consolidation Coal Co., in October 1976, completed negotiations with six Japanese steelmakers for price increases on its low-volatile coking coal. The agreement calls for the shipment of 1.5 million tons per year of low-volatile coking coal from Consolidation Coal's Pocahontas field in southern West Virginia to Japan until March 31, 1979. Consolidation Coal was to receive a $1-per-long-ton price increase, effective October 1, 1976, and an additional estimated $2.20 per ton in mid-December 1976, to cover cost escalation. Another price increase of $2 per long ton on 1 million tons of this coal was to become effective April 1, 1977. The price for the remaining 500,000 tons was to be at market value of April 1977. The new agreement also provided for the sale of 850,000 long tons of medium-volatile, Rowland-type coking coal to the Japanese customers until March 31, 1980.[39]

Eastern Gas and Fuel Associates, through its export subsidiary, Castner, Curran and Bullitt, Inc., in November announced a tentative agreement with its Japanese customers to supply low-volatile coking coal under new contractual agreements over a 6-year period beginning April 1, 1977. Eastern will supply 750,000 tons per year, with negotiations to be held every 2 years to determine prices and quantities to be shipped. The tentative agreement provides for an increase in the price per long ton, reaching a level of $68.49 by April 1977, on about two-thirds of the coal shipped. The price for the remaining one-third of the coal will be determined on an annual basis as of each April 1. The agreement also includes the right to escalate to cover increased costs.[40]

In March 1976, Pittston Coal Export Co. agreed to lower its price on medium-volatile coal for Japanese steel mills by $1.70 per metric ton to $61.00 per ton f.o.b. for fiscal 1976. The agreement was made on the condition that the Japanese mills would purchase a total of 5.2 million tons during the year and review with Pittston the price situation for the second half of fiscal 1976.[41]

Because of decreased steel demand, Japan was attempting to reduce imports of coking coal from Australia, Canada, the United States, and the Republic of South Africa. Japan's stocks of coking coal were increasing and were expected to exceed 9 million tons in 1976. Japan had total coking coal supply contracts for 64 million tons but on the basis of an estimated 1,102 million tons of steel, 55 million tons of coking coals would satisfy industrial requirements.[42]

In 1976, Nippon Steel Corp. developed an automatic system to quickly and accurately evaluate the coking properties of coal. The system stored the measurement of the reflectance distribution of a coal, as determined by cathode-ray tube, on a disc file.[43]

South Africa, Republic of.—In early March 1976, Nippon Steel Corp. and other Japanese steelmakers reached an agreement with South African coking coal shippers to retain the Witbank coking coal prices for fiscal 1976, beginning April 1. The agreement stemmed from negotiations in which Japanese buyers initially called for a reduction in the past price of $34 per long ton f.o.b., because of a recent accord on a reduction of U.S. coal prices.[44]

The South African Iron and Steel Industrial Corp. (Iscor), in 1976, was developing a new mine for the production of high-grade-blend coking coal near Ellias in the northwestern Transvaal. The mine was expected to start operating in early 1978, and in its first phase of development will produce 1.8 million tons of washed coal annually.[45]

South African experiences with preheated coal operations are described for a coke plant having 66, 13-feet-high coke ovens, two preheaters, and two larry cars. The objectives were to improve the abrasion resistance of the coke; to use more "blend" coal in the oven charge, thus conserving the limited reserves of coking coal; to increase oven throughput 15%; to improve working conditions on the top of the oven batteries; and to obtain a more consistent coal plasticity zone during the coking process.[46]

TECHNOLOGY

Coking coals.—A panel of speakers at the April 1976 meeting of the National Open Health and Basic Oxygen Steel Conference of AIME conceded that steelmakers have become more dependent upon coals with increased ash and sulfur content and decreased fluidity, resulting in less stable and otherwise inferior coke. Decreasing coke stability was reported to relate to about a 0.5% to 1.7% change in iron production per 1.0% change in coke stability. One speaker suggested that purchased coals be processed at captive cleaning plants to produce coals of more uniform composition, thereby eliminating the problem of handling many individual coals at the coke plant.[47]

Petrographic analysis has become the primary tool at Bethlehem Steel Corp. for evaluating purchased and captive coal, evaluating undeveloped coals, resolving operational problems associated with coal composition, and providing compositional control for research projects.[48]

Application of the M-curve, developed by Karl Reinhardt in 1926, can result in substantial reductions in time and labor, compared with other current methods. Venkatesan's analysis shows how the addition of coal dust and/or slurry to the clean coal, or the additional of unwashed coal to a clean coal, increases the yield of coking steam coal to the required ash content. This is done through the use of the M-curve, which does not require the use of mechanical equipment.[49]

It has been shown that the total sulfur

lost when coking coal and limestone mixtures decreased and the percentage of FeS, originating from the disassociation of pyrite, and conversion to CaS, increases as the amount of lime added increases. Although the total sulfur content of coke produced in the presence of CaO is higher than when the coal is coked without lime, the pyrite sulfur is converted to CaS, which is more amenable to chemical conversion to H_2S. A method is outlined for determining CaS in the coked mixture in the presence of FeS.[50]

Coal ash, sulfur, and coking properties have effects on the coke produced, which, in turn, affects blast furnace performance. Analyses of blast furnace data for a given plant established relationships between coke properties and furnace output. The relationships of new tons per day of hot metal production were shown by equations.[51]

By mid-1976, Armco Steel Corp. at its Ashland, Ky., plant was able to replace as much as 18% of the Amanda furnace's coke requirements and 28% of the coke requirements of the Bellefonte furnace with pulverized coal.[52] Pulverized coal injection into the Amanda furnace has enabled Armco to reduce ironmaking costs in this furnace by $2.85 per ton based on 100,000 tons of hot metal production per month. Using metallurgical coal for injection, Armco was able to replace 1.1 pounds of coke per pound of coal injected. When injecting higher ash, nonmetallurgical coals, 0.78 pound of coke was replaced per pounds of such coal injected.[53]

Frank W. Luerssen, Vice-President of Research at Inland Steel Corp., stated that there has been adequate demonstration that preheating coal charged to coke ovens is one approach to enable the steel industry to use a higher proportion of more plentiful coals. Mr. Luerssen made it clear that pioneering work in the field of coal and coke involves great expense and much time in development activity.[54]

A new test procedure to determine the reactivity of coke was developed that overcomes the shortcomings of conventional testing methods. The rate of reaction between CO_2S and carbon was found to be dependent on the rate of CO_2 flow through the coke bed. Using this method, the reactivity of 13 samples of coke from many different coal ranks, chars, and briquettes was determined.[55]

Eastern Associated Coal Corp. at Everett, Mass., in work done for Bethlehem Steel Corp. and the American Iron and Steel Institute, performed Micum Drum tests to determine the physical strength on a shipment of Russian coke. The Everett, Mass., Research Center has the only full Micum Drum in the United States that can be used for the Micum tumbler test.[56]

Bethlehem Steel Corp. and Inland Steel Corp. requested detailed information from the Sumitomo Metal Industries, Ltd., on two Sumitomo processes for producing coke partly and wholly from noncoking coal. The Sumicoal system reportedly was designed to produce coke in a conventional coke oven from coking coal and briquettes made by blending noncoking coal, coking coal, asphalt, and pitch, whereas Sumitomo's formed-coke system produces coke solely from noncoking coal in a specially developed coke oven.[57]

Coke ovens.—The Illinois State Geological Survey conducted more than 100 tests on coals and coal blends that were preheated before they were charged into a 700-pound pilot coke oven. The preheater used was of simple design and proved to be satisfactory for the test program. The test results indicated that preheating caused a consistent decrease in time required for complete carbonization. Coke strength, as measured by the ASTM Tumbler Test, was not materially affected by preheating coal blends, which produced stabilities in the mid-1950's, when they were charged without preheating. However, preheating resulted in a material increase in stabilities of

the cokes from poorer coking coals. Other physical properties of the cokes were not greatly affected. The rapid evolution of gas when preheated coals were carbonized proved to be a major problem that was not completely solved.[58]

A preheated coal-pipeline-charging system is described that overcomes one of the major pollution sources at coke plants. One advantage of the system is that the coal enters the ovens through a closed, stationary network so that dust cannot escape. This is a major consideration because it has been estimated that as much as 70% of all coke-oven emissions occur during oven charging.[59]

The input fuel gas for heating any oven battery increases as coking rates increase within the normal range of coking operation. Pushing higher temperature coke to minimize emissions increases the fuel gas requirement. The combination of fast coking rate and higher coke temperature results in a higher fuel-gas temperature, which also increases the fuel-gas requirement. High coal moisture increases the fuel-gas requirement. Large amounts of excess combustion air, which is necessary under certain conditions, also increases the fuel-gas requirement. Waste-gas temperature can be controlled by regenerator design so that it does not increase the fuel-gas requirement. The properties of the coal mix determine the net exothermic heat of reaction within the coal charge and have a substantial effect on the fuel-gas input. Because of the many variations in operating conditions and properties of the coal mix it is impossible to make a meaningful guarantee of the full gas input to modern coke oven.[60]

Some experimental coke ovens of Bergbau-Forschung GmbH at the Ruhrkohle AG central coking plant at Prosper, West Germany, were lined with magnesite bricks. However, according to a U.S. observer, the magnesite liners were a complete failure because of uncontrolled expansion and contraction.[61]

In October 1976, Bethlehem Steel Corp., Republic Steel Corp., and Inland Steel Co. announced that each has purchased a new enclosed one-spot, coke-pushing system from Koppers Co., Pittsburgh, Pa. Each unit, costing about $3 million to $3.5 million, is designed to control emissions released during the pushing of hot coke from coke ovens. Apparently, the interest of the three steel producers stemmed from results achieved with a similiar Kopper's product at the Weirton Steel Div. of National Steel Corp.[62]

The Colorado Air Pollution Variance Board in November 1976 approved plans furnished by the CFI Steel Corp. to change its method of controlling coke-oven emissions while ruling that the project must be completed by October 15, 1979. The new method, estimated to cost $6 million, will provide for collection of particulates emitted from 143 ovens by a hood installed over the coke ovens.[63]

The Granite City Steel enclosed one-spot, coke-pushing control system comprises four major units, as follows: Enclosed coke guide; enclosed coke receiver; evacuation and gas-cleaning car; and conventional coke quench tower with modified water piping. With this system, any smoke or fumes that emanate from the oven-pushing and transfer of the hot coke to the quench tower are collected and passed through a high-energy venturi scrubber prior to discharge to the atmosphere.[64]

The Chemico enclosed, coke-quench, car-emission-control system appears to have replaced the coke-side shed system that was developed in 1973. Reportedly, the Chemico system, which does not need a hood-enclosure seal, is guaranteed to meet both Federal and State emission control standards.[65]

The British Steel Corporation has ordered 2,000 new combined respirator and safety

helmets, each having a fan that directs clean, filtered air across the wearer's face under conditions of fumes or dust. The first helmets will be provided as part of a package of improvements for protecting the health of coke-oven operators. The original prototype of the helmet was designed by the Safety in Mines Research Establishment. Racal-Amplivoc Communications, Ltd., Wembley, Middlesex, cooperated closely during the development of the helmet.[66]

A sealing device for use in charging coke ovens is described in British Patent 1,391,881. The bottom face of the telescopic charging sleeve on each charging-car hopper has a part-spherical surface that mates with a sealing ring to form a ball-and-socket joint. The ring is resiliently mounted on lugs on the sleeve and its position relative to the axis of the sleeve can be adjusted. The arrangement allows a smoke-tight connection to be made with displaced or tilted chargehole frames.[67]

Coke plant water pollution.—Researchers at ERDA's Oak Ridge National Laboratory developed a process that uses microscopic organisms to destroy phenolics in aqueous wastes of coke plants and coal conversion facilities. The process uses a vertical, tapered column containing pulverized coal suspended in the waste water. By substituting different kinds of microorganisms, the same process can be used to remove ammonia, nitrates and other organic compounds.[68]

Republic Steel Corp.'s research department conducted extensive laboratory, semipilot plant, and pilot plant studies in an effort to control coke-plant major process streams. Pollution problems, resulting from coke plants include crude ammonia liquor, barometric condenser water from ammonium sulfate crystallizers, and interception sump water from conventional light oil refining plants. Studies resulted in the development of a modular system to treat waste water.[69]

Coke plant wastewater sources, energy requirements for wastewater treatment, effluent limitations for selected coke plant pollutants, and cross-media analysis are discussed.[70]

Used ... thousands	$242,118	--	$242,118
Sold ... do	$139,337	--	$139,337
Ammonia products[7] ... do	$29,066	--	$29,066
Crude light oil and derivatives[8] ... do	$107,193	--	$107,193
Surplus gas ... do	$402,120	--	$402,120

W Withheld to avoid disclosing individual company confidential data.
[1]Not separately recorded.
[2]Plants associated with iron blast furnaces.
[3]Data may not add to totals shown because of independent rounding.
[4]Included with beehive coke sold "to blast furnace plants" to avoid disclosing individual company confidential data.
[5]Included with "To other industrial plants" to avoid disclosing individual company confidential data.
[6]In terms of sulfate equivalent.
[7]Includes ammonium sulfate, ammonia liquor, and diammonium phosphate.
[8]Includes intermediate light oil.

Table 3.—Summary of oven-coke operations in the United States in 1976, by State

State	Plants in existence Dec. 31	Coal carbonized (thousand short tons)	Yield of coke from coal (percent)	Coke produced (thousand short tons)
Alabama	7	6,588	70.77	4,662

Furnace plants	5.11	3,978	68	1,194	1,363	40,880	705	25,525	1,725	54,798	931
Total 1975	5.21	4,281	257	4,413	1,202	36,900	715	20,615	1,953	62,897	1,035

[1]Calculated by dividing production by coal carbonized at plants actually recovering breeze.
[2]Included with "Undistributed" to avoid disclosing individual company confidential data.
[3]Data may not add to totals shown because of independent rounding.

Table 10.—Oven- and beehive-coke breeze used and sold in the United States, by use

(Thousand short tons)

Year	Used by producers: In steam plants	Used by producers: In agglomerating plants	Used by producers: For other industrial use	Sold	Average value per ton
1972	265	1,305	704	[1]2,113	$10.59
1973	234	1,689	917	[1]2,165	10.39
1974	204	1,470	971	2,310	17.83
1975	257	1,202	715	1,953	32.21
1976	197	1,363	838	1,846	32.56

[1]Does not include beehive-coke breeze sold (to avoid disclosing individual company confidential data).

Table 11.—Apparent consumption of coke in the United States

(Thousand short tons)

Year	Total production	Imports	Exports	Net change in stocks	Apparent consumption[1]	Consumption: In iron furnaces[2]: Quantity	Consumption: In iron furnaces[2]: Percent	Consumption: All other purposes: Quantity	Consumption: All other purposes: Percent
1972	60,507	185	1,232	-586	60,046	54,607	90.9	5,439	9.1
1973	64,325	1,078	1,395	-1,757	65,765	60,720	92.3	5,045	7.7
1974	61,581	3,540	1,278	-249	64,092	58,441	91.2	5,651	8.8
1975	57,207	1,819	1,273	+4,066	53,687	48,817	90.9	4,870	9.1
1976	58,333	1,311	1,315	+1,495	56,834	51,561	90.7	5,273	9.3

[1]Production plus imports, minus exports, plus or minus net change in stocks.
[2]American Iron and Steel Institute; figures include coke consumed in manufacturing ferroalloys.

Table 12.—Coke and coking coal consumed per short ton of pig iron and ferroalloys produced in the United States

Year	Coke per short ton of pig iron and ferroalloys[1] (pounds)	Yield coke from coal (percent)	Coking coal per short ton of pig iron and ferroalloys (pounds, calculated)
1972	1,221.6	69.0	1,767.9
1973	1,200.0	68.4	1,754.4
1974	1,218.7	68.4	1,782.8
1975	1,221.6	68.4	1,786.0
1976	1,187.0	68.9	1,722.8

[1]American Iron and Steel Institute; consumption of pig iron only, excluding furnace making ferroalloys, was 1,216.2, 1972; 1,193.8, 1973; and not available in 1974, 1975, and 1976.

Table 13.—Oven coke produced in the United States, used by producers, and sold in 1976, by State

(Thousand short tons and thousand dollars)

State	Produced (quantity)	Used by producing companies: In blast furnaces		Used by producing companies: For other purposes[1]		Commercial sales: To blast furnace plants

ALL OTHER TYPES[10]			
Europe: Germany, East[11]	6,467	6,115	[e]6,100
Asia: India[e]	4,100	4,100	4,100
Total all other types	10,567	10,215	10,200
Grand total	[r]425,028	419,286	422,936

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Algeria, Australia, Malaysia, the People's Republic of China, Mexico, Norway, Romania, and the U.S.S.R. have produced gashouse coke in previous years and may have continued production during the time period covered by this table. However, no official statistics are available and information is inadequate to make reliable estimates of production levels. Except where otherwise noted, coke breeze has been excluded from this table.

[2]Coke produced at high temperatures in conventional carbonizing equipment (including slot and beehive coke ovens).

[3]Includes breeze.

[4]Includes relatively small amounts of gas coke.

[5]May include gas coke.

[6]Includes relatively small amounts of low-temperature coke.

[7]Data are total of so-called hard coke production from collieries and coke plants (including those at steelworks).

[8]Includes coke produced at high temperatures in carbonizing equipment designed primarily for gas manufacture (horizontal and vertical coal-gas retorts). In addition to the countries listed, Canada and Finland produce gas coke. However, this figure is not reported separately and has been included with metallurgical coke.

[9]Less than 1/2 unit.

[10]Includes coke produced at low and medium temperatures, as well as that produced in unconventional equipment (chain-grate cokers). In addition to the countries listed, the U.S.S.R. may produce coke from brown coal, but output is not officially reported and no basis is available for reliably estimating output levels.

[11]Includes coke produced from lignite at high temperature.

Table 25.—Average value per short ton of coal carbonized at oven-coke plants in the United States, by State

State	1975	1976
Alabama	$40.27	$40.05
California, Colorado, Utah	37.11	40.55
Illinois	39.80	38.48
Indiana	47.25	40.64
Kentucky, Missouri, Tennessee, Texas	42.87	44.67
Maryland and New York	57.27	56.65
Michigan	55.43	53.46
Minnesota and Wisconsin	48.37	48.70
Ohio	42.12	40.90
Pennsylvania	40.69	43.45
West Virginia	40.59	43.93
Average	44.21	44.16
Value of coal per ton of coke	64.55	64.03

Table 26.—Average volatile content of bituminous coal carbonized by oven-coke plants in the United States

(Thousand short tons)

Year	High		Medium		Low		Total	
	Quantity	Volatile content (percent)	Quantity	Volatile content (percent)	Quantity	Volatile content (percent)	Quantity	Volatile content (percent)
1972	60,536	34.7	8,754	26.4	16,923	16.8	86,213	30.3
1973	64,486	34.6	10,090	26.6	17,762	16.2	92,338	30.2
1974	61,344	34.8	10,763	25.6	16,303	17.9	88,410	30.6
1975	57,488	34.8	9,619	25.7	15,040	18.3	82,147	30.7
1976	56,847	34.9	9,982	26.4	16,554	17.4	83,383	30.4

Table 27.—Coal received by oven-coke plants in the United States in 1976, by consuming State and volatile content[1]

(Thousand short tons)

Consuming State	High volatile		Medium volatile		Low volatile		Total coal receipts[2]
	Quantity	Percent of total	Quantity	Percent of total	Quantity	Percent of total	
Alabama	1,830	28.0	3,906	59.9	787	12.1	6,524
California, Colorado, Utah	3,803	75.6	1,101	21.9	128	2.5	5,032
Illinois	2,145	78.8	194	7.1	383	14.1	2,722
Indiana	7,522	59.3	1,977	15.6	3,183	25.1	12,682
Kentucky, Missouri, Tennessee, Texas	1,091	62.0	71	4.0	599	34.0	1,761
Maryland and New York	5,928	63.2	1,011	10.8	2,437	26.0	9,377
Michigan	2,599	56.4	568	12.3	1,442	31.3	4,609
Minnesota and Wisconsin	353	39.6	198	22.2	340	38.2	891
Ohio	9,674	75.5	571	4.5	2,566	20.0	12,812
Pennsylvania	16,979	73.2	1,452	6.3	4,769	20.5	23,200
West Virginia	4,154	78.5	31	.6	1,105	20.9	5,290
Total 1976[2]	56,080	66.0	11,080	13.1	17,739	20.9	84,899
At merchant plants	2,392	40.5	837	14.2	2,670	45.3	5,898
At furnace plants	53,688	67.9	10,243	13.0	15,070	19.1	79,000
Total 1975	56,437	66.5	10,939	12.9	17,509	20.6	84,886

[1]Volatile matter on moisture-free basis: High volatile—over 31%; medium volatile; 22% to 31%; and low volatile; 14% to 22%.
[2]Data may not add to totals shown because of independent rounding.

Table 31.—Month-end stocks of bituminous coal at oven-coke plants in the United States

(Thousand short tons)

Month	1975	1976
January	7,140	8,115
February	8,010	8,514
March	8,665	9,334
April	8,980	9,931
May	9,603	10,612
June	10,009	11,257
July	8,126	8,715
August	7,340	7,258
September	7,003	8,164
October	7,729	9,037
November	8,468	9,605
December	8,671	9,804

Table 32.—Month-end stocks of anthracite coal at oven-coke plants in the United States[1]

(Thousand short tons)

Month	1975	1976
January	171	114
February	165	89
March	159	77
April	145	84
May	135	85
June	131	81
July	125	83
August	127	91
September	128	93
October	129	101
November	133	107
December	126	98

[1]Includes petrocoke.

Table 33.—Coal-chemical materials, exclusive of breeze, produced at oven-coke plants in the United States in 1976[1]

Product	Produced	Sold			Stocks, Dec. 31
			Value		
		Quantity	Total (thousands)	Average per unit	
Tar, crude ---- thousand gallons	636,382	290,536	$96,417	$0.332	44,649
Tar derivatives:					
Sodium phenolate or carbolate ---- do	2,482	2,352	351	.149	116
Crude chemical oil (tar acid oil) ---- do	5,678	5,679	2,143	.377	87
Pitch of tar:[2]					
Soft ---- thousand short tons	516	274	25,347	92.507	13
Hard ---- do	([2])	([2])	([2])	([2])	([2])
Other tar derivatives[3]	XX	XX	15,079	XX	XX
Ammonia products:					
Sulfate ---- thousand short tons	522	585	28,504	48.725	55
Liquor (NH_3 content) ---- do	5	6	562	93.667	2
Diammonium phosphate ---- do	([4])	([4])	([4])	([4])	([4])
Total ---- do	XX	XX	29,066	XX	XX
Sulfate equivalent of all forms ---- do	539	608	XX	XX	61
NH_3 equivalent of all forms ---- do	139	157	XX	XX	16
Gas:					
Used under boilers, etc ---- million cubic feet	[5]912,399	168,042	121,302	.722	--
Used in steel or allied plants ---- do		318,416	243,758	.766	--
Distributed through city mains ---- do		10,065	5,125	.509	--
Sold for industrial use ---- do		41,907	31,935	.762	--
Total[6] ---- do	[5]912,399	538,430	402,120	.747	--
Crude light oil ---- thousand gallons	[7]198,056	104,645	52,532	.502	8,831
Light oil derivatives:					
Benzene:					
Specification grades (1°, 2°, 90%) ---- do	60,411	59,822	47,526	.794	2,809
Other industrial grades ---- do	([8])	([8])	([8])	([8])	([8])
Toluene (all grades) ---- do	8,824	8,446	4,642	.550	788
Xylene (all grades) ---- do	1,496	1,251	732	.585	409
Solvent naphtha (all grades) ---- do	1,968	1,792	713	.398	223
Other light oil derivatives ---- do	3,993	1,398	505	.361	202
Total[6] ---- do	76,692	72,708	54,118	.744	4,431
Intermediate light oil ---- do	5,419	1,923	543	.282	456
Grand total[6]	XX	XX	677,716	XX	XX

XX Not applicable.
[1]Includes products of tar distillation conducted by oven-coke operators under the same corporate names.
[2]Soft-water-softening point less than 100°to 160° F, hard-over 160°F. Figures on soft pitch includes hard pitch to avoid disclosing individual company confidential data.
[3]Creosote oil, cresols, cresylic acid, naphthalene, phenol, refined tar, tar paint.
[4]Included with sulfate to avoid disclosing individual company confidential data.
[5]Includes gas used for heating ovens and gas wasted.
[6]Data may not add to totals shown because of independent rounding.
[7]Includes 89,841,000 gallons refined by coke-oven operators to make derived products shown.
[8]Included with "Specification grades" to avoid disclosing individual company confidential data.

Table 34.—Coal equivalent of the thermal materials, except coke, produced at oven-coke plants in the United States

Year	Materials produced				Estimated equivalent in heating value[1] (Billion Btu)					Coal[2] equivalent (thousand short tons)
	Coke breeze (thousand short tons)	Surplus gas (billion cubic feet)	Tar (thousand gallons)	Light oil (thousand gallons)	Coke breeze	Surplus gas	Tar	Light oil	Total	
1972	4,261	534	747,186	214,201	85,220	293,700	112,078	27,846	518,844	19,803
1973	4,902	596	732,455	226,110	98,040	327,800	109,868	29,394	565,102	21,569
1974	5,094	574	677,447	217,416	101,880	315,700	101,617	28,264	547,461	20,896
1975	4,281	527	645,537	194,814	85,620	289,850	96,831	25,326	497,627	18,993
1976	4,342	538	636,382	198,056	86,840	295,900	95,457	25,742	503,939	19,234

[1]Breeze, 10,000 Btu per pound; gas 550 Btu per cubic foot; tar, 150,000 Btu per gallon and light oil, 130,000 Btu per gallon.
[2]At 26,200 Btu per short ton of coal.

Table 35.—Average value of coal-chemical materials used or sold and of coke and breeze per short ton of coal carbonized in the United States

	1972	1973	1974	1975	1976
Ammonia products	$0.141	$0.177	$0.418	$0.397	$0.347
Light oil and its derivatives	.350	.418	1.276	1.233	1.273
Surplus gas used or sold	1.660	2.052	3.366	3.549	4.801
Tar and its derivatives (including naphthalene):					
Tar burned by producers[1]	.366	.572	.753	.945	2.890
Sold	.720	.611	1.528	1.616	1.663
Total	3.237	3.830	7.342	7.740	10.974
Coke produced[2]	22.978	26.315	50.005	57.843	59.284
Breeze produced	.533	.558	1.022	1.414	1.626
Grand total	26.748	30.703	58.369	66.997	71.884

[1]Includes pitch-of-tar.
[2]Average value of coke used or sold.

Table 36.—Percentage of coal costs recovered from the recovery of coal-chemical materials in the United States

	1972	1973	1974	1975	1976
Product:					
Ammonia products	1.0	1.0	1.2	1.0	1.0
Light oil and its derivatives	3.2	2.3	3.5	3.1	2.9
Surplus gas used or sold	10.6	11.2	9.2	8.0	10.9
Tar and its derivatives used or sold (including naphthalene)	8.0	6.5	6.3	6.2	10.3
Total	22.8	21.0	20.2	18.3	25.1
Value of coal per short ton	$15.74	$18.32	$36.49	$44.21	$44.16

Table 37.—Production and disposal of coke-oven gas in the United States in 1976, by State

(Million cubic feet)

State	Produced		Used in heating ovens	Surplus used or sold			Wasted
	Total	Thousand cubic feet per ton of coal		Quantity	Value: Thousands	Value: Average per thousand cubic feet

Columbium and Tantalum

By Henry E. Stipp[1]

U.S. consumption of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials totaled approximately 3.4 million pounds of contained columbium and tantalum, compared with consumption of 3.3 million pounds in 1975. Ferrocolumbium and other columbium and tantalum materials were consumed mainly in producing specialty steels and superalloys.

Consumption of columbium raw materials increased to approximately 3.4 million pounds of contained columbium compared with 2.1 million pounds in 1975.

Reported consumption of tantalum contained in raw materials increased to about 2.0 million pounds contrasted with the 1.1 million pounds in 1975. Increased demand for tantalum electronic capacitors for use in citizen band radios, smoke detector devices, heart pacemakers, and automobiles was reported to be the main reason for the rise in tantalum consumption.

Columbium mineral concentrates imported for consumption increased sharply to 3,968,000 pounds, gross weight (1,595,000 pounds contained columbium and 118,000 pounds contained tantalum). In 1975 columbium mineral concentrates imported for consumption totaled 1,542,000 pounds, gross weight (606,000 pounds contained columbium and 47,000 pounds contained tantalum). Tantalum mineral concentrates (including synthetic concentrates) imported for consumption increased to 2,557,000 pounds, gross weight (709,000 pounds contained tantalum, and 606,000 pounds contained columbium), compared with 1,753,000 pounds, gross weight (584,000 pounds contained tantalum, and 239,000 pounds contained columbium) in 1975. Imports of columbium concentrates in 1976 came mainly from Brazil, 47%; Canada, 30%; Nigeria, 12%; the People's Republic of China, 5%; Malaysia, 4%; and others, 2%. Tantalum concentrates came chiefly from West Germany, 42%; Canada, 20%; Australia, 9%; Thailand, 8%; Zaire, 6%; Brazil, 6%; and others, 9%.

Legislation and Government Programs.—Sales in 1976 of columbium materials from U.S. Government stockpile excesses by the General Services Administration (GSA) totaled 68,908 pounds of contained columbium in columbium concentrates. There were no sales of tantalum materials. Columbium concentrates shipped from U.S. Government stockpile excesses totaled 70,089 pounds of contained columbium; tantalum concentrates shipments were 8,028 pounds of contained tantalum. On October 1, the Federal Preparedness Agency (FPA) of GSA announced new stockpile goals, which were to be updated as necessary. These new goals for columbium and tantalum are shown in table 3 but are subject to change.

In an investigation started on August 3, 1976, the U.S. International Trade Commission determined that the U.S. tantalum industry was not being injured and was not likely to be by the importation of tantalum electrolytic fixed capacitors from Japan (other than those produced and sold by Matsushita Electric Industrial Co. Ltd.).[2]

Metal: Stockpile grade	1,650	201	--	--	201

[1]Stockpile goals established as of Oct. 1, 1976.

DOMESTIC PRODUCTION

There was no domestic production of columbium and tantalum minerals reported in 1976. However, Buttes Gas & Oil Co. was investigating a large titanium deposit in the Powderhorn area of Southwestern Colorado. The deposit reportedly contains significant quantities of columbium in the form of the mineral perovskite.

Tantalum metal powder (including capacitor-grade powder) produced from imported concentrates increased in quantity to 1,873,000 pounds compared with 844,000 pounds in 1975. Demand for tantalum powder for use in electronic capacitors was mainly responsible for the increased tantalum metal production. Production of tantalum metal ingots increased to 576,000 pounds, a 57% increase over the 367,000 pounds of 1975.

Columbium metal production data were withheld to avoid disclosing individual company confidential information. Data on production of columbium metal ingot also were withheld for the same reason. Four domestic companies produced 1,565,000 pounds of contained columbium in ferrocolumbium, valued at about $6.4 million.

Molycorp, Inc. at White Plains, N.Y., proposed to purchase about 1 million shares (32%) of the common stock of Kawecki-Berylco Industries, Inc. (KBI). At yearend Molycorp announced that it controlled 49.7% of the common stock of KBI.[3]

A new 1,200-kilowatt electron beam furnace was placed in operation at the Boyertown, Pa., plant of KBI, increasing capacity to produce ingots of high-quality electronic- and metallurgical-grade columbium and tantalum metal and their alloys.

H. K. Porter Co., Inc. of Pittsburgh, Pa., acquired 85% of the common stock of Fansteel, Inc., Chicago, Ill., manufacturers of columbium, tantalum, and their alloys.[4]

Norton Co., Newton, Mass., sold its metals division, a large producer of tantalum metal and mill products, to NRC Inc., a corporation jointly owned by Herman C. Starck, Berlin, West Germany, and Samincorp Inc., New York, N.Y. Samincorp is a subsidiary of South American Consolidated Enterprises, S.A., and Starck is a European manufacturer of special metals and alloys.[5]

KBI and Herman C. Starck contracted for Starck to process tin slags, owned by KBI, for consumption in Kawecki's plant at Boyertown, Pa.[6]

CONSUMPTION AND USES

Primary columbium metal consumption increased 124% to 291,000 pounds compared with 130,000 pounds in 1975. High-purity columbium metal in powder and ingot form was used mainly in preparing superalloys for the aerospace industry.

Tantalum metal consumption, including capacitor-grade powder, increased 144% to 1,098,000 pounds. In 1975 approximately 450,000 pounds of tantalum metal was consumed. The principal end use for tantalum metal powder was in the manufacture of capacitors for use by the electronics industry. Tantalum metal ingot was used mainly to fabricate corrosion-resistant chemical equipment.

Approximately 89% of the ferrocolumbium consumed in 1976 was added to alloy steels such as high-strength, low-alloy (HSLA) steels for the manufacture of oil and gas pipelines, structural steel, plate for ships, machinery, automobiles and atomic reactor steels. Construction of pipelines in the market economy countries during 1976 reportedly increased 45% above the annual average mileage for the previous 5 years. New pipelines in 1976 were estimated to cost a record $6.76 billion, a 48% increase over that of 1975.[7]

Table 5.—Reported shipments of columbium and tantalum materials

(Pounds of metal content)

Material	1975	1976	Change (percent)
Columbium products:			
Compounds, including alloys	930,800	791,300	-15
Metal, including worked products	112,700	101,600	-10
All other	21,200	41,000	+93
Total columbium	1,064,700	933,900	-12
Tantalum products:			
Oxides and salts	127,400	55,400	-57
Alloy additive	8,500	13,200	+55
Carbide	106,500	93,300	-12
Powder and anodes	436,600	759,000	+74
Ingot (unworked consolidated metal)	1,000	7,700	+670
Mill products	172,000	238,500	+39
Scrap	13,000	130,700	+905
Total tantalum	865,000	1,297,800	+50

Source: Tantalum Producers Association.

Specialty steel producers reported that sales in the aircraft engine market during 1976 were slow, but a pickup was expected during the first quarter of 1977. However, some producers reported an increase in demand for specialty steel in the nuclear reactor field during the second half of 1976.

An area of potential growth in consumption of columbium is in nickel- and cobalt-based alloys for use in automobile turbine engines. Superalloys containing columbium were used for aircraft turbines and nuclear powerplants.

A report by engineers of a major automobile manufacturer listed a number of unusual applications for HSLA steel that included door panels, front suspension cross members, idler arm brackets, and rear anchor cross members. However, widespread use of HSLA steel in automobile body applications has been slowed in favor of increased use of nitrogenized or strain aging steel. Reportedly, nitrogenized steel is more economical to use and more adaptable to conventional manufacturing techniques.[8]

Table 6.—Consumption of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials in the United States in 1976, by end use

(Pounds)

End use	Contained columbium and tantalum
Steel:

Total	3,389,279

W Withheld to avoid disclosing individual company confidential data; included with "Steel: Unspecified."

STOCKS

Processor and dealer inventories of columbium and tantalum materials at yearend were as follows, in pounds, contained columbium (Cb) and tantalum (Ta):

Material	Dec. 31, 1975	Dec. 31, 1976
COLUMBIUM		
Primary metal	54,560	81,401
Ingot	33,344	65,902
Scrap	55,453	106,958
Oxide	r663,584	524,579
Other compounds	r14,279	14,515
TANTALUM		
Primary metal	232,003	302,274
Capacitor-grade powder	97,457	94,088
Ingot	84,527	114,349
Scrap	312,960	174,457
Oxide	r61,394	49,174
Potassium tantalum fluoride	r45,409	88,572
Other compounds	r45,080	45,028

rRevised.

Stocks of columbium and tantalum raw materials reported by processors and dealers at yearend 1976, in thousand pounds of contained Cb or Ta (yearend 1975 figures in parentheses), were as follows: Columbite, Cb-491, Ta-465 (Cb-552, Ta-69); tantalite, Ta-424, Cb-206 (Ta-976, Cb-545); tin slag, Ta-2,431, Cb-1,946 (Ta-2,667, Cb-2,092); pyrochlore, Cb-143, Ta— (Cb-28, Ta—).

Consumer stocks of ferrocolumbium, ferrotantalum-columbium, and other columbium and tantalum materials as of December 31, 1976, were as follows, in pounds of contained Cb and Ta (stocks on December 31, 1975 in parentheses): Ferrocolumbium—923,655 (1,091,372); ferrotantalum-columbium—8,589 (10,500); and other columbium and tantalum materials—30,361 (30,744). Producer stocks of ferrocolumbium at yearend 1976 were 794,612 (1,077,500).

[8]American Metal Market. Nitrogenized Steels Capturing Automotive Favor for Body Use. V. 83, No. 51, Mar. 15, 1976, p. 13.

PRICES

Columbite and pyrochlore prices increased in 1976 mainly because of higher costs for mining and processing. Contract prices for Canadian pyrochlore, f.o.b. mine and mill, increased from the \$1.56 per pound of contained Cb_2O_5, that carried over from that of 1975, to about \$1.75 to \$1.85 per pound of Cb_2O_5 on March 11, and for the rest of the year they were quoted as nominal or about \$2.00 to \$2.25 per pound Cb_2O_5. Spot columbite concentrate prices, c.i.f., U.S. ports, increased from the \$1.80 to \$1.90 per pound of contained pentoxides, that was quoted on January 1, for material having a Cb_2O_5 to Ta_2O_5 ratio of 10 to 1, to \$2.40 to \$2.60 per pound of contained Cb_2O_5 and Ta_2O_5 on February 5; and to \$2.40 to \$2.70 per pound of contained Cb_2O_5 and Ta_2O_5 on May 21. On November 11 prices for spot columbite concentrate increased further to \$3.00 to \$3.50 per pound of contained Cb_2O_5 and Ta_2O_5.

U. S. reactor-grade columbium metal ingot prices were \$18.00 to \$25.00 per pound of columbium throughout the year; U.S. reactor-grade columbium metal powder was priced at \$30.00 to \$45.00 during 1976.

Ferrocolumbium prices per pound of contained columbium, ton lots, f.o.b. shipping point, were as follows on January 1: Spot, low-alloy, \$4.30 per pound; high-purity grade, \$8.61 to \$9.50 per pound. On July 1, the spot price for low-alloy ferrocolumbium increased to \$4.73 per pound and remained at that price for the rest of the year. On July 1, the price for high-purity grade ferrocolumbium increased to \$10.90 to \$11.83 per pound and on October 18 increased again to \$11.80 to \$14.30 and remained in that range for the remainder of the year.

On January 1 the price of nickel columbium increased to \$11.35 per pound of contained Cb, from \$10.40 per pound at yearend 1975. Effective October 18, the price of nickel columbium moved to \$14.30 per pound of contained Cb and remained at that price for the remainder of 1976.

Spot tantalite ore was quoted at \$15.50 to 16.50 per pound of contained Ta_2O_5, 60% basis, c.i.f. U.S. ports, at the beginning of the year. On June 18, the price advanced to \$16.00 to \$17.25 per pound; on November 11, the price increased further to \$17.25 to \$18.00 per pound and remained at that price for the rest of the year. Tantalum Mining Corporation of Canada (Tanco) tantalite was quoted at \$16.00 per pound of contained Ta_2O_5 throughout the year. Thailand tin slags were quoted as nominal throughout the year.

U.S. grade tantalum metal powder was listed at \$35.40 to \$48.00 per pound of tantalum throughout 1976, U.S. grade tantalum metal rod was quoted at \$52.00 to \$80.00 per pound, and U.S. tantalum metal sheet was quoted at \$48.00 to \$118.00 per pound throughout the year.

On November 1 the price of tantalum carbide increased to \$33.50 to \$34.50 per pound from the \$30.25 per pound that carried over from that of 1975.

FOREIGN TRADE

Unwrought columbium and columbium alloys, waste and scrap exported from the United States went mainly to West Germany (69%) and the United Kingdom (27%). Wrought columbium and columbium alloys were exported from the United States chiefly to the Netherlands (44%), Canada (17%), the United Kingdom (11%), West Germany (9%), and Japan (7%).

Tantalum ores and concentrates were exported from the United States mainly to West Germany (60%) and Japan (40%). U.S. exports of unwrought tantalum metal, alloys, and waste and scrap were shipped for the most part to West Germany (64%), the United Kingdom (18%), and Japan (14%). Tantalum metal powder and tantalum-alloy powder exports went mainly to West Germany (36%), Japan (34%), and the United Kingdom (13%). U.S. exports of wrought tantalum and tantalum alloys went chiefly to West Germany (31%), Japan (28%), the United Kingdom (22%), and France (4%).

Unwrought columbium metal, waste and scrap imports, all from West Germany, totaled 72 pounds valued at $2,765. Wrought columbium metal imported was not significant (1 pound). There were no U.S. imports of unwrought columbium alloys.

U.S. imports for consumption of unwrought tantalum metal, waste and scrap totaled 97,100 pounds valued at about $2.1 million, mainly from West Germany (57%), Mexico (18%), and France (9%). Wrought tantalum metal imports, chiefly from Belgium (80%) and Austria (12%), were 1,861 pounds valued at $158,560. There were no imports of unwrought tantalum alloys in 1976.

Columbium mineral concentrates imported for consumption increased 157% (gross weight) compared with those of 1975. Imports for consumption of tantalum mineral concentrates increased 46% (gross weight) compared with those of 1975.

Imports of tin slags, which increased 92%, gross weight, over those of 1975, came chiefly from Thailand and Malaysia.

Table 8.—U.S. exports of columbium and tantalum, by class

(Thousand pounds, gross weight, and thousand dollars)

Class	1975		1976	
	Quantity	Value	Quantity	Value
Columbium and columbium alloys, unwrought, and waste and scrap	17	61	24	175

WORLD REVIEW

Austria.—Treibacher Chemische Werke AG, Treibach, appointed Metallurgical International Inc., Tinton Falls, N.J., exclusive sales agent in the United States for its cemented carbide cutting tools, mining tools, and wear parts. Treibacher employs 1,300 people manufacturing carbides of columbium, tantalum, vanadium, tungsten, molybdenum, and titanium. The company also produces optical pure tantalum oxide, columbium oxide, ferroalloys, abrasives, hard metals, and detergents.[9]

Brazil.—In 1975 Companhía Brasileira de Metalurgia e Mineração (CBMM) produced 21.5 million pounds of pyrochlore concentrate containing an estimated 12.5 million pounds Cb_2O_5. The company also produced about 9 million pounds of ferrocolumbium containing almost 5.9 million pounds of columbium. In 1976 CBMM produced 23 million pounds Cb_2O_5 valued at $31.6 million. Production of ferrocolumbium was about 12 million pounds containing about 7.5 million pounds of columbium.

Production of tantalite in 1975 by a number of small producers totaled 209,437 pounds containing approximately 75,400 pounds Ta_2O_5 and 56,550 pounds Cb_2O_5.

The concentrating plant of CBMM located next to the pyrochlore mine, about 5 miles south of the city of Araxá in Minas Gerais, currently has the capacity of producing about 53 million pounds of pyrochlore concentrate per year containing about 28 million pounds Cb_2O_5. The concentrate is converted into ferrocolumbium in CBMM's metallurgical plant located in the same industrial complex. The metallurgical plant has the capacity to produce about 26.5 million pounds of ferrocolumbium containing around 17.2 million pounds of columbium.[10]

A deposit containing from 25 million to 30 million tons of manganese ore with associated columbium reportedly was discovered at Morro de Sete Lagoas in the Uapes district near the Venezuelan border.[11]

The tantalum resources of Brazil were described by region, and reserves for the State of Minas Gerais were reported. According to the National Department of Mineral Production of Brazil, proven reserves of tantalite ore in the State of Minas Gerais in 1973 were 47,822 short tons, and indicated reserves were 80,050 tons. No information was available on reserves in other regions of Brazil. It was concluded that currently worked deposits were nearing depletion, but output could be expected to continue from other areas that contain numerous pegmatite dikes and alluvial gravels favorable for the occurrence of columbite and tantalite.[12]

Brasimet Commercio e Industria, S.A., shipped pyrochlore concentrates to European consumers in July. At yearend a 3,307 short-ton-per-year ferrocolumbium plant, located at Catalão, Goías State, was scheduled to begin operating.[13]

Canada.—Tanco was operating profitably although earnings reportedly were badly hit in 1976 by a strike, which lasted for several months. However, Tanco produced 281,777 pounds Ta_2O_5 valued at $3.5 million. Exploratory drilling added 175,000 short tons of ore grading 0.203% Ta_2O_5 to reserves, which were considered sufficient to last to 1980 at current rates of depletion.[14]

Reportedly the Manitoba Development Corp., an agency of the Manitoba Government, was considering purchase of the shares of stock of Tanco held by International Chemalloy Corp. The Manitoba Corp. currently holds a 25% interest in Tanco, Chemalloy Minerals Ltd. has a 50.1% interest, and KBI holds a 24.9% interest.[15]

St. Lawrence Columbium & Metals Corp. closed its mine and mill in early February, reportedly because of a strike by underground workers. In late June the company went into receivership. At yearend the mine, mill, and equipment were put up for sale.[16]

The pyrochlore mine of Niobec Inc. located near Chicoutimi, Quebec, was officially opened on June 7. Two shipments of concentrate were made in May, but it was expected that the mill would take 6 months to reach

optimum operating capacity.[17]

Germany, West.—Patents owned by Herman C. Starck on an economical process for recovering tantalum from low-grade slags could give its U.S. affiliate NRC Inc. an advantage in the world tantalum market. This could be significant if reserves of tantalite ore become scarce after 1980.

Japan.—Mitsui Mining and Smelting Corp. was scheduled to start production of tantalum metal powder early in 1977. Mitsui purchased equipment and technology from Shinetsu Chemical Industry, which stopped producing tantalum metal powder in May 1976. Tantalum concentrates will be purchased by Mitsui from Australia, and tantalum slags, from Thailand and Malaysia. The company produced tantalum oxide in a plant rated at 7 tons per month in 1976.[18]

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Excludes columbium and tantalum-bearing tin concentrates and slag.

[2]In addition to the countries listed, Burundi, Spain, the Territory of South-West Africa, the U.S.S.R. and Zambia also produced or are believed to produce columbium and tantalum mineral concentrates, but information is unavailable to make adequate estimates of output levels.

[3]Data on gross weight generally has been presented as reported in sources, divided into concentrates of columbite, tantalite, pyrochlore, and microlite where information is available to do so, and reported in groups such as columbite-tantalite where it is not.

[4]Unless otherwise specified, content is estimated on the basis of the content reported for United States imports from the country in question. Estimates specifically marked as estimates are based on an estimated gross weight.

[5]Content calculated in terms of metal from data reported in source publication in terms of contained pentoxide.

[6]Less than 1/2 unit.

TECHNOLOGY

High-purity single crystals of tantalum were deformed under tension and compression at 4.2 kelvin in order to determine the type of deformation that occurred. In tension the principal mode of deformation of pure tantalum was slip, whereas in compression it was twinning. The addition of up to 4% rhenium to the tantalum eliminated twinning at 77 kelvin and facilitated slip deformation at 4.2 kelvin for certain crystal orientations.[19]

Preparation of hafnium-tantalum alloys containing 40% to 50% tantalum, by direct reaction between hafnium carbide and tantalum oxide was studied. Several pelletized samples of different oxygen-to-carbon ratios were sintered in a vacuum induction furnace for 2 hours at 1,650° C and at 2,000° C. After sintering the pellets were heated in an electron beam furnace at from 1 to 2.7 kilowatts of power for a period of 2 to 3 hours. Analysis and hardness values of the hafnium-tantalum alloys established the feasibility of preparing the alloys under vacuum by this method.[20]

The tantalum-hydride system was studied for various concentrations of hydrogen by resistivity measurements of tantalum wires doped with hydrogen. Results indicated the formation of a phase transformation on cooling below 149 kelvin, 156 kelvin, and 189 kelvin for three different ratios of hydrogen to tantalum of 0.25%, 0.40% and 1.4%, respectively.[21]

The discovery of a new mineral, olmsteadite, containing columbium and tantalum was reported. It occurs as deep brown to black prismatic crystals at the Hesnard and Big Chief pegmatites, Black Hills, S.Dak.[22]

The crystal structure of columbium hydride (CbH) was studied for its potential application to fusion-reactor technology. Two beta-phase precipitations of the CbH system were found. These consisted of dendritic crystals at high supersaturations of hydrogen and crystal plates at low supersaturations. The domain configuration of the beta-phase was given as an orthorhombic unit cell and multiple twinning intersecting the a axis and parallel to the b and c axes (100), during beta-growth.[23]

A similar study showed that the morphology of the beta-phase of columbium hydride depended on the cooling rate and on the degree of undercooling. The volume change caused by hydride precipitation resulted in plastic deformation of the matrix. Elastic and plastic adjustment for change in volume had a major effect on the equilibrium of the beta and alpha phases.[24]

A new type of ductile superconducting material was formed by incorporating 10% of columbium in a ductile metal, such as copper containing about 1% tin. The new material was formed into a copper base alloy with a small quantity of superconducting filaments in the matrix. The cost was reported to be not much more than ordinary copper wire.[25]

Several U.S. patents were issued in 1976 for the recovery of columbium and tantalum from low-grade raw materials.[26]

Copper

By Harold J. Schroeder [1] and George J. Coakley [1]

In 1976 world mine production of copper recovered from the decline of 1975 with a 7% increase to a record high output of 8.2 million tons. The United States continued to lead the world in mine production with 20% of the total, followed by Chile, the U.S.S.R., Canada, Zambia, Zaire, and Poland. Improvement in demand during the first half of the year, concern over disruption of transport systems used by central African producers, and speculative buying of copper contributed to an advance in the

rRevised.

price of copper on the London Metal Exchange (LME) from 54 cents per pound for January to 75 cents for July. A slowdown in demand and a buildup in world refined copper stocks to record high levels during the second half of the year resulted in a downtrend in prices to an average 58 cents for December.

In the United States, mine, smelter, and refinery outputs of copper, consumption of copper, and net imports of copper were all substantially larger when compared with 1975, but, except for mine production, were still below 1974 levels. The supply of refined copper from domestic production and net imports exceeded consumption and resulted in a substantial combined increase for producer, consumer, and exchange warehouse stocks. Producer prices in the United States approximated the LME pattern with increases in March, April, and July totaling 11 cents, followed by cuts of 4 cents in October and 5 cents in December to a quotation of 65 cents per pound for refined cathode copper.

Legislation and Government Programs.—The Federal Preparedness Agency (FPA) completed an interagency study of stockpile policy and procedures during 1976 and on October 1 announced new stockpile goals, including a goal of 1,299,000 tons for refined copper. Disposal of nearly 252,000 tons of copper from the stockpile in 1974 had reduced the inventory to only 489 tons which was disposed of by August 1976. Initial purchases against the new goal have not been scheduled. However, 20,261 tons from the previous stockpile that remained unused from transfers to other Government agencies was transferred back into the new stockpile.

The U.S. Department of Commerce amended Schedule A of Defense Materials System Order 4, effective November 1, to revise the base period and the set-aside percentages for copper-controlled materials. The amendment changes the base period from calendar year 1971 to calendar year 1975 and the set-aside percentages from 9% to 7% on unalloyed rod, bar, shapes, and wire; from 4% to 2% on alloyed plate, sheet, strip, and rolls; from 10% to 2% on alloyed rod, bar, shapes, and wire; and on alloyed tube for which no reserve space was previously required, a 10% set-aside was established.

Import duties on copper ores, concentrates, blister, and refined copper remained at 0.8 cent per pound. The duty remained suspended on copper and copper-base scrap through June 1978.

The Generalized System of Tariff Preferences (GSP) was implemented January 1, 1976, in accordance with Title V of the Trade Act of 1974. The system consists of duty-free treatment for a period up to 10 years, on a wide range of designated articles imported directly from any developing country designated as a beneficiary developing country (BDC). All copper items imported from BDC's have been granted GSP status. There are a number of limitations to the program such as the provision that a country does not receive GSP coverage if the imports of a particular article from that country exceed 50% by value or more than $25 million of the particular item during the previous calendar year. This provision is reviewed every year for possible changes.

DOMESTIC PRODUCTION

PRIMARY COPPER

Mine Production.—Domestic mine production of recoverable copper was 1.61 million tons, a 14% increase from 1975. Principal copper producing States were Arizona, with 63.8% of the total, Utah (11.6%), New Mexico (10.7%), Montana (5.7%), Nevada (3.6%), and Michigan (2.7%). These States accounted for 98.1% of total production. In the latter part of the year, output was curtailed at a number of operating properties as an adjustment to a growing imbalance of new supplies to demand.

Open pit mines accounted for 84% of mine output, and underground mines accounted for 16%. The production of copper from dump and in-place leaching, mainly recovered by precipitation with iron, was 126,144 tons or 8% of mine output. Total mine production of copper recovered by leaching methods was 282,501 tons, of which 207,309 tons was precipitated with iron and 75,192 tons was electrowon.

Duval Corp., a subsidiary of Pennzoil Co., operated the Sierrita, the Esperanza, and the Mineral Park copper-molybdenum open pit mines in Arizona and the Copper Canyon open pit copper mine in Nevada. Sales of copper in the form of concentrates and

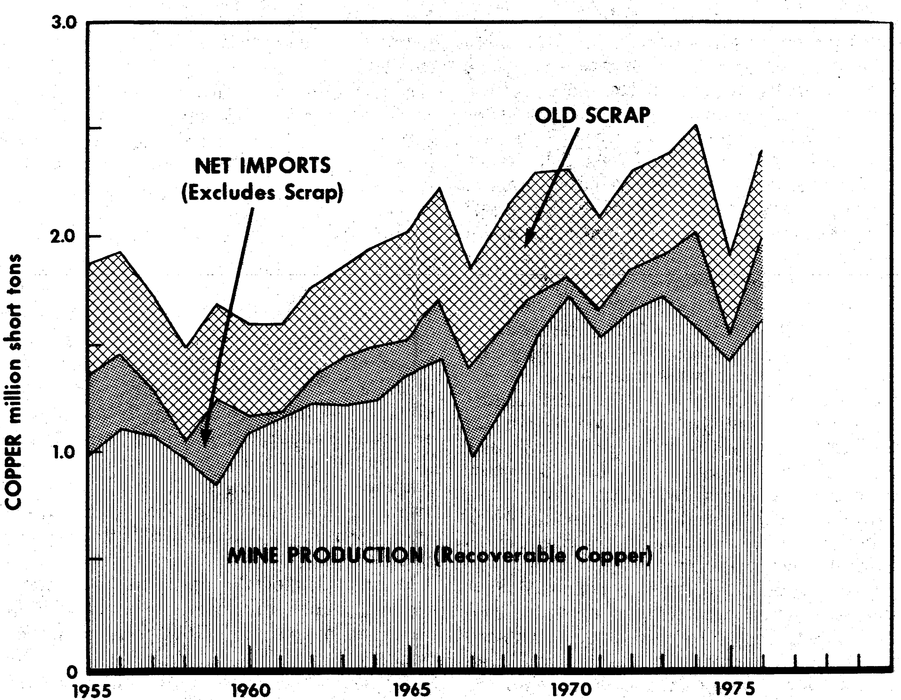

Figure 1.—Sources of copper supply for United States copper consumption.

precipitates from these four operations totaled 100,680 tons compared with 156,608 tons in 1975.

The Anaconda Company produced 91,259 tons of copper at the Berkeley pit at Butte, Mont., compared with the reduced output of 75,030 tons in 1975. Output of copper from the Yerington mine at Weed Heights, Nev., and the Victoria mine near Ely, Nev., totaled 36,920 tons compared with 41,190 tons in 1975. A major underground copper mine, the Carr Fork project in the Bingham district of Utah, was under development with completion scheduled for 1979. The initial rate of production was planned to be 48,000 tons per year with an increase to 65,000 tons 3 years later.

Anamax Mining Co., a joint venture of The Anaconda Company and AMAX Inc., operated the Twin Buttes, Ariz., open pit mine and produced 247,825 tons of copper concentrates from processing sulfide ore and 28,962 tons of electrowon refined copper from processing oxide ores. The 40,000-ton-per-day sulfide mill resumed operation in January after a 10-month shutdown. The 10,000-ton-per-day oxide ore leach-electrowinning plant had its first full year of operation.

Anamax and ASARCO Incorporated entered into a partnership known as the Eisenhower Mining Co. to develop the Palo Verde copper deposit, which is 6 miles from the Twin Buttes operation and between two ASARCO operations. Stripping of overburden from the deposit, which is estimated to contain 125 million tons of ore averaging 0.6% copper, began in the third quarter.

Kennecott Copper Corp. operated mines in Arizona, Nevada, New Mexico, and Utah; these mines produced a combined total of 346,427 tons of copper, a 20% increase from the 1975 output. The Utah Copper Div. accounted for 188,917 tons of the total followed by Chino Mines Div. (New Mexico) with 57,202 tons, the Ray Mines Div. (Arizona) with 88,089 tons, and the Nevada Mines Div. with 12,219 tons. Mining and milling operations were suspended early in 1976 at the Nevada operations because of high operating costs and closure of an associated smelter pending resolution of disagreements on required pollution control facilities. Development work on a potential copper deposit beneath the perimeter of the Utah Copper Div.'s Bingham Canyon open pit mine continued during 1976. A contract was awarded for the erection of surface ancillary facilities which will allow sinking of a shaft during 1977. An environmental impact statement for development of a copper mine near Ladysmith, Wis. was found to be adequate and in compliance with State requirements. Delays anticipated in obtaining permits and meeting other obstacles will probably defer the startup of the project until at least 1980. Plans call for an initial annual production of 11,000 tons of copper in concentrates. Engineering plans progressed during 1976 in anticipation of possible expansion of productive capacity at Chino Mines Div. and Ray Mines Div.

ASARCO operated three copper mines in the vicinity of Tucson, Ariz. The Mission and Silver Bell units, in response to a weak-market situation, were operated on a reduced schedule from mid-1975 until August 1976, when they were restored to normal production rates. Outputs at the two units were 35,200 tons and 22,300 tons of copper in concentrates and precipitates compared with 26,900 tons and 18,300 tons in 1975. The San Xavier mine and leach plant operated at normal levels throughout the year and produced 11,400 tons of copper in precipitates. The Sacaton open pit mine and mill near Casa Grande, Ariz. produced 22,000 tons of copper in concentrates. Development work for the mining of a deeper ore body by underground block-caving methods was suspended in 1976 because of low copper prices and high capital costs, but the project was scheduled for reactivation in the first quarter of 1977.

Mines of the Phelps Dodge Corp. produced a record high 331,000 tons of copper in 1976. Production at the Metcalf mine near Morenci, Ariz., which began operation in 1975, produced 52,700 tons of copper in concentrates. Output in concentrates at Morenci, Ariz.; Ajo, Ariz.; and Tyrone, N. Mex., were 104,500 tons, 50,200 tons, and 87,400 tons, respectively. Leaching of waste dumps and tailings and other miscellaneous sources contributed 36,100 tons of copper. Underground development work continued at Safford, Ariz., toward eventual mining of a deep ore body containing an estimated 400 million tons of ore with an average grade of 0.72% copper. However, no decision was made on when to bring this property into production.

