Direct reduction research was slanted more to application and use of the directly reduced materials than it has been in the past. An international seminar on utilization of prereduced materials in iron and steelmaking was held at Bucharest, Romania, May 24-28, 1976. Forty-six papers from 14 different countries were presented, but only part of the papers dealt with utilization. Those that did covered use of directly reduced materials in electric arc and induction furnaces to produce superior steels, in cupolas for iron castings, and in basic oxygen furnaces for cooling. Other papers dealt with (1) transportation and storage of directly reduced materials, (2) reoxidation and pyrophoric properties, (3) gases used for the reductant, (4) application of direct reduction to lateritic ores containing chromium and nickel, and (5) the present status of direct reduction and its future impact on the iron and steel industries. (These papers are as yet unpublished.)

A study of direct reduction plants in operation, under construction, or in planning stages throughout the world indicated a capacity of 6.6 million tons per year in 1976, rising to 25.5 million tons per year by 1980. Of this capacity, 90% of the reduction would be by gas and 10% by solid fuels; 55% of the reduction would be in shaft furnaces, 33% in retorts, 8.5% in rotary kilns, and 3.5% in fluidized beds.

A theoretical study to improve the blast furnace system based on blast furnace research over the last 25 years was published.[32] The basic parts of the proposed system reportedly had been tested in various parts of the world, but a working unit had yet to be built. The improved system would utilize regulated reducing gas injected above the melting zone of the furnace so that all of the iron oxide would be reduced at the lower temperatures in the upper zone of the furnace. About half the amount of coke per ton of iron produced would be required compared with that needed in the conventional blast furnace, and injection of natural gas or oil would not be required. The reducing gas would be generated in a gas converter from noncoking coal, oil-contaminated mill scale, limestone, basic oxygen furnace and blast furnace top gases and dust residues, moisture, air, and oxygen. Overall cost savings of 10% were estimated.

Bureau of Mines Research.—Bureau of Mines Report of Investigations 8147, Steel From Urban Waste, described a series of steel heats made by Bureau researchers in a 1-ton arc furnace from ferrous scrap obtained from incinerated refuse, as-received steel cans, and detinned steel cans, both alone and blended with heavy melting scrap. The steel products were cast into ingots and rolled into reinforcing bars. Tensile and bending tests indicated that reinforcing bars of acceptable quality can be made from urban refuse components such as steel cans.[33] The researchers recommended that municipal waste processing systems be designed to avoid excessive oxidation or contamination of the ferrous products and to provide for detinning and baling or fragmentation prior to charging to a steelmaking furnace.

A study conducted for the Bureau of Mines by Battelle Columbus Laboratories based on 1973 data indicated that the energy requirement for production of steel slabs was 24 million British thermal units (Btu) per ton, or a total energy requirement for U.S. steel slab consumption of 3,350 trillion Btu. The energy requirements for gray iron castings were 34 million Btu per ton and 366 trillion Btu total, and for steel castings, 42 million Btu per ton and 54 trillion Btu total.[34]

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Steel formed in first solid state after melting, suitable for further processing or sale.

[2]In addition to the countries listed, Vietnam produces steel, but output is not reported and available general information is inadequate to permit formulation of reliable estimates of output levels.

[3]Data from American Iron and Steel Institute (AISI). Excludes steel produced by foundries not reporting output to AISI but reported to Bureau of the Census as follows (in thousand short tons): 1974—2,091; 1975—[r]1,937; 1976—1,804.

Iron and Steel Scrap

By K. W. Palmer[1]

Reflecting the general improvement in the economy, domestic consumption of iron and steel scrap in 1976 increased 9% compared with that of 1975. Net receipts of scrap by users were 13% above those for 1975, while yearend stocks increased 14% to 10 million tons.[2]

January's consumption (close to the 6.9-million-ton monthly average for 1975) was followed by an increase to 8.4 million tons in May. Consumption then fell irregularly to the year's low of 6.7 million tons in December.

Reported consumption of direct-reduced iron (prereduced iron ore), used as a scrap substitute by some of the smaller steelworks and foundries was 351,000 tons, about 32% less than in 1975. The decline was mainly due to the relatively low prices for ferrous scrap in 1976.

U.S. exports of scrap were 17% less than in 1975, reflecting the depressed condition of the world steel market. For the first time, shredded scrap was the principal grade exported.

The domestic scrap industry continued to seek lower rail freight rates. Pending results of an investigation of rate structures by the Interstate Commerce Commission (ICC), the scrap industry was temporarily exempted from a 4% increase in freight rates authorized at yearend for other commodities.

Research was continued by the Bureau of Mines on treatment of urban waste and junk automobiles for scrap recovery with the eventual aim of recycling as much as feasible.

Legislation and Government Programs.—Public Law 94-210 (Railroad Revitalization and Regulatory Reform Act of 1976) became effective in February 1976. The law charged the ICC to investigate within 12 months the railroads' rate structure and its effect on the ultimate usage of "recyclable or recycled materials and competing virgin natural resource materials." The ICC on its own initiative started such an investigation in 1973 under

Table 1.—Salient iron and steel scrap and pig iron statistics in the United States

(Thousand short tons and thousand dollars)

	1975	1976
Stocks Dec. 31:		
Scrap at consumer plants	8,766	9,988
Pig iron at consumer and supplier plants	1,435	1,519
Total	10,201	11,507
Consumption:		
Scrap	82,331	89,910
Pig iron	79,638	87,045
Exports:		
Scrap (excludes rerolling material and ships, boats, and other vessels for scrapping)	9,442	7,877
Value	$762,976	$601,826
Imports for consumption:		
Scrap (includes tinplate and terneplate scrap)	305	507
Value	$25,250	$35,120

Ex-Parte 270-6 which was completed in March 1976. The ICC rejected the ferrous scrap industry's allegations of rate discrimination by the railroads, stating that scrap and iron ore are "in almost all cases complementary and not competitive." At yearend the report required by Public Law 94-210, due by February 5, 1977, was being assembled.

On December 22 the ICC granted a 4% increase in freight rates to the Nation's railroads but temporarily exempted the recycling industry. The new rates were to be in effect not earlier than January 7, 1977.

On October 20 the President signed into law an act authorizing a 6-month study by the Department of the Treasury in cooperation with the Environmental Protection Agency (EPA) on tax incentives for recycling waste materials. The Department was to study tax provisions which "currently impede or discourage the recycling of solid waste materials" as well as to determine what actions Congress may take under the internal revenue laws to increase and encourage the recycling of solid waste materials.

AVAILABLE SUPPLY

The new supply of iron and steel scrap, available for consumption at consumers' plants in 1976, totaled 91.4 million tons. It consisted of 50 million tons of home scrap and 41.4 million tons of purchased scrap (net receipts). These quantities were both 11% higher than those of 1975.

CONSUMPTION

Consumption of iron and steel scrap in 1976 was 89.9 million tons, or 9% more than in 1975. Manufacturers of pig iron, steel ingots, and castings consumed 68.4 million tons (76%); iron foundries and miscellaneous users consumed 18.6 million tons (21%); and steel foundries consumed the remainder.

The proportion of shredded scrap consumed domestically or exported declined from 6.3% to 5.8% of total scrap consumption. Ohio consumers accounted for 17% of total consumption of shredded scrap, followed by Illinois (15%) and Michigan (11%).

STOCKS

Consumers' stocks reported on hand as of December 31, 1976, totaled 10 million tons or 14% more than those at yearend 1975. The increase resulted from a slow climb in stocks until June, after which the raw steel production rate dropped and stocks of scrap accumulated more rapidly. Yearend stocks were the highest since 1959.

PRICES

At approximately $70 per long ton, the composite price for steel scrap at the end of 1976 was almost the same as that at the beginning of the year. The Iron Age weekly composite price for No. 1 heavy melting scrap rose from $68.17 per long ton on January 2 to a 1976 high in early April of $94.83, then declined irregularly to a low of $62.83 on November 1, recovering to $70.17 at yearend. This resulted in an average annual price for No. 1 heavy melting scrap of $77.79, 8% above the average price of $71.86 for 1975. These price trends were reflected in prices of other grades of ferrous scrap.

FOREIGN TRADE

Exports of iron and steel scrap, excluding rerolling material and vessels for scrapping, amounted to 7.9 million tons in 1976, 16% less than the 9.4 million tons exported in 1975. The decline reflected the depressed condition of the steel industries of the major scrap importing countries with the exception of the Republic of Korea.

Spain replaced Japan as the largest importer of U.S. scrap, taking 23% of the total in 1976. Japan was the second largest importer, receiving 15%, the lowest tonnage received since 1958. The third largest importer was the Republic of Korea, with 12%, followed by Canada with 11%.

For the first time, shredded and fragmentized steel scrap (27% of total exports) replaced No. 1 heavy melting steel scrap (26% of scrap exports) as the leading export grade.

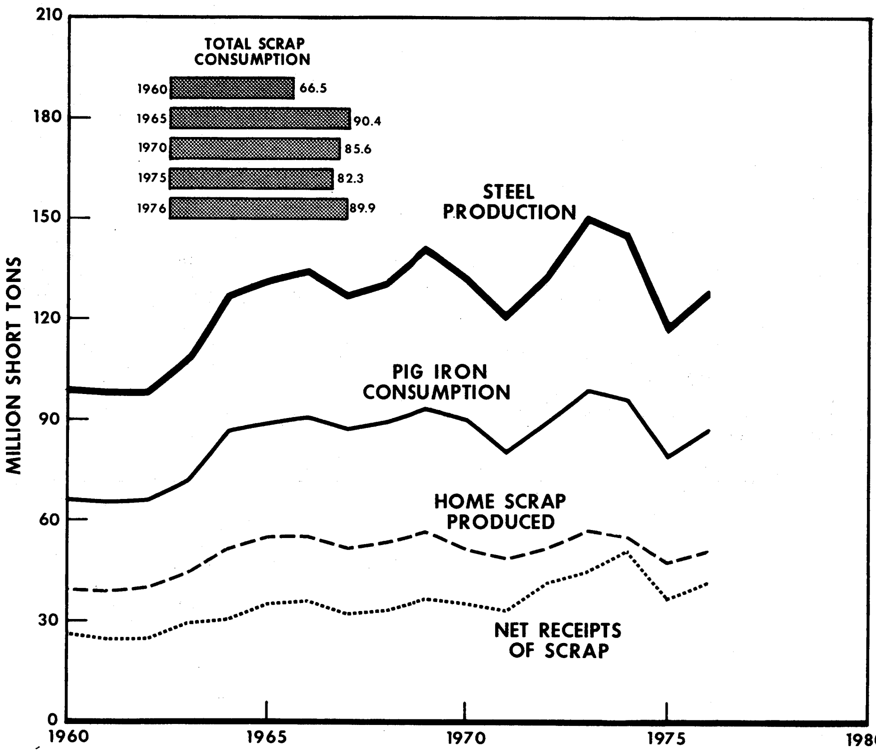

Figure 1.—Steel production (AISI), total iron and steel scrap consumption, pig iron consumption, home scrap production, and net scrap receipts.

WORLD REVIEW

Apparent world consumption of ferrous scrap in 1976, as estimated from data available for the principal consuming countries, appeared to increase about 6% compared with apparent consumption in 1975. The increase was approximately proportional to the rise in world output of raw steel. The United States remained the largest exporter of iron and steel scrap to world markets in 1976, while Italy was the leading importer.

Preliminary statistics on apparent consumption and prices of ferrous scrap in the principal consuming countries in 1976 are summarized below.

Country	Raw steel production[1] (million short tons)	Iron and steel scrap: Apparent consumption[1 2] (million short tons)	Iron and steel scrap: Average 1976 price (dollars per long ton)[3]
U.S.S.R.	162.0	93.5	NA
United States	128.0	90.0	$77.79
Japan	118.5	42.0	99.50
Germany, West	47.0	19.5	82.30
China, People's Republic of	[e]28.5	[e]5.0	NA
Italy	26.0	16.0	64.10
France	25.5	11.0	71.60
United Kingdom	25.0	17.5	60.46
Poland	17.5	[e]11.5	NA
Czechoslovakia	16.0	8.0	NA
Canada	14.5	8.0	--
Belgium	13.5	5.0	[4]80.00
Spain	12.0	8.0	59.50
Total listed	634.0	335.0	--

[e]Estimate. NA Not available.
[1]Rounded to nearest 500,000 tons.
[2]Including consumption in foundries, except for the People's Republic of China.
[3]Grade of scrap approximately equivalent to U.S. No. 1 heavy melting.
[4]Average of high and low figures.

Relationships between apparent consumption of scrap and production of raw steel continued to differ rather widely from country to country because of differences in metallurgical practice, magnitude of foundry consumption, availability of scrap, and other factors. For example, relatively large proportions of the raw steel output of Italy and Spain were produced from scrap in electric furnaces, whereas steel produced in France and Japan was made largely in converters using hot metal and relatively low proportions of scrap. Foundry consumption of scrap in the United States and the United Kingdom was proportionately larger than in most other countries. Consumption of scrap in the U.S.S.R. appeared to be relatively low, partly because of the extensive use of pig iron in open-hearth furnaces.

In world trade, France exported 3 million tons of scrap in 1976 and was the leading exporter outside of the United States. Net exports of scrap by West Germany and the U.S.S.R. amounted to about 1 million tons each. Imports of scrap by Italy totaled 5.9 million tons, with France being the largest supplier. Spain imported 2.9 million tons and Japan 2 million tons with 63% to 64% in each country coming from the United States. The United Kingdom, which had been a small net exporter of scrap in 1974 and 1975, became a net importer in 1976 with 507,000 tons imported from the United States.

Japanese imports of ferrous scrap in 1976 dropped to the lowest level since the 1950's. Japanese steel production, which was well below capacity in 1976, had started to decline in the first half of 1975, but imports of scrap were not reduced appreciably until November of that year. Consequently, there was an accumulation of scrap stocks which depressed demand for scrap imports in 1976. This was also the first year since the early 1950's that Japan was not the leading importer of scrap from the United States.

In other developments, the British Steel Corp. (BSC) continued its policy of designating less than 20 British firms as direct suppliers of scrap to the corporation. This policy aroused much criticism from the British Scrap Federation (BSF), the majority of whose members were not allowed to deal directly with BSC. Since most BSF members were not large-volume dealers and could not take advantage of potential economies of scale, the drop in average scrap prices in the United Kingdom (from $76.70 per short ton in 1974 to $54.00 per short ton in 1976) resulted in financial difficulties for many of these firms.

TECHNOLOGY

Many orders for automobile shredders were placed prior to 1975 when the market outlook for scrap was more favorable. This resulted in long lead times for delivery so that, despite a generally weak scrap market in 1976, the number of shredders installed rose to 157 by yearend and resulted in over capacity.[3] Shredded scrap consumed domestically or exported in 1976 totaled 5.2 million tons or 0.5% more than in 1975.

In the scrap-handling equipment field, a motor puller for automobile hulks that would fit most front-end loaders has been developed. There was also a trend in equipment purchases during 1976 toward smaller balers and larger shears, but no noticeable trend was noted in size of shredders.

At the beginning of 1976, only one scrap dealer operated a hot briquetter for borings and turnings. During the year, two more briquetters came onstream. Four additional hot briquetters were planned or ordered by other companies during the year.[4]

Toll arrangements for briquetting other companies' scrap were reported in 1976; these have been rare in the ferrous scrap trade. A few small steel mills were installing scrap processing equipment such as shredders and briquetters.

A study by A. T. Kearney Inc., a Chicago consulting firm under contract to the Bureau of Mines, estimated U.S. geographical distribution of newly available ferrous scrap supply and demand from 1975 through 1985. The study indicated that the net balance between the total supply of newly available ferrous scrap and total domestic demand for consumption would be positive, although small, for all but 2 years; these 2 years would have a small negative balance.[5] Another study contracted for by the Bureau of Mines in 1975 for a period of 2 years was concerned with the identification of legal and regulatory barriers to the expanded use of secondary ferrous and nonferrous metals. It was to be completed and a report issued by mid-1977.

Several resource recovery facilities to separate ferrous scrap from refuse came onstream in 1976. By yearend there were nine operational facilities with a total refuse processing capacity of 8,570 tons per day. In addition, seven facilities with a total processing capacity of 8,950 tons per day were under construction.

At the Bureau of Mines Salt Lake City Metallurgy Research Center, research was continued to develop or improve methods for reclaiming plastics or vinyl-free combustible materials from shredded junk automobile rejects, and to recover and separate nonferrous metals and nonmetals contained in such rejects. Late-model cars were dismantled to determine the amounts and types of construction materials present and to ascertain the plastics content of the cars.

At the Bureau's Twin Cities Metallurgy Research Center, ferrous scrap from raw refuse was successfully used as 60% of the charge in a basic-lined cupola, with shredded automobile scrap as the remainder of the charge. Tests prior to 1976 were made with a maximum of 35% scrap from raw refuse. Cupola tests were also conducted using 25% to 100% direct-reduced iron pellets with automobile scrap as the remainder of the charge and 25% to 50% direct-reduced pellets with raw refuse scrap as the rest of the charge.

[1]New supply available for consumption is a net figure computed by adding production to receipts and deducting scrap shipped during the year. The plus or minus difference in stock levels at the beginning and end of year is not taken into consideration.
[2]Data may not add to totals shown because of independent rounding.
[3]Includes scrap shipped, transferred, or otherwise disposed of during the year.

Table 7.—Consumption of iron and steel scrap and pig iron[1] by State and region, by type of manufacturer in 1976

(Thousand short tons)

Kyanite and Related Materials

By Michael J. Potter[1]

Kyanite, andalusite, and sillimanite are anhydrous aluminum silicate minerals that are alike in both composition and use patterns and have the same chemical formula, $Al_2O_3 \cdot SiO_2$. Related materials include synthetic mullite, dumortierite, and topaz, also classified as aluminum silicates, although the last two additionally contain substantial proportions of boron and fluorine, respectively. All of these kyanite-group substances have the capability of serving as raw materials for manufacturing special high-performance refractories in the high-alumina category, but there has been no record in recent years of significant utilization of either dumortierite or topaz for this purpose in the United States.

Although published statistics are not sufficiently complete to be wholly conclusive, it appears that the United States, India, and the Republic of South Africa are the leading world producers of kyanite-group minerals. It can be presumed that the U.S.S.R. and perhaps a few other industrialized nations also produce significant quantities of these materials.

U.S. kyanite production in 1976 was slightly higher in tonnage and value than in 1975. During 1976 the expanded processing facilities of C-E Minerals, Inc., were successfully debugged. Partly because of sluggish sales, completion of Kyanite Mining Corp.'s third plant is now scheduled for 1977.[2]

Legislation and Government Programs.—The allowable depletion rates for kyanite, established by the Tax Reform Act of 1969 and unchanged through 1976, were 22% for domestic production and 14% for foreign operations.

DOMESTIC PRODUCTION

Kyanite was produced in the United States in 1976 at three open pit mines: Two in Virginia and one in Georgia. Kyanite Mining Corp. operated the Willis Mountain mine in Buckingham County, Va., and the Baker Mountain mine in adjoining Prince Edward County, Va. C-E Minerals, Inc., operated the Graves Mountain mine in Lincoln County, Ga.

Domestic kyanite output in 1976 was slightly higher in tonnage and value than in 1975. Specific kyanite production statistics for 1976 (as well as for all previous years since 1949) are withheld to avoid disclosure of individual company confidential data.

Synthetic mullite production showed a substantial increase in both tonnage and value compared with 1975 and output was largely of the high-temperature sintered variety. The four producers of this material were A. P. Green Refractories Co. at Philadelphia, Pa.; C-E Minerals, Inc. at Americus, Ga.; Harbison-Walker Refractories Co. at Eufala, Ala.; and Taylor Refractories Division, NL Industries, Inc., at Greenup, Ky. Electric-furnace-fused mullite was produced by The Carborundum Co. at Niagara Falls, N.Y.

Table 1.—Synthetic mullite production in the United States

Year	Quantity (short tons)	Value (thousands)
1972	46,389	$4,080
1973	58,176	5,211
1974[r]	41,508	5,895
1975	24,147	3,350
1976	42,228	5,453

[r]Revised.

CONSUMPTION AND USES

Kyanite and related materials, conforming to established end use patterns, were consumed in 1976 mostly in the manufacture of high-alumina or mullite-class refractories and in lesser quantities as ingredients in some ceramic compositions. Domestic kyanite, already ground to minus 35-mesh as required by the flotation process used in its separation and recovery, was marketed in the raw form or after heat treatment; that is, as mullite, which was sometimes further reduced in particle size before use. In the 35- to 48-mesh range, the mineral was used mostly in monolithic refractory applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories, or with clays and other ingredients in refractory compositions for making kiln furniture, insulating brick, firebrick, and a wide variety of other articles. More finely ground material, minus 200-mesh for example, was used in body mixes for sanitary porcelains, wall tile, precision casting molds, and miscellaneous special-purpose ceramics.

PRICES

Engineering and Mining Journal, December 1976, listed prices for kyanite, f.o.b. Georgia, ranging from $63 to $118 per short ton for bulk shipments and $9 more per ton for bagged material.

Price ranges quoted for kyanite-group materials in Ceramic Industry Magazine, January 1977 follow:

	Per short ton
Andalusite	$30-$60
Kyanite	63-125
Mullite, calcined	302-313
Mullite, fused	160-450

The December 1976 issue of Industrial Minerals (London) quoted kyanite-group price ranges approximately equivalent (with some uncertainty due to a floating exchange rate) to the following:

	Per short ton
Andalusite, Transvaal, c.i.f. main European port	$100
Kyanite, Indian, f.o.b.	93
Sillimanite, Indian, natural bagged, f.o.b.	[1]57
Kyanite, Indian, calcined, f.o.b. Calcutta	136-$143

[1]Nominal.

FOREIGN TRADE

The amount of kyanite-group material exported in 1976 showed a substantial decrease compared with 1975. It can be supposed that the greater part of material currently being exported by the U.S. consists of mullite. It should be noted, however, that some element of uncertainty is inherent in such conclusions because Bureau of the Census export figures, on which they are based, do not clearly distinguish synthetic mullite from some other mullite-containing materials prepared by high-temperature processing of certain bauxitic and kaolinitic minerals.

The tonnage of imported material continued to be small, although it showed an increase over that of 1975. For the first time, India did not appear as an exporter to the United States.

WORLD REVIEW

France.—Imports of kyanite-group minerals amounted to 7,860 tons in 1974. The principal countries of origin and the percent supplied were India, 34%; the United States, 31%; and Belgium-Luxembourg, 15%. In 1975, kyanite-group imports totaled 6,000 tons. Principal countries of origin and share supplied were India, 32%; the United States, 22%, and Belgium-Luxembourg, 13%.[3]

Although the Republic of South Africa is the principal producer of andalusite, France is now said to be in second place with production of "Kerphalite," a type of andalusite mined near Kerphales in Brittany. A publication described the operation and extraction (at Glomel) and the properties and refractory applications of the products.[4]

Germany, West.—Imports of kyanite-group minerals in 1975 amounted to 26,100 tons. Principal countries of origin and the share supplied were the Republic of South Africa, 27%; India, 25%; and the United Kingdom, 14%.[5]

India.—A report entitled "Kyanite and Sillimanite, a Market Survey" was released by the Mineral Economics Division of the Indian Bureau of Mines. The report includes an estimate of kyanite and sillimanite demand in India and elsewhere over the next 10 years. Also included are sections on uses and specifications, supply, trade, and prices.[6]

The Geological Sur'ey of India planned to investigate reserves at sillimanite deposits

[6]Industrial Minerals (London). Publications. No. 108, September 1976, p. 56. Report is available from Regional Controller of Mines, Plot No. 95, Bungalow No. 267, East High Court Road, New Ramdaspeth, Nagpur 440010, India.

in Meghalaya. Mines at these deposits were leased by Assam Sillimanite Ltd. (ASL) until 1973, with some 143,000 tons of sillimanite being mined since 1950. Hindustan Steel Ltd. took over the mines from ASL.[7]

Japan.—Imports of kyanite-group minerals amounted to 31,785 tons in 1974. The principal countries of origin and the percentage supplied were the Republic of South Africa, 65%; India, 25%; and the United States, 10%. In 1975 kyanite-group imports were 25,950 tons. Principal countries of origin and percent supplied were the Republic of South Africa, 58%; India, 31%; and the United States, 10%.[8]

Nigeria.—The Nigerian Government was to invest $760 million in exploiting mineral and water resources during the current plan period. Of this amount, $5.3 million was to be spent on development of known deposits of several nonmetallic minerals, including kyanite.[9]

United Kingdom.—For the first 6 months of 1975, imports of kyanite-group minerals amounted to 18,800 tons. Principal countries of origin and the share supplied were the Republic of South Africa, 64%; France, 14%; the United States, 12%; and India, 5%. Imports of kyanite-group minerals for the first half of 1976 were 18,535 tons. The principal countries of origin and percentage supplied were the Republic of South Africa, 65%; France, 24%; India, 5%; and the United States, 5%.[10]

Synthetic mullite	41,508	24,147	42,228

[e]Estimate. [p]Preliminary. [r]Revised. W Withheld to avoid disclosing individual company confidential data.
[1]Owing to incomplete reporting, the table has not been totaled.
[2]In addition to the countries listed, a number of other countries presumably produced kyanite and related minerals, but output data are not reported and no basis is available for estimates of output levels.
[3]In addition, sillimanite clay (also called kaolinized sillimanite) is produced, but available information is inadequate to make reliable estimates.

TECHNOLOGY

A patent was granted for making aluminum powder from kyanite. The procedure includes mixing beneficiated kyanite and powdered coal to make briquets or pellets, reducing the agglomerates in an electric furnace, grinding and hydroaluminating the aluminum-silicon alloy, and pyrolyzing or decomposing the resultant material in an oil medium to form aluminum powder.[11]

In its annual review of materials for ceramic processing, an industrial journal presented brief studies of the kyanite-group minerals and their contributions to modern technology.[12]

The Federal Bureau of Mines ran some acid leaching studies on a high-iron kyanite concentrate produced from a North Carolina weathered surface ore. Results indicated that specification-grade kyanite concentrates could be produced from this material by leaching with acid to react with the contained iron. In other Bureau work, in cooperation with the U.S. Forest Service, kyanite and garnet analyses were run on some samples from Idaho. The analytical treatment involved scrubbing, acid leaching, heavy-liquid separation, and magnetic separation.

A patent was granted for the fabrication of structural bodies from mullite powder.[13]

A journal article described the occurrence, characteristics, and purification of Korean andalusite. The ore, which contained mainly andalusite, muscovite, biotite, and small amounts of other minerals, was studied by optical microscopy, X-ray diffraction, and other methods. After hand cobbing, stage crushing of the ore increased the distribution of andalusite in coarse particles and that of mica in fine particles.[14]

Lead

By J. Patrick Ryan,[1] John M. Hague,[1] and John A. Rathjen[2]

In 1976 world mine production of lead at 3.7 million tons represented a slight decline from the 1975 level. Smelter production, however, recovered from the low level of 3.66 million tons in 1975, rising to 3.79 million tons in 1976. World metal consumption was estimated to be about 4.7 million tons, including use of refined secondary metal, a 9% increase above consumption in 1975. The increase came in part from increased secondary production and in part from drawdown of stocks. World producers' stocks outside planned economy countries decreased from 298,000 tons at the beginning of the year to 223,000 tons at yearend.

The U.S. producer price of lead increased in several steps throughout the year from 19 cents per pound in January to a split price of 25.5 to 26 cents at yearend. The London Metal Exchange (LME) price ranged from an average of 15.2 cents per pound in January in terms of U.S. currency to 23.1 cents in July and then retreated through the succeeding months, ending the year at 21.7 cents. During the first half of the year the LME price was only 1 or 2 cents below the U.S. price but during the second half the spread became 3 to 5 cents per pound.

Domestic mine production decreased 2% from the 1975 level to 609,500 tons in 1976. Primary refinery production from domestic and foreign concentrates on the other hand increased 3% over that of 1975 to 657,519 tons in 1976, despite a strike at one smelter. Secondary smelter production increased 10% to a record level of 726,600 tons, more than half of the total lead production.

Consumption of lead in the United States recovered from the depressed level of 1975, increasing 15% to 1.49 million tons in 1976. The increase in demand was caused by the need for original equipment batteries in a greater number of new cars and by sales of more replacement batteries toward the end of the year as severe winter weather increased battery replacements. Lead requirements for battery manufacture used 55% of the total supply; gasoline antiknock compounds, 16%; pigments, 7%; ammunition, 5%; and other uses, 17%.

Stocks of refined and antimonial lead at primary smelters decreased from 81,300 tons at the beginning of the year to 43,700 tons at yearend, and consumers' stocks of soft lead and lead in antimonial lead and other alloys changed from 131,700 tons on January 1 to 127,900 tons on December 31, resulting in a substantial reduction of 41,400 tons in combined stocks.

Legislation and Government Programs.—The General Services Administration (GSA) reported net sales of lead from the Government stockpile totaled 459 tons in 1976. The total uncommitted inventory at yearend was 601,160 tons, as primary producers stocks remained above the 52,584-ton trigger point for GSA lead released through September 1976.

GSA announced on October 1 that the stockpile goal for lead had been raised from 65,100 tons to 865,000 tons and that the Government was canceling its obligation to deliver any lead remaining to be delivered under contracts with producers.

Public Law 94-413, known as the Hybrid Vehicle Research, Development, and Demonstration Act of 1976, was enacted on September 17, 1976. The law authorized a $160 million Federal program to foster development and demonstrate over a 5-year period (1977-81), the commercial feasibility of electric vehicles. The program, to be carried out by the Energy Research and Development Administration (ERDA), provided for production of 7,500 cars for demonstration by Government agencies and the public. Because a substantial part of the authorized funds were to be allocated for battery research, including the lead-acid

[1]Physical scientist, Division of Nonferrous Metals.
[2]Mineral specialist, Division of Nonferrous Metals.

battery, the program could have a major impact on the battery manufacturing industry and the future demand for lead.

On June 23, 1976, the Lead-Based Paint Poisoning Prevention Act was extended and revised by enactment of the National Consumer Health Information and Health Promotion Act of 1976, (Public Law 94-317). The Act directs Federal agencies to take action with respect to determining a safe level of lead in paint. Public hearings were held on September 13, 1976.

On petition by interested parties requesting revocation of its earlier dumping findings on imports of lead metal from Australia and Canada, the International Trade Commission, on review of the evidence and factual data, determined that if the findings were revoked, an industry in the United States would not likely be injured by importation of such primary lead metal at less than fair market value.

[1]Quotation on nationwide, delivered basis.

The International Lead and Zinc Study Group (ILZSG) held its 20th session in Geneva, Switzerland, November 8-12 to review the situation in lead and zinc and the outlook for 1977, and long-term lead and zinc trends. ILZSG provided estimates of world production and consumption of lead and zinc that reflected a strong recovery in world economic activity from the low levels of 1975. ILZSG estimates for 1976 and forecasts for 1977 showed lead supply and demand in close balance with little change in stock levels. A review of new mine and smelter projects disclosed several new zinc-lead mines under development and scheduled for production in 1977 and 1978, including Tara in Ireland and Rubiales in Spain. Several new and expansion smelter projects, both primary and secondary, also were scheduled for startup in 1977 and 1978.

DOMESTIC PRODUCTION

MINE PRODUCTION

Output of lead from U.S. mines in 1976 totaled 609,500 tons, about 2% less than in 1975. Monthly production reached a maximum in March of 57,800 tons, about 1% less than the maximum achieved in the same month in 1975. Production from Missouri mines decreased 3% to 501,000 tons and accounted for 82% of the Nation's total output of lead. Production in Idaho, which provided 9% of the total, was 6% more than in 1975 reflecting increased output at the Lucky Friday and Star mines. Colorado's production was down 1% but mine output in Utah continued to rise for the second consecutive year in 1976 after reaching a 70-year low in 1974. The 29% gain in Utah's output was attributed to increased production from the Ontario mine near Park City which more than offset lower production from the Burgin mine.

The Buick mine, jointly owned by AMAX Lead Co. of Missouri and Homestake Lead Co., was the Nation's leading lead producer for the sixth consecutive year although output of ore, concentrates, and contained lead declined moderately from the record levels achieved in 1975. Ore milled in 1976 totaled 1.61 million tons averaging 9.9% lead and 3.9% zinc from which 204,574 tons of lead concentrate and 94,734 tons of zinc concentrate were produced. Ore reserves decreased 0.78 million tons to about 28 million tons at yearend. Average grade of reserves was 7.0% lead and 2.0% zinc.[3]

The seven leading mines, all in Missouri, provided 78% of the total U.S. mine production of lead compared with 79% in 1975. The 12 leading mines produced 91% and the 25 leading mines accounted for 99% of the total, the same as in 1975. About 4,700 persons were employed at the Nation's lead

[3]Homestake Mining Co. 1976 Annual Report. P. 17.

lead-silver, and lead-zinc mines and mills in 1976. Output of lead and zinc from these mines was approximately 165 tons per man-year. Average grade of lead ore mined was 5.89% lead and 0.97% zinc, compared with 6.17% lead and 0.89% zinc in 1975.

St. Joe Minerals Corp., the Nation's largest lead-mining and smelting company, operated its four underground mine-mill units in the New Lead Belt of southeast Missouri at full capacity during the year. The four units, Fletcher, Brushy Creek, Viburnum, and Indian Creek, accounted for approximately one-third of the total U.S. mine production in 1976. The company reported that concentrate production was 316,570 tons containing 221,404 tons of lead, compared with 284,200 tons of concentrate and 201,434 tons of lead produced in 1975. St. Joe mines also produced 17,936 tons of zinc in concentrates and 3,169 tons of copper in concentrates. Tons produced per man-shift worked underground ranged from a low of 30 tons to a high of 55 tons.[4]

In Idaho, Hecla Mining Co. reported that its Lucky Friday mine produced 186,520 tons of ore assaying 14.41 ounces of silver per ton, 10.91% lead, and 1.47% zinc in 1976, compared with 173,245 tons assaying 14.96 ounces of silver per ton, 10.71% lead, and 1.29% zinc in 1975. About 20,100 tons of lead, 2.64 million ounces of silver, and 2,600 tons of zinc were contained in the concentrates produced. Ore reserves at yearend at Lucky Friday totaled 475,000 tons compared with 505,000 tons at yearend 1975. Hecla also reported that mine production at the Star-Morning mine, jointly owned by Hecla (30%) and The Bunker Hill Co. (70%), totaled 282,037 tons of ore, slightly less than in 1975. Hecla's share of the 1976 production was 84,612 tons of ore assaying 2.98 ounces of silver per ton, 5.61% lead, and 6.05% zinc. Hecla's 30% share of the computed ore reserves was 344,000 tons, about 50,000 tons less than at yearend 1975.[5]

The Bunker Hill Co. (a subsidiary of Gulf Resources and Chemical Corp.) reported production from company-owned mines aggregated 35,000 tons of lead, about 2,000 tons more than in 1975. Ore production at The Bunker Hill mine increased approximately 10% to a record level. At the Pend Oreille mine ore production increased about 25%. The company also reported that proven and probable ore reserves at yearend 1976 in the Bunker Hill mine totaled 3.09 million tons averaging 2.2% lead, 3.4% zinc, and 1.4 ounces of silver per ton. In addition, the company's 70% interest in proven and probable ore at the Star mine totaled 703,000 tons averaging 6.9% lead, 8.0% zinc, and 4.0 ounces of silver per ton.[6]

In Colorado, Idarado Mining Co. mined and milled 361,000 tons of ore averaging 2.40% lead, 3.83% zinc, and 0.49% copper, compared with 406,000 tons of ore averaging 2.28% lead, 3.24% zinc, and 0.63% copper treated in 1975. Ore reserves at yearend were 3.48 million tons, about 5% less than at yearend 1975. The company reported an 11% reduction in ore milled, reduced development activity, and increased mine productivity which lowered mine operating costs and partly offset sharply higher smelter treatment charges. At the Leadville mine, also known as the Resurrection mine, a joint venture of ASARCO Inc. and Newmont Mining Corp., 200,000 tons of lead-zinc-silver ore was treated, slightly less than in 1975. The average grade of ore milled in 1976 was 4.25% lead, 9.26% zinc, and 2.2 ounces of silver per ton compared with 4.23% lead, 8.68% zinc, and 2.2 ounces of silver per ton in 1975.[7] Lead metal production was about 7,300 tons, 200 tons less than in 1975.[8] Ore reserves at yearend 1976 were estimated at 1.96 million tons averaging 4.96% lead, 9.94% zinc, 2.71 ounces of silver and 0.08 ounce of gold per ton, down from 2.27 million tons at the end of 1975.

SMELTER AND REFINERY PRODUCTION

Output of primary refined lead and lead in antimonial lead from the Nation's five primary refineries in 1976 totaled 657,519 tons, about 3% more than in 1975. About 87% of the total output was recovered from domestic ores. Antimonial lead production at primary refineries increased about 12% to 6,743 tons. The average antimony content of the alloy increased from 9.4% to 10.8%.

St. Joe's smelter-refinery at Herculaneum, Mo., the largest in the United States, operated at close to capacity in 1976. Production of lead and lead alloys totaled 222,483 tons, 20% more than in 1975 reflecting strong demand for lead throughout the year particularly from the battery industry and manufacturers of lead alkyls for gasoline.[9]

[9]Page 8 of work cited in footnote 4.

ASARCO reported that its Omaha, Nebr., and Glover, Mo., refineries produced 197,300 tons of lead, slightly less than in 1975. The company began work at midyear on a comprehensive modernization and air-quality control program designed to bring its copper and lead smelters at El Paso, Tex., into compliance with government standards. The new facilities will include a totally enclosed ore handling system to minimize air pollution from incoming copper and lead ores, a new lead sintering plant, and an 800-ton-per-day sulfuric acid plant to control sulfur dioxide emissions from the copper concentrate roasters and the lead concentrate sinter machine. Construction of these facilities was to begin in 1977 and the entire $98 million modernization program is scheduled for completion in 1978. At the company's East Helena, Mont., lead smelter a $37 million modernization program, underway in 1976, included a 500-ton-per-day acid plant and extension of the updraft sinter machine. Completion of the project was scheduled for the third quarter of 1977. Base bullion produced at the El Paso and East Helena custom smelters was treated at the Omaha refinery. The Glover smelter-refinery, which treated concentrates from the Ozark mine at Sweetwater, Mo., was closed by a strike extending through the last 4 months of the year resulting in a loss of 32,000 tons of refined lead production.[10]

The East Helena smelter processed ores and concentrates from about 115 domestic mines in 10 States and from mines in Australia, Canada, Colombia, Honduras, and Peru. The El Paso smelter processed ores and concentrates from approximately 28 domestic mines in 5 States and from mines in Canada, Honduras, Mexico, Nicaragua, and Peru.

The AMAX-Homestake smelter-refinery at Boss, Mo., processed 196,800 tons of concentrates and produced 134,100 tons of refined lead, slightly less than in 1975. Approximately one-half of the production of refined lead at the smelter was tolled for others.[11]

The Bunker Hill smelter-refinery of Gulf Resources and Chemical Corp. produced 108,000 tons of lead in all forms, about 12% less than in 1975. The company reported that the falloff in production in 1976 resulted from curtailment of smelter operations in order to comply with pollution control regulations; however, completion of a tall chimney (stack) in mid-1977 should enable the smelter to operate near capacity. The Bunker Hill smelter processed concentrates from mines in seven States, Canada, Greenland, and Peru.

Secondary smelter production from recycled materials in 1976 increased 10% to a record high level of 726,600 tons of lead, about 52% of the total smelter and refinery production. Approximately 115 secondary plants were engaged in recovering lead and lead alloys from recycled scrap during the year. Secondary metal output represented nearly 49% of the total lead consumption in 1976. Approximately 43% of the total secondary lead production was recovered in the form of lead metal, 47% as antimonial lead, and the remaining 10% in other lead alloys.

RAW MATERIAL SOURCES

Primary smelters and refineries processed ores and concentrates from domestic mines yielding 570,800 tons of refined lead and antimonial lead, about 87% of the total primary refinery production. Refined and antimonial lead recovered from imported concentrates smelted during the year totaled 86,700 tons, 19,700 tons less than in 1975. Lead recovered from lead scrap processed at primary plants dropped to 1,400 tons, largely contained in antimonial lead.

Scrap materials consumed in 1976 totaled about 1 million tons, 93,800 tons more than in 1975. New scrap in the form of purchased drosses and residues from a variety of sources aggregated 151,000 tons, about 11% more than in 1975 and a record high consumption. New scrap accounted for 15% of the total scrap processed, the same as in 1975. The remainder, old scrap, was largely battery plates, cable lead, soft and hard lead with smaller quantities of type metal, solder, and babbitt. About 4,400 tons of reclaimed scrap was imported from foreign countries for processing in domestic plants.

[10]Pages 9 and 11 of work cited in footnote 8.
[11]Page 17 of work cited in footnote 3.

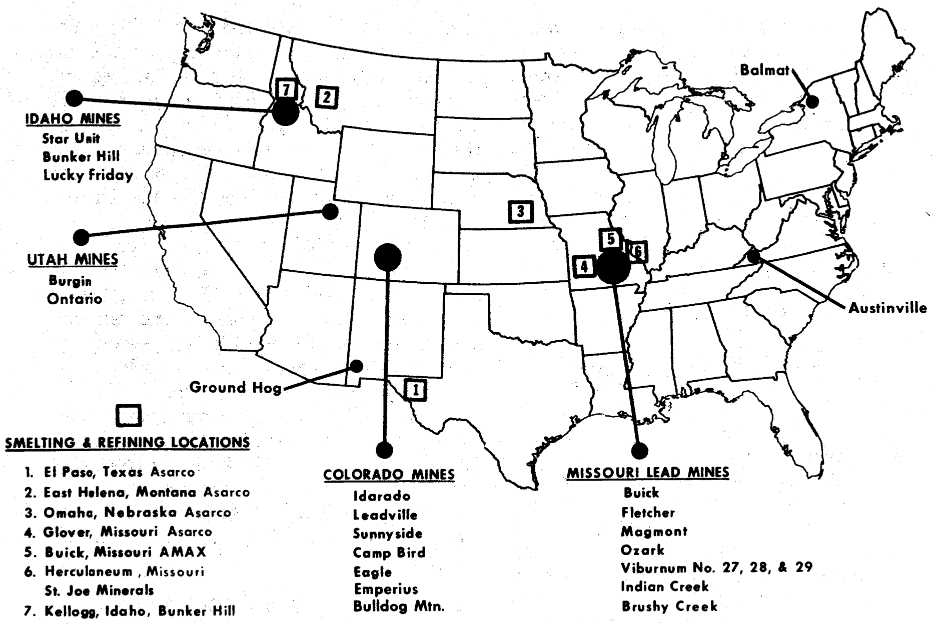

Figure 2.—Lead mines and smelters in the United States.

CONSUMPTION AND USES

Domestic consumption of lead in 1976 totaled 1.49 million tons, 15% above the 8-year low level of consumption established in 1975. On a monthly basis, consumption ranged from a low of 103,400 tons in July to a high of 137,400 tons in October. The use of lead increased in all major product categories. In metal products, battery requirements were up nearly 18%, ammunition was down 2%, but solders increased 10%. Lead used in pigments, principally red lead and litharge was up 33%, and lead used in gasoline antiknock compounds was 15% greater than in 1975. Miscellaneous and other unclassified uses of lead combined increased 30%. According to type of material consumed, soft refined lead represented 67% of the total consumption; antimonial lead accounted for 28%; lead in other alloys accounted for 4%; and lead in copper-base scrap accounted for about 1%.

The 18% gain in lead requirements for battery grids and oxides was attributed to increased demand for original equipment starting, lighting, and ignition (SLI) batteries, reflecting a 28% gain in production of motor vehicles, and to increased requirements for replacement batteries attributed mainly to severe winter weather conditions in many parts of the country. Approximately 62.1 million SLI-type batteries were produced in 1976, 14.9 million more than in 1975. Of the total battery production 48.2 million were replacement and 13.9 million were original equipment, representing gains of 18% in replacement and 114% in original equipment. The 15% gain in the quantity of lead used in antiknock additives in 1976 was attributed essentially to increased gasoline production, increased exports, and buildup of stocks. Lead used in battery manufacture accounted for about 55% of total lead consumption. Lead requirements for antiknock compounds represented 16% of the total; pigments accounted for 7%; ammunition, 5%; miscellaneous and other unclassified uses, 4%; and other metal products, the remaining 13%.

The domestic supply of lead metal from all sources—primary and secondary production, imports for consumption, industry stock changes, and stockpile releases—totaled about 73,700 tons more than reported consumption and exports. The apparent excess supply in 1976 was attributed largely to unreported consumption, incomplete export data, and stock buildup, especially by small producers, consumers, and dealers that do not report to the Bureau of Mines.

LEAD PIGMENTS

Consumption of pig lead for manufacture of lead oxides, pigments, and compounds was 516,768 tons in 1976, an increase of 21,082 tons from the 1975 total. A small decline in use for manufacture of litharge, and white lead was more than offset by increased use for production of black oxide and red lead. The largest increase was in requirements for battery oxide, which rose to 374,761 tons in 1976, an increase of 7% from the 1975 total. Most of the litharge and black oxide produced went to battery manufacturers. Total shipments of litharge in 1976 were 122,462 tons, a gain of 1,987 tons from that reported in 1975. A decline in use for ceramics and rubber was offset by a sharp increase in demand for litharge by the paint industry. Shipments of white lead continued on the down trend with only 1,625 tons of domestic production shipped during the year.

Prices.—The published price for litharge as listed in the Chemical Marketing Reporter was 24 cents per pound in carload lots, ex-works, on January 1. During the week of January 5 the price softened and was quoted in a range of 23.75 to 24.00 cents per pound. The price for litharge remained at this level until mid-May, when it was increased to 24.25 to 26.25 cents per pound. The quotation remained firm until the week of October 11, when a price of 30.25 cents per pound was established which held through the remainder of the year. The quoted price for red lead (Pb_3O_4), 95%, carload lots at plant, followed a similar pattern, rising in several steps from 24 cents per pound in January to 31.25 to 32.5 cents per pound in October, where it remained firm through yearend. Basic carbonate of white lead advanced 6 cents per pound, from 32.5 cents in January to 38.5 cents per pound in October.

The total value of shipments for litharge and red and white lead in 1976 was $79.4 million, an increase of $20.0 million from the 1975 total. The average value per ton was $553.71 compared with $427.78 in 1975. The increase in value was attributed to higher pricing in all categories.

Foreign Trade.—Exports of pigment-grade lead oxides and compounds totaled 2,965 tons with a gross value of $2.1 million. Venezuela and Brazil accounted for 57% of the total shipments; the remainder was shipped to 32 other countries. Imports of lead pigments and compounds increased in 1976 to 17,836 tons with a total value of approximately $9.5 million. Litharge accounted for 77% of the tonnage with a value of almost $5.7 million. Mexico was the prime source of supply for litharge accounting for 99.9% of the total. Chrome yellow was second in volume at 2,747 tons; Canada and Japan supplied 73% and 25%, respectively, of the total chrome yellow, with a small quantity from West Germany. The remainder of pigments and compounds was received from a total of 11 countries.

STOCKS

Industry stocks of lead at producers and consumers plants dropped sharply during 1976 from a high level of 206,300 tons in March to a low of 151,800 tons in November. The closing inventory of 171,600 tons at yearend, including refined lead, lead in antimonial lead, and lead in alloys, was 19% less than in 1975.

The downtrend was virtually all reflected in primary producer stocks, which dropped to a low of 43,716 tons in December from a peak of 92,034 tons recorded in February. The decrease was primarily in holdings of refined pig lead, which declined 36,844 tons to a low of 39,869 tons at yearend. Lead in antimonial lead, base bullion, and ore and matte also contributed to the lower stock figures and collectively were 15,143 tons less than the comparable 1975 total. The largest drop in primary producer stocks, other than refined pig lead, was attributed to lead contained in ore and matte, which fell to 54,140 tons, a decline of 14,369 tons from that of 1975.

Consumer and secondary smelter stocks of lead in all forms declined slightly in 1976 to 129,610 tons, a drop of 3,705 tons from 1975. Increased stocks of refined soft lead, alloys, and lead in copper-base scrap were more than offset by a drop in antimonial lead to 34,106 tons, a reduction of 7,463 tons from that of 1975.

Scrap in the hands of all consumers rose about 7% to 101,670 tons. Reduced inventories of soft and hard lead were more than offset by gains in all other categories. The largest increase was in drosses and residues which rose by 4,889 tons to 36,737 tons.

Total stocks of lead in LME warehouses dropped about 19% to 76,058 tons during 1976. The decline from 94,467 tons in January was steady until the end of May when a short upturn through July indicated a slight recovery. However, from this minor peak in July there was a sharp drop to a low of 70,878 tons in late October. Slight gains in inventory continued into December when the stocks began to drop again ending the year on a definite downtrend.

PRICES

The U.S. producer price for common and corroding-grade pig lead as reported by Metals Week on a nationwide, delivered basis, was 19.0 cents per pound through March 9, 1976. Effective March 10, ASARCO raised its price to 20 cents per pound. Several other producers quoted a 2-cent increase to 22 cents per pound on the same day. On April 14, St. Joe Minerals raised its quotation by 2 cents, to a level of 23 cents per pound. St. Joe was quickly followed by all producers with the exception of ASARCO, which announced an increase of 1.5 cents to 22.50 cents per pound on April 15. The split price prevailed through May 13, when ASARCO declared an increase of 0.5 cent per pound, which established all producers at the 23-cent-per-pound level. During July there was a series of price changes, and on July 12, the producer price was established in a split range of 24.50 to 25.00 cents per pound, where it stayed until September 30. On September 30, St. Joe Minerals increased its lead price by 1 cent to 26 cents per pound. The other producers followed this move on October 2, resulting in a split price of 25.50 to 26.00 cents per pound which was maintained through the remainder of the year.

The cash bid price for lead on the LME during the first quarter ranged from 15.2 to 17.4 cents per pound in terms of U.S. currency. The average parity margin was 3.1 cents per pound for the period, indicating that foreign lead could be shipped competitively to the United States. However, in the period covering March through July the LME quotations rose more rapidly than the U.S. producer price and the margins narrowed accordingly. The low price during this period was 20.6 cents per pound and the high was 23.12 cents per pound with a corresponding average difference of 1.2 cents per pound. At this level the cost of freight, duty, brokerage, and profit would not permit the movement of foreign metal to the U.S. market. In August the traditional spread reappeared with the price at 21.8 cents per pound where it remained relatively unchanged through the remainder of the year. The average marginal parity for this 5-month period was about 3.9 cents per pound. The average annual price for lead on the LME in 1976 was 20.46 cents per pound (based on a monthly average Sterling exchange rate of 180.542 cents) compared with the 1975 price of 18.73 cents per pound (basis a Sterling exchange rate of 222.15 cents)

FOREIGN TRADE

Exports of lead metal, lead alloys, and lead in scrap materials in 1976 totaled 52,760 tons, 26% less than in 1975. Metal and alloy exports were reduced substantially but scrap exports at 46,883 tons were down only by 6% and continued to represent a significant outflow of lead. Canada received about 33% of the total exports of metal and scrap, Venezuela received 10%, Taiwan 9%, Mexico 8%, Brazil 7%, and about 32 nations divided the remainder. Shipments of lead and zinc concentrates continued to move overseas, but no statistical division between lead and zinc was available. The gross weight of concentrates was 148,787 tons valued at $28.9 million. Belgium and West Germany together received 59% of the shipments by weight.

Export of gasoline antiknock additives containing tetraethyl lead or tetramethyl lead was estimated to contain 28,000 tons of lead valued at $86.5 million based on trade data from the Bureau of the Census.

General imports of lead, comprising 148,266 tons of metal, 76,365 tons in ores and concentrates, and 4,413 tons in scrap, totaled 18% more than in 1975. Imports of ores and concentrates for consumption totaled 88,988 tons, almost twice those of 1975, reflecting increased withdrawal of material from bond. The principal source countries were Honduras, Peru, Australia, Mexico, and Canada. Imports for consumption of metal were 45% over those of 1975 reversing the declining trend of previous years. Source countries for metal imports were Canada 33%, Mexico 32%, Yugoslavia 14%, Peru 14%, Australia 1% and others 6%.

Basic tariff rates remained unchanged in 1976 at 0.75 cent per pound of lead in ore and concentrates and 1.0625 cents per pound on bullion, metal and dross for most favored nations. The statutory rate of 2.125 cents per pound for other nations remained in effect during 1976.

WORLD REVIEW

World mine production of lead in 1976 declined for the third year to 3.70 million tons, about 1% down from production in 1975. Smelter production, on the other hand, increased by 4% to 3.79 million tons and refined lead consumption reported by the World Bureau of Metal Statistics rose by 9% to 4.69 million tons.

Mine production in 1976 by market economy countries totaled 2.68 million tons, 3% less than in 1975. Smelter production in market economy countries, limited to primary metal where information was available, was 2.73 million tons, a 3% gain over that of 1975. The mine production of centrally planned economy countries, except Yugoslavia, was estimated at 1.02 million tons and smelter production at 1.06 million tons with a small part of the assigned smelter production coming from secondary sources. These estimates indicated a slight increase, less than 1%, from those of 1975.

The United States was the leading country in lead mine production and accounted for 16% of the world total. Other countries producing significant percentages of the total were the U.S.S.R. 14%, Australia 12%, Canada 8%, Mexico 6%, Peru 5%, Yugoslavia 4%, North Korea 4%, Bulgaria 3%, and the People's Republic of China 3%. The United States was also the leading producer of refined lead followed in order by the U.S.S.R., Australia, Japan, Mexico, Canada, France, Yugoslavia, Bulgaria, Belgium, West Germany, and the People's Republic of China. The smelter outputs assigned to Bulgaria, France, and Yugoslavia may include recovery from secondary sources.

Total world consumption of refined lead in 1976 was reported by the World Bureau of Metal Statistics as 4.7 million tons, 9% more than in 1975. This total includes some secondary lead, but excludes remelted pig lead and remelted antimonial lead. If all secondary metal consumption were included, the world total would be in the range of 5.3 to 5.5 million tons. The United States was the leading consuming country using 1.5 million tons and accounting for 27% of the total.

Australia.—Mine production of lead, 439,000 tons in 1976, was 2% less than in 1975. Australia retained its position as the third ranking source of lead in ores and concentrates. The combined production of refined lead and lead bullion, 378,000 tons, was 10% over that of 1975 making Australia third in lead metal production.

The lead dumping case against Australian and Canadian lead producers, started in 1973, was reviewed by the U.S. International Trade Commission early in 1976. In April, the Commission found in favor of the foreign producers with a ruling that allowed them to make less than fair value sales as long as there is no injury to domestic industry. This encouraged refined lead imports from Australia to increase from none in 1975 to 6,123 tons in 1976.

Australian Mining and Smelting Ltd., St. Joe Minerals Corp., and Phelps Dodge Corp. reached an agreement for the development of a zinc-lead-copper deposit in the Woodlawn area of New South Wales. Drilling indicated 10 million tons of ore averaging 9% zinc, 3.5% lead, 1.8% copper, and 56 grams of silver per ton of ore.

North Broken Hill Ltd. continued to prospect a possible extension of its orebody and diamond drill holes showed encouraging results.

Bolivia.—The three mine groups in Bolivia, Corporación Minera de Bolivia (COMIBOL), the medium miners, and the small miners, combined to produce for export over 18,000 tons of lead in concentrate in 1976. COMIBOL was the main producer with 68% of the total production mainly from the Tatasi and Telemayu mines. Plans to construct a lead-silver smelter were advanced with the intention of asking for supplier bids in 1977. The project was to cost $110 million with an estimated capacity of 24,000 tons of lead per year and was to be located near Potosi in southern Bolivia.

Canada.—Mine production of lead, as recoverable content of ores, was 283,000 short tons in 1976, a reduction of 25% from 1975 production and the lowest level of lead mined in 12 years. Production of primary refined lead was 193,000 tons, a 2% increase from output in 1975. Production of secondary lead was about 37,000 tons, slightly more than in 1975.

Lead in Canada was mined as a byproduct or coproduct of zinc, copper, or silver, and production was depressed as the output of zinc and copper was scaled down to suit market conditions. Canadian consumption in 1976 was estimated to be 69,000 tons of primary and 39,000 tons of secondary lead, an increase of 10% from 1975.

Exploration continued in Canada on several base metal deposits containing byproduct or coproduct lead. In New Brunswick, Canex Placer Ltd. was developing its Restigouche and Murray-Brook properties, Anaconda Canada, Ltd., continued feasibility studies on the Caribon property, and Texasgulf Inc. continued diamond drilling at Half Mile Lake, but the exploration shaft was deferred because of poor metallurgical test results. In Yukon Territory, development work continued on the Grum deposit with Kerr Addison Mines Ltd. and Canadian Natural Resources Ltd. concluding a feasibility study looking toward a decision on the next step in 1977. Canex Placer Ltd. had a joint project with United States Steel Corp. drilling the Howards Pass deposit, and Hudson Bay Mining and Smelting Co. Ltd. was exploring and drilling the Tom deposit through an adit. Vangorda Mines Ltd. at Vangorda Creek conducted a feasibility study which indicated that production would probably depend on development of the nearby Grum deposit. In the Northwest Territories, Cominco Ltd. completed its underground work and feasibility study at Arvik on Little Cornwallis Island and future production was to depend on the results of negotiations with the Federal Government. Texasgulf Inc. continued work at Izok Lake, 225 miles north of Yellowknife, with drilling on three separate zones indicating over 12 million tons of ore grading 13.77% zinc, 2.8% copper, and 1.4% lead.

Mine production of lead (recoverable content) came from eight provinces and territories, the four major sources being British Columbia—98,000 tons, New Brunswick—68,000 tons, Northwest Territories—60,000 tons, and Yukon—42,000 tons. Major mine producers of lead in concentrate were Cominco's Sullivan mine in British Columbia—85,000 tons, Cominco's Pine Point mines in Northwest Territories—60,000 tons, Brunswick Mining and Smelting Corp. Ltd. Bathurst mines in New Brunswick—40,700 tons, and Cyprus Anvil Mining Corp. mine at Faro, Yukon—36,500 tons.

Metal production came from two smelters. The Cominco smelter at Trail, British Columbia produced 142,000 tons and the Brunswick Mining and Smelting Corp. plant at Belledune, New Brunswick, produced 51,400 tons of lead. Brunswick is a subsidiary of Noranda Mines, Ltd.

Greenland.—The Black Angel mine in west Greenland was operated by Greenex AG, a subsidiary of Vestgron Mines Ltd., and produced 157,000 tons of zinc concentrate and 42,000 tons of lead concentrate from 663,000 tons of ore assaying 14.7% zinc and 5.2% lead. Cominco Ltd. holds a 61.5% interest and Northgate Exploration Ltd. a 9.6% interest in Vestgron.

Ireland.—Tara Exploration and Development Co. Ltd. at Navan, County Meath, planned to begin production of zinc and lead concentrates early in 1977. Tara is owned in part by a consortium of mining companies: Noranda Mines Ltd. 19.93%; Cominco, Ltd. 17.43%; Charter Consolidated Ltd. 10.75%; Northgate Exploration Ltd. 9.9%; and the remaining interest is held by the Irish Government and other private investors. The mine was expected to produce about 500,000 tons of concentrates per year in the ratio of 5 parts of zinc to 1 part lead.

Bula Ltd., controlling the northern part of the deposit at Navan, planned to begin construction of its separate concentrator in 1977. The Tynagh lead-zinc-silver mine in County Galway, owned by Irish Base Metals Ltd., continued production of concentrates in 1976. A total of 27,000 tons of lead concentrate and 26,000 tons of zinc concentrate were shipped to European smelters. Kerr Addison Mines Ltd. acquired a 75% interest in the Silvermines property in County Tipperary (formerly Mogul of Ireland Ltd.) in March 1976. The Mogul or Silvermines mine produced zinc and lead concentrates containing 54,760 tons of zinc and 14,870 tons of lead (metal content).

The total lead production in Ireland in 1976 was estimated to be 35,000 tons.

Japan.—Production of refined lead increased by 13% to over 241,000 tons in 1976 as better demand developed from the automobile and construction industries. A strike at Cyprus Anvil Mining Corp. in Yukon, Canada, forced Toho Zinc Co. Ltd. to purchase metal and concentrates elsewhere to keep its lead plant operating. The domestic mine production of Japan was about 57,000 tons of lead in concentrates, one-fourth of total metal requirements. The Ministry of International Trade and Industry (MITI) planned to begin a stockpile of nonferrous metals including lead. The objective for lead was 9,900 tons but no purchases were scheduled for 1976. Japan, often an exporter of lead, imported 35,000 tons in 1976 against exports of 9,500 tons.

Mexico.—Regulations fulfilling the Mining Law of 1975 were issued in November 1976. A compromise was reached in negotiations between the Government and Camara Minera de Mexico (CMM) representing the private mining firms in Mexico. If these regulations were strictly enforced, Government ownership or participation in mining enterprises would increase, entry of foreign capital would be permitted only on a minority basis, and expansion by private enterprises could be limited.

During 1976, Industrias Peñoles S. A. announced plans to market about 40% of its refined lead production in the United States. The new silver-lead refinery at Torreon was completed in January but startup problems prevented normal production until late in the year.

Industrial Minera Mexico S.A. (IMM) completed the modernization of three of its major mines increasing its capacity to produce lead-zinc ores. During 1976 it produced 96,800 tons of lead metal from the smelter in Chihuahua and refinery in Monterrey.

Until recently Mexico was a source of lead concentrates and flue dusts imported into the United States, but in 1975 and 1976 practically none appeared in general imports. On the other hand, lead imported in pigs and bars was 44,290 tons in 1976, a 49% increase over imports in 1975 representing 21% of Mexico's total lead metal production in 1976.

South Africa, Republic of.—The Republic of South Africa produced only a few thousand tons of lead concentrate from the Prieska mine in 1976. However, exploration at the Broken Hill and Black Mountain holdings of the Phelps Dodge Corp. near Aggeneys in northwest Cape Province disclosed ore reserves that could make South Africa a substantial lead producer. Reports indicated that Broken Hill reserves were over 79 million tons of ore averaging 0.38% copper, 4.28% lead, 2.32% zinc, and 1.7 ounces of silver per ton; Black Mountain contained 30 million tons averaging 0.60% copper, 2.30% lead, 0.5% zinc, and 0.73 ounce of silver per ton. Most of this tonnage is amenable to open pit mining. A feasibility study indicated that the project could produce 145,000 tons per year of lead concentrates within 3 or 4 years if transportation and water supply facilities can be arranged.

Yugoslavia.—Exploration for new mines and expansion of existing lead-zinc mines was planned as part of a program designed to double 1975 production of lead raw materials by 1980. The aim of the program was to eliminate the need for imports of concentrates to keep Yugoslavian smelters producing at capacity. A new lead mine was brought into production late in 1976 and expansion continued at three other mine-mill units. During 1976 about 18 mines and 14 flotation plants were producing. Two lead smelters, one lead refinery, and one lead-zinc Imperial smelting furnace were in operation. Exports of lead from Yugoslavia to the United States totaled 19,944 tons, 16% of Yugoslavia's total refined lead production. Trepca was the largest lead-zinc producing entity, operating the Stari Trg mine and lead smelter and refinery at Zvecan.

TECHNOLOGY

Much of recent technological progress with respect to lead was related to the solution of environmental problems including control of toxic emissions from smelters and the treatment of solid and liquid wastes from mines and mills, foundries, and lead fabricating plants to reduce or eliminate health hazards.

The Bureau of Mines began to evaluate the economic feasibility of its newly developed hydrometallurgical process for extracting lead, zinc, and associated metals from sulfide mineral concentrates in a continuous pilot plant operation. The process, which uses a ferric chloride-brine leach and fused-salt electrolysis procedure to recover lead from galena concentrates, produces metallic lead without generating sulfur oxides and minimizes the emission of lead vapors.

Several direct smelting processes for treating lead concentrate to produce metallic lead and slag have been developed in recent years to the pilot plant stage. These processes offer several potential advantages over blast furnace smelting by eliminating the sintering operation, reducing fuel requirements due to the use of exothermic heat of smelting reactions, and producing a richer SO_2 gas than is obtainable with sintering. One of these processes, the Q-S process being tested by St. Joe Minerals, is based on autogenous flash oxidation of the lead concentrate followed by submerged oxygen injection into the bath in a long reactor vessel. Lead is recovered as PbS, which redissolves in the bullion under the slag. The process produces bullion and SO_2 in such concentrations that air pollution can be minimized. In a further development of the Q-S process by Lurgi GmbH, designated the QSL lead recovery process, pelletized concentrates are continuously charged into a reactor in which injected oxygen produces rapid melting due to intense oxidation. Lead metal is recovered with a slag low in lead for rejection to waste. Reported advantages of the process include lower capital investment, less unit equipment and lower operating costs compared with conventional processes.[12]

The Kivcet-CS process for treating lead sulfide concentrate, developed to industrial scale in the U.S.S.R., combined the functions of sintering, blast furnacing and slag fuming in one autogenous smelting operation. The process is reportedly characterized by high metal recoveries, low environmental contamination, and low labor and capital costs compared with a conventional smelter.[13]

A flash agglomeration method of treating flue dust produced in smelting scrap automobile batteries developed by Paul Bergsoe and Son Co., Denmark, reduces airborne emissions of sulfur and lead particulates to allowable limits. By a closed conveyor, flue dust from the baghouse hopper is transported directly into a flash agglomeration furnace, forming a molten slag which is tapped from the furnace and allowed to solidify. The agglomerated material is recycled to the smelter furnace with no flue dust leaving the system, thus minimizing health hazards associated with toxic substances contained in the dust.[14]

Significant progress was made in developing lighter weight, more efficient lead-acid batteries in an effort to improve the power-to-weight ratio and expand the market for these batteries in the field of transportation. Notable advances were made toward increasing the oxide-to-metal ratio and improving grid patterns. New grid alloys were developed through research that give promise for use in longer life maintenance-free batteries. Some of the newer alloys contain such elements as strontium and cadmium in addition to those that contain calcium, tin, and antimony.[15]

Hecla Mining Co. in cooperation with the Bureau of Mines developed a technique of destressing blasting to reduce rock bursts in the Star mine. The combination of mining depth, rugged surface terrain, and geological conditions has imposed high residual horizontal stress in the rocks which, influenced by mine openings and rock composition, creates a favorable environment for rock bursts. Guided by seismic monitoring the destressing blasting consists of drilling long holes into vein walls and blasting to relieve stress on walls ahead of stoping.[16]

Table 6.—Refined lead produced at primary refineries in the United States, by source material

(Short tons)

	1972	1973	1974	1975	1976
Refined lead:[1]					
From primary sources:					
Domestic ores and base bullion	577,398	567,256	580,078	530,215	568,536
Foreign ores and base bullion	103,001	107,260	92,946	105,907	84,341
Total	680,399	674,516	673,024	636,122	652,877
From secondary sources	1,189	--	--	--	29
Grand total	681,588	674,516	673,024	636,122	652,906
Calculated value of primary refined lead (thousands)[2]	$204,528	$219,757	$303,265	$273,914	$301,643

[1]GSA metal is not included in refined lead production.
[2]Value based on average quoted price and excludes value of refined lead produced from scrap at primary refineries.

Table 7.—Antimonial lead produced at primary lead refineries in the United States

Year	Production (short tons)	Antimony content		Lead content by difference (short tons)			
		Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total
1972	15,051	1,050	7.0	6,136	2,049	5,816	14,001
1973	15,455	1,167	7.5	9,020	4,203	1,065	14,288

Table 10.—Secondary lead recovered in the United States

(Short tons)

	1972	1973	1974	1975	1976
As metal:					
At primary plants	1,189	--	--	--	29
At other plants	172,168	186,124	238,216	271,297	310,981
Total	173,357	186,124	238,216	271,297	311,010
In antimonial lead:					
At primary plants	5,816	1,065	1,549	3,337	1,371
At other plants	340,066	374,713	369,954	311,783	340,596
Total	345,882	375,778	371,503	315,120	341,967
In other alloys	97,358	92,384	88,979	72,039	73,592
Grand total:					
Quantity	616,597	654,286	698,698	658,456	726,569
Value (thousands)	$185,349	$213,166	$314,833	$283,531	$335,675

Table 11.—Lead recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1975	1976	Form of recovery	1975	1976
New scrap:			As soft lead:		
Lead-base	90,712	100,750	At primary plants	--	29
Copper-base	3,252	3,420	At other plants	271,297	311,010
Tin-base	250	165	Total	271,297	311,039
Total	94,214	104,335			
Old scrap:					
Battery-lead plates	417,489	461,391	In antimonial lead[1]	315,120	341,967
All other lead-base	136,280	148,981	In other lead alloys	58,485	59,502
Copper-base	10,471	11,860	In copper-base alloys	13,523	14,025
			In tin-base alloys	31	36
Tin-base	2	2	Total	387,159	415,530
Total	564,242	622,234	Grand total	658,456	726,569
Grand total	658,456	726,569			

[1]Includes 3,337 tons of lead recovered in antimonial lead from secondary sources at primary plants in 1975 and 1,371 in 1976.

Table 12.—Lead consumption in the United States, by product

(Short tons)

Product	1975	1976	Product	1975	1976
Metal products:			Pigments—Continued:		
Ammunition	75,081	73,478	Pigment colors	10,618	16,634
Bearing metals	12,184	13,063	Other[1]	499	561
Brass and bronze	13,404	15,660	Total	79,072	105,591
Cable covering	22,099	15,930	Chemicals:		
Calking lead	14,296	12,475	Gasoline antiknock additives	208,605	239,758
Casting metals	7,711	6,708	Miscellaneous chemicals	181	146
Collapsible tubes	2,216	2,329	Total	208,786	239,904
Foil	3,205	5,126	Miscellaneous uses:		
Pipes, traps, bends	14,233	13,789	Annealing	2,629	2,893
Sheet lead	24,859	24,438	Galvanizing	1,228	1,252
Solder	57,344	63,324	Lead plating	376	386
Storage batteries:					
Battery grids, posts, etc	326,714	383,844	Weights and ballast	20,018	22,366
Battery oxides	372,700	438,560	Total	24,251	26,897
Terne metal	1,511	1,595	Other, unclassified uses	21,221	32,354
Type metal	16,211	15,007	Grand total[2]	1,297,098	1,490,072
Total	963,768	1,085,326			
Pigments:					
White lead	2,498	2,993			
Red lead and litharge	65,457	85,403			

[1]Includes lead content of leaded zinc oxide and other pigments

[2]Includes lead that went directly from scrap to fabricated products.

Table 13.—Lead consumption in the United States, by month

(Short tons)

Month	1975	1976	Month	1975	1976
January	105,091	116,253	August	115,510	120,656
February	98,866	123,270	September	122,985	127,399
March	99,216	136,065	October	133,696	137,447
April	105,105	125,735	November	115,757	128,009
May	102,255	123,381	December	115,323	125,152
June	94,700	123,335	Total[1]	1,297,098	1,490,072
July	88,594	103,370			

[1]Includes lead that went directly from scrap to fabricated products and lead contained in leaded zinc oxide and other pigments.

Table 14.—Lead consumption in the United States in 1976, by class of product and type of material

(Short tons)

Product	Soft lead	Lead in antimonial lead	Lead in alloys	Lead in copper-base scrap	Total
Metal products	151,652	51,887	47,796	11,587	262,922

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Uganda and Egypt may produce lead, but available information is inadequate to make reliable estimates.

[2]Recoverable metal content of lead in concentrates for export plus lead content of domestic products (refined lead, antimonial lead, mixed bars, and other unspecified items).

[3]Recoverable metal.

[4]Production by COMIBOL plus exports by medium, small, and other mines.

[5]Recoverable metal; content of lead in concentrates for exports plus lead content of domestic smelter products (refined lead, antimonial lead, and bismuth-lead bars).

[6]May include small quantities of zinc.

[7]Data compiled from operating company reports of Tsumeb Corp. Ltd., South West Africa Co. Ltd., and South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[8]Content of concentrates.

[2]Includes recovery from secondary materials.
[3]Refined from domestic and foreign ores; excludes lead from imported base bullion.
[4]Includes primary lead content of antimonial lead.
[5]Primary smelter lead plus lead content of all antimonial lead. (May include some secondary lead in antimonial lead.)
[6]Lead bullion from imported ores and concentrates.

Lime

By J. W. Pressler[1]

Lime output in 1976, including that for Puerto Rico, increased 6% to 20.3 million tons. Total value established a new annual record, increasing 16% to $612 million.

Output of most types of lime increased. Agricultural lime was up 40%, refractory dolomite 10%, and chemical and industrial lime 6%; construction lime remained the same.

DOMESTIC PRODUCTION

Lime producers sold or used 20.3 million tons, compared with 19.2 million tons in 1975. Sales of lime increased 9% to 14.1 million tons. Captive lime used by producers declined 1% to 6.2 million tons.

Output of quicklime increased 7% to 17.9 million tons. Production of hydrated lime decreased 2% to 2.3 million tons. Output of dead-burned dolomite increased 10% but was 58% below the 1956 record high level.

Six States—Ohio, Pennsylvania, Missouri, Michigan, Texas, and Alabama—accounted for 57% of the total output. Production increased 9% in Ohio, 8% in Missouri, 7% in Pennsylvania, and 2% in Michigan and Alabama, but decreased 16% in Texas.

Leading producing companies were Marblehead Lime Co. with two plants in Illinois and one each in Indiana, Michigan, Pennsylvania, and Utah; Mississippi Lime Co. in Missouri; Bethlehem Steel Corp. with two plants in Pennsylvania and one in New York; Martin Marietta Corp.'s Chemical Div. in Alabama and Ohio; Allied Chemical Corp. in New York; The Flintkote Co. with two plants in California, two in Nevada, and one each in Arizona, Utah, and Virginia; Allied Products Co. with two plants in Alabama; Pfizer, Inc. in California, Connecticut, Massachusetts, and Ohio; United States Gypsum Co. in Louisiana, Ohio, and

[1]Physical scientist, Division of Nonmetallic Minerals.

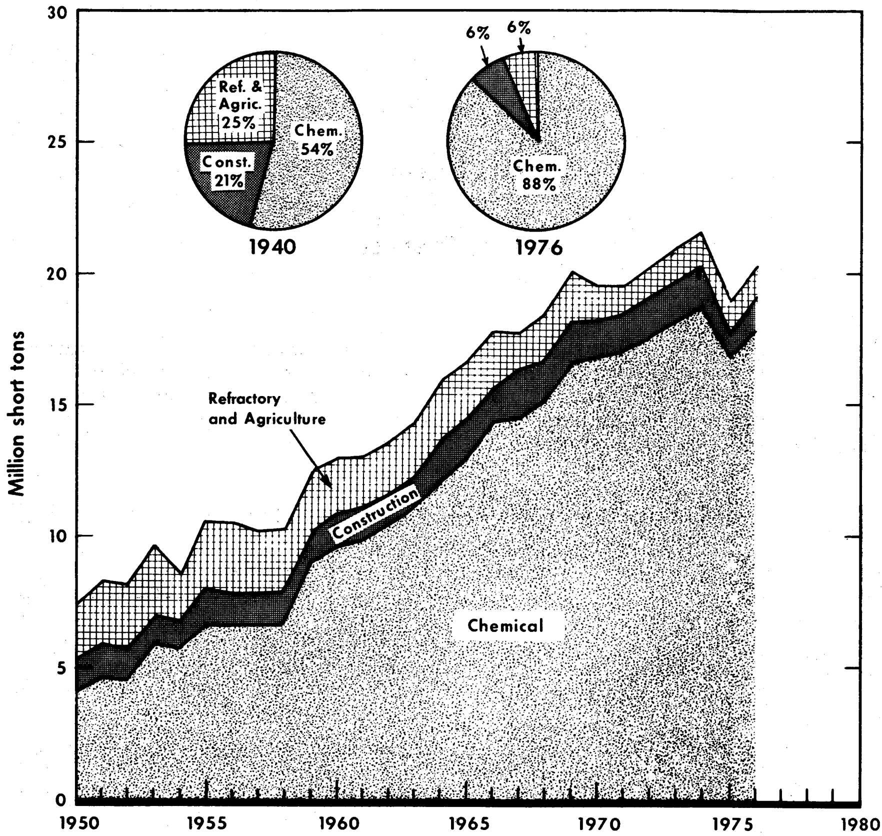

Figure 1.—Trends in major uses of lime.

Texas; and Diamond Shamrock Corp. in Ohio. These 10 companies, operating 30 plants, accounted for 43% of the total lime production.

The eight largest lime plants, each producing more than 400,000 tons, accounted for 26% of the total lime output. Thirty-four plants produced more than 200,000 tons and accounted for 64% of the total.

Leading individual plants were Mississippi Lime's Ste. Genevieve plant, Marblehead's Buffington plant, Allied Chemical's Syracuse plant, Martin Marietta's Woodville plant, and Bethlehem's Annville plant.

A total of 532 kilns were operational during the year: 310 vertical kilns; 170 rotary kilns; 25 pot kilns (primitive vertical); 15 "Calcimatic" traveling hearth kilns; 6 fluidized bed kilns; 4 "Ellernan" kilns; and 2 traveling-grate rotary kilns.

In 1976, the number of lime plants in the United States decreased from 172 to 164, but the average output per plant increased from 111,400 to 123,500 tons per year. Nine lime plants were closed and reported no production in 1976: The Carley L. Moore plant in Globe, Ariz.; the Great Western Sugar Co. plant in Eaton, Colo.; the Olin Corp. plant in Lake Charles, La.; the Allied Chemical Corp. plant in Baton Rouge, La.; the Pacific Carbide & Alloys Co. plant in Portland, Oreg.; the Tennessee Lime Co. plant in Knoxville, Tenn.; the Round Rock Lime Co. plant in Dolomite (Williamson County), Tex.; the Mountain States Lime, Inc., plant in Provo, Utah; and the Jones & Laughlin Steel Corp. plant in Martinsburg, W. Va. One rehabilitated plant started up in 1976—Limestone Products Corp.'s Limecrest plant in Sussex County, N.J.

W Withheld to avoid disclosing individual company confidential data; included in "Other States."
[1]Excludes regenerated lime. Includes Puerto Rico.
[2]Data may not add to totals shown because of independent rounding.
[3]Less than 1/2 unit.
[4]Includes data for 35 lime plants, as follows: 4 each in Idaho and Nebraska; 3 each in Illinois, Nevada, Washington, and Wyoming; 2 each in Indiana, New York, New Mexico, and North Dakota; West Virginia (2 in 1975 and 1 in 1976); 1 each in Iowa, Kansas, Kentucky, Oklahoma, and South Dakota; and New Jersey (1 in 1976). Also includes States indicated by symbol W and exports.

Riverton Corp., headquartered at Riverton, Va., acquired the assets of Jones & Laughlin Steel Corp.'s Blair Division. Located at Riverton, W. Va., the Blair facilities manufactured lime, limestone products, construction aggregates, and ballast. The 108-year-old Riverton firm was a pioneer in developing colored cements. Its rapidly expanding stone division now produces from five quarries.[2]

New plants and expansions.—Western Lime & Cement Co. purchased a 10- by 150-foot rotary kiln and ancillary equipment from Louisville Cement Co. and installed it in its Green Bay, Wis., lime plant. The gas-, oil-, or coal-fired kiln with preheater had a 200-ton-per-day lime capacity and doubled the plant capacity to 400 tons per day.

Dravo Corp.'s new $60 million underground limestone mine and three 1,000-ton-per-day preheater lime kilns at Maysville, Ky., went into test operation and debugging in late 1976. At yearend, its "Thiosorbic" specialty lime output was already 75% sold to utilities in Pennsylvania and Ohio under long-term contracts for use as scrubber lime.

The Flintkote Co.'s U.S. Lime Division in Nelson, Ariz., placed into production in 1974 its new 800-ton-per-day preheater lime plant. Construction was initiated in 1976 for a second, larger lime kiln with a production capacity of 1,000 tons per day, reportedly to be operational by mid-1978.

Black River Mining Co., located at Carntown, Ky., a joint venture of Armco Steel Corp. and Jones & Laughlin Steel Corp., placed into operation in mid-1976 a third lime kiln, doubling the plant's production capacity to 2,000 tons per day. The new Allis-Chalmers 13-1/2- by 14-1/2- by 400-foot rotary kiln reportedly is the largest rotary lime kiln in the United States.

The S. I. Lime Co., a subsidiary of Southern Industries Corp., installed a third kiln at its Saginaw plant near Birmingham, Ala., doubling its capacity to 1,000 tons per day. A lime distribution terminal was also opened at Tampa, Fla.

Chemical Lime, Inc., initiated construction at midyear for the installation of a 10-1/2- by 340-foot Allis-Chalmers rotary kiln and auxiliary equipment. Production will be increased from the present 350 tons per day to 750 tons per day. The kiln will burn a blend of Texas lignite coal and natural gas and will be operational at yearend 1978.

Energy.—The lime industry in 1976 made some progress in its utilization of energy with the addition of preheaters to kilns and by improvements in internal agitation in the kilns; these changes resulted in a 3.3% improvement in energy consumption compared with the base year of 1972. British thermal unit (Btu) consumption per ton of lime produced in 1976 was 7.79 million, compared with 8.06 million in 1975.

As reported by the National Lime Association, the fuel sources for the lime industry in 1976 were as follows: Coal and coke, 50.7%; natural gas, 40.7%; oil (No. 2 and No. 6), 7.0%; and electricity, 1.6%. Compared with the base year of 1972, significant improvements were made in 1976 with a 24% reduction in the use of scarce natural gas and an 80% increase in the use of coal and coke.[3]

[2]Data do not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Lime was consumed in every State. Leading consuming States were Ohio, Pennsylvania, Michigan, Indiana, Texas, New York, and Illinois, each of which consumed more than 1 million tons. These seven States accounted for 62% of the total lime consumed.