Cities Service Co. operated mines in Arizona and Tennessee that produced 86,600 tons of copper compared with 46,900 tons in 1975. The increased output reflected an achievement during the second full year of operation of the Pinto Valley open pit mine and mill facilities near Miami, Ariz., of an operating rate 6% above the design capacity of 40,000 tons of ore per day. A program to expand production to 50,000 tons per day is planned for completion in 1978. A solvent extraction-electrowinning plant replaced the leach-precipitation plant at the Miami mine in midyear. Startup of the underground Miami-East mine, originally scheduled for 1976, was postponed because of escalated costs and adverse market conditions.

The White Pine, Mich., operations of White Pine Copper Co., in response to continued depressed business conditions in the copper industry and as part of a plan to conserve cash and reduce expenditures, curtailed mine operations during the year to an average 43.2% of design capacity. Selective mining resulted in an average 1.38% copper ore grade compared with 1.01% in 1975, and the mill achieved a recovery rate of 87.8% compared with 85.6% in 1975. The smelter operated with only one of the two reverberatory furnaces and produced 45,912 tons of refined copper.

Magma Copper Co. operated two underground copper mines in Arizona with a combined output of 145,000 tons of copper compared with 139,000 tons in 1975. The San Manuel mine was operated at a curtailed level during both 1975 and 1976. At the smaller Superior mine, production was maintained at full capacity.

Inspiration Consolidated Copper Co. operated the Thornton, Live Oak, Red Hill, and Joe Bush open pit copper mines in the vicinity of Inspiration, Ariz.; 8.8 million tons of waste and 4.6 million tons of ore were mined for a combined 13.4 million tons of material handled. Approximately 4.4 million tons of the ore was treated in the concentrator with part of the concentrator feed first processed in leaching tanks to recover acid-soluble copper. The combined production from in-plant processed ore in the form of concentrates, precipitates, and electrowon cathodes was 25,586 tons of copper. Waste dump leaching of mined material, too low in copper content for in-plant treatment, yielded an additional 10,339 tons of copper. At the Ox Hide mine, 2.2 million tons of ore was mined for heap leaching dumps and 3,968 tons of copper was recovered in the form of precipitates. At the Christmas open pit mine, southeast of Miami, Ariz., output was 6,971 tons from processing 1.6 million tons of ore and removal of 4.8 million tons of waste. Total mine production from all operating mines was 48,864 tons of copper compared with 55,815 tons in 1975.

The Cyprus Pima Mining Co. operated

the open pit Pima mine near Tucson, Ariz., milling 19.6 million tons of ore averaging 0.47% copper. Proven ore reserve at yearend was estimated to be sufficient to sustain the operation for about 8 years at the 1976 production rate. Cyprus Bagdad Copper Co. at its Bagdad, Ariz., property mined 2.0 million tons of sulfide ore averaging 0.60% copper. In addition 7,600 tons of cathode copper produced by a leach-electrowinning process were sold. Progress continued on a major mine-mill expansion program designed to handle 40,000 tons of ore per day with initial production using the new facilities scheduled for September 1977. Ore reserves at yearend were nearly 300 million tons of proven ore averaging 0.49% copper. Exploratory drilling during the year indicated the probability of additional reserves. The Cyprus Bruce Copper and Zinc Co. operated its underground copper-zinc mine near Bagdad, Ariz., and mined 90,300 tons of ore grading 3.5% copper and 13.0% zinc. Ore reserves at yearend were 127,600 minable tons, sufficient for only a little more than 1 year's operation. The Cyprus Johnson Copper Co. mined 1.3 million tons of oxide-copper ore from a deposit near Johnson, Ariz., in the first full year of operation. The ore contained 0.418% acid-soluble copper and was treated by a leach-electrowinnning process to produce refined copper cathodes. Reserves of oxide-copper ore with 0.50% acid-soluble copper were estimated to be sufficient for at least 8 years of operation at the 1976 rate of production.

Ranchers Exploration and Development Corp. produced in excess of 8,000 tons of copper cathodes-a record high-by a leaching-solvent extraction-electrowinning process at its Bluebird mine near Miami, Ariz. The in situ leaching operation at the Old Reliable deposit near San Manuel, Ariz., and the leaching operation at the Big Mike mine near Winnemucca, Nev., were on standby throughout 1976, awaiting more favorable marketing conditions.

Hecla Mining Co. in a joint venture with El Paso Natural Gas Co. completed mine development and plant construction at the Lakeshore copper mine south of Casa Grande, Ariz., and placed the project in operational status on April 1. The plant was designed to mill 11,000 tons per day of sulfide ore with the concentrate treated by roasting, leaching, and electrowinning to produce 30,000 tons per year of refined cathode copper. The roasting operation will produce 200 tons per day of sulfuric acid for use in a 6,000-ton-per-day vat leaching plant to process oxide ore. The leach plant design capacity was 35,000 tons of copper per year in the form of precipitate copper. Mine output for 1976 was 8,215 tons as refined copper and 11,405 tons as copper in precipitates. An additional 8,758 tons of refined copper was produced from processing purchased concentrates.

UV Industries, Inc., operated the Continental mine near Bayard, N.Mex., mining 668,435 tons of ore with an average copper assay of 1.66% from underground operations and 1,650,352 tons of ore with an average copper assay of 0.83% from open pit operations. Concentrates produced from milling the ore totaled 88,862 tons with an average copper content of 26%. Estimated reserves at yearend were 18.8 million tons averaging 0.88% copper suitable for open pit mining and 18.9 million tons averaging 1.96% copper suitable for underground mining.

Smelter Production.—Output of copper at primary smelters in the United States was 1.59 million tons, a 6% increase from production of the preceding year.

ASARCO completed and placed in operation a new baghouse to filter gases from the metallic arsenic plant at its Tacoma, Wash., smelter. Major repairs and modifications were made to the sulfuric acid plant originally built in 1971 at the Hayden, Ariz., smelter. The acid plant, together with the air monitoring system installed in 1975, enabled the plant to qualify for a conditional operating permit from State authorities. At El Paso, Tex., work began on the first phase of a comprehensive modernization and quality control program designed to bring both the copper and lead smelters into compliance with governmental standards. The initial work will improve fugitive emissions at ground level by enclosing completely and ventilating the building housing the converter furnaces.

Kennecott closed its McGill, Nev., smelter on August 1 as a result of a rejection by the Environmental Protection Agency (EPA) of the company's plans for meeting emission standards. A court ruling late in the year supported the company's position and plans were to reopen the smelter early in 1977. At the Garfield, Utah, smelter, work was well advanced on an extensive construction project for improved environmental controls to be partly phased into operation in 1977. Included in the project will be the replacement of existing reverberatory furnaces and converters with a continuous smelting-converting unit and also construction of an additional sulfuric acid plant.

Phelps Dodge began operation of a new copper smelter in Hidalgo County, N. Mex. Cost of the smelter project, including a townsite and a 36-mile industrial railroad, was placed at $268 million. It is the first smelter in the United States to utilize the flash smelting process. Initially the facility has the capacity to treat about 1,400 tons of concentrates daily, equivalent to about 100,000 tons of anode copper annually. In accord with an agreement to smelt concentrates from the Bagdad, Ariz., operation of Cyprus Mines Corp., beginning in 1978, additional construction to increase the smelter capacity was underway.

San Manual smelter operations of Magma Copper Co. were adversely affected during the fourth quarter by an unusually high number of intermittent curtailments required for air pollution control during atmospheric inversions. The intermittent cooling and reheating resulted in deterioration in the physical condition of the furnaces and consequently lower efficiency and throughput. Operating practices were being developed to reduce the frequency and severity of such curtailments.

Refined Production.—In 1976 production of refined copper from primary materials increased 7% to 1.54 million tons, a partial recovery from the low output of 1975. Refined copper produced from scrap was 375,150 tons compared with 344,500 tons in 1975. Total production of refined copper in the United States was 1.91 million tons derived 80% from primary and 20% from scrap sources.

A new refinery of ASARCO at Amarillo, Tex., rated at 420,000 tons of annual copper capacity was operated for the first full year. This refinery replaced the company's Baltimore refinery, closed in 1975 and the Perth Amboy, N. J., refinery closed in 1976.

Kennecott completed an expansion project at the Ray Mines Div. (Arizona) to increase the silicate copper leaching - electrowinning plant by 40%. Overall performance of the new plant exceeded design projections.

As described in detail under mine production projects, associated copper electrowinning units were placed in operation during the year by Hecla Mining Co. and Cities Service Co.

Copper Sulfate.—Copper sulfate was produced from electrolytic tankhouse solutions, blister copper, and secondary metal by companies with plants located as follows:

Company	Plant location
The Anaconda Company	Great Falls, Mont.
Chevron Chemical Co	Richmond, Calif.
Cities Service Co	Copperhill, Tenn.
Phelps Dodge Refining Corp	Laurel Hill, N.Y., El Paso, Tex.
Van Waters & Rogers Inc	Wallace, Idaho.

Copper sulfate production decreased to 32,122 tons, and was the smallest quantity since 1935. Production exceeded shipments plus consumption by producing companies by 1,691 tons and ending stocks of 8,557 tons were the highest yearend levels since 1970. Of the total 30,431 tons shipped, producers reports indicated that 13,479 tons was for agricultural uses, 16,710 tons was for industrial uses, and 242 tons was for other uses.

Byproduct Sulfuric Acid.—Sulfuric acid was produced at 14 copper smelters from the sulfur contained in offgases, and output increased for the ninth consecutive year from 1,784,700 tons to a record 2,281,600 tons on a 100% acid basis. New sulfuric acid plants were brought into production at the Hidalgo County, N. Mex., smelter and the new Casa Grande, Ariz., roasting-electrowinning plant.

SECONDARY COPPER AND BRASS

Domestic recovery of copper in all forms from all classes of purchased scrap totaled 1.15 million tons in 1976, an 18% increase from the 1975 total. Recovery from copper-base scrap advanced from 0.95 million tons to 1.11 million tons. Brass mills accounted for 47% of the recovered copper, primary producers for 26%, and secondary smelters for 22%. The remaining 5% was reclaimed at chemical plants, foundries, and manufacturers.

Consumption of purchased copper-base scrap in 1976 was 1.51 million tons consisting of 62% new scrap and 38% old scrap. Of the major categories of copper and copper-alloy products derived from scrap, the output of unalloyed copper, brass mill products, and brass and bronze ingots were 390,700 tons, 649,700 tons, and 228,700 tons.

CONSUMPTION

Consumption of refined copper increased substantially during the year from that of 1975, with peak consumption levels reached during the second quarter of 1976. Total consumption for the year was 2.0 million tons, an increase of 30% from 1975 but 9% below 1974. Wire mills accounted for 68% of refined copper consumption, brass mills accounted for 29%, and all other categories accounted for the remaining 3%.

Apparent withdrawals of primary refined copper on domestic account was 1.82 million tons compared with 1.31 million tons in 1975.

STOCKS

Stocks of refined copper at primary producers were 207,000 tons at the start of the year, increased to 216,500 tons by the end of April, decreased to 164,200 tons by August, then were built up to 190,000 tons by yearend. At wire rod mills, brass mills, other refined copper consumers, and secondary smelters yearend refined copper stocks of 157,000 tons were slightly higher than at the start of the year. Refined copper stocks reported by the New York Commodity Exchange (COMEX) rose from 100,000 to 201,000 tons.

PRICES

Prices on the LME increased from a monthly average of 54.1 cents per pound for January to 74.7 cents in July, and then declined to 58.4 cents in December. The average LME price for 1976 was 63.9 cents compared with 56.1 cents in 1975.

Producer prices in the United States approximated the LME pattern with increases of 3 cents in March, 4 cents in April, and 4 cents in July, followed by cuts of 4 cents in October and 5 cents in December to a quotation of 65 cents per pound for refined cathode copper. Electrolytic wirebar quotations were 0.625 cent above the quotations for cathode copper. Average quoted prices for electrolytic wirebar copper was 69.6 cents compared with 64.2 cents for 1975.

FOREIGN TRADE

Net imports of copper were a relatively large supply component in 1976 as imports of unmanufactured copper, excluding alloyed copper scrap, were 534,700 tons compared with 324,100 tons in 1975, while exports decreased from 233,900 to 172,000 tons. The largest trade category, refined copper, increased from 146,800 tons to 381,500 tons for imports, while exports declined from 172,400 tons to 111,900 tons. Canada supplied 29% of the total imports, followed by Zambia with 24% and Chile with 19%. Imports of blister copper were 44,500 tons compared with 89,000 tons in 1975. The other import categories of ore, concentrates, matte, and unalloyed copper scrap totaled 108,700 tons and the other export categories of ore, concentrates, matte, blister, unalloyed scrap, and ash and residues totaled 60,200 tons.

Exports of alloyed copper scrap, in gross weight, were 76,700 tons compared with 99,200 tons in 1975. Imports of alloyed copper scrap were 14,600 tons, gross weight, or 9,600 tons copper content.

WORLD REVIEW

World mine production of copper increased 7% to 8.21 million tons in 1976. The United States continued to lead the world in mine production with 20% of the total, followed by Chile 13%, the U.S.S.R. 11%, Canada 10%, Zambia 10%, Zaire 6%, Poland 4%, Philippines 3%, Australia 3%, Peru 3%, the Republic of South Africa 3%, and Papua New Guinea 2%.

World stocks of refined copper, as reported by the World Bureau of Metal Statistics, continued to reflect oversupply conditions. Stocks grew to 1,843,000 tons by yearend, representing an increase of 9% over 1975. The reported stocks included producer, consumer, and merchant inventories of 623,000 tons (including 201,000 tons in COMEX warehouses) of refined copper in the United States, 283,000 tons in Japan, 199,000 tons combined between France, West Germany, and the United Kingdom, plus 665,000 tons held in LME warehouses. The total reported world stock level, valued at $2.4 billion, represented the equivalent of a 3.1-month demand based on the average monthly world market economy consumption of refined copper of 590,000 tons in 1976.

The major copper producing and consuming countries held three meetings in 1976 under the auspices of the United Nations Conference on Trade and Development (UNCTAD) to examine the causes of market instability and to consider possible ways to correct the problem. At the initial meeting in March, set up on an ad hoc basis at the request of the Conseil Intergouvernemental des Pays Exportateurs de Cuivre (CIPEC), general support was given toward establishment of a permanent consultative body for copper to provide the means for further work on the problem.

The direction of the subsequent copper meetings was strongly affected by Resolution 93 IV, An Integrated Program for Commodities, issued at the UNCTAD IV meeting between the developed and developing countries at Nairobi, Kenya, in May 1976. Resolution 93 IV called for a cycle of preparatory meetings on 18 commodities, including copper, designed to explore possible solutions to the problems of their markets. Among items to be considered were the possible formation of commodity agreements involving the use of buffer stocks and the formation of an international Common Fund to finance commodity agreement operations.

The September 1976 meeting in Geneva then became the first UNCTAD preparatory meeting on copper. It was decided to set up an Intergovernmental Expert Group on Copper (IEGC) composed of representatives from countries with a significant interest in production, consumption, or trade in copper. The IEGC mandate called for the collection and examination of basic data on the industry and for consideration of possible solutions to problems of the industry, including, among others, interim base-price contract measures and buffer stock agreements. The first formal meeting of the IEGC, held in Geneva in November, was mainly organizational with final agreement made on a list of studies to be carried out by individual members prior to a 2-week working meeting in February 1977.

In general, the three 1976 meetings delineated the complexities of the world copper market and highlighted the difficulties involved in reaching a workable solution to its problems.

At the ninth annual Ministerial Conference of CIPEC held at Santiago, Chile, in December 1976, continued concern was expressed about the gravity of the world economic and monetary climate as it affected current world copper market prices and the future of new copper developments.

The Ministers voted to continue support of the UNCTAD producer-consumer dialogue seeking a solution to these problems. An extraordinary session was to be called in early 1977 to discuss possible interim measures for stabilizing copper prices while awaiting agreement on other long term solutions. In other policy action, CIPEC announced that it would increase support to existing national copper development centers. Support would include granting of interim financial assistance to help the centers defend markets and develop new copper uses.

Australia.—Mine production decreased 1% to 239,680 tons, smelter production dropped 6% to 186,840 tons, and refinery output decreased 3% to 177,190 tons from 1975. Mine and smelter production was down over 13% each from peak output levels of 1974. In response to requests from the depressed domestic copper industry, the Australian Government approved two major actions in 1976. The Industries Assistance Commission recommendation on assistance to the copper ore and concentrate industry was accepted, whereby, the Government will guarantee repayment of principal and interest on commercial loans made by qualifying copper companies. These guarantees will apply to loans of companies which are judged viable under normal conditions but are taking a cash loss on current production. The size of the loan is designed to bring the companies to a cash break-even position from January 1, 1976, until June 30, 1977. In August 1976, under other governmental action, the Price Justification Tribunal announced it will not impose an artificial ceiling price on copper sold in Australia by the market leader, Mount Isa Mines Ltd. (MIM).

MIM Holdings Ltd., operated its copper-lead-zinc-silver mine and copper smelter at Mount Isa and a copper refinery at Townsville, Queensland. For the fiscal year ending June 30, 1976, MIM treated 4.77 million tons of copper ore grading 3.4% copper compared with 5.46 million tons grading 3.2% copper in 1975. Blister copper output decreased 7% to 164,926 tons while production of refined copper dropped 9% to 160,700 tons. Remaining copper ore reserves were estimated at 150 million tons of 3.21% copper.

Mount Lyell Mining & Railway Co., Ltd., a subsidiary of Consolidated Gold Fields Ltd., for the year ended June 30, 1976, decreased production 18% to 22,560 tons of copper in concentrate from 2.44 million tons of ore grading 1.09% copper mined and milled at its Queenstown, Tasmania, operation. In December, in response to depressed copper prices, Mount Lyell announced plans to reduce production from 24,250 tons per year to 16,500 tons. Reserves in all ore zones were estimated at 30 million tons of proven ore grading 1.46% copper and 11.1 million tons of probable ore grading 1.41% copper.

Gunpowder Copper Ltd., owned 48% by Consolidated Gold Fields and located 80 miles north of Mt. Isa, operated at a loss for the year ending June 30, 1976, while increasing production 14% to 9,150 tons of contained copper. A development program will double capacity to 600,000 tons of ore annually by late 1978. Reserves at Gunpowder's Mammoth mine stand at 8.8 million tons grading 3% copper.

Cobar Mines Pty., Ltd., fully owned by BH South Ltd., in the year ending June 30, 1976, treated 655,240 tons of ore averaging 1.9% copper producing 9,420 tons of copper contained in 36,930 tons of concentrates. Byproduct zinc and lead were also recovered. Production for the foreseeable future will be concentrated in more highly productive open stopes at a rate of 660,000 tons per year. Advance underground development work was suspended.

Kanmantoo Mines Ltd., in Kanmantoo, South Australia, also held by BH South Ltd., decreased production for the fiscal year ending June 30, 1976, 5% to 7,098 tons of copper contained in 30,180 tons of concentrates recovered from 916,700 tons of copper ore milled. An additional 800 tons of copper contained in concentrates was obtained from treatment of stockpiled oxide ore. Development work on an adjacent underground ore body was almost completed when the entire operation was placed on a care and maintenance basis on June 30, 1976. Remaining reserves have been estimated at 8 million to 13 million tons of 1% copper.

Peko-Wallsend Ltd., operated the copper-gold mine at Mount Morgan, Queensland, and the Tennant Creek copper-gold-bismuth mines in the Northern Territory. At the Tennant Creek operations, the suspension of all copper mining and smelting activities continued throughout the year. During

1975-76 fiscal year, Mount Morgan produced 9,100 tons of contained copper in 1 million tons of ore treated. Remaining reserves were estimated at 330,000 tons grading 0.90% copper. The smelter produced 10,960 tons of blister copper, up 15% over 1975.

Botswana.—Bamangwato Concessions, Ltd. (BCL), operated the Pikwe open pit and underground nickel-copper mine and flash smelter. Development work on the Selebi underground ore body continued with startup planned for January 1980. Production at Selebi must be phased in to offset the depletion of the open pit by July 1980. BCL overcame its prolonged startup problems and by yearend was operating at a near capacity rate of 1.3 million tons of ore and 46,000 tons of matte annually. Proven and probable ore reserves as of December 31, 1976, were estimated at 48.3 million tons grading 1.10% nickel and 1.20% copper.

During the year, ore milled increased 81% to 2,292,600 tons grading 1.07% nickel and 0.86% copper compared with 1,267,500 tons grading 1.15% nickel and 0.94% copper in 1975. Production of a 75% to 80% copper-nickel matte nearly doubled from 18,200 to 35,830 tons during the year. Matte production is shipped to AMAX's Port Nickel, La., plant for refining. Port Nickel received 14,224 tons of imported matte from Botswana in 1976.

Canada.—Mine production increased 2% in 1976 to 823,570 tons of recoverable copper. Smelter output decreased 2% to 538,580 tons, and refinery production decreased 4% to 562,750 tons of copper. Mine production increased in nearly all Provinces in 1976 except for Manitoba, New Brunswick, and Newfoundland. British Columbia was the leading copper-producing Province with 36% of the total, followed by Ontario 35%, Quebec 16%, Manitoba 8%, and the remaining Provinces 5%.

Reviewing the activities of the Canadian copper industry for the year by Province, in British Columbia, Afton Mines Ltd., controlled 54% by Teck Corp. Ltd., began construction in May 1976 on a new $80 million mine, mill, and smelter complex. With a capacity of 30,000 tons per year of blister copper, construction is scheduled for completion in late 1977.

Bethlehem Copper Corp. Ltd. milled 7.5 million tons of ore grading 0.44% copper from open pit mines in the Highland Valley, and produced a 36.74% concentrate containing 27,560 tons of copper compared with 27,300 tons of copper in 1975. Reserves at the operating Iona and Jersey mines total 44.9 million tons of 0.46% copper. Reserves at the Huestis mine were exhausted by yearend. A stripping program to remove 25 million tons of overburden to prepare the Jersey extension reserves for mining is scheduled for completion in 1977. At 1976 production rates, reserves were sufficient to provide mill feed through 1982. Bethlehem is currently investigating the feasibility of developing 130 million tons grading 0.51% copper and 0.027% molybdenum of the 286-million-ton J-A ore body by underground block-caving methods. Ore would be transported by an 8,000-foot-long conveyor belt from the mine to the existing 21,000-ton-per-day capacity Bethlehem mill for beneficiation.

The Granduc Operating division of Newmont Mines Ltd. located north of Stewart, British Columbia, operating at 60% of capacity, produced 17,300 tons of copper in concentrate from 1.45 million tons of ore grading 1.26% copper. While producing at about a break-even cash level, Granduc resumed underground development work, which will be needed to make more ore available for mining in 1978. Reserves at yearend were 18 million tons of 1.68% copper.

Lornex Mining Corp. Ltd., controlled by the Rio Tinto-Zinc Corp., Ltd., operated an open pit copper-molybdenum mine in the Highland Valley and produced 72,857 tons of copper up 36% from 1975 and 1,885 tons of molybdenum in concentrate from 17 million tons of ore milled.

The Bell Copper Div. of Noranda Mines Ltd., in Granisle, British Columbia, affected by a 29-week-long strike, mined only 2.1 million tons of ore grading 0.49% copper in 1976. Concentrate output of 28,310 tons contained 7,300 tons of copper, down 60% from 1975.

Brenda Mines Ltd. (50.9% Noranda), located in Peachland, British Columbia, operating one of the lowest grade porphyry copper-molybdenum mines in the world, produced a record 11.2 million tons of ore averaging 0.167% copper and 0.045% molybdenum yielding 16,100 tons of copper in concentrates. The record production was attributed to the successful use of computer-controlled grinding circuits. During the year, new contracts with Japanese and Korean smelters were negotiated. Yearend reserves were 118 million tons of 0.171% copper and 0.043% molybdenum.

Placer Development Ltd. (33% Noranda) operated the Craigmont mine in Merritt, British Columbia, and the Gibralter mine in McLeese Lake, British Columbia, during the year. The Gibralter mine, closed by a strike for 19 weeks, milled 8.5 million tons of ore grading 0.45% copper. Production of copper in concentrates from the Granite Lake pit was reduced 24% to 31,852 tons. Production from the Pollyanna pit was scheduled to begin in late 1977. Reserves decreased to 300 million tons, with an average grade of 0.36% copper. At Craigmont 1.95 million tons of ore grading 1.35% copper was milled. The 88,200 tons of concentrates produced contained 25,283 tons of copper, a decrease of 6% from 1975. Ore reserves of 5.7 million tons of 1.85% copper are sufficient to maintain operations at the 1976 level for 2 to 3 years.

Similkameen Mining Co. Ltd., a subsidiary of Newmont Mining Corp., operated its open pit mine near Princeton, British Columbia, at an expanded concentrator capacity of 22,000 tons of ore per day. Output for the year increased 56% to 25,500 tons of copper in concentrate from milling 7 million tons of 0.42% copper ore. Ore reserves at yearend were estimated at 54 million tons averaging 0.53% copper.

Utah International Inc., shipped concentrates containing 50,000 tons of copper, down 14% from 1975, and 43,000 ounces of gold, down 31%, from its Island Copper mine on the northern end of Vancouver Island in British Columbia. Decreases were attributed to lower mine ore grades and mill recovery rates.

Granby Mining Corp. operated the Granisle open pit mine near Babine Lake. Granisle treated 4.3 million tons of 0.42% copper ore compared with 4.9 million tons of 0.46% ore the previous year. Production of recoverable copper in concentrates decreased 20% to 15,336 tons from 1975. The decrease was attributed to a 24-day-vacation shutdown and to the harder, lower grade ore treated.

In Manitoba, the newly formed Canadian Metals Div. of Hudson Bay Mining & Smelting Co. Ltd. operated six of nine copper and zinc mines full time and one copper smelter in the Flin Flon-Snow Lake area. Approximately 1.56 million tons of ore with an average grade of 2.3% copper and 2.75% zinc were mined and milled to produce 192,541 tons of a 17.02% concentrate containing 32,770 tons of copper, equal to 1975 output. The copper smelter produced 62,050 tons of anode copper from feed supplied 49% from Hudson Bay mines, and 51% from purchased concentrates. The Flin Flon production, representing 48% of total mine production, was chiefly from pillars and remnants. The Dickstone mine remained closed, Schist Lake was depleted in March, and White Lake ceased production in August to allow for further development work. Construction and development work at the new Centennial and Westarm mines was nearly complete, with production start-up scheduled for mid-to-late 1977. Total ore reserves at yearend were about 17.5 million tons grading 2.66% copper, 2.9% zinc, 0.035 ounce of gold per ton and 0.55 ounce of silver per ton. Reserves are based on 17% mine dilution and 91% recovery.

Sheritt Gordon Mines Ltd. operated the Fox, Lynn Lake, and Ruttan Lake mines in Manitoba with a combined output of 37,920 tons of copper in concentrates compared with 44,350 tons in 1975. Copper production was down 9% to 25,030 tons at the Ruttan open pit mine, with 2.66 million tons of ore averaging 1.08% copper and 2.14% zinc milled. At Ruttan preparations were being made to move to an underground mining operation by 1979. At the Fox underground mine, 832,000 tons of ore averaging 1.56% copper and 1.68% zinc were milled with production of copper in concentrates decreasing 23% to 12,116 tons. The Lynn Lake nickel-copper mine was closed in June 1976 for economic reasons. Remaining ore reserves at the Ruttan and Fox mines consisted of 39.9 million undiluted tons grading 1.77% copper and 1.41% zinc. Open pit ore comprised 20% of the total reserves.

The Ontario-based Falconbridge Nickel Mines Ltd. delivered 62,550 tons of copper from five nickel-copper mines in Sudbury, Ontario, and Manibridge, Manitoba, and from seven copper-zinc, copper, and iron-copper mines in Lake Dufault and Opemiska, Quebec, Sturgeon Lake, Ontario, and Tasu Harbor, British Columbia. Concentrates from the nickel-copper operations were processed at the company smelter in

Sudbury and from the other copper-zinc operations at the Noranda Mines Ltd. smelter at Noranda. Deliveries of copper from the integrated nickel operations decreased 16% to 17,040 tons. Sudbury operations remained at a reduced level as four mines, one mill, and one of two blast furnaces remained closed throughout 1976. The company resumed both the development of the 5,000-foot deep Fraser No. 1 shaft at Sudbury and the construction of the $95 million Sudbury Smelter Environmental Improvement Program. Expansion of the Strathcona mill to 8,500 tons of ore per day was also completed. Ore reserves at yearend at Sudbury were 83.4 million tons averaging 1.46% nickel and 0.68% copper. Ore reserves at Manibridge, Manitoba were nearly exhausted and the mine was to close in early 1977.

Deliveries of copper from Falconbridge Copper Ltd. increased 7% to 41,470 tons including 7,140 tons from the new Sturgeon Lake zinc-copper mine.

INCO Ltd., formerly International Nickel Co. of Canada Ltd., mined 19.8 million tons of ore with an average grade of 1.41% nickel and 0.97% copper from 12 mines in Ontario and 3 mines in Manitoba in 1976, compared with 21.2 million tons of ore with an average grade of 1.40% nickel and 0.92% copper in 1975. Deliveries of copper metal from the Copper Cliff refinery increased 6% to 177,995 tons. At yearend, INCO estimated that proven ore reserves in Canada were 412 million tons, containing 1.65% nickel and 1.07% copper. In April, production at the Victoria mine was resumed following a yearlong redevelopment program. The small Kirkwood ore body was depleted by March. Development work at Sudbury on the Clarabelle open pit extension and on the new Levack East mine continued during the year with production startup scheduled for 1978 and 1983, respectively.

At Mattagami Lake Mines Ltd., Mattabi zinc-copper mine in northwestern Ontario, the concentrator treated 1.07 million tons of ore grading 1.23% copper yielding 10,900 tons of contained copper in concentrate. Measured reserves were 9.6 million tons of 7.1% zinc, 0.58% copper, 0.95 ounce of silver per ton, and 0.015 ounce of gold per ton. Development work on Mattagami's new underground mine at Lyon Lake, in the Sturgeon Lake area, continued with initial production of 1,000 tons per day of ore scheduled to begin in 1978. Reserves at the Lyon Lake deposit were 4 million tons of 6.66% zinc, 1.15% copper, 0.63% lead, 3.39 ounces of silver per ton, and 0.010 ounce of gold per ton.

The Geco Div. of Noranda Mines Ltd., in Manitouwadge, Ontario, produced 1.7 million tons of ore grading 1.69% copper, 2.55% zinc, and 1.29 ounces of silver per ton. Concentrates contained 26,300 tons of copper, a decrease of 4%. Reserves at yearend were 27.5 million tons grading 1.87% copper, 3.59% zinc, and 1.49 ounces of silver per ton.

Texasgulf Canada Ltd. operated the Kidd Creek mine near Timmins, Ontario, and milled 3.57 million tons of ore in 1976, down 2% from 1975. Mill feed from the open pit diminished to 43% of the total, with operations expected to be fully underground by 1977. The mill yielded 234,700 tons of copper concentrates, down 2% from 1975. In 1974 and 1975 average concentrate grade was 23.65% copper. At the end of 1976, measured and indicated reserves above the 2,800-foot level were estimated at 85 million tons containing 2.73% copper, 6.08% zinc, 2.30 ounces of silver per ton, and 0.22% lead. In addition, good copper mineralization occurs to at least 5,000 feet. Construction on a $350 million project to increase the mine production rate from 3.6 to 5.0 million tons per year and to build a 100,000-ton-per-year smelter-refinery complex continued during the year. About 10% of the work was complete on the surface metallurgical plants. Startup is scheduled for late 1979.

Union Minière Canada Ltd., on August 24, 1976, started its new Thierry copper mine and mill at Pickle Lake, Ontario. By yearend output was at a rate of 3,500 tons per day. In total, the concentrator treated 254,200 tons of lower grade 1.17% copper ore from the poor upper section of the pit, yielding 10,727 tons of concentrates grading 24.93% copper. Proven reserves amounted to 15 million tons averaging 1.63% copper and exploration work in progress indicated further potential.

In Quebec, Campbell Chibougamau Mines Ltd. finally negotiated a successful new labor contract on August 31, 1976. Production for the year from the Cedar Bay and Henderson mines was 530 tons of copper compared with an annual capacity of over 15,000 tons. Reserves remaining in the Chibougamau area mines totaled 10 million tons grading 1.66% copper and 0.043 ounce of gold per ton.

The Lake Dufault Div. of Falconbridge Copper Ltd., in 1976, produced 14,777 tons of copper in concentrate, up 13% over that of 1975. Underground development and exploration work on the Corbet mine continued during the year. Reserves at yearend were 1.41 million tons of ore grading 3.75% copper and 4.80% zinc. The Opemiska Div. milled 1 million tons of 2.1% copper in 1976 to produce 20,025 tons of copper in concentrate. Remaining reserves for the Springer, Perry, and Cooke mines consist of 14.5 million tons of 2.37% copper. Development of the Cooke mine continued with production startup scheduled for the third quarter of 1977.

Madeleine Mines, operated by McIntyre Mines Ltd. near Ste. Anne des Monts, Quebec, milled 814,000 tons of 1.07% copper yielding 8,147 tons. On October 28 the company suspended operations and placed the mine on a care and maintenance basis.

Noranda Mines Ltd. had a full or partial interest in the treatment of 44 million tons of ore containing 183,100 tons of contained copper from 16 copper and zinc-copper mines in Quebec, British Columbia, Ontario, and New Brunswick. The company's two copper smelters at Noranda, Quebec, and Gaspé Copper in Murdochville, Quebec, treated 710,900 tons of concentrates from Noranda operations and 890,800 tons of custom material from other Canadian copper mines and from overseas. The 1.6 million tons of total material treated yielded 302,600 tons of copper contained in anodes for a decrease of 1% from 1975. The Noranda smelter accounted for 76% and Gaspé accounted for 24% of anode production. Canadian Copper Refineries (CCR) in Montreal East, Quebec, operated by Noranda, was the world's largest copper refinery with an annual capacity of 480,000 tons. In 1976, refinery production decreased 2% to 387,000 tons of copper. CCR processes the output of the Noranda smelters, the Flin Flon smelter of Hudson Bay Mining & Smelting Co. Ltd., and from imported and some secondary sources. After 50 years of operation, Noranda's Horne ore body in Noranda, Quebec, was exhausted in mid-1976, having produced 59 million tons of ore containing 1.3 million tons of copper, 10 million troy ounces of gold, and 22.3 million troy ounces of silver during its lifetime. The Horne Div.'s New Insco mine with reserves of 811,000 tons of 2.8% copper, 0.02 troy ounce per ton of gold, and 1 troy ounce per ton of silver was developed for production during the year.

Gaspé Copper Mines Ltd. (Noranda) milled 1.57 million tons of 1.20% copper ore from the Needle Mountain mine and 10.7 million tons of 0.43% copper ore from Copper Mountain mine yielding approximately 48,200 tons of copper contained in concentrates. Reserves at the two mines were 28 million tons of 1.32% copper, of which 51% is in pillars, and 193 million tons of 0.38% sulfide copper plus 30 million tons of 0.44% oxide copper.

Mattagami Lake Mines Ltd. (43% Noranda) treated, at the Mattagami Lake mine, 1.23 million tons of ore averaging 7.3% zinc and 0.55% copper. Copper contained in concentrates decreased 17% to 4,970 tons. Remaining undiluted ore reserves totaled 9.6 million tons grading 7.1% zinc, 0.58% copper, 0.95 troy ounce of silver per ton, and 0.015 troy ounce of gold per ton.

In the Yukon Territory, Whitehorse Copper Mines Ltd., owned in part by Hudson Bay and Anglo American Corp. of Canada Ltd., mined and milled 800,836 tons of 1.51% copper ore and produced 29,693 tons of concentrate containing an estimated 10,690 tons of copper. Production increased about 7% despite a 70-day strike during the year.

Chile.—In attaining it's highest mine production on record, Chile increased production 21% over that of 1975 to 1,108,000 tons of copper. Production by Corporacion Nacional del Cobre Chile (Codelco-Chile) from the large mines was as follows: Chuquicamata, 491,100 tons compared with 335,800 tons in 1975; El Teniente, 288,500 tons compared with 257,900 tons; El Salvador, 91,200 tons compared with 89,600 tons; and Andina, 62,700 tons compared with 68,800 tons. Mine production exceeded reported capacity at Chuquicamata and suggests that Codelco-Chile was mining a higher grade of copper ore than average during the year. The average grade of proven reserves at Chuquicamata is 1.38% copper.

In the medium and small mine production area, Mantos Blancos increased output by 3% to 33,200 tons, Empresa Nacional de Minera (ENAMI) decreased output 4% to

81,900 tons, and Disputada raised production 10% to 39,400 tons of copper.

Minera Sagasca, S.A., controlled 59% by Continental Copper & Steel Industries, Inc., operated at 50% of capacity for the year and produced 11,400 tons of cement copper. The company, despite a $4 million partial write down of investment, continued a $3.6 million improvement project to increase recovery efficiencies and increase production to 80% of capacity by mid-1977.

Production of blister copper at Chile's six smelters increased 18% over 1975 to 943,900 tons. Electrolytic and fire refined copper output also increased 18% to 696,700 tons. In 1976, Chile increased exports by 39% to 1,082,300 tons of copper contained in all classes valued at $1.23 billion. Under Decree Law No. 1350 effective April 1, 1976, the five major copper mining companies were dissolved and a new State-owned enterprise, Codelco-Chile, was created. Codelco-Chile will operate as a single company, with four operating divisions in Chuquicamata, Salvador, Andina, and El Teniente. The Chuquicamata Div. encompasses both the Chuquicamata and Exotica mines. Codelco-Chile invested over $110 million during the year to replace equipment and improve operating efficiency. Major improvements include the enlargement of the Chuquicamata smelter to handle a capacity of 4,000 tons of feed per day and the installation of the new Sapos reservoir and the Coya-to-Colon water supply system plus a new tailings pond at El Teniente. At El Teniente engineering plans were completed to update mine and mill systems to handle the harder, lower grade ore as mining moves into the deeper primary copper sulfide portion of the ore body.

At El Salvador work has begun on the modernization of all old production facilities from mine through refinery. Work was to be completed between 1977 and 1981. At Andina, work continued on a project to increase mine and mill capacity to 15,400 tons of ore per day and a new molybdenite recovery plant, capable of producing 2 tons of molybdenite concentrate daily started up in October 1976. A molybdenite leach plant was to be completed in 1977.

The Chilean Government continued to delay consummation of several new foreign investment contracts, under negotiation to exploit the undeveloped Andacolla, El Abra, Quebrada Blanca, and Los Pelambres copper deposits. In an effort to improve the foreign investment climate, Chile withdrew from the Andean Pact on October 30, 1976, and the obligations to the Pact's Decision No. 24, restricting foreign investment, the repatriation of capital, and import tariff levels within the region. On March 18, 1976, the Foreign Investment Statute was modified under Decree Law No. 1748 to extend the commitment to complete investment in mining from 8 to 12 years, to limit total tax load for income to 49.5%, and to lighten tariffs on imported machinery and equipment. Also legal discrimination between foreign and local companies would not be allowed.

Iran.—Sar Cheshmeh Copper Mining Co., an Iranian Government-owned company, continued development of the copper mine and metallurgical complex in southern Iran. Delays and cost escalation raised the expected cost of the 160,000-ton copper mine-smelter-refinery complex to $1.4 billion with initial production scheduled for late 1977, and with the refinery due onstream by yearend 1978. Further development drilling suggested that reported reserves of 500 million tons of ore averaging 1.13% copper and 0.03% molybdenum could be more than doubled.

Japan.—Mine production of copper decreased 4% from 1975 to 89,600 tons contributing only 8% to the consumption of refined copper. Reflecting a general pickup in the business activity in the Japanese economy, blister copper production increased 5% to 946,700 tons and refined copper output increased 6% to 952,800 tons. These smelter and refinery production rates represented approximately 70% of capacity.

Japan, the world's third largest consumer of refined copper, following the United States and the U.S.S.R., consumed 1,157,700 tons of copper, an increase of 27% from that of 1975 and the highest consumption since 1973.

With improved consumption and the easing of the Japan Ministry of International Trade and Industry (MITI) ban on exporting copper in July, producers of 172,100 stocks were down 17% from 1975. Japanese merchants and consumers reduced stocks 9% to 111,300 tons. Supported by Government loans of nearly $83 million repayable at an interest rate of 6.5% the nonprofit Metallic Mineral Stockpiling Association, founded by 25 refiners and manufacturers of electrical wire and copper mill products, purchased 55,560 tons of copper. The stockpile purchases were made in four stages, 14,330 tons each in August, September, and October, and 12,570 tons at the end of October.

Korea, Republic of.—In September the Korean Government awarded a contract to three European firms to build a $183 million flash smelter, acid plant, and electrolytic copper refinery complex at Onsan. The Onsan complex will have an initial capacity of 88,000 tons of copper per year and is scheduled to be completed by March 1979.

Malaysia.—The Mamut Mines Development Co., under the management of Overseas Mineral Resources Development Sabah Bhd., a consortium of seven Japanese firms, in a joint venture with the Sabah Government and other Malaysian interests, completed the first full year of production from the Mamut mine in Sabah. The 85,600 tons of a 23.5% concentrate yielded 20,100 tons of contained copper at a rate equal to 67% of planned capacity.

Mexico.—Mexican copper production improved substantially in all areas during the year. Mine production increased 14% to 98,070 tons, smelter output up 12% to 93,890 tons, and refined copper 19% to 83,130 tons.

Industrial Minera Mexico, S.A., in which ASARCO has a 34% interest, increased the output of blister copper 15% to 40,200 tons. Expansion programs completed during the year raised capacities by 85% at the San Martin copper-zinc mine and by 30% and 25% at the Charcas and Santa Barbara lead-zinc-copper mines. Exploration and feasibility work continued on the large El Arco porphyry copper deposit near Guerrero Negro in the Baja California peninsula with reserves estimated at 770 million tons of about 0.5% copper. Development plans called for the treatment of El Arco concentrates at the proposed new La Caridad smelter— refinery complex at Empalme.

Compañia Minera de Cananea, S.A., operated the Cananea mine and smelter to produce 53,800 tons of copper compared with 44,100 tons in 1975. An expansion program designed to increase capacity from 44,000 to 77,000 tons of copper was expected to be completed in early 1977. A further increase to 111,000 tons was under study.

Mexicana de Cobre, S.A., 44% owned by the Mexican Government, continued development of the $600 million La Caridad copper project in Sonora. The 79,000-ton-per-day open pit mine-mill operation was to be followed by a flash smelter and refinery complex at the Port of Empalme near Guaymas with a planned capacity of 175,000 tons of copper per year by early 1978. A detailed description of the project was presented in the June 19, 1976, issue of Skillings Mining Review. Ore reserves were reported at 760 million tons of 0.76% copper and 0.16% molybdenum.

Panama.—On February 25, 1976, the Government of Panama and Texasgulf Inc. signed a joint venture agreement to develop the Cerro Colorado copper deposit. Under the landmark agreement, which may serve as a model for future contracts between national governments and multinational mining companies, Texasgulf will have a 20% equity in the Cerro Colorado Mining Corp. and an option from Panama for the purchase of Texasgulf's 20% equity after 20 years. Texasgulf will conduct and share in the cost of a $50 million feasibility study scheduled for completion by April 1978. In addition, Texasgulf will receive management fees for overseeing the design and construction phase and during the first 15-year management phase of the project. Estimates call for an $800 million mine-smelter-refinery complex with a capacity between 150,000 and 170,000 tons of copper annually to be in production by about 1982. By yearend Texasgulf had confirmed that ore reserves were slightly improved with grades and tonnages in excess of previous estimates of 1 billion tons of 0.65% copper. Indications were that higher copper grades in the upper portion of the ore body may add to the economic viability of the project in its early years.

Papua New Guinea.—Bougainville Copper Pty., Ltd., controlled 53.6% by Conzinc Riotinto of Australia Ltd. (CRA), 20% by the Papua New Guinea Government, and 26.4% by the public, milled 34.4 million tons of a lower grade ore containing 0.64% copper and 0.025 troy ounce of gold per ton. Copper production increased 2% with 658,000 tons of 29.58% copper concentrate containing 193,800 tons of copper. Estimated ore reserves in the Panguna ore body at the end of 1976 were approximately 881 million tons of ore averaging 0.45% copper and 0.015 troy ounce of gold per ton. Differences between the Central Government and Bougainville Island leaders were resolved with Bougainville renamed North Solomons and having more autonomy over local matters. Papua New Guinea, however, will retain control over import-export taxes, corporate taxes, and royalties on natural resources.

Exploration drilling of the OK Tedi deposit in Western Papua New Guinea was completed in 1976 with reserves identified in four areas. The portion of the OK Tedi deposit minable by open pit methods contains 275 million tons grading 0.85% copper, 0.012% molybdenum, and 0.019 troy ounce of gold per ton plus an additional 27.6 million tons averaging 0.084 troy ounce of gold per ton. Outside the pit design limits there are 61 million tons of 0.57% copper plus 29 million tons of underground reserves grading 2.33% copper and 0.052 troy ounce of gold per ton. The Mt. Fubilan Development Co., a consortium, was formed to undertake a 31-month, $9 million feasibility study of the OK Tedi deposit. Dampier Mining Co., a subsidiary of the Broken Hill Proprietary Co. Ltd., was to manage and hold a 37.5% interest in Fubilan. Kupferexplorations Gesellschaft m.b.H., a West German group comprised of Metallgesellschaft, Kabel, and Metallwerk, Gutehoffnungshute, and Siemens, and Degussa held 25% while Amoco Minerals Co., a subsidiary of Standard Oil Co. of Indiana, held the remainder. If OK Tedi is developed the Papua New Guinea Government would have the right to acquire a 20% equity interest with Dampier and Amoco reverting to 30% each and Kupferexplorations to 20%.

With respect to the Frieda River deposit, having known reserves of 400 million tons of 0.47% copper, MIM signed a joint prospecting venture with the Metal Mining Agency of Japan and a consortium of five private Japanese copper smelters. The venture calls for a 5-year exploration and feasibility study over the Frieda River area.

Peru.—Aided by an improved labor situation and the opening of a major new open pit mine, Peruvian copper mine and smelter production increased 12% and 18% to 221,330 and 204,530 tons. Refinery production, with the help of the first full year of operation of the new Ilo plant, increased 165% to 154,451 tons of electrolytic copper. Copper exports in all forms increased 26% to 208,300 tons with refined exports representing 69% of the total compared with only 27% in 1975.

Southern Peru Copper Corp. (SPCC), Peru's largest copper company, milled 16 million tons of 1.05% copper ore at Toquepala compared with 13.8 million tons of 1.06% copper in strike-affected 1975. An additional 8.5 million tons of heap-leach ore grading about 0.38% copper were also treated. SPCC is controlled by ASARCO Inc. (51.5%), Cerro-Marmon Corp. (22.25%), Newmont Mining Corp. (10.25%), and Phelps Dodge Corp. (16%). SPCC (88.5%), in a joint venture with the Royal Dutch Shell-owned company Billiton, B.V. (11.5%), started copper production at its new $726 million Cuajone mine late in the second quarter. The mine is located 550 miles southeast of Lima and over 11,000 feet high in the Andes Mountains. The development period spanned 10 years including 6-1/2 years of construction and involved the removal of 240 million tons of overburden, construction of plant facilities, two new townsites, 130 miles of roads, 17 miles of railroad tunnels, a 35-mile water pipeline, and a seawater desalination plant at the Ilo complex. Ore reserves at yearend 1976 were estimated at 470 million tons of 0.98% copper at a cutoff of 0.45%; 108 million tons of low-grade sulfide reserves ranging from 0.20% to 0.45% copper, and nearly 14 million tons of oxide ore with an average grade of 1.20% copper.

At full capacity of 180,000 tons per year of copper contained in concentrates and oxide ore, Cuajone is exceeded in size by only a few copper mines in the world such as Bingham, Utah, Chuquicamata, and El Teniente in Chile and Bougainville in Papua New Guinea. The mill was initially designed to handle 45,000 tons of ore daily and was operating at about 90% of capacity by yearend. In 1976, the mill produced 117,400 tons of concentrates grading 41.65% copper from 3.86 million tons of 1.61% ore treated. Of the additional 7 million tons of oxide ore mined 2.6 million tons of 2.3% ore was stockpiled, 4.4 million tons of 1% ore was sent to leach dumps and 33,000 tons of 4% copper was used as a smelter flux. Concentrates are moved by rail through 17 miles of tunnel through the mountains to the Toquepala mine and then for 117 miles down to the coastal smelter at Ilo. In conjunction with the Cuajone project, SPCC completed the more than twofold expansion of the Ilo smelter by yearend to a rated capacity of 1,450 dry tons of feed daily or over 520,000 tons annually. In 1976, the Ilo smelter produced 148,100 tons of blister copper, with three quarters credited to Toquepala and the remainder to Cuajone.

Northern Peru Mining Corp., an ASARCO subsidiary, operated the Quiruvilca mine and produced 3,800 tons of copper in concentrates compared with 6,200 tons in 1975.

Compañía Minera del Madrigal, a subsidiary of Homestake Mining Co., processed 277,370 tons of ore, an increase of 7% from that of 1975, at its Madrigal copper-lead-zinc mine near Arequipa, Peru, and produced approximately 11,260 tons of copper concentrates, down 8%. Ore reserves of 1.15 million tons averaged 1.5% copper, 2.6% lead, and 5.0% zinc. The program to increase the mill capacity from 770 to 1,100 tons of ore per day will be completed in 1977.

Most of the approximate 57,000 tons of remaining mine production came from Empresa Minera del Centro del Perú (Centromin), the State-owned mining agency, which operates six underground mines and one open pit copper mine. Centromin has arranged for $176 million in local and external loans to finance the modernization and expansion of its existing copper facilities. At the Cerro de Pasco mine, $15 million will be invested to replace the cementation plant with a solvent extraction-electrowinning plant having a capacity of 7,000 tons per year of copper cathodes. The plant was to be operational by 1979. At the Cobriza mine a $161 million expansion program, to be completed in 1980, will increase mine capacity from 0.7 million to 3.5 million tons of ore per year, and mill capacity to 10,000 tons of ore daily. Annual concentrate output will be increased from 50,000 to 222,000 tons.

Empresa Minera del Peru (Minero Peru) continued development of the $100 million Cerro Verde mine and heap leaching project with production at a rate of 36,000 tons per year of copper scheduled to begin in June 1977. Development of the massive underlying Santa Rosa ore body and expansion of the Ilo refinery from 165,000 to 330,000 tons of refined copper per year are not envisaged for completion until after 1980.

Of the major deposits still awaiting development, SPCC is negotiating with Minero Peru with regard to development of the Quellaveco ore body located between the Toquepala and Cuajone mines. Quellaveco reserves have been reported at 440 million tons grading 0.80% copper. A feasibility study on the Michiquillay project was completed in October by the Metal Mining Agency of Japan and a group of seven Japanese smelters led by Mitsui Mining & Smelting Co., Ltd. The study confirmed ore reserves at 1 billion tons grading 0.69%-0.76% copper and estimated 6 years and $700 million would be required to develop the mine. The project would be developed as a joint venture between Minero Peru (51%) and Japanese interests (49%), and it would include a 44,000-ton-per-day mill with a capacity to produce 113,500 tons per year of copper in concentrates. Concentrates will be slurried and piped from the mine site to the Port of Pacasmayo for export to Japan.

Philippines.—The Philippines maintained its eighth ranking among world copper producers with 14 mining companies increasing production 2% to 255,185 tons of copper contained in concentrates and direct shipping grade ore. Plans for a Government-sponsored copper smelter appeared to firm up by late 1976. The former Copper Smelter Corp. has been reorganized into the Philippine Associated Smelting and Refining Corp. (PASAR). PASAR is a consortium of 11 local mining companies led by Atlas Consolidated Mining and Development Corp., Marcopper Mining Corp., Lepanto Consolidated Mining Co., Philex Mining Corp., and Marinduque Mining & Industrial Corp. These five companies will provide 36%, the Government 34%, and as yet unselected foreign investors 30% of the estimated $250 million needed to build a 93,000-ton Outokumpu flash smelter. Pending final environmental clearances the smelter site will be located 60 miles from Manila at Bantiqui Point, San Juan Batangas Province. The smelter is scheduled to come onstream in 1979-80.

Atlas Consolidated., one of the largest copper producers in Asia, milled 24.5 million tons of 0.51% copper ore, improved its recovery rates, and increased production of copper contained in 374,550 tons of concentrates by 1% in 1976 to 113,600 tons. The company operated the Frank, Lutopan, and Biga mines on Cebu Island, Central Philippines. On June 1, construction began on the new $100 million Carmen open pit located between the Frank and Biga pits and an associated 35,000-ton-per-day mill with startup scheduled for late 1977. With the completion of the Carmen project, the combined Atlas milling capacity of 104,000 tons of ore per day will equal the Bougainville, Papua New Guinea mine in size. Atlas reports reserves at yearend at 1.08 billion tons grading 0.46% copper.

Marcopper Mining Corp., a subsidiary of Placer Development Ltd., operating at the expanded capacity of 27,000 tons per day of ore, milled 9.7 million tons of 0.59% copper ore, and increased production of copper contained in concentrates 37% to 52,400 tons. Minable reserves at yearend in the Tapian ore zone were 85 million tons at a 0.40% cutoff and a 0.58% average grade of copper. At the Tapian mine site a discovery of a new San Antonio ore body located under the tailings disposal area was announced. Preparations for developing this deposit, containing 200 million tons of 0.57% copper, were underway.

Marinduque Mining & Industrial Corp. operated the Sipalay open pit in Negros Oriental and the Bagacay pit in Samar. At Sipalay, a record production of 30,000 tons of copper from 6.3 million tons of ore represented increases of 12% and 14% over 1975. Production at Bagacay decreased 15% to 5,980 tons of copper contained in 26,190 tons of concentrates. In addition, the mine produced 13,750 tons of direct shipping grade ore. Grade of the direct shipping ore was 11.52% copper. Ore reserves were reported at 718 million tons of ore grading 0.492% copper at Sipalay and 1 million tons of 4.42% copper and 2.78% zinc at Bagacay.

Philex Mining Corp. increased production 13% in 1976 to 33,780 tons of copper contained in concentrates. The company operated the Santo Thomas II underground mine near Benguet, northern Luzon, with reserves of 166 million tons of ore grading 0.43% copper and 0.031 troy ounce of gold per ton. With production of 190,000 ounces of gold, Philex was also the largest gold producer in the country.

Lepanto Consolidated Mining Co. resumed operations at the Lepanto underground mine in Mt. Province, northern Luzon on September 15. Production through yearend amounted to 4,600 tons of copper contained in concentrates. The mill treated 226,600 tons of ore yielding 14,815 tons of a 31% copper concentrate. However, during the year approximately 58,000 tons of concentrates were shipped to ASARCO's Tacoma, Wash., smelter for processing reducing the stockpile of concentrates on hand to about 17,000 tons. Reserves at the Lepanto mine were reduced at yearend to 8 million tons of 2.57% copper and 0.013 troy ounce of gold per ton.

Western Minolco, operator of the Boneng and Lobo mines in Benguet, northern Luzon, produced 39,270 tons of concentrates from 4.5 million tons of ore milled in 1976 containing 9,860 tons of copper. The bulk of production came from the Lobo pit during the year. An expansion program to increase the initial mill capacity of 16,500 tons to 33,000 tons of ore per day will be completed in April 1977. Combined ore reserves at Boneng-Lobo are estimated at 102 million tons of 0.338% copper and 0.012 troy ounce of gold per ton.

Several new copper projects progressed during the year in both the planning and construction phases. These included Consolidated Mines Ino project scheduled to be operational by mid-1977 at a mill capacity of 16,500 tons of ore per day. Mining will be based on reserves of 112 million tons of 0.53% copper. Benquet Consolidated Inc. is currently arranging financing for a $100 million, 19,000-ton-per-day mine-mill development of its Dizon deposit containing reserves of 86 million tons of 0.47% copper. CCDP Mining Corp. is planning an 11,000-ton-per-day milling operation by 1979 at its Basay, Negros Oriental property. Reserves are reported at 113 million tons of 0.544% copper. Sabena Mining Corp. is planning to develop reserves of 38 million tons of 0.502% copper at New Bataan on Davao Del Norte. Mining plans call for an 11,000-tons-per-day ore handling capacity to be in place by 1979.

Poland.—In 1976 ore mined totaled 21.7 million tons yielding 300,000 tons of copper, an increase of 15% over that of 1975. Copper mine production came mainly from three underground mines; Lubin, Polkowice, and Rudna, all located in the sedimentary Kupferschiefer beds of the Legnica—Glogow copper region. The two older Konrad and Lena mines also contributed to mine production. Smelter and refinery production increased 9% and 8%, respectively, to 305,000 and 297,600 tons each during the year. Initial production from the new 165,000-ton Glogow copper refinery was reported to have begun in late 1976. Full production is expected by 1980.

Rhodesia, Southern.—M.T.D. (Mangula) Ltd., a Messina Transvaal subsidiary, operated the Mangula, Norah, and Silverside mines during the year ended September 30, 1976. At the Mangula mine, located 80 miles northwest of Salisbury, 1.3 million tons of 1.08% copper ore were treated yielding 13,250 tons of copper contained in concentrates, down 11% from that of 1975. The Norah and Silverside mines produced an additional 2,474 tons and 2,227 tons of copper in concentrates. Proven ore reserves were 3.1 million tons of 1.21% copper at the Norah mine with Silverside mine reserves expected to be depleted by March 1977.

Lomagundi Smelting and Mining Ltd., also a Messina Transvaal subsidiary, produced 1,442 tons of copper in concentrate from mining and milling 261,200 tons of 0.86% copper ore from the Alaska mine. At 1976 copper prices, operation at the Alaska, Hans, and Angwa sections of the Alaska mine was no longer viable and production was stopped. The Shackleton mine yielded 9,950 tons of copper in concentrate from 657,000 tons of 1.62% copper ore. Proved reserves at yearend were 1.4 million tons of 1.80% copper at the Shackleton mine. Production for the year ending September 30 at the Coronation Syndicate's Inyati mine amounted to 5,175 tons of copper.

South Africa, Republic of.—O'okiep Copper Co. Ltd., a subsidiary of Newmont Mining, mined and milled 2.6 million tons of ore with an average grade of 1.35% copper which yielded 32,600 tons of blister copper compared with 33,800 tons in 1975. Development work was resumed at the Divide and Brandkloof mines to bring them into production in late 1977 and 1978. The Nababeep South mine was activated in late 1976 and the Hoits mine was to be restarted in early 1977. A $20 million development effort began in midyear aimed at bringing the Carolusberg deep ore body into production in 1981. Carolusberg reserves were currently estimated at 11 million tons of 1.82% copper with substantial additional potential. Total ore reserves at O'okiep mines at yearend 1976 were estimated at 30 million tons averaging 1.67% copper.

Palabora Mining Co. Ltd. produced 102,900 tons of copper, a 2% increase over that of 1975. The 21 million tons of 0.55% copper ore milled was equal to the 1975 level. A $100 million expansion of the open pit mining and ore processing facilities was completed by yearend. Milling capacity was increased from an average 58,000 tons to 82,000 tons of ore per day equivalent to 138,000 tons of copper annually. The capacity of the electrolytic refinery was expanded 95% to 156,000 tons to handle the entire Palabora copper output.

Messina (Transvaal) Development Co. mined and milled 860,000 tons of 1.24% copper ore from its Messina mine which yielded 9,810 tons of copper in concentrate, down 6% from that of 1975. The tonnage of proved ore reserves at yearend was estimated at 4.7 million tons averaging 1.37% copper.