Leading quicklime-consuming States were Ohio, Pennsylvania, Michigan, Indiana, and New York, each of which consumed more than 1 million tons. These five States accounted for 53% of the total quicklime consumed.

Leading hydrate-consuming States were Texas, Pennsylvania, Louisiana, Ohio, and Illinois, each of which consumed more than 100,000 tons. These five States accounted for 53% of the total hydrate consumed.

Lime sold by producers was used for chemicals, 88%; construction, 6%; refractories, 5%; and agriculture, 1%. Captive lime used by producers was 31% of the total, compared with 33% in 1975. Captive lime was used mainly for alkalies, 33%; basic oxygen steel furnaces (BOF's), 26%; and sugar refining, 15%.

Leading individual uses were BOF's, alkalies, water purification, paper and pulp, refractories, and sugar refining, which together accounted for 69% of the total consumption.

Of the main chemical and industrial uses, lime for BOF's was produced principally in Ohio (26%), Indiana (15%), Pennsylvania (14%), and Illinois (10%). Lime for alkalies was produced mainly in Michigan, New York, Ohio, and Texas. Lime for water purification was produced mainly in Missouri (28%), Pennsylvania (17%), Texas (7%), and Alabama (7%). Lime used for paper and pulp, excluding regenerated lime, was produced mainly in Alabama (30%), Texas (14%), Wisconsin (10%), and Tennessee (5%). Lime for refining sugar was produced mainly in California (23%), Idaho (12%), and Colorado (9%).

Mason's lime was produced in 35 plants in 17 States, including Puerto Rico. Some of the leading States were Wisconsin with five plants (20%), Pennsylvania with four plants (18%), and Ohio with four plants (10%). Finishing lime was produced in 12 States in 17 plants, including Puerto Rico. The leading State was Ohio with four plants (60%).

The use of lime in agriculture has decreased from 250,000 tons per year in 1956 to 140,000 tons per year in 1976, indicating a negative annual growth rate of about 4.5%. The high cost of energy-intensive lime, compared with that of pulverized limestone for controlling the adverse acid condition of soil, and the attainment of maximum fertilizer utilization have diverted farmers to the use of the cheaper commodity, even though its reactivity response is considerably less. During the same period, the use of crushed and pulverized limestone in agriculture has increased from 20 million tons per year in 1956 to about 39 million tons per year in 1976, a growth rate of 2.0% per year.

The growth rate of 2.0% in the use of agricultural limestone is similar to that of total plant nutrients in fertilizers used, and also to the growth in the harvested crop acreage. Inadequate lime usage in agriculture is one of the most important factors limiting more efficient crop production throughout much of the country. Undoubtedly, a major reason why farmers fall so far short of using the needed lime is the nature of the crop response obtained. Whereas crop response to fertilizers is rapid, the response to lime applications is much slower. It is frequently unnoticed until at least 1 year after application, especially when pulverized limestone is used. Although the effects of a single application of lime may last several years, many farmers do not recognize this and are not willing to wait for the returns on their investments.[4]

PRICES

The average value of lime sold or used by producers in 1976 was $30.19 per ton, an increase of 10% over the 1975 price of $27.46 and an increase of 73% over the 1973 price of $17.42.

Values ranged from $29.56 for chemical and industrial lime to $33.12 for construction lime, $36.82 for refractory dolomite, and $34.99 for lime used in agriculture.

Values for quicklime sold ranged from $29.14 for chemical lime to $33.53 for construction lime, $33.52 for lime used in agriculture, and $36.85 for dead-burned dolomite, and averaged $29.82, an increase of 6% over the 1975 value.

Values for hydrated lime ranged from $33.13 for construction lime to $34.84 for chemical lime and $36.53 for lime used in agriculture, and averaged $34.02, an increase of 15% over the 1975 price.

FOREIGN TRADE

Exports of lime increased 4% to 55,900 tons but were 19% below the 1968 record. Of the total exports, Canada received 87%, and Mexico and Panama received 3% each. The remaining 7% went to 36 countries, listed in order of shipments as follows: Guyana, United Arab Emirates, Bahamas, Bermuda, El Salvador, New Zealand, Philippines, Honduras, the United Kingdom, Venezuela, Saudi Arabia, Bahrain, Spain, Egypt, West Germany, Surinam, Australia, Brazil, Gabon, Colombia, Argentina, the Pacific Trust Islands, Netherlands Antilles, Peru, Jamaica, Japan, Iraq, the French Pacific Islands, Belize, Haiti, the Netherlands, Nicaragua, Guatemala, Iran, the Republic of South Africa, and Italy.

Imports of lime increased 41% to 364,900 tons. Imports were mainly from Canada.

Table 6.—U.S. exports of lime

Year	Quantity (short tons)	Value (thousands)
1974	31,639	$1,516
1975	53,853	2,746
1976	55,852	2,981

WORLD REVIEW

Lime is produced all over the world, mainly in the heavily industrialized nations. Source materials are adequate. The United States, with 17% of the total, ranks second in world production.

Canada.—During 1976, 18 companies operated 24 lime plants in Canada: 10 in Ontario, 4 in Quebec, 4 in Alberta, 3 in Manitoba, 2 in British Columbia, and 1 in New Brunswick. Of the 85 kilns in operation, 54 were vertical, 27 were rotary, 3 were rotary grate, and 1 was vibratory grate. Total lime output was 2.0 million tons, of which 341,000 tons, with a customs-declared value of $29.42 per ton, was exported to the United States.

China, People's Republic of.—Imperial Krauss Maffei Industrieanlagen GmbH (Munich, West Germany) will supply a lime plant to the People's Republic of China. The 600-ton-per-day facility, to be erected near Wuhan, will produce a highly reactive lime for the Chinese steel industry.[5]

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Lime is produced in many other countries besides those listed. Mexico, Venezuela and the United Kingdom are among the more important countries for which official data are unavailable.
[2]Less than 1/2 unit.
[3]Hydraulic lime.
[4]Excludes output by small producers.
[5]Revised to zero.
[6]Year ending June 30 of that stated.

Germany, West.—Brisk demand in 1976 for one-family and multifamily houses led to a 16% increase in sales of lime in West Germany.[6]

New Zealand.—In spite of reduced demand for cement in 1976, New Zealand Cement Holdings Ltd. reported increased sales of lime, mainly owing to an increase in agricultural lime demand, with an expansion to 134,000 tons in 1976 compared with 97,000 tons in 1975.[7]

Qatar.—Newell Dunford Engineering (London, England) was awarded a $4 million contract to supply a complete lime calcination plant to Qatar. The plant will be built at Umm Bab for the Qatar National Cement Co.[8]

South Africa, Republic of.—Union Lime Co. Ltd. of Ulco commissioned a lime plant in April 1976 at Danielskuil, Ouplaas Farm. F. L. Smidth & Co., Ltd. supplied two 12-1/2- by 466-foot rotary kilns. The cost of the total project—quarry, crushing plant, two kiln plants, unloading plant, and infrastructure—will amount to $28 million. The new plant had a capacity of 1,400 tons per day and, combined with the original 11-vertical-kiln plant, increased the company's quicklime capacity to 840,000 tons per year. Union Lime now has a 35% share of the total South African burned-lime market.[9]

Switzerland.—Although the market for hydraulic lime in Switzerland showed a slight overall decline, Cement- und Kalkfabrik Unterterzen AG reportedly increased sales 12% to 10,100 tons by the takeover of deliveries from Cement- und Kalkwerk Liesberg AG's lime plant, which had suspended production.[10] At the Cementfabrik Holderbank plant in Holderbank, the Lime Division increased its sales of hydraulic lime 16% to 14,400 tons.[11]

United Arab Emirates.—Holderbank Management and Consulting Ltd., Engineering Division, reportedly received a contract for a new lime plant at Al-Ain in the Emirate of Abu Dhabi.[12]

TECHNOLOGY

The installation of preheaters on two 11- by 10- by 314-foot rotary lime kilns lowered fuel consumption and increased production at the Woodville, Ohio, plant of Martin Marietta Corp. An overall fuel saving of 1.5 million Btu per ton of lime produced and an increased production of 98,000 tons per year of lime from the two kilns were realized.[13]

Although a preheater lime kiln gives excellent fuel economy and greater throughput, a long rotary kiln without preheater is sometimes preferable because it produces a lower sulfur product, can handle smaller stone sizes, can treat stone that becomes soft when semicalcined, and is simpler to operate than a preheater. If a long lime kiln is fitted with all of the heat-exchanging internal equipment possible, it can still achieve excellent fuel economy, and the extra capital cost can be justified by the money saved in fuel.[14]

Excessive particulates emitted from most lime-producing kilns require expensive dry collection systems, as well as efficient wet scrubbing systems. Corrosion of parts and material buildup with subsequent loss of production can result unless operating variables are closely controlled. High water-to-gas ratios, saturation of inlet gas, neutralization of recycled slurry water and of pipeline slurries, and an extended humidification zone in the gaseous phase of the wet scrubber unit are all important requirements.[15]

Lithium

By C. K. Quan[1]

Although domestic production of lithium minerals and compounds showed a minimal growth in 1976, consumption rose about 9% over that of 1975. The United States continued as the world's leading producer, supplying about 79% of total demand. Other primary producers of lithium materials included the U.S.S.R., Brazil, South-West Africa, and Southern Rhodesia. West Germany, although not a primary producer, was an important supplier of lithium products manufactured from imported lithium carbonate and lithium hydroxide.

The largest end use of lithium was as lithium carbonate in aluminum potlines, where it increases capacity, lowers energy requirements, and reduces fluoride emissions. It is estimated that aluminum production accounted for 50% of total domestic consumption of lithium and 38% of world consumption in 1976. Other major applications of lithium were in glass and ceramics and in lubrication, together accounting for 40% of domestic demand and 43% of world demand. Continued growth of lithium consumption in these major end uses is expected.

A highlight of the lithium industry consisted of the startup, at yearend, of a 12-million-pound-per-year lithium carbonate plant at Kings Mountain, N.C. The new facility of Foote Mineral Co. represented a 20% increase in lithium production capacity of market economy countries.

Legislation and Government Programs.— Imports of lithium materials are subject to the following tariff structure:

Tariff class	TSUS No.	Rate of duty	Statutory rate
Lithium mineral concentrates	423.81	None	None
Lithium metal	415.30	12.5% ad valorem	25% ad valorem
Lithium compounds	419.10	5% ad Valorem	25% ad valorem

A 22% depletion allowance against Federal income tax is granted on the mining of domestic reserves, compared with 14% for foreign reserves.

The General Services Administration (GSA) continued selling surplus lithium hydroxide monohydrate, depleted of its Li-6 isotope, to domestic and foreign consumers. During 1976 about 1.98 million pounds were disposed of, for a total value of $1.52 million. At yearend total disposable inventory was reported at 3.11 million pounds valued at $4.18 million. However, an additional 80 million pounds of surplus material have since become available from Energy Research and Development Administration (ERDA) stockpiles.[2] It is understood that Lithium Corp. of America (Lithcoa) and Foote Mineral Co. are considering long-term commitments to purchase 20 million pounds each, under the proviso that the material be used in the production of lithium carbonate or lithium carbonate-based products. Twenty-eight million pounds are being offered for sale to any other firm (or firms) that desires to participate in the disposal program, provided that it has the financial and technological capability of becoming a domestic primary lithium producer or producer of lithium carbonate or

[1]Physical scientist, Division of Nonmetallic Minerals.
[2]GSA stockpile information, No. P-2164, Jan. 7, 1977.

lithium carbonate- based products. The remaining 12 million pounds of surplus material have been set aside for sale under sealed bid on an unrestricted-use basis to any firm other than Lithcoa and Foote Mineral.

DOMESTIC PRODUCTION

To avoid disclosure of individual company confidential data, the Bureau of Mines continued its policy of withholding from publication statistics on domestic production that it obtained from official canvasses. However, in response to a growing need by the public, data currently available in other published sources will be presented.

Table 2 summarizes estimates of domestic production for the years 1971-76, as published by the Canadian Department of Energy, Mines and Resources and by Gulf Resources and Chemical Corp. of which Lithcoa is a wholly owned subsidiary.

Canadian data, traditionally reported in terms of lithia (Li_2O) content, have been converted to a lithium carbonate (Li_2CO_3) equivalent basis by a multiplicative factor of 0.464. Consistently, Canadian estimates of total U.S. production have been higher than Lithcoa's estimates. It is believed, however, that Canadian data represent upstream production of mineral concentrates and lithium carbonate, while Lithcoa's data are based on total downstream production of a variety of lithium products.

As in previous years, Lithcoa, Foote Mineral Co. and Kerr-McGee Corp. accounted for the entire domestic production, with an estimated total annual capacity of some 28,500 tons of lithium carbonate equivalent at yearend 1976.

Table 2.—Domestic production of lithium

(Short tons of Li_2CO_3 equivalent)

	Total Domestic Production		Lithcoa production[2]
	Canadian estimate[1]	Lithcoa estimate[2]	
1971	17,311	15,250	7,831

Table 3.—Domestic producers of lithium

Company	Plant location	Estimated capacity (short tons Li_2CO_3 equivalent per year)
Lithium Corp. of America	Bessemer City, N.C	13,500
Foote Mineral Co	Silver Peak, Nev	8,000
	Kings Mountain, N.C.[1]	6,000
Kerr-McGee Corp	Searles Lake, Calif	1,000

[1]Onstream December 1976.

Lithcoa operated an open pit mine and a beneficiation plant at Bessemer City, N.C., where it has a reserve of 29.6 million tons of spodumene ore, averaging 1.38% Li_2O, in pegmatite dikes. All of Lithcoa's mill output, exclusive of concentrate tolled for others, provided feed for its chemical plant in Gastonia, N.C., where more than 70 different lithium products were manufactured, of which 30 were marketed in commercial quantities. Products of major importance included lithium hydroxide, lithium carbonate, lithium chloride, lithium bromide, lithium hypochlorite, butyllithium and lithium metal. During 1976, approximately 39% of Lithcoa's sales were absorbed by foreign markets. The balance went to several hundred customers in many diverse industries in the United States, no single customer accounted for more than 10% and no single industry for more than 30% of total sales. In addition, feldspathic sands were produced by Spartan Minerals Co. of Pacolet, S.C., a subsidiary of Lithcoa, from feldspar-rich mill tailings of the parent company and marketed to the ceramic and glass container industries. Currently, Lithcoa reportedly accounts for half of the lithium production in market economy countries, and plans are underway to expand capacity of the Gastonia plant to 22,000 tons of lithium carbonate equivalent, at an estimated cost of $12 million.

Foote Mineral Co., 92% owned by Newmont Mining Corp., has an open pit mine and beneficiation plant at Kings Mountain, N.C., where reserves are estimated to be adequate to sustain forecasted production levels for more than 40 years. It was the major supplier of spodumene concentrates to the ceramic industry. At yearend 1976 a new lithium carbonate facility came onstream at Kings Mountain, adding approximately 6,000 tons to the total annual capacity of market economy countries. An additional source of lithium carbonate evolves from Foote's brine operations at Silver Peak, Nev., conducted under sodium and potassium leases and prospecting permits issued by the Bureau of Land Management of the U.S. Department of the Interior.

During the fourth quarter of 1976, Foote completed modification of its Sunbright, Va., lithium hydroxide facility. With an estimated annual capacity of 2,500 tons of lithium hydroxide monohydrate, the plant will utilize lithium carbonate from the Kings Mountain operations as plant feed. A variety of other lithium chemicals were also produced by Foote at Fraser, Pa., and at New Johnsonville, Tenn., where organolithium products such as normal butyllithium and secondary butyllithium were manufactured.

Minor amounts of lithium carbonate, approximately 900 tons per year [3], continued to be extracted as a byproduct of Kerr-McGee's brine operations at Searles Lake, Calif. Although the Searles Lake potash operations are being expanded, it is understood that no increase in lithium carbonate capacity is envisaged.

CONSUMPTION AND USES

Lithium minerals, compounds and metal command a variety of industrial and institutional uses. The minerals lepidolite, petalite, and spodumene find direct application in specialty glasses, enamels, glazes, and whitewares. Small amounts of spodumene in glasses, about 0.1% to 0.2% lithia, reduce operating temperatures and fuel consumption and increase pull and furnace life. Also, the addition of spodumene in container glass batches is believed to reduce stack emissions of fluorides and provides for the chemical durability of the glass. Lithium additives were incorporated in U.S. specifications for black and white television tubes many years ago, and other countries have presumably adopted the same specifications. It is understood that a 21-inch tube

[3]Rykken, L. E. Lithium Production From Searles Valley. Ch. in Lithium Resources and Requirements by the Year 2000. U.S. Geol. Survey Prof. Paper 1005, 1976, pp. 33-34.

utilizes about 0.2 pound of lithia. Recrystallized glasses, a relatively recent development, utilize low-iron spodumene or petalite to impart strength and durability. Supplemented by lithium compounds, spodumene or petalite is used in quantities making up as much as 50% of the glass batch. In enamels and glazes, an addition of about 1% lithia in ground and cover coat frits increases the fluidity of the coats, improves gloss, and produces a high-strength glaze with low thermal expansion. In whitewares, lithia is added in various amounts depending on whether it is used as a fluxing agent or as a low-expansion constituent. As a flux, spodumene can impart lower absorption to china bodies than can be obtained with feldspar alone. Also, maturing temperatures are decreased and strength is increased with spodumene additions. Larger amounts of lithia in whiteware bodies result in a marked reduction in thermal expansion and improved resistance to thermal shock. In addition to direct-use ores, various amounts of lithium carbonate, lithium fluoride, lithium borosilicate, and lithium manganite are also used in glass and ceramic applications. In 1976, total consumption of lithium, in all forms, by the glass and ceramic industries was estimated at 4,700 tons of Li_2CO_3 equivalent, up 6% from 1975 consumption.

Table 4.—Estimated domestic consumption of lithium

(Short tons of Li_2CO_3 equivalent)

End Use	1975	1976
Aluminum production	6,500	7,500
Ceramics and glass	4,450	4,700
Lubrication	1,350	1,400
Air-conditioning	800	700
Synthetic rubber	500	600
Others	400	400
Total	14,000	15,300

By far the most significant development in recent years has been the increased use and perhaps final acceptance of lithium carbonate in aluminum potlines. The addition of lithium carbonate to the electrolyte baths results in a 25% reduction in fluoride emissions, a 10% reduction in power requirements, and a 7% to 10% increase in potline capacity. The optimum concentration of lithium in the bath appears to be 4% to 5% of the bath content. In new cells, absorption of lithium by the potlining is abnormally high, and it is sometimes preferable to initiate lithium additives only after the first 2 months of operation. Typically, a 100,000-ton-per-year potline is thought to require an initial charge of 600 tons of lithium carbonate, and an additional makeup charge of 250 tons is required annually to compensate for process losses. The initial charge is needed only at the startup of a new cell. At the end of the cell life, usually after 3 years or 1,000 tons of aluminum, the contents of the cell are recycled by transferance to a new cell. In consequence, this makeup charge will very likely constitute the major end use of lithium carbonate in aluminum potlines over the long haul. According to the Aluminum Association, domestic production of primary aluminum in 1976 amounted to 4.25 million tons, up about 10% from that of 1975. It is estimated that 35% of the production came from potlines using lithium carbonate, the consumption of which probably amounted to 7,500 tons.

As a raw material in the manufacture of greases, the use of lithium hydroxide monohydrate has expanded considerably over the past 25 years at the expense of calcium and sodium compounds. Today, over half of all greases produced domestically are lithium-based. Lithium hydroxide monohydrate is added to lubricating oils where it saponifies into lithium stearate and acts as a thickener. Major advantages of lithium greases include effectiveness over a wide range of temperatures, from subzero to over 300°C, good water resistance, resistance to oxidation, and stability under cyclic heating and cooling. The lithium content of the greases varies but is understood to average 1.2% lithium hydroxide monohydrate. According to the National Lubricating Grease Institute, 69% of member producers responding to a national survey reportedly produced some 244 million pounds of lithium greases in 1975. Presumably, the remaining 31% who chose not to respond represented minor producers with little or no lithium grease production. Thus, total lithium grease production in 1975 is estimated at 256 million pounds, requiring approximately 3.07 million pounds of lithium hydroxide monohydrate, or 2.70 million pounds of lithium carbonate equivalent. While a more recent survey has yet to be commissioned, it may be estimated that lithium grease production in 1976 probably amounted to some 265 million pounds, requiring about 3.18 million pounds of lithium hydroxide monohydrate, or 2.80 million pounds of lithium carbonate equivalent.

Lithium bromide is used in absorption air-conditioning systems because it is hygroscopic, is able to maintain a constant humidity in air, and is soluble at low temperature. On account of their size, absorption machines constitute only a minor component of the total air-conditioning and refrigeration market. Typically, a 100 refrigerated-ton system uses about 1,500 pounds of lithium bromide, while a 1,250-refrigerated-ton machine uses 8,000 pounds. Since 1967, when some 2,700 absorption units were assembled, production has declined and by 1975 only 730 units were reportedly assembled. A further erosion probably occurred in 1976 owing to a drop in commercial and industrial building starts. While the capacities of the machines are generally not known, lithium bromide consumption probably did not exceed 1,900 tons in 1975 and 1,600 tons in 1976, equivalent to 800 tons and 700 tons of lithium carbonate in those 2 years.

Several organolithium compounds are used as catalysts in the manufacture of polymers in the chemical industry, and perhaps the most important usage in this field is that of n-butyllithium in synthetic (polyisoprene) rubber production. Among alkali- metal-based catalysts, n-butyllithium is found to be the most effective in directing the reaction towards the cis-1,4 structure which confers properties most closely resembling those of natural rubber. While polyisoprene rubber accounts for about 10% of total domestic production of all synthetic rubber, it is believed that only a part of this 10% is made using lithium catalysts. Reliable estimates of the consumption of organolithium compounds are currently unavailable but it is probably about 500 to 600 tons lithium carbonate equivalent per year.

Miscellaneous applications of lithium and its compounds are found in storage batteries, pharmaceuticals, paints, dyes, resins, laundry bleach and bactericide, welding and brazing fluxes, and specialty alloys, all of which account for perhaps no more than 400 tons of lithium carbonate equivalent consumed annually. Two applications, a rechargeable lithium battery for automobile propulsion and thermonuclear fusion reactors, currently under various stages of development, may well alter the future consumption pattern if proven successful.

PRICES

Yearend prices of elemental lithium and its typical compounds posted gains in 1976. Among high-volume products marketed, lithium carbonate had price increases of 6% to 9%; lithium hydroxide monohydrate, 8%; lithium bromide, 17%; and lithium chloride, 8% to 31%. High value products included lithium metal and lithium hydride, prices of which rose 5% to 35% and 2% to 31%, respectively.

[r]Revised. NA Not available.

[1]Only in the case of lithium hydroxide are U.S. exports of lithium chemicals reported seperately in official U.S. trade statistics. Other lithium compounds as well as lithium metal are reported in basket categories. Data in this table are derived from import statistics of the listed major trading partner countries.

[2]Officially reported U.S. exports total 613 short tons, distributed as follows: Belgium-Luxembourg—15, Bolivia—12, Brazil—2, Canada—25, Chile—9, France—143, West Germany—33, India—29, Indonesia—42, Iran—2, Ireland—2, Japan—117, Mexico—54, the Netherlands—49, Pakistan—3, the Philippines—2, the Republic of South Africa—11, Spain—11, Sweden—5, Switzerland—8, Thailand—5, and the United Kingdom—35.

[3]Figures represent estimated gross weight of lithium bromide included in a basket category of lithium bromide and potassium bromide (50% of the total of lithium bromide and potassium bromide is assumed to be lithium bromide).

[4]Less than 1/2 unit.

[5]Officially reported U.S. exports total 267 short tons, distributed as follows: Argentina—1, Belgium-Luxembourg—1, Canada—6, France—30, India—10, Israel—11, Japan—77, the Republic of Korea—1, Mexico—31, the Netherlands—39, Spain—41, Switzerland—17, and the United Kingdom—2.

FOREIGN TRADE

Exports of lithium hydroxide declined substantially in 1976, particularly to France and Japan, which were major recipients in 1975. Totally clouding the export picture is the lack of data on shipments of lithium carbonate and other lithium compounds. A clearer picture of U.S. exports may be gleaned from import statistics of major trading partner countries.

Official trade statistics are generally incomplete and in some cases inaccurate. According to the Bureau of the Census, U.S. Department of Commerce, imports of lithium ores dropped to about 68 tons in 1976 from about 4,548 tons in 1975. On the other hand, imports of lithium compounds rose to some 42 tons, compared with 10 tons in 1975. It is not entirely clear what lithium compounds were imported in 1975-76 or in years past.

WORLD REVIEW

Worldwide, consumption of lithium in all forms increased approximately 8% over that of 1975, reflecting a general recovery from the recession of that year. As with the United States, the use of lithium carbonate in the aluminum industry of Europe is steadily rising, to make it a major end use for lithium. While in past years lithium carbonate had not been consumed in significant quantities in the aluminum potlines in Japan, it is likely that there is now a growing acceptance of the additive, especially in the face of escalating energy costs.

Ranking among the major consumers of lithium ores and compounds are the glass and ceramics industries of Europe and Japan. A pottery and whiteware industry has thrived in Japan since early times and today represents an important contributor to export earnings. Japan is also the world leader in the production of black-and-white television receivers, which utilize lithium additives in the composition of the tubes.

Absorption air-conditioning, a major end user of lithium bromide, showed a slight downturn in the United States and a dramatic decline in Japan during 1976. This use for lithium is expected to recover gradually with a recovery in commercial and industrial building starts.

There is a dearth of published information on actual world lithium consumption by end uses, and table 13, which represents gross estimates, must be interpreted with caution.

Argentina.—While official statistics are unavailable, it is believed that Argentina has a small annual production, not more than 300 tons of crude lithium ore, mainly from minor workings in the States of San Luis, Cordoba, and Catamarca. Minable reserves in these areas are estimated at 154,000 tons.

Australia.—Despite the lifting of a ban of lithium exports to centrally planned economy countries in 1967, Australia has not been a significant lithium producer even though reserves in excess of 4 million tons are known, particularly in Western Australia. Most Australian production, probably several hundred tons of petalite per year, is a byproduct from a feldspar quarry at Londonderry, near Coolgardie, operated by Australian Glass Manufacturers Co. Intermittent shipments of petalite ore have been made to consumers in the United States and Japan in some years, and it is likely that production has been curtailed or suspended in recent times.

Bolivia.—Preliminary investigations by the U.S. Geological Survey have confirmed the presence of large, high-grade deposits of lithium and potassium in the Salar de Uyuni and nearby salars in southwestern Bolivia.[4] The lithium is contained primarily in brines, salt crusts, and interbedded clays, and indications are that the deposits may rank among the largest known lithium reserves in the world. Plans for commercial development have not been announced, but it is understood that major U.S. producers have shown some interest in their further exploration.

Brazil.—An important source of ceramic-grade lithium minerals is Brazil, where the only known concessions are held by Companhia Estanifera do Brasil (CESBRA), partly owned by Patino Mining Corp. of Canada. The concessions cover some 29 outcrops discovered at Aracuai in the Province of Minas Gerais. Small amounts of hand-cobbed spodumene ore have been produced for domestic consumption and export. Other areas producing minor amounts of spodumene and amblygonite as byproducts of beryl mining include the northern provinces of Paraíba, Rio Grande do Norte, and Ceará. In addition to crude ore, some lithium carbonate, not more than 50 tons annually, is produced presumably by Orquima S.A. Total minable reserves in the producing provinces are estimated at a little over 800,000 tons.

Canada.—Although substantial deposits of lithium minerals are known in Canada, there has been no commercial exploitation since 1965 when the Quebec lithium division of the Sullivan Mining Group ceased operations at Amos, Quebec. The Quebec lithium property consists of pegmatite dikes, individually up to 2,000 feet in length and 100 feet in width. Total reserves have been estimated at 20 million tons of spodumene grading about 1.2% lithia.

As a result of recent developments on lithium deposits at Bernic Lake, the Province of Manitoba may well emerge as a significant producer. Situated some 110 miles northeast of Winnipeg, lithium occurs in pegmatite zones within the world's larg-

---

[4]Ericksen, G.E., J.D. Vine, and R.A. Ballon. Lithium-Rich Brines at Salar de Uyuni and Nearby Salars in Southwestern Bolivia. U.S. Geol. Survey Open-file Report No. 77-615, 48 pp.

est tantalum deposit and its only known commercial deposit of pollucite. A spodumene zone containing 5 million tons of 3% lithia over a width of 30 feet occurs in the main pegmatitic sill, and exploratory drilling underground indicates additional ore beneath present workings. For years tantalum and cesium have been extracted from Bernic Lake by Tantalum Mining Corp. (Tanco), a joint venture of Chemalloy Minerals of Toronto, the Manitoba Development Corp. (MDC), and Kawecki Berylco Industries (KBI) of New York. In 1973 a pilot plant was installed for the beneficiation of spodumene ore. Trial shipments to consumers during the year demonstrated the suitability of the concentrate for ceramic applications. Soon after KBI's acquisition of a 25% interest in Tanco in 1974, plans were laid for upgrading lithium production with a lithium carbonate facility. Scheduled for completion in 1976, the pilot plant is designed to process 100 tons of concentrate per day. Further into the future, mine and plant expansions will increase output to 15,000 tons of low-iron spodumene concentrate and 6,000 to 7,000 tons of lithium carbonate.

Chile.—About to become a potentially important lithium source are the subsurface potassic brines in the Salar de Atacama of northern Chile. The lithium occurs in very rich brines which are estimated to contain 1.2 million tons of lithium and 14 million tons of K_2O. Corporación de Fomento de La Produccion (CORFO) reports that Foote Mineral Co. has signed an agreement with the Chilean Government for the commerical development of these deposits. Foote, which owns 55% of CORFO, is reportedly planning a $10 million investment in the project.

China, People's Republic of.—Although high-purity lithium metal is produced for atomic energy applications, very little else is known about the lithium industry of the People's Republic of China. Two salt lakes, Charkhan and Idsaydam, in the Tsaidam basin of Tsinghai are believed to be similar in chemical composition to Searles Lake in California. It has been suggested that lithium is probably being extracted as a byproduct of borate and potash operations at these lakes.

France.—Some lithium compounds, particularly lithium hydroxide for use in grease manufacture, have been produced in France by Rhône-Poulenc, presumably from imported ore and carbonate.

Germany, West.—A major processor in Europe is Metallgesellschaft AG, which operates from the Hans-Heinrich- Hütte plant at Langelsheim and produces a wide variety of lithium compounds as well as lithium metal. Until recently, the main source of Metallgesellschaft's ore has been spodumene from Kings Mountain, N.C., under an agreement with Foote Mineral Co. dating from 1964. Today, feedstock for the Langelsheim plant comprises lithium carbonate from the United States and the U.S.S.R. as well as surplus lithium hydroxide from the U.S. Government.

Japan.—Japan ranks among the world's major consumers and processors of lithium minerals and compounds, all of which are imported. Honjo Zinc Co., a leading processor, utilizes lithium carbonate and lithium hydroxide from the United States and the U.S.S.R. to produce a variety of secondary lithium products, including lithium chloride and bromide. Asahi Glass, part of the Mitsubishi Group, has been manufacturing about 240 tons of lithium bromide monthly at Kita, Kyushu, and reportedly has a production capacity of 300 tons per month. Nihon Lithium, a joint venture of Foote Mineral Co., and Sumitomo Shoji, is not yet a lithium processor but plans to produce some 300 tons of lithium bromide, 100 tons of lithium chloride, and 30 tons of butyllithium annually in the future. Meanwhile, Asian Lithium Co., a joint venture of lithium Corp. and Honjo Zinc, has been producing butyllithium for domestic consumption since its inception in late 1971.

Mozambique.—Minor amounts of lepidolite have been produced intermittently in the Zambesia district of Mozambique, possibly by Empressa Mineira do Alto Ligohna Ltda. Although substantial shipments of lithium minerals have been made to Belgium and the Netherlands in recent years, it is believed that they represent Rhodesian production.

Rhodesia, Southern.—Lithium minerals are widespread in Southern Rhodesia, occurring in the tin fields of Bikita; in the districts of Salisbury, Umtali, Mtoko, and Gwanda; and at Mozoe, Fort Rixon, Shamva, Inyanga, and near Gadzema. The most important occurrence is at Bikita, where lithium pegmatites contain substantial amounts of lepidolite and petalite, with lesser amounts of spodumene and eucryptite. Reserves of hand pickable ore are estimated at over 5 million tons averaging 2.5% lithia. Prior to United Nations trade sanctions against Rhodesia in 1968, Bikita Minerals Ltd., a subsidiary of Selection Trust Ltd., was a major world producer of lithium minerals with an annual output exceeding 60,000 tons, most of which was exported. Since then production has declined and while official statistics have not been available, it is believed that production has been suspended and shipments are being made from stockpile. Small amounts of lithium carbonate may be produced by a local company, Lithium Products Ltd., in Gwelo.

South Africa, Republic of.—As with Mozambique, South Africa's production of lithium minerals, principally by the Otavi Mining Co. Ltd. at Mica, Transvaal, has been insignificant. Shipments made to Europe in recent times probably represent output from Southern Rhodesia and South-West Africa.

South-West Africa, Territory of.—S.W.A. Lithium Mines Ltd., acquired in 1968 by Klockner & Co., a West German industrial group, produces lepidolite and petalite and small quantities of amblygonite from the Helicon and Rubicon mines southeast of Karibib. Reserves of hand-cobbed ore are said to be minimal, but more than 1 million tons of millable ore is known to be available for upgrading in a 10,000-ton-per-year flotation plant.

U.S.S.R..—Lithium occurrences in the U.S.S.R. are numerous and widespread. The more important include spodumene in the Kola Peninsula; lepidolite and spodumene in Muzinskoe, Lipovka, and Boevskoe in the Urals; spodumene and lithium phosphate in the Kablinsk and Turkestan ranges; spodumene, lepidolite, and petalite in the Transbaikal Territory in Siberia; and lithium micas in Volynia in the Ukraine. Also, several lakes in the Minusinsk-Abakansk area in old Transbaikal may have commercial concentrations of lithium in brines. For many years now the U.S.S.R. has marketed in Europe and Japan between 1,000 and 3,000 tons annually of lithium salts, mainly lithium carbonate and lithium hydroxide. Presumably, the lithium hydroxide is deficient in the Li-6 isotope and can only represent stockpiled residue from Li-6 processing. At the same time it is quite likely that spodumene in the Kola Peninsula is currently being mined and processed into lithium chemicals for domestic consumption and export. In view of the growing domestic demand, it is believed that exports of lithium compounds will be sharply curtailed or else suspended in years to come.

Table 9.—Lithium minerals: World production, by country

(Short tons)

Country[1] and mineral produced	1974	1975	1976[p]
Argentina (minerals not specified)	181	276	[e]275

United States (minerals not specified)	W	W	W

[e]Estimate. [p]Preliminary. W Withheld to avoid disclosing individual company confidential data.

[1]In addition to the countries listed, other nations may produce small quantities of lithium minerals, but output is not reported and no valid basis is available for estimating production levels.

[2]Figures presented are U.S. imports from Canada; official Canadian sources report no production since 1965, but the United States has imported lithium minerals from Canada in most years since that time. It is not clear whether these imports are from: accumulated stocks, test production quantities not reported in official Canadian statistics, Canadian imports, or a combination of these sources.

[3]These estimates denote only an approximate order of magnitude; no basis for more exacting estimates is available. Outputs by the People's Republic of China and the U.S.S.R. have not been reported since 1964.

[4]Output has not been officially reported since 1966, but presumably has continued since a number of countries record imports from South Africa.The total quantity considerably exceeds reported output by the Republic of South Africa proper, and presumably include shipments from South-West Africa. Quantities given represent imports by the United States and the European Community reported as originating in South Africa, but the reader is cautioned that a portion of the material may have been mined in Southern Rhodesia. In 1966, actual output from South-West Africa totaled 1,739 short tons, as follows: amblygonite 30 tons; lepidolite, 365 tons; petalite, 1,344 tons.

[1]Compiled from import statistics of listed importing countries unless otherwise noted. Conversion from reported metric tons to short tons was accomplished by multiplying metric tons by 1.10231. Conversions to lithium content from reported gross weights were accomplished through the use of the following conversion factors: lithium carbonate, multiply by 0.188; lithium hydroxide, multiply by 0.165; lithium chloride, multiply by 0.164; lithium bromide, multiply by 0.080. It should be noted that most of the countries provide data for a basket category of "lithium oxide and hydroxide"; this has been assumed to be largely, if not entirely, the monohydrate form of lithium hydroxide ($LiOH \cdot H_2O$), and the factor selected for converting this material to lithium content is based on this assumption.

[2]Less than 1/2 unit.

[3]Source: West German official export statistics.

[4]Revised to zero.

[5]Source publication reports imports of the total of lithium bromide and potassium bromide as a single figure; entry here is an estimate based on the assumption that half of the total is lithium bromide.

[6]Totals are of listed figures only; as such, they are only partial totals in most instances.

Zaire.—Following the discovery in 1975 of some 35 million tons of spodumene ore in the Manano pegmatites in Zaire, Zairetain, a Government-owned mining company, announced plans for the commercial development of the ore. Included in the plans is the construction of a spodumene concentrator and a 5,000-ton-per-year lithium carbonate plant. The Government of Zaire has since been in consultation with a major U.S. lithium producer in connection with the proposed project, and it is understood that the World Bank may be asked for financial assistance in feasibility studies on the property.

TECHNOLOGY

After a hiatus of nearly 50 years, electric vehicles are poised for a comeback. Pressure to conserve petroleum supplies and to preserve the environment has stepped up funding, through the Electric and Hybrid Vehicle Research, Development and Demonstration Act of 1976, for advanced battery systems capable of meeting energy requirements of a short-range commuter-type vehicle. Among those under various stages of development, through ERDA contracts administered by Argonne National Laboratory, is a lithium-sulfur battery whose unit cell consists of a solid lithium-aluminum cathode, an iron sulfide or disulfide anode, and a molten salt eutectic of lithium chloride and potassium chloride. The electrolyte has a melting point of 352°C, and because cell operating temperatures are between 380° and 450° C, the batteries require thermal insulation. Developed at Argonne, the cell has a theoretical energy density of 430 watt-hours per pound, but because alloys and metal sulfide compounds are used (instead of elemental lithium and sulfur), Argonne's target density is 80 to 85 watt-hours per pound. At the Atomics International, division of Rockwell International, a similar cell with a lithium-silicon cathode has been successfully tested, demonstrating the technical feasibility of building large, high-density batteries of this type. More recently, Exxon Enterprises has revealed promising research on a lithium battery that operates at room temperature. The Exxon battery employs metallic lithium for the cathode and titanium disulfide for the anode and has a lithium perchlorate electrolyte. The battery is expected to have an energy density of 50 to 60 watt-hours per pound, lower than higher temperature lithium batteries, but it eliminates the need for temperature- and corrosion-resistant materials as well as for insulation.

According to Argonne, a typical vehicle with a 150-mile range would be equipped with a 42-kilowatt-hour battery, weighing about 900 pounds and containing 60 pounds of lithium. The current projection is for 18 million vehicles powered by lithium batteries to be on the road by the year 2000, requiring about 70 million pounds of new lithium annually, in addition to lithium recycled from scrapped batteries. Also, by the year 2000 as much as 3% of the projected domestic energy consumption may be supplied by lithium-sulfur offpeak energy-storage batteries, whose total lithium content may amount to a little over 1 billion pounds.

Still in the developmental stage is a fusion-type thermonuclear reactor that has been proposed as an alternative to the conventional fission reactor or to the controversial fast breeder reactor. The amount of lithium required in fusion reactors depends in part on the particular reactor design chosen. Reactors in which lithium is used both as a neutron-absorbing blanket around the reactor core and as a heat-transfer medium may require about 10 times as much lithium as designs in which it forms a blanket only. According to ERDA, between 200 and 2,000 pounds of lithium are required per megawatt of fusion capacity, and a large fusion power industry in the 21st century may thus require 200 million to 2 billion pounds of lithium.

Lithium batteries and fusion power, together with their potential impact on the lithium industry, were discussed at a symposium held in January 1976, at Golden, Colo. Proceedings of the symposium have since been published by the U.S. Geological Survey.[5]. A second symposium on lithium has been scheduled for October 1977, at Corning, N.Y.

The search for a less-energy-intensive method of aluminum production led to the revolutionary Alcoa Smelting Process, implemented at midyear in a newly built smelter in Palestine, Tex. Based on the electrolysis of aluminum chloride, to which minor amounts of lithium chloride and sodium chloride are added, the process is expected to reduce power requirements to 5 kilowatt-hours per pound of aluminum, compared with 6.5 kilowatt-hours per pound in today's most efficient conventional smelters. Although published data are as yet unavailable, it is understood that the process requires about 20 pounds of lithium chloride per ton of aluminum produced, and its impact on the lithium industry may be profound should it prove successful and be implemented in new smelters worldwide.

The feasibility of utilizing synthesized benzene and simple alkylated derivatives as nonpetrochemical gasoline components has been proposed.[6] Feasible raw materials include coal, coke, charcoal, and carbonaceous wastes. The basic synthesis consists of the formation of lithium carbide by reaction of the metal with carbon, hydrolysis of the carbide to acetylene, cyclization of acetylene to benzene and regeneration of lithium metal.

Magnesium

By Benjamin Petkof[1]

Domestic metal production was strong during the year but declined slightly from that of 1975. The recovery of secondary magnesium metal continued to increase. Total exports of magnesium declined in both quantity and value. Imports of all classifications of magnesium metal increased in both quantity and value. The quoted price of magnesium metal ingot increased $0.09 during the year. World primary production, excluding that of the United States, was slightly higher than that of 1975.

Legislation and Government Programs.—The General Services Administration strategic and critical stockpile contained 1,121 tons of magnesium at yearend. There was no stockpile goal for magnesium. During April 1976, 500 tons of magnesium metal were released from the stockpile. There were no accessions during the year.

[1]Excludes United States production.

DOMESTIC PRODUCTION

Domestic production of magnesium metal ingot was strong in 1976 but was slightly below that of 1975. Publication of Bureau of Mines data on domestic production must be withheld to avoid disclosing individual company confidential data.

During the year, magnesium ingot was produced by American Magnesium Co., Snyder, Tex., with an annual production capacity of 10,000 short tons and The Dow Chemical Co., Freeport, Tex., with an annual production capacity of 120,000 short tons. NL Industries, Inc., halted magnesium production at its Rowley, Utah plant during the first quarter of 1976 in order to resolve technical and equipment problems. The company was expected to resume operations in 1977. Northwest Alloys, Inc., a wholly-owned subsidiary of Aluminum Co. of America (Alcoa), began magnesium ingot production during the first quarter of 1976 at its new plant near Addy, Wash. The

[1]Physical scientist, Division of Nonferrous Metals.

announced production capacity was 24,000 tons per year. All domestic magnesium producers except Northwest Alloys, Inc., used the electrolytic method; Northwest Alloys used the silicothermic process.

Secondary recovery of magnesium metal increased.

CONSUMPTION AND USES

Total domestic consumption of primary magnesium in 1976 increased almost 11% over that of 1975 but did not reach the consumption level of 1974. Magnesium was consumed in structural products that included castings and wrought products, and in sacrificial purposes where advantage was taken of the metal's chemical and alloying properties. The metal's useful structural properties such as low specific weight, good machinability, hot formability, and high strength-to-weight ratio resulted in about 17% being used in aircraft, automotive, and other types of transportation equipment, materials handling equipment, and the manufacture of items such as power tools. The remainder was used for sacrificial purposes, primarily alloying with other metals, cathodic protection, production of nodular iron, and reducing agents for metals such as titanium, zirconium, uranium, and beryllium.

PRICES

The base price of magnesium ingot was increased during the year. As of January 1, 1976, the quoted price was: $0.87 per pound; July 1, 1976, $0.92 per pound; and January 1, 1977, $0.96 per pound.

STOCKS

Producer and consumer stocks of primary magnesium declined 12% to 17,295 tons at yearend 1976. Yearend stocks of primary magnesium alloy ingot dropped 35% to 988 tons. Stocks of primary metal at yearend 1975 were 19,664 tons and those of alloy ingot were 1,512 tons. New and old magnesium scrap stocks declined 34%.

FOREIGN TRADE

Magnesium exports declined 59% from 32,591 tons in 1975 to 13,444 tons in 1976. The value also declined sharply from $48.2 million in 1975 to $26.9 million in 1976. Shipments to Brazil, West Germany, and Mexico represented 76% of the total. Most of the metal exported (91%) consisted of primary metals and alloys.

Total imports for consumption increased 89% from 7,903 tons valued at $11.5 million in 1975 to 14,907 tons valued at $22.7 million in 1976. Imports of metal accounted for 65% of total imports; waste and scrap, 23%; and alloys and other forms, 12%. Major sources of magnesium imports were: Norway (62%); Sweden (11%); and Canada (5%).

WORLD REVIEW

World magnesium production, excluding that of the United States, increased 7% to 148,094 tons. The U.S.S.R. accounted for 47% of this total followed by Norway (29%); Japan (8%); France (6%). The remainder was supplied by Canada, the People's Republic of China, and Italy.

Canada.—In 1975 Canada imported 9,241 tons of magnesium and exported 4,152 tons of metal. Canadian aluminum alloy, casting, and other industries consumed 5,609 tons of metal in 1975.

Norway.—Norsk Hydro-Elektrisk A/S announced plans to build a new magnesium plant at Mongstad with an initial planned capacity of about 33,000 tons per year and an eventual capacity of 110,000 tons per year. Construction was expected to begin in 1978 with initial plant startup planned for 1981.

[1]Primary only.
[2]Secondary production was as follows, in short tons: 1974—11,990; 1975—10,171; and 1976—NA.
[3]Excludes United States production, which in previous years accounted for approximately 50% of the total.

TECHNOLOGY

Conditions for fluxless melting of magnesium metal in an air/sulfur hexafluoride atmosphere were described. Sulfur hexafluoride concentration levels to protect molten magnesium metal and alloy were determined to be a function of surface temperature and degree of surface agitation. The possible toxic effects of sulfur hexafluoride were also evaluated.[2]

A model was developed describing the rates of back reaction in a magnesia reduction cell. It was concluded that the chlorine dissolution rate was not the limiting factor in the back reaction between magnesium and chlorine in the electrolytic production of magnesium, flow of the molten bath in the cell was turbulent, transport of reactants to the reaction zone did not control the reaction; and small variations in the dispersion of magnesium metal droplets in the melt could increase the magnesium dissolution rate and cause significant current loss.[3]

A paper described the silico-thermic magnesium plant operated by the Société Française d' Electrométallurgie at Marignac, France.[4]

A new anodic electrolytic treatment for magnesium and its alloys that produces a protective coating superior and economically competitive with available commercial coating was described.[5]

Molten pig iron was desulfurized by injecting a mixture of lime and particulate magnesium metal or magnesium-aluminum alloy beneath the surface of sulfur containing pig iron. This process also avoided excessive slag buildup.[6]

A method for selective solution mining of magnesium chloride hexahydrate from an underground deposit of carnallite or bischofite was described. A low saturated monohydric aliphatic alcohol containing 1 to 4 carbon atoms per molecule was injected into the deposit to dissolve magnesium chloride hexahydrate. The solvent containing magnesium chloride hexahydrate was pumped to the surface for processing leaving a leached residue containing potassium chloride and sodium chloride. The magnesium chloride could be used in the production of magnesium metal. The remaining undissolved residue could be pumped or gaslifted to the surface for extraction of other mineral values.[7]

Magnesium Compounds

By Benjamin Petkof[1]

Austria, Greece, the U.S.S.R., the People's Republic of China, and North Korea continued to provide the major portion of world magnesite supply. Domestic production of almost all categories of magnesium compounds increased compared with 1975.

Exports of magnesite and magnesia totaled 81,494 short tons, a decline of 11% from those of 1975. Imports of processed magnesite declined sharply from those of 1975.

DOMESTIC PRODUCTION

Magnesium compounds were produced primarily from some type of natural brine solution. Natural magnesite and olivine were produced only at a few operations in the United States.

Barcroft Co.; The Dow Chemical Co.; Harbison-Walker Refractories Co.; Kaiser Aluminum & Chemical Corp.; Merck & Co., Inc.; and Michigan Chemical Corp., produced magnesium hydroxide from seawater and well brines. This magnesium compound was used primarily to produce magnesia for the manufacture of basic refractories. Refractory magnesia was produced by Basic, Inc.; Basic Magnesia, Inc.; Corhart Refractories Co., Inc.; A. P. Green Refractories Co.; Harbison-Walker Refractories Co.; Kaiser Aluminum & Chemical Corp.; and Martin-Marietta Chemicals. Total production of refractory magnesia in 1976 was 727,622 tons.

[1]Physical scientist, Division of Nonferrous Metals.

Total 1976 production of caustic-calcined magnesia was 160,364 tons. Producers of caustic-calcined magnesia were Basic, Inc.; Basic Magnesia, Inc.; The Dow Chemical Co.; Kaiser Aluminum & Chemical Corp.; Martin Marietta Chemicals; and Michigan Chemical Corp. Merck & Co., Inc.; Michigan Chemical Corp.; and Morton Chemical Co.; produced 15,236 tons of specified magnesia. The Dow Chemical Co., Mallinckrodt Chemical Works, and Philadelphia Quartz Co., produced magnesium sulfate. Magnesium carbonate was produced by Mallinckrodt Chemical Works; Merck & Co., Inc.; Michigan Chemical Corp.; and Morton Chemical Co.

Magnesium chloride was produced by American Magnesium Co., The Dow Chemical Co., Western Magnesium Corp. (formerly FMC Corp., plant facilities sold to Western Magnesium Corp., March 1976), Great Salt Lake Minerals & Chemicals Corp., and Kaiser Aluminum & Chemical Corp. Magnesium chloride was used primarily to produce magnesium metal. Domestic producers of magnesium compounds by raw material source, location, and capacity follow:

Raw material source and producing company	Location	Capacity (short tons of MgO equivalent)
Magnesite: Basic, Inc	Gabbs, Nev	150,000
Lake brines:		
Great Salt Lake Minerals & Chemicals Corp	Ogden, Utah	100,000
Kaiser Aluminum & Chemical Corp	Wendover, Utah	50,000
Well brines:		
The Dow Chemical Co	Ludington, Mich	250,000
Martin Marietta Chemicals	Manistee, Mich	280,000
Michigan Chemical Corp	St. Louis, Mich	25,000
Morton Chemical Co	Manistee, Mich	5,000
Seawater:		
Barcroft Co	Lewes, Del	5,000
Basic Magnesia, Inc	Port St. Joe, Fla	100,000
Corhart Refractories Co	Pascagoula, Miss	40,000
The Dow Chemical Co	Freeport, Tex	100,000
Harbison-Walker Refractories Co	Cape May, N.J	100,000
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif	150,000
Merck & Co., Inc	South San Francisco, Calif	10,000
Western Magnesium Corp	Chula Vista, Calif	5,000
Total		1,370,000

CONSUMPTION AND USES

Domestic use of almost all magnesium compounds increased in 1976, a reversal from the pattern of 1975. Refractories manufacture continued to be the major end use for magnesia. Refractory magnesia consumption increased 8% in quantity and 3% in value over 1975. Consumption of caustic-calcined and specified magnesias increased 12% in quantity and 64% in value, magnesium hydroxide increased only slightly in quantity but 44% in value, and magnesium sulfate increased 18% in quantity and 54% in value. Magnesium carbonate consumption decreased 21% in quantity and 7% in value.

The quantity of caustic-calcined and specified magnesias used to prepare agricultural, nutritional, and pharmaceutical products increased 13%; construction materials decreased 36%; and chemical processing, manufacturing, and metallurgical increased 22%.

Magnesia had a broad area of use including the production of animal feed, fertilizers and pharmaceuticals, and other chemical processing and manufacturing applications.

PRICES

The prices for magnesia, natural, technical, heavy, 85% and 90% (bulk, carlot and truckload, f.o.b. Luning, Nev.) were quoted at yearend at $120 and $140 per short ton, respectively, according to the Chemical Marketing Reporter. Magnesia, technical, neoprene-grade, light, was quoted at $346 per ton (bags, carlot and truckload, works).

Prices throughout 1976 for magnesium carbonate, technical (bags, carlot, freight-equalized) were quoted at $0.22 to $0.23 per pound, and NF-grade, $0.30 to $0.31 per pound. During the year, the price for magnesium hydroxide, NF, powder, (drums, carlot and truckload, works) was $0.35 to $0.36 per pound. Magnesium chloride, hydrous, 99%, flakes (bags, carlot, works) was quoted at $140 per ton at yearend.

The price for magnesium sulfate, technical (bags, mixed carlot, 10,000-pound minimum, works) was quoted at $0.09 per pound at yearend. In bulk lots it was $0.085 per pound.

FOREIGN TRADE

Dead-burned magnesite and magnesia exports declined 14% in quantity and 5% in value from those of 1975. Shipments to major countries decreased significantly during the year. Canada received 59% of total exports; West Germany, 24%; and Mexico, 5%.

Magnesite exports including crude, caustic-calcined, lump or ground, declined 11% in quantity and 19% in value from those of 1975. Shipments to Canada, Venezuela, Australia, West Germany, and Mexico accounted for 66% of exports in this category.

Imports of lump, ground and caustic-calcined magnesia increased 43% in quantity to 8,194 tons and 61% in value in 1976. Most of the imports were from India (66%), Australia (18%), and Turkey (11%). Imports of dead-burned and grain magnesia and periclase containing a maximum of 4% lime decreased 34% from 125,540 tons in 1975 to 82,676 tons in 1976. Imports of this category have declined annually since 1973. Imports of the same material, but containing over 4% lime, declined 83% in quantity and 87% in value to 5,359 tons and $542,000, respectively. Total imports of crude and processed magnesite declined 41% from 162,048 tons in 1975 to 96,229 tons in 1976.

Imports of specified magnesium compounds and compounds not specifically provided for were valued at $2,266,000, an increase of 26% over that of 1975.

WORLD REVIEW

Greece.—In October 1976, the Financial Mining-Industrial & Shipping Corp. (FIMISCO) of the Scalistiri Group began tests at its pilot plant at Mantoudi, Euboea for its proposed $50 million plant for the production of refractory-grade magnesia from seawater and dolomite. Harbison-Walker Refractories International (a division of Dresser Industries, Inc.) will provide technical assistance for this project. Ten percent of investment costs were budgeted for environmental protection.

Near the end of 1976, FIMISCO began production of Magflot, a briquetted deadburned magnesite produced from processed low-grade magnesite and wastes by proprietary technology. This new $10 million 50,000 ton-per-year-plant at Mantoudi, has a flotation plant, a Herreshoff and shaft kiln, and a briquetting press.

The Macedonian Magnesite Mining-Industrial and Shipping Corp., another Scalistiri Group company, received Government approval to expand and improve magnesite mining and shiploading facilities at Ormilia, Chalkidiki. Authorization was also received for construction of a deadburned magnesite briquetting plant similar to FIMISCO's operation.

Magnomin General Mining Co., S.A., a General Refractories' subsidiary, began operation of ore beneficiating facilities in Chalkidiki using Belgian-Yugoslav technology for preparing magnesite ore and tailings.

India.—The Government placed an export ban on calcined magnesite containing less than 9% silica. However, magnesite containing more than 9% silica remained exportable to all countries. According to Government sources the ban was prompted by an increasing domestic demand for magnesite.

The Indian Mineral Exploration Corp., delineated areas containing magnesite deposits. The Dewalthal deposit near the town of Pithoragarh was selected for initial development with a planned initial capacity of 15,000 tons per year. Almora Magnesite Ltd., owned by Tata Iron & Steel Co., Ltd., and Didier-werke of West Germany opened a dead-burned magnesite plant at Almora in 1975.

[1]Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria and Canada produce magnesite, but output is not reported and available information is inadequate to make reliable estimates of output levels.
[2]Year beginning March 21 of that stated.

TECHNOLOGY

The Bureau of Mines developed a specially formulated magnesium oxysulphate cement for use as a sealant in underground coal mines. The cement was designed to reduce sloughing of shale roofs and coal ribs, to reduce air losses through block stoppings, for constructing sprayed stoppings over jute cloth or metal lath, and to decrease combustibility of polyurethane foam. The cement was evaluated underground.[2]

Blast furnace operation was improved by the addition of 1% to 2% crushed olivine to a charge containing a high alkali metal oxide content. The addition of the olivine removed a substantial part of the alkali metal oxides. The olivine was included in the ore briquettes, fine iron oxides, coke, or other charge materials.[3]

Samples of commercial burned magnesite refractories, as well as specially prepared samples of magnesite were studied to determine fracture energies. It was noted that the factors of temperature, chemistry, and microstructure significantly affected the fracture energies of these materials. The experimental results indicated that control of the coarse grain size distribution can be used to prepare refractories with improved fracture and thermal shock resistance.[4]

Manganese

By Gilbert L. DeHuff[1]

There was neither production nor shipments of manganese ore containing 35% or more manganese in the United States in 1976. Production of ferromanganese fell off in the second half of 1976, while imports of the alloy exceeded the high level of 1975 and were the highest on record. Imports of manganese metal were high, coming mostly from the Republic of South Africa. The price for imported standard high-carbon ferromanganese fell during the year to levels considerably below the published producer price, which remained unchanged at $425 per long ton after a $15 drop early in January. Overall consumption of manganese increased over that of 1975. The General Services Administration (GSA) established new stockpile goals for manganese ores, alloys, and metal, but these were later suspended by the new administration. There were few sales of Government manganese stockpile excesses, but deliveries continued to be made in fulfillment of earlier sales contracts. These were mostly of ore.

Legislation and Government Programs.—On October 1, GSA established new stockpile goals for manganese. These are listed here in short tons, gross weight, with the immediately previous objectives shown in parentheses: Natural battery ore, 12,736 (10,700); synthetic dioxide, 19,105 (zero); chemical ore (no longer broken down into two types), 247,136 (25,600 equally divided between types A and B); metallurgical ore, 2,052,000 (750,500); high-carbon ferromanganese, 439,000 (200,000); medium-carbon ferromanganese, 99,000 (10,500); silicomanganese, 81,000 (15,900); and electrolytic metal, 15,000 (4,750). These goals were suspended by the new administration early in 1977 pending further study.

Sales of Government manganese stockpile excesses for the calendar year, as reported by GSA, were as follows in short tons (gross weight): Natural battery ore of stockpile grade, 123; synthetic dioxide, 545; chemical ore, 1,000 of type A and 6,000 of type B; metallurgical ore, 20,613 of stockpile grade and 22,047 of nonstockpile grade.

Government stockpile physical inventory changes for manganese items in calendar year 1976, all decreases, consisted of the following (short tons, gross weight): Stockpile-grade natural battery ore dropped 1,631 tons to 250,441 tons; synthetic dioxide,

rRevised.

2,832 to 3,006 tons; chemical ore, 10,770 to 230,863 tons; metallurgical ore, stockpile grade, 644,884 to 4,969,528 tons; metallurgical ore, nonstockpile grade, 21,686 to 1,319,030 tons; and high-carbon ferromanganese, 7,721 to 599,757 tons. Stocks of nonstockpile-grade natural battery ore remained unchanged at 54,899 tons; medium-carbon ferromanganese at 28,920 tons; silicomanganese at 23,574 tons; and electrolytic manganese metal at 14,171 tons.

In May, the Environmental Protection Agency issued national air pollution control regulations for electric submerged arc furnaces and associated dust-handling equipment, construction or modification of which began after October 21, 1974. For such furnaces producing manganese ferroalloys, particulate emissions to the atmosphere were limited by these regulations to less than 0.51 pound per megawatt-hour.

The National Stockpile Purchase Specification for Manganese Metal, Electrolytic, was revised June 9, 1976 (P-98-R3) by the Bureau of Domestic Commerce, U.S. Department of Commerce, with approval of the Federal Preparedness Agency, GSA. It specified the minimum manganese content by weight as 99.9% total, 99.7% metallic; decreased maximum hydrogen from 0.015% to 0.010%; increased maximum sulfur from 0.024% to 0.030%; and decreased maximum carbon and phosphorus from 0.01% and 0.005% to 0.005% and 0.001%, respectively.

DOMESTIC PRODUCTION

There was neither production nor shipments of manganese ore, concentrate, or nodules, containing 35% or more manganese, in the United States. Ferruginous manganese ores or concentrates containing 10% to 35% manganese were produced and shipped in the Cuyuna Range of Minnesota, and manganiferous iron ore containing 5% to 10% manganese was produced and shipped in New Mexico. Manganiferous schist, clay, or other earthy material, associated with the manganiferous member of the Battleground schist of the Kings Mountain area, was mined in Cherokee County, S.C., by brick manufacturers or contractors for use in coloring brick at South and North Carolina brick plants. Material from some pits had a manganese content greater than 5% and less than 10%, or possibly 15% at the most, whereas material from others contained less than 5% manganese. Because few operators analyze the material, the quantity that might contain 5% or more manganese can only be estimated. The total such quantity mined in 1976 appears to have been about 9,000 tons.

Table 2.—Manganese and manganiferous ore shipped[1] in the United States, by State

eEstimate. rRevised.

[1]Shipments are used as the measure of manganese production for compiling U.S. mineral production value. They are taken at the point at which the material is considered to be in marketable form for the consumer. Besides direct-shipping ore, they include, without duplication, concentrate and nodules made from domestic ores.

[2]Miscellaneous ore.

CONSUMPTION, USES, AND STOCKS

In the production of raw steel (ingots, continuous- or pressure-cast blooms, billets, slabs, etc., and including steel castings), consumption of manganese as ferroalloys, metal, and direct-charged ore, as reported to the Bureau of Mines by consumers, was 12.2 pounds per short ton of raw steel produced. Of this total, 10.6 pounds was ferromanganese; 1.4 pounds, silicomanganese; 0.01 pound, spiegeleisen; 0.2 pound, metal; and 0.01 pound, manganese ore (containing 35% or more manganese). The comparable 1975 total, on the same basis, was 13.3 pounds with ferromanganese at 11.4, silicomanganese at 1.6, spiegeleisen at 0.03, metal at 0.2, and ore at 0.02. In addition to the aforementioned consumption of manganese in 1976, there was consumed per ton of raw steel produced approximately 1.0 pound of manganese contained in manganese ore used in making pig iron or equivalent hot metal. The comparable figures for 1975, 1974, and 1973 were 1.3, 1.2, and 1.1 pounds, respectively.

Producers of manganese ferroalloys and metal were beset with problems of rising transportation, labor, raw material, pollution control, and energy costs; availability of sufficient energy without interruption; general inflation; a deluge of imports at low prices; and a demand that fell short of expectations because of a poor second half year for the steel industry.

Electrolytic Manganese Metal.—All of the manganese metal produced domestically, and virtually all of that imported, was electrolytic metal. Virtually all of the metal consumed was electrolytic metal, although some low-carbon ferromanganese (such as the domestically produced "Massive Manganese" or the imported "Gimel Metal") and some manganese-aluminum additives may have been erroneously reported by consumers as manganese metal. The metal that was used to make manganese-aluminum additives is included in table 4 under the "Alloys (excludes alloy steels and superalloys)" category. These additives are not knowingly included in the table, it being desired to report consumption at the metal rather than the additive level of the usage cycle.

Production of electrolytic manganese metal increased to 23,966 short tons from 22,141 tons in 1975. Production was by the same three plants of the same three companies: Foote Mineral Co., New Johnsonville, Tenn.; Kerr-McGee Chemical Corp., Hamilton (Aberdeen), Miss.; and Union Carbide Corp., Marietta, Ohio. Newmont Mining Corp.'s interest in Foote Mineral Co. was 90.6%.

Ferromanganese.—Bethlehem Steel Corp., at Johnstown, Pa., and United States Steel Corp., at McKeesport, Pa., were the only domestic blast furnace ferromanganese producers. U.S. Steel stopped production in March and Bethlehem had its ferromanganese furnace on pig iron for part of the year. As in 1975, electric furnaces were used to produce ferromanganese by six companies in eight plants: Airco Alloys Div., Airco Inc., Calvert City, Ky.; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Co. (Engelhard Minerals & Chemicals Corp.), Rockwood, Tenn.; Satral-

[1]Containing 35% or more manganese (natural).
[2]Includes ore used in producing silicomanganese and metal.
[3]Includes ore used in producing silicomanganese.
[4]Ratio of ore consumed to ferromanganese produced if silicomanganese is considered a special grade of ferromanganese.

loy Inc. Div., Satra Corp., Steubenville, Ohio; Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W.Va., Marietta, Ohio, and Portland, Oreg. Fused-salt electrolysis continued to be used by Chemetals Div., Diamond Shamrock Corp., Kingwood, W.Va., to make low-carbon ferromanganese sold under the trade name of Massive Manganese. Doubling of plant capacity to 17,000 short tons of product per year was completed. Tenn-Tex Alloy Corp. of Houston, a subsidiary of Sandgate Corp., continued to operate under a 6-year lease agreement that provided for all production to go to Union Carbide Corp. U.S. shipments of ferromanganese from furnaces totaled 494,000 tons, compared with 556,000 tons in 1975.

The production reported in the various tables of this chapter is net production; that is, the quantity of ferromanganese produced for shipment outside the producing ferroalloy facility. It does not include the remelt material; that is, the fines, offgrade, or other ferromanganese output of the furnace that was fed back to the furnace or lost in the plant, and which is included in gross data reported by the furnace operator. It does include ferromanganese made for use in the company's steel furnaces at the same or other locations.

Table 6.—Manganese ore used in producing ferromanganese, silicomanganese, and manganese metal in the United States in 1976, by source of ore

Unidentified	48,769	--
Total	1,261,968	47

[1]Most, if not all, from U.S. Government surplus stockpile disposals.

Silicomanganese.—Production of silicomanganese in the United States decreased to 129,000 short tons from the 143,000 tons of 1975. This is net production produced for shipment and does not include silicomanganese produced for use as an intermediate in the same plant for the production of medium- or low-carbon ferromanganese. Silicomanganese shipments from furnaces were 132,000 tons, compared with 126,000 tons in 1975 and 192,000 tons in 1974. Six companies used nine plants to produce silicomanganese for shipment in 1976: Airco Alloys Div., Airco Inc., Calvert City, Ky., and Theodore (Mobile), Ala; Interlake Inc. (Globe Metallurgical Div.), Beverly, Ohio; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Co. (Englehard Minerals & Chemicals Corp.), Rockwood, Tenn.; Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W.Va., Marietta, Ohio, and Portland, Oreg. End-use consumption of silicomanganese—that is, consumption outside the ferroalloy plants—was 17.2% that of ferromanganese, compared with 18.2% in 1975 and 15.9% in 1974.

Spiegeleisen.—The New Jersey Zinc. Co. stopped its production of spiegeleisen at midyear. Production was from electric furnaces at Palmerton, Pa.

Pig Iron.—A total of 368,000 short tons of manganese-bearing ores containing 5% or more manganese (natural) was consumed in the production of pig iron (or its equivalent hot metal). Domestic sources supplied 237,000 tons, of which 191,000 tons was manganiferous iron ore containing 5% to 10% manganese, 33,000 tons was ferruginous manganese ore containing 10% to 35% manganese, and 13,000 tons was manganese ore containing 35% or more manganese that was apparently obtained from GSA through its program for disposal of stockpile excesses. Foreign sources supplied 131,000 tons, of which 1,000 tons was manganiferous iron ore and 130,000 tons was manganese ore containing 35% or more manganese.

Battery and Miscellaneous Industries.—The ore reported in table 3 includes that consumed in making synthetic manganese dioxide by both electrolytic and chemical means, but it does not include consumption of the synthetic dioxide. Although some synthetic dioxide is used for chemical purposes, most of it is used in the manufacture of dry-cell batteries, particularly for the manganese-alkaline type, premium or heavy-duty Leclanché (manganese dioxide-ammonium chloride-zinc) cells, and as a blend with natural ore in ordinary Leclanché cells.

The domestic ore and much of the foreign ore used for chemical and miscellaneous purposes did not meet national stockpile specification P-81-R for chemical-grade ore.

PRICES

Manganese Ore.—All manganese ore prices are negotiated. In addition to the manganese content, they are dependent on the chemical analysis otherwise, the physical character, quantity offered, delivery terms, fluctuating ocean freight rates, insurance, inclusion or exclusion of duties if applicable, needs of the buyer, and the general availability of ores that will fill these particular needs. Trade journal quotations reflect the paper's evaluation of the market. Contract prices for 1976 delivery of metallurgical manganese ore, having a minimum manganese content of 47% to 48%, ranged from $1.45 to $1.53 per long ton unit, c.i.f. U.S. ports. Because of large stocks in the hands of consumers and low demand, most contracts were not finalized before April. Normally they are signed in October or November of the preceding year.

Although spot purchases of ore were at one time a factor in the market, they were of little consequence in 1976 and immediately preceding years. Contracts for ore to be delivered in 1977 had not been negotiated by yearend 1976.

Manganese Alloys.—The published domestic producer price for standard high-carbon ferromanganese, having a minimum manganese content of 78%, was cut $15 early in January to $425 per long ton of alloy, and it remained at that figure for the remainder of the year. Quotes for imported alloy of the same grade dropped during the year from a range of $390 to $415, delivered in the Midwest, to $345 to $355 per long ton at yearend. Lower prices of the range, at least in the latter part of the year, were reported to be for large tonnages deliverable through 1977; the higher prices were for smaller spot tonnages. Lower grades of alloy reportedly brought even lower prices.

Manganese Metal.—In September, the price of standard and comparable grades of electrolytic manganese metal chips, packed in pallet boxes, increased by 4 cents to 58 cents per pound, f.o.b. producer plant, for shipments of 30,000 pounds or more. The bulk price continued to be 1 cent lower. These prices prevailed for the remainder of the year.

FOREIGN TRADE

Exports of ferromanganese totaled 6,789 short tons valued at $3,461,560, compared with 32,300 tons valued at $10,601,354 in 1975. Of the 1976 total, Canada took 3,346 tons; Sweden, 2,076 tons; West Germany, 828 tons; Mexico, 166 tons; Venezuela, 133 tons; the Dominican Republic, 121 tons; Brazil, 44 tons; Jamaica, 20 tons; Colombia, 15 tons; Bolivia and Guatemala, each 11 tons; Italy, 10 tons; Israel, 5 tons; Malaysia, 2 tons; and Chile, 1 ton. Exports classified as "manganese and manganese alloys, wrought or unwrought, and waste and scrap" totaled 4,654 tons valued at $3,433,918, compared with 3,256 tons valued at $3,318,322 in 1975. This classification includes electrolytic manganese metal and manganese-copper alloys, but it does not include ferromanganese. Exports of ore and concentrate containing more than 10% manganese amounted to 127,971 tons valued at $7,509,928, compared with 204,523 tons in 1975 valued at $13,886,100. Of the 1976 total, large quantities having relatively low average values were distributed as follows: Mexico, 34,000 tons; Norway, 22,000 tons; and Spain, 18,000 tons. For the most part, these tonnages appear to have been metallurgical ore obtained from GSA sales of Government excess stocks. Most of the remainder is believed to have been imported manganese dioxide ore that may or may not have been subjected to grinding, blending, or otherwise classifying in the United States.

The average grade of imported manganese ore was 49% manganese in 1976, the same as in 1975. Gabon supplied 41% in 1976; Brazil, 25%; Australia, 18%; and the Republic of South Africa, 10%. There were no imports of manganiferous ore (more than 10% but less than 35% manganese).

Table 7.—U.S. imports[1] of manganese ore (35% or more Mn), by country

Country	1975			1976		
	Gross weight (short tons)	Mn content (short tons)	Value (thousands)	Gross weight (short tons)	Mn content (short tons)	Value (thousands)
Australia	171,146	86,541	$8,443	234,636	117,367	$12,048
Brazil	633,076	307,367	30,012	333,479	161,108	18,033
Congo[2]	--	--	--	26,572	13,286	2,238
Gabon[3]	488,073	244,796	26,526	513,078	256,412	31,731
Mexico	52,327	23,171	1,724	39,831	18,485	1,994
Morocco	--	--	--	25,782	18,688	1,545
South Africa, Republic of	206,013	92,211	9,663	137,316	60,963	5,890
Zaire	23,410	11,444	735	6,118	2,936	148
Total	1,574,045	765,530	77,103	1,316,812	649,245	73,627

[1]Quantities for general imports and imports for consumption were identical.
[2]Actually from Gabon.
[3]In addition in 1976, Gabon imports reported as Congo were 26,572 tons (gross weight).

Ferromanganese imports for consumption increased 28% over the record high attained in 1974, or 35% over the 1975 tonnage. The Republic of South Africa, France, and Japan were the principal suppliers. Silicomanganese imports for consumption totaled 80,118 short tons containing 53,693 tons of manganese. Sources and gross weight tonnages follow: Norway, 31,825; Yugoslavia, 13,630; Brazil, 10,995; Spain, 6,646; Japan, 4,981; France, 3,472; Portugal, 3,362; the Republic of South Africa, 2,759; Mexico, 1,775; Canada, 578; Chile, 73; and Belgium, 22. Imports for consumption classified as unwrought manganese metal, except alloys, and metal waste and scrap totaled 7,082 short tons, compared with 4,378 tons in 1975. Of the 1976 total, 6,181 tons were from the Republic of South Africa, 483 tons from Japan, and 418 tons from Canada. It is most probable that the metal from Canada originated in the Republic of South Africa.

Imports for consumption classified as "manganese compounds, other" totaled 3,467 short tons, compared with 1,394 tons in 1975 and 3,086 tons in 1974. The sources, gross weights, and values per pound in 1976 follow: Japan, 2,796 tons (36 cents); Belgium, 458 tons (30 cents); the United Kingdom, 147 tons (4 cents); West Germany, 44 tons (75 cents); the Netherlands, 20 tons (31 cents) ;Ireland, 1 ton (49 cents); Brazil, 1 ton (32 cents); and Greece, 1/2 ton (37 cents). The imports from Japan, Belgium, the Netherlands, Ireland, Greece, and possibly Brazil appear to have consisted largely, if not entirely, of synthetic manganese dioxide. Manganese sulfate imports totaled 50 tons, of which 40 tons was from Belgium and 10 tons from Japan.

Tariffs.—Suspension of the duty on manganese ore from most nations, Rate 1, was extended another 3 years (through June 30, 1979) by Public Law 94-560. The suspended tariff remained at 0.12 cent per pound of contained manganese. The statutory rate continued to be 1 cent per pound of contained manganese, still applicable to ore of the U.S.S.R. and the People's Republic of China. The respective rates of duty for metal and the principal manganese ferroalloys remained unchanged. However, as of January 1, 1976, the United States accorded duty-free treatment under the Generalized System of Preferences (GSP) to imports of ferromanganese and silicomanganese from developing nations. A petition of The Ferroalloys Association to the Office of Special Representative for Trade Negotiations for relief from this action was rejected.

WORLD REVIEW

An agreement in principle was reached by subsidiaries of Lockheed Aircraft Corp. (Lockheed Missiles & Space Co., Inc.), Standard Oil Co. of Indiana (Amoco Minerals Co.), and Royal Dutch-Shell (Billiton International Metals B.V.) for a joint venture to develop technology for mining and processing deep-sea manganese nodules. It was expected that Lockheed would be the operator for the venture.

Algeria.—Deposits of manganese ore at Guettara, estimated to have an average manganese content of 45% to 50%, were deemed to be of sufficient size by Société Nationale de Recherche et d'Exploitation Minière (SONAREM) to warrant further investigation.

Australia.—Groote Eylandt Mining Co. Pty. Ltd. completed its planned expansion of capacity at its Groote Eylandt, Northern Territory, open pit mine to 2 million metric tons of shipping products per year and was giving consideration to further expansion in the near future if market conditions permit. The affiliated Tasmanian Electro Metallurgical Co. Pty. Ltd. (TEMCO) completed the first stage of its expansion program at its Bell Bay, Tasmania, plant with the installation of a 600-ton-per-day Lurgi sintering machine to be used for sintering Groote Eylandt fines for feed to its two furnaces that currently produce ferromanganese and silicomanganese. A new 27-megavoltampere (MVA) furnace, which will increase production of these alloys, was to come onstream before yearend. Any sinter excess to the company's own requirements will be exported.

Bolivia.—The Government of Bolivia decreed that all manganese ore and iron ore deposits belong to the state, and that companies operating concessions do so in accord with guidelines to be established by Empresa Siderúrgica Boliviana S.A. (SIDERSA), the Government-owned iron and steel company. Nonoperating concessions were canceled. SIDERSA engaged Arthur G. McKee Co., Cleveland, Ohio, to make a feasibility study of an integrated steel industry based on the iron-manganese deposit at Mutún, located about 19 miles south of Puerto Suarez, Santa Cruz, not far from the Urucum manganese deposits of Brazil. After some drilling, it appears that the San Pedrito manganese occurrence at Mutún is a lens of limited extent, less than 10 feet thick, at the base of the primary iron ore formation (Banda Alta). There are reported to be other manganese beds or lenses in the Banda Alta, but it is not clear as to what their significance might be. The Banda Alta primary iron ore formation is some 650 to 1000 feet thick. All manganese ore production will be for export under control of SIDERSA, with expectations for marketing 30,000 metric tons in 1977 to Argentina, West Germany, or Brazil. Hand mining of small deposits of manganese ore in the Western Cordilleras has been responsible for Bolivia's production of recent years, and this production is expected to continue with marketing also through SIDERSA. The ore occurs as pyrolusite filling of faults and fissures in rhyolitic beds.

Botswana.—The manganese deposit of the formerly worked Kgwakgwe mine area, south of Kanye, lies in a shale horizon with an upper zone, some 6 feet thick, of metallurgical ore and a lower layer consisting of a massive accumulation of battery-grade manganese nodules having a manganese dioxide content greater than 70%. This latter material has been almost exhausted, but more than 200,000 metric tons of the metallurgical ore is estimated to remain. The Otse deposit, near the southeast coast and associated with conglomerates and chert breccias overlying shales and quartzites, was being reinvestigated. The ore analyzes approximately 40% to 47% manganese dioxide. The deposit at the Lobatse mine area is of variable grade occurring in shales at the base of a quartzite horizon. It was formerly worked on both sides of the Transvaal border, and remaining reserves are thought to be small although the reef has a strike length of approximately 2 miles. Mining has also been done in the past in the same general region some 2 miles south of Ramotswa. The ore occurs in a friable sandstone horizon associated with quartzite, and reserves are not known. Farther north in the Chadibe and Tswapong areas there is a manganiferous sandstone horizon with a thickness of 3 to 6 feet, and grades estimated to vary between 30% and 60% manganese dioxide. The bed has not been systematically explored but has a total strike length of about 28 miles.[2]

Brazil.—Shipments of Amapá manganese ore by Indústria e Comércio de Minerios,

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the countries listed, Colombia, Cuba, and the Territory of South-West Africa may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels. Low grade ore not included in this table has been reported as follows in short tons: Czechoslovakia (about 17% Mn) 1974—1,072, 1975—1,101, 1976—1,212; Malaysia (grade unspecified but apparently a manganiferous ferruginous ore) 1974—93,985, 1975—146,947, 1976—103,741; Romania (about 22% Mn) 1974—155,000, 1975—155,000, 1976—155,000; the Republic of South Africa (15-30% Mn, in addition to material listed in table) 1974—98,769, 1975—123,131, 1976—56,178; Turkey (under 35% Mn, in addition to material listed in table) 1974—1,550, 1975—16,846, 1976—NA.

[2]Estimated on the basis of reported contained manganese.

[3]Exports.

[4]Figures are the sum of: 1) sales of direct shipping manganese ore, and 2) production of beneficiated ore, both as reported in the 1975 and 1976 editions of Anuario Mineral Brasileiro.

[5]Source: The National Economy of the U.S.S.R., Central Statistical Administration, Moscow. Grade represents the annual averages obtained from reported metal contents of the gross weights shown in the table.

[6]Of total 1973 output, 64% graded below 35% Mn and 36% exceeded that grade. Comparable production breakdowns for 1974-1976 are not available, but 71% of total 1974 exports of 1,140,453 short tons were below 35% Mn.

[7]Reported as if data are for calendar years, but may actually represent output for Iranian calendar years beginning March 21 of the year stated.

[8]May include some ore under 35% Mn (see footnote 1).

S.A. (ICOMI) were 1,047,000 metric tons, including 149,300 tons of pellets, in 1976 compared with 1,254,055 metric tons, including 100,509 tons of pellets, in 1975. The 1976 shipments were loaded out to export and domestic markets in 59 vessel cargoes, with those for export going to 15 countries besides the United States: Argentina, Belgium, Canada, Chile, Czechoslovakia, England, France, Germany, Greece, Italy, Japan, the Netherlands, Norway, Romania, and Spain.[3] Domestic sales in 1976 were approximately 120,000 tons.

In April, a new company, Urucum Mineração S.A., was formed to mine the Urucum manganese ore deposit near the Bolivian border in the Corumba area of the State of Mato Grosso. The Government-owned Cia. Vale do Rio Doce S.A. (CVRD), the State-owned Cia. Matogrossense de Mineração (METAMAT), and the privately owned Cia. Vale do Paraupeba (Alcindo Vieira group), each held one-third interest. The ore was previously mined by SOBRA-

[3]Skillings' Mining Review. V. 66, No. 11, Mar. 12, 1977, p. 21.

MIL, a company in which United States Steel Corp. had a substantial interest, but there has been no mining since 1972. Before the deposits can be fully developed, problems of transportation and of high alkali and high phosphorus content must be overcome. Output was expected to be for both domestic consumption and export with mining to start before yearend.

Cia. Paulista de Ferro-Ligas, a ferroalloy producer headquartered in São Paulo, was readying a new plant at Corumba for production of ferromanganese from Urucum ore by mid-1977. The plant will use two 4-MVA furnaces in a two-step process expected to solve the high-phosphorus, high-alkali problem, while producing 24,000 metric tons per year of high-carbon ferromanganese and silicomanganese. Approximately half of the production will be for export. Company plans also propose two similar furnaces to begin producing ferromanganese and silicomanganese at Macapa, Amapá, by the end of 1977. The annual capacity of this plant would be 24,000 tons, also.