South-West Africa, Territory of.—Tsumeb Corp. Ltd. mined 489,000 tons of ore from the Tsumeb mine averaging 4.25% copper, 9.04% lead, and 2.39% zinc. The Kombat and Asis Ost mines produced 65,300 tons of ore containing 1.49% copper and 1.92% lead before operations were suspended in March. Mining was to be resumed at these mines in late 1978 at the same time production from the new Asis West is scheduled to begin. The Matchless mine, near Windhoek, produced 112,000 tons of ore averaging 2.40% copper.

Oamites Mining Co. (Pty.) Ltd. (75% Falconbridge) milled 662,500 tons of ore grading 1.31% copper. Metal recovery decreased 7% to 7,037 tons of copper.

Yugoslavia.—Estimated primary production of copper by Rudarsko Topionicarski Bazen (RTB), Bor, Serbia, in 1976 included 132,400 tons of copper in concentrates, 181,200 tons of blister copper, and 134,000 tons of refined copper. RTB operated a mine, a flotation plant, and smelter at Bor, and a mine and a flotation plant at Majdanpek. Development work continued on the 660-million-ton, 0.5% copper deposit at Veliki Krivelj with plans for an annual capacity of 66,000 tons of copper to be reached by 1981. Work also continued on the development of the second major copper-producing facility in Yugoslavia at Bucim, near Radoviste, Macedonia. Work on mine and beneficiation plant at the Bucim copper deposit, designed to handle 4 million tons of ore annually, continued during the year and was scheduled to reach an annual capacity of 23,000 tons of copper in concentrates by 1978. A 28,000-ton electrolytic refinery will also be built near Bucim.

Zaire.—Mining the highest grade copper ore in the world with an average reserve content of 4.52% copper, Zaire produced ore containing 490,100 tons of copper, 10% lower than in 1975. Total smelter and refinery production dropped by 12% and 71% to 450,000 tons and 72,750 tons respectively, from that of 1975. Disruptions caused by the closure of the Benguela railroad from Shaba Province to the Angolan Port of Lobito, a result of the Angolan Civil War, and the closure of the Mozambique-Rhodesian border had a strong impact on the economy and copper industry. Transportation difficulties in getting food, spare parts, coke, coal, and diesel oil into Shaba were major factors in the reduced levels of production experienced, particularly in the smelters and electrolytic refineries. Copper exports are channeled out of Shaba by way of a tedious internal route to the Zairian Port of Matadi: by southern railroads to the Port of East London, South Africa; or by the Tanzania-Zambia Railway (Tazara) to the Port of Dar es Salaam, Tanzania.

The Government mining agency, La Générale des Carrières et des Mines du Zaire (Gécamines), which operates 10 mines, 5 mills, 1 copper smelter at Lubumbashi, and 2 copper-cobalt refineries at Shituru and Luilu in Shaba Province, produced 449,410 tons of copper including 147,700 tons of blister and 302,030 tons of copper in refined shapes. Plans to increase annual production of copper to 628,000 tons were still in progress with completion scheduled for 1979 at a cost of over $600 million. Plans called for the construction of a 138,000-ton-per-year flash smelter and a 100,000-ton-per-year electrolytic copper refinery, all near Kolwezi, Shaba. As part of the expansion program, two new open pit mines at Dikuluwe and Mashambe, with combined reserves estimated at 171 million tons of 4.1% copper and 0.3% cobalt, opened in late 1975 but operated at a low rate because of diesel fuel shortages. Gécamines refinery at Lubumbashi was scheduled to be expanded from 143,000 tons per year to 176,000 tons per year by 1980.

The joint Zairian Government-private Japanese concern Société de Dévelopment Industriel et Miniére du Zaire (SODIMIZA), operated the Mushoshi mine and mill in Shaba Province. Production for 1976 increased 11% to 39,600 tons of copper contained in 111,660 tons of concentrates. SODIMIZA continued development of the Kinsenda mine during the year with production expected to begin in late 1977. Reserves at Kinsenda are reported at 35 million tons of 5.5% copper.

Société Minière de Tenke-Fungurume (SMTF) is controlled by the Republic of Zaire (20%) and a consortium comprised of Charter Consolidated Ltd. and associated companies (28%), Amoco Minerals Co. (28%), Mitsui & Co. (14%), Bureau des Recherches Geologiques et Miniéres (3.5%), Omnium des Mines, S.A. (3.5%), and Leon Templesman & Son Inc. (3%). In January 1976, owing to regional fuel shortages and serious financial support problems, all work was suspended on the 7,150-ton cobalt and 165,000-ton copper mine-electrowinning refinery complex originally scheduled for completion in 1977. Cost estimates had escalated from $600 million to $900 million. Approximately $275 million had been expended on the project when the suspension decision was made. If construction is resumed, a smaller 95,000-ton facility will probably be built. In the interim, the project will be kept on a care-and-maintenance basis at a cost of about $400,000 per month.

Zambia.—The Zambian copper industry, which was nationalized in 1975, continued to be plagued by low copper prices and rapidly escalating costs. As a result of the tight financial situation most new development programs were deferred. The opening of the Tazara railroad to the port of Dar Es Salaam in Tanzania eased export transportation problems. However, difficulties in maintaining spare part inventories and in retaining skilled expatriate mining engineers and technicians seriously affected copper production levels. Mine production in 1976 increased 5% to 781,391 tons of recoverable copper, while blister production increased 7% to 778,127 tons, and refined production increased 10% to 766,040 tons.

In the year ended June 30, 1976, Roan Consolidated Mines, Ltd. mined 17.3 million tons of ore with an average grade of 1.99% yielding 304,100 tons of copper from the Mufulira, Luanshya, Chambishi, Chibuluma, and Kalengwa mines. RCM also operated two smelters at Mufulira and Luanshya which produced 306,932 tons of anode copper. The Mufulira and Ndola Copper refineries produced 347,850 tons of copper cathodes, 275,680 tons of which were cast into wirebars. The electrowinning plant at Chambishi produced 17,330 tons of leach cathodes. Work continued on a $200 million expansion program to increase mine production at the Baluba section of Luanshya, Chibuluma, and Chambishi and to extend the Chambishi leach plant. The new anode slimes treatment plant at Ndola was scheduled to start production in October 1976. Ore reserves at all RCM mines were estimated to total 362 million tons of ore with an average grade of 2.88% copper. The Mufulira and Luanshya mines contain 83% of this reserve total.

Nchanga Consolidated Mines, Ltd., for the year ended March 31, 1976, produced 424,842 tons of finished copper from operations at the Rokana, Konkola, and Chingola mine divisions, the smelter-refinery complex at Kitwe, and from the refinery at Chingola. At the Rokana division, mine output from the Mindola and Bwana Mkubwa operations decreased 22% to 122,230 tons of copper. Breakdowns at the concentrator and in the tailings pipeline contributed to the production losses. The 14,000-ton-capacity Mindola open pit mine and oxide treatment plant were placed on a care and maintenance basis for economic reasons at yearend 1975, while expansion of the Mindola underground operations continued. At the Konkola division, mine production decreased 15% to 48,930 tons. Production of copper at the Chingola division decreased 7% to 341,160 tons. Of this total, 35% came from the Chingola underground mine, 51%

from the Nchanga open pit, and the balance from four other open pits. The Chingola tailings leach plant during the fiscal year treated 9.3 million tons of low-grade tailings and oxide concentrates yielding 81,800 tons of electrowon cathode copper. NCCM controlled, as of December 30, 1975, 637 million tons of ore reserves averaging 2.96% copper with 55% of these held within the Chingola division. Reserves reported include indicated and possible ore.

TECHNOLOGY

An article described the history of exploration for porphyry copper deposits in the Southwestern United States and speculated on the discovery of additional deposits buried under gravels and volcanics.[2] Another article detailed the use of mapping, geochemical, electromagnetic, and gravity work in discovery of strata-bound massive sulfide copper deposits.[3] The mechanism for the dissolution and precipitation of copper in strataform deposits, especially of the red-bed type, was the subject of a published study.[4] A geologic description and postulated genesis of a stratabound massive sulfide nickel-copper deposit was published.[5] Estimated costs to produce 165,000 tons per year of white metal from two copper-nickel hypothetical open pit mines operating on the Duluth gabbro was the subject of an open-file report.[6] Review of the development of selected copper deposits indicated that the required lead times ranged from 1 to 15 years for major exploration, 1 to 4 years for open pit development, and 4 to 8 years for underground development.[7]

An article reviewed the properties of ocean nodules and the economic parameters of several proposed processing methods.[8] Details were published on a smelt-leach process[9] and on an ammoniacal leach-ion exchange-selective stripping process to recover the copper, nickel, and cobalt in the nodules.[10]

The application of rock mechanics technology to design open pit mines for proper safety and efficient operation was described.[11] Techniques have been developed to stabilize tailings material to prevent an increase into underground mine workings caused by subsidence of ground beneath the tailings pond.[12] Research on thermal fragmentation of semiconductive rock indicated an unlikely application to a copper-bearing shale formation.[13]

Leaching experiments in columns simulating 80 and 200-foot deep cores through a leach dump were performed. Results indicated that in the 200-foot system lack of oxygen restricted biological activity; activity increased when air was introduced. However, the free diffusion of oxygen was restricted by clay formation and fines accumulation at specific levels within the column.[14] Research showed that presence of thermophylic bacteria enhanced copper extraction in leaching of prophyry copper samples containing chalcopyrite as the primary mineral.[15] An analysis of a ferric

chloride leaching process on chalcopyrite concentrate indicated favorable operating costs.[16] Studies were conducted on the use of solvent extraction systems in conjunction with leaching sulfides with a ferric or cupric chloride solution.[17] A kinetic investigation of copper cementation in a revolving drum and a pilot-scale test on the use of shredded automobile scrap for cementation were reported.[18]

It was established that an arseniferous copper concentrate could be smelted in an electric-arc furnace with results comparable to use of a gas-fired reverberatory furnace.[19] An electrothermic reduction process to produce blister copper from dead-burned copper sulfide concentrates recovered 98.4% of the contained copper and permitted efficient collection of the sulfur.[20] Fuel consumption, economic advantage, and compliance with environmental regulations were considered in a review article on various pyrometallurgical processes to replace the reverberatory furnace.[21] A review of sulfur dioxide emission control data for major Japanese smelters showed capture of 91% to 99.7% of the sulfur in the smelter feed.[22]

Studies showed that an individual, with proper equipment, could disassemble about 100 automobile starters or 150 generators in 8 hours with a scrap copper yield of 280 and 390 pounds, respectively.[23] Other studies detailed energy requirements for production of refined copper.[24]

Research on use of zinc-based solders on copper and copper alloys indicated a fourfold increase in service life over conventional solders.[25]

A case study of the development of a medium-size massive sulfide copper deposit, including a required environmental impact statement was published.[26]

Method of treatment	Ore treated (thousand short tons)	Recoverable copper: Thousand pounds	Recoverable copper: Percent yield	Remarks
Copper ore:				
By concentration	258,371	2,600,209	0.50	See table 9.
By smelting	260	1,678	.32	See table 10.
By leaching	25,105	[1]312,714	.62	See table 11.
Total	283,736	2,914,601	.51	
Dump and in-place leaching	--	252,288	--	See table 11.
Miscellaneous from cleanup, tailings, and noncopper ores	--	44,282	--	
Total	XX	3,211,171	XX	--

XX Not applicable.
[1]Includes 150,384,677 pounds of electrowon copper.

Table 8.—Copper ore shipped directly to smelters or concentrated in the United States, by State in 1976, with copper, gold, and silver content in terms of recoverable metal

State	Ore shipped or concentrated (thousand short tons)	Recoverable metal content: Copper, Thousand pounds	Copper, Percent	Gold (troy ounces)	Silver (troy ounces)	Value of gold and silver per ton of ore
Arizona	173,472	1,657,015	0.48	97,636	7,276,850	$0.25
Idaho	141	1,852	.66	W	W	W
Michigan	3,801	87,414	1.15	--	310,837	.36
Montana	16,781	156,001	.46	19,843	2,935,682	.91
Nevada	7,820	76,498	.49	28,819	486,325	.73
New Mexico	25,016	298,991	.60	13,219	765,800	.20
Tennessee[1]	2,034	22,261	.55	W	W	W
Utah	29,567	301,854	.51	W	W	W
Other States	--	--	--	[2]166,264	[2]1,856,641	[2].91
Total[3]	258,631	2,601,887	.50	325,781	13,632,135	.39

W Withheld to avoid disclosing individual company confidential data; included in "Other States."
[1]Copper-zinc ore.
[2]Includes data for Idaho, Tennessee, and Utah.
[3]Data may not add to totals shown because of independent rounding.

Table 9.—Copper ore concentrated[1] in the United States, by State in 1976, with content in terms of recoverable copper

State	Ore concentrated (thousand short tons)	Recoverable copper content: Thousand pounds	Percent
Arizona	173,292	1,655,558	0.48
Idaho	141	1,852	.66
Michigan	3,801	87,414	1.15
Montana	16,781	156,000	.46
Nevada	7,790	76,302	.49
New Mexico	24,966	298,967	.60
Tennessee[2]	2,034	22,261	.55
Utah	29,567	301,854	.51
Total[3]	258,371	2,600,209	.50

[1]Includes following methods of concentration: "Dual process" (leaching followed by concentration); "LPF"(leach-precipitation-flotation); and froth flotation.
[2]Copper-zinc ore.
[3]Data may not add to totals shown because of independent rounding.

Table 10.—Copper ore shipped directly to smelters[1] in the United States, by State in 1976, with content in terms of recoverable copper

State	Ore shipped to smelters: Short tons	Recoverable copper content: Pounds	Percent
Arizona	180,069	1,457,523	0.40
Montana	35	702	1.00
Nevada	29,788	195,752	.33
New Mexico	50,173	23,644	.02
Utah	1	118	5.90
Total	260,066	1,677,739	.32

[1]Primarily smelter fluxing material.

Table 11.—Copper precipitates (from dump or in-place leaching) shipped directly to smelters and copper ore and tailings leached (heap, vat, or tank) in the United States, by State in 1976, with content in terms of recoverable copper

State	Precipitates shipped (short tons)	Recoverable copper content (pounds)	Ore leached (short tons)	Recoverable copper content (pounds)	Percent
Arizona	70,117	98,625,236	[1]20,574,374	[2]287,527,188	0.70
California	102	124,534	--	--	--
Montana	22,785	25,824,354	--	--	--
Nevada	10,821	14,619,681	4,530,184	25,186,416	.28
New Mexico	28,227	44,778,845	--	--	--
Utah	42,604	68,314,990	[3]15	[4]300	1.00
Total	174,656	252,287,640	25,104,573	312,713,904	.62

[1]Includes 11,355,466 short tons of ore leached for electrowinning, and excludes newly generated tailings.
[2]Includes 150,384,377 pounds of electrowon copper.
[3]Ore leached for electrowinning.
[4]Electrowon copper.

Table 12.—Copper ore smelted and copper ore concentrated in the United States, and average yield in copper, gold, and silver

Year	Smelting ore		Concentrating ore		Total				
	Thousand short tons	Yield in copper, percent	Thousand short tons[1] [2]	Yield in copper, percent	Thousand short tons[1]	Yield in copper, percent	Yield per ton in gold, ounce	Yield per ton in silver, ounce	Value per ton in gold and silver
1972	484	1.68	248,663	0.55	266,831	0.55	0.0019	0.059	$0.21
1973	337	1.40	272,688	.53	289,998	.53	.0018	.058	.32
1974	305	1.26	269,016	.50	293,443	.49	.0014	.048	.45
1975	357	1.85	239,614	.48	263,003	.47	.0014	.051	.44
1976	260	.32	258,371	.50	283,736	.51	.0013	.053	.39

[1]Includes some ore classed as copper-zinc and minor amount of tailings.
[2]Excludes tank or vat and heap leaching. (See tables 7 and 11.)

Table 13.—Copper produced by primary smelters in the United States

(Short tons)

Year	Domestic	Foreign	Secondary	Total
1972	1,649,130	41,263	69,017	1,759,410
1973	1,705,065	38,898	77,815	1,821,778
1974	1,532,066	37,750	79,543	1,649,359
1975	1,374,324	72,804	49,357	1,496,485
1976	1,461,256	73,366	51,045	1,585,667

Table 14.—Primary and secondary copper produced by primary refineries and electrowinning plants in the United States

(Short tons)

	1972	1973	1974	1975	1976
PRIMARY					
From domestic ores, etc.:[1]					
Electrolytic	1,499,005	1,510,334	1,275,545	1,140,754	1,221,140
Electrowon	21,938	26,485	23,167	30,972	103,941
Fire refined	159,469	161,518	122,193	114,463	97,642
Total	1,680,412	1,698,337	1,420,905	1,286,189	1,422,723
From foreign ores, etc.:[1]					
Electrolytic[2]	160,781	170,151	233,753	157,189	116,585
Electrowon	--	--	W	W	W
Fire refined	32,040	W	W	W	--
Total refinery production of primary copper	1,873,233	1,868,488	1,654,658	1,443,378	1,539,308
SECONDARY					
Electrolytic[2]	341,581	377,523	398,976	265,413	281,070
Electrowon	--	--	W	W	W
Fire refined	16,667	14,290	13,543	5,467	7,616
Total secondary	358,248	391,813	412,519	270,880	288,686
Grand total	2,231,481	2,260,301	2,067,177	1,714,258	1,827,994

W Withheld to avoid disclosing individual company confidential data; included in "Electrolytic."
[1]The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation is not possible at this stage of processing.
[2]Includes electrowon and fire refined quantities indicated by symbol W.

Table 15.—Copper cast in forms at primary refineries in the United States

	1975		1976	
	Thousand short tons	Percent	Thousand short tons	Percent
Billets	61	3	50	3
Cakes	67	4	76	4
Cathodes	765	45	910	50
Ingots and ingot bars	132	8	125	7
Wire bars	676	39	643	35
Other forms	13	1	24	1
Total	1,714	100	1,828	100

Table 16.—Production, shipments, and stocks of copper sulfate

(Short tons)

Year	Production		Shipments	Stocks Dec.31[1]
	Quantity	Copper content		
1972	38,052	9,513	37,964	5,828
1973	43,360	10,840	44,092	4,580
1974	42,092	10,523	43,598	3,074
1975	35,614	9,204	31,822	6,866
1976	32,122	8,421	30,431	8,557

[1] Some small quantities are purchased and used by producing companies, so that the figures given do not balance exactly.

Table 17.—Byproduct sulfuric acid[1] (100% basis) produced in the United States

(Short tons)

Year	Copper plants[2]	Lead plants	Zinc plants[3]	Total
1972	1,010,614	859,103 (lead and zinc plants combined)		1,869,717
1973	1,088,322	146,591	819,537	2,054,450
1974	1,277,440	132,594	830,969	2,241,003
1975	1,784,744	129,756	711,769	2,626,269
1976	2,281,591	145,872	799,773	3,227,236

[1]Includes acid from foreign materials.
[2]Excludes acid made from pyrites concentrates.
[3]Excludes acid made from native sulfur.

Table 18.—Secondary copper produced in the United States

(Short tons)

	1972	1973	1974	1975	1976
Copper recovered as unalloyed copper	447,409	484,623	513,308	355,512	390,729
Copper recovered in alloys[1]	853,564	892,534	831,012	616,453	754,545
Total secondary copper[1]	1,300,973	1,377,157	1,344,320	971,965	1,145,274
Source:					
New scrap	842,779	890,943	860,888	602,792	726,148
Old scrap	458,194	486,214	483,432	369,173	419,126
Percentage equivalent of domestic mine output	78	80	84	69	71

[1]Includes copper in chemicals, as follows: 1972—3,038; 1973—3,704; 1974—2,649; 1975—2,480; and 1976—4,007.

Table 19.—Copper recovered from scrap processed in the United States by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1975	1976
New scrap:		
Copper-base	585,426	705,392
Aluminum-base	17,103	20,444
Nickel-base	248	282
Zinc-base	15	30
Total	602,792	726,148
Old scrap:		
Copper-base	358,496	404,144
Aluminum-base	10,226	14,516
Nickel-base	349	321
Tin-base	7	8
Zinc-base	95	137
Total	369,173	419,126
Grand total	971,965	1,145,274

Form of recovery	1975	1976
As unalloyed copper:		
At primary plants	270,880	288,686
At other plants	84,632	102,043
Total	355,512	390,729
In brass and bronze	571,991	700,844
In alloy iron and steel	1,927	2,186
In aluminum alloys	39,583	47,017
In other alloys	472	491
In chemical compounds	2,480	4,007
Total	616,453	754,545
Grand total	971,965	1,145,274

Table 20.—Copper recovered as refined copper, in alloys and in other forms from copper-base scrap processed in the United States

(Short tons)

Recovered by—	From new scrap		From old scrap		Total	
	1975	1976	1975	1976	1975	1976
Secondary smelters	53,606	57,419	162,508	188,162	216,114	245,581
Primary copper producers	139,230	144,215	131,650	144,471	270,880	288,686
Brass mills	381,744	486,878	26,140	30,207	407,884	517,085

Aluminum bronze	284	1,319	868	503	1,371	251
Low-grade scrap and residues[3]	22,917	266,722	110,826	147,731	258,557	31,082
Total	123,084	1,535,577	942,389	571,553	1,513,942	147,460

[1]Brass-mill stocks include home scrap; purchased scrap consumption assumed equal to receipts, so lines in brass-mill and grand total sections do not balance.

[2]Of the totals shown, chemical plants reported the following: Unalloyed copper scrap, 2,287 tons new and 1,936 old.

[3]Includes refinery brass.

Table 24.—Consumption of copper and brass materials in the United States by principal consuming groups

(Short tons)

Year and item	Primary producers	Brass mills	Wire mills	Foundries, chemical plants, and miscellaneous users	Secondary smelters	Total
1975:						
Copper scrap	372,505	518,364	--	60,098	301,601	1,252,568
Refined copper[1]	--	438,970	1,061,255	29,800	4,483	1,534,508
Brass ingot	--	5,645	--	[2]188,669	--	194,314
Slab zinc	--	106,942	--	2,084	6,300	115,326
Miscellaneous	--	--	--	150	12,717	12,867
1976:						
Copper scrap	425,790	662,454	--	68,912	356,789	1,513,945
Refined copper[1]	--	584,755	1,364,048	35,563	7,519	1,991,885
Brass ingot	--	8,320	--	[2]228,204	--	236,524
Slab zinc	--	157,398	--	2,252	6,594	166,244
Miscellaneous	--	--	--	200	5,702	5,902

[1]Detailed information on consumption of refined copper will be found in table 28.
[2]Shipments to foundries by smelters minus increase in stocks at foundries.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Data presented represent copper content (recoverable where indicated) of ore mined wherever possible. If such data are not available the nonduplicative total copper content of ores, concentrates, matte, metal and/or other copper-bearing products measured at the least stage of processing for which data are available has been used.

[2]Recoverable.

[3]Copper content of concentrate produced.

[4]Corporacion Minera de Bolivia (COMIBOL) production plus exports by medium and small mines.

[5]Smelter production.

[6]Includes copper content of cupriferous pyrites.

[7]Excludes an unreported quantity of copper in iron pyrites which may or may not be recovered.

[8]Year ending September 30 of that stated.

[9]Data are compiled from operating company reports of Tsumeb Corp., Ltd., General Mining and Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth, and Falconbridge Nickel Mines Ltd. for Oamites Mining Co. (Pty.) Ltd., Oamites mine. Data for General Mining and Finance Corp. Ltd. are for fiscal years ending June 30 of that stated, while data for the other companies are for the calendar years.

[10]Copper content of matte produced.

[11]Year beginning March 21 of that stated.

[12]Copper content of run-of-mine production was as follows in short tons: 1974—90,985; 1975—93,952; 1976—90,181.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Unless otherwise noted, data presented for each country represent primary copper metal output, whether produced by thermal or electrowinning. To the extent possible, refined copper produced from imported blister or electrolytic anode copper has been excluded.

[2]Copper content of impure bars and electrolytic copper.

[3]Smelter output of domestic and foreign ores, exclusive of that from scrap; production from domestic ores only was as follows in short tons: 1974—1,532,066; 1975—1,374,324; 1976—1,461,256.

[4]Figures presented are total blister and equivalent copper output including that blister subsequently refined in Chile and copper which is produced by electrowinning.

[5]Revised to zero.

[6]Belgium reports a large quantity of refined copper, but this is mainly from imported blister; domestic smelter production is reported output of blister copper from ores.

[7]Reported Norwegian copper output is derived in part from copper-metal matte imported from Canada, and reported Canadian smelter production may also contain this material. Norwegian smelter output from domestic ores was as follows (approximately) in short tons: 1974—6,500; 1975—7,500; 1976—7,600.

[8]Year ending September 30 of that stated.

[9]Data from Tsumeb Corp., Ltd.

[10]Data include refined copper plus exported blister and leach cathodes.

[11]Includes secondary.

Diatomite

By A. C. Meisinger[1]

U.S. production of processed diatomite in 1976 increased 10% in quantity and 20% in value compared with that of 1975. Filtration, with 60% of domestic demand, continued to be the major use for diatomite during the year. Exports of processed diatomite also increased and represented 24% of domestic production in 1976. Diatomite imports totaled 5,154 tons (a record quantity) in 1976 and were primarily from West Germany.

DOMESTIC PRODUCTION

Production of domestic processed diatomite in 1976 was 631,380 tons valued at nearly $55 million, or increases of 10% in quantity and 20% in value compared with that of 1975.

Production continued to come from five States: California, Kansas, Nevada, Oregon, and Washington, where companies operated 16 mine and plant facilities. Domestic producers in 1976 were Johns-Manville Sales Corp., with operations at Lompoc, Calif.; Grefco, Inc., Lompoc, Calif., and Mina, Nev.; Excel-Minerals Co., Taft, Calif.; Airox Earth Resources, Inc., Santa Maria, Calif.; NL Industries, Inc., Wallace, Kans.; Eagle-Picher Industries, Inc., Sparks and Lovelock, Nev.; Cyprus Mines Corp., Fernley, Nev.; American Fossil, Inc., Christmas Valley, Oreg.; and Inorganic Specialities Div., Witco Chemical Corp., Quincy, Wash.

Witco Chemical Corp. revealed plans in early 1976 to construct a new plant to manufacture diatomite products by 1978. Site of the plant was not announced by the company.

Table 1.—Diatomite sold or used by producers in the United States

	1972	1973	1974	1975	1976
Domestic production (sales) short tons	576,089	608,906	664,303	572,582	631,380
Average value per ton	$65.19	$59.26	$76.31	$80.01	$87.08

CONSUMPTION AND USES

Compared with 1975 consumption, all reported end uses of diatomite increased in quantity with the exception of silicate compounds and additives. Filtration continued to be the major end use with 60% of domestic demand for diatomite in 1976, followed by fillers, lightweight aggregates, and insulation. Miscellaneous end uses included abrasives, absorbents, additives, admixtures, carriers, and coatings for numerous applications, primarily in the agricultural, chemical, construction, and paint industries.

[1]Industry economist, Division of Nonmetallic Minerals.

Table 2.—Domestic consumption of diatomite, by principal use

(Percent of total consumption)

Use	1972	1973	1974	1975	1976
Filtration	58	61	60	60	60
Fillers	W	W	W	W	W
Insulation	4	4	5	4	5
Miscellaneous	38	35	35	36	35

W Withheld to avoid disclosing individual company confidential data; included with "Miscellaneous."

PRICES

The weighted average price per ton of processed diatomite sold by producers was $87.08, an increase of 9% compared with the 1975 price of $80.01. Price increases were substantial for diatomite used in filtration and fillers (table 3) in 1976. Average prices per ton for diatomite used as abrasives and lightweight aggregates also increased compared with 1975 prices. The only major end use for diatomite that did not increase in average price in 1976 was insulation.

Table 3.—Average annual value per ton of diatomite, by use

Use	1975	1976
Filtration	$91.73	$99.34
Insulation	62.61	62.36
Abrasives	145.56	146.04
Fillers	79.66	92.44
Lightweight aggregate	52.69	55.87
Miscellaneous	45.63	48.10
Weighted average	80.01	87.08

FOREIGN TRADE

The quantity and value of U.S. exports of processed diatomite increased 1% and 11% respectively, compared with those of 1975. The quantity exported (149,200 tons) represented 24% of domestic production (631,380 tons) in 1976, or 2% less than in 1975. Principal countries of destination were Canada, 41,675 tons; Japan, 15,083 tons; West Germany, 14,845 tons; the United Kingdom, 14,386 tons; and Australia, 12,002 tons. The average value of exports was $113.64 per ton, compared with $104.18 in 1975. Diatomite imports totaled 5,154 tons, of which 96% came from West Germany. The 1976 import total was a record quantity and exceeded by 34.5% the previous record quantity imported in 1975.

Feldspar, Nepheline Syenite and Aplite

By Michael J. Potter[1]

Feldspar production in 1976 increased by 10% compared to 1975. Sales to the glass industry were unusually high during the first half of 1976. However, the electrical porcelain industry, although not a large consumer of feldspar, was plagued by a series of lengthy strikes. No spot shortages of feldspar, including potash feldspar, occurred during the year.

The feldspar industry continued to face some difficult factors. Possible stricter controls on land use could make new mining permits very difficult to get. Other situations to be faced are long-range goals to strictly regulate waste water discharges and air emissions, rising costs of mining machinery and milling equipment, and enormous construction costs.[2]

Legislation and Government Programs.—According to provisions of the Tax Reform Act of 1969, which continued in force throughout 1976, the depletion rate allowed on feldspar production (both domestic and foreign operations) was 14%.

[2]Measured by quantity sold or used plus imports.

FELDSPAR

DOMESTIC PRODUCTION

The 1976 domestic output of feldspar ready to be put into final form for use (that is, the total quantity of hand-cobbed feldspar, flotation-concentrate feldspar, and feldspar content of feldspar-silica mixtures) was 10% higher in tonnage than in 1975. The value for the 1976 output also increased; the values for 1976 in table 2 represent a more highly refined product and are not comparable to previous years. Actual market prices for most types of feldspar increased 6% compared with those of 1975.[3]

Feldspar was mined in 10 States; North Carolina led, followed in descending order by Connecticut, Georgia, California, Okla-

[1]Physical scientist, Division of Nonmetallic Minerals.
[2]Rogers, C., Jr. Feldspar. Min. Eng, v. 29, No. 3, March 1977, p. 59.
[3]Work cited in footnote 2.

homa, South Dakota, Arizona, Wyoming, Maine, and Colorado. The combined outputs of the first four States named amounted to 93% of the U.S. total.

Most of the feldspar used in glassmaking is ground no finer than 20 mesh, and substantial tonnages of feldspathic sands (feldspar-silica mixtures) enter into glass furnace feeds with no further reduction in particle size. Feldspar to be used in ceramic and filler applications is usually pulverized to minus 200 mesh or finer. In 1976, 14 U.S. companies operating 16 plants produced feldspar in 10 States for shipment to destinations in at least 21 States, Puerto Rico, Canada, and Mexico. North Carolina had seven plants, and California had two. Arizona, Connecticut, Georgia, Maine, South Carolina, South Dakota, and Wyoming each had one plant. A change at one company took place as Sobin Chemicals, Inc., became part of IMC Chemical Group, Inc.

Table 2.—Feldspar sold or used by producers in the United States

(Thousand short tons and thousand dollars)

[1]Feldspar content.
[2]Data may not add to totals shown because of independent rounding.

CONSUMPTION AND USES

In 1976 there was as usual no significant consumption of feldspar in the raw, unprocessed state in which it is taken from the mine. The majority of users acquired their supplies already ground and sized either by the primary producers or by merchant grinders, although some manufacturers of pottery, soaps, and enamels continued their custom of purchasing crude feldspar for grinding to their preferred specifications in their own mills. The Bureau of Mines canvass of producers and merchant grinders does not provide information concerning the end use distribution of the material handled in this way. It should be noted that a substantial portion of the material classified as feldspar-silica mixtures serves in glassmaking without additional processing.

The 1976 end use distribution of feldspar in the United States indicated that 67% of the total was consumed in glassmaking and 30% was used in pottery. The remaining 3% was used in a diversity of applications, including glazes, enamels, soaps, abrasives, sanitary ware, rubber products, and electrical insulators. The end use data in table 3 for 1976 represent more comprehensive canvass coverage than in 1975.

Table 3.—Feldspar sold by producers, by use

PRICES

Engineering and Mining Journal, December 1976, listed the following prices for feldspar, per short ton, f.o.b. mine or mill, carload lots, bulk, depending on grade (prices were generally about $1 to $8 per ton higher than the corresponding quotations of the preceding year):

North Carolina:	
20 mesh, flotation	$18.75
40 mesh, flotation	$27.50- 29.00
200 mesh, flotation	28.75- 41.00
Georgia:	
40 mesh, granular	27.50
200 mesh	40.00
Connecticut:	
20 mesh, granular	22.50
200 mesh	28.00- 30.00

Feldspar prices were quoted by Industrial Minerals (London), December 1976, as follows (converted from pounds sterling per long ton to dollars per short ton):

Ceramic grade, powder, 200 mesh, bagged, ex-store	$50-$54
Sand, 2-3 millimeters, ceramic and/or glass grade, c.i.f. main European port	29- 39

No explanation was offered for the fact that the ceramic-grade quotations were about 17% lower than their 1975 counterparts, while those for ceramic and/or glass material were 26% lower.

FOREIGN TRADE

In 1976, U.S. exports classified as feldspar, leucite, and nepheline syenite (but presumably all or mostly feldspar) amounted to 6,144 tons valued at $352,492, which was approximately two-thirds the tonnage reported in 1975 and about one-half the value. Chief recipients of the exported material were Canada, 58%; Mexico, 19%; and Venezuela, 12%. The remaining 11% was shared by nine other countries.

U.S. imports for consumption of feldspar in 1976 were lower than in 1975 and amounted to only a small fraction of the quantity exported (2% of the tonnage, 5% of the total value). In addition to feldspar and nepheline syenite, U.S. imports in 1976 included 1,018 tons of material, probably feldspathic in nature, that was classified as "Other mineral fluxes, crushed" with a total value of $197,959.

The tariff schedule in force throughout 1976 provided for a 3-1/2% ad valorem duty on ground feldspar; imports of unground feldspar were admitted duty-free.

Table 4.—U.S. imports for consumption of feldspar

Country	1975		1976	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)
Crude:				
Canada	--	--	93	$17,614
South Africa, Republic of	[1]209	$17,138	--	--
Total	209	17,138	93	17,614
Ground, crushed, or pulverized:

WORLD REVIEW

South Africa, Republic of.—Pegmin (Pty) Ltd. was to acquire all the base mineral claims, surface permits, mining, crushing, and milling plant, stores, buildings, vehicles, and raw materials of South African Feldspar (Pty) Ltd. (SAF). Pegmin is a wholly owned subsidiary of Rand London Corp. Ltd. SAF is South Africa's largest feldspar producer and, along with Pegmin, has activities concentrated in the Phalaborwa district. The payment for the purchase was to total some $1 million.[4]

Spain.—Detailed discussions of Spain's industrial minerals, including feldspar, were featured in a journal article.[5]

Sri Lanka.—A series of mineral exploration programs involving industrial minerals was being conducted by the Sri Lanka Geological Department. Feldspar exploration was to be in cooperation with the Ceylon Ceramic Corp.[6]

United Kingdom.—Feldspar imports for 1975 amounted to 147,000 tons and came principally from Norway, 56%; Finland, 25%; and Sweden, 11%. In 1974, feldspar imports were 153,000 tons, mainly from Norway, 65%, Finland, 18%; and Sweden 12%. Nepheline syenite imports were 61,000 tons in 1974 and 41,600 tons in 1975 and came from Norway and Canada.[7]

U.S.S.R.—The U.S.S.R., which lacks large, commercially viable bauxite reserves, has done pioneering work in the production of alumina from nepheline and other alumina-containing minerals, which are plentiful in the country. An article in the Soviet foreign trade bimonthly, Soviet Export, stated that production techniques are now used at two aluminum smelters near Leningrad and at an alumina complex in Siberia. In producing alumina from nepheline, the only other raw material said to be required is limestone, with the complete processing cycle yielding alumina, potash, soda, portland cement and metallic gallium.[8]

[e]Estimate. [p]Preliminary. [r]Revised.
[1]In addition to the countries listed, the People's Republic of China, Czechoslovakia, Romania, and the Territory of South-West Africa produce feldspar, but available information is inadequate to formulate reliable estimates of output levels.
[2]Described in source as lump feldspar; does not include nepheline syenite as follows in short tons: 1974, [r]214,591; 1975, [r]203,326; 1976, [e]200,000.
[3]Includes pegmatite.
[4]Chiefly labradorite.
[5]In addition, the following quantities of aplite were produced in short tons: 1974, 539,670; 1975, 357,056; 1976, 394,533.

TECHNOLOGY

The Federal Bureau of Mines continued its work on new or improved beneficiation methods with domestic raw ores, including some New Hampshire granites. Included in these granites are potash and soda feldspar, quartz, and biotite. In other Bureau research, work was initiated on recovering alumina from anorthosite (high lime soda feldspar) using the lime-sinter process.

Sobin Chemical's Ceramic & Glass Products Division plant installed horizontal filters to decrease product moisture content at its facility which went onstream in May 1975 at Spruce Pine, N.C. The feldspar concentrate slurry is pumped to an 8-foot-diameter filter for dewatering to 8% moisture. The product is then dried and screened for shipment to customers.[9]

[9]Chemical Processing. Two Horizontal Filters Handle 52,000 Pounds Per Hour. V. 39, No. 11, October 1976, p. 47.

A U.S. and a Japanese patent were awarded on the use of sulfuric acid instead of hydrofluoric acid in the flotation process for separating feldspar from quartz. Pilot results at North Carolina State University's Minerals Research Laboratory at Asheville have indicated that recoveries are not quite as high as with hydrofluoric acid. Also, the ore has to be ground to a finer mesh to effect adequate separation. This could result in a dustier product, a disadvantage in the average glass furnace.[10]

Steps were taken at the Owens-Illinois, Inc., glass container manufacturing plant in Winston-Salem, N.C., to bring about greater fuel efficiency. These fuel-saving steps were brought about by using a new type of oil burner on the melting tanks which improves heat distribution; by bubbling the glass to accelerate melting and better utilize heat input; and by using ample insulation, especially under the melter bottom.[11]

Investigations were made into origins of bubble defects in commercial soda-lime-silica compositions melted in large float and window glass tanks.[12]

Molded insulating fiber glass components are said to be finding broad applicability in such automotive uses as hoodliners, headliners, and various insulations for side cowls, floors, van engines, and bus panels. The insulating material, which is strong, lightweight, and semirigid, provides greater thermal insulating efficiency than heavier weight hardboard or molded plastic products for similar applications.[13]

Major articles on electric melting of glass from the beginnings to the foreseeable future, compiled from The Glass Industry Magazine, were published in book form.[14]

Several research papers were published relating to various types of feldspar.[15]

NEPHELINE SYENITE

Nepheline syenite, a rock of igneous origin with a texture similar to that of granite, consists essentially of mixtures of nephelite with varying proportions of the alkali feldspars. Nepheline syenite found thus far in the United States has been of a quality suitable only for use as crushed stone. Canada, however, has an immense deposit at Blue Mountain, Ontario, from which two firms, Indusmin Ltd., and International Minerals & Chemical Corp. (Canada) Ltd., mine high-grade material that serves advantageously as an alumina-bearing ingredient in furnace feeds for glassmaking, as either a body component or a fluxing agent for ceramics, and increasingly in recent years as a filler for plastics, latex articles, paints, and paper.

Canadian production of nepheline syenite in 1975, the last year for which an estimate is available, totaled approximately 520,000 tons with a value of $8.7 million. This represented a 16% decrease in tonnage and a 6% decrease in value compared with that of 1974. The quantity exported to the United States in 1976 was back up to the 500,000-ton level.

Other than Canada, only two countries produce significant quantities of nepheline syenite—Norway, with 345,000 tons in 1975 and 297,000 tons in 1976, and the U.S.S.R. where, although production figures are not released, the mineral is known to serve the customary applications of the glass and ceramics industries and also to be a major source of cell-feed alumina for electrolytic aluminum plants.

The price range quoted for imported nepheline syenite in Ceramic Industry Magazine, January 1977, was from $13.00 to $31.45 per ton, depending upon grade, purity, grind, packaging, transportation, quantity sold, and other factors. Industrial Minerals (London), December 1976, quoted price ranges for Norwegian nepheline syenite, c.i.f. main European port (with a minor degree of uncertainty because of the floating sterling-dollar exchange rate), as follows:

Glass grade, 32 mesh (Tyler), bulk, per short ton	$34
Ceramic grade, 325 mesh (Tyler), bagged, per short ton	51

Prices for Canadian material were listed as "nominal."

1976	2,112	38	499,135	8,785

APLITE

Aplite is a fine-grained granitic rock containing quartz mixed with varying proportions of soda, lime-soda, or potash feldspars, any or all of which make it potentially useful as a raw material for manufacturing container glass. However, to be made acceptable for that purpose, the material occurring in most deposits must first be processed to eliminate most of the iron-bearing substances it usually contains. Japan, with about 500,000 tons annually, at least through 1974, is the world's foremost producer.

Aplite of glassmaking quality was produced in the United States in 1976 only from two open pit operations in central Virginia. The Feldspar Corp. mined aplite near Montpelier, Hanover County, and treated the material by wet-grinding, classification, and gravity separation, followed by dewatering, drying, and high-intensity magnetic separation to eliminate iron minerals. IMC Chemical Group, Inc. (formerly Sobin Chemicals, Inc.) operated an aplite mine near Piney River, Nelson County, and removed iron from the dry-ground ore by a high-intensity magnetic process.

Specific annual data on domestic aplite production, sales, and value have not been released for publication since 1962, when the output amounted to 140,000 tons, valued at $0.9 million. Domestic production in 1976 declined slightly in tonnage compared with that of 1975.

Aplite prices are not commonly quoted in trade journals, but the product traditionally commands a somewhat lower per ton price than feldspar. Prices of $15.25 per ton for low-iron material, f.o.b. producing point, and ranging downward to $11.50 per ton for grades higher in iron, were mentioned in early 1976.[16]

Ferroalloys

By Thomas S. Jones [1]

Modest recovery in steel production, led by a strong advance in production of stainless and heat-resisting steel, and an improved level of foundry activity were reflected in trends for domestic ferroalloy production and consumption in 1976. Shipments increased about one-tenth while production declined very slightly. Both were below 2 million short tons for the second consecutive year. Production was up for ferroalloys of silicon and of chromium but down for manganese ferroalloys. Silicon ferroalloys, including silicon metal, continued to be the leading ferroalloy group in both quantity and value of production and shipments, and also attracted the greatest attention for investment by domestic producers. Among the major ferroalloys, significantly higher consumption was recorded for those of silicon, chromium, and nickel; among specialty ferroalloys, for those of boron, phosphorus, and tungsten. Accompanied by instances of excessive inventory holdings by traders, stocks of chromium ferroalloys grew even further while those of manganese ferroalloys declined by about one-fifth. Because stocks were still high worldwide and demand was not strong, downward pressure on prices was evident among major ferroalloys. However, prices of specialty ferroalloys increased, most sharply for ferroalloys of molybdenum and of tungsten.

The net deficit in U.S. foreign trade in ferroalloys grew 21% to just under 1 million tons, as imports increased 13% while exports declined 49%. The value deficit dropped a small amount as average unit value of imports generally decreased. Imports of ferroalloys of manganese and of silicon were both up by about two-fifths, while those of chromium ferroalloys were down about one-fifth. For both manganese and chromium ferroalloys, imports approximately equalled domestic production; imports of 75% ferrosilicon were more than half of production. Leading import sources were again the Republic of South Africa, Japan, and France. Of expansions in productive capacity underway in foreign countries, some of the more significant were in the Republic of South Africa for manganese and chromium ferroalloys and in Mexico for manganese ferroalloys; growth in ferrosilicon capacity was widespread. Substantial increases in

XX Not applicable.
[1]Does not include alloys consumed in the making of other ferroalloys.
[2]Includes fused-salt electrolytic low carbon ferromanganese ("massive manganese").
[3]Includes silicon metal, silvery iron, and miscellaneous silicon alloys.
[4]Includes chromium briquets, exothermic chromium additives, other miscellaneous chromium alloys, and chromium metal.
[5]Includes ferroaluminum, ferroboron and other complex boron additive alloys, ferromolybdenum, ferronickel, ferrotitanium, ferrotungsten, ferrovanadium, ferrozirconium, spiegeleisen, and other miscellaneous alloys.

electrical energy costs in many foreign countries that produce ferroalloys, such as the Republic of South Africa and Japan, was a development that might possibly favor U.S. producers in the long run.

New materials for alloying made commercially available by U.S. producers included a complex, rare earth-containing version of magnesium-ferrosilicon for production of compacted-graphite cast iron and, for steelmaking, a vanadium additive termed ferrovanadium carbide.

Detailed information concerning production, trade, and use of specific alloys can be found in the respective chapters on columbium, chromium, manganese, molybdenum, nickel, silicon, tungsten, and vanadium.

Legislation and Government Programs.—Effective May 4, 1976, the U.S. Environmental Protection Agency (EPA) issued a set of national air pollution control standards applicable to electric submerged-arc furnaces and associated dust-handling equipment, construction or modification of which began after October 21, 1974. Production of all the alloys commonly produced in submerged-arc furnaces was covered, excepting ferrophosphorus. The regulations called for in-plant control of furnace emissions. Collection hoods were required that capture all emissions generated within the furnace and all tapping emissions during at least 60% of tapping time. Removal of particulate matter by air pollution control equipment was required to keep discharges into the atmosphere below 0.99 pound per megawatt-hour (lb/MW-hr) for furnaces producing ferrosilicon and silicon metal and below 0.51 lb/MW-hr for furnaces producing manganese and chromium alloys. Producers were also required to continuously monitor the opacity of emissions and to keep comprehensive records of smelting operations.[2]

On October 1, 1976, the Federal Preparedness Agency of the General Services Administration (GSA) announced a new set of stockpile goals as flexible targets under a long-range plan calling for review as required by circumstances. These goals were established by a study of national needs in the event of 3 years of an emergency, with defense and civilian requirements estimated separately. Actual stockpile activities were to be determined annually subject to Congressional and other constraints.

Government inventories of ferroalloys are listed in table 1. Shipments of stockpile excesses during 1976 consisted of 7,721 tons of high-carbon ferromanganese and most of the remaining ferromolybdenum.

[2]U.S. Code of Federal Regulations. Title 40—Protection of Environment; Chapter I—Environmental Protection Agency; Subpart Z—Standards of Performance for Ferroalloy Production Facilities (Sections 60.260-60.266). July 1, 1976, pp. 57-61.

DOMESTIC PRODUCTION

Production and shipments of ferroalloys fell below 2 million tons for the second consecutive year, according to data provided by the firms listed in table 3. The quantities shipped advanced over those in 1975 by 9% at nearly 10% greater value, whereas production volume dropped by 1%. Silicon was again the leading alloy group in domestic production, shipments, and value. Increased production of silicon alloys and chromium alloys, stimulated by recovery in the foundry and stainless steel industries, was not enough to offset a 16% decrease in production of manganese alloys. Product mix was such that The Ferroalloys Association reported consumption of 8.95 billion kilowatt-hours (kW-hr) of electric energy for the year, a 10% increase. Production of high-carbon ferrochromium, 50% ferrosilicon, and especially standard ferromanganese, all large-volume alloys, declined in the last part of the year. Some firms had operating rates as low as 50% to 65% of capacity in the fourth quarter.

Producers continued to concentrate their investments in silicon alloys facilities against a backdrop of plentiful domestic and worldwide supplies of ferrosilicon that included important new sources in nearby Canada. At the Niagara Falls, N.Y., plant of the Airco Alloys division of Airco, Inc., a 36 megavolt-ampere (MVA) furnace with annual capacity of over 40,000 tons of 50% ferrosilicon was brought into service in the second half of the year. Northwest Alloys, Inc., a subsidiary of Aluminum Co. of America, activated a ferrosilicon furnace rated at 18,000 annual tons in the first part of the year at a new plant at Addy, Wash. Initially, the product was to be used mostly for making magnesium, but eventually quantities were to be available for sale. Foote Mineral Co. made major modifications to its furnaces for silvery pig iron at Keokuk, Iowa, an upgrading action which necessitated production curtailments. Ohio Ferro-Alloys Corp. completed startup of all three furnaces at its new silicon metal plant at Montgomery, Ala. New facilities other than those for air pollution control were not involved in the decision by Chromasco Ltd. to start producing ferrosilicon again at the plant of its Chromium Mining & Smelting Corp. division near Memphis, Tenn.

In chromium alloys, Airco took steps to increase the capability of its Charleston, S.C., plant by upgrading a furnace from 40 to 60 MVA. The Satralloy, Inc., division of Satra Corp. activated a 10 MVA furnace at its Steubenville, Ohio, plant in midyear in order to make high-carbon ferrochromium, while Foote Mineral Co. ceased furnace production of special chromium alloys formerly made at its Graham, W.Va., plant, a decision influenced by the cost of complying with environmental regulations.

In other alloys, the number of ferrophosphorus producers remained unchanged as the Tennessee Valley Authority permanently ended production at the end of May, whereas the Electro-Phos Corp., owned by Japanese interests, restarted facilities at Pierce, Fla. which were operated several years ago by the Agrico Chemical Co. division of Continental Oil Co. Teledyne Wah Chang Albany, included in table 3 for the first time, has been producing ferrocolumbium for several years; therefore, 1975 and 1976 figures for ferrocolumbium in table 2 are not directly comparable. An affiliation between producers of specialty alloys that developed during the year was the acquisition by Molycorp, Inc., of just under 50% of the shares of Kawecki-Berylco Industries, Inc.

Expenditures for air pollution control continued to consume a significant portion of investment dollars. International Minerals & Chemical Corp., which is managing construction at Bridgeport, Ala., of the 40 megawatt (MW) ferrosilicon furnace plant of its Tennessee Alloys Co. joint venture with the Allegheny Ludlum Steel division of Allegheny Ludlum Industries, Inc., attributed 24% of project cost to air pollution control facilities.

CONSUMPTION AND USES

Reported consumption increased over that for 1975 for all ferroalloy categories except silicomanganese, ferromolybdenum, and ferrovanadium. According to the usage patterns of the respective ferroalloys, consumption trends generally paralleled modestly increased raw steel production, stronger recovery in iron foundry activity, and nearly 50% greater production of stainless and heat-resisting steels.

The largest ferroalloy consumption component was manganese alloys in carbon steel, within which consumption of medium and low-carbon grades of ferromanganese increased by the highest percentage. For silicomanganese, declines in consumption in carbon and in alloy steel together exceeded the one-third increase in use of this alloy in cast iron. After manganese alloys, silicon alloys were used in greatest quantity in carbon steel, mostly as 50% ferrosilicon. Consumption of this ferrosilicon grade and of other silicon alloys was largest in cast iron, and grew for both alloy groups by about one-third in that end use. Consumption increases of 30% and more were reported for ferroboron each in alloy and in carbon steel, evidencing the trend toward more utilization of the hardening action of boron in such specific applications as bolts. Use of ferrophosphorus was up by a similar amount in carbon steel and by an even greater percentage in cast iron. The Association of American Railroads adopted a 3% phosphorus cast iron as the standard for metal brake shoes on freight cars. Figures for ferrophosphorus do not include the substantial amount consumed in producing vanadium.

Significantly increased production of stainless and heat-resisting steels called forth expected sizable increases in consumption of chromium alloys and of ferronickel, and also similarly raised demand in the stainless category for ferrotitanium and for manganese and silicon alloys. Spread of argon-oxygen decarburization in stainless steelmaking increased the need in ferronickel for both new physical forms and medium-carbon grades. The 80% increase in consumption of ferrotitanium in stainless and heat-resisting steels arose from a combination of greater production and strong automotive industry demand, especially for titanium-containing muffler grade Type 409. Of the remaining ferroalloy groups, consumption rose markedly only for ferrotungsten, for which demand was up 20% in tool steel. Consumption of ferromolybdenum also increased in tool steel, by 26%, but otherwise declined in all steel end uses and overall. The drop in production of high-strength low-alloy steel held back growth in ferrocolumbium con-

sumption and mainly caused ferrovanadium to show the largest overall percentage decrease in consumption.

In steelmaking, ferroalloy elements were used almost entirely in ferroalloy form except for molybdenum, nickel, and tungsten. Molybdenum oxide was preferred over ferromolybdenum by a 7:1 ratio. The opposite was true in cast iron, wherein consumption of ferromolybdenum dominated over that of the oxide by 4:1. Iron foundries consumed relatively minor amounts of nickel, mostly in forms other than ferronickel.

STOCKS

Yearend industry stocks of manganese alloys decreased 19%, those of silicon alloys were little changed, and those of chromium alloys increased 17%. The most significant change in manganese alloys was a 38% decrease in consumer stocks of high-carbon ferromanganese, of which stocks declined almost continuously during 1976. Stocks of chromium alloys gained mainly because of a 45% increase in producer stocks of high-carbon ferrochromium, holdings of which peaked in September. Consumer stocks of chromium alloys increased only slightly but still represented a record total for the second consecutive year. For most major ferroalloys, industry inventories at yearend constituted a 2- to 3-month supply; however, stocks of high-carbon ferrochromium and silicomanganese amounted to about a 5-month supply at prevailing rates of consumption.

PRICES

Producer prices of major ferroalloys declined except for a few advances that were in keeping with the general level of inflation. Declines were attributable to the combined effects of large inventories, only moderate demand from major consuming sectors, competition among domestic producers, and competition between domestic and imported alloys. Strong downward pressure on price was most evident for both high- and low-carbon grades of chromium alloys. Pricing actions in chromium alloys included the offering by Union Carbide Corp. of 3-year long-term contracts containing future discounts. Standard ferromanganese decreased 3% in price in January; further market weakness was signified by gradual declines in price for imported ferromanganese, which at yearend for delivery in 1977 was more than $50 per ton below

producer price. A midyear price increase of about 6% for the more common silicon alloys held for 50% ferrosilicon but within a few weeks was nearly completely retracted for the 75% grade.

Prices of specialty ferroalloys increased, by contrast, by 8% to 29%. In ferronickel, competition between domestic and foreign alloy and between ferronickel and alternate forms of primary nickel led to a succession of pricing moves, the net effect of which about equalled an 8% October list price increase. Prices of ferrocolumbium (spot low-alloy) and ferrovanadium both increased 10% in July. A rapid rise in concentrate prices contributed to a two-step increase of 19% in the price of ferrotungsten. Ferromolybdenum prices increased an even larger amount, by 29%, as a consequence of both worldwide demand and cost of recent investments in molybdenum facilities.

Representative producer prices are given in the following table:

Alloy	Price in 1976[1]	
	Beginning	Yearend
Charge chromium (66% to 70%)	$0.50	$0.43
Low-carbon ferrochromium, 0.02% maximum carbon ("Simplex")	.92	.85
Standard 78% ferromanganese, per long ton of alloy	440.00	425.00
Ferromolybdenum, lump	3.44	4.43
Ferronickel	2.16	2.34
Ferrosilicon, 50%	.325	.345
Ferrosilicon, 75%	.365	.37

[1]Per pound contained, except as noted otherwise.

FOREIGN TRADE

Imports of ferroalloys were nearly 21 times as great as exports at a value over 8 times as much. The net trade deficit was slightly less than a million tons, a 21% increase over that of 1975, and the value deficit decreased 2% to just under $400 million. For quantity by alloy group, the deficit increased the most for manganese alloys, by nearly half again as much as in 1975, while that for silicon alloys almost tripled, for the biggest percentage increase.

Exports declined 49% largely because of sizable decreases in exports of ferromanganese and ferrosilicon. Value of exports fell off much less, however, as average unit value rose 76% because relatively high-value specialty alloys accounted for a larger share than in 1975. Ferrochromium led in export volume, while the unclassified group led in value. Ferrocerium was by far exported in the smallest quantity but was shipped to the largest number of countries. Of more than 50 countries to which ferroalloys were exported, chief recipients were Canada (for roughly two-fifths of both quantity and value), Japan, the Netherlands, Sweden, West Germany, and Brazil.

Imports of ferroalloys increased 13% to a total of over a million tons. The most significant changes were a 37% rise in imports of manganese alloys and a 20% decrease in imports of chromium alloys. Manganese alloys accounted for 60% of all ferroalloy imports, with import volume of high-carbon ferromanganese more than twice that of high-carbon ferrochromium, the alloy imported in next largest quantity. Imports of high-carbon ferromanganese and of silicomanganese were both considerably increased and those of medium-carbon ferromanganese doubled, while the small amount of low-carbon ferromanganese imported dropped 39%. By contrast, in chromium alloys imports of the low-carbon grade slightly increased at the same time that those of high-carbon ferrochromium reversed the previous year's performance and decreased about one-third. Imports of ferrosilicon were up by 40%, the largest percentage increase of any alloy group, chiefly because of a doubling in import volume of alloys with 8% to 60% silicon. For alloys in this range, average silicon content rose to 44.3%, signifying that the alloy mainly imported in larger quantity was 50% ferrosilicon.

Value of ferroalloy imports was slightly less than in 1975 as average unit value decreased universally for manganese, silicon, and chromium alloys and by 14% for all ferroalloys. Alloys of manganese and of chromium accounted for about 70% of total value of imports. For these two alloy groups, declines in average unit value ranged from as low as 2% for ferrochromium-silicon to as much as 25% for high-carbon ferrochromium. Average chromium content of high-carbon ferrochromium dropped 1.4% to 60.0%. Silicon alloys declined in unit value the most, by one-third for the entire group and by 39% for alloys containing 8% to 60% silicon.

Ferronickel, which accounted for most of the remaining 6% of alloy imports, was down 14% in volume at a 24% increase in unit value. The "Other ferroalloys" category remained insignificant as a percent of total volume but advanced as a group to 4% of total value.

Total[1]	46,715	37,656	97,365	58,888	49,631	52,833

[1]Data for spiegeleisen, added beginning with figures for 1973, are reflected in totals from that year on.

Imports of ferroalloys and ferroalloy metals were received from over 30 countries, with about one-third of the total each coming from Western Europe and Africa. Asia plus Oceania supplied one-fifth, while the contribution of countries in the Western Hemisphere, chiefly Brazil, Canada, and the Dominican Republic, grew to 12% of the total. Main import sources were mostly the same as in 1975, but with some changes in relative importance. The three leading supplying countries were again the Republic of South Africa ($93 million and 283,000 tons), Japan ($77 million and 162,000 tons), and France ($51 million and 137,000 tons). Because of the relatively high unit value of ferronickel, the Dominican Republic ($47 million and 30,000 tons) was next in value of

imports although only tenth in volume. The descending order of quantity supplied was, for manganese alloys, the Republic of South Africa, France, and Japan; for silicon alloys, Canada, Norway, and France; for chromium alloys, the Republic of South Africa, Southern Rhodesia, and Japan. In ferronickel, the Dominican Republic with over half the total took first position as an import source away from New Caledonia, which supplied most of the rest. In specialty alloys, Brazil was the leading source of ferrocolumbium, France accounted for all imports of ferrozirconium, and about two-thirds of ferrotitanium imports came from the United Kingdom.

Imports in relation to domestic production and reported consumption were greatest for manganese and chromium alloys. In these two groups, imports approximately equalled production and were about three-fifths of consumption. More high-carbon ferromanganese was imported than was produced, while for high-carbon ferrochromium amounts imported and produced were similar. Imports of low-carbon ferrochromium were more than twice the quantity produced and corresponded to four-fifths of consumption. Imports were less of a factor in silicon alloys, for which roughly one-seventh as much was imported as was produced or consumed. However, imports of 75% ferrosilicon came to half or more of totals for both production and consumption.