In June, Construtora Alcindo Vieira—CONVAP S.A. (CONVAP), a Brazilian contracting company, together with METAMAT formed a new company, Cia. Matogrossense de Ferro-Ligas (FERMAT), with plans to install five 20-MVA furnaces by 1982 in a new plant at Três Lagoas, near the Jupiá hydroelectric plant northwest of São Paulo at the eastern boundary of the state of Mato Grosso. Plans called for the first two furnaces to begin production of high-carbon ferromanganese and silicomanganese from Urucum ore in 1981, half for domestic consumption and half for export. Research was conducted in 1976 on the best metallurgy to use on the iron-rich, high-alkali Urucum ore.

France.—Société Française d'Électrométallurgie (SOFREM), a subsidiary of Pechiney Ugine Kuhlmann, brought onstream new capacity for production of low- or medium-carbon ferromanganese, in the amount of 12,000 metric tons per year, at its St. Beron plant in southeastern France (Savoie). This brought SOFREM's total productive capacity for manganese ferroalloys to 60,000 tons per year.

Gabon.—All of the metallurgical manganese ore produced at Moanda by Cie. Minière de l'Ogooué (COMILOG) was for export, with the United States taking 42%, France 22%, and Japan 12%. West Germany and the United Kingdom were other major customers. United States Steel Corp. was COMILOG's principal shareholder with 44% interest; Gabonese interests, either principally or entirely as the Government, held 10% or 11%; and the remainder was held by the French Government's mining exploration company (BRGM), the French mining group Mokta, and interests of the Banque de Paris et des Pays-Bas (PARIBAS). Negotiations were conducted with the Congolese transportation authorities to improve the Congo-Ocean Railway's portion of the present route that the ore must take for export; that is, via the Congolese port of Point Noire. In the meantime, work began on construction of the Transgabon Railroad, expected to reach Moanda by the end of 1980. This will provide an all-Gabon route, permitting exports of 4 to 4.5 million tons per year by this route alone by the late 1980's via Gabon ports near Libreville. Société Gabonaise de Ferro-Alliages (SOGAFERRO) was formed with the objective of constructing a manganese ferroalloy plant near Moanda, dependent on completion of the railroad and expansion of the present hydroelectric installation at Poubara by construction of a large new dam, Grand Poubara. Feasibility studies were underway for both the dam and the ferromanganese projects, with thinking for the latter in terms of a plant to produce 85,000 tons of ferromanganese and 50,000 tons of silicomanganese per year. COMILOG held a 15% interest in SOGAFERRO; Japanese interests 25% (Okura Trading, Nippon Kokan K.K., and Nippon Denko K.K.); Union Carbide Corp, 10%; and the Gabon Government, 10%; the remainder was divided among French (Aciers de Paris), Norwegian (Elkem), Belgian (SADACEM), and Italian (Tassara) firms. In addition to being exported, Moanda's battery ore is consumed locally in the dry-cell plant of SOGAPIL, which produces 6 million dry cells annually for the Gabon market and for export. Another company, SOGADEMA, has been formed by COMILOG, or affiliates, together with United States and Belgian interests, to use manganese derivatives in the manufacture of glass and pharmaceutical products in the Moanda area.[4] Battery- and chemical-grade ore produced in 1976 totaled 65,000 metric tons. This ore is obtained by selective mining; it is not a separate ore body. The deposit is essentially horizontal, and manganese carbonates underlie the oxide ore.

---

[4]Wall Street Journal. Gabon Pursues Its Ambitious Development Program. V. 188, No. 61, Sept. 29, 1976, p. 23.

Ghana.—Both battery-grade and metallurgical-grade oxide ore continued to be produced. Nationalization of manganese mining operations was completed in 1975, and mining continued by Ghana National Manganese Corp. Manganese exports in 1976 were approximately 350,000 tons, of which roughly 150,000 tons was carbonate ore and 200,000 tons was oxide, mostly metallurgical, ore. Battery ore exports all went to the United Kingdom. Carbonate ore went to synthetic dioxide plants in Japan and Ireland, and to electric furnace ferromanganese plants in Norway, Portugal, and elsewhere, where it was used to make up about 15% of the charge to the furnaces. It appears that the oxide ores will be exhausted within the next 5 years. Reserves of carbonate ore, a grayish mixed carbonate, were estimated from drilling to amount to 20 million tons averaging 30% manganese.

Greece.—Exports of pyrolusite in 1975 were 1,900 metric tons, of which 1,600 tons went to West Germany and 300 tons went to other countries.

Hungary.—Reserves of oxide ore occur in the Urkút area. Carbonate ore reserves are located at Urkút, Eger, and Demjen, but production of this ore was very limited for lack of technology to use it economically.[5] Ore produced in 1975 averaged about 27.8% manganese content.

India.—During the period 1968 through 1974, 88.5% of the manganese dioxide consumed in India was for the manufacture of dry-cell batteries, 8.5% went to the chemical industry, 1.6% to paints, 0.9% to glass, and the remaining 0.5% to the electrode, foundry, and ceramic industries. A total of 16,600 metric tons was consumed in 1974, of which 2,240 tons was electrolytic manganese dioxide. Preliminary production figures for manganese dioxide ore in 1975 totaled 11,700 tons, of which 4,400 tons came from Maharashtra and the remainder from Orissa. Imports of 4,800 tons in the first half of 1975 came from Gabon. For batteries, the imported ore is usually blended with the domestic ores, and supply of the latter of suitable character was a problem.

The only producer of electrolytic (synthetic) manganese dioxide in 1976 was Electrolytic Manganese Co., Division of Union Carbide India Ltd, Thana, Maharashtra, with licensed capacity of 2,500 tons and production in 1974, 1973, and 1972 of 2,229, 1,479, and 1,600 tons, respectively. Four other firms have received letters of intent or industrial licenses for its manufacture at annual capacities ranging from 1,000 to 4,000 tons, but it was doubted that any of these proposals could contribute to supply within the next 3 or 4 years.[6]

The average pit head price for manganese ore produced in 1976 was $8.07 per metric ton, compared with $7.61 in 1975. In February 1976, 182 mines reported production. Central Provinces Manganese Ore Co. Ltd. continued to hold 49% interest in Manganese Ore India Ltd. (MOIL) with the remaining ownership held by the Government of India and the State governments of Maharashtra and Madhya Pradesh. Developments suggested that MOIL would become a fully-owned public sector company before the end of 1977. Based at Nagpur, Maharashtra, it operated five mines in Maharashtra and three in Madyha Pradesh. One of the latter, the Balaghat mine 120 miles northeast of Nagpur, is the largest manganese mine in India with three steeply dipping ore zones, six levels, and a 600-foot shaft, annually producing approximately 75,000 tons of ore. Only about 55% of the manganese contained in the deposit is recovered in the concentrate shipped, but it has been estimated that additional milling facilities might improve this to 75%.

Manganiferous ore containing 30% to 35% manganese was used in the blast furnaces of the Durgapur, Bhilai and Bokaro steel plants at a rate of 50 kilograms per ton of hot metal produced; the rate at the Rourkela plant was nearly 150 kilograms per ton.

Indonesia.—All manganese ore produced in 1976 came from West Java or Central Java, and almost all was of battery grade, which was used domestically or exported to Japan.

Ireland.—The electrolytic manganese dioxide plant of Mitsui Denman (Ireland) Ltd. started production in February and by mid-July was operating at 70% of its capacity of 12,000 tons per year. The Irish Government has a 5% equity interest in the plant with the balance held by Mitsui Mining & Smelting Co., Ltd, Tokyo, and Mitsui & Co., Ltd., Tokyo. All production will be for export.[7]

[7]LeCerf, B. Mitsui's Manganese Refinery In Ireland Hits 70% Capacity. Am. Metal Market, v. 83, No. 139, July 16, 1976, p. 23.

Italy.—Mining of manganese ore ended in 1975 with exhaustion of Italsider's Gambatesa mine in Genoa Province.

Japan.—Production of ferromanganese in 1976 was 632,000 metric tons; silicomanganese, 373,000 tons; electrolytic manganese metal, 6,752 tons; and synthetic manganese dioxide, 32,540 tons. The manganese ore produced in 1976 had an average manganese content of 27.3%, except for 17 tons of dioxide ore having a manganese dioxide content of 65%.

Mexico.—In September, Cía. Minera Autlán S.A. de C.V., brought the first of its manganese ferroalloy furnaces onstream at its new plant at Tamos in the municipal district of Pánuco, State of Veracruz, 12 miles from Tampico.

Morocco.—The manganese ore produced in 1975 was chemical-grade ore or concentrate with an average manganese dioxide content of 83%.

New Hebrides.—Manganese ore (concentrate) produced and exported in 1975 had a minimum guaranteed manganese content of 40%, and the exports were estimated to run about 43%.

Norway.—Production of ferromanganese was 354,000 metric tons in 1976 and 331,000 tons in 1975; silicomanganese production was 173,000 and 200,000 tons, respectively.

Peru.—The manganese ore produced in 1975 had a manganese content of 37.5%. That produced in 1974 averaged 36.2% manganese (previously reported provisionally as 31% manganese).

Philippines.—An average manganese content of 44% to 45% was reported for the manganese ore produced in 1976.

Portugal.—Manganiferous iron ore produced in 1976 totaled 17,870 metric tons averaging 40.7% iron and 8.5% manganese.

South Africa, Republic of.—Production of electrolytic manganese metal in 1976 was 32,750 metric tons, almost equally divided between Delta Manganese (Pty.) Ltd. (DELTA) at 16,500 tons and Electrolytic Metal Corp. (Pty.) Ltd. (EMCOR) at 16,250 tons. Manganese-bearing effluents from the processing of uranium ores were originally used as the raw material for South Africa's electrolytic manganese metal industry. However, because of cobalticyanide impurities and other problems peculiar to use of this manganese source, it was decided in 1968 to use ore from northern Cape Province in spite of its high iron content of 10% to 12%. Normally low-iron ores, 1% to 2% iron, are used in the electrolytic production of the metal. Consequently, some changes were necessary in order to adapt to this ore. The resulting Delta flow sheet has four main components: 1) Reduction of the manganese in the ore from valence 4 to valence 2 to make it readily soluble in sulfuric acid; 2) reverse leaching in spent sulfuric acid electrolyte to minimize solution of iron; 3) purification of the leach solution; and 4) electrolysis of the purified solution. Electrolytic manganese metal production's overall efficiency is 68%, compared with 98% for copper. The South Africans claim to be the lowest cost electrolytic manganese metal producers, but recent and projected electric power costs could change this position. Power costs constitute approximately 25% of total production costs. Because use of the argon-oxygen process for the production of stainless steel allows the use of high-carbon ferromanganese instead of the electrolytic metal normally used in production of stainless steel, and use of this process is growing, the outlook for growth in demand for electrolytic manganese metal has shifted to an expanding use in aluminum resulting from growing popularity of the all-aluminum beverage can, containing 1% to 1.2% manganese, and to the high-strength low-alloy steels used in high-rise buildings and in large-diameter pipe lines for Arctic areas.[8] South Africa's production capacity for electrolytic manganese metal at the end of 1976 was 35,000 metric tons, divided equally between the two companies.

Northern Cape Province ores are of four general types: 1) In the Western and Eastern Belts of the Postmasburg field, brecciated unconsolidated ore and replacement bodies associated with dolomite karst topography; 2) in the Western Belt of the Postmasburg field, replacement of Gamagara shale closely associated with dolomite; 3) at Rooinekke, replacement and surface enrichment of banded iron formation and flagstone in the uppermost succession of the Dolomite Series; and 4) in the Kalahari (Kuruman) field, syngenetic deposits with three horizons of manganese oxides in banded iron formation near its base, the iron formation overlying Ongeluk lava and containing a band of calcareous dolomite in its upper portion. Low-grade metamorphism has transformed the manganese occurrences of the Postmasburg and Kalahari

fields into hard, compact ores consisting mainly of braunite and bixbyite with minor quantities of hausmannite, jacobsite, todorokite, manganite, etc.[9]

Marble Lime & Associated Industries, Ltd. was reported to have sold its Gopani manganese mine for approximately $138,000 to Rand Corp.[10] —apparently Rand London Manganese Mines (Pty.) Ltd., a subsidiary of Rand London Corp. The Gopani mine, located near Zeerust, Transvaal, is an underground producer of battery grade (plus 65% manganese dioxide) and uranium-grade (plus 40% manganese dioxide) ore. It has a long-term contract to supply uranium-grade ore to the Rossing Uranium operation in the Territory of South-West Africa (Namibia). Anglo-American Corp. of South Africa Ltd. began development of an underground manganese ore mine at the Middleplaats deposit northwest of Kuruman. Substantial reserves averaging 38% manganese were indicated, together with a large tonnage of lower grade material that might be recoverable. The ore lies approximately 1,300 feet below the surface. It was planned to produce annually, by mechanical methods, 900,000 metric tons of metallurgical-grade ore and 200,000 tons of lower grade ferruginous ore.

Highveld Steel and Vanadium Corp., Ltd., a subsidiary of Anglo-American Corp. of South Africa Ltd., in July acquired a 65% equity interest in Transalloys (Pty.) Ltd., a manganese ferroalloy producer with a plant adjacent to Highveld's steel plant. Equipment at the Transalloys plant included two smelting furnaces for silicomanganese and two melting furnaces for medium-carbon ferromanganese. An additional large smelting furnace for production of silicomanganese was under construction with completion scheduled for mid-1977. Transalloys is an important supplier to Highveld as well as an exporter. Increasing power costs were adversely affecting its competitive position in world markets, although its sales were reported as satisfactory for the last half of 1976.

Production of the various grades of ore in 1976 and 1975 follow, in metric tons (1975 in parentheses): Metallurgical ore— 30% to 40% manganese, 3,358,000 (3,872,000); 40% to 45%, 209,000 (233,000); 45% to 48%, 1,517,000 (1,379,000); over 48%, 270,000 (199,000); chemical ore—35% to 65% manganese dioxide, 95,000 (79,000) tons; 65% to 75%, 3,000 (7,000) tons. Production of ferruginous manganese ore containing 15% to 30% manganese and 20% to 35% iron was 51,000 tons in 1976 and 112,000 tons in 1975. Local sales of the various grades of ore in 1976 and 1975 follow (1975 in parentheses): Metallurgical ore—30% to 40% manganese, 1,135,000 (1,013,000); 40% to 45%, 60,000 (34,000); 45% to 48%, 460,000 (517,000); over 48%, 20,000 (zero); chemical ore— 35% to 65% manganese dioxide, 82,000 (78,000); 65% to 75%, 3,000 (9,000). Local sales of ferruginous ore were zero in both years. Similarly, exports for the 2 years follow: Metallurgical ore—30% to 40% manganese, 2,015,000 (2,076,000); 40% to 45%, 51,000 (70,000); 45% to 48%, 1,258,000 (1,174,000); over 48%, 123,000 (82,000); chemical ore—35% to 65% manganese dioxide, zero both years; 65% to 75%, estimated 215 (1,000); ferruginous ore—estimated 295,000 (238,000).

Spain.—Approximately 60% of the labor force at Hidro Nitro Española's ferromanganese plant at Monzon went on strike December 17 over pay rates.[11] In 1976, the company produced 32,000 metric tons of ferromanganese and 36,000 tons of silicomanganese. Production in 1975 was 29,000 and 34,000 tons, respectively.[12]

Thailand.—Production of battery-grade manganese ore (75% manganese dioxide) in 1976 was 3,000 metric tons, while exports were 1,000 tons. Chemical ore production (75% manganese dioxide and up) was 130 tons with no exports. The metallurgical ore produced was reported to range in manganese content from 46% to 50%; exports were 42,000 tons, compared with 23,000 tons in 1975.

U.S.S.R.—The contract for the previously proposed large new high-carbon ferromanganese plant was awarded to Japan's Tanabe Kakoki over the bids of United States, Norwegian, and West German firms. Six fully sealed 75,000-kilovoltampere furnaces will have shell diameters in excess of 15 meters; each will use three 2-meter electrodes.[13] The 1976 delivered price of $34.25 per metric ton for ferruginous manganese ore containing 28% to 29% manga-

nese was agreed to by Soyuzpromexport and Japan's Nippon Kokan for 1977 delivery of 100,000 metric tons with buyer's option for an additional 50,000 tons.[14]

The Ordzhonikidze Complex (Kombinat) in the Nikopol' basin of the Ukraine, producing approximately 4.3 million tons of concentrated shipping products per year, has seven open pits, three beneficiating plants, and one sintering plant. Roughly 55% to 60% of the concentrates were used in the U.S.S.R., and the remainder was exported to other East European countries. The ore occurs as a gently south-dipping sedimentary bed up to 10 feet thick—carbonates on the south grading into oxides on the north—lying under 160 to 260 feet of overburden consisting of rich black topsoil above layers of clay, loess, sands, shells, and in some places limestone. Large bucket-wheel excavators in conjunction with extensive systems of portable and fixed conveyors remove the overburden, stacking the respective materials in separate piles for subsequent blending in the reclamation operations. Average thickness of the ore mined in the north pit in 1973 was 6 feet; ratio of overburden to ore was 27 cubic yards per ton. The ore has an average manganese content of 25% and is all beneficiated to two products for shipment: First class, with a manganese content of 45% to 50%, for the production of manganese ferroalloys; and second class, containing 35% to 38% manganese, for use in iron blast furnaces. Heavy media and flotation methods are employed, and 80% of the manganese in the ore is recovered. The tailings, which contain 20% manganese, are saved, and plans call for their later recovery in an electrolytic manganese metal plant to be built before 1980. The land is reclaimed, not to its original contour but improved for present and future agricultural, recreational, and aesthetic needs. This involves the management of some 260 million cubic yards of displaced material per year. With the aid of agronomists and much research since 1962, better agricultural yields have been obtained for a variety of crops than were had before mining.

United Kingdom.—In 1975, 85,000 metric tons of ferromanganese and 100 tons of spiegeleisen were produced, compared with 83,000 and 8,000 tons, respectively, in 1974.

Yugoslavia.—Production of ferromanganese in 1974, 1973, and 1972 was 23,000, 19,000, and 19,000 metric tons, respectively; similarly, silicomanganese production was 17,000, 12,000, and 15,000 tons. The only producer was Tvornica Elektroda I Ferolegura, in Croatia.

Zaire.—The Kisenge deposits in southwestern Shaba are almost vertical lenticular deposits of primary, very hard manganese carbonate ore, having a manganese content of 30%, oxidized to the enriched, also very hard, oxide ores analyzing up to 57% manganese. Although the tonnages of carbonate ore mined have been small, consideration was being given to their greater utilization. There were four open pits—Kisenge, Kamata Principale, Kamata Rive Gauche, and Kapolo—aligned along an east-west axis over a distance of 10 kilometers. Extraction of the ore has required the removal of twice as much overburden, by volume, as ore. Bucyrus-Erie shovels and Euclid trucks, working one shift per day, annually send 500,000 tons of oxide ore to the washing plant where the ore is crushed, washed free of clay and talc, sized into two fractions by screening or elutriation, and the fines further classified into two fractions.[15]

Although no manganese ore was shipped in 1976 owing to continued closure of the Benguela Railroad since August 1975, Zaire's only manganese producer, Société Minière de Kisenge (SMK), continued to mine and stockpile the ore at Kisenge, operating by means of a monthly subsidy from the Government of Zaire. The stockpile was estimated to contain approximately 550,000 tons of ore by yearend, roughly representing 2 years of production.

TECHNOLOGY

The Bureau of Mines extended its research on manganese-copper damping alloys from the cast alloys to powder metallurgy consolidations. Damping capacity was enhanced, and potential savings in material and labor were suggested. Strength and ductility were considerably lower, however, than for comparable cast alloys.[16]

The Panel on Manganese Recovery Technology of the Committee on Technical

[14]Metals Week. V. 48, No. 4, Jan. 24, 1977, p. 6.

[15]Elima (Lubumbashi, Zaire). L'exploitation du manganèse au Zaire. Feb. 5, 1975, pp. 2-4. (From Bulletin No. 9, Institut de Gestion du Portefeuille, Lubumbashi, Zaire, January 1975.)

[16]Holman, J. L., and L. A. Neumeier. Proc. 5th Internat. Powder Met. Conf., Chicago, Ill., June 27-July 3, 1976, pp. 1-25.

Aspects of Critical and Strategic Materials, National Materials Advisory Board, National Research Council/National Academy of Sciences, assessed the present technology for recovering and processing manganese from domestically available resources. It concluded that the two land-based domestic resources best suited for development on a significant scale were the Cuyuna deposits of Minnesota and the Aroostook deposits of Maine; also, that the deep-sea nodule deposits, particularly some in the Pacific Ocean, were a very important potential source of manganese and that the lower grade Atlantic Ocean deposits of the Blake Plateau might be considered to be domestically available. The most feasible manganese recovery processes were considered to be the ammonium carbamate process and the sulfur dioxide roast (high-temperature differential sulfatization) process. In both cases, however, "Questions concerning performance, cost, and environmental impact remain to be resolved" even though extensive development work has been done in the past at scales of 200 and of 2 tons of ore per day, respectively.[17]

Factors to be considered in the selection of a suitable mine site for recovery of ocean floor manganese nodules follow: Nodule population—the percentage of the sea floor covered by visible nodules; nodule concentration—the weight per unit area, a function of population, size, shape, and specific gravity; nodule assay—many published analyses are too high because the barren core was not included in the material analyzed; bathymetry—water depth; topography of the sea floor; geotechnic data—bearing strength of the floor; environmental data; and ecological requirements.[18] Although the nodules typically lie only on the surface, some nodule layers are buried a few centimeters in the sediments. These sediments in great part are quite weak, but they can change quickly to firm. A difficult decision to be made for the nodule-collecting machinery and operation is the trade-off between velocity and collecting width; 3 kilometers per hour and a width greater than 10 meters are a likely optimum.[19]

In a discussion of the past, present, and future role of manganese in the production of steel, it was concluded that the declining use of manganese as a desulfurizer and deoxidant, as a result of improvements in steelmaking techniques, was being countered by a growing realization of the importance of manganese as an alloying element in itself.[20]

The Carpenter Steel Div., Carpenter Technology Corp., made commercially available its patented 18-18 Plus stainless steel, containing approximately 18% manganese and 18% chromium. Yield strength is twice that of Type 304 stainless, and corrosion resistance is similar to that of Type 316 in most applications. Prices approximated those of Type 316 products[21]

Continuous production of "Massive Manganese" is accomplished by Chemetals Div., Diamond Shamrock Corp., by its patented fused-salt electrolytic process. The product is in lump form, and the regular grade typically analyzes 93% manganese, 6% iron, 0.14% carbon, 0.15% silicon, 0.16% phosphorus, and 0.02% sulfur; the high-purity grade analyzes 98% manganese, 1.8% iron, 0.12% carbon, 0.06% silicon, 0.01% phosphorus, and 0.02% sulfur. The reduction cell used resembles that used to produce aluminum by the Hall process. Feed typically consists of manganous oxide in the form of a reduced ore, fluorspar (CaF_2), and calcium oxide (lime), with CaF_2 making up at least 50% by weight of the fused electrolyte. The operating temperature is approximately 1,300° C, and the melt is removed by tapping in much the same manner as an open hearth melting furnace is tapped.[22]

Mercury

By Harold J. Drake[1]

U.S. mine production of mercury in 1976 totaled 23,133 flasks[2] valued at an estimated $2.8 million. Production was reported from seven mines, five in California and two in Nevada. Production tripled for the second consecutive year, primarily because output at the new McDermitt mine in Nevada nearly reached design capacity.

Secondary production continued to decline and totaled 3,363 flasks including 520 flasks sold by the General Services Administration (GSA).

Consumption rose 28% to 64,870 flasks. The advance was led by sharply increased demand for use in electrical apparatus, which was accompanied by increases in demand for use in catalysts, chlorine and caustic soda production, industrial and control instruments, and mildew-proofing paints. Declines were reported for dental preparations and pharmaceuticals.

Producer, consumer, and dealer stocks continued to rise and by yearend totaled 31,734 flasks, a level 24% above that at yearend 1975. Producer stocks nearly doubled, while consumer and dealer stocks rose about 7%.

Prices declined through the first 8 months of 1976, but rose thereafter and finished the year at $135 per flask in New York and $103 per flask in London. The monthly average flask price in New York was $121.25, compared with $158.12 in 1975. Comparable figures for London were $91.97 and $130.11, respectively.

Exports and reexports totaled 513 flasks, compared with 494 flasks in 1975. Imports for consumption increased slightly to 44,415 flasks, a level that accounted for 68% of the U.S. market for mercury. Algeria, Italy, Yugoslavia, Spain, and the People's Republic of China were the principal sources of imported mercury.

World production in 1976 totaled 243,987 flasks, compared with 252,429 flasks in 1975. Producers in Italy, Spain, and the U.S.S.R. reportedly discontinued sales of mercury in 1976; concomitantly, Italian and Mexican producers sharply curtailed or completely shut down mercury mining operations. Canadian mining operations, suspended in 1975, did not reopen in 1976. An international association of mercury producers reportedly met intermittently during 1976.

Legislation and Government Programs.—The Government, through the Office of Minerals Exploration, U.S. Geological Survey, is authorized to loan up to 75% of approved costs for mercury exploration, but no new funds were available for contracts in 1976. GSA offered for sale 500 flasks of mercury monthly during 1976 but sold only 520 flasks.

In December 1975, an administrative law judge for the Environmental Protection Agency (EPA) ruled that phenylmercurials could be used in latex paint products and certain other products but not in oil-based paints. The ruling ended nearly 4 years of administrative proceedings, including hearings, which began when EPA attempted to cancel registrations of all biocides containing mercury but met legal challenges from biocide producers. EPA placed a ban on all mercury-containing biocides. Pesticide producers again challenged the ban and EPA postponed the ban first to June 30, 1976, and then to November 30. A final settlement was reached in August which provided for the use of mercury in water-based paints and other coatings and the temporary use of mercury biocides to treat

[1]Physical scientist, Division of Nonferrous Metals.
[2]Flask as used throughout this chapter refers to the 76-pound flask.

summer golf turf diseases and certain farm seeds until August 31, 1978, or whenever the equivalent of 2 years production of the latter biocides is attained. Use of mercury-based biocides on winter golf turf diseases under strictly controlled conditions was also allowed by EPA.

Congress took no action on authorizing the release of surplus mercury in the strategic stockpile. At yearend, the stockpile contained 191,407 flasks. GSA established a new goal of 54,004 flasks, leaving 137,403 flasks available for disposal.

DOMESTIC PRODUCTION

Production of primary mercury totaled 23,133 flasks in 1976 compared with 7,366 flasks in 1975. Only six mercury mines reported production: the Oat Hill, the Aetna, the New Almaden, the Knoxville, and the Manhattan-One Shot in California, and the McDermitt in Nevada. Byproduct mercury was produced at a gold mine in Nevada. The sharply increased output of primary mercury was accounted for by the new McDermitt mine in Nevada. Startup problems at the mine's ore-processing facilities were resolved by the end of 1975, and full-scale production was achieved throughout most of 1976.

The average grade of all ore processed in 1976, including ore processed at concentrators, increased to 9.5 pounds of mercury per ton. The increase in the grade of ore was accounted for by the McDermitt mine.

Production of secondary mercury, exclusive of GSA sales, amounted to 2,843 flasks, 62% below that of 1975. Most of the decline in secondary production was due to the low price of mercury, which made it cheaper to buy mercury by the flask than to process scrap into usable mercury. Major sources of secondary mercury were industrial and control instruments, batteries, sludges, and dental amalgams.

Year	Ore treated (short tons)	Mercury produced: Flasks	Mercury produced: Pounds per ton of ore
1972	82,580	[2]7,004	6.5
1973	26,257	[2]2,101	6.1
1974	28,858	[2]1,680	4.4
1975	76,772	6,905	6.8
1976	185,103	23,042	9.5

[1]Excludes mercury produced from old surface ores, dumps, and placers, and as a byproduct.
[2]Includes mercury contained in concentrate for export.

Table 4.—Production of secondary mercury in the United States

(Flasks)

Year	Industrial production	GSA releases	Total
1972	12,139	512	12,651
1973	7,746	2,583	10,329
1974	5,940	2,353	8,293
1975	7,538	500	8,038
1976	2,843	520	3,363

CONSUMPTION AND USES

Consumption, reversing a decline in 1975, resumed the upward trend of recent years and increased 28% from the 1975 level to 64,870 flasks. Of the major uses, electrical apparatus rose 62% to 27,498 flasks, and mildew-proofing paint rose 13% to 7,845 flasks. Use in the production of chlorine and caustic soda rose 5% to 16,054 flasks, and use in industrial and control instruments rose 10% to 5,067 flasks. Other unspecified uses, in the aggregate, rose 66% to 2,909 flasks. Other major changes were dental preparations, down 15%; and catalysts, up 51%. Use in pharmaceuticals fell sharply, from 445 flasks in 1975 to 60 flasks in 1976.

Of the 64,870 flasks consumed in 1976, 78% consisted of primary mercury, 19% was redistilled mercury, and 3% was secondary mercury. Primary mercury was used throughout the whole range of applications, while redistilled mercury was used primarily in electrical apparatus, industrial and control instruments, and dental preparations. Secondary mercury was used mainly in industrial and control instruments, electrical apparatus, dental preparations, and catalysts.

Table 5.—Mercury consumed in the United States, by use

(Flasks)

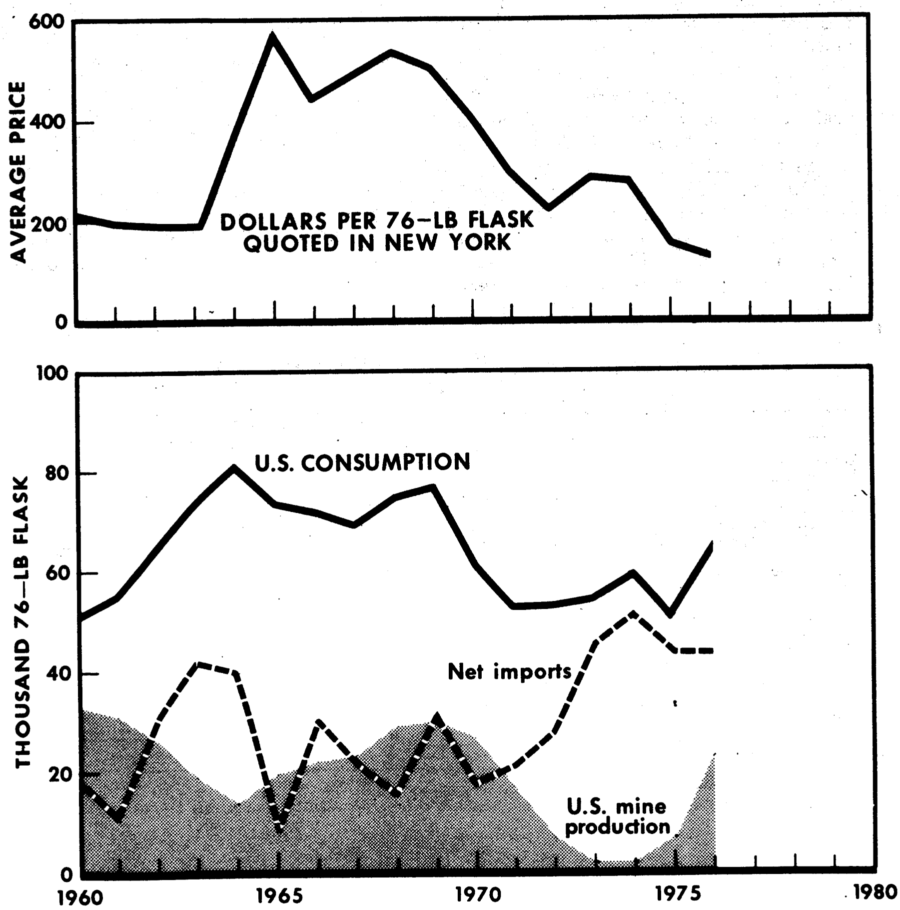

Figure 1.—Trends in production, consumption, and price of mercury.

Table 7.—Stocks of mercury, December 31

(Flasks)

Year	Producer	Consumer and dealer	Total
1972	4,171	11,537	15,708
1973	3,927	14,019	17,946
1974	4,100	15,777	19,877
1975	4,858	20,691	25,549
1976	9,494	22,240	31,734

STOCKS

Stocks of mercury at yearend 1976 totaled 31,734 flasks, compared with 25,549 flasks at yearend 1975. Producer stocks were up sharply from 4,858 flasks at yearend 1975 to 9,494 flasks at yearend 1976. The increase in producer stocks was accompanied by an increase of 1,549 flasks to 22,240 flasks held by consumers and dealers.

PRICES

Prices of primary mercury rose in the early part of 1976 but fell back during the middle months before resuming the rise in September. On January 8, 1976, the New York price of mercury was $116 to $122 per flask, compared with $132 to $135 per flask on December 28, 1976. The average monthly New York price was $121.25 per flask in 1976, compared with $158.12 per flask in 1975. The London price showed similar fluctuations. At the beginning of 1976 the London price was $80 to $85 per flask, compared with $104 to $110 per flask at yearend 1976. The average annual London price was $91.97 per flask in 1976, compared with $130.10 per flask in 1975. The national and international price increases late in 1976 were attributed to the reported discontinuance of mercury sales by Italy, Spain, and the U.S.S.R. and to reduction in output by producers in Mexico.

Table 8.—Average monthly prices of mercury at New York and London

(Per flask)

	1975		1976

FOREIGN TRADE

Exports of mercury totaled 501 flasks valued at $306,000, compared with 339 flasks valued at $152,000 in 1975. Reexports totaled 12 flasks valued at $6,000 in 1976.

Imports for consumption increased 1% in quantity but declined 43% in value to 44,415 flasks valued at $4.3 million. The average unit value for the year was $97.38 per flask, compared with $173.24 per flask in 1975. The share of the U.S. market for mercury supplied by foreign countries amounted to 68%.

Italy continued to raise exports to the United States, and recorded a 79% increase in 1976 to 13,172 flasks valued at $1.2 million to become the largest foreign supplier of mercury. Imports from Algeria, the next largest supplier, rose 10% to 10,248 flasks valued at $1.1 million, while imports from Yugoslavia, the third largest source, rose 55% to 6,739 flasks valued at $658,000. Imports from Spain rose 5% to 4,824 flasks valued at $461,000. Imports from Canada, which in past years accounted for the largest share of imports, fell drastically to 2,853 flasks valued at $249,000 as a result of the cessation of mercury-mining operations in Canada. The People's Republic of China in 1976 became a significant exporter of mercury to the United States when its shipments reached 4,353 flasks valued at $360,000. Shipments from Mexico, another major source of imported mercury in past years, continued to decline and reached 1,719 flasks valued at $137,000 in 1976.

Imports from the principal supplying nations in the Western Hemisphere (Canada, Mexico, Peru, and the Philippines) in the aggregate, continued to decline, and totaled 4,872 flasks in 1976 compared with 16,129 flasks in 1975. Conversely, imports from the other principal suppliers (Algeria, Italy, Spain, and Yugoslavia) in the aggregate, rose during this time from 21,832 flasks in 1974 to 25,547 flasks in 1975 and 34,983 flasks in 1976.

The U.S. rate of duty on mercury imports during 1976 was 12.5 cents per pound ($9.50 per flask) with the duty on waste and scrap suspended until June 30, 1978. This rate applied to imports from market economy countries. The statutory rate of 25 cents per pound ($19 per flask) applied to centrally controlled economy countries.

1975	339	152	155	$68
1976	501	306	12	6

WORLD REVIEW

World production of primary mercury declined 3% to 243,987 flasks in 1976. Although demand increased during 1976, large inventories throughout the world acted to reduce production and to moderate the upward movement of prices late in the year. An international organization of mercury producers reportedly met intermittently during 1976 mainly to review the mercury situation and try to bolster prices.

Canada.—Canadian mining operations, suspended because of low prices in 1975, did not reopen in 1976. Exports of inventory mercury continued in 1976, but by yearend these stocks were believed to be exhausted.

China, People's Republic of.—Production of mercury was estimated to total 26,000 flasks in 1976. In addition to sharply increased exports of mercury to the United States, significant quantities were reportedly exported to European countries.

Italy.—Mine production of mercury totaled 22,278 flasks, compared with 31,677 flasks in 1975. Italy's nonferrous metal agency, Ente Gestione Azienda Minerali Metallurgiche, reportedly closed its mercury mining operations and halted sales of the metal during 1976 because of low prices.

Spain.—Production of mercury totaled 44,000 flasks, compared with 44,010 flasks in 1975. Spanish producers reportedly discontinued sales of mercury during 1976 because of low prices.

U.S.S.R.—Production of mercury was estimated to total 56,000 flasks. Because of low prices, Soviet suppliers reportedly withdrew from the international market in 1976.

TECHNOLOGY

Scientists at the Federal Bureau of Mines Reno Metallurgy Research Center conducted an investigation of improved processes for recovering mercury from cinnabar ores.[3] The research was conducted on eight different mercury ores ranging in grade from 0.7 pound to 18 pounds of mercury per ton of ore and demonstrated that cinnabar ores were amenable to hydrometallurgical recovery by an electrooxidation procedure that recovered 88% to 96% of the mercury at a considerable savings in energy consumption.

A study of energy use patterns in the production of mercury and other metals was conducted for the Bureau of Mines.[4] The report detailed energy consumption in each operation in the production of mercury metal and concluded that total consumption of energy per ton of metallic mercury amounted to 395 million Btu.

A new mercury monitor to determine the occupational exposure of workers to mercury was developed at the National Bureau of Standards, U.S. Department of Commerce.[5] The monitor is extremely sensitive, portable, easy to use, inexpensive, and reusable. Use of mercury cells to produce chlorine may decline further as the result of the development of new membranes for use in diaphragm cells that also produce chlorine and caustic soda.[6] The new membrane, made from perfluorsulfonic acid resin, lasts much longer than the asbestos membranes currently in use and produces a more concentrated caustic soda containing less salt and chlorine containing no hydrogen. A patent was issued for treating roaster gases with sulfuric acid and potassium thiocyanate and treating the condensate solutions with sodium sulfide to precipitate mercury metal.[7]

Mica

By Stanley K. Haines[1]

Production of sheet mica was limited to a small quantity of handpicked muscovite from North Carolina. Domestic production of scrap and flake mica decreased 6% in quantity while sales of ground mica increased 4%.

Consumption of block and film mica continued to decline reaching 534,229 pounds, a drop of 14%. Mica splittings consumption rebounded to 5,025,152 pounds. Exports of all forms of mica increased 40% in quantity and 2% in value. Imports of all forms of mica dropped 45%, led by a 61% decline in imports of waste and scrap mica.

Legislation and Government Programs.—The Defense Materials Inventory stockpile goals for sheet mica were revised in October. The goals for all forms except muscovite film were increased. The new goals are given in table 2. Shipments of excess mica by the General Services Administration (GSA) amounted to 3,319,348 pounds.

DOMESTIC PRODUCTION

Sheet Mica.—A small quantity of sheet mica was produced and sold locally in North Carolina. Oxford Feldspar Co., West Paris, Maine, produced and stockpiled sheet mica in 1976. The sheet mica in both areas was generally of low quality and grade, and was not mined as the primary product of the producing company.

Scrap and Flake.—North Carolina retained its position as the leading producing State with 55% of the total U.S. production of 127,312 short tons. The value of the North Carolina mica was $3,793,295 or 67% of the national total. The remaining 45% of scrap and flake mica output came from Alabama, Arizona, Connecticut, Georgia, New Mexico, Pennsylvania, and South Carolina. Scrap and flake mica was produced from the beneficiation of pegmatite ores, clays, weathered pegmatites, and schists.

Leading producers of scrap and flake mica were Harris Mining Co., Spruce Pine, N.C.; Western Mica Co., Div. of United States Gypsum Co., Chicago, Ill.; Mineral Industrial Commodities of America, Inc., Santa Fe, N.Mex.; The Feldspar Corp., Spruce Pine, N.C.; and Kings Mountain Mica Co., Inc., Kings Mountain, N.C.

Ground Mica.—Sales of ground mica increased 4% in quantity and 9% in value over the revised 1975 totals. Dry-ground mica was 89% of the total, with wet-ground mica representing the remaining 11%. Both wet- and dry-ground mica production increased in quantity and value. Seventeen companies, operating a total of 19 plants, processed scrap and flake mica. Fourteen of these plants produced dry-ground mica, 3 produced wet-ground mica, and 2 produced wet- and dry-ground mica.

[r]Revised.
[1]Domestic and some imported scrap.
[2]Data may not add to totals shown because of independent rounding.

Leading producers of ground mica were Harris Mining Co., Spruce Pine, N.C.; United States Gypsum Co., Chicago, Ill.; Deneen Mica Co., Inc., Micaville, N.C.; and Mineral Industrial Commodities of America, Inc., Santa Fe, N.Mex.

CONSUMPTION AND USES

Sheet Mica.—Consumption of block and film mica dropped for the third consecutive year. Fabrication of block and film mica (muscovite and phlogopite) declined 14% to 534,229 pounds. Of the total consumption, 90% was muscovite block, 8% was phlogopite block (magnesium mica), and 2% was muscovite film.

Vacuum tubes required 66% of the total muscovite block fabricated. The remaining fabricated block was used in gage glass and diaphragms (3%) and capacitors and others uses (31%). Stained quality muscovite block mica was in greatest demand and accounted for 63% of consumption; lower than Stained, 35%; and Good Stained or better, 2%.

Muscovite film consumption increased from 7,243 pounds in 1975 to 10,266 pounds. The film was consumed primarily in the fabrication of capacitors.

Muscovite block and film were consumed by 10 companies in 7 States. North Carolina had three consuming plants, New Jersey had two, while Massachusetts, New York, Ohio, Pennsylvania, and Virginia had one plant each.

Phlogopite block consumption increased from 28,512 pounds in 1975 to 43,865 pounds. Phlogopite was consumed by eight companies in five States. Virginia and New Jersey were the primary fabricating States.

Consumption of mica splittings (muscovite and phlogopite) increased 6% from a total of 4,746,000 pounds in 1975 to 5,025,000 pounds. India and the Malagasy Republic supplied the bulk of the splittings consumed domestically. Splittings were fabricated into various built-up mica products by 10 companies with 11 plants in 8 States. Five plants located in Ohio, New York, and New Hampshire consumed 3.9 million pounds of splittings, or 79% of total consumption.

Built-Up Mica.—This mica-based product was made in various forms, primarily for

use as electrical insulating material. Molding plate, segment plate, heater plate, and other uses registered gains in production. Segment plate was the form in greatest demand, with 33% of the total, followed by molding plate with 28% and tape with 17%.

Reconstituted Mica (Mica Paper).—Five companies consumed 4,227,427 pounds of scrap mica to produce 2,715,158 pounds of mica paper in 1976. The manufacturing companies were General Electric Co., Schenectady, N.Y.; U.S. Samica Corp., Rutland, Vt.; Kirkwood Acim Paper Co., Hempstead, N.Y.; Essex Group, United Technologies Corp., New Market, N.H.; and Corona Films Inc., West Townsend, Mass.

Ground Mica.—Ground mica sales increased 4% above the revised 1975 level of 115,401 short tons. The principal end uses were joint cement (44%), paint (18%), roofing (4%), and rubber (4%).

STOCKS

Yearend stocks of sheet mica were 3.7 million pounds. Of this total 88.6% was splittings, 11.2% was block, and 0.2% was film. This information was obtained by direct canvass of consumers of sheet mica.

PRICES

The average value of muscovite sheet in 1976, based on consumption data, follows: Block, $2.68 per pound; film, $4.33 per pound; and splittings, $0.64 per pound. The average value of phlogopite sheet mica, also based on consumption data, follows: Phlogopite block, $1.89 per pound, and phlogopite splittings, $0.87 per pound.

The average value of scrap and flake mica produced during 1976 was $44.67 per ton. Prices for wet- and dry-ground mica quoted in the Chemical Marketing Reporter essentially remained at 1975 levels.

Table 10.—Price of dry- or wet-ground mica in the United States in 1976[1]

	Cents per pound
Dry-ground:	
Joint cement, 100 mesh	4-5
Plastic, 100 mesh	4-5
Roofing, 20 to 80 mesh	2.5-3.5
Wet-ground:[2]	
Paint or lacquer, 325 mesh	11.75-13
Rubber	11.75-13
Wall paper	12-18

[1]In bags at works, carlots, unless otherwise noted.
[2]Freight allowed east of the Mississippi River.

Source: Chemical Marketing Reporter. V. 210, No. 26, Dec. 27, 1976.

FOREIGN TRADE

Exports of all forms of unmanufactured mica increased 32%, from 10,977,353 pounds in 1975 to 14,449,150 pounds. Canada led the increase with a jump of 96% to 6,660,106 pounds and an average value of slightly over 7 cents per pound indicating that the vast majority of the mica exported was ground. West Germany was the second leading country of destination for the exports, followed by Japan, France, and Guatemala. The overall average value of the exported mica was 24 cents per pound in 1976 as compared with 28.7 cents per pound in 1975. The average value indicates that most of the material exported was ground mica, but there was a large enough quantity of the more expensive sheet mica to raise the average value.

Imports of all classes of mica declined from 16,651,263 pounds in 1975 to 9,195,508 pounds in 1976. The largest changes were in the waste and scrap category with a drop of 61% to 4,212,574 pounds and splittings with a decrease of 55%. India was the leading source country with 60% of total imports with Brazil second with 20% of the total.

WORLD REVIEW

World production of all forms of mica declined 6% from 1975 to 1976. India was the world leader for production of sheet mica. Brazil and the Malagasy Republic were other major sheet mica producing countries. The United States remained the world leader in production of scrap and flake mica (for ground mica).

India.—The Government of India remained firm in their recommendation re-

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, the People's Republic of China, Romania, Southern Rhodesia, the Territory of South-West Africa and Sweden are known to produce mica, but available information is inadequate to make reliable estimates of output levels.

[2]Exports.

[3]Includes micanite and other built up mica.

[4]Includes condensed film, washer and disks.

[5]Includes sheet, strips, and powder.

[6]Less than 1/2 unit.

quiring 40% of all orders to be placed through the Government's Mica Trading Co. (MITCO), with the remaining 60% to be placed with traditional suppliers. MITCO concluded agreements with the U.S.S.R. for the supply of sheet mica in 1976. The U.S.S.R. was to receive about 35% of India's total mica exports on a value basis. East Germany also contracted for a large supply of sheet mica from India.

Malagasy Republic.—Mica (phlogopite) mining operations were shut down in January 1976 owing to lack of demand for phlogopite block and splittings. The 1,023 tons of mica exported was from stockpiles. Mining is expected to resume in mid-1977.

TECHNOLOGY

The U.S. Bureau of Mines research station in Tuscaloosa, Ala., successfully conducted preliminary tests to air classify mica from a mica mill tailings dump. The mica in these samples did not respond adequately to conventional beneficiation techniques. A sample containing 7% mica was screened and then air classified to recover the mica. This process resulted in a 72% mica concentrate.

Molybdenum

John T. Kummer[1]

World output of molybdenum increased about 8% over that of 1975, but was exceeded by demand. The result was some tightness in the molybdenum market, especially during the second half of 1976, and a drawdown of producer stocks. In the United States, mine production increased approximately 7% while total industry stocks were reduced almost 20%. Although reported domestic consumption of molybdenum products was down slightly, apparent demand increased 8.6% to almost 60 million pounds. Reduced availability of some molybdenum materials was reported during the latter part of 1976. The price of molybdenum concentrate and other primary products was increased three times during 1976, on each occasion by 8% to 10%. These increases were attributed to higher operating costs, large capital expenditures, and the increased demand for molybdenum materials during the year.

Legislation and Government Programs.—During 1976, the General Services Administration (GSA) sold 130,151 pounds of excess molybdenum contained in molybdenum disulfide, and as a result, no uncommitted molybdenum materials remained in the Government stockpile. The revised stockpile goals announced in October 1976 by the Federal Preparedness Agency (FPA) of GSA did not include molybdenum materials. Shipments from the stockpile during the year totaled 1,594,378 pounds of excess molybdenum, including 1,263,831 pounds in molybdenum disulfide, 257,851 pounds in ferromolybdenum, and 72,696 pounds in molybdenum oxide. GSA reported an inventory of 22,231 pounds of molybdenum in ferromolybdenum at yearend 1976.

DOMESTIC PRODUCTION

Reported domestic mine output of molybdenum increased by 7.3 million pounds, or 6.8% over that of 1975. Production from primary molybdenum ores totaled 75.2 million pounds, 6.4% higher than in 1975. Production from byproduct molybdenum sources, which are predominantly copper porphyry ores, totaled 38 million pounds, 7.8% higher than in 1975. The amount of molybdenum produced as a byproduct of tungsten and uranium mining operations is normally small and decreased slightly in 1976.

Molybdenum ores were mined in Colorado at the Climax and Henderson mines, both owned by AMAX Inc., and in New Mexico at the Questa mine, owned by Molycorp Inc. A record production of nearly 61 million pounds of molybdenum was attained by underground and open pit operations at the Climax mine. Production of molybdenite (MoS_2) concentrate began in August 1976 at the Henderson mine; output of molybdenum totaled 3 million pounds in 1976 and is scheduled to be approximately 20 million pounds in 1977. Production of molybdenum at the Questa mine also reached a new high of 11.5 million pounds.

Byproduct molybdenum was produced from 14 mines, 12 of which were low-grade copper porphyry deposits. As in previous years, the two major byproduct producers were the Sierrita mine of the Duval Corp., a subsidiary of Pennzoil Co., and the Utah copper mine of Kennecott Copper Corp. Both firms operate other open pit copper mines which produced byproduct molybdenum; together with AMAX Inc., and Molycorp Inc., the four corporations accounted for almost 94% of domestic production. Other producers of byproduct molybdenum included Magma Copper Co., Cyprus Mines Corp., and Anamax Mining Co., all of which operate surface copper mines located in Arizona. Mining, concentrating, and smelting activity at Kennecott's Nevada Mines division near McGill was suspended during 1976 because of escalating costs and environmental mandates. Late in the year, Kennecott announced plans to reopen the copper mine and concentrator during 1977.

The startup of operations at AMAX's Henderson mine near Empire, Colo., was the most significant development in the expansion of molybdenum production capacity during the year. The Henderson orebody was discovered in 1964, and construction of mining, milling, concentrating, and haulage facilities has been in progress over a 10-year period. Designed capacity of 50 million pounds of molybdenum per year is projected for 1980, by which time capital expenditures

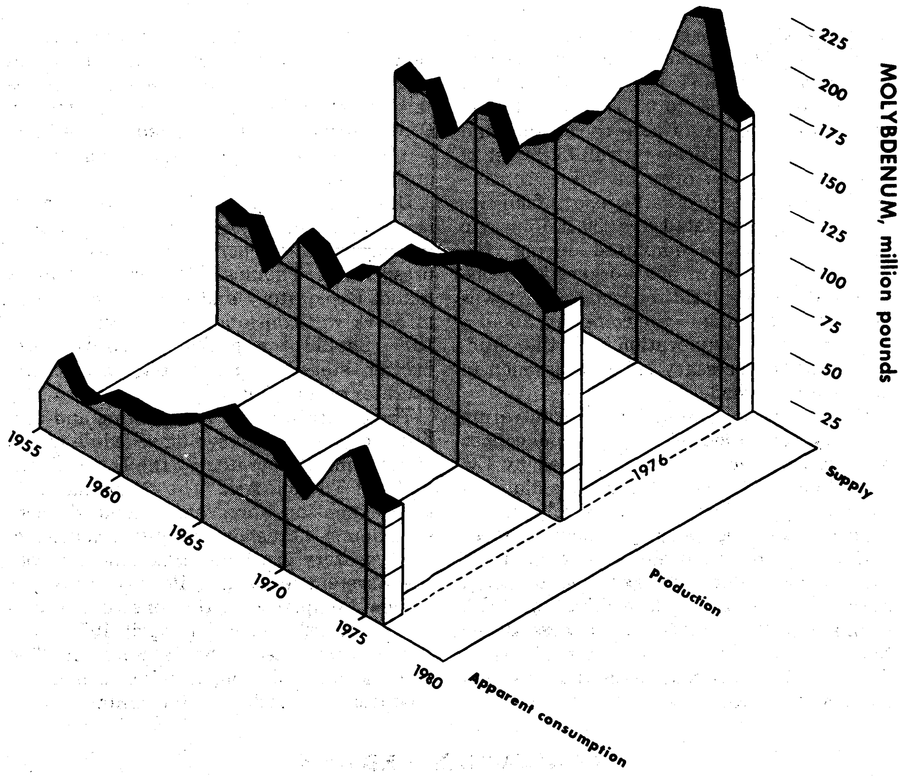

Figure 1.—Apparent consumption, production, and supply of molybdenum in the United States.

on the Henderson facility will approximate $500 million. The project was cited as the Outstanding Engineering Achievement of 1976 by The Northern Chapter of The Professional Engineers of Colorado. Ore reserves approximate 300 million tons averaging 0.49% molybdenite, and account for about 25% of the estimated reserves of molybdenum in the United States.

Startup of the first roaster and a sulfuric acid plant at AMAX's new conversion facility near Fort Madison, Iowa, was scheduled for mid-1977. High-purity molybdic oxide and molybdates were first produced at the plant in 1975. A sulfuric acid plant under construction at AMAX's Langeloth, Pa., conversion facility was nearing completion at yearend.

Questa Molybdenum Co., a partnership formed in 1975 by Molycorp Inc., and Kennecott Copper Corp., announced the results of an exploratory drilling program to delineate additional molybdenite mineralization on Molycorp's Questa property in New Mexico. During 1976, the partnership completed about 130,000 feet of drilling and outlined an estimated 91 million tons of ore with an average grade of 0.34% molybdenite at a 0.20% MoS_2 cutoff. The ore, reported to occur in two separate zones, was thought to be amenable to underground block-caving methods. Additional mineralization was also indicated within the outlined zones and in another area on the Questa property. A feasibility study was conducted to evaluate mining programs and to make cost estimates for production from the newly outlined ore zones. The feasibility study and further exploratory work are expected to be completed by mid-1977. An operating program which would produce 300 million pounds of molybdenum in concentrate over a 15-year period reportedly is necessary if Kennecott continues in the partnership for a production phase.

The discovery of a substantial molybdenum deposit in the Ketchikan area of southeastern Alaska was made by the U.S. Borax

& Chemical Corp., a subsidiary of Rio Tinto-Zinc Corp., Ltd. The ore body was reported to have a potential size of 100 million short tons grading 0.20% to 0.35% molybdenite. Mineralization is at or near the surface and thus amenable to open pit mining. Cost of construction of an open pit mine, concentrating plant, and other support facilities was initially estimated at $250 million. Up to 1,000 would be employed during construction, and about 500 workers would be required once full-time operation was reached. According to the company, about 3 years of further exploration and other studies would be necessary before a decision to mine could be made.

Expansion of mining and concentrating capacity continued at the open pit copper mine near Bagdad, Ariz., operated by Cyprus Bagdad Copper Co., a subsidiary of Cyprus Mines Corp. A 5,800 ton-per-day concentrator has been producing copper and molybdenum concentrates at the mine. The new concentrator, expected to begin operating during the latter half of 1977, would have the capacity to process 40,000 tons per day. Future production of byproduct molybdenum could exceed 1.2 million pounds per year. The company reported that exploratory drilling at the Bagdad deposit encountered additional mineralization but that further work would be necessary to determine its economic importance. Proven reserves at the Bagdad mine totaled 300 million tons of copper-molybdenum ore at the end of 1976.

During 1976, Cyprus Mines Corp. began negotiations on a joint-venture agreement to develop and operate its molybdenum prospect at Thompson Creek in central Idaho. Exploratory and other developmental work will continue on the prospect into 1977. Should the project reach the production stage, Cyprus would become the operator of the mine.

The construction of new mining and milling facilities progressed on schedule at the Sierrita mine, operated by the Duval Corp., south of Tucson, Ariz. The major facets of the expansion program included construction of a crusher building to house two new gyratory crushers, a 2.8-mile ore conveyor system, and a 1.5-mile waste conveyor system. Completion of the construction program was scheduled for April 1977, at a total cost reported to be $30.6 million. The Sierrita open pit copper mine is a major producer of byproduct molybdenum.

CONSUMPTION AND USES

The quantity of molybdenum in concentrate consumed by roasting to produce technical-grade molybdic oxide decreased by 5.1 million pounds and was 5.6% less than in 1975. Some molybdenum concentrate was purified to lubrication-grade molybdenum disulfide, and a small amount was added directly to iron and steel furnaces. Molybdic oxide, the primary form of molybdenum produced at conversion plants, was consumed directly in end-use applications or converted to other molybdenum materials such as ferromolybdenum, molybdates, or metal powder.

Total reported end-use consumption of molybdenum materials decreased 1.3 million pounds, 2.5% below that of 1975 and 20.5% below the record high established in 1974. On the other hand, apparent domestic consumption increased to 59.8 million pounds, 8.6% higher than that of 1975. According to most industry accounts, worldwide demand was strong relative to 1975, and some consumers reported difficulty in obtaining certain molybdenum materials.

The decrease in reported consumption of molybdenum was predominantly due to reduced usage of molybdic oxide and ferromolybdenum in steel production. For all categories of steel output, molybdenum consumption decreased 3.5 million pounds, or 9.3%, compared with that of 1975. The only steel category in which molybdenum use increased was that of tool steels. The steel industry accounted for 67% of the total molybdenum consumed domestically in 1976, down from 72% in 1975.

Aside from steels, consumption of molybdenum increased in most of its other end-use applications. Compared with 1975, consumption of molybdenum in metal mill products increased 60% to 3.3 million pounds; in superalloys, 17% to 2.7 million pounds; and in chemical and ceramic uses, 24% to 4.2 million pounds. Use of molybdenum in the production of cast irons increased marginally.

Table 3.—Consumption of molybdenum materials, by end use in 1976

[1]Includes calcium molybdate.
[2]Includes purified molybdenum disulfide, molybdenite concentrate added directly to steel, molybdenum metal powder, molybdenum metal, pellets, and other molybdenum materials.
[3]Includes magnetic and nonferrous alloys.

STOCKS

Total industry stocks of molybdenum decreased significantly during 1976 reflecting heightened worldwide demand. At yearend, stocks of molybdenum totaled 32.5 million pounds, or about 20% less than at the close of 1975. Especially marked was the drop in stocks of molybdenum contained in products at conversion plants. During the year, inventories of molybdenum at conversion plants decreased from 22.9 million pounds to 13.2 million pounds, the lowest level in about 10 years. Stocks of molybdenum in concentrate at mines and plants also decreased, from 10.7 to 9.4 million pounds during the year. The trend in consumer inventories of molybdenum was in the opposite direction, rising from 6.8 to 9.9 million pounds by the close of 1976. The increase in consumer inventories reflected the growth in demand for molybdenum during the year and, according to some accounts, a degree of hedge buying in anticipation of later price increases.

PRICES

During 1976, the quoted prices for molybdenum concentrate and other molybdenum products were increased three times, on each occasion by 8% to 10%. The price of molybdenum per pound contained in concentrate began the year at $2.62, and was raised to $2.90 in March, to $3.20 in August, and to $3.45 in December. The weighted average price for the year was $2.94 per pound of contained molybdenum. Higher operating expenses, the need to recover the cost of expanding productive capacity, and increasing demand were cited as factors in the price increases. At yearend, the published prices of products per pound of contained molybdenum were as follows:

Climax concentrate	$3.45
Byproduct concentrate	3.25-3.45
Climax oxide/cans	3.82
Dealer oxide	4.10-4.20
K-1 oxide/cans	3.82
K-2 oxide/cans	3.75
Ferromolybdenum/Climax lump	4.43
Ferromolybdenum/Climax powder	4.49
Ferromolybdenum/dealer export	4.60-4.75

FOREIGN TRADE

Exports.—Exports of molybdenum in concentrate and oxide totaled 62.5 million pounds, compared with 62.6 million pounds in 1975. However, because of the higher average prices during the year, the value of exports increased to $183.5 million, 15% higher than in 1975. Foreign shipments of concentrate and oxide represented 55% of domestic production during the year. As in 1975, the Netherlands, Japan, West Germany, and Belgium-Luxembourg were the major countries of destination, receiving 87% of the oxide and concentrate exported.

Exports of ferromolybdenum amounted to 3.6 million pounds, 60% greater than in 1975. Japan, the Netherlands, and India received 49% of the ferromolybdenum exported. The total value of ferromolybdenum exported was $9.4 million, almost twice that of 1975.

Other exports of molybdenum products and their value were metal and alloys in crude form and scrap, $390,000; wire, $3.7 million; powder, $136,000; and semifabricated forms, $1.6 million. The total value of these exports did not vary appreciably from that of 1975; however, their combined gross weight decreased 19% to 775,000 pounds.

Imports.—Molybdenum materials imported during 1976 included concentrate, ferromolybdenum, metal products, and chemicals. Since the United States is self-sufficient in molybdenum materials, the quantity of these imports was only a minor component of domestic supply. Molybdenum concentrate, the major form of imported molybdenum and received only from Canada, continued at the relatively high level of 1975 compared with previous years. During 1976, the molybdenum contained in concentrate imports totaled 2,092,623 pounds with a value of $4.8 million. The average declared value of concentrate imports was $2.32 per pound of contained molybdenum, considerably below the average domestic price of $2.94.

Other molybdenum materials imported included ferromolybdenum containing 7,173 pounds of molybdenum valued at $27,644, also supplied exclusively by Canada. Wrought molybdenum metal with a gross weight of 63,500 pounds and valued at $705,274 was imported from seven countries. Austria supplied 96% of the wrought metal, while Sweden, Austria, and West Germany supplied unwrought metal, containing 72,608 pounds of molybdenum and valued at $138,700. Waste and scrap containing 297,554 pounds of molybdenum valued at $1,183,037 were imported from seven countries. The Netherlands, West Germany, Austria, and Australia were the major suppliers. Imported material in which the chief value was molybdenum came from Canada and Japan and contained 34,083 pounds of molybdenum valued at $70,570.

Imports of molybdenum orange totaled 665,821 pounds (gross weight), valued at $599,273. Canada was the origin of 89% of the molybdenum orange. Unspecified compounds and mixtures in which the chief value was molybdenum were imported from eight countries and contained 27,858 pounds of molybdenum valued at $405,162. Italy, West Germany, and Canada were the major sources of these materials.

[1]Ferromolybdenum contains about 60% to 65% molybdenum.
[2]Less than 1/2 unit.

Table 7.—U.S. import duties

Item	Article	Rate of duty, Jan. 1, 1977[1]
601.33	Molybdenum ore	12 cents per pound on molybdenum content.
603.40	Material in chief value molybdenum	10 cents per pound on molybdenum content plus 3% ad valorem.
607.40	Ferromolybdenum	Do.
	Molybdenum:	
628.70	Waste and scrap	10.5% ad valorem.[2]
628.72	Unwrought	10 cents per pound on molybdenum content plus 3% ad valorem.
628.74	Wrought	12.5% ad valorem.
	Molybdenum chemicals:	
417.28	Ammonium molybdate	10 cents per pound on molybdenum content plus 3% ad valorem.
418.26	Calcium molybdate	Do.
419.60	Molybdenum compounds	Do.
420.22	Potassium molybdate	Do.
421.10	Sodium molybdate	Do.
423.88	Mixtures of inorganic compounds, chief value molybdenum	Do.
473.18	Molybdenum orange	5% ad valorem.

[1]Not applicable to countries that have centrally controlled economies.
[2]Duty on waste and scrap temporarily suspended.

WORLD REVIEW

World production of molybdenum was estimated at 191.3 million pounds, or about 14.6 million pounds higher than that of 1975. On a worldwide basis, about half the molybdenum produced was as a byproduct, chiefly from copper mining operations. Among market economy countries, the United States, Canada, and Chile continued as the major producers of molybdenum. Although mine production of molybdenum in the U.S.S.R. must be estimated, it was the major producer among central economy countries. The People's Republic of China was probably a significant producer of molybdenum also, but it has been omitted from the table of world production due to lack of data on which to base a reliable estimate of its mine output.

Argentina.—If undertaken, development of the El Pachón copper-molybdenum deposit would take at least 4 years with initial production in 1981. An estimated $750 million would be needed to finance the development, according to its owners, Cia. Minera Aguilar, S.A., a subsidiary of St. Joe Minerals Corp. Exploratory work completed as of mid-1976 established about 860 million tons of ore, grading 0.59% copper and 0.016% molybdenum. Facilities for extracting molybdenum would be included in the mining complex.

Brazil.—The Brazilian Government announced the discovery of a molybdenum deposit in the northern territory of Roraima. The discovery was the first significant deposit of molybdenum found in Brazil. Although no estimate of the deposit's size was given, preliminary tests indicated a possible ore grade of 1% molybdenum or higher.

Canada.—Craigmont Mines, Ltd., began an exploratory drilling program on the Carmi molybdenum property located in southern British Columbia. Drilling commenced soon after Craigmont optioned the property from Vestor Explorations, Ltd., in May. Previous drilling on the property had outlined two mineralized zones with a total reserve estimated at 40 million tons of ore grading 0.15% molybdenite. Both zones were undefined laterally and to depth. The drilling undertaken by Craigmont later in the year resulted in the finding of additional mineralized zones. Considerable further exploration was planned in order to define more fully the extent and grade of the deposits.

Noranda Mines Ltd., announced that an additional $900,000 would be spent on drilling and other development work in order to evaluate the possibility of open pit mining at its Boss Mountain molybdenum mine near Hendrix Lake, British Columbia. According to Noranda, the property appeared to have the potential to support a 20,000-ton-per-day milling operation of low-grade surface material. The company stated that a pilot plant stage of ore testing might be necessary to confirm metallurgical findings. Higher grade ore, which was being worked by underground methods, was reported to be sufficient to sustain current operations until the end of 1977.

The Noranda Exploration Co., Ltd., was given an option to explore the Ruby Creek molybdenum prospect in northern British Columbia by Adanac Mining and Exploration, Ltd. The property had been explored previously by Climax Molybdenum Corp. of British Columbia, Ltd. The Ruby Creek property is reported to contain about 104 million tons of ore grading 0.16% molybdenite.

Midas Resources, Ltd., obtained an option on 10 copper-molybdenum claims in Powell Township, near Matachewan, Ontario. Mineralization was reported to be intermittently exposed over a distance of approximately 500 feet in length. The company planned to conduct exploration and survey work on the claims.

Chile.—It was announced that financing of a new molybdenum conversion plant would be provided by the Chilean Copper Workers Federation, the Inter-American Development Bank, and Chile's Central Bank. The plant will have facilities for converting molybdenum concentrate to molybdic oxide and ferromolybdenum. After the plant becomes operational, exports of the higher priced oxide and ferromolybdenum will be increased, thus generating additional foreign exchange revenue for Chile.

Iran.—Development of the Sar Cheshmeh copper-molybdenum porphyry deposit in south-central Iran continued, but scheduled initial production has been delayed, possibly to late 1977. Reasons cited for the delay include late deliveries of necessary equipment, setbacks in worker training programs, and a considerable increase in capital cost of the project to over $1 billion from an original estimate of $430 million. The mining facility will include a molybdenum recovery plant and a smelter to produce blister copper at an initial rate of about 160,000 tons per year. Expected output of molybdenum has not yet been reported. However, reserves are presently estimated to total about 470 million tons of ore with an average grade of 1.12% copper and 0.03% molybdenum.

Mexico.—Startup of milling and concentrating operations at the La Caridad copper-molybdenum porphyry deposit was scheduled for late 1977. The mine, located in the State of Sonora about 200 miles northeast of Hermosillo, is operated by Mexicana de Cobre S.A., a company owned by the Mexican Government and private Mexican interests. Work at the mine site during 1976 consisted of a preproduction stripping program, construction of crusher and concentrator plants, and operation of a 100 ton-per-day pilot plant to test mill design circuitry. Various methods of molybdenum recovery were studied in the pilot plant. When operational, the concentrator will initially treat about 80,000 tons of ore per day.

Papua New Guinea.—A consortium was formed by Broken Hill Pty. Co. Ltd., of Australia with the Government of Papua New Guinea and mining interests from the United States and West Germany to undertake a feasibility study of the Ok Tedi copper deposit. Drilling completed by mid-1976 established an orebody of at least 275 million tons with an average of 0.85% copper, 0.012% molybdenum, and some gold values. The study should take about 2 years, and if mine development is warranted, production may be possible by 1983.

Molybdenum mineralization was reported by Triako Mines N.L. at the Yandera copper prospect. Exploratory drilling completed in early 1976 outlined indicated reserves of 124 million tons and inferred reserves of 214 million tons grading 0.42% copper and about 0.02% molybdenum, with gold and silver values. Additional mineralization was found but had not been adequately explored for reserve calculations. The company and its associates, Buka Minerals N.L. and a Kennecott Copper Corp. unit, were evaluating exploration data in consideration of further exploratory work.

Peru.—Production of concentrates began in July 1976 at the Cuajone copper-molybdenum mine operated by Southern Peru Copper Corp. (SPCC). Full production capacity of 170,000 tons of copper in concentrate per year was nearly reached by yearend. The open pit mine site, concentrator, and auxiliary facilities required 6 years of development work at an approximate cost of $730 million. The Caujone project is a joint venture of SPCC, a consortium of U.S. mining companies, and Billiton N.V., a subsidiary of the Royal Dutch / Shell Group. Billiton's equity is about 11.5% of the total investment. The mine is located at an elevation of about 12,000 feet within 15 miles of SPCC's previously operating Toquepala open pit copper-molybdenum mine. A rail line connects the two mines and runs to the southern coastal town of Ilo where the company's newly enlarged smelter is located. The Cuajone orebody contains reserves of 470 million tons of ore with approximately 1% copper and 0.03% molybdenum.

TECHNOLOGY

During 1976, research programs in general were directed towards improved methods of molybdenum recovery at ore concentrating facilities and new end-use applications for molybdenum materials.

Bureau of Mines investigators described an electrooxidation process to recovery molybdenum and rhenium from offgrade concentrates.[2] The process consisted of dissolution of metal values by electrooxidation, liquid-solid separation by thickening, acidification and chlorate ion removal by sulfur dioxide treatment, solvent extraction to concentrate the molybdenum and rhenium, separation of the two metals by carbon adsorption, and metal recovery by crystallization. An offgrade molybdenite concentrate containing about 36% molybdenum and 1,330 parts per million (ppm) of rhenium was used to test the process. Extraction of about 99% of both metals was obtained by electrooxidation with an energy consumption of 13.7 kilowatt-hours per pound of molybdenum extracted. After separation of the two metals using a carbon adsorption column, the final recovery of molybdenum and rhenium was 96% to 98%.

Pilot-scale demonstration of the electrooxidation process was successfully completed during the year at the Nevada Mines Division of Kennecott Copper Corp. near McGill, Nev. Extraction of 94% to 98% of molybdenum and rhenium was routinely achieved from offgrade concentrates produced by the concentrator at the mine site.

A steam injection method for flotation separation of molybdenum from copper sulfide concentrate developed by the Bureau of Mines was tested at the Mineral Park property in Arizona owned by the Duval Corp. Steam injection prior to and during flotation resulted in a higher grade of molybdenum in rougher concentrate and greater copper rejection.

Bureau of Mines researchers were also engaged in a project to decrease the molybdenum content of waste waters from ore-processing operations at the Questa mine owned by Molycorp Inc. An ion exchange technique which reduced the molybdenum concentration in waste water from 4 ppm to 0.3 ppm was developed. A technique which involved coprecipitation of molybdenum with ferric hydroxide was also evaluated.

The results of numerous metallurgical studies of molybdenum-containing steels and alloys were published during the year. A standard constructional steel (SAE 4135), modified by increasing the molybdenum content and adding columbium, was tested for the effects of various production variables on its mechanical properties and sulfide stress cracking (SSC) resistance.[3] Steels with high strength and high SSC resistance, such as this modified SAE 4135, are required for casing, tubing, and tool joints used in the drilling of and production from deep oil and gas wells where hydrogen sulfide or "sour gas" is encountered. Among the conclusions reached by the cited study were that the SSC resistance of the modi-

[3]Grobner, P. J., D. L. Sponseller, and D. E. Diesburg. The Effects of Processing Variables on Mechanical Properties and Sulfide Stress Cracking Resistance of SAE 4135 Steel Modified With 0.75 Percent Mo and 0.035 Percent Cb. J. Eng. for Ind., v. 98, No. 2, May 1976, pp. 708-716.

fied steel was clearly greater than that of unmodified SAE 4130 steel and that this advantage in SSC resistance increased with greater hardness and yield strength of the steel.

A group of highly alloyed, austenitic stainless materials were examined for their applicability in the high-pressure, high-temperature, and corrosive environments encountered in deep gas wells.[4] The study identified certain of these materials which performed well on tests for sulfide stress cracking, chloride stress corrosion cracking, pitting, crevice corrosion, and general weight-loss corrosion performance in the absence of a corrosion inhibitor. The inert alloys that exhibited high resistance in all of the tests contained 7% to 15% molybdenum in addition to 55% to 70% nickel plus cobalt and 15% to 20% chromium.

The corrosion-resistant properties and applications of ferritic stainless steels, several of which contain molybdenum as a vital alloying element, were reviewed.[5] Several of the newer ferritic stainless steels, containing 1% to 4% molybdenum, combine resistance to chloride stress corrosion cracking with better weldability than established ferritic grades. The production of these steels has become possible with the development of new production processes such as argon-oxygen decarburization (AOD), electron-beam melting, and vacuum induction melting.

The use of soluble molybdates as corrosion inhibitors in cooling water systems was described.[6] When used at low concentration levels with other soluble corrosion inhibitors, molybdate-containing formulations were shown to be effective in both low- and high-hardness water systems and to be cost competitive with established water treatments. The very low toxicity of soluble molybdates makes their usage desirable from an environmental standpoint.

The addition of soluble molybdate was also found to retard corrosion of SAE 1010 steel in aerated solutions containing chloride and sulfate.[7] Electrochemical tests were also performed in order to study the behavior and mechanism of the molybdate ion as a corrosion inhibitor.

Other areas that experienced considerable technological interest during the year included the use of purified molybdenum disulfide as an additive in oils and greases, the application of molybdenum compounds as flame retardants and smoke suppressants, the development of molybdenum monocarbide as a potential substitute for tungsten carbide in cutting tools and high-speed steels, and the recycling of molybdenum catalysts used in petroleum refining.

U.S. patents granted during 1976 that dealt with the processing of molybdenum materials included ones for purification of technical-grade molybdenum oxide by mixing with sulfuric acid, roasting, and leaching with ammonium hydroxide;[8] for the extraction of molybdenum values from an ore leach solution with an organic solvent;[9] for the separation of tungsten and molybdenum from an alkaline leach solution;[10] for the production of molybdenum trioxide by roasting molybdenite concentrate in a recirculating fluidized bed reactor;[11] for the purification of molybdenum oxide by reroasting and formation of soluble molybdates;[12] for the production of molybdenum metal by direct dissociation of molybdenite;[13] for the carbonyl extraction of molybdenum and other metal values from low-grade ore, filter cake, or mine tailings;[14] for the recovery of molybdenum from a leach solution containing tungsten by oxidation of molybdic acid ions and the precipitation as molybdenum sulfide;[15] for the purification of molybdenite concentrate by treatment with hydrofluoric and sulfuric acids;[16] for the extraction of molybdenum from mo-

Natural Gas

By Gordon W. Koelling[1] and Leonard L. Fanelli[2]

Marketed production of natural gas in the United States declined 0.8% to 20.0 trillion cubic feet (Tcf) in 1976.[3] Although this was the third consecutive annual decrease in production, the rate of decline was considerably less than that registered during the 2 previous years.

Total consumption of natural gas (including extraction loss) increased 1.9% to 20.8 Tcf during 1976 in conjunction with the persistence of considerably lower than normal temperatures in most of the country east of the Rocky Mountains from October through yearend. Residential and commercial use of natural gas increased 2.6% and 5.0%, respectively, and consumption by the industrial sector, the largest user, declined slightly. The electric utilities sector registered a 2.2% decline.

Table 1.—Salient statistics of natural gas in the United States

	1972	1973	1974	1975	1976
Supply:					
Marketed production[1] million cubic feet	22,531,698	22,647,549	21,600,522	20,108,661	19,952,438
Withdrawn from storage do	1,757,218	1,532,820	1,700,546	1,759,565	1,921,017

Stored do	1,892,952	1,974,324	1,784,209	2,103,619	1,755,690
Adjustments[2] do	328,002	195,863	288,731	235,065	216,240
Total do	25,308,412	25,213,270	24,260,352	22,821,234	22,837,223
Value at wellhead:					
Total thousand dollars	4,180,462	4,894,072	6,573,402	8,945,062	11,571,776
Average cents per thousand cubic feet	18.6	21.6	30.4	44.5	58.0

[1]Marketed production of natural gas represents gross withdrawals less gas used for repressuring and quantities vented and flared.
[2]Includes transmission losses, changes in aboveground storage and gas unaccounted for.

NOTE.—Domestic production as used in the Bureau publication "Minerals and Materials/monthly survey" represents marketed production less the shrinkage (extraction loss) resulting from the extraction of natural gas liquids.

Proved reserves of natural gas declined 5.3% from 228.2 Tcf at yearend 1975 to 216.0 Tcf by yearend 1976 as annual discoveries failed to equal production for the eighth time in the last 9 years. Extensions to known fields during 1976 totaled 5.3 Tcf, and new reservoir discoveries in old fields and new field discoveries accounted for 3.4 Tcf. Revisions of previous reserve estimates and changes in underground storage resulted in a net reduction of 1.4 Tcf.

The average wellhead value of natural gas increased 30.3% to 58.0 cents per thousand cubic feet (Mcf) in 1976. During the same year the average retail price for gas delivered to consumers rose 22.8% to 146.5 cents per Mcf.

---

[1]Mineral Specialist, Division of Petroleum and Natural Gas.
[2]Survey Statistician, Division of Fuels Data.
[3]All gas volumes in this chapter are on a pressure base of 14.73 psia at 60° F.

Exports of 65 billion cubic feet (Bcf) in 1976 were 11.0% less than in 1975. Almost 77.0% of total 1976 exports was shipped from Alaska to Japan as liquefied natural gas (LNG). The remaining exports, which were transported by pipeline, were almost equally divided between Canada and Mexico.

Natural gas imports increased 1.1% to 964 Bcf in 1976. Almost all of this gas was shipped from Canada via pipeline. LNG shipments from Algeria totaled approximately 10 Bcf and for the second consecutive year, no imports were received from Mexico.

Efforts to supplement natural gas supplies through the manufacture of synthetic natural gas (SNG) from liquid fuels for peakshaving purposes continued. Twelve SNG plants were operational and one was under construction as of yearend 1976.

Seven pilot projects for the development and testing of processes for the production of high-Btu gas from coal were operational at yearend 1976. An additional four projects involving the production of low-Btu gas from coal were also operational or under construction, and both government and industry were engaged in research involving the output of low-Btu gas from in situ coal gasification. The Bureau of Mines continued its experiment in gathering methane from a West Virginia coal deposit, and in November 1976 entered into a cooperative agreement for testing the use of hydraulic fracturing to stimulate methane recovery from a Pennsylvania coalbed prior to mining. During 1976, several gasification projects involving biomass conversion were also under development.

Research programs involving fracturing techniques to stimulate flow from economically submarginal gas reservoirs were continued during 1976. Most of this activity was in Colorado, Wyoming, Utah, and Texas, but several projects involved efforts to fracture reservoirs in the Upper Devonian Shales of the eastern United States. During 1976, a Government-industry contract was signed for the investigation of methane-saturated gulf coast salt water aquifers.

The Federal Power Commission (FPC) regulates the sale, transportation, and price of gas moved in interstate commerce. During 1976, the FPC increased the uniform national base rate from its previous level of $0.52 per Mcf to $1.42 per Mcf for sales of natural gas from wells commenced on or after January 1, 1975, with an automatic quarterly escalation of $0.01 per Mcf beginning October 1, 1976. A ceiling for natural gas from wells commenced during 1973 and 1974 was set at $0.93 per Mcf, with a $0.01 per annum escalator. Natural gas from wells commenced prior to January 1, 1973, was to be allowed to rise from the previous level of $0.29 per Mcf to $0.52 per Mcf when contracts expire by their own terms.

Leasing of public lands for the exploration and development of natural gas (and crude oil) resources continued under the authority of various public land acts. In 1976, the Federal Government leased a total of 1.3 million acres in the Gulf of Mexico, Gulf of Alaska, and Mid-Atlantic Outer Continental Shelf areas for bonus bids aggregating $2.3 billion.

The Office of Pipeline Safety (OPS), which is responsible for safety regulation of natural gas pipelines, reported that the total number of pipeline failures in 1976, and the fatalities resulting from these failures, were the highest since it began reporting these data pursuant to the Natural Gas Pipeline Safety Act of 1968. Pipeline failures during 1976 were 15% higher than in 1975, and fatalities resulting from these failures jumped from 14 to 63. Damage by outside forces was the cause of 55.6% of total failures in 1976 (table 2).

Federal gas pipeline safety standards, contained in 49 CFR Part 192 of Title 49 of the Code of Federal Regulations, were amended during 1976 to update existing referenced documents, provide protection for buried cast iron pipelines, clarify requirements for operator emergency plants, establish new performance standards for joint sealing methods for cast iron pipe, provide more appropriate bending requirements for steel pipe, and delineate the safety regulations for offshore gas pipelines. Notices of proposed rulemakings were issued with respect to modified corrosion control requirements for small isolated metal fillings in plastic pipelines, modified bending requirements, and occupational safety and health requirements for pipeline personnel.