Under the General System of Preferences (GSP) that became effective January 1, 1976, the Government accorded duty-free status to imports from developing countries of ferromanganese (all grades), silicomanganese, ferrosilicon with 60% to 80% silicon, ferrophosphorus, chromium metal, and silicon metal with 99% to 99.7% silicon.

WORLD REVIEW

Statistics on world production of ferroalloys are summarized in table 9. Facilities for significantly increasing productive capacity during the period, 1976-1978, were being installed for manganese alloys (over 300,000 tons) in Australia, Brazil, India, Mexico, and the Republic of South Africa; for silicon alloys (approaching 200,000 tons) in Australia, Canada, France, Portugal, and Spain; and for chromium alloys (nearly 300,000 tons) in the Republic of South Africa and Turkey.

Argentina.—Ferroalloy production amounted to nearly 49,000 tons, mostly standard ferromanganese and 75% ferrosilicon, plus a small quantity of silicomanganese. Industria Siderúrgica Grassi, S.A., Electrometalúrgica Andina, S.A., and Carbometal, S.A. planned to install a number of relatively small furnaces in the period 1976 to 1978, amounting together to 58 MVA of additional furnace capability.

Australia.—Tasmanian Electrometallurgical Co. Pty. Ltd. (Temco), the sole producer and a subsidiary of Broken Hill Pty. Co. Ltd., began manufacturing 75% ferrosilicon in July at its Bell Bay plant on the northern coast of Tasmania. This new production was from a 45 MVA furnace rated at over 27,000 tons per year. A 27 MVA furnace was expected to begin augmenting ferromanganese and silicomanganese production in 1977. Temco's expansion program was expected to allow exporting in addition to satisfying steel production needs of Broken Hill.

Brazil.—Production increased by 22% to 344,000 tons, a growth rate comparable to that having been experienced for some years by the Brazilian ferroalloy industry but one-fourth below that required to achieve a total of over 1 million tons that had been projected for 1980. Silicomanganese production grew strongly, reflecting the addition of a 24 MVA furnace rated at about 30,000 tons per year by Electrosiderurgica Brasileira S.A. (Sibra) at its plant near Salvador in northeastern Brazil. This furnace plus a ferromanganese furnace with the same power rating were installed with technical and financial aid from Japanese interests. Cia. Paulista de Ferro Ligas announced plans to increase ferromanganese production by about 24,000 tons per year by mid-1977 by setting up a plant near the Urucum manganese deposit in Mato Grosso. These high-phosphorus and high-alkali ores were to be smelted by duplex furnacing. Another new plant for manganese alloys in Mato Grosso was projected by the newly formed Cia. Matogrossense de Ferro-Ligas (Fermat). Initial plans of this partly State-owned company were for five 20 MVA furnaces to be built at Três Lagoas, with production to commence in 1981 using hydropower from Jupiá. Production of ferrocolumbium, which had dropped off in 1975, rose sharply to a new record of 11,000 tons. Additional capacity of over 3,000 tons per year was expected to be available in 1977 from the new mine and smelting operation of Mineração Catalão de Goias S.A.

Canada.—SKW Electro-Metallurgy Canada Ltd. (SKW-Canada) began production at Becancour, Quebec, of ferrosilicon and silicon metal from two furnaces in the third quarter, at a time when other Canadian producers of silicon alloys were operating substantially below capacity. Activation of a third furnace early in 1977 was to make fully available new capacity of 30,000 tons per year of 50% and 75% ferrosilicon from a 30 MW furnace and 25,000 tons per year of silicon from two 20 MW furnaces. Downriver on the St. Lawrence at Beauharnois, Chromasco Ltd. continued phasing in capacity for ferrosilicon, also about 30,000 tons per year.

France.—Cie. Universelle d'Acetylene et d'Electrométallurgie, a part of Société Française d'Electrométallurgie (Sofrem), planned to increase its production of principally 75% ferrosilicon by building a coastal plant at Dunkirk. An Elkem furnace with power-recycling system was to be installed in the new plant for startup in 1978. This would add 55,000 tons per year of ferrosilicon capacity; however, some of the company's older units at Les Clavaux were to be phased out.

Gabon.—A manganese alloys plant was scheduled to be built near Moanda for production beginning in 1981. Planning for the plant was being done by Société Gabonaise des Ferro-Alliages (Sogaferro), a company which associates Cie. Minière de l'Ogooué with the Gabonese Government and firms from six foreign countries. Annual output was projected at 85,000 tons of ferromanganese and 50,000 tons of silicomanganese. Success of the project would be contingent on building both the Grand Poubara Dam to furnish hydropower and the Transgabon railway to carry the finished alloy to the coast for export.

Greece.—Future production of ferronickel on Euboea Island, perhaps by 1980, was indicated by plans of two companies. One project by Soc. Minière et Métallurgique de Larymna S.A. (Larco) at Politika, would add an additional 14,000 tons per year of nickel content to smelter expansion already underway at Larymna on the adjoining mainland. Eleusis Bauxite Mines had under development a program that would produce ferronickel at 10,000 tons per year of nickel content from low-grade lateritic ores. Production of ferrochromium from Greek ore was being studied by the newly formed Hellenic Industrial & Mining Investments Co. (Himic).

Iceland.—Norway's Elkem-Spigerverket A/S (Elkem) assumed Union Carbide's former 45% share in a joint ferrosilicon project with the Government of Iceland. A new company, Islenska Jarnblendifelagid, was organized to replace Icelandic Alloys Ltd. Start of production of 50,000 tons per year of 75% ferrosilicon was delayed 2 years to 1979-80, with Elkem to build the two furnaces planned and to market the product.

India.—Ferroalloy production increased over that in 1975 by 19% to the highest level in 5 years. Ferromanganese production recovered from several years of decline and was to grow further beginning early in 1977 with installation of a furnace for standard ferromanganese in the center of the country at Chandrapur. This unit,

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, the People's Republic of China and North Korea are known to produce both blast furnace and electric furnace ferroalloys, but output is not reported and available general information is inadequate for the formulation of reliable estimates of output levels. (Estimates of pig iron production for these countries that appear in the iron and steel chapter of Minerals Yearbook include an inseparable quantity for their ferroalloys production.) Romania is known to produce electric furnace ferroalloys, but output is not reported and no basis is available for estimation.

[2]To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallothermic operations is included with electric furnace production.

[3]To the extent possible, ferroalloy production of each country has been separated so as to show individually the following major types of ferroalloys: Spiegeleisen, ferromanganese, silicomanganese, ferrosilicon, ferrochromium, ferrochromium-silicon and ferronickel. Ferroalloys other than those listed that have been identified specifically in sources, as well as those ferroalloys not identified specifically but which definitely exclude those listed previously in this footnote have been reported as "Other." For countries for which one or more of the individual ferroalloys listed separately in this footnote have been inseparable from some other ferroalloy production has not been subdivided in such deviations are indicated by individual footnote. In instances where ferroalloys owing to the nation's reporting system, sources, and where no basis is available for estimation of individual component ferroalloys, the entry has been reported as "Undistributed."

[4]Electric furnace output, if any, is not reported, and no basis is available for estimation.

[5]Includes spiegeleisen.

[6]Includes silicomanganese.

[7]Includes ferrochromium (1974 only), ferrochromium-silicon (if any), and ferronickel.

[8]Less than 1/2 unit.

[9]Includes silicospiegeleisen.

[10]Includes ferrochromium-silicon.

[11]Includes ferronickel, if any.

[12]Revised to zero (production terminated in 1973).

[13]Ferronickel and silicomanganese also are produced, and ferrochromium-silicon also may be produced, but no basis is available for estimation.

[14]Ferrovanadium only; additional types may be produced, but data are not published and no basis is available for estimation.

[15]Previously reported incorrectly as blast furnace.

[16]Soviet production of electric furnace ferroalloys is not reported; estimates provided are based on crude source material production (reported and estimated) and upon exports of ferroalloys which are reported in detail, by type.

[17]Includes ferronickel.

[18]In addition to blast furnace production reported, other ferroalloys are known to be produced, but data are not published and no basis is available for estimation.

[19]Includes spiegeleisen and ferronickel.

[20]Spiegeleisen for West Germany included with ferromanganese.

[21]Of the totals, the following quantities (in thousand short tons) are specifically identifed as ferrosilicon: 1974—130; 1975—103; 1976—100; the differences between the foregoing figures and the reported totals are not identified in any way, except that they are neither spiegeleisen nor ferromanganese.

[22]Silicomanganese for Canada included with ferromanganese.

[23]Includes silicospiegeleisen for France.

[24]Ferrochromium-silicon for France included with ferrochromium.

[25]Ferrochromium (for 1974 only), ferrochromium-silicon (if any) and ferronickel for Canada included with unspecified.

[26]Ferronickel (if any) for France, India, Norway, the U.S.S.R., the United States and Yugoslavia included with "Other."

being built by Maharashtra Elektrosmelt Ltd. with Norwegian technical assistance, was to be fed local raw materials and, with a rating of about 50,000 tons of alloy per year, would substantially enhance India's export capabilities.

Indonesia.—Ferronickel developments included completion ahead of schedule of a smelter for the 25% alloy by State-owned P.T. Aneka Tambang. Production of ferronickel from this plant at Pomalaa in southeast Sulawesi was expected to grow to over 20,000 tons per year. Japanese interests provided financial backing both for this plant and for another ferronickel project proposed for Gebe Island. Indonesia Nickel Development Corp. (Indeco) was formed to carry out the Gebe Island undertaking, but future of the project was being seriously questioned by the end of the year.

Japan.—Production of ferroalloys again slackened, by 6%, to 2.2 million tons overall, but was still greater than that of the United States. In thousands of tons, main items produced were: Ferromanganese, 697; ferrochromium, 511; silicomanganese, 411; ferrosilicon, 345; and ferronickel, 219. Japan Metals and Chemicals Co. Ltd. brought a 32 MVA ferrosilicon furnace into production near yearend at Wakagawa. Capacity of the furnace was rated at about 19,000 tons per year, but the company's net increase in ferrosilicon capacity will be only half this amount because of the shutting down of several small furnaces. The new furnace became the largest such furnace in Japan to operate on geothermal power, a source of relatively cheap power which became all the more attractive when thermal power costs went up in Japan by 30% or more at midyear. Competitive pressure from imports also was a problem for producers, as six major firms making ferrochromium formed a cartel effective throughout 1976 for setting minimum prices on exports.

Mexico.—Production of manganese alloys began in the fall from the first of two new completely closed 33 MVA furnaces of Cia. Minera Autlán S.A. de C.V., with the second furnace expected to start up early in 1977. These furnaces were installed with Japanese technical assistance in a new plant at Tamós near the Gulf Coast port of Tampico and were to provide annually over 100,000 tons of standard ferromanganese and silicomanganese. As the Tamós plant comes into full operation, adjustments were to be made in the product mix of the company's older plants at Aire Libre and Tezuitlán. The two other Mexican producers, Ferroaleaciones de Mexico, S.A., and Ferralver, S.A., had expansions underway on a smaller scale.

New Caledonia.—Output of ferronickel was to be raised by Société Métallurgique Le Nickel (SLN) to over 100,000 tons per year, nickel content, by 1981. This approximately 20% capacity increase was to be achieved by a combination of mining expansion and smelter improvement beginning in 1977. Upgrading of the Doniambo smelting plant at Noumea was to be directed at ore preparation and calcining rather than installation of additional furnace capacity.

Portugal.—Cia. Portuguesa de Fornos Electricos (CPFE) and Milnorte-Metalurgia do Norte S.A.R.L. (Milnorte) were both reported adding capacity for silicon alloys. Installation by CPFE of a 25 MVA furnace at Canas was estimated to permit production of an additional 15,000 tons per year of ferrosilicon. Two new 24 MVA furnaces were scheduled by Milnorte to begin production of some 20,000 tons per year of ferrosilicon and silicon metal at a Douro River location in northern Portugal.

South Africa, Republic of.—Ferroalloy production registered a 10% advance to over 900,000 tons with a product mix of 4 ferromanganese—2 ferrochromium—1 ferrosilicon.

Chromium.—In December the first of three 30 MVA furnaces began operating at the new Steelpoort plant of Tubatse Ferrochrome (Pty.) Ltd., a joint venture of Union Carbide and South Africa's General Mining and Finance Corp. Ltd. All three furnaces were expected to be operating by the end of 1977, which would bring the plant's capacity for producing charge chromium containing 50% to 55% chromium from plentiful local ores up to 120,000 tons per year. A ferrochromium plant of the same rating being installed at Lydenburg by Johannesburg Consolidated Investment Co. Ltd. with Japanese technical assistance also was expected to start up in 1977. These two plants largely account for a projected doubling of South Africa's ferrochromium capability between 1976 and 1980. However, this possibly overly rapid growth in facilities plus a 60% increase in electric power costs in the past 2 years continued to raise questions about international competitiveness of South African producers.

Manganese.—Modernization and expansion by South African Manganese Amcor Ltd. (Samancor) at its Kookfontein Works at Meyerton included uprating two standard ferromanganese furnaces from 48 to 75 MVA and starting installation of a 75 MVA furnace ordered from Japan, from which production was expected to begin in 1978. Highveld Steel & Vanadium Corp. Ltd. acquired a majority interest in Transalloys (Pty.) Ltd., whose new silicomanganese furnace was slated to be operating by mid-1977.

Spain.—Startup of a new furnace for 75% ferrosilicon at Monzon by Hidro Nitro Española S.A. was now projected for the first part of 1977. Hidro Nitro also was reported planning to build its own hydroelectric facilities on the Yesa Dam. Ferroaleaciones Españolas, S.A. (Fesa), increased its ferrochromium capabilities with activation of a 7.5 MVA furnace at midyear at its Medina del Campo plant. Production of a total of about 3,000 tons per year of specialty ferroalloys was expected to commence about the middle of 1977 by Ferroaleaciones Especiales Asturianas S.A. at a new works at Avilés, using imported feedstock.

Sweden.—Airco's subsidiary at Vargon, Airco Alloys AB, announced its intention to discontinue ferromanganese production and to concentrate on ferrochromium and ferrosilicon. Inability to meet pollution control regulations led to a decision by Avesta Jernwerks AB to stop its captive production of about 25,000 tons of ferrochromium per year.

Turkey.—Built with Japanese technical assistance, the high-carbon ferrochromium plant of State-owned Etibank came into operation near yearend. The two-furnace plant was rated at over 50,000 tons per year.

United Kingdom.—Willan-Wogen Alloys Ltd., with plans for becoming one of the largest European producers of ferrotitanium, was formed by Aurora Holdings Ltd., which had acquired G. L. Willan Ltd., and Wogan Resources Ltd. Capacity of over 3,000 tons per year for largely the 70% alloy was expected to be attained by mid-1977 from the combination of a new induction furnace being installed in a plant at Catcliffe, Sheffield, with already existing facilities at the former Willan plant.

U.S.S.R.—Japan's Tanabe Kakoki was awarded a contract to build six 75 MVA closed furnaces for producing high-carbon ferromanganese. Presumably these units were ordered for installation by about 1980 at the Nikopol manganese complex in the Ukraine, but details were not announced. Other future major expansion was reported scheduled by 1980 at Yermakovsky in western Siberia, where capacity for mostly silicon and chromium alloys has nearly tripled during the last 5 years.

Venezuela.—Hornos Electricos de Venezuela S.A. (Hevensa) installed two 7.5 MVA furnaces of Hungarian manufacture for production of 75% ferrosilicon, ferromanganese, and silicomanganese. Further expansion through addition of a 25 MVA furnace was expected by 1979.

TECHNOLOGY

A single-addition foundry alloy for production of compacted-graphite (CG) cast iron has been developed by joint research between Foote Mineral Co. and the British Cast Iron Research Association. This alloy is based on regular-grade magnesium ferrosilicon and contains controlled amounts of calcium, titanium, and rare earths (about 0.3% cerium). Use of this complex alloy permits reproducible manufacture of cast iron with an interconnected graphite flake morphology. Such a cast iron has a blend of properties intermediate to those of gray and ductile irons. Potential applications suggested for CG cast iron include a number of automotive and machine parts.[3]

Another new alloying material introduced, by Reading Alloys, was a vanadium additive termed ferrovanadium carbide. This additive contains about 68% vanadium and 15% each of carbon and iron and was marketed to compete with other proprietary vanadium additives commonly used by steelmakers. Manufacture of this ferrovanadium carbide is by a patented high-temperature solid-state reduction process whereby powder mixtures, typically of carbon and oxides of iron and vanadium, are reaction-sintered at atmospheric pressure under reducing conditions.[4]

Plasma smelting of ferroalloys, while not yet commercial, continued to interest researchers, particularly with respect to ferrovanadium and ferrochromium. A plasma

reactor system for ferrovanadium has been developed at Bethlehem Steel Corp.[5] This system was operated at 100 and 500 kW levels, and scale-up to a plant capable of producing over 1 million pounds of vanadium per year was projected. The process entails high-temperature reaction in a plasma between a carbon and a metal oxide with accumulation of product in a molten iron charge held in a receiving crucible. Efficiency of operation was improved by using finely ground coke and vanadium pentoxide prereduced to trioxide. A 50% ferrovanadium was produced in the 500-kW equipment with an energy consumption of about 3 kw-hr/lb of vanadium. Mostly on a theoretical basis, possibilities for applying plasma methods to ferroalloy production were outlined by Westinghouse Electric Corp. researchers, who analyzed the feasibility of making high-carbon ferrochromium from low grade ore.[6]

High-temperature fused-salt electrolysis is used to reduce manganese from ore, by methods developed by Diamond Shamrock for producing "Massive Manganese." This alloy, as made directly from ore, typically contains about 0.14% carbon and 6% iron as major impurity, and is regarded by the Bureau of Mines for statistical purposes as low-carbon ferromanganese. However, a 98% manganese product can be manufactured using a feed of pure manganous oxide obtained from beneficiation of ore. Reaction in the electrolytic cell at about 1,300° C is between carbon anodes and oxide electrolyte to yield a molten metallic product. Fluorspar is used as fluxing agent in the electrolyte, and lime is also added to maintain a balance with acidic constituents of the feed ore.[7]

Introduction of hydrogen into steel by way of ferromanganese and silicomanganese and ways of lowering the hydrogen content of these manganese alloys by heat treatment have been studied. Part of the hydrogen in manganese alloys was found to be dissolved, and part bound as an oxyhydroxide coating which forms when there is contact between the alloy and water in liquid form. The level of hydrogen in ferromanganese could be lowered to that in freshly manufactured alloy by heating to 900° C at atmospheric pressure or to 600° C in a partial vacuum.[8]

International Nickel (U.S.) Inc. announced formation of International Metals Reclamation Company, Inc., to establish and operate a facility near Pittsburgh, Pa., for commercial reclamation of specialty steelmaking waste products. Plans are for the facility to begin processing over 40,000 tons per year of wastes into a nickel-chromium remelt alloy and a zinc-lead oxide product by mid-1978. Process descriptions so far available indicate that a proprietary smelting operation with full allowance for environmental considerations has been developed.[9] Studies by the Bureau of Mines of pyrometallurgical treatment of stainless steelmaking dusts for conservation of chromium, nickel, lead, and zinc progressed from laboratory to semicommercial scale.

Ferrophosphorus has been found acceptable as a partial replacement for zinc in corrosion resistant coatings on steel. Substitution for up to 50% by weight of zinc was feasible in automotive primers. In addition to being more economical, use of ferrophosphorus in place of zinc in primers improved welding and torch cutting operations and lowered associated evolution of fume.[10]

Fluorspar

By C. K. Quan[1]

World fluorspar production dropped from the 1975 level, despite a slight increase in consumption resulting from a general recovery in aluminum and steel production. Mexican output, which attained a record 1.30 million tons in 1971, fell to a little under 1 million tons in 1976, the consequence of a continuing decline in U.S. reliance on Mexican fluorspar. Partially balanced against this is the Republic of South Africa's rise as an important producer, whose vast reserves, if exploited, may well make it a world leader in fluorspar production.

Environmental concerns over the possible effects of fluorocarbons on stratospheric ozone continued to depress the acid-grade fluorspar market, causing an oversupply situation which is expected to prevail until about 1980. Meanwhile, exploration for fluorspar and mine plant expansions were reported in several parts of the world, in anticipation of increased demand in the early eighties.

By far the largest users of fluorspar were steel furnaces, with 60% of estimated world consumption in 1976, followed by aluminum smelters with 19%, and fluorocarbons with 15%. Historically, growth in fluorspar demand roughly paralleled growths in aluminum and steel production. In recent times, however, growth projections are being tempered by new technology and stringent environmental regulations on fluorine emissions. The revolutionary Alcoa Smelting Process, which uses no fluorides in the production of aluminum, may well be a harbinger of difficult days ahead for the fluorspar market. Similarly, more efficient utilization and recycling of raw materials in

new or existing smelters may result in further erosion of fluorspar demand, the extent of which is not yet readily predictable.

Legislation and Government Programs.—A House bill, H.R. 6254, was introduced in Congress on April 24, 1975, to provide for a 2-year suspension of tariff on imported fluorspar. The bill lapsed with the adjournment of Congress in 1976.

In mid-September, the National Academy of Sciences announced that chlorofluorocarbons (more commonly called fluorocarbons) posed a legitimate threat to man's environment.[2] Fluorocarbons, particularly those used as aerosol propellants, rise through the atmosphere and are subsequently photolyzed by ultraviolet radiation into chlorine atoms which then react catalytically with ozone, depleting it. The consequence of ozone diminution in the stratosphere is an increase in the amount of damaging ultraviolet radiation reaching the earth's surface, which may potentially raise the incidence of skin cancer, cause eye damage, and accelerate aging, as well as modify the earth's climate. In the wake of the National Academy of Sciences pronouncements, the Food and Drug Administration (FDA) proposed rules requiring warning labels on most aerosol products containing fluorocarbon propellants.[3] The labels would read: "Warning: Contains a chlorofluorocarbon that may harm the public health and environment by reducing ozone in the upper atmosphere." At yearend, the FDA, the Consumer Product Safety Commission, (CPSC) and the Environmental Protection Agency (EPA) announced plans to phase out nonessential uses of certain fluorocarbons. Rules pertaining to fluorocarbon manufacture and use are expected in early 1977. The potential technologic and economic impact of possible legislation on the fluorspar, fluorocarbon, and related industries have been examined by Shamel;[4] Brennan;[5] the Department of Commerce;[6] and Commodities Research Unit, Ltd.[7]

New emission standards for aluminum smelters being modified or under construction were finalized by the EPA in January 1976,[8] and require the removal of 95% of fluoride emissions from stack gases before release into the atmosphere. Emissions from prebake plants were limited to 1.9 pounds of fluoride per ton of aluminum produced, and 2.0 pounds per ton from Soderberg plants. For either process, opacity of the emissions was limited to 10%. Fluorine emissions from anode bake plants were limited to 0.1 pound per ton of anode produced, and opacity of the emissions to 20%.

Government stockpiles of strategic and critical materials contained 890,000 tons of acid-grade and 412,000 tons of metallurgical-grade fluorspar. On October 1, 1976, the Federal Preparedness Agency (FPA) of the General Services Administration (GSA) announced new stockpile goals, increasing the acid-grade fluorspar goal to 1,594,000 tons and metallurgical-grade fluorspar goal to 1,914,000 tons. These new goals would have significant impact on the fluorspar industry should Congress decide to fulfill them through short-term purchases.

As in years past, mining of domestic reserves was granted a 22% depletion allowance against Federal income tax, compared with 14% for foreign reserves.

DOMESTIC PRODUCTION

Domestic shipments of all grades of fluorspar were 188,270 tons, 35% over 1975 shipments. Shipments from the Illinois-Kentucky district represented 85% of the total volume; the balance came from Arizona, Montana, Nevada, Texas, and Utah. Three major companies operating nine mines and three flotation circuits in Illinois and Kentucky accounted for 83% of the total output. Small, intermittent operations or shipments from inventory in Illinois and the Western States accounted for the remainder of the supply. A list of domestic producers with reported output in 1976 follows:

State	Company	Mines	Type of mills
Arizona	Tonto Mining and Milling Co	Bluebird[1]	Flotation.
	Western Fluorspar Co	Turkey	None.
Illinois	Allied Chemical Corp	Spivey, Gaskin, Deardorf and Minerva No. 1.	Heavy-medium and flotation.
	Ozark-Mahoning Co	Barnett, Knight, Oxford and H-M shaft.	Heavy-medium, flotation and briquetting.
	Hastie Mining Co	Spar Mountain	Heavy-medium.
	Tamora Mining Co	None[2]	Washing and screening.
Kentucky	Frontier Spar Corp	Babb-Barnes	Heavy-medium and flotation.
	Kenspar Co	Various residual deposits.	Do.[3]
Montana	Roberts Mining Co	Crystal Mountain[4]	Heavy-medium.
Nevada	J. Irving Crowell, Jr. & Sons	Daisy	None.
Texas	D & F Minerals Co	Paisano	Do.
Utah	U.S. Energy Corp	Fluoride Queen	Do.

[1]Processed crude ore from Bluebird and Turkey mines.
[2]Shipments of purchased ore.
[3]Plant undergoing expansion.
[4]Shipments from inventory only.

Estimated annual production capacity was some 350,000 tons, and domestic producers operated at about 54% of capacity in 1976. This compared with a 40% capacity utilization in 1975, a relatively poor year for an industry impacted by a 3-month labor dispute and a generally weak fluorspar market. In terms of demand, domestic producers provided 15% of total reported consumption, compared with 11% in 1975.

In Kentucky, Minerals Exploration Co. and Armco Fluorspar Corp., a wholly owned subsidiary of Armco Steel Corp., entered into a joint venture, giving rise to Kenspar Co. Initial production was to come from various residual deposits on previously owned Minerals Exploration properties near Mexico, Ky., but plans were underway for extensive underground exploration by diamond drilling and drifting from a vertical shaft nearby. Included in the plans was an expansion program incorporating a new flotation circuit in a mill leased from Ozark-Mahoning Co. When completed, the Kenspar project will provide output for captive usage by Armco Steel as well as for commercial sales.

At yearend, Pan Ocean Oil Co., a wholly owned subsidiary of Marathon Oil Co., announced the acquisition of Frontier Resources Inc. of Denver, renaming Cerro Spar Corp.'s operations near Salem, Ky., Frontier Spar Corp. Prior to the acquisition by Pan Ocean Oil, Cerro Spar was a 95% subsidiary of Frontier Resources, with the remaining stock held by a private individual. Mine and mill activities initiated by Cerro Spar were continued under the new ownership, and plans were made for the possible development of a new mine near Hampton, Ky., and the expansion of the existing mill in 1977.

Ozark-Mahoning Co., a subsidiary of Pennwalt Corp., and Allied Chemical Corp. continued as the largest domestic producers of fluorspar, with their operations in Pope and Harding Counties in southern Illinois. Output by Ozark-Mahoning consisted of acid and metallurgical grades of fluorspar, including briquets, while Allied Chemical's output comprised acid and ceramic grades. Both operators also recovered various amounts of lead, zinc, and barium concentrates as byproducts from their flotation circuits.

Tonto Mining and Milling Co., inactive in 1975, resumed shipments from its Tonto Basin, Ariz., operations in 1976. Feed for its flotation plant was derived from Tonto's Bluebird mine as well as from the Turkey mine of Western Fluorspar Co. Reportedly, shipments were made intermittently to Allied Chemical's hydrofluoric acid plant in Pittsburgh, Calif.

In Idaho, Domestic Power Co. continued exploration and evaluation of its fluorspar deposits located west of Challis. At yearend, a heavy-medium separation plant was reported to have been purchased for assembly on the property.

Extensive exploratory drilling was reported by Ozark-Mahoning and Allied Chemical in Illinois and by U.S. Borax and Chemical Corp. in Tennessee. Some 300,000 feet of drilling was logged in these two States. U.S. Borax, a subsidiary of Rio Tinto Zinc Co., is known to have delineated 50 million tons of ore containing 17% CaF_2 in a fluorspar-barite deposit in the Sweetwater district, some 40 miles southwest of Knoxville, Tenn. Some development of the ore body has been planned for 1977, but full production is not likely to materialize for several years.

Seven processors, operating at 58% of estimated annual capacity, supplied the steel industry with 292,000 tons of fluorspar briquets, valued at slightly in excess of $24 million, in 1976. The shipments represented gains of 34% in volume and 36% in value over those of 1975. With the exception of Ozark-Mahoning's plant in Illinois, plants elsewhere utilized imported fluorspar of various grades, averaging 78% CaF_2, to fabricate a finished product averaging 66% CaF_2. A list of domestic briquettors follows:

Processor	Location
Cametco, Inc	Duquesne, Pa.
Delhi Foundry Sand Co	Brownsville, Tex.
Mercier Corp	Dearborn, Mich.
National Briquet Corp	East Chicago, Ind.
Oglebay Norton and Co	Brownsville, Tex.
Ozark-Mahoning Co	Rosiclare, Ill.
Do	Brownsville, Tex.

Of increasing importance as a secondary source of domestic fluorine for the chemical and aluminum industries is byproduct fluosilicic acid, H_2SiF_6, recovered from the wet-process manufacture of phosphoric acid from fluorapatite. Eleven phosphoric acid plants processing some 9 million tons of phosphate rock recovered 70,000 tons of fluosilicic acid in 1976, a gain of 17% over 1975 byproduct recovery. Of the 70,000 tons of fluosilicic acid recovered, 47,000 tons was subsequently shipped to the consuming industries. Thus, the phosphoric acid industry supplied an equivalent of 38,000 tons of fluorine, or about 7% of total fluorine consumption. A list of domestic phosphoric acid plants reporting fluorine recovery in 1976 follows:

Processor	Location
Agrico Chemical Co	Pierce, Fla.
Borden Chemical Co	Norfolk, Va.
Central Phosphates, Inc	Plant City, Fla.
Farmland Industries	Bartow, Fla.
Gardinier (SOPAG), Inc	Tampa, Fla.
Mississippi Chemical Corp	Pascagoula, Miss.
Stauffer Chemical Co	Salt Lake City, Utah.
U.S.S. Agri-Chemicals	Bartow, Fla.
Do	Wilmington, N.C.
Do	Nashville, Tenn.
W. R. Grace & Co	Bartow, Fla.

At yearend, producers' inventories consisted of 9,063 tons of acid-grade fluorspar, up 66% from the 1975 figures, and 5,807 tons of metallurgical-grade material, down 2%.

Domestic reserves were estimated at 16 million tons of ore containing 35% CaF_2. Illinois and Kentucky accounted for 56% of total reserves; Colorado and Idaho, 36%; and Montana, Nevada, New Mexico, Texas, and Utah, the remainder. Domestic resources were described in two U.S. Geological Survey publications.[9]

CONSUMPTION AND USES

Fluorspar is an important industrial mineral, valued for its fluxing properties and as a principal source of fluorine. Although not a major commodity in terms of total quantity produced annually, it is a critical raw material for the steel, aluminum, and chemical industries.

Different grades of fluorspar are required for various uses. Acid-grade, containing more than 97% CaF_2, is feedstock for the manufacture of hydrofluoric acid, a key ingredient for the aluminum and fluorochemical industries. Ceramic-grade, containing between 85% and 97% CaF_2, is used in the ceramics industry for the production of glass and enamel. Increasingly, acid-grade material is being used by the ceramics industry in order to capitalize on its low import duty. On the other hand, some hydrofluoric acid manufacturers are finding it economically advantageous to utilize ceramic-grade material, provided some contaminants are properly controlled. Metallurgical-grade fluorspar, containing between 60% and 85% CaF_2, is used almost exclusively in the iron and steel industries. In the United States, metallurgical-grade fluorspar is customarily quoted in terms of effective units, obtained by subtracting two and a half times the silica content of the ore from the CaF_2 content. Traditionally, a minimum of 70% effective CaF_2 has been used in the steel furnaces, but in recent times lower grade material, including briquets, is gaining widespread usage.

Most of the ceramic and metallurgical applications for fluorspar are derived from its ability to form lower melting eutectics with refractory materials. In steelmaking it assists in the effective desulfurization and dephosphorization of the melt, promotes slag fluidity, and enhances the solution of lime. Of particular importance to basic oxygen furnace use is its ability to sustain a stable foam emulsion during the refining process. Fluorspar usage in steelmaking varies considerably among individual companies and mills. In 1976, major U.S. steel mills reportedly consumed 606,578 tons of fluorspar; open hearth furnaces accounted for 92,792 tons, basic oxygen furnaces, for 423,493 tons and electric furnaces for 90,293 tons (table 4). According to the American Iron and Steel Institute, domestic production of raw steel for the year amounted to 127,943,000 tons, of which 23,470,000 tons was from open hearth furnaces, 79,918,000 tons from basic oxygen furnaces, and 24,555,000 tons from electric furnaces. Overall, the steel industry consumed about 9.5 pounds of fluorspar per ton of crude steel produced. On the basis of furnace type, the average fluorspar consumption per ton of raw steel is computed as follows:

Type of furnace	Fluorspar consumption pounds per ton
Open hearth	7.9
Basic oxygen	10.6
Electric	7.3

Briquets averaging 76% CaF_2 accounted for a little over 30% of the total fluorspar consumption by the steel industry. With rapidly diminishing supplies of good-quality metallurgical-grade fluorspar, it is anticipated that the trend towards increased usage of briquets will continue. The uniformity in grade of the briquet and its convenience in handling make it an attractive alternative to natural fluorspar.

Hydrofluoric acid is made by the reaction of acid-grade fluorspar with sulfuric acid. About 2.2 tons of fluorspar are required per ton of acid produced. Acid-grade fluorspar consumption by 12 domestic hydrofluoric acid plants amounted to 631,284 tons, down 6% from that of 1975. A contributing factor to the decline in consumption was the cessation of DuPont's production at Deepwater, N.J., at yearend 1975, and the partial shutdown of Allied Chemical's plant at Claymont, Del., during 1976. It is anticipated that Du Pont's future requirements will be met by Quimica Fluor, S.A., whose hydrofluoric acid plant came onstream in 1976 at Matamoros, Tamaulipas, Mexico. Du Pont is part owner of Quimica Fluor. A list of domestic hydrofluoric acid plants follows:

Producer	Plant location	Estimated capacity tons per year
Aluminum Company of America (Alcoa).	Point Comfort, Tex	55,000
Allied Chemical Corp	Baton Rouge, La	
	Geismar, La	
	Nitro, W.Va	108,000
	North Claymont, Del	
	Port Chicago, Calif	
Du Pont Company	Strang, Tex	75,000
Essex Chemical Corp	Paulsboro, N.J	11,000
Harshaw Chemical Co	Cleveland, Ohio	18,000
Kaiser Aluminum	Gramercy, La	50,000
Pennwalt Corp	Calvert City, Ky	25,000
Stauffer Chemical Co	Houston, Tex	18,000
Total		360,000

Source: Chemical Marketing Reporter.

Total hydrofluoric acid produced for captive usage as well as for general consumption in 1976 amounted to 288,200 tons, according to the U.S. Department of Commerce. An additional 85,500 tons, worth about $41 million, was available from imports, principally from Mexico and Canada. Total hydrofluoric acid supply, therefore, amounted to 373,700 tons. Major end uses of hydrofluoric acid comprised fluorocarbon production, aluminum refining, petroleum alkylation, uranium enrichment, stainless steel pickling, the production of fluorine compounds other than fluorocarbons, and miscellaneous uses.

The term "fluorocarbons" is applied to all organic fluorine chemicals, most of which are chlorofluorocarbons and the remainder fluorocarbons and other fluorine chemicals. Fluorocarbons possess properties that render them eminently useful as refrigerants and aerosol propellants. They are nontoxic, odorless, and nonflammable. Being chemically stable, they do not react with the products with which they are packaged. They also have the advantage of liquefying easily under slight pressure.

Five fluorocarbons account for nearly 95% of total domestic fluorocarbon production, as follows:

Fluorocarbon No.	Chemical name	Molecular formula
F11	Trichlorofluoromethane	CCl_3F
F12	Dichlorodifluoromethane	CCl_2F_2
F22	Chlorodifluoromethane	$CHClF_2$
F113	Trichlorotrifluoroethane	$CCl_2F\text{-}CClF_2$
F114	Dichlorotetrafluoroethane	$CClF_2\text{-}CClF_2$

Most fluorocarbons are manufactured by by the catalytic reaction of hydrofluoric acid with carbon tetrachloride, chloroform, or perchloroethylene. The average consumption of hydrofluoric acid is 0.25 to 0.50 pound per pound of fluorocarbon produced, depending on the product, but for the foregoing major products an average of 0.35 pound per pound appears reasonable. Six producers with an estimated annual capacity of 595,000 tons account for the entire domestic fluorocarbon output:

Producer	Plant location	Estimated capacity tons per year
Allied Chemical Corp	Baton Rouge, La	
	Denville, Ill	150,000
	Elizabeth, N.J	
	El Segundo, Calif	
Du Pont Company	Antioch, Calif	
	Pennsville, N.J

Prior to 1974, approximately half of all fluorocarbon production was used as aerosol propellants in antiperspirants, deodorants, hair sprays, paints, and household disinfectants. This market was growing at about 8% annually then. The second major use for fluorocarbons was as a refrigerant, accounting for 28% of all fluorocarbons. Foamblowing accounted for about 7% of total consumption; solvents, 5%; plastics and resins, 4%; and exports and other uses, 7%. Since late 1974, however, the growth in aerosol propellant usage has been significantly slowed by controversy over environmental degradation due to the presence of fluorocarbons in the stratosphere. It has been estimated that aerosol propellants now account for only 30% of U.S. fluorocarbon consumption and will continue to decline in years to come as laws are promulgated restricting nonessential uses of fluorocarbons.

Production of fluorocarbons F11 and F12, amounted to 312,100 tons in 1976, according to the U.S. International Trade Commission. While data on other fluorocarbons are unavailable, total production of all fluorocarbons is estimated at 450,000 tons, down 7% from that of 1975. This production accounted for 157,500 tons of hydrofluoric acid, or 42% of total supply for the year.

Hydrofluoric acid is not consumed directly in aluminum smelting but is used to produce aluminum fluoride (AlF_3) and synthetic cryolite (Na_3AlF_6) by reaction with alumina and caustic soda, respectively. Subsequently, cryolite and aluminum fluoride are used with alumina in the molten bath from which aluminum is produced by electrolysis. Aluminum fluoride is added to the electrolyte to lower its melting point, but only a limited amount can be added because it also reduces the electrical conductivity. Small amounts of fluorspar are therefore added to further reduce the melting point without also reducing the electrical conductivity. Previously, some natural cryolite, primarily from Greenland and now very rare, was used in the potlines, but today nearly all the fluorides are produced from hydrofluoric acid. The fluorides do not enter the final product but are absorbed in potlinings or discharged into the air as particulates or gases. Fluoride consumption varies with individual smelters but averages 60 pounds of aluminum fluoride and 50 pounds of cryolite per ton of aluminum ingot produced. This is equivalent to about 70 pounds of hydrofluoric acid per ton of aluminum. In recent times, however, the actual amount of hydrofluoric acid required is probably 20% less, or 56 pounds, owing to recycling of fluoride values from potlines and flue gases, as well as the manufacture of aluminum fluoride and cryolite from fluosilicic acid.

Six major companies - Aluminum Company of America, Allied Chemical Corp., Kaiser Aluminum, Olin Corp., Stauffer Chemical Co., and Reynolds Metals Co. - account for most of the domestic production of aluminum fluoride and synthetic cryolite. All are partially or completely integrated with facilities producing hydrofluoric acid and aluminum. For some years Kaiser has also produced cryolite from sodium silicofluoride, while Alcoa produced both cryolite and aluminum fluoride from fluosilicic acid. This is in addition to their cryolite and aluminum fluoride production from hydrofluoric acid.

According to the Aluminum Association, domestic production of primary aluminum in 1976 amounted to 4,251,500 tons, up 10% from that of 1975. This accounted for about 119,000 tons, or 32% of total hydrofluoric acid supply for the year.

The enrichment of uranium in the fissile isotope, U_{235}, is either by the conventional gaseous diffusion process or by the more recent gas centrifuge process. Both processes involve the use of uranium hexafluoride, UF_6, as the form in which the isotope separation takes place. Uranium hexafluoride is convenient for this purpose because it is gaseous at moderate temperatures. Yellowcake, containing 80% to 85% U_3O_8, is first refined to purified UO_3. This is followed by reaction with anhydrous hydrofluoric acid to produce greensalt, UF_4. The final stage involves the conversion of greensalt to uranium hexafluoride by means of elemental fluorine. Total hydrofluoric acid requirement by the entire process is estimated at 1.1 tons per ton of uranium hexafluoride produced.

It is estimated that about 11,000 tons of U_3O_8 were processed in 1976, requiring 12,100 tons, or 3% of total hydrofluoric acid supply. Uranium enrichment is probably the fastest growing end use market for hydrofluoric acid. Although a relatively minor demand, it is important and will continue to grow in parallel with the growth of nuclear power facilities.

The hydrofluoric acid alkylation process is one of several processes available for the alkylation of propene- and butylene-type olefins. Approximately 0.33 pound of hydrofluoric acid is used in the production of 1 barrel of alkylate. Estimated 1976 consumption by this end use was about 12,000 tons, or 3% of total hydrofluoric acid supply.

Apart from uranium enrichment, the largest single use of anhydrous hydrofluoric acid is in stainless steel pickling, which utilizes the acid for descaling after rolling operations. However, not all grades of stainless steel are pickled with hydrofluoric acid, some requiring only nitric acid or a molten caustic bath. Consumption of hydrofluoric acid varies but apparently averages 25 pounds per ton of stainless steel pickled. Domestic production of stainless steel amounted to 1,684,000 tons in 1976, up 52% from that of 1975. Assuming that 42%, or 707,000 tons, was pickled by hydrofluoric acid, the total hydrofluoric acid consumption amounted to about 8,800 tons, or 2% of total supply.

Inorganic fluorides other than aluminum fluoride and cryolite are also produced from hydrofluoric acid, but are difficult to define in quantities and end uses because of the large number of individual salts and their relatively small volume. Sodium fluoride is the largest volume inorganic fluoride in this group. In the past it was used primarily in water fluoridation, steelmaking, wood preservatives, insecticides, fungicides, and fluxing agents. Use for water fluoridation has declined in favor of lower cost silicofluorides. Sodium bifluoride is used in the electrotinning of steel and in laundry applications. Boron trifluoride is used as a catalyst in the production of alkylated phenols, coumarone-indene resins, and petroleum resins, and as an accelerator in epoxy hardeners. Fluoboric acid has applications in the electropolishing of aluminum, while stannous fluoride is well known as a decay preventive in toothpaste.

Seven major companies - Allied Chemical Corp., Olin Corp., Essex Chemical Corp., Harshaw Chemical Co., Kawecki-Berylo Industries, Inc., Mallinckrodt, Inc., and Chemtech Industries, Inc. - account for most of the inorganic fluoride production and in 1976 probably consumed about 9,000 tons, or 2% of total hydrofluoric acid supply.

Miscellaneous uses of hydrofluoric acid include the production of specialty metals, such as beryllium, columbium, tantalum, and yttrium; etching and frosting of glass; and use in the electronics industry. These numerous end uses probably consumed half the balance of the 1976 supply of hydrofluoric acid, about 54,000 tons; the remainder went into inventory.

In addition to the fluorspar consumed in the steel and hydrofluoric acid industries, some 35,636 tons of fluorspar was reportedly used in the manufacture of glass, enamel, welding rod coatings, primary magnesium, iron and steel castings, and special ferroalloys. These miscellaneous end uses represented about 3% of the entire domestic fluorspar consumption in 1976.

In summary, reported domestic fluorspar consumption amounted to 1,273,458 tons in 1976, up only 2% from that of 1975. About half of the total consumption was acid-grade; the remainder was metallurgical-grade. Raw steel production accounted for 48% of total fluorspar consumed; fluorocarbons and other fluorine compounds, 22%; and primary aluminum, 16%. The remaining, 14%, was used in stainless steel pickling, uranium enrichment, petroleum alkylation, primary magnesium and ferroalloy production, ceramics, welding rod coatings, etching and frosting of glass, and various other end use categories.

Supplementing the domestic supply of fluorine was byproduct fluosilicic acid recovered from wet-process phosphoric acid plants. In 1976, some 47,000 tons of fluosilicic acid was shipped, 77% to producers of synthetic cryolite and aluminum fluoride, 21% to manufacturers of other fluorine compounds, and the balance to water fluoridation plants.

At yearend, consumers' inventories comprised 66,641 tons of acid-grade fluorspar, up 33% from 1975 inventories, and 211,142 tons metallurgical-grade material, down 22%.

PRICES

Prices rose slightly at the beginning of the year but stabilized thereafter. Yearend quotations by the Engineering and Mining Journal are presented in table 5. Domestic metspar (metallurgical-grade fluorspar) briquets sold for $91 per ton, 3% over the 1975 price. At the Mexican border, metspar prices gained 3% to 4% compared with 7% to 8% for acidspar (acid-grade fluorspar). The devaluation of the Mexican peso appeared to have no significant impact on prices, presumably because most contracts were drawn in terms of U.S. dollars. European and South African acid-grade concentrates suffered some price fluctuations, but averaged about 3% lower than the average price in 1975.

FOREIGN TRADE

Fluorspar exports, principally to Canada, have always been an insignificant part of the U.S. trade balance. In 1976 some 4,900 tons were reportedly shipped abroad (table 6), Canada absorbing 86% of the total volume; prices were not certain.

As domestic production has been inadequate for domestic demand since the early fifties, the United States continues to rely heavily on foreign sources of fluorspar. From a record 1.34 million tons in 1974, U.S. imports fell to 1.05 million tons in 1975 and further to 0.89 million tons in 1976 (table 7), reflecting a steady decline in import reliance. About two-thirds of total imports in 1976 consisted of acid-grade fluorspar; the balance was metallurgical-grade material. The aggregate value was $64.88 million, not including duty, at ports of entry. Traditionally, Mexico has been the largest source of imported fluorspar, accounting for well over 70% of all imports since the early sixties, but in 1976 its share of the U.S. market fell to about 61%, giving way to incursions of South African material. Presumably, most South African fluorspar, which represented 14% of total imports, entered the United States for captive usage by a parent steel company. Other countries contributing significantly to U.S. imports included Spain (12%) and Italy (6%).

Since 1972, imports of hydrofluoric acid have been steadily rising, from about 14,000 tons to well over 85,000 tons in 1976 (table 8). Until recently, Canada was the major supplier, accounting for over 90% of U.S. imports. The position changed somewhat in 1975 when Mexico, in line with her new export policies, increased shipments almost sevenfold over those of 1974, thereby claiming a third of the U.S. market. Mexican shipments more than tripled in 1976, largely the result of the first full year of operations of the Quimica Fluor plant at Matamoros, establishing Mexico as the leading supplier of hydrofluoric acid to the United States. Despite its low volume, the total value of hydrofluoric acid imports amounted to $41 million, almost comparable to that of the relatively high-volume fluorspar. Unlike fluorspar, hydrofluoric acid is not subject to import duty.

Supplementing domestic supplies of cryolite, some 11,300 tons of the commodity, valued at $5.14 million, were imported in 1976 (table 9). The principal foreign suppliers of cryolite, most of which was synthetic, were Japan, the People's Republic of China, and Denmark, together accounting for 86% of total imports.

The current tariffs on imported fluorspar, established in 1951, remained effective in 1976, as follows:

Tariff class	TSUS No.	Tariff rate: Per long ton	Tariff rate: Per short ton	Statutory rate per long ton
Fluorspar containing more than 97% CaF_2	522.21	$2.10	$1.87	$5.60
Fluorspar containing less than 97% CaF_2	522.24	8.40	7.50	8.40

WORLD REVIEW

World production of fluorspar in 1976, table 10, estimated at 4.89 million tons, was down 3% from the 1975 level of 5.01 million tons. Mexico remained the leading producer, with 20% of the total output, followed by the U.S.S.R., 11%; France, 8%; the People's Republic of China, 8%; Mongolia, 7%; Spain, 7%; and the Republic of South Africa, 7%. More than 60% of the total output, almost equally divided between acid-grade and metallurgical-grade fluorspar, probably entered the export markets in 1976 (as in 1975, table 11), with the remainder consumed by captive markets in producer countries or else stockpiled for future demand.

Producer inventories, built up in 1975 on account of worldwide industrial recession, remained virtually unchanged at yearend 1976. Presumably, well over half a million tons of fluorspar existed in producer stockpiles, leading to an oversupply situation expected to prevail for the next few years. Depressed market conditions notwithstanding, plant expansions and exploration continued in several countries in anticipation of improved demand by the early 1980's.

World consumption of fluorspar in 1976, estimated at 4.57 million tons, rose 4% over the estimated consumption level of 4.41 million tons in 1975, reflecting a recovery in the steel and aluminum industries. Environmental concerns over the possible damage of the ozone layer in the earth's stratosphere by fluorocarbons continued to depress the fluorocarbon industry.

At yearend 1976, world fluorspar production capacity was estimated at 6.5 million tons, about 54% of which was acidspar and the remainder metspar or other grades of fluorspar. This installed annual capacity was considered adequate to meet projected demands until the early 1980's after which time production facilities will have to expand with consumption. World reserves of fluorspar have been variously estimated at between 222 million tons and 360 million tons of ore containing a minimum of 25% to 35% CaF_2. At current rates of extraction, it is anticipated that these reserves will be depleted within the next two decades. However, new technology and additional exploration, coupled with a more attractive price structure, are expected to enhance the reserve base in years to come.

WORLD PRODUCTION

Argentina.—Output from Argentina, which attained a high of 80,000 tons in 1971, dropped in succeeding years to its present level of about 41,000 tons, and recovery is not anticipated in the near future. Practically all output came from the operations of one company, the Sierra Grande Co., in the Province of Chubut and Rio Negro.

Brazil.—Brazilian output has consistently increased or else held firm since 1973, the first year of reported production, and provides adequately for the country's developing aluminum, steel, and chemical industries. In line with the national policy of self-sufficiency, exports are under strict government control, although in recent years shipments have been made to the United States and Japan. Four companies, the largest of which was Mineracao Santa Catarina, accounted for all of Brazilian output, which amounted to about 71,000 tons in 1976. Most production came from the Crisciuma-Tubaro district in the State of Santa Catarina.

Canada.—Canadian fluorspar production continued to be inadequate to meet domestic needs. From a record 180,000 tons in 1972, production fell considerably to 70,000 tons in 1975, owing to a labor strike that began at midyear and continued into February 1976. The Aluminum Co. of Canada (Alcan), through a subsidiary, Newfoundland Fluorspar, Ltd., is the sole producer of fluorspar in the country. Production from Alcan's mines near the village of St. Lawrence, Newfoundland, did not exceed 80,000 tons in 1976, most of which was for captive usage at Alcan's aluminum fluoride and synthetic cryolite plant at Arvida, Quebec. In the face of accelerating production costs and recurrent labor problems, previously announced plans for mine and mill expansion are not expected to materialize in the immediate future. Increasingly, Canada's fluorspar requirements will continue to be met by low-cost supplies from Spain and Mexico.

China, People's Republic of.—Ranking among the world's leading producers and exporters of fluorspar, China's output in 1976 probably reached 385,000 tons. In contrast to its substantial production, domestic consumption by the still-developing aluminum, steel, and chemical industries has for years been rather modest. In consequence, a large surplus has always been available for export, primarily to Japan and the Soviet Union. China's output consists essentially of metallurgical-grade fluorspar, in which form it is exported, but some acid-grade material is produced at the Taoling mine in Hunan Province, which has an annual capacity of some 80,000 tons. In July 1976 a small shipment, some 6,900 tons, of acid-grade fluorspar was reported to have entered the United States on a trial basis; it is believed, however, that the shipment contained very high-grade lump material, and not flotation concentrates.

France.—French production was derived mainly from deposits in the Massif Central, the Eastern Pyrénées, and the Var District of Provence. Two private corporations, Péchiney-Ugine-Kuhlmann (PUK) and Sté. de Concentration des Mineraux Fluorés (Comifluor), provided about 70% of French output, which totaled 391,000 tons in 1976. For some years now French production has been more than adequate for domestic needs, with the result that about one-third is usually exported, primarily to West Germany.

Germany, West.—Mainly because of dwindling reserves, resulting in several mine closures, West German production has been steadily declining in recent years, from about 102,200 tons in 1972 to about 74,200 tons in 1976. Currently, output is based largely on the operations of Fluss und Schwerspatwerke Pforzheim, GmbH and VAW Flusspat Chemie, A.G. in the Black Forest and Bavaria.

Italy.—Italian production, almost entirely by two private corporations, Mineraria Silius, S.p.A., and Montecatini-Edison, S.p.A., is centered largely in the Brescia, Trento, Bolzano, and Bergamo areas of Northern Italy, and near Cagliari in Sardinia. Output from these areas is mainly acid-grade material, although some briquets have also been produced from flotation fines in recent years. Also in recent years, production has been steadily declining, from about 319,000 tons in 1970 to some 232,400 tons in 1976. About one-third of total production is generally exported to the United States, West Germany, and other European countries.

Kenya.—Of 24 mineral commodities produced in Kenya, fluorspar remains the chief contributor to export earnings. Exports of fluorspar earned $4.5 million in 1976. The

Fluorspar Co. of Kenya, partly owned by International Minerals and Chemical Corp., continued as the sole producer, with operations in the Kerio Valley of the Rift Valley Province. Largely as the result of the first full year of operations of the Fluorspar Co.'s new 165,000-ton-per-year flotation plant, Kenya became firmly established as the second largest producer on the African continent, with a total output of some 82,700 tons in 1976, compared with 60,200 tons in 1975. Development work continued on the extensive reserves of fluorspar, all of which occur as replacement bodies in limestone of the Mozambique crystalline basement.

Mexico.—Although Mexican production in 1976 was 18% less than in 1975, Mexico continued as the world's leading producer. Its output of 988,300 tons represented 20% of the world total. This sharp decline in production has been ascribed to a generally soft market as well as to declining U.S. import reliance on Mexican fluorspar. The erosion of Mexico's share of total U.S. imports, from 80% in 1974 to 61% in 1976, reflected a current trend for its traditional trading partners to seek alternative sources of cheap or captive material. To some extent, loss of sales to the United States has been offset by new markets in Europe and by increased domestic consumption. The domestic market for acid-grade material expanded considerably as result of the first full year of operation of the Quimica Fluor, S.A., hydrofluoric acid plant, rated to have an annual consumption of 165,000 tons of fluorspar. Partly owned by Du Pont, a large fraction of Quimica Fluor's hydrofluoric acid was presumably shipped to the United States for captive usage, thereby absorbing a significant portion of the lost export market for acidspar.

Seven major producers with an annual capacity of about 1 million tons currently account for more than 80% of total production. For the most part, the fluorspar industry is Mexicanized (at least 51% Mexican ownership). Principal producing areas include the States of San Luis Potosi, Chihuahua, Coahuila, and Guanajuato. Weak market conditions notwithstanding, several of the leading producers have planned capacity expansions in coming years. In particular, Industrias Peñoles S.A., is investing $10 million to raise output at its Rio Colorado property from 110,000 tons to 300,000 tons in 1977.

Reportedly, a new flotation plant, with an initial feed capacity of 250 tons per day, came onstream towards yearend [10] in Durango, Mexico. Using crude ore from deposits in the Coneto de Comonfort area, the plant is rated to produce about 60 tons of acid-grade concentrate per day. Although undisclosed, the operator of this new facility is thought to be Minerales Productos y Metallurgicos S.A., 49% owned by Seaforth Minerals Co. of Ohio.

Previously a tax-exempt mineral commodity, fluorspar was subjected to a 7.5% export duty by the Mexican Government in early November. At yearend, the export duty was lowered to 5% in view of a worsening market condition.

Mongolia.—Mongolian production, most of which is traditionally exported to the U.S.S.R., probably topped 333,000 tons in 1976 as a result of continued expansion. A significant portion of the output came from the Berh mine in Eastern Mongolia, whose capacity has doubled in the current 5-year plan period and is expected to undergo further expansions, according to the Mongolian Soviet Nonferrous Metals Association (Mongolsovtsvetmet). Current production from the Berh mine is estimated at 150,000 annual tons, and this is expected to double in the near term.

Morocco.—Morocco's production evolved solely from one operator, Sté. Anonyme des Enterprises Minéres (Samine), an affiliate of PUK, whose fluorspar mine at El Hamman, near Meknes, increased output to 56,700 tons from 52,300 tons in 1975.

South Africa, Republic of.—Among fluorspar producing countries on the African continent, the Republic of South Africa is by far the largest, with three major companies, all subsidiaries of multinational corporations, accounting for about 80% of South African output. Principal producing areas are in Northern and Western Transvaal. In its first full year of operation, Marico Fluorspar (Pty), Ltd., a wholly owned subsidiary of the United States Steel Corp., established itself as the major fluorspar producer in South Africa. Onstream at yearend 1975, the unit is designed to produce 130,000 tons of acid-grade and 55,000 tons of metallurgical-grade fluorspar annually by 1977-78. All of Marico's production is scheduled for export to the United States and to captive consumers in

[10] Industrial Minerals. No. 111, December 1976, p. 64.

Western Europe. Largely on the strength of Marico's presence as a major new producer, South Africa's output topped 320,000 tons in 1976, up a staggering 44% from that of 1975. The most optimistic fluorspar reserve figure yet published by Gössling[11] places South African reserves at 116 million tons of ore averaging 26% CaF_2, or some 36% of known world reserves. With domestic output currently accounting for only 6% of world output, it seems likely that future exploitation of these vast reserves will ultimately make South Africa a world leader in fluorspar production.

Spain.—Although Spanish output has been gradually declining in recent times, it still ranks fourth in world prominence. Two companies, Minerales y Productos Derivados, S.A. (Minersa) and Fluoruros, S.A., accounted for about 85% of output, which totaled 324,700 tons in 1976. Principal producing areas are currently located near Aviles, Gerona, Almeria, Seville, and in the Asturias region of Northern Spain. Most of Spanish output is geared to export markets in Canada, West Germany, and the United States. Reportedly, some agglomerated material is also being made and marketed by Fluoruros.

Thailand.—In general, Thailand's fluorspar industry is fragmented and production has declined sharply in recent years, owing to a poor export market. Two foreign-owned companies, Thai Fluorspar and Minerals Co., Ltd., and Universal Mining Co., are the major producers. The main producing areas are found in the northern Provinces of Lamphun, Chiangmi, Mae Hong Song, and Lampang, and in the southern Provinces of Petchburi, Kanchanaburi, and Ratburi.

Mainly on account of severe sales reductions to Japan, production in Thailand fell from a record 471,000 tons in 1971 to 190,700 tons in 1976. Japan's waning interest in fluorspar, particularly the metallurgical variety, was due to increased usage of dolomite as a substitute flux in its steel industry. Further declines in fluorspar consumption are anticipated in 1977, and several Japanese steelmakers are understood to be negotiating with Thai, Kenyan, and Chinese suppliers for a reduction of total shipments by as much as 20%. Meanwhile, exports to the U.S.S.R. are reportedly also on the wane because Thai exporters are unable to accept barter payments in machinery and earthmoving equipment as proposed by Soviet trading agencies. As a result of this development, no fluorspar sales were made to the U.S.S.R. in the first 6 months of 1976. The outlook for a recovery in Thai production of metallurgicalfluorspar therefore appears bleak in the short term, in view of current technological trends in the Japanese steel industry and unfavorable Soviet trade policies. In contrast, acid-grade fluorspar output from the country's sole flotation plant, operated by Thai Fluorspar and Mining Co., Ltd., an affiliate of Kaiser Cement and Gypsum Corp., continued to rise, possibly attaining a record 80,000 tons in 1976. Part of Thai Fluorspar's output was shipped to the United States, and it is believed that new markets are being sought in Europe and the Middle East for the balance of its production.