DOMESTIC PRODUCTION

Gross withdrawals of natural gas; including marketed production, gas returned to the formation for pressure maintenance, and that vented or flared; totaled 20.9 Tcf in 1976, only 0.8% less than in 1975. Marketed production, which totaled 20.0 Tcf in 1976, was also only 0.8% less than during 1975. Gas used for repressuring and quantities vented and flared in 1976 totaled 0.9 Tcf and 0.1 Tcf, respectively, approximately the same as in 1975. Data on gross withdrawals and disposition of natural gas appear in table 3.

Gross withdrawals from gas wells declined 1.1% in 1976 to 17.2 Tcf and gas withdrawals from oil wells increased 0.8% to 3.8 Tcf. Increased gross withdrawals were registered by 20 of the 31 producing States, but the quantities involved in most cases were small. The largest gain, 121 Bcf, was in Oklahoma. Gross production in Texas, the largest producing State, declined 4.0%.

Most of the total marketed natural gas production was from Texas and Louisiana. Marketed production data for leading producing States are shown in the following tabulation:

State	Marketed production in 1976 (Bcf)	Change from 1975 (percent)	Percent of total U.S. marketed production in 1976
Texas	7,192	-3.9	36.0
Louisiana	7,007	-1.2	35.1
Oklahoma	1,727	+7.6	8.7
New Mexico	1,231	+1.2	6.2
Kansas	829	-1.8	4.2
California	354	+11.3	1.8
Wyoming	329	+4.1	1.6
Others	1,283	+4.1	6.4
Total	19,952	-0.8	100.0

Gas well completions (table 4) increased 19.9% to 9,085 in 1976. Approximately 37.6% of the total net increase was accounted for by Ohio, where most of the wells completed were shallow and self-help drilling (drilling by gas consumers on their own property) was also an important factor. Another 29.4% of the total net growth was registered in Louisiana, were the bulk of the increase in completions resulted from in-fill drilling on closer spacing in the northern part of the State in response to rising intrastate gas prices. In Texas, which accounted for 20.0% of the total increase, continuing development of the Laredo field and exploratory and development drilling in the Ozana-Sonora area in the southwest part of the State were partially responsible for increased activity.

Completions of exploratory wells (table 5) in 1976 increased 19.7% to 1,402. Texas accounted for 49.4% of these completions.

Data in gas well completions include condensate wells. The latter are wells that produce from high-pressure natural gas reservoirs, some of which contain considerable quantities of liquid hydrocarbons in the pentanes and heavier range described generically as "condensate."

The number of gas condensate wells producing at yearend 1976 totaled 137,443 (table 6). This was an increase of 4.0% over the 1975 yearend total and 13.4% more than the number of wells producing at yearend 1972.

CONSUMPTION AND USES

Consumption (wet) of natural gas in 1976 totaled 20.8 Tcf, 1.9% higher than in 1975 (table 7). Gas delivered to consumers increased 1.2% to 17.8 Tcf during 1976 when it accounted for 85.4% of total consumption. Of the remainder, 7.9% was used as lease and plant fuel, 2.6% was used for pipeline fuel, and 4.1% was accounted for by extraction losses (shrinkage) at gas-processing plants.

Residential use increased 2.6% in 1976 to 5,051 Bcf when it accounted for 28.4% of the total deliveries to consumers (table 8). Increases in residential use occurred in all census regions except the Pacific and West North Central.

The total number of residential consumers declined slightly during 1976. Data on the number of residential customers by census regions for the years 1966, 1975, and 1976 are as follows:

Census regions	Residential consumers (thousands)		
	1966	1975	1976
New England	1,532	1,626	1,556
Middle Atlantic	7,490	7,594	7,512
East North Central	8,181	9,493	9,453
West North Central	3,001	3,587	3,415
South Atlantic	3,005	3,597	3,493
East South Central	1,679	1,967	1,798
West South Central	4,081	4,698	4,923
Mountain	1,580	2,227	2,184
Pacific	5,535	6,727	6,904
Total	36,084	41,516	41,238

The use of gas by the commercial sector increased 5.0% to 2,383 Bcf in 1976 despite a 1.6% decline in the number of customers. This sector accounted for 13.4% of total deliveries to consumers.

The industrial sector remained the largest user of natural gas, accounting for 39.2% of 1976 deliveries to consumers. Total consumption by this sector declined only slightly to 6,967 Bcf during the year. Most of the gas used by industry was consumed as fuel with petroleum refineries, which used 19 Bcf, comprising the largest fuel-consuming industrial sector. Other important industrial users of gas for fuel included the primary metal, nonmetalic, paper, and food products sectors.

The principal non-fuel use of gas involved the petrochemicals industry. This sector's use of gas as a feedstock in 1976 accounted for 8.7% of total industrial use and 3.4% of all U.S. natural gas consumption. Of the 607 Bcf of natural gas used by the petrochemicals industry as a raw material in 1976, nearly 435 Bcf went into production of ammonia. The second largest use, nearly 75 Bcf, was used for production of methanol. Manufacturers of acetylene, carbon black, and hydrogen were also significant consumers of natural gas for raw material use, collectively accounting for an additional 75 Bcf. Producers of hydrogen cyanide, carbon disulfide, chloroform, methyl chloride, methylene chloride, and carbon tetrachloride accounted for most of the remaining consumption of gas as a raw material.

Use of gas by electric utilities continued to decline in 1976 when consumption by this sector dropped 2.2% to 3,078 Bcf. Decreases occurred in all regions except New England, West South Central, and Pacific, which registered relatively small volume gains.

The continued shortage of natural gas supplies during 1976 forced many gas-distribution companies to deny service to new customers and to curtail supplies to some existing users (tables 10-14). FPC reported that net curtailments of firm delivery commitments of the major interstate pipeline companies for the year April 1976 through March 1977 totaled 3,380 Bcf, a deficiency of 23.0%. Net interruptible curtailments for the same period were reported at 475 Bcf, a deficiency of 70.9%. Firm curtailments for the year ending March 1977 were 20.7% higher than those for the preceding period and interruptible curtailments rose 43.9%.

The mileage of field and gathering, transmission, and distribution pipelines in service at the end of 1976 was up only 0.8% from that of the previous year. Data on the Nation's natural gas pipeline network are as follows, in thousands of miles:

	1964	1974	1975	1976
Field and gathering	61.0	66.4	68.5	70.3
Transmission	205.4	262.2	262.6	258.2
Distribution	469.8	645.6	r648.2	659.1
Total	736.2	974.2	r979.3	987.6

rRevised.

RESERVES

Discoveries of natural gas failed to equal production during 8 of the last 9 years, and proved reserves declined 26% during the period. In 1975, the quantity of gas discovered was considerably less than that produced and proved reserves dropped 5.3% from 228.2 Tcf at yearend 1975 to 216.0 Tcf by yearend 1976 according to the Committee on Natural Gas Reserves of the American Gas Association (AGA).

Net additions, before production, to proved reserves reported in 1976 aggregated almost 7.4 Tcf, approximately 31% less than in 1975. Almost 53% of net additions to reserves in 1976 were offshore in the Gulf of Mexico. Extensions to known fields accounted for the largest addition to reserves, 5.3 Tcf, approximately 52% of which were in Texas and Louisiana (including offshore). About 59% of the 2.0 Tcf total for new

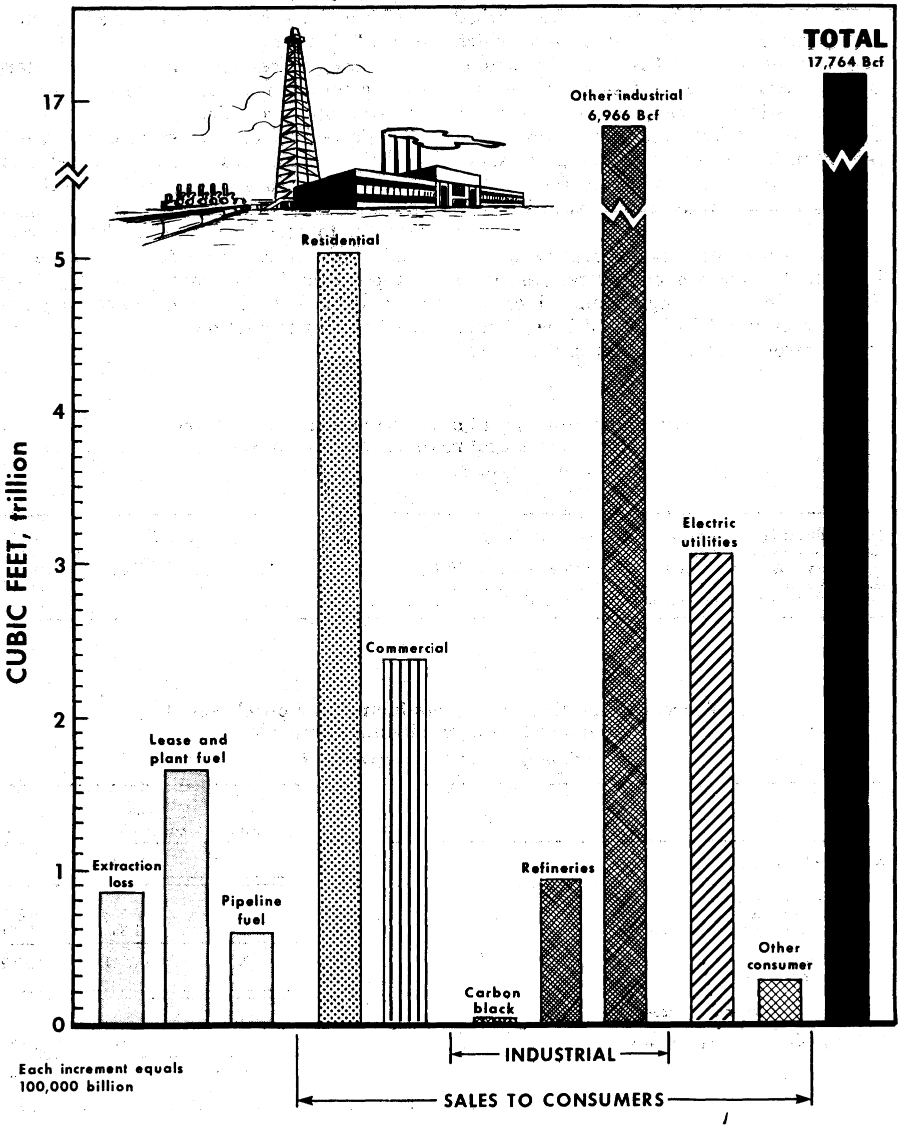

Figure 1.—Disposition of natural gas consumed in the United States, by principal use.

reservoir discoveries in old fields were in Louisiana. New field discoveries totaled approximately 1.4 Tcf, over 68% of which was accounted for by Texas and Louisiana. On the negative side, revisions of previous reserve estimates resulted in a net reduction of 1.2 Tcf, and there was a net reduction in underground storage of about 0.2 Tcf. Details on proved reserves of natural gas in the United States are shown in table 16.

There were some net increases during 1976 in the reserves of natural gas in 11 States. However, significant increases occurred only in Montana and New Mexico where reserves rose 0.18 Tcf and 0.16 Tcf, respectively. Reserves in Texas dropped 6.4 Tcf, or 9.0%, and those in Louisiana declined 3.8 Tcf, or 6.2%.

Natural gas reserves committed to interstate pipelines declined during 1976 for the ninth consecutive year.

Dedicated domestic reserves dropped 8% in 1976, and domestic gas produced and purchased by interstate pipelines declined approximately 5% from the 1975 total of 12.0 Tcf to 11.4 Tcf in 1976. The reserve-production ratio for interstate reserves dropped from 8.9 at yearend 1975 to 8.6 by yearend 1976. Additional data are shown in the following tabulations:

Preliminary summary of domestic natural gas reserves, interstate natural gas pipeline companies

(Billion cubic feet at 14.73 psia and 60° F)

Total dedicated gas reserves as of December 31, 1975	r106,816
Revisions and additions during 1976	2,814
Gas reserves as of December 31, 1975 and changes during 1976	109,630
Gas produced during 1976	11,361
Total dedicated gas reserves as of December 31, 1976	98,269

STORAGE

The practice of storing natural gas, primarily near market areas, dates back to 1916. The purpose of this storage program is to help meet peak demand during the winter months when the capacities of long-distance transmission systems are inadequate and, hence, total demand cannot be met directly from producing areas. The total quantity of natural gas stored in underground reservoirs in the U.S. has expanded steadily since 1960, except during 1972 when inventories at yearend matched those of the preceding year, and in 1976 when colder than normal weather in the eastern two-thirds of the country resulted in a net drawdown of about 161 Bcf.

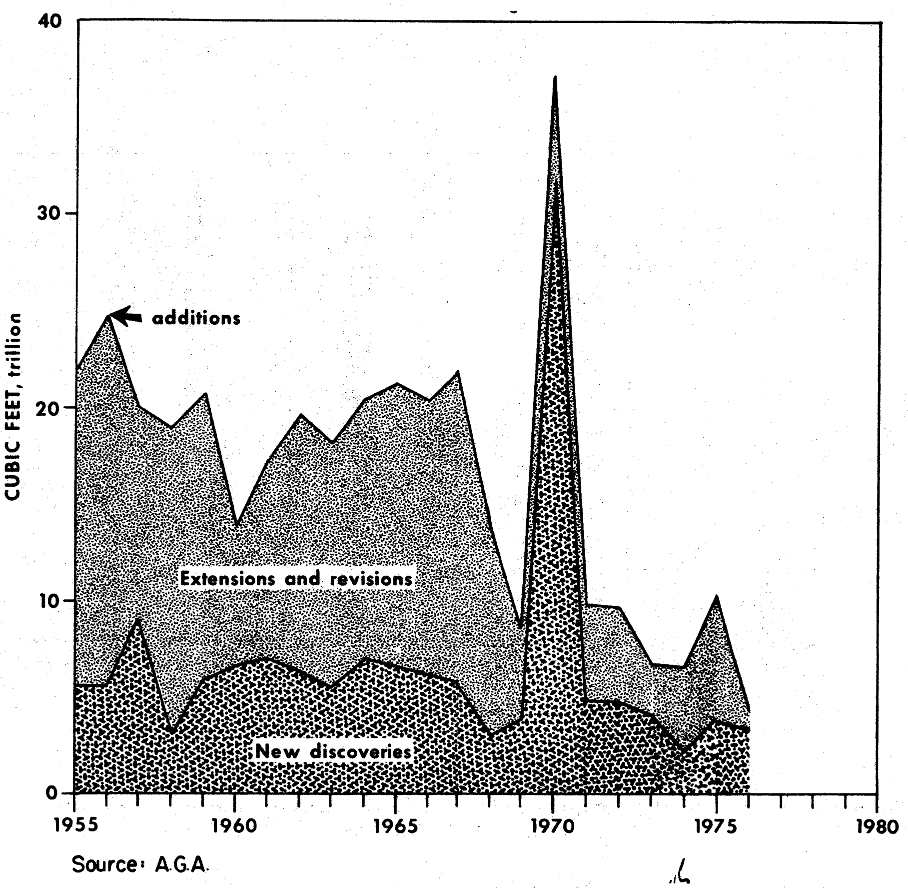

Figure 2.—Trends in annual additions to natural gas reserves.

By the end of 1976 there were 380 underground storage reservoirs with a capacity of 6,580 Bcf in use (table 17). An estimated four-fifths of the total were depleted oil and gas fields, and most of the remainder were of the aquifer type. A few salt caverns and an abandoned coal mine were also in use. Underground reservoirs were located mainly in the midwestern and northeastern U.S. where demand during the peak winter months is heaviest and markets are remote from their sources of supply. The greatest concentration of reservoirs was in Pennsylvania where 61 former oil and gas fields were in use. West Virginia and Michigan had 38 and 37 reservoirs in use, respectively, and Illinois followed closely with 34.

Total quantities of injected natural gas in underground storage at the beginning of 1976 were 4,400 Bcf (table 18). During the months of January, February, March, November, and December a total drawdown of 1,626 Bcf took place, while net injections during the remaining months totaled only 1,465 Bcf. The resultant net drawdown of 161 Bcf reduced yearend stock levels to 4,239 Bcf.

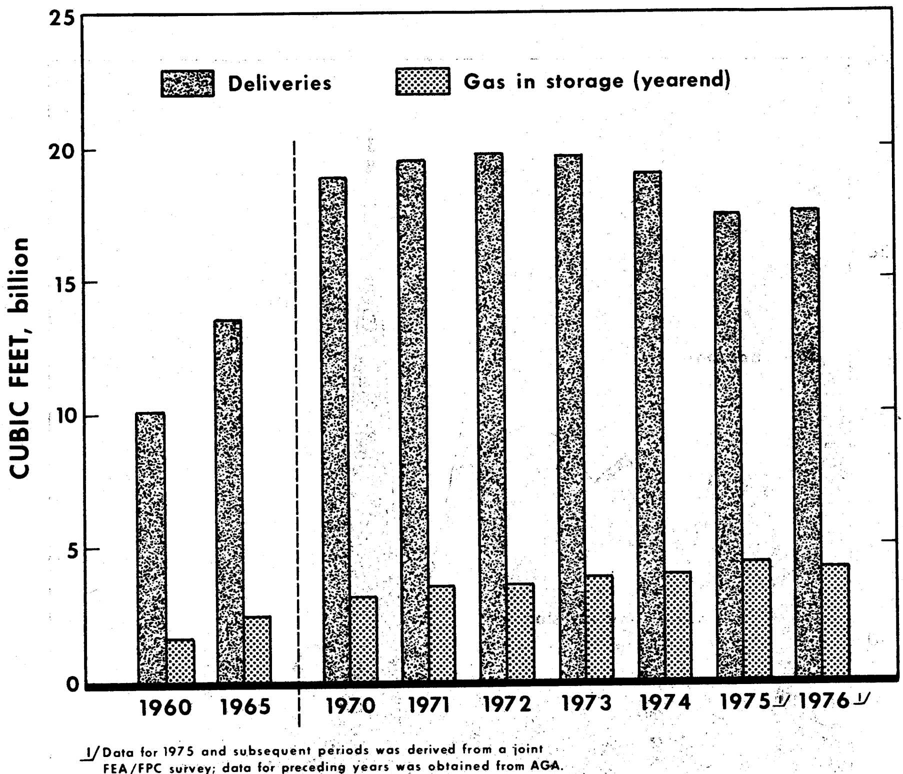

Figure 3.—Trends in total natural gas deliveries to consumers, and quantities of injected gas in underground storage (yearend).

In addition to supplies of natural gas in underground storage, smaller quantities are stored aboveground in liquefied form near markets or import terminals.

The following tabulation summarizes LNG storage data:

Facility	Status	Capacity (Bcf)	Number of plants
Peak shaving	Operational	53.7	54
Do	Under construction	5.2	6
Large satellite	Operational	6.3	22
Do	Under construction	1.5	1
Small satellite	Operational	0.2	31
Import-receiving terminals	Do	11.2	3
Do	Under construction	10.2	3
Total	Operational	71.4	110
Do	Under construction	16.9	10

In general, peakshaving facilities have both liquefaction and regasification capabilities while satellite facilities have only regasification equipment.

VALUE AND PRICE

Total wellhead value of marketed natural gas production increased 29.4% to $11,572 million in 1976, despite a 0.8% decline in production volume (table 19). This occurred as a result of a 30.3% increase in average wellhead value to 58 cents per Mcf. Texas and Louisiana accounted for 48.7% and 8.5%, respectively, of the $2,627 million increase in total value during 1976.

Wholesale prices.—Average wholesale prices for natural gas in the 14 large metropolitan areas for which FPC collects such data rose significantly between July 1, 1975 and July 1, 1976. Increases for individual metropolitan areas ranged from 7.5% to 52.2%, and the median price rise was 19.0%. Excluding the Los Angeles area average price of 82.09 cents per Mcf, which was actually the price at the California State line, the lowest wholesale price reported as of July 1, 1976 was 89.69 cents per Mcf in the Chicago area. The highest average price reported was 185.31 cents per Mcf in the Boston area.

A 7-year historical series of average wholesale natural gas prices in the 14 large metropolitan areas is shown in table 20. The wholesale prices for gas in those cities listed are based on the effective FPC gas tariffs. In cities served by more than one pipeline, prices are based on weighted average charges. Prices reflect deliveries at the city gate except for Los Angeles and San Francisco where distributors purchase gas at the California-Oregon and California-Arizona State lines.

Retail prices.—The average retail price for natural gas delivered to all classes of consumers increased 22.8% above 1975 levels to 146.5 cents per Mcf in 1976. The largest average increase was in the industrial sector where retail prices increased 28.6% to an average 124.0 cents per Mcf. Residential users paid an average 197.8 cents per Mcf in 1976 and the average price to commercial consumers was 169.3 cents per Mcf. Retail costs to electric utilities averaged 98 cents per Mcf.

Monthly data, collected by the Bureau of Labor Statistics on the average price of residential heating gas in 20 standard metropolitan areas, indicate an average increase of 19.4% in such costs between January 1976 and January 1977. Increases for individual areas ranged from 5.3% in Philadelphia to 43.9% in Cincinatti. The largest price increases occurred where prices have generally been lower, thus the disparity in prices between the 20 selected metropolitan areas narrowed significantly in 1976. A historical summary of average residential heating gas prices in 20 standard metropolitan statistical areas appears in table 21.

FOREIGN TRADE

Exports of natural gas totaled 64.7 Bcf in 1976, a decline of 11.0% from 1975. Of the total 1976 volume, 76.9% was shipped from Port Nikiski, Alaska to Japan as LNG. Exports via pipeline to Canada and Mexico were almost equally divided with Canada receiving 50.3% of the total deliveries.

The LNG exported to Japan in 1976 totaled 49.8 Bcf valued at $83 million compared with 53.0 Bcf valued at $73 million in 1975. Since no receiving terminals exist on the U.S. west coast and there were no U.S. flag LNG tankers capable of transporting LNG from Alaska to the east coast, all Alaskan LNG was exported. Federal Maritime law requires U.S. flag ships for all interstate seaborne trade. Statistics on LNG exports for 1976 are shown in table 22.

Exports via pipeline to Canada in 1976 totaled 7.5 Bcf compared with 10.2 Bcf in 1975, a decline of 26.6%. Detroit was the exit point for most of these shipments. Natural gas exports via pipeline to Mexico continued to decline from 9.5 Bcf in 1975 to 7.4 Bcf in 1976. Comparisons of exports in 1975 and 1976 are shown in table 23.

Pipeline imports of natural gas from Canada totaled 953.6 Bcf in 1976, an increase of 0.6%. These imports were valued at $1,652 million, compared with $1,147 in 1975. This large increase in value resulted from the continuing rapid increase in the average price of gas from 55.35 cents per Mcf in 1974 to 121.03 per Mcf in 1975 and 173.27 Mcf in 1976. Nine companies imported Canadian gas in 1976.

For the second consecutive year since 1955 there were no imports of natural gas from Mexico. Data on pipeline natural gas imports are shown in table 24.

Imports of LNG totaled 10.2 Bcf during 1976, more than double the 1975 total of 4.9

Bcf. These imports, shipped from Algeria to Everett, Mass., the U.S. receiving point, were valued at $7.9 million. There were no LNG imports from Canada in 1976. LNG import data are summarized in table 25.

The El Paso Algeria Corp.'s 25-year contract with Société Nationale pour la Recherche, la Production, le Transport, la Transformation et la Commercialisation des Hydrocarbures (SONATRACH), the Algerian National Oil and Gas Co., which has been approved by FPC, calls for the delivery of LNG equivalent to about 1 Bcf per day. This LNG will be transported from Algeria in a fleet of 9 tankers, owned and operated by El Paso. Each tanker will carry the equivalent of 2.6 Bcf of natural gas. Three of these ships, which were built in France, were completed as of the end of 1976, and the remaining six were in various stages of construction in U.S. shipyards. Deliveries to Cove Point, Md. and Elba Island, Ga. are expected to begin in 1978.

The receiving terminal at Cove Point, Md., which is jointly owned by Columbia LNG Corp. and Consolidated System LNG Co., will handle a quantity of LNG equivalent to 650 million cubic feet (MMcf) of gas per day when completed in 1977. Columbia will receive 300 MMcf and Consolidated 350 MMcf per day. After regasification of the LNG at Cove Point, the gas will be shipped by an 87-mile, 36-inch pipeline, completed in 1976, to a compressor station at Loudoun, Va., and then to transmission, distribution and storage facilities.

Construction of the receiving terminal on Elba Island near Savannah, Ga., owned by Southern Energy Co., was about 80% complete at yearend 1976 and is scheduled for completion in 1977. Southern will receive 350 MMcf of gas per day from El Paso.

Other proposed LNG projects were awaiting FPC approval. Among these, was that filed by Trunkline Gas Co. to import the equivalent of 168 Bcf of natural gas per year from Algeria, over a 20-year period, beginning in 1980. Trunkline requested approval to construct a receiving terminal with storage and regasification facilities near Lake Charles, La., at an estimated cost of $164.3 million.

Another project awaiting approval was that of Tenneco Corp. to import LNG from Algeria to the U.S. via Canada. This 20-year contract calls for the delivery of the equivalent of 397 Bcf of natural gas per year to St. Johns, New Brunswick, Canada. After regasification, 280 Bcf of gas per year would enter the U.S. by pipeline and the remainder would be used in Canada. This would involve the construction of a pipeline, at an estimated cost of $546.4 million, consisting of about 391 miles of 30-inch line from the Maine-New Brunswick border to Albany, N.Y. and 107 miles of 30-inch line extending from there to Tennessee Gas Pipeline Co.'s main transmission line near Milford, Pa.

An application was filed with FPC by Pacific Indonesia LNG Co. to import LNG equivalent to about 539 MMcf of gas per day from Indonesia for a 20-year period. Western LNG Terminal Co. requested approval to construct and operate an LNG receiving terminal near Oxnard, Calif. to handle these imports.

El Paso Eastern Co. requested approval to import LNG from Algeria to a terminal in Matagorda Bay on the Texas Gulf Coast. This 20-year contract with SONATRACH calls for the delivery of 1 Bcf per day of LNG, scheduled to begin in 1984. The LNG would be shipped by a fleet of 12 cryogenic tankers, with El Paso Atlantic Co. providing 6 of the ships and the remaining 6 to be provided by SONATRACH. After regasification of the LNG, 65% would be sold to El Paso Natural Gas Co. and 35% to United Gas Pipe Line Co. El Paso would construct a terminal and 463 miles of pipeline to existing pipeline systems at an estimated total cost of $720 million. The proposed pipeline would connect with El Paso's Waha gas plant in Reeves County, Tex., and would intersect with United's existing line near Victoria, Tex.

WORLD REVIEW

World marketed production of natural gas totaled 49.4 Tcf in 1976 (table 26), an increase of 1.9 Tcf or 3.96% from that in 1975. The United States was the largest producer, accounting for 40.4% of the total.

Algeria.—SONATRACH expanded its natural gas production and processing facilities, and marketed production during the year increased 10% to 370.8 Bcf. Almost all marketed natural gas production was exported as LNG.

Early in 1976, SONATRACH issued a contract valued at $480 million to the C. Itoh Commercial Group and Japan Gasoline

Co., Ltd., to install gas processing units at Hassi R'Mel gasfield rated at 3,860 MMcf per day that will have the capacity to produce 300,000 barrels per day (bpd) of condensate and 95,000 bpd of liquefied petroleum gas (LPG).

Construction of SONATRACH's Arzew No. 1 gas liquefaction plant continued during 1976. Deliveries of LNG from this plant for export to the United States were expected to commence early in 1978.

During 1976 SONATRACH finalized plans to construct two LNG plants at Bettioua, near Arzew on Algeria's western coast. Both facilities were scheduled to begin operations in 1979. One of the plants, to be built by Foster Wheeler Corp., will have the capacity to liquefy up to 1.5 Bcf of gas per day for export. The Algerians contracted Pullman Inc. to design and build the other plant at Bettioua with six liquefaction units, each with a capacity to liquefy in excess of 150 MMcf of gas per day for export to Europe and the United States.

Société d'Etudes du Gazoduc de la Mediterranee Occidentale (SEGAMO), an organization owned by Algeria, France, and Spain, examined possible routes for a long-distance, natural gas pipeline to deliver Algerian gas across the Mediterranean Sea to Europe and contracted Williams Companies to prepare a study of the seafloor between Algeria and Spain. The projected 1,550-mile gasoline crossing the Mediterranean Sea between Algeria and Italy and passing through Tunisia was reportedly cancelled at yearend 1976, when Tunisia rejected its permission to build the trunk line across its territory.

Canada.—Marketed production of natural gas in Canada which ranked fourth in total world output, totaled 3.067 Tcf in 1976, a decrease of 0.7% from that of 1975. Most of this production was from the Province of Alberta, although significant quantities were also produced in British Columbia. Exports of natural gas to the United States totaled 954 Bcf in 1976, up 0.6% from 1975.

The Canadian Petroleum Association estimated natural gas reserves at 58.3 Tcf as of yearend 1976, an increase of 1.3 Tcf from yearend 1975. Exploratory drilling for natural gas continued at a high level in western Canada, but continued to decline in the Arctic region during 1976. The decrease in Arctic activity was due in part to the uncertainty of Government energy policies and extremely high operating costs.

Petro-Canada Ltd., the newly-formed national oil and gas entity, signed joint venture agreements with several companies to explore for natural gas off Canada's east coast. The joint ventures included an $18 million project with Shell Canada Ltd. and Shell Explorer Ltd. to drill four wells; a $3 million project with Mobil Oil Canada Ltd. to drill a well near Banquereau Bank; and a $3 million project with Francana Oil and Gas Ltd., Murphy Oil Co., Ltd., and Soquip, the Quebec Governmental oil and gas concern, to drill a well offshore Sydney, Nova Scotia.

Other offshore exploration programs included that initiated by Dome Petroleum Ltd. to drill several wells in the Beaufort Sea offshore the Mackenzie Delta. Eastcan Exploration Ltd. planned to use drillships and a semisubmersible rig to explore for natural gas on the Labrador Shelf.

Gulf Oil Canada Ltd. and Mobil Oil Canada Ltd. tested a development well in the Parsons Lake Field, Mackenzie Delta, at up to 20.5 MMcf per day, and Eastcan Exploration Ltd. tested a discovery well on the Labrador Shelf some 700 miles north of St. Johns, Newfoundland, at 9.8 MMcf per day. Other significant new gas wells tested during 1976 included: Husky Oil Ltd., near Chatham, Ontario, 16.5 MMcf per day; Panarctic Oils Ltd., two discoveries off Melville Island in the Arctic Islands, one at 6.5 and the other at 6.8 MMcf per day; and Shell Canada Ltd., 90 miles northwest of Calgary, Alberta, up to 12.7 MMcf per day.

Several natural gas pipeline projects were completed or in the planning stage during 1976. Alberta Gas Trunk Line, Ltd. completed over 500 miles of various-diameter lines and announced plans to construct 134 miles of large-diameter lines. TransCanada Pipe Lines Ltd. planned the addition of about 70 miles of loop lines to its gas pipelines system in Central Canada. Alberta Oil Sands Pipeline Ltd. planned to build a 170 mile, 16-inch pipeline to transport gas to the Syncrude Ltd. tar sands extraction plant, and West Coast Transmission Co. approved a 4-year program to lay over 440 miles of natural gas gathering lines in western Canada. An 87-mile pipeline is to be constructed in British Columbia from the Grizzly gasfield to a proposed sulfur-scrubbing plant near Chetwynd.

Competing projects were under consideration to move natural gas by pipeline from northern producing areas to markets in the southern Provinces. Two proposals called for the construction of large-diameter international gas pipeline's through Canada from the Alaskan border to existing pipelines in Alberta and British Columbia. Either of these trunklines would be used to deliver Alaskan gas to consumers in the lower 48 States and eventually, to move gas from Canada's Mackenzie Delta to markets in the lower Provinces.

Another plan under consideration called for the construction of a domestic gas line, costing about $3 billion, from the Mackenzie Delta to existing facilities in Alberta.

Indonesia.—Expanded production and processing facilities resulted in Indonesia's total marketed production of natural gas increasing by nearly 54% to 126.4 Bcf in 1976, three times greater than the country's output 2 years earlier. Atlantic Richfield Co. completed the construction of an offshore natural gas processing plant in the Ardjuna Field, in the Java Sea near Jakarta, Java, that will produce up to 20,000 bpd of liquefied petroleum gas and supply the residue gas to onshore industries at the rate of about 200 MMcf per day. A 150-mile gas pipeline was being laid from the plant to a steel mill at Cilegon and to a fertilizer plant at Ceribon.

Two LNG plants and export terminals were under construction by Pertamina, the Government-owned oil and gas entity, one at Badak Field near Balikpapan, Kalimantan, and the other at Aceh Field, North Sumatra. Shipments of Indonesian LNG will be made from these facilities to Japan and possibly, the United States. The Kalimantan plant, which was scheduled to begin operations in 1977, will be capable of processing about 5,700 bpd of natural gas liquids from associated gas and will have the capacity to liquefy about 550 MMcf of natural gas per day. The Sumatra plant, which will be capable of liquefying about 1 Bcf of natural gas per day, was scheduled for completion in 1978.

Mexico.—Marketed production of natural gas by the Government-owned oil and natural gas entity, Petróleos Mexicanos, S.A. (Pemex) totaled 577.9 Bcf in 1976, a decrease of 1% from that in 1975. Large quantities of the gas produced contained hydrogen sulfide and required treatment prior to delivery to the market. Half of the gas was produced in association with the production of crude oil, and the remainder was nonassociated natural gas. Nearly 70% of the output came from fields in southern Mexico, 22% from northern fields, and 8% from fields in the Poza Rica area near the Gulf of Mexico midway between the two major producing areas.

Extensive facilities were being developed in the States of Chiapas and Tabasco in southern Mexico to process large quantities of sour gas from the recently discovered Reforma fields. Units rated at a total capacity of 600 MMcf per day were under construction or operating at Cactus in 1976, and more units will be added during 1977 to increase the capacity there to 1 Bcf per day.

Production from the promising Reforma fields was expected to raise Mexico's total gas output considerably within the next few years, and significant volumes may become available for export, possibly to the United States.

Netherlands.—Natural gas reserves fell by 3% to 83.9 Tcf at yearend 1976, the first decline since the discovery of the prolific Groningen Field in 1959. Total reserves included offshore North Sea fields 13.2 Tcf, Groningen 62 Tcf, and other onshore fields 8.7 Tcf. Marketed production of natural gas in the Netherlands increased by 7.1% to a record 3.4 Tcf during 1976, and the country maintained its position as the world's third largest producer of natural gas.

Norway.—As of yearend 1976, numerous projects were underway or completed in Norway's sector of the North Sea to transport natural gas to markets on the European continent. Deliveries of natural gas from the offshore Ekofisk Field to Emder, West Germany, via a 274-mile pipeline completed in 1976, were scheduled to begin in 1977. Natural gas will be piped from the Emden terminal to consumers in Belgium, France, Netherlands, and West Germany.

Norway and the United Kingdom signed an agreement for the joint development of the Frigg gasfield in the North Sea, and the Norwegian Government initiated a study on the feasibility of gas pipeline construction from offshore fields to markets in Norway.

United Kingdom.—Developments in the North Sea dominated the natural gas industry in the United Kingdom during 1976, and the country maintained its position as the third largest producer of marketed natural gas in Europe. Eleven gas compressing and processing units were under construction at Brent Field to compress gas initially for reinjection and later to process the gas to be piped to shore installations. A $40 million, 200,000 ton, concrete gas treatment platform was installed at Frigg Field, and construction teams laid twin 31-inch, 217-mile gas pipelines from the field to St. Fergus, Scotland. A new gas well in the Morecambe Field of the Irish Sea tested 10-15 MMcf per day.

Gas discoveries in the North Sea during

1976 included a well near Brae Field, which tested 12 MMcf per day, one near Beryl Field, which tested 23.7 MMcf per day, and one near Bacton, England, which tested 18 MMcf per day.

At yearend 1976, the Government was studying a proposal to construct approximately 840 miles of gas gathering lines from producing fields in the North Sea to Peterhead, Scotland.

U.S.S.R.—The U.S.S.R. was second to the United States accounting for 23% of world production. Its 1976 marketed production of natural gas reached a record 11.3 Tcf, up 11% from 1975 and more than 50% above that produced 5 years earlier. Most of the Soviet output came from the Ukraine, Turkmenistan and western Siberia.

Construction was completed during 1976 at the Orenburg gas processing complex, one of the largest in the world. Approximately 1.9 Bcf per day of gas from nearby fields will be processed for the removal of natural gas liquids and sulfur, and then piped to consumers in the U.S.S.R. and other European countries.

Plans were finalized for the development of the Golitsyna gasfield in the Black Sea, about 43 miles west of the Tarkhankut. A confirmation well completed in 1976 flowed 35.3 MMcf per day.

Several thousand miles of natural gas pipelines were built during 1976, with more than 4,000 miles of lines scheduled to be constructed in 1977. Construction was completed during 1976 on nearly half of the 1,680-mile, large-diameter, natural gas trunk lines from the Orenburg Field near the Caspian Sea to Uzhgorod, on the border with Czechoslovakia. Scheduled for completion during 1978, the line will have a design capacity to transport 2.7 Bcf per day of natural gas to several European countries.

The looping of a 600-mile section of the gas pipeline from the giant Vuktyloskoye gasfield, north of Ukhta and near the Arctic Circle, to Torzhok, in European Russia between Leningrade and Moscow at Torzhok was completed in 1976. The line connects with international gas lines serving Czechoslovakia and Poland.

At yearend 1976, a major natural gas trunk line was under construction in western Siberia from the huge Urengoiskoye Field to Nadym. Projects remained in the planning stage to construct long-distance gas pipelines to Japan from Sakhalin Island and from near Yakutsk, in eastern Siberia.

TECHNOLOGY

Government and industry activities in the development of technology designed to increase gas supplies continued in 1976. These efforts involved several techniques to produce gaseous fuel from coal, the gasification of petroleum liquids, the recovery of gas from low permeability formations and methane saturated aquifers, and the production of gas from biomass.

Research involving the gasification of mined coal to produce high-Btu gas was expanded during 1976 as the total number of pilot plants in operation was increased to seven by the completion of four new facilities. In addition, two pilot projects involving the production of low-Btu gas from coal were operational, one was being modified, another was under construction, and two were in the design stage as of yearend 1976. The Energy Research and Development Administration (ERDA) initiated negotiations during the year with private firms for the design of high-Btu and low-Btu coal gasification demonstration projects, and private interests filed applications with the FPC for the construction of two commercial high-Btu plants.

Research involving the production of low-Btu gas by in situ gasification of coal seams was in progress. During 1976, the Laramie Energy Research Center conducted experiments near Hanna, Wyo., which produced low-Btu gas of uniform quality over sustained periods. A consortium of three Texas electric utilities, Texas Utilities Services, Inc., initiated tests involving the in situ gasification of lignite using technology developed in the Soviet Union.

A Bureau of Mines demonstration project continued to gather methane from an operating coal mine near Bula, W. Va. Deliveries of small quantities of methane from this project to Consolidated Gas Supply Corp. occurred during 1976. The Bureau also signed a contract with Emerald Mine Corp. involving a pre-production methane gathering project at a coal mine in Green County, Pa. The goal of both these projects was the development of techniques which would provide additional natural gas supplies for distribution, and also reduce coal-mining hazards.

SNG plants, using naphtha and natural gas liquids as feedstocks, continued to provide supplemental gas supplies, primarily during the winter months. As of yearend 1976, 12 SNG plants were in operation and 1 was under construction.

Research has also focused on fracturing techniques that stimulate flow from economically submarginal gas reservoirs. During 1976, a total of nine fracturing projects were in progress in Wyoming, Colorado, Utah, and Texas, and five projects were underway in the Appalachian area. Several of the latter projects involved fracturing of the Upper Devonian gas shales which underlie about 12 eastern States, including those that comprise the major northeastern markets.

During 1976, a Government-industry contract was signed for the investigation of methane-saturated Gulf coast salt water aquifers. A previous study by the U.S. Geological Survey indicated that these aquifers in onshore reservoirs alone may contain up to 24,000 Tcf of methane.

A program to encourage the development of techniques from the conversion of renewable biomass resources into methane by biochemical, thermochemical, and photochemical processes was initiated by ERDA in 1976. Several resource inventory and technology assessment contracts were awarded universities and other private research organizations. In addition, a contract was awarded for the construction of a pilot plant to test the technical and economic feasibility of converting garbage to methane using anaerobic digesters.

Table 2.—Gas pipeline failures reported during 1975-76

System and cause of failure	Total number of failures		Fatalities				Injuries

[1]Includes multiple completion wells that produce gas from all zones.
[2]Includes multiple completion wells that produce gas from one or more zones but oil from at least one zone.

[1]Includes refinery fuel use of 918,856 million cubic feet and 28,033 million cubic feet for carbon black production.
[2]Includes deliveries to municipalities and public authorities for institutional heating, street lighting, etc.

Note: All quantities at pressure base of 14.73 psia.