At yearend, some 2,700 workers were operating 30 mines, compared with 5,200 workers and 80 mines 2 years previously, indicating clearly a disruption of an already fragmented industry structure.

Tunisia.—Tunisia's output from its sole producer, Sté. Tunisienne d'Expansion Minière (Sotemi), near Zaghouan, south of Tunis, amounted to 38,000 tons in 1976, compared with some 37,400 tons in 1975. In years past, most of Tunisian production was exported, but with the coming onstream of the Industries Chimiques du Fluor (ICF) aluminum fluoride plant at Gabes in 1976, a significant portion of domestic output will be consumed locally. Reportedly, a contract has been drawn by ICF and Sotemi for the supply of 34,000 tons of fluorspar per year.

United Kingdom.—Among fluorspar producers in the United Kingdom, Laporte Industries Ltd. is by far the largest, with mining and milling facilities near Stoney Middleton in Derbyshire. With the closing of the C. E. Giulini, Ltd. operations in Derbyshire in August 1975, annual production capacity in the United Kingdom declined by about 120,000 tons, or 29%. Further complicating the industry was the threat that Laporte's fluorspar and fluorine chemical operations could run into severe difficulties by 1977 through lack of waste disposal facilities at the Cavendish mill. A proposed new dam for tailings containment in the Peak District National Park was turned down by the Peak Park Planning Board in 1975. In May 1976 the United Kingdom Environment Secretary reversed the Board's ruling for reasons of public interest and national economy, and allowed Laporte to proceed with its project.

[11]Gössling, H. H. An Updated Summary of the World's Fluorspar Industry, 1975. National Institute for Metallurgy (Johannesburg), Rept. No. 1814, Mar. 9, 1976, 29 pp.

Meanwhile, negotiations went underway between Imperial Chemical Industries (ICI) Ltd., the parent company of Weardale Lead Co., and Swiss Aluminium Mining (United Kingdom), Ltd., the subsidiary of the Alusuisse group of Zurich, over possible collaboration in fluorspar mining and processing. A fluorspar reserve of some 800,000 tons in the Greenclough Vein in the Rookhope Valley has recently been acknowledged by Weardale Lead, which currently operates a heavy-medium and flotation plant at Rookhope using feed from its nearby Red Burn mine. Swiss Aluminium, on the other hand, is not yet a producer but has holdings in, and plans to redevelop, a number of old fluorspar mines in Durham to supply a new flotation plant to be constructed at Broadwood Quarry near Fosterly. An initial production capacity of 50,000 tons per year has been planned for the flotation plant at Broadwood Quarry, with the possibility of expanding to 175,000 at a later date.

In another industry development, British Steel Corp. has received planning permission for the construction of a fluorspar beneficiation plant at West Blackdene in Weardale, Durham.

Total fluorspar production in the United Kingdom amounted to some 260,000 tons in 1976, compared with 254,400 tons in 1975. Production is expected to increase by mid-1978 when Giulini's operations in Derbyshire are resumed by new owners.

U.S.S.R.—Despite efforts at self-sufficiency, fluorspar output from the Soviet Union remained below domestic requirements. Total production from the Maritime Kray, Transbaykal, Uzbekistan, and Kazakhstan areas is estimated at 540,000 tons, up 4% from 1975, owing to continued expansions in those areas. An additional 500,000 tons were probably imported from Mongolia, the People's Republic of China, Japan, and Thailand. To enhance the reserve base, exploration continued at the Suppatash, Kengutan, and Shabres deposits throughout 1976.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the countries listed, Bulgaria is believed to have produced fluorspar, but production is not officially reported and available information is inadequate for the formulation of reliable output level estimates.

[2]An effort has been made to subdivide production of all countries by grade (acid, ceramic, and/or metallurgical). Where the subdivision is available in offical reports of the subject country, the data have been entered without qualifying notes; where a secondary source has been used to subdivide production by grade, the source of the information for this subdivision has been identified by footnote. Where no basis for subdivision is available, the country entry has been identified with the notation "grade unspecified."

[3]Information on grade obtained from Bundesanstalt Für Bodenforschung Hannover and Deutsches Institut Für Wirtschaftsforschung Berlin. Untersuchungen über Angebot und Nachfrage Mineralischer Rohstoffe IV. Flusspat, March 1974, p. 39.

[4]Exports.

[5]Figures represent the difference between reported exports (divided by grade) and total production (reported without differentiation by grade), and presumably are domestic consumption plus or minus changes in stocks of both acid and metallurgical grade.

[6]Data for Brazil exclude some crude ore mined, but neither sold as direct-shipping ore nor beneficiated during year specified. Total crude ore production follows in short tons: 1974—116,705, 1975—120,346, 1976—NA. Of this output, crude ore beneficiated totaled as follows in short tons: 1974—97,044, 1975—120,532, 1976—NA; producers' initial stocks (as of January 1) totaled as follows in short tons: 1974—3,167, 1975—[r]10,777, 1976—NA; producers' yearend stocks totaled as follows in short tons: 1974—11,704, 1975—10,524, 1976—NA; and transfers totaled as follows in short tons: 1974—9,568, 1975—zero, 1976—NA. The acid-grade fluorspar reported in last year's chapter has been eliminated since no information is available on output.

[7]Figures reported represent marketable production (the summation of direct-shipping ore and finished concentrates). Total run-of-mine production (direct-shipping ore plus ore destined for concentration) follows in short tons: 1974—761,000, 1975—805,000, 1976—744,000. Much of this material requires beneficiation before it becomes a salable product.

[8]Includes materials recovered from lead-zinc mine dumps.

[9]Figures presented are the calculated salable acid-grade fluorspar equivalent of officially reported actual mine production of flotation plant feedstock reported in Thai sources as "low grade ore," which were as follows in short tons: 1974—[r]96,927, 1975—122,611, 1976—79,184. In 1976, flotation plant output reportedly reached a record high, apparently as a result of the processing of material mined previously but not processed when mined.

[10]Figures presented are officially reported mine production of high-grade ore.

[11]Estimate revised to zero.

[e]Estimate. XX Not applicable.

[1]Compiled from official import data of listed countries of destination except where otherwise specified by footnote; figures in total receipts by listed countries column are simply summations of reported imports for all listed destinations, in contrast to figures in total recorded exports column which are either (1) actual reported exports of listed source countries or (2) estimates of total exports. Differences between these two columns are attributed to (1) time lag between date of shipment and date of receipt, (2) concealment policies of some countries, and (3) reshipment of material by intermediate countries which may be credited as the origin in the trade returns of the final destination countries.

[2]Imports for year beginning July 1, 1974.

[3]No recorded production of fluorspar; exports are generally derived from imported materials.

[4]A substantial part of total imports are not distributed by destination; such undistributed imports may have originated in any country carrying the footnote and/or in other nations not specifically listed in the first column of this table.

[5]Official import statistics show no receipts from this country, but do include a substantial quantity of material from undisclosed sources. Figure entered here represents reported export of source country to this destination. (An equal amount has been substracted from the destination country's reported import from undisclosed sources).

[6]Data compiled from official import statistics of 10 nations and export statistics of 6 significant producing nations, the latter to determine apparent imports for 13 other countries for which official fluorspar import figures are not available. Nations reporting imports and total recorded imports for each are as follows in short tons: Denmark—3,179; Finland—4,834; India—4,636; the Republic of Korea—7,420; Mexico—less than 1/2 unit; Spain—10; Taiwan—8,745; Thailand—14; Turkey—176; and Venezuela—520. Nations for which apparent imports have been derived and apparent imports for each are as follows in short tons: West Germany—6,059; Italy—2,678; the Republic of Korea—4,354; Mexico—169; Spain—2,757; and Thailand—11,504.

[7]Figure includes fluorspar as well as any feldspar, nepheline, and/or nepheline syenite exported.

[8]Excludes trade between the Netherlands and Belgium-Luxembourg.

WORLD CONSUMPTION

World consumption of fluorspar in the aluminum and steel industries can generally be estimated with some degree of accuracy, but consumption in other end uses, notably fluorocarbons, is more difficult to estimate owing to scarcity of data.

As in the United States, consumption of fluorspar in the steel industries around the world varies according to furnace types and among individual furnaces. On the average, it is estimated that open hearth furnaces account for about 4.0 pounds of fluorspar per ton of crude steel; basic oxygen furnaces, 11.4 pounds per ton; and electric furnaces, 8.9 pounds per ton. While figures are not yet available for the division of steel production by process in 1976, it would appear from the International Iron and Steel Institute data for 1974 that 62% of total output from 24 reporting countries came from basic oxygen furnaces, 19% from electric furnaces, 16% from open hearth furnaces, and the balance from other types of furnaces. Thus, with the exception of the United States and Japan, free world consumption of fluorspar is estimated at 8.5 pounds per ton of raw steel on the average. In the United States an average consumption of 9.5 pounds per ton was reported. Japanese consumption, on the other hand, has continually been on the decline, owing largely to improved smelter technology and the use of substitute fluxes, particularly dolomite. It is probable that overall consumption in Japanese steel furnaces is about 4.0 pounds per ton, and it may be as low as 2.0 pounds per ton in 1977. In contrast, 65% of crude steel output from central economy countries is believed to evolve from open-hearth furnaces, 24% from basic oxygen furnaces, 10% from electric furnaces, and the remainder from other types of furnaces. Thus, it appears likely that fluorspar consumption in the steel industries of these countries may average about 6.6 pounds per ton of crude steel.

Estimated fluorspar consumption in the steel industries worldwide amounted to 2.73 million tons in 1976, compared with 2.56 million tons in 1975, (table 12), reflecting a general recovery in steel production. The United States and the U.S.S.R. continued as major consumers, accounting for 22% and 19%, respectively, of total consumption in this end use, followed by Japan (9%) and West Germany (7%).

The next major end use of fluorspar, particularly the acid-grade variety, is in the aluminum industry. In most countries, it is assumed that fluorspar is first converted into hydrofluoric acid, and subsequently into aluminum fluoride and synthetic cryolite. Based on current estimates, aluminum potlines around the world consume an average of 130 pounds of fluorspar per ton of primary aluminum produced.

Fluorspar consumption in the aluminum smelters worldwide is estimated at some 880,700 tons in 1976, up 3% from an estimated 854,300 tons in 1975, (table 13). As in the case of steel, major consuming countries were the United States and the U.S.S.R., accounting for 30% and 13%, respectively, of the total consumed in this category, followed by Japan (7%) and West Germany (6%).

Fluorspar consumption in fluorocarbon manufacture and other end use categories, while representing a significant portion of overall consumption, is not susceptible to close accounting owing to scarcity of data. It is generally believed, however, that the United States produces about half the world's supply of fluorocarbons and possesses half the world's installed uranium-enrichment capacity. These generalizations provide the basis for the estimates shown in table 14. Fluorocarbon production dropped slightly in 1976, and recovery is not anticipated in coming years in the face of environmental concerns over its usage. Consequently, acidspar demand in this end use is expected to exhibit a downturn in the short run, pending unfavorable legislation on fluorocarbon usage. On the other hand, fluorspar requirements in uranium enrichment are expected to expand by as much as 15% as nations develop alternative sources of nuclear energy to supplement energy from petroleum. Estimates of fluorspar consumption in petroleum alkylation, stainless steel pickling, glass and enamels, foundries, and miscellaneous other end uses are educated guesses and should be interpreted with caution.

Overall, world consumption of fluorspar in all categories is estimated at 4.57 million tons in 1976, compared with 4.41 million tons in 1975, reflecting a general recovery in the aluminum and steel industries. Steel production accounted for 60% of total consumption, followed by aluminum production (19%) and fluorocarbons (15%). Uranium enrichment, petroleum alkylation, stainless steel pickling, glass and enamels, foundries, and miscellaneous other end use categories accounted for the remaining 6% of total consumption.

TECHNOLOGY

Following the publication in 1974 of the Molina and Rowland theory suggesting that fluorocarbons could cause a depletion of stratospheric ozone,[12] many investigations were initiated to verify the theory. Results of these independent studies have recently been released by the National Academy of Sciences, the Environmental Protection Agency,[13] the Manufacturing Chemists Association,[14] the United Kingdom Department of the Environment,[15] and the United Kingdom Atomic Energy Authority.[16] Although estimates vary as to the extent of ozone depletion that can be attributed to fluorocarbon releases within certain time frames, the consensus appears to be that fluorocarbons are a legitimate cause for environmental concern.

The search for less-energy-intensive method of aluminum production led to the revolutionary Alcoa Smelting Process, implemented at midyear in a newly built smelter in Palestine, Tex. Based on the electrolysis of aluminum chloride, to which minor amounts of lithium chloride and sodium chloride are added, the process is expected to reduce power requirements to 5 kilowatt-hours per pound of aluminum, compared with 6.5 kilowatt-hours per pound in today's most efficient conventional smelters. Since no fluorides are used in the process, its impact on the fluorspar industry may be far reaching should it prove successful and be adopted in new smelters worldwide.

The Bureau of Mines continued its research into byproduct fluosilicic acid recovery from phosphate rock. Using phosphoric acid as an acidulating-defluorinating medium, it has been demonstrated that over 80% of the fluorine can be evolved and recovered as a dilute solution of fluosilicic acid. Meanwhile, new processes have been developed in the United Kingdom, Ireland, and West Germany for the conversion of fluosilicic acid into synthetic fluorspar and anhydrous hydrofluoric acid.[17]

In the Republic of South Africa, Gössling[18] investigated the feasibility of pelletizing acid-grade concentrates. Tests have shown that pellets of 95% effective CaF_2, with 0.5% sodium silicate as a binder, can be economically produced for export to the United States and Western Europe. In a separate report, Simonsen and Levin[19] discuss the beneficiation of a complex ore containing fluorspar, dolomite, and pyrophyllite, with minor amounts of quartz, muscovite, and chloritic and ferruginous material.

According to van Alstine,[20] major fluorspar districts are localized chiefly along and near continental rift zones and lineaments. This association of major fluorspar districts with continental rifts and lineaments is regarded as a regional guide in the search for new fluorspar deposits.

Gallium

By Benjamin Petkof[1]

The domestic gallium industry increased both production and production capacity during 1976. Data on rest-of-world production and consumption were not available. U.S. imports of gallium declined. Most gallium consumption continued to be in the production of various gallium compounds used to produce gallium-based electronic devices.

Legislation and Government Programs.—Gallium was classified by the Materials Transportation Bureau, U.S. Department of Transportation, as a hazardous material for purposes of transportation, and regulations were published in the Federal Register (September 2, 1976), effective September 4, 1976, specifying materials for the inner and outer packaging of gallium shipments. Gallium must be in the solid state during the time of transportation.

Table 1.—Salient gallium statistics in the United States

(Kilograms)

	1973	1974	1975	1976
Production	W	W	W	W
Imports for consumption	11,124	6,536	6,830	4,920
Consumption	8,496	6,939	7,493	8,880
Price per kilogram	$750	$750	$750-$800	$750-$800

W Withheld to avoid disclosing individual company confidential data.

DOMESTIC PRODUCTION

Domestic gallium production remained strong in 1976 and was estimated to have increased over that of 1975. Two companies with three facilities recovered metallic gallium in 1976. The Aluminum Co. of America (Alcoa), using proprietary gallium production technology at its Bauxite, Ark., alumina plant, recovered gallium as a coproduct from residues of its alumina production process. In addition, at midyear Alcoa announced the commencement of gallium recovery at its Mobile, Ala., alumina plant. Eagle-Picher Industries, Inc., continued to produce gallium metal, oxide, and trichloride from zinc production residues at its Quapaw, Okla., facility. Canyonlands 21st Century Corp. reprocessed gallium from gallium arsenide at its plant in Blanding, Utah. Other domestic companies produced high-purity gallium metal and gallium compounds such as arsenide, oxide, phosphite, and trichloride for the manufacture of electronic devices.

CONSUMPTION

Total domestic gallium consumption increased almost 19% over that of 1975. Electronic usage increased almost 12% and consumption for research and development increased more than sixfold. The quantity of metal used to prepare dental alloys declined significantly. The bulk of the gallium was consumed for the manufacture of electronic devices such as light-emitting diodes and other semiconductor devices. Most of the gallium used was high-purity metal. Gallium in the form of intermetallic

[1]Physical scientist, Division of Nonferrous Metals.

compounds such as arsenide, phosphide, and arsenide-phosphide was also used for the manufacture of light-emitting diodes and semiconductor devices. Gallium oxide was used for the preparation of phosphors.

The general acceptance of devices such as solid state calculators, digital clocks and watches, and visual display instrumentation using gallium-based components helped sustain the demand for gallium. Interest in the development of gallium-based solar-cells for the production of electricity and the use of gallium-based, light-emitting diodes as a source of light energy for transmission along fiber-optic cables may also stimulate future demand for gallium.

Table 2.—Consumption of gallium, by end use

[1]Consumers only.
[2]Ending stocks for 1975 do not equal 1976 beginning stocks because of reported beginning stock adjustments.

PRICES

Prices paid for gallium are not reported and are subject to negotiation between buyer and seller. However, during 1976 the American Metal Market quoted metal of 99.999% purity at $750 to $800 per kilo in 100-kilogram lots.

FOREIGN TRADE

Data on exports of gallium minerals are not reported separately but are included in the category "base metals and alloys, not elsewhere classified, wrought or unwrought, waste and scrap." Significant quantities of gallium and gallium compounds are probably exported in the form of manufactured gallium-based electronic components and equipment.

Total U.S. imports of gallium declined 28% in quantity and 35% in value from those of 1975. West Germany and Switzerland supplied 85% of these imports. The average value of imports was $473 per kilo.

Table 4.—U.S. imports for consumption of gallium (unwrought, waste and scrap), by country

Country	1975		1976	
	Kilograms	Value	Kilograms	Value
Canada	242	$129,745	214	$100,706
China, People's Republic of	--	--	50	19,633

Netherlands	269	147,920	40	21,078
Switzerland	6,001	3,103,364	1,799	873,854
United Kingdom	17	8,414	90	40,319
U.S.S.R	--	--	12	2,719
Total	6,830	3,555,355	4,920	2,326,176

WORLD REVIEW

World production and consumption data for gallium are not available. It is believed that significant quantities of gallium metal and compounds are consumed by countries with large, well-developed electronic and electrical industries. It is also thought that production of gallium declined in countries other than the United States.

TECHNOLOGY

A technique was described to successfully etch polish gallium phosphide single crystals using an aqueous solution of chlorine.[2]

A process was patented whereby gallium was extracted from sodium aluminate liquor formed in processing bauxite by the Bayer process. The liquor was cooled to about 60° C to precipitate the soda. The purified liquor was mixed with additional mother liquor and contacted with a liquid gallium-aluminum alloy to cause cementation of gallium from the liquor. The gallium was then recovered.[3]

Gem Stones

By W. Timothy Adams[1]

The production value of gem stones and mineral specimens in the United States during 1976 was estimated to be $8.9 million, an increase of 2% over that of 1975. Most of the value was contributed by the few companies that operated deposits for emerald, jade, opal, sapphire, and turquoise. Amateur collectors were important even though their total contribution was surpassed by the commercial operators. The commercial operators sold mainly to wholesale or retail outlets and occasionally to jewelry manufacturers.

DOMESTIC PRODUCTION

Mines and collectors in 39 States produced gem materials estimated at $1,000 or more for each State. Ten States supplied 90% of the total value as follows: Arizona, $4.0 million; Nevada, $1.3 million; Maine, $1.1 million; Oregon, $525,000; California, $231,000; New Mexico, $210,000; Montana, $170,000; Texas, $168,000; Washington, $168,000; and Wyoming, $147,000.

Park authorities at the Crater of Diamonds Park in Arkansas reported the finding of 398 diamonds, of which 1 was 3 carats and 3 were 2 carats each. No value was placed on the stones.[2]

A report was published on the evaluation of diamond-containing weathered kimberlite pipes in Colorado and Wyoming.[3]

A 200-carat emerald crystal was found at the Big Crabtree emerald mine near Little Switzerland, N.C. The stone appeared to be of fine quality and could yield a stone of 40 carats if cut. It would be larger than the Carolina emerald of 14 carats. Peridot was mined by about 200 individuals of the San Carlos Apache Tribe at Peridot, Ariz., and no estimate of quantity and value of the peridot was available.

The production of turquoise of all grades and quantities reported was 221 tons, valued at $3.9 million and was principally from Arizona, Nevada, and Colorado. The great interest in Native American style jewelry continued throughout 1976. Many articles appeared in various publications describing the qualities of genuine turquoise and Native American jewelry.[4]

CONSUMPTION

Domestic gem stone output went to amateur and commercial rock, mineral, and gem stone collections, objects of art, and jewelry. Apparent consumption of gem stones (domestic production plus imports minus exports and reexports) was $705 million, 51% more than that of 1975.

PRICES

Typical costs to a retail jeweler in December 1976 for representative better quality gem stones as reported by 15 typical importers were as follows:[5]

[5]Jewelers' Circular — Keystone. JC-K's Colored Stone Price Index. V. 147, No. 5, February 1977, p. 84.

Gem stone	Carat weight	Median price per carat	Price range per carat
Amethyst	10	$15	$11-$17.50
Aquamarine	8	120	75-260
Cat's eye	5	1,100	750-1,100
Citrine	10	8	5-10
Emerald	1	2,875	1,500-5,000
Garnet, green	1	475	400-600
Man's sky blue star	10	300	190-450
Opal, black	3	438	300-500
Opal, white, fiery	5	62	60-70
Peridot	10	50	45-60
Ruby	2	1,875	1,250-3,500
Sapphire	2	725	400-1,200
Tanzanite	5	300	150-250
Tourmaline, green	10	55	55-100
Tourmaline, pink	10	100	75-125

NOTES.—Ten-carat cat's eyes and 15-carat peridot, both of which were on the 1974 list, became unavailable during 1975, but the median price per carat of the smaller stones held at the levels of the larger stones.

No survey was made of diamond prices; price trends indicated higher prices for cut diamond 1 carat and smaller, but no change in larger cut diamond.

FOREIGN TRADE

Exports of all gem materials amounted to $326.7 million, and reexports to $155.5 million. Diamond accounted for 94% of the value of exports and 92% of the reexports. Exports of diamond totaled 312,853 carats valued at $306.1 million. Of this total, diamond cut but unset, suitable for gem stones not over 0.5 carat, was 53,375 carats valued at $21.1 million; and cut, but unset, over 0.5 carat was 258,738 carats valued at $284.9 million.

Reexports of diamond amounted to 1,198,805 carats, valued at $142.7 million, in categories as follows: Rough or uncut, suitable for gem stones, not classified by weight, 1,025,183 carats valued at $88.9 million; cut but unset, not over 0.5 carat, 45,127 carats valued at $9.2 million; cut but unset, over 0.5 carat, 128,450 carats, valued at $44.6 million.

The 10 leading recipients of diamond exports accounted for 89% of the carats and 98% of the value and were as follows: Hong Kong, 98,102 carats valued at $132.5 million; the Netherlands, 39,033 carats valued at $39.7 million; Switzerland, 32,480 carats valued at $37.2 million; Japan, 46,924 carats valued at $33.5 million; Belgium, 25,827 carats valued at $25.8 million; France, 6,288 carats valued at $14.5 million; West Germany, 5,416 carats valued at $7.1 million; the United Kingdom, 4,671 carats valued at $4.7 million; Israel, 9,670 carats valued at $3.2 million; and Canada, 8,952 carats valued at $2.3 million.

The eight leading recipients of diamond reexports accounted for 96% of the carats and 97% of the value and were as follows: Belgium, 432,030 carats valued at $41.1 million; Israel, 403,017 carats valued at $34.3 million; the Netherlands, 213,537 carats valued at $25.2 million; the United Kingdom, 32,830 carats valued at $11.7 million; Switzerland, 7,832 carats valued at $8.9 million; France, 20,884 carats valued at $6.9 million; Japan, 26,764 carats valued at $5.6 million; and Hong Kong, 10,797 carats valued at $4.5 million.

Exports of all other gem materials amounted to $20.6 million. Of this total, pearls, natural and cultured, not set or strung, were valued at $0.6 million. Natural precious and semiprecious stones, unset, were valued at $18.0 million; and synthetic or reconstructed stones, unset, were valued at $2.0 million. Reexports of all other gem materials amounted to $12.8 million in categories as follows: Pearls, $0.8 million; natural precious and semiprecious stones, unset, $11.8 million; synthetic or reconstructed stones, unset, $0.1 million.

Imports of gem materials increased about 39% in value over those of 1975. Diamond accounted for 86% of the total value of gem material imports.

Although rough and uncut diamond imports were reported from 24 countries, over 99% of the value was from 9 countries as follows: The Republic of South Africa, 1,194,128 carats, $257.2 million; the United Kingdom, 494,884 carats, $113.8 million; Sierra Leone, 331,554 carats, $42.9 million; the Netherlands, 50,393 carats, $20.5 million; Israel, 38,573 carats, $8.2 million; Belgium-Luxembourg, 37,885 carats, $6.7 million; Venezuela, 260,066 carats, $6.0 million; Liberia, 2,790 carats, $2.9 million; and the Central African Republic, 36,006 carats, $2.2 million.

Cut but unset diamond, not over 1/2 carat, was imported from 38 countries; however, the imports of this category from 10 countries amounted to 99% of total carats and value as follows: Israel, 1,100,253 carats, $178.7 million; Belgium, 1,011,991 carats, $157.1 million; India, 498,996 carats, $64.7 million; the Netherlands, 68,419 carats, $9.6 million; the U.S.S.R., 35,794 carats, $8.1 million; the Republic of South Africa, 13,747 carats, $3.7 million; Switzerland, 12,673 carats, $1.7 million; the United Kingdom, 11,243 carats, $1.6 million; France, 9,276 carats, $1.9 million; and Hong Kong, 8,981 carats, $1.3 million. Cut but unset diamond, over 1/2 carat was imported from 30 countries; the imports from 9 countries amounted to 99% of the total carats and 98% of the value as follows: Belgium, 156,083 carats, $66.8 million; Israel, 102,563 carats, $32.5 million; the Republic of South Africa, 8,178 carats, $6.0 million; the Netherlands, 9,717 carats, $3.3 million; the U.S.S.R., 6,660 carats, $2.5 million; the United Kingdom, 2,661 carats, $2.0 million; Switzerland, 1,142 carats, $1.1 million; India, 3,389 carats, $0.8 million; and Hong Kong, 860 carats, $0.7 million.

Imports of emeralds increased 45% in quantity and 37% in value. Emerald was imported from 33 countries; the imports from 9 countries amounted to 96% of the carats and 94% of the value as follows: Colombia, 57,252 carats, $21.6 million; India, 578,780 carats, $9.7 million; Switzerland, 28,457 carats, $6.9 million; Brazil, 207,620 carats, $3.8 million; Israel, 76,805 carats, $2.7 million; the United Kingdom, 76,069 carats, $2.5 million; Hong Kong, 49,730 carats, $2.1 million; West Germany, 34,817 carats, $1.7 million; and France, 3,745 carats, $1.1 million. Ruby and sapphire were imported from 34 countries; the imports from 7 countries amounted to 91% of the value as follows: Thailand, $15.6 million; Sri Lanka, $2.3 million; India, $2.0 million; Switzerland, $2.0 million; Hong Kong, $1.8 million; West Germany, $0.7 million; and Canada, $0.4 million. Natural pearls and parts from 11 countries increased 12% in value of imports; 5 countries accounted for 91% of the value as follows: India, $371,000; Japan, $104,000; France, $85,000; Burma, $82,000; and Hong Kong, $48,000. Cultured pearls increased 52% in value of imports which were received from 20 countries of which Japan, at $10.6 million, accounted for 95% of the value. Imports of imitation pearls increased 32% in value; Japan, at $569,000, accounted for 84% of the value. Coral, cut but unset, and cameos suitable for use in jewelry increased slightly in value of imports, which were received from 20 countries; 3 countries accounted for 94% of the value as follows: Italy, $3.4 million; Taiwan, $1.5 million; and Japan, $1.2 million.

Imports of other precious and semiprecious stones, rough and uncut, increased 30% in value and came from 46 countries of which 7 countries accounted for 78% of the value as follows: Brazil, $2.5 million; Australia, $2.0 million; Colombia, $1.1 million; Hong Kong, $0.3 million; India, $0.2 million; the Republic of South Africa, $0.2 million; and Zambia, $0.2 million. Other precious and semiprecious stones, cut but unset increased 26% in value and were imported from 59 countries, of which 7 countries accounted for 87% of the value as follows: Hong Kong, $15.4 million; Brazil, $5.3 million; West Germany, $3.5 million; Australia, $2.9 million; Taiwan, $1.5 million; Iran, $1.0 million; and India, $1.0 million. Synthetic gem stones, cut but unset, increased 26% in value and came from 17 countries of which 6 countries accounted for 96% of the value as follows: West Germany, $5,639 million; France, $1,226 million; Switzerland, $1,191 million; Japan, $1,099 million; Taiwan, $0.272 million; and Hong Kong, $0.259 million. Imitation gem stones increased 9% in value and came from 18 countries, of which 5 countries accounted for 98% of the value as follows: Austria, $4,959 million; West Germany, $2,618 million; Czechoslovakia, $0.961 million; Japan, $0.252 million; and Hong Kong, $0.106 million.

WORLD REVIEW

Australia.—Turquoise was discovered in Australia in 1967. The deposits are located in the remote central region of the Northern Territory approximately 265 miles northeast of the railhead at Alice Springs. The turquoise occurs in a series of Cambrian siltstone-mudstone beds that form part of the Sandover Beds of the Georgina Basin. A range of phosphate types is produced from the mine. Microscopic and X-ray diffusion examination have shown the typical high-grade material to be composed of very-fine-grained, close-packed nodules of turquoise. The turquoise has been formed by the chemical combination of phosphates and alumina in the phosphate-rich beds and copper leached from the overlying copper-rich tuffaceous siltstones. Mining is by open-cut methods. Specimens up to three-quarters ton have been recovered. Proven reserves are considerable, and continuity of supply is offered. A wide range of material is available for gem cutters and the carving trade. The area is not open to collectors and hobbyists.[6]

New markets for Australian opals are being opened both at home and in Japan. Stones from Cooper Pedy and Andamooka are being used in a variety of styles in watch bracelets and pendants. A new manufacturing process is reported to insure high durability of the stone.[7]

Botswana.—A new tax regime instituted by the Government of Botswana established an effective partnership between the Government and the De Beers Group. The Orapa mine produced 2,360,945 carats of diamond from 3,428,985 tons of ore in 1976. Construction work is in progress at Orapa to increase the capacity of the mine from 2.3 million carats to 4.5 million carats per year. The new Letlhakine mine, 24 miles southeast of Orapa was commissioned, and production began at the rate of 320,000 carats per year. The mine treated diamondiferous gravels surrounding the pipe. Design work was in progress for the second stage of development to treat the kimberlite. Prospecting continued at a kimberlite pipe discovered in Jwaneng in the south of the country. The pipe is overlain by 150 feet of overburden and represents a considerable technical achievement. A drilling program has established that the pipe is large and contains diamond in economic quantities.[8]

Burma.—The Mogok ruby that made Burma one of the gem capitals of the world has also been the cause of the country's plunder by smugglers and black marketeers. The gem industry was nationalized in 1969, and 18 kinds of precious stones including rubies, sapphires, and jade were brought under official control. Officials admit that thieves are still active despite strong security at the mines.[9]

[1] Less than 1/2 unit.

Significant quantities of Burmese jadeite ends up in Thailand through various smuggling routes. The price of fine apple and emerald green jadeite is such that a market has been created for the once-neglected yellow, red, and apricot colors. Much of the yellow and red material being offered is not jadeite but dyed quartz. The fraud may be detected by concoidal fractures on a chipped edge rather than the fibrous fracture displayed by jadeite.[10]

Colombia.—Two years ago small emeralds of little commercial value were discovered in alluvial sands near the small town of Yacopi. The discovery coincided with the closing of Muzo, the major emerald mine in Colombia. The increasing production from the Yacopi area gives evidence to the belief that soon something of real value will be discovered there. A major find at Yacopi would give Colombia a new source of foreign exchange.[11]

Guatemala.—Rough Maya jade will be made available to wholesale gem distributors and rockhounds. The jadeite is of excellent carving quality. The colors range from a pearly white and a richer green to a dark green that appears black when polished. The quality of the jade has been evaluated, and it compares favorably with Wyoming jade. Larger rough-cut boulders have been exported to Hong Kong for statue carving.[12]

Lesotho.—The Letseng-la-Terai mine began producing at a rate of 4,000 tons of ore per day. Systematic mining began in May with the object of exposing hard kimberlite at depth and stockpiling the overlying soft weathered kimberlite. At yearend, 500,000 tons of the weathered kimberlite had been stockpiled. The profitability of the mine depends on the production of a comparatively small quantity of large, high-quality stones.[13]

India.—The Indian diamond industry, which is export-oriented and cottage based, has grown twelvefold in the past decade and now provides employment to approximately 150,000 workers, mostly skilled artisans. The United States has emerged as one of the principal buyers of Indian diamond accounting for more than 27% of India's exports. India's share in the world diamond trade is about 7% to 8% in terms of value and 1.2% to 1.5% in terms of caratage. A combination of skills developed over the years and low production costs have enabled India to specialize in the polished small diamonds known as "makeables." The bulk of India's raw material requirments, namely, rough diamonds, is supplied by the Diamond Trading Company (DTC), London. The outlook for the industry is encouraging.[14]

Iran.—Iranian production of turquoise from March 21, 1975 to March 20, 1976, was reported as 68.2 short tons. Proven reserves were reported as 11,000 short tons and resources as 22,000 short tons.[15]

Pakistan.—The Government of Pakistan decided to set up an organization to buy uncut emeralds, diamonds, and other precious stones from the mines at Swat in the North West Frontier Province and export them in finished form. The mines have been sealed by the police and mining operations suspended for the present. Of the 800 carats of emerald produced per month, a large proportion was said to be smuggled out of the country.[16]

South Africa, Republic of.—The Central Selling Organization reported diamond sales in 1976 of $1,555 million, 46% greater than in 1975. During 1976, sales exceeded production, and the excess was provided from stocks. The Central Selling Organization increased the price of diamond twice in 1976, by 3% in January and 6% in September. The demand for the smaller sizes and the lower qualities of larger diamonds was very strong in 1976. Toward the end of the year, there was improvement in demand for better quality large stones. No breakdown of gem stones or industrial diamond sales was given.[17]

South-West Africa, Territory of.—The Consolidated Diamond Mines of South-West Africa (Proprietary) Ltd. reported an increase in ore treated in 1976 to 14,167,067 short tons, from 13,498,048 tons in 1975. The average stone size increased from 0.73 carat per stone to 0.95 carat per stone in 1976. Overburden stripped increased from 46,389,670 short tons in 1975 to 54,996,027 tons in 1976. Diamond production decreased to 1,693,994 carats in 1976 from 1,747,739 carats in 1975.

Further refinements made to the dewatering systems and stability improvements to the sea wall enabled operations to advance 150 feet further seaward of the high water mark. Fewer minor breakdowns were experienced with the bucketwheel excavator during the year, but three major component failures decreased overall availability.

Thailand.—Many of Thailand's precious and semiprecious stone mines are nearing depletion, resulting in a marked increase in importation of blue sapphires from Australia. Smuggling of gem stones from Burma and Cambodia also increased.[18]

U.S.S.R.—Soviet geologists are reported to have made diamond finds in ancient Timan paleozoic deposits west of the Urals.[19]

The Frankfurt diamond bourse has gone into receivership. German promoters attempted to make Frankfurt a world diamond market using cutters from Idar-Oberstein to challenge the dominance of Israel, Antwerp, New York, and Bombay. Breaking into a trade that is divided between De Beers and the many Israeli and Belgian craftsmen was too big a task for the Germans even with Soviet help.

It is reported that the U.S.S.R. has opened an export office in Antwerp under the name of RUSSALMAZ MV. It is also reported that the U.S.S.R. is selling the bulk of its finished goods to the Diamond Trading Co. marketing network since attempts to compete directly had failed.[20]

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Total (gem plus industrial) diamond output for each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of every country except Lesotho (1974-75), Liberia (1974), Venezuela (all years), and Zaire (1974-75) where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.
[2]Exports of diamond originating in Lesotho; excludes stone imported for cutting and subsequently reexported.
[3]Exports.
[4]Partial figure; January 1 through December 15 only.
[5]All company output from the Republic of South Africa except for that credited to the Premier mine; also excludes company output from the Territory of South-West Africa and Botswana.

TECHNOLOGY

Ruby crystals were subjected to a static pressure greater than 1 megabar in a diamond-windowed pressure cell. The pressure was monitored continuously by observing the spectral shift of the sharp fluorescent Ri ruby line excited with a calcium-helium gas-diffusion laser beam. One megabar appears to be the highest pressure ever reported for a static experiment in which an interval calibration was employed. The accessibility of this pressure range, coupled with the high temperature already reached, makes it possible to experiment directly at the conditions of the earth's core.[21]

General Electric (GE) scientists successfully tested a new machine that can apply pressures greater than 8 million pounds per square inch. To achieve and maintain these pressures, GE created a pair of tungsten carbide pistons tipped with the company's manufactured industrial diamonds. The apparatus will be used to study changes that occur in materials under high pressures and temperatures.[22]

Two distinct suites of minerals included in natural diamond are described. It is indicated that they probably represent different physical and chemical conditions during diamond growth. Detailed mineralogical and chemical study of the minerals included in diamond during its growth can provide significant data regarding the chemistry and physics of the upper mantle, as well as providing insight into the genesis of diamond.[23]

A detailed analysis of the composition of gaseous inclusions in seven Arkansas diamonds ranging in size from 0.37 to 2.06 carats and containing other inclusions was made by mass spectrographic techniques. The released gases were found to be of variable compositon and similar to those reported earlier from diamonds of African origin. Based on the tentative assumption that the gases are genetically related to the host diamond, a theoretical gas-solid diamond growth model was presented, which can account for the observed compositional variations in the included gases.[24]

There are three significant features in the typical appearance of opal that provide clues to the mechanism responsible for the color display: (1) The color is associated with small grains, and throughout each grain the color is fairly uniform, (2) the color of the grains changes as the orientation of the stone is changed with respect to the light source and the observer, and (3) generally the colors are spectrally pure. Electron micrographs revealed regular geometric patterns of tiny holes across the entire surface of a grain. These arrays of holes are sufficiently regular to act as three-dimensional diffraction gratings that give rise to the stones' characteristic fire.[25]

The Spencer mines in Idaho produced gem opal, which not only has the intense color of Australian doublets and triplets, but has an additional feature of displaying a star of brilliant colors. There are three types of stars to be found among the Idaho gems: A cat's eye stone that exhibits a single streak of dispersed colors across the triplet, a three-ray star, and a six-ray star. Stars such as these have not been reported for Australian opal.[26]

Two major techniques, flux and hydrothermal, have been used to grow emerald crystals, and various solvents have been employed. The lithium molybdate flux has proved to be commercially viable in the hands of Chatham and Gilson. Hydrothermal work, using two acid mineralizers, which gave satisfactory growth, did not prove to be commercially viable.[27]

Color changes were observed on gamma-ray irradiation of over 500 colorless, pink, blue, and green tourmalines. The only significant changes observed were the development or intensification of pink or the development of yellow superimposed on the preexisting color. Some of these colors are stable to heat, and some are not.[28]

The well-known brown color produced by the irradiation of topaz has been reexamined particularly with respect to the kinetics

of the color formation. The known color is produced at two different rates. Heating to 200 for a few hours removes essentially all the color of the specimens tested.[29]

A completely new comparison microscope assists the geologist and mineralogist in the accurate identification of minerals by color. The Lovibond-Nelson microcolorimeter is based on an optically linked pair of microscopes using a single light source. Accurately graded glass filters are calibrated to the Lovibond subtractive color system and give an optical match with a sample.[30]

An automatic cutting machine, The Piermatic, an English invention, cuts small diamond stones with efficiency and consistency of make. Machines are in use in Israel, New York, and Puerto Rico. Use of the machine is usually limited to stones of about 30 points.[31]

Modern technology in the form of aerial photographs offers major assistance to mineral collectors. Photograph prints available from film libraries show settlers' homesteads, derelict railways, ghost towns, or any kind of habitation or clearing. Fifty-year-old bush trails show plainly no matter how overgrown they have become. Careful study of photographs will often save many miles of wandering in search of prospective sites.[32]

Gold

By John M. West[1] and W. C. Butterman[2]

A 22% drop in the price of gold discouraged producers and favored consumers in 1976. International Monetary Fund (IMF) sales, totaling 3.9 million ounces, had a major impact on prices, which reached a low in August after the second sale had taken place. Thereafter, prices tended to recover despite additional sales. Another factor in prices was the accelerated sale of gold to U.S. markets from stocks of foreign-owned metal on deposit at the Federal Reserve Bank in New York City which amounted to 2.13 million ounces in 1976 versus 0.58 million ounces in 1975. During the year, an increasing quantity of unaccountable gold apparently was accumulated in private stocks being held for speculative and investment purposes. Reported stocks of industry and trading firms increased 0.14 million ounces. Exports (nonmonetary) exceeded imports in 1976 by 0.22 million ounces, up from 0.03 million ounces excess in 1975. Consumption was 0.66 million ounces higher than in 1975.

Refined production from domestic primary and secondary sources declined 13% and 7% respectively. Mine production was down slightly, mostly because of the closing of the Cortez mine in Nevada. Heap leaching of gold, a recently developed technology, provided 3% of U.S. production, slightly less than in 1975. Because of price drops, some producers chose to hold gold in unrefined form in anticipation of higher prices. Similarly, the supply of gold to scrap processors was somewhat less because refining and turnaround time was a less significant factor with dropping prices, and scrap was held for improved markets.

Futures trading in gold was active, mainly in the New York and Chicago markets, with volume about 15% higher than in 1975. In New York, Commodity Exchange Inc. (COMEX) had a trading volume of 48 million ounces compared with 36 million in 1975; in Chicago, the International Monetary Market (IMM) reported a volume of 34 million ounces compared with 36 million ounces in 1975. Monthly volume of the COMEX ranged between 1.9 million ounces in April and 8.75 million ounces in December. An exceptional jump was noted from October, when volume was 2.90 million ounces, to November, when volume was 8.51 million ounces. December 13 was a record day for trading when 1.08 million ounces changed hands. On the IMM, monthly volume ranged from 1.83 million ounces in April to 4.74 million ounces in November, while December volume declined to 3.88 million ounces. Gold moved into and was delivered from the exchanges and the net stocks declined about 0.2 million ounces during the year.

IMF gold sales began in midyear for the purpose of providing capital for low interest loans to developing countries. Dates of sales were as follows: June 2, July 14, September 15, October 27, and December 8. Each sale amounted to 780,000 ounces, except for the October sale, which was 779,200 ounces. The gold was delivered at the Federal Reserve Bank in New York, except for that from the December sale, which was delivered in London. Sales in June, July, and December were by the common lowest-accepted-price Dutch auction method; the others were by the bid price method. Prices were $126, $122.05, and $137 per ounce in the June, July, and December sales, and averaged $109.40 and $117.71 in the September and October sales. The IMF planned to sell a total of one-sixth of its stocks, or 25 million ounces, over a 4-year period, and planned to restore an equal portion to member countries. Restitution was scheduled to begin in January 1977, and it was uncertain whether central banks receiving such gold would place it on the market immediately or hold it for the longer term.

---

[1]State liaison officer, Bureau of Mines, Salem Oreg.
[2]Physical scientist, Division of Nonferrous Metals.

The Bank for International Settlements (BIS) estimated an increase in 1976 of world gold supplies by 25% to 45.2 million ounces from all sources, including primary production of 30.4 million ounces, net sales from centrally planned economies of 11.3 million ounces (up 75% from 1975), and 3.5 million ounces from official gold stocks. Gold reserves of the South African Reserve Bank declined 5.14 million ounces, mainly because of an agreement between a group of commercial banks and the Reserve Bank to swap gold, which was similar in effect to a futures trade; however, this had no impact on overall stock balances. The BIS reported that fears of revived inflationary pressures and disappointment with performance of equity markets probably contributed to an increased investment demand for gold.

World consumption was up 29%, according to Consolidated Gold Fields Ltd., largely stimulated by an increased demand for jewelry and investment items, such as small bars for delivery in the Middle East and the Far East. Fabrication in karat jewelry rose 83%. Sales of South African krugerrand gold coins containing 1 troy ounce per coin declined to 3.0 million ounces content compared with 4.7 million ounces in 1975. To expand sales, International Gold Corp., the krugerrand marketing agency, launched a major advertising campaign. Private bullion purchases, excluding coins, were estimated to have dropped sharply to 2.9 million ounces from 5.3 million ounces in 1975. U.S. Treasury stocks of gold were lower at yearend owing to use of gold in Bicentennial medals, which were sold by the American Revolution Bicentennial Administration and manufactured by the Bureau of the Mint. Gold content of the medals sold was 22,756 ounces, and sales, which were by subscription, totaled $6.8 million. The Royal Canadian Mint issued two gold coins in commemoration of the Olympic Games consuming about 0.34 million ounces of fine gold in 1 million coins.

Table 1.—Salient gold statistics

	1972	1973	1974	1975	1976
United States:					
Mine production thousand troy ounces	1,450	1,176	1,127	1,052	1,048

[4]Gold content of all products in stocks held by manufacturers, and refiners, 1972-74; gold content of bullion only in 1975 and 1976 (excludes trading stocks). Stocks at beginning of 1975 amounted to 1,896,000 ounces of bullion.
[5]Engelhard Industries quotations.
[6]Held by market economy central banks and governments; gold valued at $38 per troy ounce in 1972, and $42.22 per ounce in 1973-76.

Legislation and Government Programs.—Public Law 94-450, The Gold Labeling Act of 1976, which amended the Act of June 13, 1906, and reduced permissible deviation in gold content of articles made in whole or part of gold, was signed October 1, 1976. The tolerance was reduced from 1/2 of 1 karat to 3 parts per thousand for most articles, or if soldered, to 7 parts per thousand. The Act was to take effect 5 years after the date of enactment and was not to apply with respect to any article of merchandise sold by any manufacturer or importer before the effective date of October 1, 1981. The purpose of the act was to assist the domestic industry to meet the requirements of foreign countries, thereby increasing U.S. exports. A major U.S. supplier to the jewelry industry announced it would entirely remove tolerances from its gold products as of January 1, 1977.

The U.S. Customs Service issued a statement repealing parts of the Gold Reserve Act of 1934 in conformance with current public laws.[3] The section repealed applied to a provision that importation and exportation were governed by laws administered by the Department of the Treasury. Public laws that went into effect December 31, 1974, say that no provision of any law, and no rule, regulation, or order in effect on that date may be construed to prohibit any person from purchasing, holding, selling, or otherwise dealing with gold in the United States or abroad.

The Commodity Futures Trading Commission voted to permit continued trading of leverage contracts in gold and silver bullion and coins while it drafted more stringent regulations on such trading. The Commission released a study of leverage transactions and proposed a number of restrictions it might impose in accordance with its authority which is specified in the Commodity Futures Trading Act of 1974. Several proposals to establish gold bullion options trading markets were delayed pending actions by the Commission.

DOMESTIC PRODUCTION

Closure of the Cortez mine in Nevada resulted in a 13% drop in Nevada production; however, increases in output from the Homestake mine in South Dakota, a placer operation at Nome, Alaska, and copper mines in Arizona and Montana offset most of the drop, and U.S. production was only slightly below that of 1975. Byproduct production supplied 36% of all primary gold output, the same as in 1975, and most of this was from copper ores mainly mined by open pit methods. Placer gold production rose from 2% to 3% of the total output in 1976 as a result of increased dredging at Nome. Alaskan sources provided 82% of the placer total.

Five leading producers accounted for 68% of U.S. production. These were Homestake Mining Co., Carlin Gold Mining Co., Kennecott Copper Corp., Standard Metals Corp., and Duval Corp. Operations in the list of 25 leading mines (table 5) supplied 95% of all production, and a large number of mines provided the remaining 5% which amounted to 55,752 ounces. Lode mines reporting gold as a principal product totaled 74, and as a byproduct, 100. Placer mines totaled 49, the same as in 1975. California and Colorado placer production included gold recovered at sand and gravel producing plants. Cyanidation was used in recovering 56% of all gold, and mercury amalgamation, 2%; 40% of all gold came from 5.9 million tons of smelted concentrates. Mills treated 290.6 million tons of ore, but most of this was copper ore in which gold was a minor constituent.

Gold refiners reported production of 3.58 million ounces of refined bullion, 11% less than in 1975 (table 10). Domestic ores and concentrates supplied 27% of the total refined, and 3% was contained in imported ores and concentrates. Scrap provided the remainder with the contribution from new scrap exceeding that from the old scrap. The total amount reported from scrap was 7% lower than in 1975.

[3]Federal Register. Rules and Regulations, Title 19 - Customs Duties, Chap. 1, U. S. Customs Service, Department of the Treasury. V. 41, No. 11, Jan. 16, 1976, p. 2383.

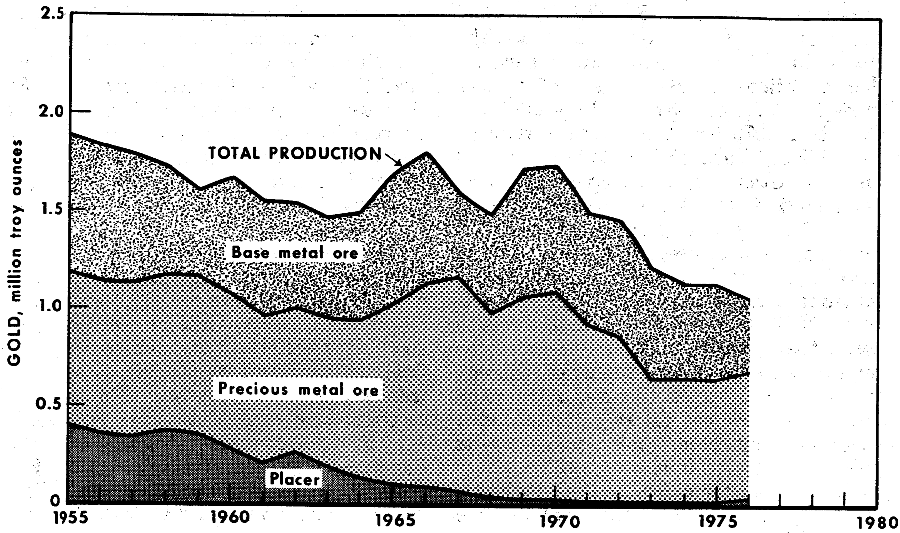

Figure 1.—Sources of U.S. gold production.

The ASARCO, Inc. Perth Amboy, N. J., refinery was closed in March 1976 and remaining gold refining operations were transferred to the company's new Amarillo, Tex., plant. AMAX Inc. produced 716,450 ounces of refined bullion at its Carteret, N. J., refinery in 1976, 15% less than in 1975. Homestake Mining Co. refined all its own production, which was up 4% in 1976, and refined some purchased or tolled material at its Lead, S. Dak., refinery. A number of secondary refiners were active in scrap processing.

Homestake Mining Co. reported an operating loss of $1.5 million in 1976 compared with $13.9 million operating earnings in 1975. In 1976, gold bullion sales were valued at $39.8 million from its Lead, S. Dak., mine. The average price realized from gold sales was $124.71 per ounce compared with $163.58 in 1975. Production was reported at 318,487 ounces from 1.66 million tons of ore, with an average recovery grade of 0.192 ounce per ton, slightly less than the 0.207 ounce figure in 1975. Gold recovery was 95.1%. Mine production came mainly from cut and fill stopes on the 7, 9, 11, 13, 19, and 21 ledges above the 6,800 level. Several shrinkage stopes and a blast hole stope located on the 2,300 level also contributed. The company completed 74,000 feet of underground exploration drilling above the 6,800 level and found additional ore in the 12 and 19 to 21 ledge areas. Ore reserves totaled 14.3 million tons averaging 0.229 ounce per ton at yearend 1976 versus 15.3 million tons averaging 0.264 ounce per ton in 1975. Construction of a new tailings dam and pumping system for pollution control was 80% complete at yearend. A 3-year labor agreement was signed in mid-1976.

The Carlin Gold Mining Co., owned by Newmont Mining Corp., reported production of 208,000 ounces of gold from 861,000 tons of ore milled in 1976; the grade averaged 0.272 ounce per ton. Production was down 2% from that in 1975, and grade was down from 0.292 ounce per ton. The tonnage of ore and waste mined more than doubled to 12.6 million tons because of modifications to open pit designs in reaching for deep ore under the main Carlin Pit. Production was mostly from the Carlin mine but included 136,731 tons averaging 0.093 ounce per ton from the Blue Star mine and 129,700 tons from the Bootstrap mine. Sales were valued at $25.9 million in 1976, 22% lower than in 1975. Ore reserves at the end of 1976, excluding 700,000 tons of high carbon material still under evaluation, totaled 5.27 million tons averaging 0.208 ounce per ton compared with 5.0 million tons averaging 0.221 ounce per ton at the end of 1975. Also, 0.8 million tons of 0.025 ounce per ton material was stockpiled from the Blue Star and Bootstrap mines for possible future extraction. A new double-oxidation cyanide process was developed for treating refractory carbonaceous ores, and additional chlorine leaching equipment was installed.

Cortez Gold Mines closed its Cortez mill in August 1976 after exhausting ore reserves at the Cortez and Gold Acres mines.

Only 9,000 ounces of gold was produced by milling, but an additional 18,700 ounces was produced by heap leaching. This compared with 48,500 ounces by milling and 25,400 ounces by leaching in 1975. Recovery of milled gold was down slightly to 77% and grade averaged 0.084 ounce per ton. Mining equipment was sold in September and most of the mill was "mothballed" pending further exploration.

At Republic, Wash., Day Mines, Inc. negotiated to acquire the Knob Hill Mines, Inc. property and facilities and planned further exploration. Day Mines produced 3,379 tons of ore averaging 0.643 ounce of gold per ton and 1.62 ounce of silver per ton from its Gold Dollar Lease, and its share of the No. 3 joint operation with Knob Hill was 6,890 tons averaging 0.441 ounce of gold per ton and 2.27 ounce of silver per ton.

Alaska Gold Co., owned by UV Industries, Inc., operated its No. 5 bucketline dredge at Nome and reequipped a second dredge located near the Nome airport. The company's smaller bucketline dredge at Hogatza in the Fairbanks area was idle. Northgate Exploration Ltd. and Westfield Minerals Ltd. drilled from ice flows to test offshore gold placer possibilities near the mouth of Daniels Creek, Alaska. ASARCO held leases to offshore gold deposits near Nome, Alaska, awaiting higher gold prices.

Bucketline dredging at the Yuba Goldfields Inc. property, Hammonton, Calif., was suspended in early 1976 because of inadequate returns. The unit had produced 5,600 ounces since startup in May 1975. Earth Resources Co. expected to begin silver-gold cyanide leaching at Delamar, Idaho, in early 1977. The property was scheduled to produce 15,000 ounces of gold annually, treating 1,700 tons of ore per day. Placer Amex Inc. terminated an agreement with Nevex Mines to explore and develop Nevex's Thunder Mountain, Idaho, gold properties. Ores generally containing 0.1 ounce of gold per ton were found during the project. Kennecott Copper Corp. shipped dump material and did development work on its Mammoth gold mine in the Tintic district of Utah. Smoky Valley Mining Co. rescheduled startup of a major heap leach gold facility at Round Mountain, Nev., delaying initial production until 1977. Standard Slag Co.'s new Atlanta mine in Nevada produced at capacity during 1976.

CONSUMPTION AND USES

U.S. consumption of gold in industry and arts, based on conversion of bullion into primary products, totaled 4.65 million ounces in 1976, 16% higher than in 1975. Consumption by end use was as follows, in thousand ounces (with 1975 figures in parentheses): Jewelry and arts, 2,562 (2,080); dental, 694 (595); industrial, 1,233 (1,059); and investment products, 159 (258). Jewelry and arts accounted for 55% of consumption; dental, 15%; industrial, 27%; and investment products, 3%. An estimated 66% of all gold went into products containing over 40% gold by weight (karat golds, dental alloys, investment products), the same as in 1975; 15% was used in electroplated products, and the rest went into rolled, gold-filled, and other forms of products. U.S. consumers also purchased gold in the form of imported gold coins, generally 900 fine or better, amounting to 1.33 million ounces content, 20% less than in 1975.

Generally, less effort was reported in reducing use of gold in 1976 owing to price declines, although research and application of more efficient fabrication techniques continued at a high level. Jewelers reported sales increases in 14-karat and gold-filled products surpassing those in more expensive items. Two-tone gold was said to be increasingly popular. Scrap refiners indicated reduced values of gold in electronic scrap and increased silver owing to more widespread silver-plating as a substitute for gold. Gold was reported to be "holding its own" in the electronic connector industry—despite efforts at substitution—owing to its outstanding properties in connecting such items as circuit boards.[4] Goldless tin alloy connectors were reported to have made market inroads, but the trend may have been reversed.[5] Selective and thinner plating and the use of smaller plated dots for contact points led to more efficient use of gold by many firms. The thick fiber process

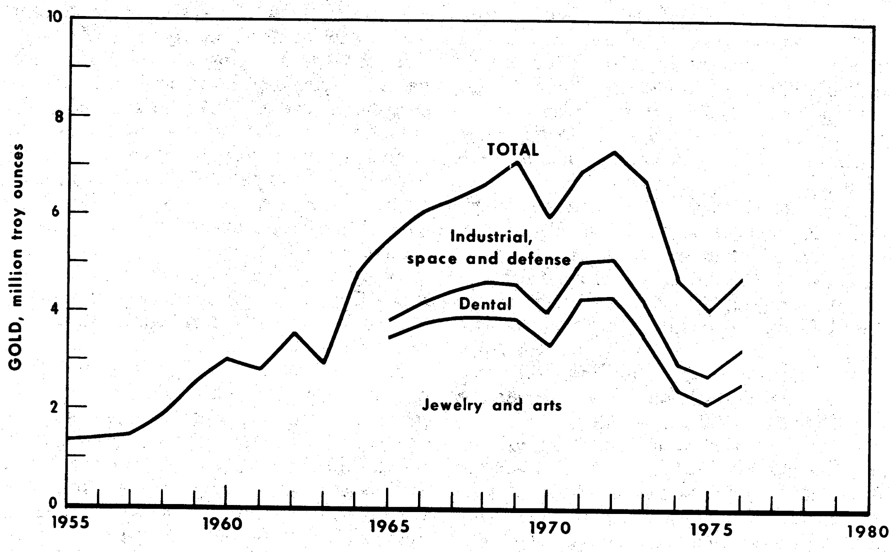

Figure 2.—Gold consumption in the United States.

of applying gold to various kinds of electronic parts was described, and the possible eventual substitution of thick-fiber copper pastes was suggested.[6] Palladium-gold conductors were compared with pure gold conductors for performance characteristics. Inlay-clad gold was used increasingly as an alternative to electrodeposited gold in electronics, with particular interest shown by telephone equipment manufacturers. An excellent description of the properties of inlay-clad products was published.[7] A growing and significant portion of dental alloys was being converted to nongold products or alloys of lower gold content. A large manufacturer expanded its line of full karat gold solders to assist users in complying with requirements of the New Gold Act requiring jewelry manufacturers to meet more exacting standards in 1981.[8]

STOCKS

Monetary.—U.S. Treasury gold stocks were valued at $11,598 million at yearend 1976, $1 million lower than at yearend 1975, and amounted to 274.70 million ounces. Monetary gold stocks remained officially valued at $42.22 per troy ounce, but no gold was bought or sold at that price. Earmarked gold held in Federal Reserve Banks for foreign official accounts amounted to 388.77 million ounces, down 7.84 million ounces from yearend 1975. Gold went to both domestic and export markets. Movements out of the Federal Reserve Bank included 3.9 million ounces sold and delivered from IMF stocks. The Federal Reserve Bank discontinued its series of statistics on world monetary stocks of gold.

The IMF reported world gold reserves in the IMF and central banks, exclusive of centrally planned economies, at yearend 1976 as 40,788 million Special Drawing Rights (SDR's) (35 SDR's equivalent to 1 ounce of gold). IMF holdings amounted to 5,233 million SDR's. Industrial countries held 84% of the gold of all countries. Gold held by the IMF declined 3% during 1976 as a result of the gold sales.

Industrial and Trading Stocks.—Industrial stocks of 995 fine or better gold held by refiners, fabricators, and dealers at yearend totaled 928,000 ounces, 18% higher than at yearend 1975. Trading stocks, held mainly by COMEX and IMM, totaled an estimated 0.3 million ounces compared with 0.5 million ounces at yearend 1975. Yearend 1976 stocks registered and eligible for trad-

ing by COMEX were 292,099 ounces; those in the IMM totaled 317,986 ounces (includes most of COMEX stocks also); the Chicago Board of Trade held 15,914 ounces.

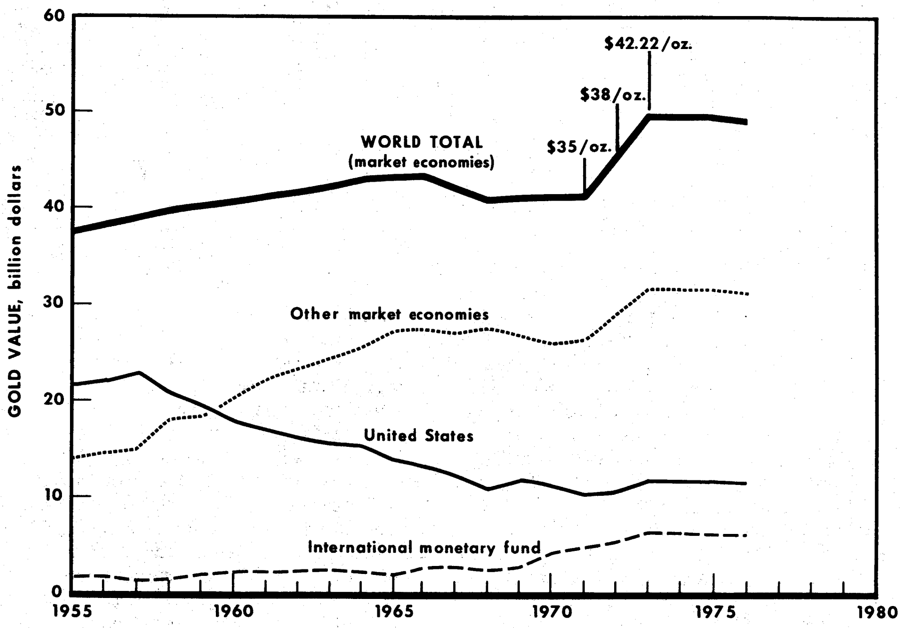

Figure 3.—World monetary gold stocks.

PRICES

Prices for unfabricated gold, quoted daily by Engelhard Industries, began the year at $140.85, the high for the year, and declined to a low of $103.50 on August 30. Thereafter, daily prices rose ending the year at $135.25. Except in March, monthly prices declined until August, thereafter they rose and were the highest for the year at $134.38 in December. Monthly prices showed the greatest stability from February through June when monthly ranges from high to low were less than $6. In July, after the IMF began selling gold, the range jumped to $15.55. In November the range reached $16.25, then dropped to $7.15 in December. The average price for the year was $125.32 compared with $161.49 in 1975. London final prices generally were 50 cents lower than Engelhard Industries prices and averaged $124.84 in 1976. Most central banks continued to value gold at an official price of $42.22 per ounce but made no sales or exchanges at that price. The IMF had a different official price, based on changes in value of a "basket" of currencies of major trading countries, and IMF gold was valued at 35 SDR's per ounce, which was equivalent to $40.66 per ounce at the arithmetical average of $1.16183 per SDR for 1976.

FOREIGN TRADE

Domestic exports of gold totaled 3.53 million ounces valued at $375.0 million in 1976, and of these exports, 0.65 million ounces valued at $27.5 million was monetary gold. This gold went to Switzerland (0.62 million ounces) and Poland (0.03 million ounces). Exports of nonmonetary refined bullion totaled 2.54 million ounces valued at $305.89

Table 2.—U.S. monthly gold selling prices, per troy ounce

Month	1976		
	Average	Low	High
January	$131.99	$125.10	$140.85
February	131.56	129.25	133.90
March	133.08	129.20	134.75
April	128.43	127.70	129.70
May	127.44	125.00	128.95
June	126.21	124.20	127.90
July	118.00	108.25	123.80
August	110.09	103.05	114.05
September	114.67	106.20	120.40
October	116.64	114.50	123.65
November	131.38	123.10	139.35
December	134.38	131.00	138.15
Year	125.32	103.05	140.85

Source: Englehard Industries.

million. Major nonmonetary exports by destination and quantity were, in million ounces: The United Kingdom, 1.46; Switzerland, 1.20; Canada, 0.19; and West Germany, 0.11. The remainder of the gold exported was scrap and base bullion amounting to 0.34 million ounces valued at $41.6 million mainly going to Belgium (40%) and the United Kingdom (33%).

Gold imports totaled 2.66 million ounces valued at $331.0 million and consisted of 2.49 million ounces of refined bullion valued at $311 million, and 0.17 million ounces in ore, scrap, and base bullion valued at $20 million. Imports were 60% from Canada, 14% from Switzerland, 4% each from Argentina, Japan, the U.S.S.R., and Yugoslavia, and 10% from other countries. The average valuation of refined bullion imports was $124.92 per ounce. Gold contained in unrefined imports amounted to 166,312 ounces, 65% in ore and 35% in scrap and base bullion. Ores came from the Philippines (37%), Canada (31%), Australia (10%), and eight other countries (22%). Scrap and base bullion came from Canada (17%), Nicaragua (15%), Singapore (13%), Venezuela (12%), and 23 other countries (43%). In addition, an estimated 1.33 million ounces was imported in the form of gold coins compared with 1.67 million ounces in 1975. In addition to imports, the gold markets were supplied with 2.13 million ounces of bullion from foreign government stocks on deposit at the Federal Reserve Bank in New York City.

The net inflow of gold to U.S. markets, exclusive of monetary movements but including supplies from foreign and IMF stocks in New York, amounted to 4.99 million ounces in 1976 compared with 0.55 million ounces in 1975.

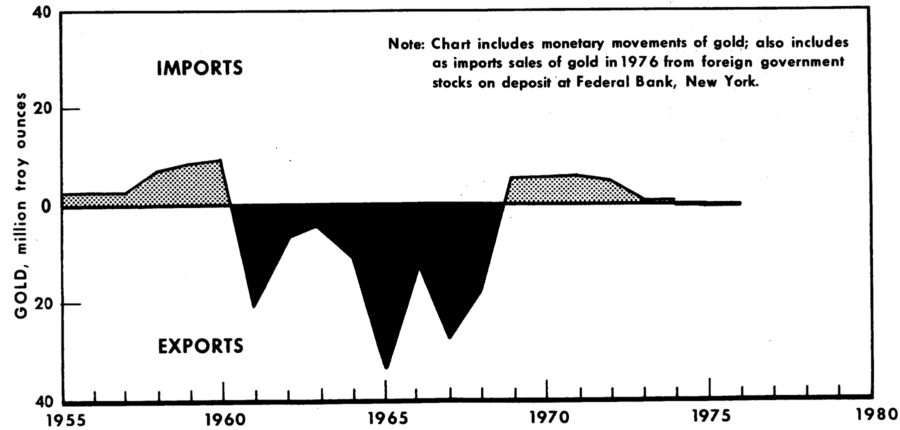

Figure 4.—Net exports or imports of gold.

WORLD REVIEW

Despite a 1% drop in gold production in the Republic of South Africa, world production was higher in 1976, with increases in byproduct production generally and in output from the U.S.S.R. and the Dominican Republic. Available information on the

U.S.S.R. mining indicated that lode mines were contributing most of the increase and placer mining may have had some setbacks. A new mine, the Pueblo Viejo, in the Dominican Republic, operated at capacity during the year and expansion was planned. The Pueblo Viejo became the Western Hemisphere's largest gold producer, exceeding the output of the Homestake mine in South Dakota by 30%.

According to the annual review of Consolidated Gold Fields Ltd., Gold 1977, the supply of gold to free markets increased 29% to 46.6 million ounces in 1976. Net bullion purchases for private speculation and investment amounted to 2.9 million ounces in 1976, about half that in 1975. Centrally-planned economies supplied 13.2 million ounces through trading, nearly triple the 1975 amount. Official sales and purchases netted 2.3 million ounces to supplies compared with 0.5 million ounces in 1975. An exceptional increase in imports of gold bullion and jewelry into the Middle East was reported, amounting to an estimated 12.9 million ounces in bullion and 2.6 million ounces in jewelry in 1976. The large offtake was explained by the great expansion in purchasing power throughout the Middle East area. In December, the United Kingdom reported receipt of 2.6 million ounces of gold bullion from the People's Republic of China, believed to have been shipped primarily to obtain foreign exchange. Net purchases of gold for fabrication were broken down into the following categories (with revised 1975 figures for comparison in parentheses), in million ounces: Karat jewelry, 30.1 (16.4); electronics, 2.3 (2.1); dentistry, 2.3 (2.1); other industrial and decorative uses, 2.0 (1.8); medals, medallions, and counterfeit coins, 1.3 (0.6); and official coins, 5.7 (7.8). Purchases for fabrication were also classified as follows, in million ounces: Developed countries, 26.5 (22.6) and developing countries, 17.2 (8.1). The leading countries in gold fabrication were as follows, in million troy ounces: Italy, 6.1 (2.6); the United States, 4.4 (3.8); Turkey, 3.7 (1.8); the Republic of South Africa, 3.0 (5.6); Japan, 2.9 (2.4); West Germany, 2.2 (1.8); Iran, 1.9 (0.9); Spain, 1.6 (1.4); Saudi Arabia and Yemen, 1.3 (0.4); Kuwait and Arabian Gulf States, 1.3 (0.5); France, 1.2 (1.1); Indonesia, 1.1 (0.5); and India, 1.1 (0.8). Gold used in official coins in 1976 was estimated to have declined 27% to 5.7 million ounces. Use in coins declined 48% to 2.9 million ounces in the Republic of South Africa, tripled to 0.9 million ounces in Austria, rose 46% to 0.5 million ounces in Mexico, and rose 6% to 0.5 million ounces in Turkey. A large increase in demand for small gold bars was indicated in the Far East. Italy was the largest consumer of gold in karat jewelry (5.69 million ounces), followed by Turkey (3.24 million ounces); Japan was the largest in electronics (0.74 million ounces), followed by the United States (0.70 million ounces); and the United States was largest in dental use (0.65 million ounces) and in other industrial and decorative uses (0.88 million ounces). Kuwait was the major consumer in medals and medallions (0.51 million ounces).

Following is a brief review of gold activities by country:

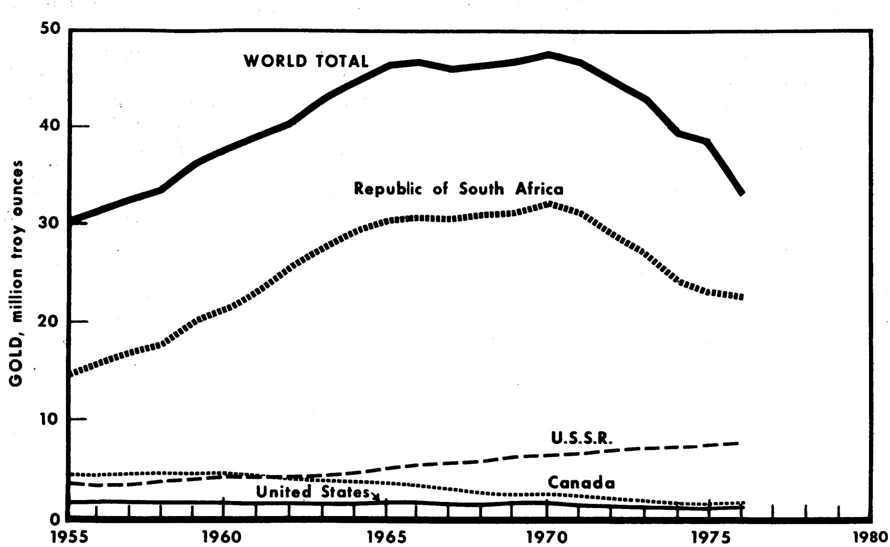

Figure 5.—World production of gold.

Australia.—Production continued to decline in 1976, with several major mines closing or about to close because of costs and a price drop in gold. Removal of a gold mining tax exemption was delayed, and the Industries Assistance Commission was asked to report by March 31, 1977, on the need to make changes in aid available to gold producers. The Australian Government reintroduced accelerated writeoffs for mining firms which was expected to benefit gold development. Projects were also made more attractive to overseas investment by a 17.5% devaluation of Australia's dollar in 1976.

Operations of Kalgoorlie Lake View Pty., Ltd. were scheduled for closing in November 1976, and the Mt. Charlotte mine was to be placed on care and maintenance. This was despite the purchase of a 48% interest in the firm in December 1975 by Homestake Mining Co. (United States) to infuse additional funds. During the financial year ending June 30, 1976, the operations produced 20% less ore, but at a 9% higher grade, than in the corresponding period a year earlier. A cleanup of the Chaffers treatment plant provided 7,162 ounces. The net result after milling was a 13% drop in gold production. Proved ore reserves reported in mid-1975 were 5.2 million tons grading 0.17 ounce per ton. Of this 63% was free-milling and the rest was refractory. At yearend, a plan was under consideration to rejuvenate the Mt. Charlotte mine with a $3 million investment in plant modifications, and closure was delayed.

Western Mining Corp. continued operations at the Norseman gold mine where high-grade ores remained profitable even at lower gold prices. Further exploration at the Jabiluka gold-uranium property of Pancontinental Mining Ltd. and Getty Oil Development Co. disclosed an ore body of 0.45 million tons indicated reserves averaging 0.47 ounce per ton and an additional 0.13 million tons inferred averaging 0.36 ounce per ton. Metallurgical tests showed 96% recovery was possible. Australian Anglo-American Pty., Ltd. began production at its Blue Spec mine in the Pilbara region of Western Australia in mid-1976. Most of the gold was said to occur in aurostibnite, an antimonial gold-arsenic compound that is metallurgically difficult to treat. About 88,000 tons of ore grading 1.34 ounces per ton of gold and 4.6% antimony were proven and further underground exploration was in progress. Development of the Telfer mine by Newmont Pty. (70%) and Dampier Mining Co. Ltd. (30%) was interrupted at midyear by a strike. The $35 million project was scheduled for completion in early 1977. The deposit, in the Paterson Range east of Port Hedland, Western Australia, had reserves of 4.2 million tons averaging 0.28 ounce per ton in gold, available by open pit mining.

Austria.—On October 22, Austria issued its first new gold coin in nearly 40 years and sold out the entire 1 million coin issue the same day. The fine gold content of the 900 fine coin was 0.434 troy ounce, and its face value was 1,000 shillings (about $58.00).

Bolivia.—Much of Bolivia's potential gold producing areas remained under Government control and unexploited as a "fiscal reserve." Production was increased with almost all of the increase coming from placer mining on the Tipuani and Kaka Rivers. The Tipuani was mined in the middle and upper reaches by gold mining cooperatives and by a dredge operation of South American Placers Inc. at the junction of the Tipuani and Kaka Rivers. Existing concessions were nearing depletion. The Banco Minero purchased gold from cooperatives and individual miners and sold it to jewelers and the Central Bank. Bolivia's Central Bank reserves at the start of 1976 were 409,499 fine ounces, 93% held in Bolivia. The Bolivian Geological Service began a 2-year exploration program on the Tuichi River in the Apolo area, Franz Tamayo sector of the Department of LaPaz, utilizing West German technical and financial assistance. New Jersey Zinc Co. was engaged in a joint venture on the mid-Tipuani River with El Camino Mines Ltd. (Canada); S. J. Groves Co. was developing a property on the lower Illichi River.

Brazil.—Ore reserves in Brazil contain an estimated 1.8 million ounces of gold, according to Government sources, about two-thirds in deposits in Minas Gerais. Production by Mineração Morro Velho S.A., owned by Anglo-American Corp. of South Africa Ltd. (49%) and Calmi Co. (51%), was scheduled to increase from 40,000 to 50,000 tons per month. A long term expansion was dependent on reevaluation of reserves. The ore grade was 0.225 ounce per ton.

British Solomon Islands.—The gold content of copper concentrates shipped from Bougainville in early 1976 was 1.05 ounces per ton.

Cameroon.—The source of placer gold in eastern Cameroon was to be investigated under a contract approved by the National Assembly.

Canada.—Gold production rose for the first time since 1961 and was 1.69 million ounces valued at $207.8 million in 1976 compared with 1.65 million ounces and $270.8 million in 1975. Higher grade ore was produced at a few lode mines as a necessity because of the drop in gold prices during the year, and some marginal gold mines were either closed or forced to reassess their financial positions. At yearend, 22 gold mines were active accounting for 73% of production. During the year two new mines opened and two mines closed. Canada's Emergency Gold Mining Assistance Act expired on June 30, 1976. It had become ineffective at higher prices. Minting of legal-tender gold coins was permitted under an amendment to the Olympic (1976) Act, and 14 and 22 karat coins were minted for sale at $105 and $150. The issue was limited to 1 million pieces.

According to preliminary data, gold output by Province, in thousand ounces (with percent change from 1975 in parentheses), was: Ontario, 734 (down 3%); Quebec, 474 (up 4%); Northwest Territories, 188 (up 7%); British Columbia, 177 (up 13%); Manitoba, 46 (down 4%); Yukon Territory, 31 (down 3%); Saskatchewan, 19 (up 30%); Newfoundland, 13 (unchanged); New Brunswick, 4 (up 18%); Alberta and Nova Scotia, minor production. Quartz lode and placer deposits supplied nearly 75% of all primary gold. Placer mining was a minor contributor and took place in the Yukon and British Columbia.

In Ontario, the source of 44% of Canadian gold in 1976, the Provincial Government sought Federal aid for gold mines in financial trouble owing to low gold prices. Eight out of 10 of Ontario's producing mines were in jeopardy, threatening 2,500 jobs. Pamour Porcupine Mines Ltd. planned to phase out lower grade operations at its five producing mines in the Timmins area, northern Ontario. Although Pamour's production rose in the first half of 1976, losses also rose and totaled $2.5 million for that period. At the beginning of 1976 ore reserves were 4.2 million tons grading 0.04 to 0.22 ounce of gold per ton. Plans were made to close the Ross mill and to center milling at the Schumacher mill. Bulora Corp. planned to close its Madsen mine at Red Lake because of mounting costs. Dickenson Mines investigated a significant new ore occurrence below the 30th level on the Dickenson and Robin properties in the Red Lake district and made smelter improvements. Rengold Mines Ltd. brought the Renabie gold mine into production in January but closed it in June because of financial problems. Northeast of Timmins, Intex Mining Co. Ltd. explored two gold-bearing zones averaging about 0.2 ounce per ton. Amoco Canada Petroleum Co. planned to drive a 2,500-foot decline, crosscut 1,000 feet, and perform 20,000 feet of diamond drilling at its Detour Lake gold discovery in northeastern Ontario.[9] Previous drilling of 136,000 feet in 129 holes outlined 10 million tons of ore expected to average 0.204 ounce per ton milling grade. Campbell Red Lake Mines, one of Canada's most profitable gold mines, produced 133,971 ounces from 225,000 tons of ore in the first 9 months of 1976, versus 133,990 ounces from 222,196 tons of ore in the comparable period in 1975. Net income for 1976 was $7.2 million compared with $11.1 million in 1975, and operating costs were reported at $47.02 per ounce, up 17.5% for the year.

In Quebec, Sigma Mines (Quebec) Ltd. produced 16,453 ounces of gold from 109,878 tons of ore milled during the third quarter of 1976. Camflo Mines Ltd. deferred exploration and development in favor of completing mill expansion and shaft sinking. In the first half of 1976, Camflo bullion production rose to 46,230 ounces from 228,633 tons of ore, and operating costs rose 15% to $59.85 per ounce compared with the first half of 1975. East Malartic Mines Ltd. production rose to a record 55,000 tons per month, and costs were reduced to $103.44 per ounce of gold. The company was preparing to reopen the Barnat mine. Teck Corp.'s Lamaque mine was phasing out operations. Belmoral Mines Ltd. planned production from the B zone at its Val d'Or, Quebec gold property where ore reserves were on the order of 1 million tons averaging 0.18 ounce per ton. Quebec Sturgeon River Mines Ltd. suspended work on potential new operations at Bachelor Lake, northwestern Quebec, and in Stock Township, northern Ontario, because of a shortage of cash to finance activities.

In the Northwest Territories, Giant Yellowknife Mines Ltd. reduced spending, lowered production costs, and increased output to 54,078 ounces during the first half of 1976, 17% above that of the comparable 1975 period. Exploration was cut in half. A net loss of $633,000 was reported in the first

[9]The Northern Miner. Amoco Goes Underground on Defour Gold Find. V. 62, No. 33, Oct. 28, 1976, pp. 1-2.

half of 1976. Cominco Ltd. settled a long strike at its Con gold mine at Yellowknife and continued an expansion program. Rayrock Mines Ltd. announced postponement of development at its Camlaren gold property near Yellowknife because of rising costs. In British Columbia, Northair Mines Ltd. began production near Brandywine Falls and milled about 300 tons of ore per day. Mill heads averaged nearly 0.4 ounce of gold per ton in May. During October, 4,300 ounces of gold was produced and mill recovery rates had reached 88% of gold in the ore. Claymore Resources reported pilot production of 300 to 500 cubic yards per day at its Laduc River district gold placer properties on the Alaska-Yukon border. Samples from one area on Kenyon Creek were said to average $20 per yard over a 6-foot thickness.

Chile.—St. Joe Minerals Corp. was developing a gold property at El Indio in the Coquimbo area. Arsenic in the ore was expected to be a problem.

Colombia.—Frontino Gold Mining Co., owner of the Vera, Cecilia, and Silencio gold mines, declared bankruptcy in late 1976 after reporting an expected $2 million loss for the year. Mineros de Antioquia S.A. (formerly Pato Gold Dredging Co.) was planning to purchase another dredge. Several small mines were opened in Nariño and Tolma.

Costa Rica.—Aquacate Consolidated Mines planned to reopen the Sacra Familia and Compania gold mines in early 1977 initially at 100 tons per day. Compañia Minera Esperanza S.A., owned by Bulora Corp. Ltd. and Brafor Capital Corp., temporarily suspended production at its gold property.

Dominican Republic.—Rosario Resources Corp. and J. R. Simplot Co. reached agreement with the Dominican Republic Government in December 1976 to sell a 13% participation each in Rosario Dominicana, S.A., which operates the Pueblo Viejo gold mine in Sanchez Ramirez Province. Each company received $3.7 milion for their shares. Also, a new 5% mining tax was expected to be levied against net income from gold and silver mining. Plans to develop the adjoining Los Cacaos gold property were delayed pending further studies. The Pueblo Viejo mine produced at full capacity in 1976. Output in dore bullion was 413,788 ounces of gold and 907,318 ounces of silver from ores averaging 0.155 ounce of gold and 0.448 ounce of silver per ton.

India.—Indian gold production was entirely from public sector mines of Bharat Gold Mines Ltd., under control of the Indian Department of Mines and from the Hutti Gold Mines Co., Ltd., under control of the Karnataka State Government. India's gold ore reserves have been estimated at 5.5 million tons containing 1.47 million ounces, 78% in the Kolar gold fields and 22% in the Hutti deposits. New reserves were found in the Ramagiri gold fields, Anantpur district, Andhra Pradesh, and additional exploration was underway at the Mysore and Nundydroog gold mines. Bharat Gold Mines production costs were reported in 1974-75 at $196.55 per troy ounce, remaining about the same in 1976. The Indian Government purchased production at a much lower price but provided a mining subsidy, which in 1975-76 amounted to $7.4 million. Gold was sold to domestic consumers at prices based on the Bombay market, which near the end of October 1976, were about $207 per ounce (exchange rate Indian Rs8.50=US$1.00). Smuggling of gold into India continued because of the spread between domestic and international prices.[10] The Indian Geological Survey planned to acquire a ship from West Germany to use in exploring for gold on the ocean floor off the mouths of the Mahanadi and Subarnarekha Rivers in Orissa State and other rivers to the South.

Indonesia.—A number of firms, mostly domestic, explored for gold in Sumatra, Kalimantan, and West Java. A subsidiary of Australian Endeaver Oil Co. explored in Gorontalo of North Sulawesi. P. N. Arneka Tambang explored an area in Central Sumatra near Logas and continued production of gold and silver at its Cikotok mine in West Java. A ban remained on gold exports, and imports faced a 30% duty. The gold content of copper concentrate exported from West Irian operations of Freeport Indonesia Ltd. averaged about 0.28 ounce per ton.

Ivory Coast.—The Pennaroya Mokta consortium completed a study of the Ity gold mine where ores averaged about 0.35 ounce of gold per ton.

Japan.—Consumption of gold was estimated in the fiscal year ending April 1976 at 3.4 million ounces; 35% in jewelry, 11% in dental and medical uses, 13% in gold plating, 9% in communication and machine

[10]U. S. Embassy, New Delhi, India. State Department Airgram A-344, Dec. 30, 1976, pp. 21-24.

parts, 5% in industrial art products, and the rest in miscellaneous uses.[11]

Liberia.—Azuza Mining Co. ivestigated lode gold concessions on the Cavalla River, near the Ivory Coast border. A $2 million investment in a mining operation was under consideration.

Mali.—Technicians from the U.S.S.R. assisted in the construction of a gold mining facility at Kalma. Production was scheduled by yearend.

Mexico.—Cia. Minera Las Torres S.A. began operation of a 2,000-ton-per-day mill at Guanajuato, Mexico, in March 1976 treating silver-gold ores from the Las Torres, Peregrina, Cebada, and Bolanitos mines.[12] The average ore grade was 12.2 ounces of silver and 0.08 ounce of gold per ton with metal recoveries averaging 90% for silver and 92% for gold. The company was owned 30% by Lacana Mining Corp., 37% by Cia. Fresnillo S.A., and 33% Industrias Penoles S.A.

Nicaragua.—A 25-ton-per-day mill was under construction at the Santa Rosa gold-silver property of Minas de Cerro Dorado in eastern Nicaragua and expansion to 100 tons per day was considered. The general ore grade was expected to range between 0.5 and 1 ounce per ton in gold and 5 and 10 ounces in silver. The company also was preparing for a small gold placer operation nearby.

Papua New Guinea.—Bougainville Copper Ltd. produced virtually all the island's gold output as a byproduct of copper mining. A small gravel pump and gold sluicing operation of New Guinea Goldfields was active on Edie Creek southwest of Wau. New Guinea Goldfields also operated a small open pit mine at Golden Ridge, northwest of Qau, where ore reserves of about 0.5 million tons were estimated to grade 0.07 to 0.09 ounce per ton. During the fiscal year ending June 30, 1976, the latter deposit produced 8,955 ounces of gold and 9,464 ounces of silver. Exploration at the Ok Tedi copper deposit revealed an estimated 177 million tons of copper ore (0.8% copper), containing 0.02 ounce per ton of gold and a small amount of molybdenum. A 40,000-ton-per-day operation was contemplated.

Philippines.—The Philippines Central Bank's new gold refinery in Quezon City, Manila, was scheduled for completion by mid-May 1977. Refining capacity was planned for 600,000 ounces of gold and 450,000 ounces of silver annually. Benguet Consolidated, Inc., the largest gold producer, reported average production costs of $143 per ounce in the third quarter of 1976, $27 per ounce higher than the comparable period of 1975, and indicated that it might cease operations because of mounting losses. Philippine gold producers sought a Government guarantee of $160 per ounce on their output, but late in 1976 the Government had not acted on a petition to reinstitute gold subsidies. However, the Governor of the Philippines Central Bank authorized creation of a Gold Market Committee to help establish a Domestic Gold Exchange. Atlas Consolidated Mining & Development Corp. planned to reactivate a gold mine at Aroroy, Masbate, and build a 3,000- to 4,000-ton-per-day mill facility. Apex Exploration and Mining Co. was expanding production capacity from 300 tons per day to a scheduled 1,000 tons per day in early 1977, based on discoveries in Masara, Davao. Metals Exploration Asia completed feasibility studies on a potential 800-ton-per-day gold operation near Longos, Paracale, where reserves of 1.3 million tons averaging 0.51 ounce of gold per ton were indicated by diamond drilling. Golden River Mining Corp. was building an 8,000-cubic-yard-per-day bucket dredge for its gold property in Paracale, southern Luzon, where placer reserves are estimated between 21 and 50 million cubic yards.

Saudi Arabia.—A study by the U.S. Geological Survey concluded that the Mahd adh Dhahab mining district between Mecca and Medina was an important source of the biblical King Solomon's gold.[13] In September, Gold Fields Mahd adh Dhahab Ltd., a Consolidated Gold Fields Ltd. subsidiary, obtained an exploration license from the Saudi Arabian Government to investigate the area in a joint venture with the General Petroleum and Mining Organization.

South Africa, Republic of.—Gold output was virtually the same as in 1975 when 22.9 million ounces was produced. All mine production was refined at Rand Refinery, Inc. facilities in Germiston, Transvaal. According to the December Analysis of Working Results by the Chamber of Mines of South Africa, member companies milled 76.2 million tons of ore to produce 22.8 million ounces of gold. The average grade, including

[12]Fish, R. Lacana Mining Helps Continue 450-Year Mexican Mining History. Can. Min. J., v. 97, No. 1, January 1976, pp. 43-47.

[13]U.S. Geological Survey. King Solomon's Gold Mine Rediscovered? Department of the Interior News Release, May 24, 1976, 4 pp.

ores of byproduct producers of uranium, was 0.30 ounce of gold per metric ton (0.27 ounce per short ton). The largest producing mine was the Vaal Reefs, with output of 2,122,107 ounces; the West Driefontein was second with 1,792,545 ounces. The West Driefontein and East Driefontein mines were the richest, with mill grades averaging 0.73 and 0.65 ounce of gold per ton. Byproduct uranum production amounted to 618 million pounds U_3O_8 from treatment of 17.3 million tons of gold-uranium ore, the grade averaging 0.4 pound U_3O_8 per metric ton (0.36 per short ton). Uranium was produced from eight mines, the most important of which were the Vaal Reefs, Buffelsfontein, Harmony, and Hartebeestfontein. Sulfuric acid or pyrite was produced at 11 mines as another byproduct. State assistance for gold mining was received by 10 producers; the largest recipient was East Rand Proprietary Mines, Ltd. followed by Durban Roodepoort Deep, Ltd. and Loraine Gold Mines Ltd.

Reserves of gold ore were reported at 199.7 million tons averaging 0.414 ounce per metric ton (0.38 per short ton) fully developed and blocked out on January 1, 1976, (based on gold price and operating costs on that date). There were large additional reserves of indicated and inferred categories of ore. The largest tonnages were at the Harmony, Vaal Reefs, St. Helena, and Hartebeestfontein mines. The highest grade was 1.01 ounce per ton for 2.77 million tons in the Ventersdrop Contact Reef of the East Driefontein mine.

Three major new mines continued under development, the Unisel mine of Union Corp. in the Orange Free State, the Deelkraal mine of Gold Fields of South Africa, and the Elandsrand mine of Anglo American Corp.; both of the last two are south of Carletonville in the Far West Rand. By yearend 1976, the Unisel main shaft had reached a depth of 5,100 feet and production plans for 1978 remained on schedule. The other mines were to begin producing in 1980-81 and were being rushed to completion. At the Elandsrand, underground development was conducted from the adjoining Western Deep Levels mine to accelerate progress. Shaft sinking methods were also improved. By yearend an ore and ventilation shaft had reached 4,100 feet and a smaller diameter men-and-supplies shaft was to a depth of 5,100 feet. The two shafts were to bottom at about 7,586 feet in early 1979. Minable reserves at Elandsrand were estimated at 66 million tons averaging 0.38 ounce of gold per ton. The cost of bringing the Elandsrand mine into production at 180,000 tons per month was estimated at $168 million (1975 dollars). Two shafts at the Deelkraal mine reached 5,500 and 5,300 feet in depth at yearend. A proposal was reported for President Steyn Gold Mining Co. Ltd. and Sentrust Ltd. to develop and mine the Video No. 305 property in the Ventersburg district of the Orange Free State.[14] Video Mining Co. Ltd. was formed as a subsidiary of President Steyn to implement agreements and act on the results of a feasibility study scheduled for completion in December 1979.

A number of uranium byproduct facilities were under construction or planned in the Republic of South Africa. The President Brand Gold Mining Co. Ltd. opened a large rehabilitated byproduct complex to treat residues from Anglo American Corp. mines in Orange Free State. Mines to supply tailings included the President Brand, President Steyn, Free State Geduld, Welkom, Western Holdings, Free State Saaiplaas, and Freddies. Tailings were to be treated by flotation at 1.5 million tons per month, with expected recoveries of 50% of the uranium, 20% of the gold, and 85% of the pyrite contained. At the Harmony mine, in the Orange Free State, plans were made to expand operations and supply tailings to a new uranium extrction facility planned at Merriespruit and an expanded unit at Virginia. A 180,000 ton-per-month plant to extract uranium from residues was opened at the Welcom mine.

Randfontein Estates Gold Mining Co. Ltd., considered the feaibility of building a new gold and uranium extraction plant near its active Cooke No.2 shaft and reopening part of its old Randfontein mine in a project estimated to cost $150 million.[15] Uranium slimes, to be treated at the mill site, were expected to grade about 0.3 to 0.4 pound per ton with recoveries of 90% to 94%.[16] The Anglo American group continued studies of a large complex to process slimes from old East Rand mines, possibly by 1978. A new company was to be formed—East Rand Gold and Uranium Co. Ltd.

[15]Mining Magazine. Randfonstein's Cooke Section - A New Gold Mine for a Famous Old Producer. V. 134, No. 4, April 1976, pp. 161-167.

[16]Mining Magazine. South African Gold Mines Uranium Production Plans. V. 134, No. 8, August 1976, pp. 103, 105.

According to spokesman for Anglo American Corp. of South Africa Ltd., uranium was becoming much more important in South African gold mining, and output could reach 17 to 18 million pounds per year in the next decade.[17] Profits from uranium in gold mines were $37 million in the first 9 months of 1976 but only $1.2 million in 1975. It was estimated that South African annual gold production would be between 23 and 26 million ounces in the coming decade but was on the last plateau before a long decline. Methods of increasing gold mining productivity in South African mines were considered.[18] The South African Mine Workers Union and Chamber of Mines agreed to initiate an 11-shift fortnight (5 days, 1 week and 6 days the next) beginning in April 1977. Labor shortages continued to be a serious problem in South Africa's gold mines limiting output growth.

Sudan.—The Sudanese Government signed an agreement with a United Kingdom firm to study and design a gold mining operation in the Serkawit region of the Red Sea Hills.

Surinam.—An estimated reserve of 70 million tons of low-grade gold ore averaging about 0.05 ounce per ton was developed in the Brokopondo area of Surinam by a Canadian firm and the Surinam Government in a joint venture.

U.S.S.R.—According to estimates of the U.S. Central Intelligence Agency, the U.S.S.R. was expected to sell 0.8 million ounces of gold per month in 1977, rising to 0.9 million ounces per month in 1978. Earnings from gold sales in 1976 were estimated at $1 billion. The information was published by the Agency in a report entitled U.S.S.R.: Hard Currency Trade and Payments 1977-78. In a prediction by a Canadian author, U.S.S.R. gold production was expected to surpass that of the Republic of South Africa in the late 1980's.[19] Production of the chernovetz, a U.S.S.R. coin containing 0.25 ounce of gold, was higher than the 250,000 minted in 1975 and was expected to exceed 1 million in 1977.

Venezuela.—The Government was investing heavily in eastern Guayana mines and planned expansions from 15,500 ounces to 165,000 ounces per year in 1980. The State-owned mining company, Minervén, planned to reactivate the El Callao gold mine, which contained estimated reserves of 2.5 million tons grading 0.7 ounce per ton in gold.

TECHNOLOGY

Twenty or more gold-leaching operations were in production or under development in the western United States during 1976 as a result of research initiated by the Bureau of Mines. Most properties had relatively small outputs, and activities tended to be intermittent. Mine owners viewed the new leaching technology as an opportunity to recover gold from shallow, low-grade deposits, or from mine wastes and tailings, with a minimum of capital investment in mine and plant facilities. Essentially, the heap leaching technique consisted of placing a low heap of gold-bearing material, either crude or partially crushed, on an impervious base, such as asphalt or plastic sheets; distributing a cyanide solution over the surface, collecting the gold-bearing solution in a sump, and extracting the gold with activated carbon. Gold was then stripped from the carbon by a hot caustic cyanide solution, or, in an improved method, by a hot alkaline-alcohol solution, electrodeposited on steel wool, and finally melted into bars. Additional studies showed that any silver values extracted in cyanidation could best be recovered by simple precipitation of the silver as a sulfide, using sodium sulfide before the carbon extraction of the gold.

Heap leaching was believed practicable on ores containing as little as 0.03 ounce of gold per ton of ore providing sufficient tonnages were available and the gold recovery factor was high. Also, the heap leach technique was applied with apparent success by at least one Nevada operator to extract silver, using the sulfide precipitation step, from low-grade silver-gold ore and dump material containing only minor amounts of gold. In general, silver has been more difficult to leach than gold, owing to complex mineral associations and slower extraction rates. Further studies were being conducted at the Reno Metallurgy Research

Center, Federal Bureau of Mines, Reno, Nev.

A mobile demonstration unit, designed to show by field tests the efficiency of the alkaline-alcohol gold stripping method, was tested at a number of locations and resulted in adoption of the method by several operators including the Homestake Mining Co., where tests showed stripping time could be reduced from 100 to 5 hours. Homestake has been recovering gold from mill slimes since August 1973 by a carbon-in-pulp method developed by the Bureau of Mines. Bench-scale tests were conducted to determine feasibility of reusing the activated carbon after it was stripped with alkaline-alcohol solutions without the usual thermal reactivation step. Through at least four cycles of loading and stripping it was feasible to recover gold from a refractory, carbonaceous ore by a modified heap leaching technique. The system included pretreatment with a hypochlorite solution to destroy organic matter which interferes with gold recovery. A 10% sodium chloride solution containing hypochlorite, generated by electrolysis in situ, was percolated through the ore bed until exposed carbonaceous matter was oxidized. The ore was then leached with a cyanide solution adjusted with lime to pH10.5, but the ore became impermeable. Research continued using other oxidants. Studies also were in progress on effects of flocculating and wetting agents on solution percolation rates in heap leach cyanidation. In other tests, electrooxidation treatment of several carbonaceous gold ores in a commercial 125-volt, 1,000-ampere bipolar flow-through cell increased extractions in subsequent cyanidation from about 72% to 90%.

A patent was issued on the process of recovering absorbed gold and/or silver from activated carbon using alcohol or ketones alone or in aqueous solution with a strong base to facilitate elution.[20] The Bureau of Mines awarded a contract to the University of Utah during 1976 to study the kinetics and thermodynamics of the gold cyanide-silver cyanide-carbon reaction. Battelle Northwest Laboratories scheduled an 18-month study to identify organic compounds in carbonaceous gold ores and the composition of surface films on gold in refractory-type ores. A publication described various analytical methods for gold and a list of commercial assay laboratories.[21] Assistance was provided to the Defense Supply Agency by Bureau of Mines specialists in identifying gold-bearing scrap from obsolete electronic and other military equipment. Gold in scrap electronic solders was recovered by drossing with aluminum or zinc in a process developed by the Bureau.[22] Drossing upgraded the product by a factor of 10; further concentration was achieved by roasting, amalgamation, and leaching. A Battelle Columbus Laboratories study of energy inputs to mineral processing showed that the energy required to produce a new ton of refined gold was 58,855 million British thermal units (Btu's).[23] Details of energy requirement by process step were provided.

Gold was extracted from a low-yield gold ore by electrolysis of a salt solution of the pulp[24] and from gold-plated scrap or ore by treatment with an aqueous solution of iodine and potassium iodide followed by sulfur dioxide, hydroxylamine, or hydrazine precipitation of the gold.[25]

An air pollution problem caused by arsenic in gold ores was eliminated by Campbell Red Lake Gold Mines in Ontario, Canada. Gas from the roaster plant was passed over precipitator collector plates where calcine dust collected; arsenic continued on to an air mixing chamber. There a temperature drop to 250°F caused precipitation and the arsenic was caught in a baghouse.[26] Also in Canada, a graphite-bearing gold ore was successfully treated by first extracting the graphite by flotation and after pyrite and gold flotation, ending with cyanidation.[27] Recoveries doubled to the 85% to 93.6% range. The effectiveness of ammonium chloride in gold milling was described.[28] Among its uses were: Cleansing agent in amalgamation, complexing agent against dissolution of copper, and sequestering agent to minimize scale formation in a lime-cyanide circuit.

[26]Canadian Mining Journal. Air Pollution Brought Under Control. V. 97, No. 3, March 1976, p. 27.

[27]Raicevic, D., and R. W. Bruce. Gold Recovery From a Refractory Carbonaceous Gold Ore. Can. Min. J., v. 97, No. 3, March 1976, pp. 40-45.

[28]Roach, A. G. Ammonium Chloride Resolves Problems in Gold Metallurgy. Can. Min. J., v. 97, No. 9, September 1976, pp. 48-50.

The National Institute of Metallurgy in the Republic of South Africa investigated procedures for recovering uranium and gold from ores of the Witwatersrand using wet high-intensity magnetic separation on cyanidation residues. It was found that 50% of the residual gold and up to 70% of the total uranium could be recovered in the magnetic concentrates.[29]

Plans by Golden Cycle Gold Corp., for reopening its properties in the Cripple Creek district of Colorado were described.[30] Shaft rehabilitation work for access to the 3,100-foot level of the Ajax mine cost $300 per foot and required 10 months. A report discussed possible costs of in situ leaching of gold ores.[31]

Details of a fire in the Homestake gold mine were disclosed in a review of events that took place before and after.[32] The fire was in a timbered section on the 3,050-foot level and caused closure of the mine for 12 days.

South African efforts to overcome problems of high rock temperatures, high rock stress, narrow working places, and hardness and abrasiveness of rock mined were described.[33] Problems were being met by greater mechanization. For instance, a high-thrust raise-borer cut a 9-foot wide overpass at the Vaal Reefs South mine in a record time. A mechanized stope-cleaning system was developed around an armoured face conveyor and a new reciprocating flight conveyor was developed.[34] Successful trials were conducted in South African mines of specially designed twin-boom drill jumbos.[35] Installation of steel arches and tests of a new tunneling machine were described.[36]

Anomalous concentrations of gold were found in samples from unproductive zones similar in character to nearby productive zones in the Goldfield, Nev., area. Two associations of elements were found, one a relict hypogene association and the other supergene, the latter formed during oxidation.[37] Statistical analysis techniques were used to assess theories of the origin of the Carlin disseminated gold deposit near Carlin, Nev.[38] Gold and mercury values showed high correlations in all areas sampled.

Evidence was given to show that in the Witwatersrand gold field of South Africa a hitherto unknown form of plant life was instrumental in concentrating gold during the Precambrian period.[39] It was believed the discovery would help in developing a better geological model of deposits and improve assessment of gold distribution. Studies were made of gold in the Precambrian Vaal Reef Placer, the Republic of South Africa,[40] in stratabound deposits in Rhodesia,[41] and in certain stratigraphic units of the Abitibi supergroup in Canada.[42]

Gold was included with other precious metals in a report describing comparative physical characteristics and engineering properties.[43] The composition of anodic films formed on gold and rate of gold dissolution in electrolyzed sulfuric acid with and without chloride ions was the subject of a study.[44] Neutron activation analysis was found to be an excellent means of studying the variations in gold concentration on silicon wafers before and after phosphorous

gettering.[45] In a two-part series on alloying, the formation of solid solutions of gold was explained in terms of atomic structures, and factors were considered affecting formation of compounds with other metals.[46] Effects of gold on biological systems and use in chemotherapy were reviewed.[47] The intake of gold in micro-organisms was shown graphically by pictures in which sites of gold deposition could be seen. Uses for gold drugs generally range from anti-inflammatory to anti-bacterial. Gold ketenide, one of a new class of organometallic compounds, was believed to have potential for use in selective oxidation catalysts.[48] Compounds formed when gold ketenide decomposed explosively were examined.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Unless otherwise indicated, production is on the basis of mine output.

[2]Gold is also produced in Bulgaria and Czechoslovakia, and probably small quanties in Burma, East Germany, Guinea, Thailand and several other countries. However, available data are insufficient to make reliable output estimates. Data are lacking on clandestine activities.

[3]Figures are reported as fine gold (that is, almost pure).

[4]Figures are reported as refined metal.

[5]Estimated level of output for all producers, chiefly contained in blister copper and refinery muds. Previously reported figures at lower level did not represent total national output.

[6]Refinery production for Japan was as follows: 1974—[r]1,123,489 ounces; 1975—[r]1,036,004 ounces; 1976—1,043,676 ounces.

[7]Bougainville Copper Ltd. produced the following amounts as a byproduct of copper mining: 1974—[r]658,575 ounces; 1975—[r]584,307 ounces; 1976—650,151 ounces. In addition, other mining operations produced: 1974—8,662 ounces; 1975—27,049 ounces; 1976—578,423 ounces.

Graphite

By W. Thomas Cocke[1]

Natural graphite remained in tight supply in 1976 as the economy strengthened. Domestic consumption increased 10% according to a canvass of major consumers. Domestic production increased appreciably over that of 1975. Although some known graphite deposits were investigated, there were no new mine openings and only one mine remained in operation. National stockpile goals were increased to 3-year totals, which precluded the sale of material previously declared excess.

Imports of natural graphite increased 21%. A 28% increase in imports of amorphous graphite compensated for a 5% decrease in imports of crystalline graphite. Total exports increased 16%. Prices of imported material increased 5% for crystalline and 26% for amorphous in 1976. Domestic prices generally follow those of imported materials.

World production of graphite increased in 1976, with nearly all producers showing some increase. While supplies of amorphous graphite were adequate, premium grades of crystalline remained tight. Substitutes of lower grade materials appear to be successful.

Production of manufactured graphite increased 3% over that of 1975, owing primarily to a 17% increase in production of electrodes. Production was still well below the 1974 high.

Legislation and Government Programs.—On October 1, 1976, the Federal Preparedness Agency of the General Services Administration increased national stockpile goals to reflect an increase in requirements of strategic materials to a 3-year period. New stockpile objectives for each type of graphite are shown in table 2. There were no disposals of strategic graphite, declared excess prior to October 1, owing to lack of congressional authorization. Careful consideration will be given to market conditions before any aquisitions will be made to reach the new goals. Import duties on crystalline graphite remained suspended for a trial period in order to stimulate imports.

[e]Estimate. [r]Revised.
[1]Estimated demand has been substituted for the consumption survey results appearing as the total of table 4, since the latter are incomplete.
[2]Includes some manufactured graphite.

DOMESTIC PRODUCTION

In 1976, natural graphite production was from a single source, the Southwestern Graphite Co. mine near Burnet, Tex. Shipments from the mine were higher than in 1975 but continued to account for only a small portion of domestic supply. Other graphite deposits in Alabama, New York, Montana, and the Province of Saskatchewan, Canada, received attention from investigators contemplating the development or redevelopment of additional mines, however, no mine openings occurred by yearend.

International Carbon and Minerals Corp. purchased mineral rights to 2,135 acres in the Alabama flake graphite district and plans to build a modern flotation plant with startup scheduled for mid-1977.[2]

Deep Bay Graphite Co. Ltd., a subsidiary of Superior Graphite Co. of Chicago, Ill., and the Saskatchewan Mining Corp. agreed to proceed with a feasibility study of a graphite mine near Reindeer Lake in northern Saskatchewan. Production of 9,000 tons of flake graphite per year is projected. Results of the study are expected late in 1977.[3]

Reported production of manufactured graphite increased 3% to 286,326 short tons. Total value of production increased 21% to $375 million. The overall increase in production was due to large increases in electrodes (17%), crucibles and vessels (32%), and motor brushes and machined shapes (64%). All other uses of manufactured graphite decreased 28%. Shipments of powder and scrap again decreased to 23,991 tons valued at $3.5 million, which indicated a doubling of value from $64 per ton in 1975 to $146 per ton in 1976. Production of high-modulus graphite fibers decreased, but a study conducted by R. M. Kossoff and Associates of New York showed manufactured graphite fibers and composites poised for a major volume breakthrough in the next decade.[4] Prices have declined from $200 per pound to about $30 per pound in 1976 and are expected to be in the $10 per pound range by the early 1980's. According to the study, 1976 consumption of manufactured graphite fibers was 260,000 pounds. This showed that demand for these fibers used in composites is two and a half times the annual production.

Manufactured graphite was produced at 24 plants in 1976, with some additional production for in-house use likely. The following is a list of principal producers in 1976:

Company	Plant location
Airco, Inc., Speer Div	Niagara Falls, N.Y.
Do	Punxsutawney, Pa.
Do	St. Marys, Pa.
Avco Corp., Avco Systems Div.	Lowell, Mass.
The Carborundum Co., Graphite Products Div.	Hickman, Ky.
Do	Sanborn, N.Y.
Celanese Corp., Celanese Research Lab.	Summit, N.J.
Fiber Materials, Inc	Graniteville, Mass.
Great Lakes Carbon Corp	Rosamond, Calif.
Do	Niagara Falls, N.Y.
Do	Morganton, N.C.
Hercules, Inc	Bacchus, Utah.
HITCO	Gardena, Calif.
Ohio Carbon Co	Cleveland, Ohio
Pfizer, Inc., Minerals Pigments & Metals Div.	Easton, Pa.
Poco Graphite, Inc	Decatur, Tex.
Polycarbon, Inc	North Hollywood, Calif.
Stackpole Carbon Co	Lowell, Mass.
Do	St. Marys, Pa.
Super Temp Co	Santa Fe Springs, Calif.
Union Carbide Corp	Niagara Falls, N.Y.
Do	Yabucoa, P.R.
Do	Columbia, Tenn.
Do	Clarksburg, W. Va.

Airco, Inc., Speer Div. completed expansion programs at plants in Pennsylvania and Niagara Falls, N.Y., which will enlarge production capacity at these facilities 20%.[5] The Carbon Products Division of Union Carbide Corp. has broken ground for a new graphite electrode plant at Clarksville, Tenn.[6] A plant capable of producing 11,000 tons per year of synthetic graphite and desulfurized petroleum coke was being constructed in Hopkinsville, Ky., by Superior Graphite Co.[7]

High-modulus fibers	49	4,965
Other	10,042	14,738
Total	262,335	371,506
Synthetic graphite powder and scrap	23,991	3,511
Grand total	286,326	375,017

CONSUMPTION AND USES

Reported consumption of natural graphite in 1976 increased 10% to 59,300 short tons. Consumption increased in all categories except steelmaking, which was stable, and foundries, which declined 22%. The three major uses, steelmaking, refractories, and foundries, accounted for 63% of reported consumption.

The actual amount of natural graphite consumed was greater than that shown in table 4, which reports only the results of a canvass of major known consumers. Total graphite consumption is estimated to have been 67,000 short tons in 1976.

Figure 1 summarizes graphite end use patterns as indicated by a canvass of major consumers. While the canvass probably gives a good indication of consumption patterns, caution is advised in use of these data for absolute amounts, due to the fact that the canvass in some years accounted for less than two-thirds of apparent consumption. Also, some major variations from year to year in various end uses may not be real because of inconsistencies in reporting.

Recent new or proposed uses for graphite-epoxy composites include the speedbrake for the McDonnell F-15 Air Force fighter to replace aluminum alloy;[8] 10% of the total structural weight of the McDonnell and Northrop F-18 Navy fighter;[9] upper aft rudders on DC-10's and payload bay doors on the space shuttle;[10] automobile leaf springs and drive shafts for weight reduction;[11] and machine tool parts for drastic reductions in weight.[12]

Total	18,271	7,908,285	41,029	8,897,449	59,300	16,805,734

W Withheld to avoid disclosing individual company confidential data; included with "Other Crystalline" and "Other Amorphous."

[1]Consumption data incomplete. Small consumers excluded.

[2]Includes mixtures of natural and manufactured graphite.

[3]Includes bearings and carbon brushes.

[4]Includes ammunition, packings, and seed coating.

[5]Includes paints and polishes, antiknock and other compounds, drilling mud, electrical and electronic products, insulation, magnetic tape, small packages, and miscellaneous and proprietary uses.

PRICES

Average prices of graphite imports continued to increase in 1976 as worldwide inflation continued. The average price of Malagasy crystalline flake and fines increased about 4%, Sri Lanka amorphous lump and chip increased about 25% and Mexican amorphous increased about 5%. Decreases in prices occurred in imports of Norwegian and West German crystalline and Korean amorphous.

Actual prices are often negotiated between the buyer and seller, so price quotations represent the average of a range of prices. The source of information for imported graphite is the average value per ton computed from table 6; however, these data mainly represent shipments of unprocessed graphite.

The following tabulation[13] shows representative price ranges for several countries from which natural graphite is imported.

	Per short ton	
	1975[r]	1976
Flake and crystalline graphite, bags:		
Germany, West	$227-$907	$272-$1,270
Malagasy Republic	200-680	136-680
Norway	145-236	150-236
Sri Lanka	225-405	163-405
Amorphous, nonflake, cryptocrystalline graphite (80% to 85% carbon):		
Korea, Republic of (bags)	36	36
Mexico (bulk)	33	44-50

[r]Revised.

FOREIGN TRADE

The broad upward trend in exports of natural graphite continued in 1976, after a slight setback in 1975. Exports increased 16% in 1976 to 12,236 short tons. Canada remained the principal buyer with 3,394 tons. Other major recipient countries were West Germany (1,638 tons), Poland (1,127 tons), and Japan (1,062 tons). Graphite was also exported to 41 other countries.

Imports of natural graphite increased 21% to 77,698 short tons in 1976 but were still below the 1974 high of 81,070. A 28% increase in imports of amorphous graphite, due mostly to the 13,007 tons from the Republic of Korea, brought the amorphous portion to 83% of all imports. This is part of a gradual change over the last 25 years which has resulted in a shift from 65% amorphous in 1950 and 1951. Imports of crystalline graphite were 5% lower than in 1975, however, imports of crystalline flake from the Malagasy Republic increased 10% to 4,071 short tons, or roughly a third of all crystalline imports.

WORLD REVIEW

World production of graphite increased slightly in 1976, with nearly all producers showing some increase. Mexico and the Republic of Korea remained the main producers of amorphous graphite. Shortages of Malagasy flake graphite have lessened, but industry continued to seek viable alternative sources.

Brazil.—A growing producer, Brazil has a current annual capacity of 8,000 tons per year of flake and powdered graphite at the principal deposits in Itapecerica.[14] This could develop into an important source of flake graphite.

Canada.—An intensive drilling and bulk sampling program is underway at a graphite deposit in the Deep Bay area near Reindeer Lake in Saskatchewan. Quality tests must be conducted before a decision is made to proceed with commercial production.[15] Deep Bay Graphite Co. Ltd., a subsidiary of Superior Graphite Co., owns a 60% interest, with Saskatchewan Mining Corp. holding the remaining 40% interest in the graphite mine. Open pit reserves are estimated to be 1.8 million tons containing 10.32% carbon. Production of 9,000 tons per year of flake graphite is projected. About 9 tons of product is being produced at a pilot plant at Lakefield Research of Canada, Ltd., to be distributed to industry for assessment in industrial processes and market acceptance. Results of the feasibility study are expected in late 1977.[16]

[15]Department of Mineral Resources, Government of Saskatchewan. Inventory and Outlook of Saskatchewan's Mineral Resources. April 1976, p. 35.
[16]Work cited in footnote 3.

Germany, West.—Production of crystalline flake graphite is by one company, Graphitwerk Kropfmuhl, which has embarked on a new investment program involving the installation of underground machinery at the mine, as well as new milling and flotation equipment.[17]

Korea, Republic of.—Production of amorphous graphite dropped 15% while production of crystalline was up 50% from 1975 and up nearly 300% in the last 2 years.[18] Korean amorphous has become a replacement for imported materials from Mexico, which have dropped off in recent years.

Malagasy Republic.—Establissements Gallois, the largest of the country's graphite producers, recently brought its new deposit into operation. Other producers also have made significant plant improvements. The island industry should be in better condition to meet increased demand.[19] French owners would reportedly sell out to the Government if reasonable terms were offered. There is still the distinct possibility of nationalization in a negotiated settlement or otherwise.[20]

Mexico.—This country can be described as a mature mining area with good deposits increasingly more difficult to locate. Output has leveled off in recent years, despite efforts to increase production.[21] Production has actually been dropping since 1973, the peak year.

Norway.—A/Skaland Grafitverk continued work on the deep shaft at mines in the Lofoten Islands, Troms County, preparatory to extraction of graphite deposits from below sea level. Improvements to surface installations include new screening equipment.[22] Development work at the mine is continuing, and further graphite grades have been produced in response to increased demands for powder fractions and larger flake grades.[23] Norway continued to be a stable and readily available source of graphite.

Sri Lanka.—Development work proceeded satisfactorily at all three principal graphite mines at Bogala, Kahatagaha, and Kolongaha along with the development of the new mine at Rangala. The State Graphite Corp., which works these mines, is installing a flotation plant for the upgrading of the ore.[24] A mine at Walakatahena, closed following a disaster in the 1930's, is of being

reclaimed. Substantial resources have been allotted to research and development for the first time in the industry's history. Equipment has been manufactured for the production of flake graphite by the sieve-rolling process, and new flotation equipment has been installed at Bogala.[25] Work also commenced on a prospective mine at Ragedera, where mining was to commence at the end of 1977.[26]

TECHNOLOGY

Graphite intercalants have been the subject of several investigations owing to their ability to modify the properties of various compounds. Graphite intercalated compounds have shown high electrical conductivity.[27] Pure graphite powder, treated with antimony pentafluoride as an intercalant, is packed into a copper tube, and the diameter is reduced by swaging from 0.25 to 0.04 inch. The resulting rod shows electrical conductivity up to 50% higher than the copper alone, owing to alinement of the intercalant layers and orientation of the graphite. Graphite intercalants might be used as electrical wire, as this process also imparts high strength, light-weight, and elasticity.[28] In a related study, electrical charge is applied through a nonaqueous lithium perchlorate solution to an electrode formed of powdered graphite and lithium fluoride.[29] The resulting electrochemically formed graphite intercalation compound is suitable for reversible positive electrodes for storage battery systems utilizing electrolytic solutions of nonaqueous lithium compounds. The formation of graphite intercalated compounds with certain reagents is a simple way to modify their reactivity. Stoichiometric reactions and electrolytic reactions were studied for intercalation of organic and inorganic molecules. More work is suggested to standardize preparation of reagents and for reuse of graphite.[30]

Direct fluorination of graphite produces carbon monofluoride, which has outstanding oxidative and thermal properties, excellent dielectric properties, and is a superior lubricant.[31] Studies continue; preparation appears to be the main problem.

New graphite products include a mold-release coat used as a release for no-bake sand cores and as an aluminum extrusion lubricant,[32] and a graphite-base adhesive which allows repair and restoration of glass-to-metal seal fixtures for use at temperatures of up to 4,500° C.[33] High-alumina compositions containing graphite are used to formulate the most successful pouring nozzles for high-manganese steel.[34] Graphite heat exchangers can now operate at temperatures up to 1,200° C, aided by a new glassy-carbon coating which seals pores to minimize shrinking. Phenolic-resin-coated units have been limited by the coating to about 340° F.[35]

Graphite substrate lead dioxide anodes have been developed with sizes suitable for use in high-amperage cells involved in producing chlorates and perchlorates.[36] Electrodeposited lead dioxide shows the promise of developing high efficiency as an inert and insoluble anode. It is the only present alternative to platinum for producing perchlorates.

The hot-pressing process used to shape flat and curved boron carbide armor plate consists of preforming the boron carbide grains and then subjecting them to simultaneous high temperature and pressure in graphite molds.[37] Graphite is the only known material that can withstand the heat (4,000° F) and pressure needed to densify the material and fuse the boron carbide grains. Graphite is also easily machinable into intricate configurations,

such as the reverse airfoil shapes required for turbine blade and vane molding, which are hot-pressed from silicon nitride and silicon carbide powders.

Graphite is the most widely used of all electrical discharge machine (EDM) materials.[38] It is very machinable, relatively low in cost, and exhibits good thermal and electrical conductivity. A copper-impregnated graphite of high density (2.6 grams per cubic centimeter) with fine grain structure permits machining of EDM materials to fine detail. While low-density graphite electrodes cost less, they wear more rapidly and unevenly, resulting in unacceptable tolerances.

Research and development continued as interest in production items of carbon and graphite fibers increased. Components fabricated of silicon-carbide-processed graphite composites can withstand temperatures of 3,250° F in reducing or inert atmospheres.[39] They also feature excellent wear and abrasion resistance. Uses include pump seals, bearings, and soldering fixtures.

Pultrusion, the process of pulling resin-impregnated fibers through shaped dies, can achieve the kind of cost effectiveness necessary for composites to get a wider foothold in industrial applications.[40] Composites made from graphite fibers created by this process are used in the manufacture of a variety of components for textile equipment, leisure products, and aerospace parts.

Some of the problems encountered in use of graphite-epoxy composites are moisture absorption and promotion of galvanic corrosion when the composites are placed in contact with certain metals.[41] Moisture absorption is the most serious problem because it can greatly affect flexural, compressive, and shear strength of the matrix. Potential methods of preventing moisture absorption include ion vapor deposition of aluminum and use of a high-vinyl modified epoxy or a new class of addition-polymerized polyaromatic melamines as the matrix. Galvanic corrosion of aluminum rivets presents a serious risk in composites. The use of chromate conversion coatings over cadmium plate or the use of titanium or A-286 superalloy fasteners could prevent this hazard.

Gypsum

By J. W. Pressler[1]

In 1976, the gypsum industry recovered from the recession in the building industries in 1975. Output of crude gypsum increased 23% to 12 million tons. Production of calcined gypsum increased 20% to 11 million tons. Sales of gypsum products increased 16% to 18 million tons. Imports of crude gypsum increased 14% to 6.2 million tons. Total value of gypsum products sold increased 27% to $655 million.

[1]Each mine, calcining plant, or combination mine and plant is counted as one establishment.

DOMESTIC PRODUCTION

The United States was the world's leading producer of gypsum, accounting for 18% of the total world output.

Thirty-nine companies mined crude gypsum at 68 mines in 22 States. Output increased 23% but was 12% below the 1973 record. Leading producing States were Michigan, California, Texas, Iowa, and Oklahoma. These five States each produced more than 1 million tons and together accounted for 64% of the total domestic production. Stocks of crude ore at mines at yearend were 2.1 million tons.

Leading companies were United States Gypsum Co. (13 mines), National Gypsum Co. and Georgia-Pacific Corp. (6 mines each), Celotex Div. of Jim Walter Corp. (4 mines), The Flintkote Co. (3 mines), and H. M. Holloway Inc. (1 mine). These 6 companies, operating 33 mines, produced 79% of the total crude gypsum.

Leading individual mines were National Gypsum's Tawas mine in Iosco County, Mich.; United States Gypsum's Plaster City mine in Imperial County, Calif.; United States Gypsum's Alabaster mine in Iosco County, Mich.; H. M. Holloway's Lost Hills mine in Kern County, Calif.; and United States Gypsum's Southard mine in Blaine County, Okla. These five mines accounted for 27% of the national total. Average output per mine for the 68 U.S. mines was

[1]Physical scientist, Division of Nonmetallic Minerals.

176,000 tons, compared with 143,000 tons per mine in 1975 and 160,000 tons in 1974.

Thirteen companies calcined gypsum at 72 plants in 29 States. Output increased 20%, but was 12% below the 1973 record. Leading States were California, Texas, Iowa, and New York. These 4 States, with 24 plants, accounted for 39% of the national total.

Leading companies were United States Gypsum Co. (23 plants), National Gypsum Co. (18 plants), Georgia-Pacific Corp. (9 plants), The Flintkote Co. (6 plants), and Celotex Div. of Jim Walter Corp. (5 plants). These 5 companies, operating 61 plants, accounted for 87% of the national total.

Leading individual plants were United States Gypsum's Plaster City plant, Imperial County, Calif.; United States Gypsum's Shoals plant, Martin County, Ind.; Georgia-Pacific's Acme plant, Hardeman County, Tex.; United States Gypsum's Southard plant, Blaine County, Okla.; United States Gypsum's Oakfield plant, Genesee County, N.Y.; United States Gypsum's Fort Dodge plant, Webster County, Iowa; and Weyerhaeuser's Briar plant, Howard County, Ark. These seven plants accounted for 21% of the national total. Average output per plant for the 72 U.S. plants was 155,000 tons, compared with 124,000 tons per plant in 1975 and 145,000 tons in 1974.

Occidental Petroleum Corp., Valley Nitrogen Producers Inc., Collier Carbon & Chemical Corp., and California Industrial Minerals Co., (all in California); Occidental Petroleum Corp. in Florida; Miles Laboratories, Inc., in Indiana; and Texasgulf Inc., in North Carolina, sold 573,300 tons of byproduct gypsum valued at $4.2 million for agricultural purposes.

During 1976, National Gypsum Co. had a golden anniversary at its National City plant and Tawas quarry in Iosco County, Mich., having started initial operations in 1926. The quarry now produces about 600,000 tons of crude gypsum per year, and the plant produces about 500,000 square feet of wallboard per day. Some of the crude gypsum is sold to the cement industry for use as a set-retardant, and the unused balance is shipped to the company's other plants in the Great Lakes area.[2]

Only one gypsumboard plant was started up during the year, while three small plants were shut down, with no gain or loss in national production capacity. American Gypsum Co.'s Albuquerque plant in Bernadillo County, N. Mex., started operations in the last quarter of 1976. Its associated White Mesa gypsum mine in Sandoval County, N. Mex., was the source of the crude gypsum feed. Three board plants were closed in 1976: Kaiser Cement & Gypsum Corp.'s Delanco plant, Burlington County, N.J.; United States Gypsum Co.'s New Brighton plant, Richmond County, N.Y.; and Temple Industries' Dallas plant, Dallas, Tex. The Locust Cove underground gypsum mine of United States Gypsum Co., Smyth County, Va., was also closed.

The Gypsum Association announced on January 3, 1977, that the available capacity of operating gypsumboard plants in the United States as of yearend 1976 was 16.5 billion square feet per year. These data were obtained from a complete survey of the industry conducted with the cooperation of the Bureau of Mines.[3] Total 1976 gypsumboard production in the United States was 13.1 billion square feet. This indicated a 79.5% national utilization of capacity for the year.

CONSUMPTION AND USES

Apparent consumption of crude gypsum (production plus imports, minus exports) increased 19% to 17.9 million tons. Imports provided 35% of the crude gypsum consumed. Apparent consumption of calcined gypsum increased 20% to 11.0 million tons.

Stocks of crude gypsum at mines and calcining plants at yearend were 2.1 million tons. Of this, 1.2 million tons (55%) was at calcining plants in coastal States.

Of the total gypsum products sold or used, 5.4 million tons (30%) was uncalcined. Of the total uncalcined gypsum, 3.4 million tons (64%) was used for portland cement, and 1.7 million tons (32%) was used in agriculture. The leading sales regions for gypsum used in cement were the West North-Central, West South-Central, and Pacific; these three regions accounted for 46% of the total. For agricultural gypsum, the Pacific sales region accounted for 86% of the total.

Of the total calcined gypsum, 94% was used for prefabricated products and 6% for industrial and building plasters. Of the prefabricated products, 80% was regular wallboard, 12% was fire-resistant Type X wallboard, and only 1% was lath. Of the regular wallboard, 84% was 1/2 inch and 9% was 3/8 inch. The leading sales regions for prefabricated products were the Pacific, East North-Central, and South Atlantic; these three regions accounted for 48% of the total. For plasters, the East North-Central, Middle Atlantic, and South Atlantic regions accounted for 59% of the total.

[1]Includes weight of paper, metal, or other material.
[2]Data may not add to totals shown because of independent rounding.
[3]Includes 1/4-inch, 5/16-inch, and 3/4-inch gypsumboard.

ENERGY

More efficient production scheduling and a higher rate of operational capacity contributed to an increase in the energy efficiency of the gypsum industry in 1976, with a 10.8% improvement compared with the base year of 1972. British thermal unit consumption per thousand square feet of gypsumboard sales in 1976 was 2.76 million, compared with 2.97 million in 1975.[4]

As reported by the Gypsum Association, the percent fuel source for the gypsum industry in 1976 was as follows: Natural gas, 76.43%; electricity, 5.92%; coal, 2.91%; propane, 2.40%; No. 1 oil, 3.00%; No. 2 oil, 9.10%; and No. 6 oil, 0.24%.

PRICES

The average value of crude gypsum increased from $4.58 per ton in 1975 to $5.00 in 1976. The average value of calcined gypsum increased from $20.31 per ton in 1975 to $21.45 in 1976. The average value of byproduct gypsum sold decreased from $7.96 in 1975 to $7.36 per ton in 1976.

The average value of gypsum products sold or used increased from $32.95 in 1975 to $36.34 per ton in 1976. Prefabricated products were valued at $48.41 per ton, industrial plasters at $54.10 per ton, building plaster at $48.74, and uncalcined products at $7.59 per ton.

Quoted prices for gypsum are published monthly in Engineering News-Record. Prices at yearend showed a wide range, based on delivered prices. Regular 1/2-inch wallboard prices ranged from $44 per thousand square feet at Dallas to $93 at Chicago. Prices for building plaster ranged from $61 per ton at San Francisco to $96 at Denver.

FOREIGN TRADE

Increased exports of gypsumboard, panels, and tile were made to Canada and the U.S.S.R. Total value of gypsum product exports to all countries was $32.6 million, a sharp increase of 211% over 1975. The gypsum industry is import reliant. In 1976, 35% of the crude gypsum consumed was imported. Imports were from Canada (72%), Mexico (21%), Jamaica (6%), and the Dominican Republic and Brazil (the other 1%). Imports increased 14% to 6.2 million tons. Most of the imported crude gypsum was mined by subsidiaries of U.S. companies in Canada and Mexico.

WORLD REVIEW

Domestic and foreign resources of gypsum are adequate for any foreseeable time. World reserves are conservatively estimated at 2 billion tons.

Brazil.—Rhône-Poulenc of Paris, France, announced that Sociedade Comercial e Industrial de Artefactos de Gesso (SCIAG), a Brazilian offshoot, will construct three plants for the conversion of phosphogypsum into materials useful in the construction industry. The first plant was to be built at Cajati where the phosphogypsum will be converted into semihydrate by a Rhône-Poulenc process, and used for the production of 110,000 tons per year of pellets for set-retarding of cement. A factory in São Paulo will also use the semihydrates to produce plaster tiles, using a Rhône-Poulenc patented process.[5]

[5]Chemical Age. SCIAG Goes Ahead With Phosphogypsum Plan. V. 114, No. 3000, Jan. 14, 1977, p. 6.

Canada.—Canada was the fourth leading producer of crude gypsum, accounting for 9% of the world total. About 80% of the gypsum mined in Canada is from the Atlantic Provinces, where quarries are operated by subsidiaries of U.S. gypsum companies and exported to the eastern seaboard of the United States to meet raw material requirements of the building industry.

Westroc Industries Ltd. announced a major expansion of its Ontario gypsum operations, including the development of a new mine in the township of Blandford-Blenheim in Oxford County, and a further increase in the capacity of its Mississauga gypsum wallboard plant. The $5 million underground mine development was initiated with the sinking of a 12-foot diameter by 400-foot deep vertical shaft. Scheduled commencement of operations was mid-1978. The deposit has at least 30 years of reserves.[6]

Anhydrite was produced in Canada by Fundy Gypsum Co. Ltd. at Westworth, Nova Scotia, and by Little Narrows Gypsum Co. Ltd. at Little Narrows, Nova Scotia. (Production and trade data on anhydrite are included with those for gypsum). Some 219,000 tons was mined in 1975 and shipped to the United States for use in portland cement manufacture and as a peanut crop fertilizer. In this latter use it is somewhat more effective on a theoretical basis, 100% compared with 79% available $CaSO_4$ in gypsum.[7]

France.—France was the third leading gypsum-producing country, with 10% of the world total.

India.—The discovery of deposits of high-grade gypsum in the States of Jammu and Kashmir, estimated at 110 million tons, was announced by the Geological Survey of India. Half of the deposits are located near Doda and the other half near Baramulla. Because of India's sulfur import dependence, a private Indian company, Orissa Cement Ltd. of Rajgangpur, Orissa, was seeking a joint venture for the production of sulfur from gypsum.[8]

Iran.—As a result of a survey conducted in 1975 and 1976, the Iranian Ministry of Mines and Industry announced the gypsum reserves of Iran to be 666 million tons of proven reserves and 1,373 million tons of probable reserves.[9]

Japan.—Japanese production of crude gypsum has been progressively reduced from 406,000 tons in 1973 to only 71,000 tons in 1976, and import-export trade was minimal in 1976. Japanese technology for the recycling of byproduct gypsum was leading the world. In 1975, a total of 5.5 million tons of chemical gypsum was produced as a byproduct of phosphoric acid production and other chemical processing such as sodium sulfite, sulfuric acid, sodium sulfate, and from 137 different thermal power plants with fluegas desulfurization systems.

Including a small amount of natural gypsum, 2.1 million tons of gypsum was used in 1975 as a set-retarder in the cement manufacturing industry, 1.4 million tons was used in the manufacture of wallboard, and 700 thousand tons was used for construction plaster and plaster of Paris. The average value of byproduct gypsum in 1976 was equivalent to $5.25 per ton. Even with this high degree of utilization, surplus byproduct gypsum was increasing, and it was becoming a problem to secure sites for storage and treatment. The Ceramic Society of Japan estimated there would be a vast oversupply of byproduct gypsum by 1980, with stocks in Japan totaling over 12 million tons despite an optimistic growth rate in the consumption level during this period.[10]

Mexico.—In 1976, Mexico produced 1.6 million tons of crude gypsum, most of which was exported to the United States. The remainder was used in the cement industry as a set-retardant and as the raw material supply for two small gypsumboard plants owned by subsidiaries of United States Gypsum Co. and Kaiser Cement & Gypsum Corp. The large amount exported came from San Marcos Island, in the Territory of Baja California Sur, and was produced by the Mexican subsidiary of Kaiser Cement & Gypsum Corp., Cia. Occidental Mexicana

S.A. This deposit has large reserves of high-quality gypsum ore and serves the West Coast of the United States. At yearend, the Mexicanization of the subsidiary was proceeding according to the plan of the Mexican Government requiring that 60% of the equity be sold to Mexican interests.[11]

Pakistan.—The gypsum reserves of Pakistan were announced as 74 million tons in 1976. Large deposits of gypsum have been found in different regions in Punjab, Sind, Baluchistan, and North-West Frontier Provinces, and were being used in the production of cement, chemical fertilizers, plaster of paris, etc. Production in 1976 was 488,000 tons and was mainly consumed by the fertilizer industry for neutralizing the effect of saline and alkaline soils.[12]

Romania.—Process Engineering Co. of France announced a contract to build a phosphogypsum processing plant at Bacau. The plant will convert residual phosphogypsum from acidulation of phosphate rock into plaster tiles for the Romanian construction industry. Output will be 110,000 tons per year, equivalent to 16 million square feet of tiles. The project will combine the Rhône-Poulenc expertise in the purification and firing of phosphogypsum and the Lambert Industries' experience in converting the material into finished products.[13]

South Africa, Republic of.—The Republic of South Africa's somewhat limited gypsum industry remained in a lethargic state throughout most of 1976, reflecting (for the second consecutive year) a slackened domestic market. Volume of local sales was off 6% compared with that of 1975. Price rises, the result of inflation, were of little help and did not present a favorable outlook for 1977. Indications were that gypsum consumed in the Republic of South Africa during 1976 declined to the level of 532,000 tons.[14]

Spain.—Production of gypsum in Spain has been quite constant since 1968, remaining between 4 and 5 million tons per year. In 1976, Spain retained its important position in world gypsum production, ranking fifth, with 7% of the total.

Spain has abundant and extensive deposits of gypsum that occur in most regions of the country. The principal areas of Spanish production are in Barcelona, Madrid, Toledo, Burgos, Castellon, Zaragoza, and Leon, and the main centers of consumption are in the large industrial areas, such as Catalonia and Madrid, and in the main tourist regions of the Mediterranean and the Balearic and Canary Islands. At least four of the larger companies are important, but very little domination of the industry was apparent. Exports have grown from about 4,000 tons in 1970 to 211,000 tons in 1974, principally to Scandinavian countries.[15]

Thailand.—Gypsum production in Thailand peaked at 344,000 tons in 1974 and has subsequently fallen to 281,000 tons in 1975, and 296,000 tons in 1976. This was largely due to the depressed state of both the domestic and overseas building industry. The bulk of the production is consumed in the local cement and gypsumboard industry. Most of the exports, which reached over 130,000 tons in 1974, went to Malaysia, Taiwan, and other Southeast Asian countries. Two Provinces had most of the production-Phichit with reserves of 25 million tons, and Nakhon Sawan with 10 million tons of reserves.[16]

U.S.S.R.—The U.S.S.R. produced 11% of the world's gypsum in 1976 and ranked second in total world production.

TECHNOLOGY

The Norwegian firm of Den Norske Gipsplatefabrikk (DNG), has commissioned the first stage of a $6.7 million plant to produce polyurethane-filled plasterboard wall structures at Svelvik, near Drammen, Norway. The new plant is the first in the world to produce such wall structures by continuous production methods. The new system jointly uses DNG's experience in plasterboard manufacture and Imperial Chemical Industries Ltd.'s urethane foam expertise. Initial production capacity of the DNG plant will be about 5.4 million square feet per year of *Gipsotex Multielement.* An eightfold expansion is planned over the next 4 years.[17]

An investigation was conducted by the Construction Materials Group of Battelle Memorial Institute's Columbus Laboratories to study the suitability of phosphogypsum as a reaction-rate controlling additive to portland cement and for the production of gypsum wallboard. The research revealed the feasibility within the cement manufacturing and wallboard markets. Results of the project revealed that the use of processed gypsum in cement had no detrimental effect on the properties of fresh concrete, such as increased air content or increased water requirements. Satisfactory wallboard was produced, and processed gypsum-stucco appeared to be as good as that of commercial plaster. The primary chemical impurities in the processed gypsum (Fe_2O_3 and $CaCO_3$) were not viewed as deleterious from the manufacturing or product performance viewpoint.[18]

Imperial Chemical Industries Ltd.'s Agricultural division (Billingham, Cleveland, England) developed a continuous process for the conversion of byproduct gypsum to the α-hemihydrate in a wet slurry, thereby producing a feedstock acceptable in plaster and gypsumboard manufacturing. The principal process characteristic was a double autoclave system, in which a slurry of gypsum, containing crystal habit modifiers, was heated by direct steam injection to 150° C at a pressure of 100 pounds per square inch to convert it to α-hemihydrate.[19]

Tightened Environmental Protection Agency pollution control standards forced several titanium dioxide producers to adopt the sulfate process, thereby getting into the byproduct gypsum business. Output of gypsum was at least five times that of titania production and similar to the production of phosphogypsum byproduct from the acidulation of phosphate rock to produce phosphoric acid. The treatment plant of American Cyanamid Co. in Savannah, Ga., developed a two-stage neutralization of the strong acid effluent stream using pulverized limestone, and produced both a high-purity gypsum product and a high-iron, low-grade product.[20]

The application of gypsum or landplaster is very important in the fertilization of peanuts in the Southeastern States. Gypsum is a soil moderator, it promotes the more efficient use of balanced fertilizers, and it is an insurance factor against the formation of "pops" or unsound kernels during dry weather. Seed quality is influenced by the availability of gypsum; seeds with less than 500 parts per million of calcium germinate below desirable levels while those with more than 500 parts per million usually germinate well and produce vigorous seedlings.[21]

Helium

By Thomas G. Clarke[1]

Total domestic sales of high purity helium (minimum 99.995% purity) in 1976 decreased 3% to 580 million cubic feet compared with 601 million cubic feet in 1975.[2] Bureau of Mines sales constituted 31% of the total; private industry accounted for the remainder. High purity helium exports, all by private industry, increased about 21% to 174 million cubic feet from 144 million cubic feet in 1975. The Bureau of Mines f.o.b. plant price for high purity helium in 1976 was $35 per thousand cubic feet, unchanged since 1961. High purity helium sold by private producers averaged about $22 per thousand cubic feet, down from $24 per thousand cubic feet in 1975.

Suits filed against the Government in 1975 were pending in the U.S. Court of Claims at yearend 1976. The suits, seeking damages up to $273 million, contended that supply contracts under the Bureau of Mines conservation program were breached. Similarly, in June 1976, a third company filed suit and asked damages of $102 million.

DOMESTIC PRODUCTION

A total of 12 plants had the capacity to extract helium from natural gas during the year. Ten of the plants were owned by private industry, and the other two were owned by the U.S. Government and operated by the Bureau of Mines at Keyes, Okla., and Exell, Tex. Six extraction plants were located in Kansas, three in Texas, and one each in Arizona, New Mexico, and Oklahoma. Three private plants were not in operation at yearend 1976 (see table 2).

Total helium extracted from natural gas by both private and government sources was 1.34 billion cubic feet, an increase of 24% compared with that of 1975. Total high purity extraction increased about 1% compared with a 7% increase in 1975; crude helium extraction was 75% higher compared with an 81% increase in 1975. Of total helium extracted during the year, crude helium comprised 44% of the total; high purity helium for sale constituted 56%. The Bureau of Mines accounted for 33% of the crude helium and 24% of the high purity helium extracted, private industry accounted for the remainder.

Initial performance tests were conducted in January on a 35-liter-per-hour helium liquefier at the Amarillo shipping terminal. Tests indicated the unit performed near rated capacity. In April, the first liquid helium dewars were received to support the liquid helium distribution operations at the terminal.

Several potential energy-saving projects were initiated at the Keyes Plant during the year. These included the installation of orifice flowmeters to measure full gas usage to engine compressors; a water meter to provide information on excess water loss; fixtures to test injection valves; equipment to determine engine turbocharger efficiency; and a kilowatt-hour meter to determine incremental electrical usage within each plant operations area.

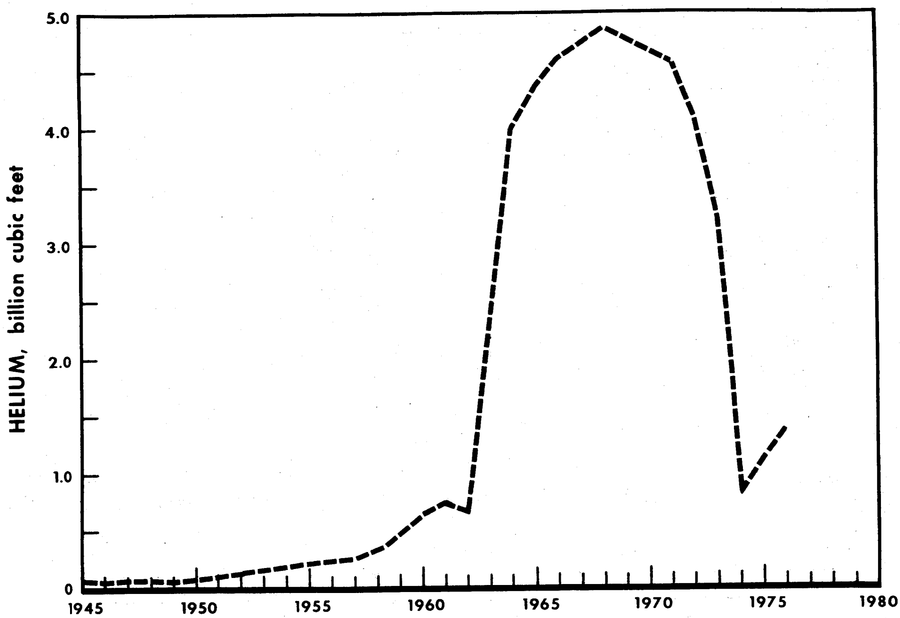

Figure 2.—Helium production in the United States, 1945-76.

CONSUMPTION AND USES

Principal domestic end uses of helium in 1976 were in welding, purging and pressurizing of rockets and spacecraft, research, and maintenance of controlled atmospheres. Other uses included lifting gas, leak detection, cryogenics, heat transfers, and synthetic breathing mixtures. Total domestic demand during the year was centered mainly in the Pacific and Gulf Coast States.

Federal agency purchases in the form of direct sales from the Bureau of Mines constituted about 54% of the Bureau's total high purity helium production. Almost all of the remaining sales of high purity helium by the Bureau were to Federal agencies through the General Services Administration contracts to private distributors, as required by law to purchase equivalent quantities from the Bureau. These contracts made relatively small quantities of helium readily available to Federal installations at reduced freight charges for small purchases.

The Bureau of Mines f.o.b. plant price of high purity helium in 1976 was $35 per thousand cubic feet, unchanged since 1961, and maintained for the purpose of financing the Government's helium conservation program. Except in special circumstances, this was not competitive with the private producer average price of $22 per thousand cubic feet, f.o.b. plant.

All high purity helium sold by the Bureau of Mines was shipped in gaseous form in cylinders, railroad tank cars, highway tanker trailers, and in liquid form in containerized dewars from the Amarillo shipping terminal. Private industry distributors shipped helium in both gaseous and liquid forms. Much of the helium transported in liquid form was delivered by semitrailer and/or containerized dewars to distribution centers where it was regasified and compressed into trailers and small cylinders for delivery to the end user.

[3]Most of this was purchased by commercial firms which sold equivalent quantities to Federal installations under contract agreements with the General Services Administration.

CONSERVATION

Helium held in the Bureau of Mines conservation storage system, which includes the conservation pipeline network and the Cliffside gasfield near Amarillo, Tex. was 39,091 million cubic feet at yearend 1976, an increase of slightly over 1% from that in 1975. Helium stored under the conservation program was 37,666 million cubic feet, an increase of 1,967 million cubic feet during 1976. Private producers had a balance of 1,425 million cubic feet stored under contract with the Bureau in the conservation system (for future redelivery) at yearend 1976.

The conservation storage system contains crude helium purchased by the Bureau of Mines under contracts entered into with four companies in 1961 and continued under court orders obtained during 1971 by three of the companies.

RESOURCES

As of December 31, 1976, domestic measured and indicated helium resources were estimated at 262.5 billion cubic feet. The resources include measured and indicated reserves estimated at 98.8 and 50.4 billion cubic feet, respectively, in natural gas with a minimum helium content of 0.3%. The remaining resource base included 39.1 billion cubic feet stored in the Bureau's conservation storage system and 74.2 billion cubic feet of helium in measured natural gas reserves with a helium content of less than 0.3%. Approximately half of the domestic helium reserves are under Federal lease. Included are the Tip Top and Church Buttes fields in Wyoming, the Keyes field in Oklahoma, and the Cliffside field in Texas.

The majority of domestic helium reserves are located in the midcontinent and Rocky Mountain regions of the United States. A total of 78 gasfields in 10 States contain measured and indicated helium reserves. About 86% of these reserves are located in the Hugoton field in Kansas, Oklahoma, and Texas; the Keyes field in Oklahoma, the Panhandle and Cliffside fields in Texas, and the Tip Top field in Wyoming. Approximately 54% of the measured and indicated reserves (0.3% or greater helium content) at yearend 1976 were in currently producing gasfields. In 1976, about 18% of the helium-rich natural gas (0.3% or greater helium content) produced was processed for helium extraction. Helium produced from the remaining helium-rich natural gas output was dissipated incident to the consumption of the gas.

The Bureau examined a total of 328 gas samples from 20 States during 1976 in connection with its efforts to survey and identify possible new sources of helium supply. None of the samples collected and analyzed indicated the presence of major new deposits of helium.

FOREIGN TRADE

Exports of high purity helium, all by private industry, totaled 174 million cubic feet in 1976, up 21% from 1975. Countries of Western Europe received 75% of the exports, as follows: Belgium-Luxembourg, 32%; the United Kingdom, 32%; and France, 11%. Exports to Japan and Australia were 9% and 2%, respectively. Canada accounted for about 2% of the exports. The continued increase of helium exported to Western Europe during 1976 was attributed primarily to its use in the exploration for and development of oil and gas deposits, especially in the North Sea area.

WORLD REVIEW

World production of helium exclusive of the United States, totaled an estimated 150 million cubic feet in 1976. Canada produced about 35 million cubic feet from a plant in Saskatchewan owned by Canadian Helium, Ltd. Production from a plant near Paris, France, was about 15 million cubic feet. The U.S.S.R. and the Central Economy Countries of Europe produced an estimated 100 million cubic feet, unchanged from the 1975 estimate.

It was reported that a fire in the methane gas drainage section of the helium extraction plant at Odolanow, Poland, in September 1975 caused a 9-month delay in the plant construction schedule. Repair and construction continued during 1976, and it was expected that this 150-million-cubic-foot-per-year plant would be operational by the spring of 1977. This plant is a complex designed to process natural gas containing 45% nitrogen and 0.4% helium. A U.S. firm, Airco, Inc., has a contract to market all helium exported from this plant.

TECHNOLOGY

Measurements of dissolved helium were made in water samples collected from several selected lakes and ponds in the Kaipokok region of Labrador, Canada. The purpose of research by McMaster University and private industry was to determine amounts of excess helium-4 from the decay of uranium and its daughter products and the relationship with surrounding uranium mineralization. The mapped quantities of helium-4 indicated a close correlation with known uranium mineralization, thus pointing up a possible new method of uranium prospecting.

New medical applications of helium have recently been developed. One new use is in a helium-filled, intra-aortic ballon device which represents promising therapy for the treatment of cardiogenic shock. Another application is a helium-breathing apparatus used as a diagnostic tool for pulmonary testing. This test most often reveals abnormalities connected with lung disease which might otherwise go undetected by routine physical examination.

Projects underway at Goodyear Tire & Rubber Co. in the United States and, in West Germany by another firm, involved testing models of helium cargo blimp aircraft capable of lifting 40- to 100-ton loads. The prototypes were constructed of a rubberized, high-tenacity fabric to contain the helium gas and provide strength necessary for heavy lifting. Flights of this type of blimp were also conducted in Ghana and other African areas so as to test the ability of the craft to operate in climactic extremes of heat and humidity. In addition, the U.S. Coast Guard was investigating the use of helium cargo blimps for possible surveillance of U.S. territorial waters.

Iron Ore

By F. L. Klinger[1] and C. T. Collins[2]

World production and trade of iron ore in 1976 were close to the levels of 1975. Production was estimated at 881 million long tons,[3] and trade was estimated at 365 million tons of which about 290 million tons was oceanborne. Demand for iron and steel increased in the United States and some other countries in 1976, but the additional ore required was largely available from producers' or consumers' stocks which had accumulated during 1975. There were noteworthy increases in production of ore in the Republic of South Africa, Canada, and Brazil, but these resulted from completion of new projects begun in previous years rather than from increased demand during the year. Production declined in some major producing countries such as Australia, France, and Venezuela, and the volume of trade appeared to be sustained mainly by commitments of consumers under previously negotiated contracts.

The leading producing countries in 1976 were the U.S.S.R., Australia, Brazil, and the United States, in that order. Brazil became the third largest producer in 1975 and increased production in 1976. Australia remained the leading exporter of iron ore, followed by Brazil. Canadian exports increased by 8 million tons in 1976 and probably exceeded those of the Soviet Union.

World output of iron ore pellets was estimated at 172 million long tons in 1976. Production capacity was increasing, as new plants or expansion projects were completed or nearing completion in the United States, Brazil, and Canada. Direct-reduction plants were completed or under construction in several countries in North and South America, Europe, and the Middle East. The use of flotation and high-intensity magnetic separation processes for beneficiating iron ore continued to grow. In the United States, the substitution of coal for natural gas or fuel oil in iron ore pelletizing was being intensively studied by the Bureau of Mines as well as by private companies.

In transportation, almost always a major element in the delivered cost of iron ore, efforts to reduce costs by the use of unit trains, larger capacity vessels, development of port facilities capable of handling larger ships, and installation of large-volume materials-handling systems at inland and coastal locations continued in 1976. A 240-mile slurry pipeline for iron ore concentrates was completed in Brazil, and shorter pipelines were completed or under construction in Mexico and Argentina.

Iron ore prices continued to rise in 1976. Most increases were about 10% to 15% above the 1975 prices. Prices for Swedish ores declined, particularly for high-phosphorus grades; this appeared to cause some realignment of production plans in Sweden, as well as concern by French iron ore producers that low prices for Swedish ores may reduce demand for French ores in domestic or intra-Community markets.

Ocean freight rates for iron ore appeared to remain close to the relatively low levels of 1975, but there were some rising trends evident in 1976, and published rates from Australia to Europe were markedly higher. Lake freight rates increased about 12% in the United States, but rail freight rates were essentially unchanged.

EMPLOYMENT

Statistics on employment and productivity in the iron ore industry in 1976 are shown in table 2. Employment data were supplied by the Mining Enforcement and Safety Administration (MESA). In table 2, statistics for all States outside the Lake

Superior district were aggregated to avoid disclosure of individual company confidential information.

The average number of persons employed in 1976 was 20,456, compared with 19,900 in 1975. The increase of 2.8% was largely due to increasing employment in Minnesota and Michigan, where several new production facilities for taconite were completed. Compared with 1975, average productivity for crude ore in 1976 rose about 4%, owing to the increasing share of taconite in domestic crude ore production. Average productivity for usable ore rose 1%.

As in previous years, statistics published in table 2 do not include office workers. The number of office workers at mines and beneficiation plants in 1976 was approximately 2,770.

DOMESTIC PRODUCTION

U.S. mine production and shipments of usable iron ore in 1976 increased 1.4% compared with those of 1975. Output of usable ore, including byproduct ore, was just under 80 million tons. Shipments totaled 77.1 million tons, valued (f.o.b. mine) at approximately $1.87 billion.

Output of crude iron ore totaled 224 million tons in 1976, an increase of 4.4% compared with that of 1975. The increase was due mainly to increased production of taconite in Minnesota and Michigan. Nationwide, the number of producing mines included 58 open pit and 6 underground mines. As in 1975, open pit mines accounted for 96% of the total output, and 99% of all ore produced was shipped to beneficiation plants. Average iron content of crude ore produced was approximately 32.7%. Beneficiating facilities, at or near mine sites, processing domestic crude ores in 1976, included 17 concentrators with associated pelletizing plants (7 in Minnesota, 4 in Michigan, 2 in Missouri, and 1 each in California, Pennsylvania, Wisconsin, and Wyoming) mostly processing ores of the taconite type; 1 plant screening, drying, and pelletizing natural ore; 1 plant pelletizing byproduct ore; 1 sintering plant; and an estimated 24 plants producing concentrates primarily by gravity methods, of which 14 were located on the Mesabi range. Nationwide, the number of tons of crude ore mined for each ton of usable ore produced in 1976 was 2.82, compared with 2.72 in 1975 and 2.57 in 1974.

Production of usable ore in 1976 consisted 81% of pellets, 17% of natural ore concentrates, and 2% of direct-shipping ore. The average natural iron content of all usable ore produced (including byproduct ore) was 61.7%. The Lake Superior district accounted for 84% of the national output. Minnesota produced 62%, Michigan 21%, and the remainder was produced in 15 other States.

In Minnesota, Hibbing Taconite Co. began production of pellets in late 1976. The plant has a production capacity of 5.4 million tons of pellets per year and was the seventh major taconite facility to be completed in Minnesota since 1965. Major expansions of taconite-processing plants at Eveleth and Keewatin were also completed by yearend; annual production capacity for pellets at Eveleth was raised by 3.6 million tons, and that at Keewatin was raised by 3.0 million tons. Additional ore requirements at Eveleth were supplied by a new mine developed for Eveleth Expansion Co., while those at Keewatin were supplied by expansion of the existing mine operated for the National Steel Pellet Project. At Mountain Iron, work was continued by United States Steel Corp. to raise production capacity of its Minntac facility by 6 million tons of pellets per year; this project was expected to be completed in 1978. At Virginia, construction of the Minorca taconite project by Inland Steel Co. was scheduled for completion in the spring of 1977; this facility will have a production capacity of 2.6 million tons annually and will raise the number of operating taconite plants in Minnesota to eight. All of the projects are based on magnetite ore.

The proposal by Reserve Mining Co. to provide for on-land disposal of taconite tailings at "Milepost 7," near the company's existing plant at Silver Bay, Minn., had not been approved by Minnesota State authorities by yearend. State agencies continued to advocate disposal sites farther north, the cost of which the company considered prohibitive. If the dispute could not be resolved by July 1977, the company would be forced by court order to cease production.

In Michigan, the Cleveland-Cliffs Iron Co. confirmed plans to expand annual production capacity for pellets by 4 million tons at the Tilden mine and by 2.8 million tons at the Empire mine by 1981. Cost of the expansion projects was estimated at $750 million, including $300 million at Tilden, $250 million at Empire, and $200 million for installation of an additional 250 megawatts of electricity-generating capacity at the company's Marquette powerplant.

Unusually cold weather in the midwestern United States caused drastic curtailments of natural gas supplies to pelletizing plants in the Lake Superior district. Curtailments began on October 18, 1976, and continued through December. Most plants were equipped to switch over to fuel oil, so that overall production in the district was not seriously affected, but higher prices of alternate fuels (including "intrastate" natural gas, as well as fuel oil) drove up costs of production and increased upward pressures on prices. These developments also focused attention on the need for some producers to use alternate sources of energy, such as coal.

In Missouri, more than 2 million tons of magnetite ore were blasted in the Pea Ridge underground mine on two occasions in 1976. On December 11, the second blasting operation, which included 3,140 drill holes and portions of four mine levels, used 1.066 million pounds of water-gel explosives to break 2.98 million tons of pillar ore, believed to be the largest quantity ever blasted in a U.S. underground iron mine.

In New Jersey, plans to reopen the Mt. Hope underground mine near Dover were announced by Mt. Hope Mining Co., Inc. Production of magnetite concentrates was expected to begin in 1977, eventually reaching an annual rate of about 400,000 tons, the concentrates to be purchased by Bethlehem Steel Corp. The venture was being financed mainly by loans totaling about $7.5 million. The Mt. Hope mine was last operated by Shamoon Industries, Inc., in 1959.

CONSUMPTION

Consumption of iron ore and agglomerates in 1976 increased about 9.9%, compared with that in 1975. Consumption in blast furnaces increased 10%, while that in steelmaking furnaces increased 6.6%. Of total consumption, blast furnaces accounted for 98.3%; steelmaking furnaces, 1%; and the remaining 0.7% was used in the manufacture of cement, heavy-media, and other miscellaneous products. In blast furnaces, the weight ratio of iron ore and agglomerates consumed to pig iron produced was approximately 1.57:1 compared with 1.56:1 in 1975.

The quantity and proportion of iron ore pellets consumed continued to increase. Pellets made up 60% of all iron ore and agglomerates consumed in 1976 and 70% of all agglomerates consumed. Sinter made up 27% of all iron ore and agglomerates consumed, and natural ores accounted for the remaining 13%.

Consumption data are shown in tables 11 and 12. In these tables, iron ore concentrate used to produce agglomerates such as pellets or sinter at mine sites is not reported as iron ore consumed; its consumption was reported only when such agglomerate was used at the furnace site (table 11). Iron ore concentrate and fines used to produce sinter at iron and steelmaking plants are reported in table 12 as iron ore consumed, while consumption of agglomerates from this source is included in table 11. In table 12, the difference in weight between iron ore consumed and agglomerate produced results from the elimination of moisture as well as the addition of materials such as flue dust, mill scale, lime, and coke.

STOCKS

Stocks of iron ore and agglomerates at U.S. mines, docks, and consuming plants totaled 75 million tons on December 31, 1976. This was 8.5% more than a year earlier and was the highest yearend total since 1971. Monthend stocks of ore at consuming plants during 1976 ranged from a low of 35 million tons in April to a high of 55 million tons in November, while those at the mines ranged from a high of 22.7

million tons in April to a low of 13.5 million tons in November. Of the 56.8 million tons on hand at U.S. docks and furnace yards at yearend, 58% consisted of domestic ores, 19% of Canadian ores, and 23% of other foreign ores.

A gain of 4.2 million tons of ore in stocks at U.S. docks and furnace yards was apparent by the end of 1976. This occurred despite an increase in domestic consumption, a decrease in ore imports, and only a slight increase in domestic mine and lake shipments compared with 1975. While the apparent statistical anomaly was not resolved by yearend, it was possibly due to stockpiling of unsold foreign ore at some locations in the United States. According to a report published in 1976 by the Venezuelan Ministry of Mines and Hydrocarbons, 1.1 million metric tons of unsold Venezuelan ore was stockpiled in the United States during 1975.

PRICES

Published prices for Lake Superior iron ores (delivered rail-of-vessel at lower lake ports) increased twice during 1976. In January, prices increased about 4% for natural ores and 6.9% for pellets, compared with prices in effect at yearend 1975. Another increase, amounting to about 5.2% for all grades, was instituted in August, after which prices were unchanged during the remainder of the year. Prices in effect from the latter half of August through December 31, 1976, were, for natural ores (basis 51.5% Fe, natural), per gross ton: Mesabi non-Bessemer, $20.26; Mesabi Bessemer, $20.41; Old Range non-Bessemer, $20.51; and manganiferous, $20.51. A premium of 80 cents per ton continued to be paid for coarse ore, and a penalty of 45 cents per ton was charged for fines. The price of iron ore pellets in late August was 53.1 cents per long ton unit of contained iron, natural. Any increases in the cost of transportation and handling subsequent to the effective dates of these prices (August 6 to August 16, 1976, depending on the producer) were to be borne by the buyer.

The average value (f.o.b. mine or concentrating plant) of usable iron ore shipped from domestic mines in 1976 was $24.28 per long ton, compared with $21.41 in 1975 and $16.34 in 1974. These values were calculated from producers' statements and approximated the commercial selling price less costs of mine-to-market transportation.

Prices for many foreign iron ores also increased in 1976. In Canada, the price of Wabush iron ore pellets, f.o.b. Pointe Noire, Quebec, in August 1976 was 47.2 cents per long ton unit of contained iron and manganese, an increase of about 12.5% compared with the price at yearend 1975. In Australia, prices paid by Japanese steelmakers under several contracts for iron ore pellets were increased 13% to 26% as of April 1, 1976; under these agreements the f.o.b. price (per dry long ton unit of contained iron) of Hamersley pellets rose to 34 cents; of Savage River pellets, to 35.1 cents; and of Robe River pellets, to 38 cents. Similarly, under a natural-ore contract with Mt. Newman Mining Co. Pty. Ltd., the Japanese agreed to pay f.o.b. prices of $15.19 per dry long ton for lump ore (64% Fe) and $11.87 for fines (62% Fe), beginning October 1, 1976; these prices were 15% higher than those paid in 1975. Price increases were also negotiated by Indian and Brazilian producers with Japanese buyers in 1976.

In contrast, contract prices for Swedish phosphoric ores declined in 1976. Prices under contracts negotiated by Belgian consumers in early 1976 were reported to be 4% to 9% below 1975 levels. The price of Kiruna D iron ore (60% Fe, 1.8% P), c.i.f. Rotterdam, was approximately $16.10 per metric ton on June 30, 1976, compared with $19.30 per ton a year earlier.

The f.o.b. value of Venezuelan iron ore exported to the United States, as indicated by U.S. Bureau of the Census data, averaged $16.85 per long ton in 1976, compared with $15.63 in 1975.

TRANSPORTATION

Iron ore shipments from U.S. ports on the Great Lakes to lower lake destinations in 1976 totaled 63.1 million tons, 0.8% more than in 1975. Shipments of ore from Canadian ports to Great Lakes destinations totaled 23.6 million tons, an increase of 34% compared with that of 1975. Nearly 90% of the increase in shipments from Canada came from the ports of Pointe Noire, Sept-Iles, and Port Cartier, each of which shipped nearly 2 million tons more than in 1975. Total shipments from U.S. and Canadian ports to lake destinations (86.7 million tons) in 1976 were 8% more than in 1975.

With the help of icebreaking and other navigational aids, the second consecutive 12-month ore-shipping season was completed between Two Harbors, Minn., and lower lake ports in March 1976. Shipments from Two Harbors totaled 568,000 tons in February and 294,000 tons in March. Shipping from other ports on Lake Superior had stopped by January 10. Efforts to extend the 1976 shipping season were hampered by unusually cold weather, and the final ore shipment was made on January 21, 1977.

Statistics on shipments of iron ore from U.S. ports on the Great Lakes during the 1976 season are shown in the accompanying tabulation:

Lake shipping port	Number of vessels loaded[1]	Total tonnage shipped[1] (thousand long tons)	Average cargo (long tons)[1]	Largest cargo (long tons)
Duluth, Minn	784	14,050	17,921	30,709
Taconite Harbor, Minn	358	10,254	28,643	58,558
Silver Bay, Minn	565	9,694	17,158	31,042
Two Harbors, Minn	262	7,506	28,650	53,920
Superior, Wis	282	6,145	21,792	25,359
Marquette, Mich	280	5,437	19,416	30,830
Escanaba, Mich	514	10,061	19,574	40,475
Total or average	3,045	63,147	20,738	XX

XX Not applicable.

[1]Not including shipments in January 1977, as follows: Two Harbors, 17 vessels (471,094 tons); Escanaba, 8 vessels (167,266 tons); and Marquette, 7 vessels (107,651 tons).

Sources: Skillings' Mining Review, various issues (1977); and Annual Report of Lake Carriers Association for 1976.

Lake freight rates for iron ore were increased in February 1976 to the following values (per gross ton): From the head of the lakes to lower lake ports, $4.05; from Marquette, Mich., to lower lake ports, $3.34; from Escanaba, Mich., to Lake Erie ports, $3.05; and from Escanaba to lower Lake Michigan ports, $2.43. These rates remained in effect through December 1976 and were 8.6% to 9.7% higher than rates prevailing in 1975. Most storage, handling, and dock charges were unchanged from 1975, although unloading charges (rail of vessel to car) at lower lake ports were increased 2% to 7%, and dockage charges for self-unloading vessels at Conneaut and Lorain, Ohio, increased about 10% during the year. The vessel freight rate from the Gulf of St. Lawrence to Lake Erie ports (excluding St. Lawrence Seaway and Welland Canal tolls) remained unchanged at $1.70 per gross ton.

Most domestic rail freight rates for iron ore were unchanged from 1975 levels. Rates for some routes from lower lake ports to inland destinations were increased less than 3%; the rate from Baltimore to Fairless, Pa., was increased about 9%; and there were slight reductions in some rates from Lake Erie ports to the Mahoning and Shenango valleys, and from Philadelphia to Detroit.

The 1,000-foot, self-unloading iron ore carrier *James R. Barker* began service on the Great Lakes in August 1976 and by late December had transported 1.2 million tons of iron ore pellets from Lake Superior to lower lake ports, including a record shipment of 58,558 tons from Taconite Harbor, Minn. The vessel was operated by Interlake Steamship division of Pickands Mather & Co. and was the third carrier of its size to enter lake service. Six more vessels of this type were under construction for various companies in 1976. In July, the new self-unloading ore carrier *Joseph L. Block* began service for Inland Steel Co.; the vessel was stated to have a cargo capacity of 31,000 tons but was reportedly carrying up to 35,000 tons of pellets from Escanaba.

Ocean freight rates from Canadian ports on the Gulf of St. Lawrence to U.S. east coast and gulf coast ports in 1976 appeared to be unchanged from the low levels of 1975, while rates to Europe and Japan appeared to vary slightly from those of 1975. Spot fixtures reported by Metal Bulletin indicated rates from Sept-Iles as follows: To Japan, $4.10 to $4.25 per ton for cargoes of 140,000 to 150,000 tons during the last 4 months of 1976 (compared with $4.60 in October 1975); to the Netherlands, $2.30 per ton for 80,000 tons in July and $1.97 to $2.20

per ton for cargoes of 125,000 tons in October (compared with $2.05 to $2.45 for cargoes of 79,000 to 90,000 tons in early 1975); and to West Germany, $3.00 to $3.30 per ton for cargoes of 70,000 to 75,000 tons in November and December (compared with $2.80 for 60,000 tons in October 1975). Rates from Brazil and Liberia to Western Europe appeared to increase slightly in 1976, but no strong trend was evident; rates from Tubarão to Dunkirk ranged from $3.65 to $3.95 per ton for cargoes of 68,000 to 90,000 tons, and rates from Monrovia (Liberia) to the Netherlands were $2.75 to $2.90 per ton for cargoes of 80,000 to 95,000 tons. Two shipments from Tubarão to Japan ranged from $3.80 to $4.25 per ton for cargoes of 110,000 to 140,000 tons. Rates from Australia to Western Europe appeared to increase sharply; rates of $5.00 to $6.15 per ton were reported for shipments of 100,000 to 145,000 tons from Cape Lambert to the Netherlands, compared with $3.50 per ton for 125,000 to 130,000-ton cargoes in 1975. Rates quoted for two shipments of 50,000 tons from Brazil and Liberia to the U.S. east coast were $3.00 and $4.20 per ton, respectively.

In the Republic of South Africa, exports of iron ore began from Saldanha Bay in 1976. The initial shipment, 119,000 tons of hematite ore destined for Rotterdam, was made on September 27.

FOREIGN TRADE

U.S. exports of iron ore in 1976 totaled 2.9 million tons valued at approximately $82 million. These quantities represented a 15% increase in tonnage and a 37% increase in value compared with 1975 figures. Virtually all exports were destined for Canada. As several Canadian steel companies held significant ownership shares in U.S. taconite projects completed or under construction in 1976, exports to Canada were expected to increase during the next several years. Average value of exported ore in 1976 (principally pellets) was $28.22 per long ton, compared with $23.68 in 1975 and $15.13 in 1974.

U.S. imports of iron ore for consumption in 1976 totaled 44.4 million tons, valued (f.o.b. country of origin) at $980 million. The tonnage imported was about 5% less than in 1975, but the total value was 14% greater and reflected rising prices of foreign iron ores. Average value of ore imported in 1976 was $22.08 per long ton, compared with $18.41 in 1975 and $14.50 in 1974. Principal countries of origin were Canada, accounting for 56% of the total tonnage; Venezuela, 20%; Brazil, 12%; and Liberia, 5%. Compared with 1975, imports from Canada increased by 5.85 million tons, while those from Venezuela and Brazil declined by 4.1 and 2.2 million tons, respectively.

Imports from Peru in 1976 were less than half of the quantity imported in 1975. Imports from that country were halted in August 1975 following nationalization of Peruvian properties of Marcona Mining Co. and did not resume until a compensation agreement acceptable to Marcona had been reached. Imports were resumed in April 1976.

The Philadelphia customs district received about 22% of U.S. iron ore imports in 1976, followed by Baltimore (21%), Cleveland (17%), Chicago (14%), Mobile (10%), Buffalo (8%), Detroit (4%), and eight other districts (4%).

World trade in iron ore in 1975 is shown in table 21.

WORLD REVIEW

Australia.—Production of iron ore declined about 4% in 1976, but exports (79.7 million tons) were slightly greater than in 1975. Shipments of iron ore products to domestic and foreign markets in 1976 totaled about 94 million tons, including 9 million tons of pellets. Consumption of iron ore in Australia was estimated at about 10.5 million tons.

Approximate shares of individual Australian producers in total shipments of ore products in 1976 were as follows: Hamersley Iron Pty. Ltd., 38%; Mt. Newman Joint Venture, 29%; Cliffs Robe River Iron Associates, 13%; Broken Hill Pty. Co. Ltd. (BHP), 9.5%; Goldsworthy Mining Ltd., 8%; and Savage River Mines, 2.5%.

Annual production capacity for ore products in 1976 totaled about 122 million metric tons, distributed as follows: Hamersley, 40; Mt. Newman, 40; Robe River, 16; BHP, 15.5; Goldsworthy, 8; and Savage River, 2.5. Production capacity of Hamersley will increase by about 6 million tons by 1979 when the concentrator for low-grade ore is completed at Mount Tom Price. The plant will include heavy-media and wet high-intensity magnetic separation sections and was designed to process about 11 million tons of crude ore per year. The decision to build the plant followed negotiation of supply contracts with Japanese consumers for an additional 185 million tons of ore between 1978 and 1990, as well as other supply contracts with European and Asian consumers.

Five 226-ton-capacity trucks began service at Mount Tom Price during 1976, and 15 150-ton trucks were ordered for the Paraburdoo mine.

Cyprus Mines Corp. reportedly sold a 10% interest in Mt. Goldsworthy Mining Associates to Mount Isa Mines Holdings, Ltd., in 1976 and agreed in principle to sell the remainder of its one-third interest in Mt. Goldsworthy to Consolidated Gold Fields Ltd. of London.

Brazil.—Statistics published by the Brazilian Ministry of Mines indicated that Brazilian output of beneficiated iron ore totaled about 88 million tons in 1975. Preliminary data indicated that production increased in 1976 although exports declined to about 66 million tons. Brazil thus appeared to have displaced the United States as the world's third largest iron ore producer in 1975 and was rivaling Australia in both production and exports.

Total shipments of iron ore products in 1976 were estimated at about 81 million tons, including 69 million tons destined for export and 12 million tons for domestic consumption. The principal shippers were Companhia Vale do Rio Doce (CVRD), 49.8 million tons; Mineracoes Brasileiras Reunidas (MBR), 13.4 million tons; S.A. Mineração da Trindade (SAMITRI), 7.8 million tons; and Ferteco Mineracão S.A., 4.3 million tons. Brazilian stocks of ore products exceeded 12 million tons at yearend.

Pellet production in 1976 may have exceeded 5 million tons. CVRD produced 4.6 million tons in two plants operated at Tubarão. Ferteco Mineracão S.A. completed construction of a pelletizing plant at the Fabrica mine in 1976. Output capacity of the plant was 2.5 million tons of pellets per year. Pellet production was expected to increase in 1977, as two plants with a total annual production capacity of 8 million tons were scheduled for completion. One of the latter was a joint venture by CVRD with Italian companies; the other was a 5-million-ton facility being built for Samarco Mineracão S.A. The Samarco project, scheduled for completion in mid-1977, was to have an initial production capacity of 7 million tons annually, including 5 million tons of pellets and 2 million tons of pellet feed. Concentrate produced by flotation at the Germano mine was to be pumped through a 20-inch, 240-mile pipeline to pelletizing and shipping facilities at Ponta Ubu.

A direct-reduction plant with production capacity of 360,000 metric tons of sponge iron per year was being built 50 miles west of Rio de Janeiro by Companhia Siderurgica da Guanabara (COSIGUA) in 1976. Production was expected to begin in 1977. The plant will use the Purofer reduction process and reportedly will be the first commercial direct-reduction plant fueled by gas produced from heavy fuel oil. Ore feed to the plant was to be supplied from the Feijao mine of Ferteco and the Mutuca mine of MBR. Two direct-reduction plants were already operating in Brazil in 1976, in Bahia and Rio Grande do Sul.

CVRD reported negotiation of new long-term iron ore supply contracts totaling more than 300 million tons in 1976.

Canada.—Production and exports of iron ore in 1976 increased about 20% and 26%, respectively, compared with those of 1975. The increase in output amounted to 9.9 million tons and was due mainly to the first year of production at Mt. Wright, where 6 million tons of concentrates was produced by Quebec Cartier Mining Co. Production of concentrates and pellets at Carol Lake by the Iron Ore Co. of Canada and of pellets at Pointe Noire by Wabush Mines was substantially greater than in 1975, and increased output was reported from most other Canadian mines and plants. Exports of iron ore to the United States increased nearly 5 million tons in 1976, while exports to Japan and Western Europe rose about 4 million tons. Consumption of iron ore in Canada in 1976 totaled 13.5 million tons, of which 81% was pellets.

Production of concentrates was expected to increase in 1977 as output from Mt. Wright approached design capacity. Production from the Mt. Wright deposits was scheduled to replace that from Lac Jeannine, where reserves were expected to be exhausted by mid-1977. Production capacity for pellets was scheduled to increase by 6 million tons in late 1977, upon completion of two pelletizing plants at Port Cartier. Iron Ore Co. of Canada will probably increase output of pelletized concentrate from Schefferville ores at Sept-Iles; output increased 15% in 1976, but the plant was still producing well below its designed capacity. Hilton Mines Ltd. was expected to cease operations in mid-1977 owing to exhaustion of ore reserves.

In other developments, Texada Mines Ltd. ceased operations in British Columbia in December 1976 owing to exhaustion of ore reserves. At Tasu, British Columbia, Wesfrob Mines decided to develop underground ore reserves in order to continue production for another few years. In Ontario, the direct-reduction plant at the Griffith mine was operated from January through March and intermittently thereafter until August, when it was closed owing to operating problems and market conditions. The plant produced about 76,000 tons of prereduced ore during 1976. The direct-reduction plant of Sudbury Metals at Falconbridge, Ontario, was officially opened on May 12, 1976, but was shut down in October following an explosion. A 67% interest in Steep Rock Iron Mines, Ltd. was reportedly acquired by Canadian Pacific Investments, Ltd., in 1976 for $16.2 million.

European Community (EC).—The principal steelmaking countries of the EC imported 127.9 million tons of iron ore in 1976. West Germany imported 36% of the total, followed by Belgium-Luxembourg (20.8%), the United Kingdom (14.5%), Italy (13%), France (10.7%), and the Netherlands (5%). Imports by Belgium-Luxembourg and West Germany included about 12.5 million tons of ore containing less than 42% iron, mostly from France. Imports of iron ore by Denmark and Ireland were negligible.

Production of iron ore in the EC in 1976 totaled about 54 million tons, of which France produced about 82%. Almost all of this ore was low grade, containing 25% to 32% Fe, and was used for consumption within the EC, in France, Belgium, Luxembourg, and West Germany.

Consumption of iron ore in the EC during the first 9 months of 1976 totaled 107.9 million tons, about 4% more than in the comparable period of 1975. Total consumption of iron ore in 1975 was 154.7 million tons, of which about 77% was consumed in agglomerating plants at iron and steelworks, 22% was charged directly into blast furnaces, and 1% was charged directly into steelmaking furnaces.

Korf Stahl AG of West Germany and A/S Sydvaranger of Norway signed a contract in 1976 for construction of a direct-reduction plant at Emden, West Germany. The plant is to have a production capacity of 1.2 million tons of direct-reduced iron per year and was scheduled for completion in 1980. Iron ore will be supplied by A/S Sydvaranger, and the plant will be fueled by natural gas piped from the Norwegian sector of the North Sea. The operating company will be Norddeutsche Ferro Werke G.m.b.H., owned 75% by A/S Sydvaranger and 25% by Korf Stahl.

Construction of a direct-reduction plant at Hunterston, Scotland, was continued by the British Steel Corp. in 1976. The plant will use the Midrex process and will consist of two modules, each having a production capacity of 400,000 tons of direct-reduced iron per year. The first module was scheduled for completion in 1977.

Finland.—The newly opened Rautavaara mine had its first full year of production in 1976. After a period of open pit mining, underground production began when the mine shaft and hoist were completed in the summer. Production totaled 779,000 tons of crude ore and 354,000 tons of concentrates. The concentrates were shipped to the blast furnaces of Rautaruukki Oy. at Raahe. The latter plant also received 243,000 tons of iron concentrates from the Otanmäki mine, as well as pelletized iron oxide and "purple ore" recovered from sulfide-processing at Kokkola.

India.—Production and exports of iron ore in 1976 were little changed from 1975 levels. Exports were estimated at 22.8 million tons, with about 74% destined for Japan and 10% destined for Romania. Domestic consumption was approximately 16.4 million tons.

Development of the Kudremukh iron ore deposits near Mangalore began in 1976. Canadian Met-Chem Consultants, Ltd., will develop the deposits for Kudremukh Iron Ore Co. Ltd., a public sector company organized under the Indian Ministry of Steel and Mines. Met-Chem will design and supervise construction of a mine, concentrator, 35-mile slurry pipeline, and port facilities at Mangalore capable of producing and loading into vessels 7.5 million tons of concentrate per year for shipment to Iran. Construction was expected to be completed by early 1980. Met-Chem will supervise all operations for the first 3 years of commercial production.

In other developments, port facilities capable of berthing and loading ore carriers of 100,000 deadweight tons were completed at Visakhapatnam outer harbor in late 1976. The National Minerals Development Corp. Ltd. announced that construction of the Bailadila No. 5 mine and plant, with production capacity of 4 million tons per year, was completed in 1976. In Goa, the pelletizing plant being built near Mormugao port by a subsidiary of Chowgule & Co. Ltd. was scheduled for completion in 1977. The plant is to have a production capacity of 1.8 million tons of pellets per year.

Japan.—Imports of iron ore by Japan in 1976 totaled 131.6 million tons. The principal source countries were Australia, which supplied 48% of the total, followed by Brazil (19%), India (13%), Chile (5.7%), and Canada (4%). Pellets made up about 8% of total imports. An additional 6.5 million tons of pellets were produced in Japan, principally from imported ores.

Consumption of iron ore in 1976 totaled 122.8 million tons, including 8.6 million tons of imported pellets. Most of this ore was apparently used in the manufacture of sinter and other agglomerates. Consumption of agglomerates in blast furnaces totaled 115 million tons.

Liberia.—Production of iron ore declined more than 20% in 1976, but exports increased about 6% compared with those of 1975. Exports totaled about 19.2 million tons, of which 48% was shipped by the LAMCO Joint Venture, 32.5% by Bong Mining Co., 10.5% by National Iron Ore Co., and 9% by Liberia Mining Co. (LMC). Production by LMC declined sharply in 1976, and operations were scheduled to cease in early 1977 owing to exhaustion of ore reserves. Bong Mining Co. expected to complete expansion of its pelletizing facilities in 1977, to a total production capacity of more than 4 million tons annually. Stocks of ore held by Liberian producers declined during 1976 but totaled at least 5 million tons at yearend.

Mexico.—Production of iron ore increased sharply in 1976 as two concentrating plants began operating in the early part of the year. Near Durango, a new concentrator was brought onstream at the Cerro de Mercado mine by Fundidora de Monterrey S.A. The plant was equipped with a flotation section and magnetic separators, and had a production capacity of about 1.7 million tons of concentrate per year. Concentrate was shipped by rail to Monterrey, where a pelletizing plant was also completed by the company in 1976. Production capacity of the latter plant, which employs the grate-kiln system designed by Allis-Chalmers, was 1.5 million tons per year of self-fluxing pellets.

In Michoacan, concentration of magnetite ore was begun at the Ferrotepec mine by Siderurgica Lazaro Cardenas-Las Truchas S.A. (SICARTSA). Production capacity of the plant was 1.5 million tons of concentrate per year. Concentrate was transported by a 10-inch pipeline 16 miles to a pelletizing plant at the steelworks in Lazaro Cardenas.

Production capacity of the pelletizing plant completed in 1975 by Consorcio Minero Peña Colorada S.A. will be increased to 3 million tons annually in 1978. Shipments of pellets from this plant totaled 1.4 million tons in 1976.

Altos Hornos de Mexico S.A. was reported to be investing about $11 million to expand production facilities for iron ore at the La Perla deposits in Chihuahua.

Philippines.—Mining of iron-bearing beach sands was suspended by the Government in mid-1976, pending submission of plans by the mining companies for restoration of mined areas. Production and exports of iron concentrates in 1976 consequently declined by more than 50% from 1975 levels. Only two companies — Inco Mining Co. and Filmag (Philippines) Inc. — were producing iron concentrates in 1976.

South Africa, Republic of.—Production and exports of iron ore in 1976 increased sharply, compared with those of 1975. The gains were mainly generated by increased production of hematite ore at the Sishen mine and the beginning of exports from Saldanha Bay. The 530-mile Sishen-Saldanha railroad was completed in May, and export shipments began in late September. Fourteen shiploads were dispatched by yearend. The shipping port is about 71 miles north of Capetown.

The initial contract between South African Iron & Steel Industrial Corp. Ltd. (ISCOR) and Japanese buyers for ore shipments from Saldanha Bay called for 2 million tons during fiscal year 1976 (year ending March 31, 1977). Contract prices (f.o.b., per dry metric ton) were $14.77 for lump ore (64% to 66% Fe) and $11.61 for fines (63% to 65% Fe). Expected ratio of lump to fines was about 2:1.

Swaziland.—Shipments of iron ore from Ngwenya by the Swaziland Iron Ore Development Corp. totaled 1.7 million tons in 1976. Production was expected to cease by the end of 1977 owing to exhaustion of ore reserves, although shipping of fines from stockpiles may continue for another 2 years.

Sweden.—Swedish production and exports declined slightly in 1976. Production by Luossavaara-Kiirunavaara AB (LKAB) totaled 24.2 million tons, about 3.5% less than in 1975, while output by Gränges AB declined about 13% to 2.4 million tons. Shipments of ore by Stora Kopparbergs Bergslags AB, destined for the domestic market, declined by 10% to 1.2 million tons.

Weak demand for Swedish ore in the European market led to lower prices in 1976, particularly for high-phosphorus ore. LKAB reported a 5% reduction in price of low-phosphorus ore for 1977, and further reductions for high-phosphorus grades. Both LKAB and Gränges reported heavy increases in ore stocks in 1976. Ore stockpiled by LKAB increased 32% during the year, to 12.4 million tons including 2.2 million tons stockpiled at continental ports. Gränges AB, faced with increasing competition from foreign ores, decided there was little likelihood of maintaining profitable exports from underground mines in central Sweden and planned a permanent reduction in output at Grängesberg. About 300 employees will be affected.

A $17 million flotation plant began production of low-phosphorus concentrate at Grängesberg in 1976. At Narvik, Norway, LKAB continued to expand its shipping facilities. Installation of a new quay and shiploader capable of accommodating vessels of up to 350,000 deadweight tons was scheduled for completion in mid-1977.

Turkey.—A pellet plant with production capacity of about 4.3 million tons per year is to be built at Divrigi in central Turkey. The Turkish Iron & Steel Works Co. contracted with the West German firm of Thyssen-Rheinstal Technik G.m.b.H. to supply the plant, which will use the Allis-Chalmers grate kiln and heat-recuperation systems.

U.S.S.R.—Production of crude iron ore in 1976 was estimated at about 490 million tons, from which 235 million tons of usable ore was obtained. Output of usable ore consisted 82% of concentrates and 18% of direct-shipping ore. Average iron content of usable ore produced was 59.3%. Production of pellets was estimated at 30 million tons, compared with 27 million tons in 1975. Production plans called for output of 60 million tons of pellets in 1980.

The Lebedinskiy iron ore mining and concentrating complex in the Belgorod region of the Kursk Magnetic Anomaly was reportedly completed in 1976. Annual production capacity was 30 million tons of crude ore and an estimated 12 million tons of ore products including 4 million tons of pellets. In the same area, a pelletizing plant with a production capacity of 3 million tons per year was reportedly completed at the Mikhaylovskiy complex. At Kremenchug in the Ukraine, construction of a 6-million-ton-per-year pelletizing plant was nearly completed, and another plant of the same capacity was reportedly under construction.

Venezuela.—Production and exports of iron ore declined by more than 20% in 1976, largely because of reduced demand for Venezuelan ore in the United States. Exports to the United States in 1976 were 4 million tons less than in 1975. Of the 15.9 million tons exported in 1976, 57% was destined for the United States, 37% was destined for Common Market countries, and most of the remainder was destined for Spain.

Ferrominera Orinoco C.A., a subsidiary of the Government-owned Corporacion Venezolana de Guayana, assumed exclusive responsibility for development of the iron ore industry on January 1, 1976. Operations were conducted under two divisions; the Piar division, which includes the mine at Cerro Bolivar and the ore-drying and screening plant and shipping facilities at Puerto Ordaz; and the Pao division, which includes the mine at El Pao and the washing plant and shipping facilities at Palua. The Piar division accounted for 83% of Venezuelan production and exports of iron ore in 1976; this included 1.1 million tons of ore produced at San Isidro for consumption by Siderurgica del Orinoco (SIDOR) at Matanzas.

Production of partly reduced ore (high-iron briquets) at Puerto Ordaz totaled 171,000 tons in 1976, compared with 203,000 tons in 1975. At Matanzas, the direct-reduction plant of Fior de Venezuela was completed in 1976. Two other direct-reduction plants were under construction at Ciudad Guayana.

A pelletizing plant designed to produce 6.5 million tons of iron ore pellets per year was under construction by Voest-Alpine AG for SIDOR in 1976. The plant will employ the Lurgi traveling-grate system and was scheduled for completion in 1978.

In December 1976, Ferrominera Orinoco awarded a contract to the Link-Belt division of FMC Corp. to expand production capacity of the ore-drying and screening plant at Puerto Ordaz. The plant's production capacity for dried ore fines will be doubled to approximately 14 million tons per year.

TECHNOLOGY

Increasing costs of materials, labor, fuels, and environmental controls continued to plague the iron mining industry in 1976. To minimize this, companies attempted to improve operating methods and to devise better cost controls. In the 10-year period 1965-75, equipment costs increased 84%, material costs increased 100%, and labor costs increased 133%.[4]

In the iron ore industry, several companies, to control costs, have reversed the trend of increasing the size of mining equipment. Reserve Mining Co. chose to continue using 100-ton trucks as well as jet-piercer drills. Likewise, Eveleth Taconite Co., for its expansion completed in 1976, purchased 85-ton trucks[5] and four 195-B electric shovels with 10-cubic-yard buckets, rather than the 150- to 350-ton trucks or the 16- to 20-cubic-yard shovels available on the market. The main reasons for using the smaller equipment were lower initial cost and higher operating availability.

Processing, on the other hand, was tending toward larger machinery. A 10-foot-diameter cone crusher for milling operations was placed in service in the Republic of South Africa, and flotation cells with volumes of more than 600 cubic feet were planned. Larger ball and rod mills were being used, as evidenced by those installed by Eveleth Taconite Co. Semiautogenous grinding was increasingly favored. The use of rubber liners in ball mills was rising because of the ease of installation, longer life, and acid-resisting characteristics.[6]

Process control was also becoming more sophisticated. Two methods were being adapted to iron ore beneficiation: Radioisotope probes in the process stream; and the ability to measure particle sizes within the stream. By using the probes, metal concentration data, essential for control, may be obtained rapidly and precisely.

A new dock facility of the Burlington Northern Railroad at Superior, Wis., capable of handling 18 million tons of pellets per year, was being built to handle the production of the Hibbing Taconite Co. and the National Steel Pellet Co. Completion of the facility was expected in early 1977.[7]

A further technological development was the increasing number of plants utilizing direct-reduction processes. Three Midrex plants added capacity or began operations during 1976: The Dalmine Siderca plant in Argentina; the Siderurgica del Orinoco C.A. plant in Venezuela; and the Sidbec-Dosco, Ltd., plant in Quebec. Predictions were that by 1980, direct-reduction plants will be providing 15 million tons per year of direct-reduced iron.[8]

The Bureau of Mines Twin Cities Metallurgy Research Center continued to investigate concentration of Western Mesabi nonmagnetic taconites by cationic flotation. Completion of these tests was not expected until 1978. The center also conducted tests in metallizing pelletized iron oxide concentrates, using lignite and coal in a rotary kiln. The tests proved that this can be done successfully.[9]

Environmental research, in reclaiming both previously mined areas and areas being mined, was being conducted by the Bureau of Mines, as well as by industry. The Bureau's research included the design of new equipment and the development of new methods for backfilling old and new workings.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Cuba and Vietnam may produce iron ore, but definitive information on output levels, if any, is not available.

[2]Insofar as availability of sources permits, gross weight data in this table represent the nonduplicative sum of marketable direct shipping iron ores, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Concentrates and agglomerates produced from imported iron ores have been excluded, under the assumption that the ore from which such materials are produced has been credited as marketable ore in the country where it was mined.

[3]Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron ore content reported, except for the following countries from which grades are U.S. Bureau of Mines estimates: Albania, Denmark, Hungary, Southern Rhodesia, the People's Republic of China, and North Korea.

[4]Gross weight and metal content of shipments of usable iron ore, including byproduct ore, dry tons.

[5]Gross weight calculated from reported iron content based on grade of 66.67% Fe.

[6]Includes byproduct ore.

[7]Nickeliferous iron ore.

[8]Includes magnetite concentrate, pelletized iron oxide (from pyrite sinter) and roasted pyrite (purple ore).

[9]Includes "roasted ore," presumably pyrite sinter, not separable from available sources.

[10]Excludes iron oxide pellets produced from pyrite sinter.

[11]Includes manganiferous iron ore.

[12]Revised to zero.

[13]For cement manufacture.

[14]Includes byproduct magnetite as follows in long tons: 1974—2,859,303; 1975—[r]2,058,294; 1976—4,244,236.

[15]Sales.

[16]Year beginning March 21 of that stated.

[17]Concentrate including concentrate derived from iron sand as follows in long tons: 1974—232,432; 1975—[r]179,166; 1976— 191,189.

[18]Largely concentrates from magnetite-titanium sands.

Table 21.—Major world trade in iron ores, concentrates, and agglomerates (excluding roasted pyrite)[1] in 1975

XX Not applicable.

[1] Disparities between recorded total exports of source countries and totals of recorded imports of recipient countries from each listed source country are generally due to (1) time lag between shipment and receipt, and (2) the fact that the latter totals are incomplete, representing only the imports of the nations listed in the column heads and in footnotes 9, 10, and 11.

[2] Unless otherwise specified, data are compiled from official import statistics of recipient countries.

[3] Unless otherwise specified, data are from official export statistics of listed source countries.

[4] Official imports statistics for Czechoslovakia, Poland, Romania, and the United Kingdom do not fully distribute total imports by country of origin, and therefore do not clearly indicate whether these nations received shipments from any of the source countries where this footnote has been entered.

[5] Exports not available. Production reported in lieu of exports as all or nearly all of output is exported.

[6] Official mineral statistics publication of the source country rather than official trade returns.

[7] Includes pyrite.

[8] Less than 500 long tons.

[9] Summation of (1) recorded exports of the following countries, with export quantity following country name in thousand long tons: Austria, 1; Belgium-Luxembourg, 3; Bolivia, 20; Denmark, 13; West Germany, 5; Hong Kong, 162; Italy, 12; the Republic of Korea, 61; Mexico, 14; Morocco, 211; the Netherlands, 94; New Zealand, 2,315; Tunisia, 291; Yugoslavia 30; together with (2) apparent exports (as measured by imports of trading partner countries) with apparent export quantity following country name in thousand long tons and trading partner countries listed in parentheses: Indonesia, 278 (Japaneses imports only); North Korea, 200 (Japanese imports only); Mozambique, 169 (Japanese imports only). In addition to the foregoing list of countries, Switzerland recorded iron ore exports of less than 500 tons.

[10] Includes the following countries with recorded total imports of each following the country name in thousand long tons: Austria, 2,537; Bulgaria, 1,660; Denmark, 1; Finland, 1,187; East Germany, 2,773; Greece, 775; Norway, 17; Portugal, 379; Spain, 6,039; Sweden, 314; Switzerland, 44; Yugoslavia, 589.

[11] Includes the following countries with recorded total imports of each following the country name in thousand long tons: Australia, 17; the Republic of Korea, 1,470; Malaysia, less than 1/2 unit; Singapore, 24; Taiwan, 141.

[12] Includes the following countries with recorded total imports of each following the country name in thousand long tons: Argentina, 1,496; Brazil, less than 1/2 unit; Mexico, 33; Venezuela, 17.

[13] Official export statistics of source country.

[14] Includes the following reported source countries with total quantity credited to each following the country name in thousand long tons: Belgium-Luxembourg, 95; Bolivia, 20; Denmark, 9; Finland, 1; East Germany, 20; Greece, 6; Hong Kong, 164; Hungary, 58; Indonesia, 287; Iran, 4; Italy, 9; Japan, 86; North Korea, 200; South Korea, 61; Libya, 57; Morocco, 128; Mozambique, 169; the Netherlands, 350; New Zealand, 2,463; Nigeria, 32; Panama, 114; Portugal, 127; Tunisia, 266; the United Kingdom, 15.

Iron Oxide Pigments

By Cynthia T. Collins[1]

Production and trade in iron oxide pigments made a strong recovery in 1976. This reflected the upturn in demand from the coatings, plastics, and other industries which serve the automotive, heavy equipment, and construction markets. The $64.5 million value of finished iron oxide pigment sales and the $16.6 million value of imports indicated an $81 million market in 1976, compared with the 1975 market of $55 million.

Legislation and Government Programs.—In November the Food and Drug Administration (FDA) permanently listed iron oxide pigments for use in cosmetics, including those intended for use in the area of the eye.[2] The ruling was to become effective on January 3, 1977. The original petition filed in August 1973 requested a permanent listing of iron oxides as additives for use in externally applied cosmetics,[3] and an amendment in March 1976 added the use of iron oxides in all types of cosmetics subject to ingestion.[4] The amendment defines the color additive iron oxides as consisting of any one or any combination of synthetically prepared iron oxides, including the hydrated forms, free from admixture with other substances. The oxides must conform to the following specifications: Arsenic, not more than 3 parts per million; lead, not more than 10 parts per million; and mercury, not more than 3 parts per million.

DOMESTIC PRODUCTION

Production of finished iron oxide pigments, as measured by sales, increased 30% over that of 1975. Finished natural pigment production increased 33%, while synthetic pigment production rose 27%. A 40% increase in value of overall sales reflected a 12% rise in the average unit value of synthetic pigments to nearly 40 cents per pound. Values of finished natural pigments remained unchanged. Average unit value of synthetic pigments was nearly five times greater than that of natural oxides.

[3]———. Notice of Filing of Petition Regarding Color Additives. V. 38, No. 150, Aug. 6, 1973, p. 21200.
[4]———. Amendment of Filing of Petitions for Color Additives. V. 41, No. 231, Mar. 5, 1976, p. 9534.

Shipments of pigments increased in all categories in 1976. In synthetic pigments, shipments of yellow iron oxides increased 40% and combined shipments of blacks and browns increased 34%. In natural pigments, the most significant increase occurred in shipments of black magnetite; eight companies produced this product in 1976, compared with four companies in 1975. Umbers, ocher, and red iron oxides also showed large gains.

Table 2 reflects data compiled from responses by 21 companies to the Bureau of Mines canvass and represents 95% coverage by quantity. All companies reported gains in 1976. One new plant came onstream in 1976. BASF Wyandotte Corp. started production in a new 3-million-pound-per-year capacity plant at Wyandotte, Mich., to produce transparent iron oxide pigments for use in metallic and wood-grain finishes. Indiana General Corp. discontinued production of iron oxides in 1976, reportedly due to unfavorable price competition from increased imports of regenerator oxides.

Domestic production of iron oxides from steel plant wastes increased 11% over that of 1975. Four companies produced iron oxides as a byproduct from steel plant dusts or regenerated pickle liquor. These oxides were used mainly in the manufacture of ferrites.

Production of crude iron oxide pigments increased 53% in 1976. Shipments rose 47% but total values increased only 16%, indicating a drop in average unit value. Crude pigments were produced by the four companies listed at the end of table 3.

Table 4 shows a 22-year analysis of finished iron oxide pigment shipments. The ratio of synthetic pigment shipments to natural pigment shipments has been nearly equal for the last 13 years, following a decade when the ratio was at or near 2:1. Ratios of synthetic to natural pigment values have fluctuated over the same period, reaching a high level of 5.4:1 in 1963, and a low of 2.7:1 in 1971. Figures shown annually in table 2 under "Unspecified" have been apportioned between synthetic and natural, as described in the footnote to table 4.

[1] Figures for "Natural" and "Synthetic" include those classed as "Mixtures and Other" in table 2. Quantities of "Mixtures and Other" apportioned one-third to "Natural" and two-thirds to "Synthetic"; value of "Mixtures and Other" apportioned one-seventh to "Natural" and six-sevenths to "Synthetic."

CONSUMPTION AND USES

Apparent domestic consumption[5] of 180,212 short tons of iron oxide pigments in 1976 was 45% above the 1975 level of 124,039 tons. Demand from the automotive, industrial, and furniture coatings industries increased strongly in 1976. All color categories of the iron oxides showed marked gains during the year, with a very strong increase in demand for transparent oxides for use in automobile and furniture coatings.

Data were not collected in 1976 by the Bureau of Mines on specific end uses for iron oxide pigments, although a revised annual canvass will request this information in the future. Figures in table 2 do not necessarily reflect all sales of iron oxides used for pigments or other nonsmelting purposes. The largest percentage of iron oxide pigment consumption was in industrial coatings and trade sales (paints, stains, and varnishes). The construction industry also consumed iron oxide pigments in coloring cement, mortar, concrete blocks, and roofing granules. The pigments were also used to color plastics, rubber, and paper. A continually growing segment of the high-purity iron oxide market was in the manufacture of ferrites for magnetic and electronic applications. Some of the natural black magnetite was sold for use in heavy media in coal preparation plants.

The use of iron oxide pigments in cosmetics increased in 1976. A September ruling by FDA terminated the provisional approval of carbon black pigment for use in cosmetics;[6] therefore, producers of mascara and eyebrow pencils substituted iron oxide pigments in their products.[7]

PRICES

Prices of finished iron oxide pigments increased in 1976 in almost all categories. Synthetic pigment prices increased by 6.5 cents to nearly 10 cents per pound, while prices of some natural pigments rose even higher. Most price changes occurred in April and May, and the price of the two American siennas increased again in October. Prices in those categories increased more than 14 cents per pound by the last quarter.

[5] Indicated by quantity of finished iron oxide pigments sold plus imports of natural and synthetic iron oxide pigments minus exports of pigment-grade iron oxides and hydroxides.

FOREIGN TRADE

The quantity of pigment-grade iron oxides and hydroxides exported from the United States in 1976 decreased 34% from that of 1975. Total value of exports, however, increased 33%, reflecting a twofold increase in average unit value. Exports to Canada, which comprise the largest percentage of total exports, fell 47% in 1976, while those to other countries either increased or remained close to 1975 levels.

The quantity of other grades of iron oxide exports increased 36% in 1976; values increased by 55%. Schedule B of the U.S. Department of Commerce Statistical Classification of Domestic and Foreign Commodities Exported from the United States defines other grade iron oxides and hydroxides as follows: Iron hydroxide, synthetic; iron oxide catalyst; iron oxide, synthetic (except pigment); and jeweler's rouge (synthetic ferric oxide).

Imports of iron oxide pigments for consumption increased 79% in 1976 compared with those of 1975, reflecting the strong upturn in demand. Value of imports increased 80%, which indicated only a small increase in average unit values.

Imports of synthetic iron oxides increased 85% over 1975 levels; 52% of synthetic imports came from West Germany and 29% came from Canada. Imports of synthetic pigments from Japan increased significantly in 1976. Imports of crude and refined natural pigments were 56% greater than 1975 imports; 71% of natural pigments were crude and refined siennas and umbers from Cyprus, while 12% were Spanish oxides.

TECHNOLOGY

Waterborne coatings were being used increasingly in industrial finishes because of greater economy in energy and air pollution control costs. Market studies indicated that nearly half of total industrial coatings will be waterborne by 1977; therefore, pigment manufacturers were conducting research into the use of their products in aqueous systems. Pfizer Inc. tested iron oxide pigments in some waterborne coatings systems and concluded that many synthetic and natural oxides were suitable for use in most aqueous primers and top coats.[8]

In an effort to replace certain pigments containing lead, manufacturers tested combinations of organic and inorganic pigments. One auto maker reportedly formulated a combination of iron oxide with quinacridone magenta which closely matched the molybdate orange pigment that had been used.[9] Other manufacturers reportedly combined iron oxides with benzidine yellow to replace chrome yellow, and with pthalocyanine green to substitute for chrome green.[10]

The nontoxic nature of iron oxide pigments reportedly makes them suitable for use in the production of food and drug containers. Increased interest in the manufacture of plastic beverage containers led to research in the use of transparent iron oxides for pigmentation. The oxides were demonstrated to offer the transparency of a dye plus the optical property of screening out harmful ultraviolet rays. Transparent red oxide produced the amber shade required to prevent product deterioration in beer, medicine, and food oil bottles.[11]

In 1976, the University of Illinois at Urbana-Champaign, under a grant from Pfizer Inc., began research into possible uses for the waste from Pfizer's East St.

Louis iron oxide pigment plant. Studies were made on the potential use of the waste material in ceramics, refractories, and soil conditioners for iron-deficient areas.[12]

Results of research on the sintering behavior of certain iron oxides were published in 1976. Specifically, oxides derived from the calcination of a variety of iron salts and their aqueous solutions were studied. It was concluded that oxides prepared from aqueous solutions absorbed more gases during sintering than those made from iron salt reagents. However, these oxides had the advantage of being more homogeneous within mixtures.[13]

A method was developed to produce an improved acicular iron oxide pigment for use in magnetic recording tape. The pigment optionally contained cobalt, nickel, and/or manganese. Improvement was reportedly due to the addition of zinc ion and phosphate ion, each in concentrations of about 0.1% to 2% by weight, during precipitation; this produced acicular iron hydroxide crystals, free from dendritic growths. Reduction and reoxidation of the dendrite-free particles produced a magnetic pigment with improved orientability.[14]

A Japanese producer of titanium dioxide developed a process for recovering sulfuric acid from plant wastes. The process features solvent extraction instead of conventional ammonia or calcium neutralizing treatments and generates a byproduct high-purity iron oxide suitable for use in pigments and ferrites.[15]

A paper, presented at the 1976 annual meeting of the American Ceramic Society, reviewed the history and development of the ferrite industry. Recent research and a bibliography were included.[16]

Iron and Steel

By H. T. Reno[1] and D. H. Desy[2]

In 1976, the world iron and steel industry had not completely recovered from the recession of 1975, although most countries produced as much or more steel than in 1975. The European Communities (EC) and Japan showed increases of 6% and 5%, respectively, while the Eastern European countries registered an increase of 3%, and the People's Republic of China showed a 6% decrease.

The United States produced 128 million tons[3] of raw steel,[4] 10% more than in 1975, but 12% less than in 1974. Weekly steel production rose from 2,005,000 tons at the beginning of the year to a high of 2,759,000 tons at the end of May before declining to 2,000,000 tons by yearend.

According to the American Iron and Steel Institute (AISI), the steel industry shipped 89.4 million tons of steel products, 12% more than in 1975. Industry sectors receiving the largest quantities of steel shipments were the automotive industry with 24% and steel service centers and distributors with 16%. Steel prices rose by an average of approximately 8.5% during the year. The United States imported 13.1 million tons and exported 3.7 million tons of steel in 1976.

Legislation and Government Programs.— Under the terms of the Trade Act of 1974, the U.S. International Trade Commission on January 16, 1976, reported to the President the results of an investigation of imports of stainless and alloy tool steel (specialty steel). The Commission determined that bars, wire rods, plates, sheets, and strip of specialty steel were being imported into the United States in such increased quantities as to cause serious injury or a threat thereof to the domestic specialty steel industry. The Commission recommended that quotas be established for these products for a period of 5 years beginning in 1976. The President first sought orderly marketing agreements with the principal countries involved and concluded an agreement with the Government of Japan. Since agreements were not reached with other countries, import quotas were established effective June 14, 1976, for a period of 3 years. Quotas were based on the annual average quantity or value of specialty steel imported during the period 1971-75.[5]

On March 29, 1976, the Environmental Protection Agency (EPA) promulgated interim final effluent (water) limitations for forming, finishing, and specialty steel operations in the iron and steel industry. These standards were developed on the average of the best performance of existing plants in the industry. Regulations for best available technology economically achievable and new source performance standards were proposed on the same date.[6]

On October 6, 1976, the Office of the Special Representative for Trade Negotiations received a petition from the AISI alleging unfair trade practices by the European Coal and Steel Community (ECSC) and the Ministry of International Trade and Industry (MITI) of Japan resulting from a bilateral agreement between ECSC and MITI, which allegedly diverted significant quantities of Japanese steel exports to the United States. The complaint was filed pursuant to Section 301 of the Trade Act of

1974. The Committee was considering the petition at yearend.

The Occupational Safety and Health Administration (OSHA) of the Department of Labor issued standards for controlling exposure of steelworkers to cancer-causing emissions from coke ovens, effective January 20, 1977. The new rules call for limiting worker exposure around the ovens to 0.15 milligram of the benzene-soluble fraction of total particulate matter per cubic meter of air as determined for an 8-hour period. Engineering controls for emissions must be instituted by January 20, 1980.[7]

rRevised. NA Not available.

[1]American Iron and Steel Institute (AISI).

[2]Based on average production in 1967 as 100. Not computed after 1974.

[3]Defined by AISI as the capability to produce raw steel for a full order book based on the current availability of raw materials, fuels, and supplies; and of the industry's coke, iron, steelmaking, rolling and finishing facilities, recognizing current environmental and safety requirements. Not computed before 1975.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron totaled 86.8 million tons in 1976, an increase of 7.1 million tons or 9% more than that produced in 1975. Average production of pig iron per blast furnace day increased to 1,930.1 tons compared with 1,837.4 tons in 1975 and 1,728.0 (revised) tons in 1974, according to AISI. A total of 119 furnaces were in blast at the beginning of the year. At yearend the total number in blast had decreased to 107, including 1 that produced ferroalloys which was relit during the year. There was a total of 196 blast furnaces at the beginning of the year and 193 at yearend, of which 7 were being relined and 1 rebuilt.

Metalliferous Materials Consumed in Blast Furnaces.—For each ton of pig iron produced in 1976, an average of 1.660 tons of metalliferous materials was consumed in blast furnaces. Total net iron ore and agglomerates consumed in blast furnaces was 136.8 million tons. The total tonnage of iron ore, including manganiferous ore, consumed by agglomerating plants at or near the blast furnaces in producing 36.7 million tons of agglomerates was 25.8 million tons. The remainder consisted of mill scale, flue dust, slag, coke breeze, limestone, dolomite, and small quantities of other materials. Domestic pellets charged to the blast furnaces totaled 69.5 million tons, and sinter charged was 36.5 million tons. Pellets and

[7]Federal Register. Title 29—Labor; Chapter XVII—Occupational Health and Safety Administraion, Department of Labor; Part 1910—Occupational Health and Safety Standards. Exposure to Coke Oven Emissions. V. 41, No. 206, Oct. 22, 1976, pp.46742-46790.

other agglomerates from foreign sources amounted to 15.2 million tons.

Blast furnace oxygen consumption totaled 26.9 billion cubic feet according to AISI, compared with 25.9 billion cubic feet in 1975 and 25.8 billion cubic feet in 1974.

Data reported to the Bureau of Mines by the iron and steel industry showed that blast furnaces, through tuyere injection, consumed 9.7 billion cubic feet of natural gas, 8.1 billion cubic feet of coke oven gas, 479 million gallons of oil, 152 million gallons of tar, pitch, and miscellaneous fuels, and 157,671 tons of bituminous coal in 1976.

PRODUCTION AND SHIPMENTS OF STEEL

The domestic steel industry produced 128.0 million tons of raw steel in 1976, 10% more than the 116.6 million tons produced in 1975. Production in 1976 equaled 80.9% of industry raw steel production capability compared with 76.2% in 1975. Of the total, 62.5% was produced by the basic oxygen process; 18.3%, by open-hearth furnaces; and 19.2%, by electric furnaces. Shipments of steel products for the year totaled 89.4 million tons, 12% more than the 80 million tons shipped in 1975.

Shipments to the automotive industry totaled 21.4 million tons, 40% higher than in 1975, and shipments to service centers were up 15%, to 14.6 million tons. Shipments to the oil and gas industries and to the construction market were down 15% and 8%, respectively.

Materials Used in Steelmaking.—Metallic materials charged to domestic steel furnaces in 1976, per ton of steel produced, averaged 1,280 pounds of pig iron, 993 pounds of scrap, and 22 pounds of iron ore, including agglomerates. Revised figures for 1975 were 1,278 pounds of pig iron, 996 pounds of scrap, and 23 pounds of ore and agglomerates.

According to AISI, steelmaking furnaces consumed 586,486 tons of fluorspar, 1.5 million tons of limestone, 7.6 million tons of lime, and 1.3 million tons of other fluxes. Oxygen consumption in steelmaking totaled the equivalent of 196.3 billion cubic feet compared with 178.4 billion cubic feet in 1975.

CONSUMPTION OF PIG IRON

Total pig iron consumed in 1976 was 87.0 million tons. In steelmaking, basic oxygen converters consumed 66.1 million tons; open hearths, 15.4 million tons; and electric furnaces, 0.4 million tons. In addition, 1.3 million tons were used by iron foundries and miscellaneous users, principally for charging cupola furnaces. Also, 3.3 million tons was used in making ingot molds and other direct castings.

PRICES

Price increases totaling 12% on sheet and strip and 6% to 8% on other steel mill products went into effect during the year. Prices of tubular products and rails were raised 6% and 7%, respectively, effective May 1, followed by a 6% rise on sheet and strip, effective June 14. Structural steel shapes and plate prices were raised 6% to 8%, effective July 16. A proposed rise in price of 4.5% on sheet and strip, announced in August, to be effective October 1, was later canceled. The final price increase of the year was an additional 6% on sheet and strip, effective December 1.

The composite price for pig iron, according to Iron Age magazine, remained throughout 1976 at $187.67 per ton where it had been since February 1975. The Iron Age finished steel composite price rose from 13.693 cents per pound at the beginning of the year to 14.880 cents at yearend, for a yearly average price of 14.213 cents per pound. This was an 8.5% increase over average 1975 prices.

FOREIGN TRADE

Exports amounted to 3.7 million tons in 1976, 8% less than in 1975. The value of steel exported totaled $2.46 billion resulting in an unfavorable balance of trade of $1.67 billion.

In 1976, the United States imported 13.1 million tons of iron and steel products valued at $4.13 billion, up 5% in tonnage but down 8% in value compared with 1975 figures.

Japan supplied 56% of the total steel mill products imported; the EC supplied 22%; and Canada, 9%. Imports were up 37% from Japan, down 23% from the EC, and up 29% from Canada compared with 1975 imports.

Japan supplied 57% of the carbon steel, 41% of the alloy steel, and 53% of the stainless steel imported, and the EC supplied 22% of the carbon steel, 24% of the alloy steel, and 23% of the stainless steel. Canada supplied 25% of the alloy steel, and Sweden, 10% of the stainless steel imports.

WORLD REVIEW

NORTH AMERICA

Canada.—Canadian industry was slightly more active in 1976 than in 1975, but Canada's steel industry lagged behind the overall economy. Compared with 1975, raw steel production increased 1% to 14.5 million tons.

In December, Sidbec-Dosco Ltd. filed a formal complaint with the Canadian Government, alleging dumping of Japanese hot-rolled angle bars. Other Canadian steel companies were expected to follow suit.

In view of the depressed market, the Steel Co. of Canada delayed until 1980 the expected completion of the first phase of its new steelmaking plant at Nanticoke, Ontario. Sidbec-Dosco Ltd. requested financial assistance from the Provincial Government.

Mexico.—The Mexican steel industry continued an expansion program with the expectation of raising annual capacity to 13.5 million tons by 1980, although some of the expansion projects fell slightly behind schedule. The newly built No. 2 steelworks of Altos Hornos de México S.A. (AHMSA) at Monclova in Coahuila was inaugurated by President Luis Echeverria on September 18, 1976. This plant will increase the raw steel production capacity of AHMSA from 2.2 to 4.1 million tons per year. The first stage of the $900 million steel plant Siderúrgica Lázaro Cárdenas-Las Truchas (SICARTSA) was essentially completed by yearend.

The Mexican steel industry experienced environmental problems similar to those of steel industries in the United States and Japan. The Fundidora steel mill at Monterrey, Nuevo Leon, reported that it had spent an estimated 400 million pesos to decrease emission of air pollutants from 4 tons to about 4 pounds per day.[8]

The Government steel research institute, Instituto Mexicano de Investigaciones Siderurgicas (IMIS), established by official decree May 13, 1975, was organized during the year. A board of directors and a Director General were appointed.[9]

SOUTH AMERICA

The annual meeting of the Latin American Iron and Steel Institute (ILAFA) was held in Caracas, Venezuela, in October 1976. Discussion of the future of the steel industry in South America was optimistic, but at the same time it was pointed out that there were still serious obstacles to growth. The most significant obstacle, according to several observers, was the lack of trained manpower, which overshadowed the limited supply of coal that was of concern in 1975. The Latin American iron and steel industry had a capital availability problem similar to that of the industries of the United States and European countries. Capital costs for new plant construction were reported to be similar to those in the United States, at approximately $1,000 per ton of raw steel capacity. There was general agreement, however, that there is no real reason why the Latin American iron and steel industry could not become a power in world steel trade. The ILAFA annual meeting was followed by a congress on basic oxygen steelmaking, part of ILAFA's long-term program to promote the industry in South America.

[9]U.S. Embassy, Mexico City, Mexico. State Department Airgram A-78, Mar. 17, 1976, 2 pp.

Argentina.—The Argentine steel industry produced 2.65 million tons of raw steel in 1976 compared with 2.50 million tons produced in 1975. Acindar, Industria Argentina de Aceros S.A., the private Argentine steel company that was authorized in January 1975 to build a new steelworks at Villa Constitucion in the Province of Santa Fe, received a $70 million loan from the Inter-American Development Bank to help finance its expansion program. The plant will include a Midrex direct-reduction plant, electric furnaces, and continuous casting equipment. An additional $20 million loan was obtained from the U.S. Export-Import Bank, mainly for the Midrex plant. The projected capacity of the plant will be 660,000 tons per year.[10]

La Cantábrica Sami y C, manufacturer of rolled steel products, contracted with a major Argentine engineering firm for a feasibility study to evaluate alternatives for improving its steel forming facilities.[11]

Bolivia.—The Government of Bolivia decided to install a $500 million iron and steel complex based on the Mutún iron ore deposit. The Mutún complex will produce 220,000 tons per year of low-carbon steel, using charcoal blast furnaces. Future plans call for an additional 660,000 tons per year of direct-reduced iron, using a natural gas process.[12] In a related operation the Bolivian Government hydrocarbons company signed an agreement with the Government of Argentina to provide an additional 2 million cubic meters (71 million cubic feet) of natural gas per year beginning in 1979. This brings the total contracted quantity to 6.5 million cubic meters (230 million cubic feet) in 1979.[13]

Brazil.—The Brazilian steel industry operated at a relatively high level of activity, producing 11% more raw steel and 24% more direct-reduced iron than in 1975. However, expansion plans under the stage 2 program were running about a year behind schedule at the Volta Redonda plant of Cia. Siderúrgica Nacional (CSN), and costs were substantially higher than previous estimates. Nevertheless, Brazilian officials affirmed that stage 3 expansion would not be significantly affected and that construction would proceed about on schedule. The expansion program apparently was being slowed by a shortage of skilled labor and late delivery of domestically produced equipment.

The Brazilian company, Siderúrgica Brasileira S.A. (SIDERBRAS), Kawasaki Steel Corp. of Japan, and Finanziaria Siderúrgica S.p.A. (FINSIDER) of Italy agreed to form a cooperative enterprise for construction of an integrated steelworks for the manufacture of semifinished steel. Initial annual slab capacity will be 3.3 million tons. First phase equipment will include a blast furnace, basic oxygen furnaces, and a slabbing mill.[14]

Chile.—Expansion plans of Compañía de Acero del Pacífico, S.A. (CAP), the State-owned vertically integrated company that produces more than 90% of Chile's iron and steel, were delayed because of the shortage of capital and losses in steelmaking operations.

Venezuela.—The Venezuelan iron and steel industry apparently was less affected by the worldwide economic stagnation than that of any other South American country. Profits from the Venezuelan petroleum industry permitted expansion of the nationalized steel industry about as planned, and the high level of economic activity enabled secondary industries in the private sector to expand operations. The only serious obstacle to steel industry growth was lack of trained manpower and the normal difficulties encountered in starting up new operations.

The Government was moving ahead rapidly with its plan to install 16.5 million tons per year of steelmaking capacity by 1990 or soon thereafter. All of the integrated steelmaking operations in 1976 were at the Government-owned plant of Corporacion Venezolana de Guayana-Siderurgica del Orinoco (CVG-SIDOR). To utilize the iron ore and natural gas resources of the Guayana region, Sidor chose the direct reduction-electric furnace route for its expansion program. Initially two plants, one using the Midrex process with a capacity of 390,500 tons and the other using the Hojalata y Lámina (HyL) process with a capacity of 396,000 tons, had been constructed. Before operation of the two systems could be compared, pressure to complete the expansion plan caused Sidor to contract for plants from both firms. The HyL plant, to be built by Pullman-Swindell, will have three mod-

ules with a total production capacity of over 2.2 million tons, and the Midrex plant, also with three modules, will have a capacity of 1.4 million tons of sponge iron per year.[15] Continuing its expansion plans, the Government approved construction of an iron and steel plant in western Venezuela in the State of Zulia having a capacity of 5.5 million tons of raw steel. The plant will be based on blast furnace-basic oxygen technology.

In the private sector, the National Steel Council approved eight new steel projects and recommended that four others be approved without State-supported financing. One of the largest projects was the second and third stage expansion program of Siderúrgica Venezolana S.A. (SIVENSA) to raise steelmaking capacity to 440,000 tons per year. However, SIVENSA's expansion will probably depend on operation of the Fior de Venezuela direct reduction plant which began operating toward the end of the year. When a steady supply of briquets from the Fior plant is available, SIVENSA is to add a second electric arc furnace, doubling its Guayana plant capacity to 220,000 tons per year. The most significant development in the private sector was the start of operations at the Fior de Venezuela fluidized-bed direct reduction process plant. CVG owns one-third of Fior de Venezuela; SIVENSA and Lukens Steel Co. of the United States are minority stockholders.

EUROPE

The steel industries of the Western European countries, whose business had been seriously damaged by the worldwide economic recession in 1975, recovered slightly in the first part of 1976, but the recovery was short-lived. Increasing costs and deteriorating domestic markets resulted in a depressed situation through most of the year.

Members of the EC were most concerned with the economic condition of their steel industries. The EC Commission studied the steel industry problems throughout the year and late in November approved a program that contained provisions for improved analysis and monitoring of steel markets, improved information exchange between nations, voluntary production targets, and minimum prices. It was determined that it would be necessary to attempt to predict fluctuations in the steel market, and in order to do so, statistical data on production, consumption, stock levels, employment, external trade, and utilization of capacity should be monitored more closely. Setting of minimum reference prices was included as a secondary measure if voluntary quotas proved inadequate as price supports. Toward the end of the year it was determined that a crisis situation existed, and the program, including voluntary quotas, was put into effect for a period of 4 months, beginning January 1, 1977.[16]

Early in the year, the national steel associations of Belgium-Luxembourg, the Netherlands, and the Federal Republic of Germany announced the formation of an international steel federation, to represent their interests before the EC. Later, an organization representing the steel producers of the entire EC was founded, known as the European Confederation of Iron and Steel Industries (EUROFER).

The Standing Commission on the Iron and Steel Industry of the Council for Mutual Economic Assistance (CMEA) of Eastern Europe reported that the CMEA countries had agreed on technical and scientific cooperation on direct reduction of iron ores and agreed to set up a coordination center in Romania. The Council approved a long-term plan for operation of the international system of scientific and technical information on ferrous metallurgy.[17]

Belgium.—Belgium's steel industry recovered slightly from the low of 1975 and it operated at 70% to 75% of capacity. Belgium's international trade in steel declined. Officials of Belgium's steel industry participated in discussions of the EC program and sought assistance in the Community. In addition, the industry was gradually instituting rationalization of operations and product specialization.

France.—The French steel industry recovered slowly from the depressed state of 1975. Operations returned to normal by April, with the resumption of full-time work schedules. However, normal operations did not continue, and in the last 2 months of the year the industry was forced to shorten the working time of approximately 50,000 steel workers. The industry experienced low worker productivity throughout the year, especially during the periods of shortened working time. Despite this depressed condition, the ECSC loaned France another

$11.5 million for the Solmer steelworks at Fos-sur-mer west of Marseilles.[18]

A new steel mill with an annual capacity of 3.5 million tons will be built by Société des Aciéries et Laminoirs de Lorraine (SACILOR) to replace an older mill at Sérémange in the Lorraine area. The mill is to have two 240-ton basic oxygen furnaces, with continuous slab casting. New coke ovens will be installed, and the blast furnaces and hot rolling mills modernized.[19]

Germany, West.—The steel industry of West Germany fared slightly better than its European Community partners because of a lower inflation rate and improved industrial economy. However, its foreign trade in steel mill products showed the effect of keen competition. Imports of steel mill products were up slightly while exports of these products were down about 10% compared with exports in 1975.

The EC Commission approved the acquisition by Klöckner-Werke AG of the majority share of Eisenwerke-Gesellschaft Maximilianshütte m.b.H. of Sulzbach-Rosenberg. The combined steel group will be the fourth largest raw steel producer in West Germany after August Thyssen-Hütte AG, Estel NV, and Fried. Krupp Hüttenwerke AG.

Italy.—Italy experienced a monetary inflation rate of about 16% during the year, and the lira continued to weaken in relation to the currency of Italy's trading partners. Among the difficulties faced by the steel industry were substantial increases in labor costs resulting from renegotiated labor contracts, and in raw material costs, partly as a result of devaluation of the lira. However, the industry was helped somewhat by heavy industrial buying of steel as a hedge against further inflation. The industry operated at less than 70% of capacity during the year.

Luxembourg.—The Luxembourg steel industry, one of the most severely affected by the recession of 1975, showed no recovery in 1976. Steel plants operated at 50% to 60% of capacity. Since steel represents 30% of gross national product and 95% of production is exported, the effect on the country's economy and trade was severe. The two largest steelworks announced a reduction from three to two shifts, affecting a total of 1,100 steelworkers. As a result, the usually harmonious relationship between the industry and labor was threatened.[20]

Spain.—Stocks of steel in Spain increased by more than 1 million tons, and raw steel production was slightly below that of 1975. As a prerequisite for funding, the Spanish Government apparently required that electric furnace steelmaking expansion include provisions for a direct reduction operation to lessen reliance on imported scrap.[21] There were two projects for direct reduction of iron ore: One was to be located in northern Spain near the port of Bilbao with two modules having a total capacity estimated at between 1 and 1.2 million tons annually; and the other was to be located on the Bay of Algeciras in southern Spain with one module and production capacity of approximately 500,000 tons per year. Both projects will use gaseous reduction and were included in Spain's new concerted action program for the iron and steel industry. They were planned for completion by December 31, 1980.[22]

Sweden.—A Government-sponsored fund for countercyclical stockpiling of steel was extended to the end of the year. Part of the increase in steelmakers' stocks was attributed to this incentive program. The purpose of the plan was to maintain employment levels and to stockpile steel in anticipation of the next economic upturn.

In the first of many reorganization moves that were being negotiated during the year among the country's specialty steel producers, Uddeholms AB agreed to purchase the specialty steel operations of Stora Kopparbergs Bergslags AB effective January 1, 1977. Uddeholms will take over Stora's main specialty mill at Söderfors, while its rolling mill at Vikmanshytten is being negotiated for by Fagersta Bruks AB. Stora agreed with Gränges AB to cease heavy plate production at Domnarvet and transfer it to Gränges' Oxelösund works.

The planned construction of a new steelworks at Lulea in northern Sweden (Steelworks 80) by the State-owned company Norbottens Järnwerk AB (NJA) was set back during the year. The Government first revised the planned capacity from 4.4 million to 2.75 million tons per year in March, and after the electoral defeat of the Socialist Government, which had sponsored the plan,

the future of the entire project was in doubt.

United Kingdom.—The British Steel Corp. (BSC) reported a loss of $459 million for fiscal 1975-76, compared with a profit of $131 million attained in 1974-75. It produced 18.9 million tons of raw steel, 17% less than in 1975. Finished steel deliveries were 13.4 million tons, 16% less than in 1975. Employment was reduced by 8% to 210,200 in the United Kingdom, and capital expenditures amounted to $954 million, 41% higher than those of 1974-75. Under the modernization plan, new equipment and construction valued at over $360 million was commissioned during the year. The corporation lost a portion of its home market to foreign competition, although its prices for most products were comparable to those prevailing in Europe. The ECSC loaned $300 million to BSC to finance modernization and expansion projects in the coal and steel sector. These funds were used to finance a major improvement program at BSC's Redcar-South Teeside complex. The planned expansion will make this complex one of the largest in the EC with a projected capacity of 5.5 million tons of raw steel per year.

After more than 9 months of delay because of a labor dispute with the National Union of Blastfurnacemen, the United Kingdom's largest blast furnace was lit on February 16, 1976, at the Llanwern works at Newport, Monmouthshire, Wales. The new furnace has a hearth diameter of 11.2 meters (36.7 feet) an inner volume of 2,652 cubic meters (93,620 cubic feet), and design production capacity of 5,500 tons per day. It is the first of the new generation of large blast furnaces being constructed under BSC's expansion plan.

The fourth mini-steelworks in the United Kingdom was commissioned by Manchester Steel Co. (part of the Norwegian group, Elkem-Spigerverket A/S of Oslo), located 3 miles from Manchester. The plant is equipped with a 50-ton electric arc furnace and a four-strand continuous casting machine to produce 90- to 115-millimeter (3.5- to 4.5-inch) square billets. Production capacity is 132,000 tons per year. A gas-fired scrap preheater is expected to increase production by about 10%.[23]

U.S.S.R.—One of the world's largest blast furnaces at Krivoy Rog in the Ukraine was reported to be operating at half of its ultimate capacity of 4.4 million tons per year. Plans were proceeding for a second unit at the same site. A new medium-size section rolling mill was installed at the Western Siberian Steel Plant, and a light section mill was added at the Nigne-Serginsky plant.

AFRICA

South Africa, Republic of.—The first stage of the Newcastle works of the Government-owned South African Iron and Steel Industrial Corp. Ltd. (ISCOR) was virtually completed during the year. Present annual production at this plant is 825,000 tons of raw steel. This is expected to increase to 2 million tons when the new No. 5 blast furnace is in production. Pig iron produced at the plant is transported by ladle car several miles to the basic oxygen shop, which consists of three 165-ton converters. The steel is continuously cast in three machines producing blooms of 315 by 205 millimeters (12.4 by 8.1 inches). The blooms are rolled to billets and to bars, sections, and wire rod. The planned capacity of the plant is 9 to 10 million tons per year.

Expansion of the Newcastle plant was deferred in favor of expanding the capacity of the Vanderbijlpark plant. This plant now has a capacity of 3.6 million tons of raw steel and is scheduled to reach 4.4 million tons soon. Reportedly, the ISCOR minimum steelmaking capacity by 1980-83 will be 7.7 million tons, as follows: Vanderbijlpark works, 4.4 million tons; Newcastle works, 2.0 million tons; and Pretoria works, 1.3 million tons.[24] Plans for the construction of a plant for production of semifinished steel products at Saldanha Bay, near the iron ore terminal, have been deferred.

ASIA

China, People's Republic of.—Information on the Chinese iron and steel industry continued to be scarce through 1976. However, the industry appears to have suffered a temporary setback probably mainly resulting from the recent severe earthquakes that affected coal and steel producing regions. China continued to import a considerable portion of its steel needs from Japan; however, the total for 1976 fell below the total of 4.4 million tons imported

[23]Hallatt, E. S. Manchester Steel: Britain's Latest Mini-mill. Iron and Steel Internat., v. 49, No. 1, 1976, pp. 19-23.

[24]U.S.Consulate, Durban, South Africa. State Department Airgram A-64, Oct. 7, 1976, 4 pp.

in 1975. Purchases of special steels were to be negotiated separately.[25]

India.—In Indian fiscal year 1975-76 (April 1-March 31), the average rate of capacity utilization was 84% compared with 74% in 1974-75. However, the steady uptrend in production and increasing rate of utilization of capacity was not accompanied by the expected growth in demand.[26] The high rate of production resulted in further accumulation of unsold stocks of both steel and pig iron to record amounts. Inability to sell in the domestic markets spurred a sharp rise in iron and steel exports, although India continued to have a trade deficit in steel.

Japan.—Japan's steel industry recovered slowly during 1976 from the recession of 1975. Domestic sales and exports improved through the end of the summer but slumped toward the end of the year owing to adverse economic conditions at home and abroad. Pig iron production was about the same as that in 1975, but raw steel production rose about 5% to 118 million tons in 1976. Steel exports amounted to 41 million tons, a 24% increase over those of 1975.

The first phase of operation of Nippon Kokan's Ogishima Works was initiated with the blowing in on November 12, 1976, of No. 1 blast furnace. This furnace has an inner volume of 4,052 cubic meters (143,092 cubic feet). The Ogishima project, which was begun in 1969 as a replacement for the Keihin works, is located on a manmade island in Tokyo Bay, 1 3/4 miles from the mainland. The first stage will include coke ovens with dry quenching facilities, two 275-ton basic oxygen furnaces, continuous slab casting, and slabbing, billet, and plate mills.

The No. 2 blast furnace at Nippon Steel's Oita Works, which started operating on October 5, 1976, was reported to be the world's largest blast furnace, with an inner volume of 5,070 cubic meters (179,042 cubic feet), a hearth diameter of 14.8 meters (48.6 feet), and an output of 13,200 tons per day.

With the lighting of No. 3 blast furnace, having an internal volume of 5,050 cubic meters (178,336 cubic feet), the Kashima Works of Sumitomo Metal Industries Ltd. became Japan's fifth largest steelworks.

Philippines.—Philippine officials considered establishment of an integrated iron and steel industry to be completed in 1981 at an estimated cost of $1.2 billion.

OCEANIA

Australia.—The possibility of constructing a large steel complex in Western Australia was still being considered. A group of Australian, American, Japanese, and European firms continued the feasibility study which began in 1974, but inflation and high construction costs delayed the project.[27] The proposed plant would use Australian iron ore and coal and produce semifinished steel for final processing by individual participants. Three major sites in Western Australia were being considered: Moore River, Kwinana, and Port Hedland. As an alternative to a conventional steel plant, direct reduction of iron ore by natural gas from the North West Shelf area was being considered.

New Zealand.—New Zealand Steel Ltd. continued planning a large expansion project including establishment of hot and cold rolling facilities and a substantial increase in capacity, to raise production capacity to a minimum of 495,000 tons per year.[28]

TECHNOLOGY

Studies on the application of nuclear energy to steelmaking were conducted in the principal steelmaking areas of the world: The United States, Japan, and Western Europe. No information was available on nuclear research in the centrally planned economy countries. These studies were justified on the basis of conservation of natural resources such as metallurgical coal and other fossil fuels, as well as possible economic advantages.

The first report of an AISI task force set up to make a technical and economic study of various nuclear steelmaking concepts was published.[29] All the concepts studied were based on direct reduction and electric arc-furnace steelmaking, in which iron ore is first reduced in the solid state to the metal with a hot reducing gas, and the metal then melted and refined in the electric arc furnace. The studies indicated that a steelmaking system using a nuclear-heated coal-gasification process to produce gas for direct reduction of iron ore could be competitive or even provide a slight eco-

nomic advantage over the present coke-oven, blast-furnace, basic oxygen furnace operation. The system studied in detail by the task force visualized a very high temperature reactor (VHTR), which would offer economic advantages over conventional methods of coal gasification only when built to a much larger scale than a conventional plant. Sharing of the gas output of a large VHTR between several steel or chemical plants would probably be necessary. It was concluded that in view of the uncertainty in the technology of the reactor, in cost estimates, and in the future availability and cost of various forms of energy, it would be desirable to conduct a research program on the VHTR. The task force recommended that the Energy Research and Development Administration (ERDA) finance such a program at the level of $3 to $5 million per year.

In Japan, studies on nuclear steelmaking have been conducted since 1968, and in 1973, a Government-supported consortium, Engineering Research Association of Nuclear Steelmaking (ERANS), was formed to conduct a 6-year research and development project. This project was directed toward construction of an integrated nuclear steelmaking plant utilizing a 50-megawatt VHTR to produce a reducing gas from petroleum refining residues. The hot gases from the reactor would be injected directly into a shaft furnace to directly reduce iron for use in electric furnace steelmaking.[30]

European nuclear steelmaking research was coordinated by the European Nuclear Steelmaking Club (ENSEC), which was established in September 1973. The Club decided initially to pursue the concept of a steelworks separated from the nuclear reactor for generating reducing gases. It was concerned with a high-temperature nuclear reactor to reform hydrocarbons to a reducing gas containing 96% hydrogen for use in blast furnaces, in direct reduction furnaces, and for other industrial uses. Nuclear research in the European countries apparently was guided by the widely divergent energy resources in Europe, which range from natural gas in the North Sea fields to lignite in Germany. A working party of ENSEC in 1976 was making a technical and economic assessment of the various possible total nuclear systems, identifying those upon which future studies should be concentrated.[31]