[1]The net difference between gas stored in and gas withdrawn from underground storage reservoirs, inclusive of adjustments and natural gas transferred from other reserve categories. (Adjustments include change of reporting basis starting in 1974 to report only gas reserves considered recoverable, in effect, reducing gas reserves by 1,024,140 MMcf that would have been reported since 1972 using the former basis).

[2]Preliminary net production.

[3]Proved recoverable gas contained in underground gas storage reservoirs, including natural and net injected gas. (First reported on a recoverable basis in 1973).

[4]Includes offshore.

[5]Reported quantities include reserves estimated to be recoverable from some reservoirs considered natural gas bearing based on electrical log, core data and other available engineering and geological data.

[6]Included with Louisiana and Texas.

Source: Committee on Natural Gas Reserves, American Gas Association.

Table 17.—Underground storage capacity, by State, December 31, 1976

State	Number of reservoirs	Total capacity (billion cubic feet)
Arkansas	6	54.4
California	8	399.7
Colorado	7	52.7
Illinois	34	786.8
Indiana	28	81.2
Iowa	9	213.0
Kansas	18	172.5
Kentucky	24	213.1

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the countries listed, Thailand and Zaire produce crude oil and presumably produce natural gas, but available information is inadequate to estimate output levels.

[2]Comprises all marketed production (see footnote 3) plus gas vented, flared, reinjected for reprocessing or for storage, and used to drive gas turbines (without being burned).

[3]Comprises all gas collected and utilized as a fuel or as a chemical industry raw material as well as that used for gas lift in fields, including gas used in oilfields and/or gasfields as a fuel by producers, even though it is not actually sold.

[4]Gas vented or flared is apparently not included; difference between gross production and marketed production is the amount reinjected into reservoirs.

[5]Gross production not reported; marketed output had been reported in lieu of estimating gross output because the quantity vented, flared or reinjected is believed to be small.

[6]Includes output from coal mines as follows in million cubic feet: Austria: 1974—71; 1975—70 (estimate); 1976—NA; Czechoslovakia: 1974—10,806; 1975—10,500 (estimate); 1976—NA; West Germany: 1974—17,940; 1975—16,000 (estimate); 1976—NA; Poland: 1974—7,451; 1975—7,400 (estimate); 1976—NA; the United Kingdom: 1974—3,991; 1975—3,800 (estimate); 1976—NA; Japan: 1974—9,747; 1975—9,500 (estimate); 1976—NA.

[7]Total production obtained from coal mines.

[8]No marketed production reported; there probably was some small field use in Denmark, Norway and Sharjah, and in Norway there was extraction of natural gas liquids in each year 1974-1976, but available information is inadequate to estimate output levels.

[9]Includes gas reinjected to reservoirs, if any.

[10]Excludes gas used for gas lift.

[11]Data are for year ending June 30 of that stated.

[12]Includes 1/2 of production reported for the former Kuwait-Saudi Arabia Neutral Zone.

[13]The Sabah region of Malaysia also reports crude oil production, and thus presumably produces some natural gas, but available information is inadequate to estimate gross output levels, and no data are available to indicate whether or not any part of gross output is classified as marketed.

Natural Gas Liquids

By Thomas G. Clarke[1] and Leonard L. Fanelli[2]

Domestic production of natural gas liquids (NGL) from gas processing plants in 1976 was 587 million barrels, 8.9 million barrels, or 1.5%, less than in 1975. This fourth consecutive annual decline in production was attributed to a decline in the availability of supplies of natural gas and to the decreased liquids content of the gas processed. The volume of natural gas processed during the year totaled 17.72 trillion cubic feet, compared with 17.75 trillion cubic feet in 1975. The total domestic apparent demand for NGL rose to 656.8 million barrels in 1976, after a 3-year decline from the alltime high of 700 million barrels recorded in 1972.

The total value of NGL production increased to $3.28 billion in 1976 from $2.77 billion in 1975. This represented an increase in the average unit value to $5.59 from $4.65 per barrel in 1975. The 1976 increase in value was the result of actions taken under the Government's pricing and allocation program administered by the Federal Energy Administration (FEA). A 1976 amendment to FEA regulations permitted sellers of NGL to pass through increases in product and distribution costs to consumers. In general, the May 15, 1973, selling price was used as a reference base price to which allowable cost increases were added to determine lawful prices. Another change eliminated certain inherent inequities regarding price adjustments by certain classes of sellers.

Presidential Proclamation 4412, issued January 3, 1976, removed all fees on imported NGL products, except for naphtha derived from natural gas. The import rate for naphtha varied from 0.25 cents to 0.5 cents per gallon, depending on the country of origin.

Natural gas liquids are extracted from natural gas at gas processing plants. The lighter products, ethane and liquefied petroleum gases (LPG—butane, propane, pentane, isobutane, and mixed gases) remain in a liquid state only under pressure or when

rRevised.
[1]Includes isopentane, plant condensate, finished gasoline, special naphtha, distillate fuel oil, kerosine, and miscellaneous.
[2]Includes 93,595,000 barrels in underground storage.
[3]Includes 81,768,000 barrels in underground storage.

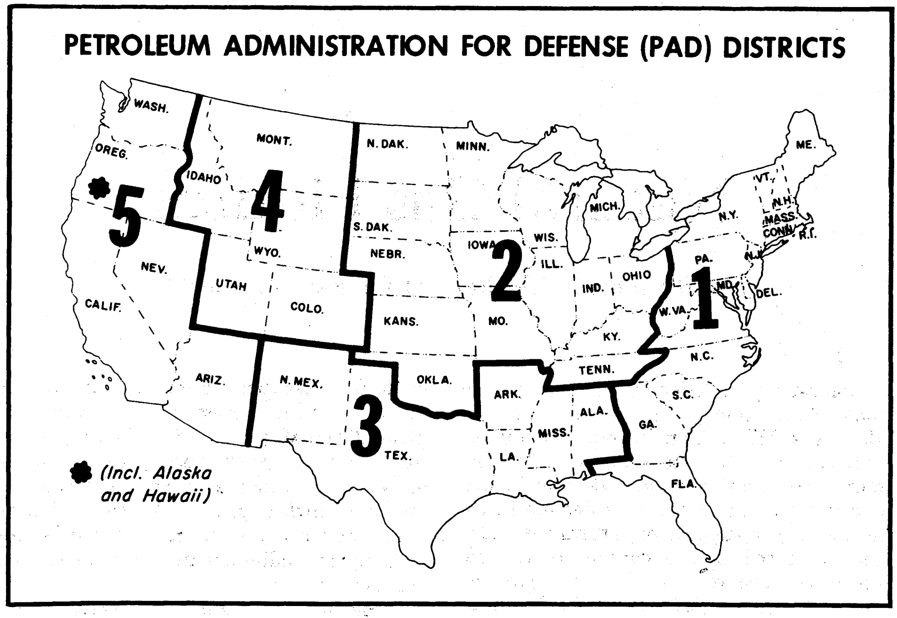

Figure 1.—Map of PAD districts.

cooled. Natural gasoline and plant condensate remain liquid at atmospheric pressure and may be run to fractionators for the production of naphtha, jet fuel, kerosine, distillate fuel oil, and other finished products.

Data presented in this chapter were compiled from reports of natural gasoline plants, cycling plants, and fractionators that process natural gas. Plant condensate is included with NGL; field condensate is included with crude oil data presented in the petroleum chapter. Ethane and liquefied gases recovered from crude oil refinery operations (such as ethane, butane, and propane) are classified as liquefied refinery gases (LRG) and are reported as refined petroleum products.

DOMESTIC PRODUCTION

Production of NGL at natural gas processing plants decreased to 587 million barrels in 1976, 8.9 million barrels less than in 1975. The output of ethane continued to increase for the eighth consecutive year, but production decreased in other NGL product categories. The rise in ethane production to about 23% of total NGL output was commensurate with increasing demand for ethane as a petrochemical feedstock, and improved NGL plant thermodynamic efficiency. LPG comprised 52% of total 1976 NGL production, while natural gasoline, condensate, and other products accounted for the remaining 25% of production. A tabulation indicating quantities and percentage change in production of the various NGL product categories between 1975 and 1976 follows:

	Thousand barrels	Percent
Ethane	+10,709	+8.70
LPG:		
Propane	-10,959	-5.46
Other	-6,470	-5.37
Natural gasoline and isopentane	-1,072	-0.08
Other natural gas liquids	-1,121	-6.21
Total	-8,913	-1.5

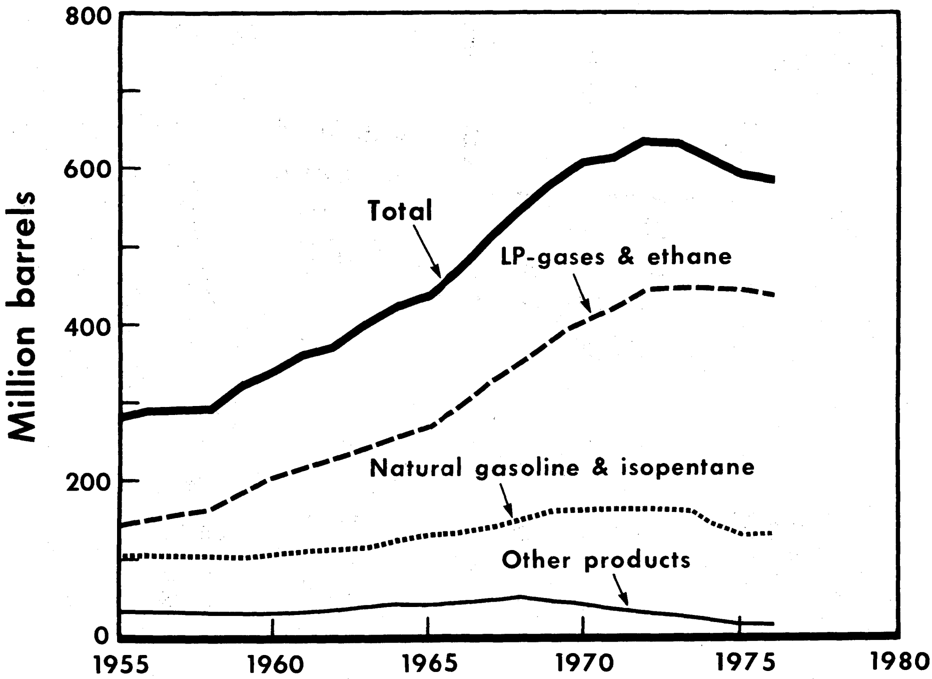

Figure 2.—Production of natural gas liquids in the United States.

At yearend 1976, the number of gas processing plants in operation totaled 763, compared with 754 a year earlier.[3] Plants were located in 23 States and were owned and/or operated by about 130 companies. Production from gas processing plants was accounted for by Texas, 46%; Louisiana, 14%; Oklahoma, 11%; California, 5%; New Mexico and Wyoming, 4.5% each; and others, 15%. Gas processing plant capacity remained almost constant at 72,610 million cubic feet (MMcf) per day, a decline of only 0.1% from that of 1975. During 1976 the gas throughput nearly maintained the level of 1975, declining only 0.4%, from 48,626 MMcf per day to 48,410 MMcf per day.

RESERVES

The American Gas Association Committee on Natural Gas Reserves estimated proved recoverable reserves of NGL in the United States on December 31, 1976, were 6,402 million barrels, an increase of 134.1 million barrels from that of 1975. This increase ended 8 consecutive years of decreasing reserves. New field and reservoir

[3]Oil and Gas Journal. V. 77, No. 28, July 11, 1977, p. 74.

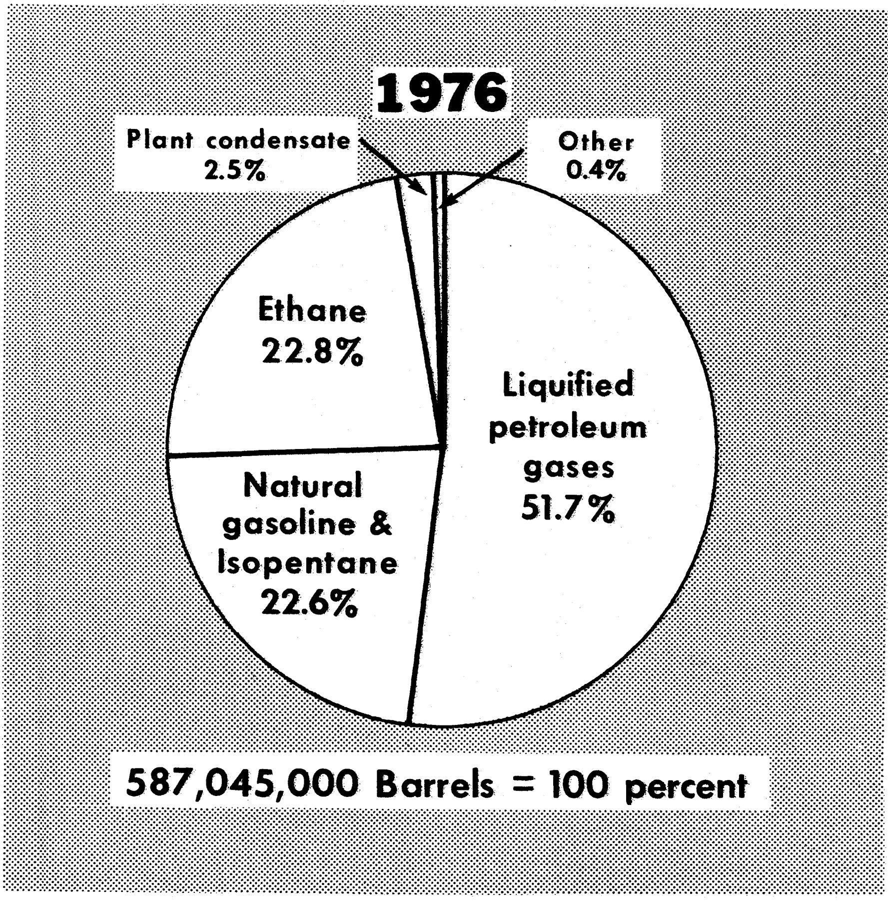

Figure 3.—Relative production of natural gas liquids components, 1976.

discoveries amounted to 61.8 million barrels, principally in Texas and Louisiana. Extensions and net revisions were 772.9 million barrels; Alaska accounted for almost 408 million barrels, the most significant addition to reserves during the year. Of total reserves at yearend 1976, Texas accounted for 39% and Louisiana accounted for 25%.

CONSUMPTION AND USES

Approximately 45% of all 1976 NGL plant output was utilized by refineries for fuel or petrochemical uses. Refinery input of natural gas products during 1976 was 265.45 million barrels, an increase of 2.4% from the 1975 level. Increases were accounted for by butane, propane, butane–propane mixtures, and plant condensate, but the input of natural gasoline declined in conjunction with the reduced domestic output of that product. The following summary shows NGL product input to refineries, in thousand barrels:

Product	1975	1976	Change (percent)
Propane	3,926	4,510	+14.9
Butane:			
Isobutane	35,760	32,200	-10.0
Normal butane	35,056	42,179	+20.3
Other butane	13,647	14,482	+6.1
Total butane	84,463	88,861	+5.2
Butane-propane mixtures	1,273	1,889	+48.4
Natural gasoline	134,087	132,320	-1.3
Isopentane	--	--	--
Plant condensate	35,570	37,871	+6.5
Grand total	259,319	265,451	+2.4

Total domestic demand for liquefied gases and ethane at gas processing plants and refineries in 1976, as indicated in table 11, was 513.97 million barrels, up about 5.7% from a demand of 486.45 million barrels in 1975. NGL processing plants supplied 388.2 million barrels, or 76% of total demand; the remainder was LRG used in petrochemical manufacture, 8%, and for fuel at refineries, 16%.

The highest domestic demand was for propane (including propylene) which accounted for 303.84 million barrels, or 59% of the total. Ethane (including ethylene) demand was 132.71 million barrels, about 26% of the total. All of the ethane was utilized for the production of petrochemicals, primarily ethylene. According to the U.S. International Trade Commission, total production of ethylene from ethane was 22 billion pounds in 1976, up almost 6% from the 20.5 billion pounds produced in 1975.

Sales of ethane and LPG in 1976 were 26.0 billion gallons, an increase of 1.4 billion gallons from the 1975 output. Propane accounted for 51.7% of the sales and ethane was 21.5%. The chemical industry was the largest user, accounting for 37.2% of total sales. Residential and commercial use was 28.2% of sales, and 15.4% was used in gasoline production.

STOCKS

Yearend stocks of NGL and ethane at plants, terminals, and refineries were 117.33 million barrels compared with 124.28 million barrels in 1975. Included in the 1976 total were 81.77 million barrels in underground storage. The decrease in stocks reflected cooler than normal temperatures during the fall and early winter, especially in the eastern half of the United States. Total stocks at plants and terminals were down 5.96 million barrels to 112.26 million barrels, and refinery stocks fell 0.99 million barrels to 5.07 million barrels. Ethane stocks at plants and terminals increased 6.6 million barrels during 1976, and natural gasoline stocks were up 0.1 million barrels. However, propane stocks at plants and terminals declined 6.6 million barrels; butane, 5.3 million barrels; and condensate, 0.2 million barrels.

PRICES AND VALUE

The average unit value of NGL production at natural gas processing plants was $5.59 in 1976, an increase of 20% from 1975. Total value of NGL was $3.28 billion in 1976, compared with $2.77 billion in 1975. LPG and ethane accounted for about 70% of total NGL value in 1976. A tabulation of average values, from 1972-76, in dollars per barrel, follows:

	1972	1973	1974	1975	1976
LPG and ethane	1.91	2.66	4.42	4.26	5.26
Natural gasoline and isopentane	3.06	3.51	6.59	5.81	6.65
Plant condensate	3.39	3.94	6.52	5.47	5.69
Finished gasoline and naphtha	4.66	4.29	7.97	7.76	9.99
Other[1]	2.58	3.25	5.39	5.35	7.52
Total (average)	2.28	2.93	5.01	4.65	5.59

[1]Includes kerosine, distillate fuel oil, and miscellaneous products.

Natural gas liquids continued to be subject to FEA mandatory allocation and price controls, and the rise in prices in 1976 was due primarily to a passthrough of product and distribution costs permitted by FEA. Propane price data for six widely separated domestic areas are presented in table 17.

FOREIGN TRADE

Net imports of NGL increased 8% to 62.9 million barrels in 1976 from 58.2 million barrels in 1975. Gross imports, consisting of LPG and plant condensate, increased 6% from 67.7 million barrels in 1975 to 71.8 million barrels in 1976. Imports of LPG increased 16%, but receipts of plant condensate declined 9.5%. The increase in LPG imports was associated with the declining availability of domestic natural gas supply for NGL plants and colder than normal temperatures in the fall and early winter, especially in the eastern half of the country. The decrease in imports of plant condensate resulted from a shift to a higher proportion of lighter fractions, especially propane, in the feedstocks shipped from Canada to synthetic natural gas plants in Michigan and Ohio.

Canada supplied 74% of LPG imports and 99% of plant condensate receipts in 1976. Venezuela was the source of 12% of LPG imports and the remaining plant condensate. Countries supplying more than 100,000 barrels of LPG imports in 1976 were Algeria, Australia, France, the Hawaiian Trade Zone, Kuwait, Saudi Arabia, and the United Kingdom.

Exports of NGL decreased 5% to 9.0 million barrels in 1976, compared with 9.5 million barrels in 1975. Small quantities of NGL were shipped to numerous countries, but 99% of the exports of NGL went to Mexico and Canada. Mexico, traditionally the largest recipient of U.S. LPG exports, received 97% of the total volume, comprised mainly of butane-propane mixtures, and 2% of the exports were dispatched to Canadian consumers. Total NGL exports consisted of butane, 2.8%; propane, 23.6%; and butane-propane mixtures, 73.6%.

WORLD REVIEW

In 1976 the United States and Canada continued as the world's largest producers of NGL, with a combined total of 692 million barrels, about 66% of total world production. Of growing importance in the world export trade was the increased production from the Middle Eastern area, mainly Iran, Kuwait, and Saudi Arabia, which produced a combined estimated total of 99.6 million barrels in 1976, compared with 80.1 million barrels in 1975.

The Government of Saudi Arabia and the Arabian American Oil Co. (Aramco) completed the first phase of construction of several NGL processing centers, including a compression center at Abqaiq and a treatment and a fractionation plant at Ra's at Tannurah, Saudi Arabia's main export terminal. The Abqaiq plant was designed with a gas processing capacity of 320 MMcf per day from gas-oil separator plants in the Ghawar and Abqaiq fields. Production of 140,000 barrels per day (bpd) of NGL will be piped to Ra's at Tannurah for export. The second phase of the $1 billion Aramco expansion will be at Berri-Al Jubayl several miles north of the Ra's at Tannurah terminal. Production capacity will be 600 MMcf per day with an NGL recovery of 70,000 bpd, a smaller yield than at Abqaiq because of the lower NGL content of Berri-Al Jubayl gas.

Northern Natural Gas Co. and Shell International Gas, Ltd. negotiated a contract valued at $1 billion for the sale of LPG to be produced from the North Sea over a 10-year period. This may be the first long-term LPG contract negotiated around future price indices: The periodic adjustments are to be based upon the prices of Arabian light crude, the U.S. Wholesale Price Index, and the U.N. Index for Exports of Manufactured Goods from Industrial Countries. Deliveries are scheduled to start after January 1, 1979, to one of five U.S. east or gulf coast ports. About 3 million barrels of LPG are to be delivered during the first year, 7 million barrels during the second, and 7.9 million barrels annually for the remainder of the contract period. The LPG would be produced from the Shell United Kingdom, Ltd. share of the Brent and other British North Sea fields. Construction of an extraction plant in Peterhead, Scotland, is planned for the gas processing.

The world's first open sea offshore NGL plant was completed and went onstream at midyear in the Ardjuna field area of the Java Sea, northeast of Jakarta, Indonesia. The Ardjuna field is operated by the Atlantic Richfield Co. under a production agreement with Pertamina, the Indonesian State-owned petroleum agency.

Pemex, the Mexican Government-owned petroleum agency, continued construction in 1976 on a large gas processing plant complex at Tabasco, in southern Mexico. When completed in 1978, it will have a throughput capacity of 2 billion cubic feet of gas per day. A sour gas feedstock will be processed for maximum ethane and other liquids by a turboexpansion process. Three gas-sweetening facilities were put onstream during the year, each with a rated throughput capacity of 400 MMcf of gas per day. The desulfurized sweet gas from these facilities is processed through two 500-MMcf-per-day turboexpanders for NGL extraction.

A subsidiary of the Fluor Corp. was granted a contract for the design, engineering, and construction of two identical NGL processing centers in Iran. The total project will be valued at $300 million, and each plant will be capable of processing 1.5 billion cubic feet of gas per day when completed in 1977. Gas from the Pazanam Dome field, located near Agha Jari in Southern Iran, will be utilized in the new processing centers. The residue gas from each of these centers will be reinjected into separate oilfields located nearby.

Combustion Engineering, Inc. and Mitsubishi Heavy Industries, Ltd. of Japan are to construct 13 offshore platforms in the Arabian Gulf for the Qatar Gas Co., Ltd. The platforms, for the $170 million NGL gathering project, will be located in the Idd el Shargi, Maydan-Mahzan, and Bul Hanine field areas, in offshore Qatar. Living quarters and production modules, including separation, compressor, cooling, and dehydration equipment, will be installed in each field. Completion of the project was scheduled for mid-1979.

The Kuwait Oil Co. recently awarded a contract to Kellogg International Corp. for the construction of gas-gathering system facilities. Associated gas will be collected from 25 gathering centers located in the main field areas of Kuwait, and the gases and field condensates will be transported to Mina al Ahmadi, a port on the Persian Gulf, for final processing in a LPG plant. The output of liquids will be at a daily design capacity of 100,000 barrels of propane, 55,000 barrels of butane, and 41,000 barrels of natural gasoline. Completion of the facilities was scheduled for 1978.

Work continued on a large NGL processing center for sour gas and condensate in the Orenburg gasfield on the Ural River in south-central U.S.S.R. Reportedly, the second of 10 plants planned for the complex was onstream at the beginning of 1976. The extraction process separates the sour gas and condensate, dehydrates the sour gas, and prepares it for final low-temperature separation of the NGL. Each plant will have extraction units capable of a throughput of 840 MMcf of gas per day.

TECHNOLOGY

During 1976, Halliburton Resource Management, Inc. began operating a newly designed, low temperature NGL field recovery unit which extracts LPG and condensate from natural gas feedstocks at rates substantially larger than conventional plants. The unit operates most efficiently at low pressures, by utilizing a vortex tube, that delivers more refrigeration with less pressure drop than a unit using a choke. Recovery rates from a gas stream are thus more efficient than from a conventional field processing unit.

Elf Aquitane of France, announced a new hydrocracking process for the production of propane from butane feedstocks that utilizes a zealite catalyst which reacts with butane to induce hydrogenation. The propane yield is about 90% of the butane feedstock, and the production of paraffins, methane, and ethane byproducts is also minimized by use of this process.

Miscellaneous[3]	315,568	527,182	917,702	r1,360,567	1,947,763

rRevised.
[1]Includes refinery fuel.
[2]Includes synthetic rubber.
[3]Includes secondary recovery of petroleum, agriculture uses, and use as substitute natural gas feedstock.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the countries listed, the People's Republic of China may also produce natural gas liquids, but information is inadequate to make reliable estimates of output levels. Every effort has been made to include in this table only those natural gas liquids produced by natural gas processing plants, and to exclude natural gas liquids obtained from field treatment facilities including wellhead separators, because the latter are normally blended with crude oil and thus are in statistics on crude oil output. In some cases, however, sources do not clearly specify whether data presented represent only output of natural gas processing plants or if they include field output. Thus, some of the figures in this table may include field condensate. Where this appears to be the case, the country has been so footnoted, but it may also be true in the case of other countries.

[2]May include field condensate.

[3]Total of listed figures only, and as such represents an incomplete total, due to the fact that in the case of some countries, only total of butane and propane or only total natural gas plant liquids are reported in sources, and insufficient data are available to estimate the distribution of the totals by individual type. Summation of totals of propane and butane thus does not equal the reported natural gas plant liquid total.

Nickel

By John D. Corrick[1]

There was a gradual improvement in demand for nickel during 1976; however, the supply of nickel proved more than adequate, as newly developing projects gathered momentum in Australia, the Philippines, Botswana, and the United States. At yearend, nickel remained in oversupply, and some major producers were cutting back production or continuing to operate below capacity.

U.S. nickel consumption increased 11% in 1976 over that of 1975; however, stocks of consumer-held nickel remained at a relatively high level. A surge in consumer-held stocks in the second half of the year could be attributed to nickel purchases being made in advance of price increases. Ferronickel increased its share of the total U.S. market in 1976 at the expense of pure unwrought nickel and recovered that share of the market that was lost in 1975. The pattern of nickel consumption remained essentially unchanged in 1976 from that of previous years.

The price of pure nickel was increased by 21 cents per pound on October 1; however, the old price of $2.20 per pound prevailed until 1977 for major consumers of nickel. Similar price increases were announced for domestically and foreign produced ferronickel at about the same time. Near yearend, most major nickel producers were offering class II products at prices reduced from those announced in October on firm orders for delivery during the first quarter of 1977.

World trade in nickel picked up during 1976 in line with the gradual increase in demand. Imports of nickel into the United States in 1976 increased 17% compared with 1975 imports. Leading suppliers of nickel to the United States, in descending order, were Canada, Botswana, Norway, the Dominican Republic, New Caledonia, and the Philippines.

Legislation and Government Programs.— During 1976 a bill was passed and signed into law closing the Glacier Bay National Monument in Alaska to new mining claims and effectively placing all existing mining claims under tight regulations, to be administered by the U.S. Department of the Interior.

[1]Mine shipments.

DOMESTIC PRODUCTION

Domestic production of nickel was on the increase as output at the AMAX Inc. nickel refinery at Port Nickel, La., continued to rise. According to the company's annual report, nickel production reached 20,000 short tons in 1976, or 50% of capacity. The one domestic mine, operated by Hanna Mining Co. at Riddle, Oreg., produced 16,469 tons of nickel from laterite ore, as measured by mine shipments. Nickel recovered at the Hanna smelter and byproduct nickel salts and metals produced at copper and other metal refineries amounted to 13,869 tons; part of the byproduct originated from scrap. Exploration for nickel in 1976 took place in the Katahdin massive sulfide deposit in Maine, Glacier Bay National Monument in southern Alaska, the Precambrian rocks of Wyoming, Montana, and Colorado, the Duluth gabbro of Minnesota, and Red Mountain in California near the Oregon border. Officials of AMAX Exploration, Inc. reported that work on its Minnamax project to evaluate copper-nickel mineralization near Babbitt, Minn., was progressing satisfactorily. In March 1976, a contract for sinking a 14-foot-diameter shaft to 1,710 feet was awarded to Centennial Development Co. A headframe was erected during the summer and shaft sinking began. By December the shaft had reached 670 feet and the contractor was averaging 10 feet per day. After the shaft is completed, planned underground development work would determine the continuity of the copper-nickel mineralization and the mining and environmental parameters. A 20,000 ton bulk sample would be mined for concentrating and metallurgical tests. Hanna Mining Co. reportedly acquired 5,000 acres on Red Mountain in northern California and staked mining claims on another 3,400 acres under the control of the U.S. Bureau of Land Management.

International Nickel, Inc., formed a new wholly-owned subsidiary, The International Metals Reclamation Co., Inc. (Inmetco), to convert specialty steelmaking waste into commercially useful metals. The facility is to be located at Ellwood City, Pa., 35 miles northwest of Pittsburgh, Pa., and will be within the U.S. Steel Corp.'s industrial park. The reclamation unit, to be completed by mid-1978, will have a capacity to process 40,000 tons per year of specialty steel mill waste. Flue dust, grinding swarf, and mill scale will be processed into a nickel-chromium stainless steel remelt alloy. The wastes currently are being discarded as landfill.

Universal Oil Product Co.'s (UOP) Tucson Technical Development Center completed its pilot plant for treating lateritic ores in 1976. The pilot plant has a nominal capacity of 5 tons of ore feed per day. Reportedly, mine-run ore can be received, crushed, dried and ground, reductively roasted, and leached to produce various commercial nickel products.

CONSUMPTION AND USES

The slower than anticipated recovery in demand for nickel during 1976 resulted in consumers delaying purchases of nickel while working off high levels of stocks. Stocks reached a yearly low of 42 million pounds at the end of June, then increased during the remainder of 1976 to a yearend level of 63 million pounds. The second-half surge in consumer-held stocks could be attributed to nickel purchases being made in advance of price increases.

Ferronickel increased its share of the total U.S. nickel market in 1976 at the expense of pure unwrought nickel and recovered that share of the market that was lost in 1975. Pure unwrought nickel accounted for 64% of the total nickel consumed in 1976, compared with 68% in 1975 and 59% in 1974. Most of the pure nickel was consumed in the production of nickel wrought products and nickel alloys, and in electroplating. Ferronickel accounted for

Table 3.—Nickel recovered from nonferrous scrap processed in the United States, by kind of scrap and form of recovery

(Short tons, contained nickel)

Kind of scrap	1975	1976	Form of recovery	1975	1976
New scrap:			As metal	1,979	701

Nickel-base	7,825	5,372	Total	17,880	13,273
Copper-base	375	415			
Aluminum-base	84	107			
Total	8,284	5,894			
Grand total	17,880	13,273			

[1]Includes only nonferrous scrap added to ferrous high-temperature alloys.

19% of the total nickel consumed in 1976 compared with 17% in 1975 and 22% in 1974. Principal consumption of ferronickel was in stainless and alloy steels.

Domestic nickel consumption increased by nearly 11% in 1976 compared with that of 1975. The pattern of nickel consumption in 1976 was as follows: 30% in stainless and heat-resisting steels, 20% in other nickel and nickel alloys, 18% in electroplating, 12% in alloy steel, and 6% in superalloys.

Total reported by companies canvassed and estimated	39,123	38,926	1,524	3,783

PRICES

The price of pure nickel was increased to $2.41 per pound effective October 1; however, the old price of $2.20 per pound prevailed until 1977 for the major consumers of nickel.

The price of domestically produced ferronickel was increased from $2.16 per pound of contained nickel to $2.34 per pound effective October 1. Late in November, Hanna announced an allowance of 8 cents per pound on its price for ferronickel, applicable to all firm orders for delivery during the first quarter of 1977. The price of foreign produced ferronickel was reflected in N. C. Trading Co.'s price increases effective October 1. The new prices, f.o.b. Baltimore, Md., follow: FN4, $2.35 per pound of nickel content; FNC, $2.37 per pound of nickel content; and FN3, $2.39 per pound of nickel content. Near yearend most major nickel producers were offering class II products at prices reduced from those announced in October on firm orders for delivery during the first quarter of 1977.

FOREIGN TRADE

The gross weight of U.S. exports of nickel, nickel alloys, and nickel catalysts was 58% more in 1976 than in 1975. Exports of unwrought nickel in 1976 more than doubled over that exported in 1975.

Canada remained the principal supplier of nickel to the United States in 1976, and accounted for 58% of the total. The next most important sources of imported nickel, in decreasing order of magnitude, were Botswana, Norway, the Dominican Republic, New Caledonia, and the Philippines. The ascension of Botswana and the Philippines as notable supply sources of nickel for the United States was directly related to their newly developed nickel industries. These five countries accounted for 88% of the total nickel imported in 1976. Imports (based on contained nickel) of ferronickel decreased from 13% of the total imports in 1975 to 9% in 1976, while unwrought nickel decreased from 67% in 1975 to 59% in 1976. The total of all forms imported for consumption in 1976 was 17% more than in 1975.

Table 9.—U.S. exports of nickel and nickel alloy products, by class

Class	1974		1975		1976	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)

[1]Ore imports in 1975 were 1,135 tons, all from New Caledonia. Ore imports in 1976 were 6,687 tons from New Caledonia and 19 tons from Canada.
[2]Nickel-containing material in slurry, or in any form derived from ore by chemical, physical, or any other means, and requiring further processing to recover nickel or other metals.
[3]Less than 1/2 unit.
[4]Formerly French Pacific Islands.

WORLD REVIEW

Australia.—Western Mining Corp. Ltd. increased production and purchases of nickel by about 9% to 47,837 tons. The increase was mainly due to the Windarra operation building up to full production. Enlargement of the Kalgoorlie smelter to 35,000 tons of nickel annually was completed during the year. The Kwinana refinery capacity was increased to 30,000 tons of refined metal annually. The ammonia plant at the refinery was completed. According to a company spokesman, sales of nickel in all forms during 1976 were 39,381 tons, a slight increase from the 38,600 tons sold in 1975. Poseidon Ltd., which shares a 50% interest in the Windarra nickel mine and concentrator with Western Mining, experienced financial problems during 1976 and was placed in receivership in October. Collapse of the company was the result of increasing costs and a depressed nickel demand that restrained prices. At yearend, the future of Poseidon was uncertain. The Australian Industrial Development Corp. (AIDC), to which Poseidon owed some $25 million, had stated that it would take an equity interest in the venture if no satisfactory sale could be made. It appeared that AIDC would continue to put money into the Windarra project to insure that a future buyer for Poseidon's share would be taking over a viable company. Windarra's proved and probable reserves were estimated at nearly 10 million tons of nickel sulfide ore averaging 1.49% nickel.

Although still experiencing some problems in mid-1976, the Greenvale metallurgical plant at Yabulu in Queensland, was approaching designed capacity. The Greenvale mine and plant generated a cash flow in 1976. The company was able to obtain this position only by virtue of debt restructuring and supplemental financing arranged in mid-1975. Freeport Minerals Co., a partner in the project, reported that output of nickel, in the form of nickel oxide, amounted to nearly 10 million pounds during the third quarter, or about 86% of capacity. The reason for not reaching capacity was the shutdown of the ammonia plant for its annual inspection during August. The output of nickel and cobalt in mixed sulfides amounted to 1,239,000 and 490,000 pounds, respectively, or about 69% of capacity. These sulfides were exported to Japan for refining. Reportedly, the poor financial performance today has been the result of rising Australian labor costs and world fuel prices. A further restructuring of Greenvale's finances was announced late in 1976. Interest payments on the company's debts were scheduled to resume during the first quarter of 1977, but capital repayment has been deferred until 1979. Overall operating capacity for 1976 was given as 80% to 90%.

At yearend 1976, the Premier of Western Australia and the joint owners in the Agnew nickel project, Western Selcast Pty. Ltd. and Mount Isa Mines Ltd., announced the completion of arrangements that will enable the project to proceed toward production. The facilities at Agnew will have an initial annual capacity to produce 10,000 tons of nickel concentrate. Production is expected to begin in late 1978. The nickel concentrate, grading 10% to 11% nickel, will be freighted 200 miles north to Western Mining Corp.'s smelter at Kalgoorlie. Spokesmen for Western Mining stated that the two partners in the Agnew venture would advance a substantial part of the funds needed for expanding the capacity of the Kalgoorlie smelter. The expansion will enable the smelter to smelt up to 110,000 tons per year of concentrate from the Agnew mine, beginning in 1979. Initially mining will take place in the higher grade shoot, 1A, which contains about 2.2 million tons of ore assaying 3.5% to 5% nickel.

Australian geologists reported the discovery of a large deposit of manganese nodules on the ocean floor 300 miles west of the Australian coast in an area known as the Scott Plateau. Reportedly, the deposit covers about 230,000 square miles. The nodules are somewhat lower in grade than the nodules from areas of the central Pacific. The combined nickel and cobalt values range from 0.32% to 1.44% and average 1.19%. The nodules are found at a depth of approximately 16,000 feet. The attractive feature of the Australian deposit is its close proximity to Fremantle, the shipping port for the State capital of Perth.

Botswana.—During the year, progress was made toward overcoming process and technical problems that have plagued the Selebi-Pikwe copper-nickel project for the past 4 years. During the first 6 months of 1976, copper-nickel matte production rose to 16,766 tons from 7,088 tons in the comparable period of 1975. At the end of 1976,

Recovery from domestic ore	13,220		
Total	[r]818,081	798,684	833,564

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Refined nickel plus nickel content of ferronickel produced from concentrates unless otherwise specified.
[2]In addition to the countries listed, North Korea is believed to produce metallic nickel and/or ferronickel, but information is inadequate for formulation of reliable estimates of output levels.
[3]Includes nickel content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.
[4]Nickel content of ferronickel only (no refined nickel is produced).
[5]Includes nickel content of metallurgical products exported.
[6]Individual figures for byproduct of metal refinery and recovery from domestic ore are withheld as company confidential information.

production was running at 70% of capacity; full production was expected early in 1977. A scheduled shutdown for furnace maintenance, planned for mid-1976, was postponed until April 1977, as the plant continued to operate satisfactorily.

Brazil.—Brazil has significant deposits of lateritic nickel. Most of the deposits are located in central Goiás, where total reserves are estimated in excess of 200 million tons of ore containing 1.5% nickel. One project was under development in 1976, two others were in various stages of evaluation, and three others were in advanced exploration stages. Construction was well underway on a $35 million first stage project of Cia. Niquel Tocantins. This was scheduled for startup in 1978. Production will be in the form of 5,000 tons per year of electrolytic nickel; an additional 5,000-ton-per-year capacity is to be installed approximately 2 years later. Nickel carbonate is to be produced at the plant, located near the mine site at Niquelandia. The nickel carbonate will be shipped to an electrolytic plant being built in São Paulo.

Baminco Mineraçãoe Siderúrgia S.A. (BAMINCO), a joint venture between INCO, Ltd. and a West German consortium that includes several steel companies and Metallgesellschaft A.G., was in the final stages of evaluating a nickel project located at Barro Alto, approximately 85 miles northwest of Brasilia. The project would have a capacity of 55,000 tons per year of ferronickel containing about 22,000 tons of nickel. Total investment in the project was estimated at $300 million. Production could start as soon as 1980. The other project being evaluated was that of Empresa de Desenvolvimento de Recursos Minerais (CODEMIN) near Niquelandia. If de eloped, the project would produce 10,600 tons per year of electrolytic nickel at an investment of $140 million.

Mineradora Montita Ltd. was exploring a deposit at Jussara during 1976. Companhia de Pesquisas de Recursos Minerais (CPRM), a federally owned minerals exploration company, was exploring two nickel deposits during 1976. Reportedly, if exploration results appear to justify a project, CPRM will ask for public bids for development of the properties. The two deposits being explored are located at Montes Carlos de Goiás and Jussara.

Burundi.—Speculation persisted during 1976 as to the size of nickel discoveries in Burundi. At yearend, most interested parties were still awaiting the results of a prefeasibility study, which may be completed by mid-1977. Results of this study and prevailing estimates of the market situation concerning the current and future consumption of nickel should provide interested companies with a basis for deciding whether to involve themselves financially in the development effort. Any project in Burundi would involve mining, metallurgical processing, electric power supply, and complete infrastructure development. Cost of the project could approach $750 million by completion.

Canada.—Mine production of nickel in Canada in 1976 amounted to 289,348 tons, compared with 266,957 tons produced in 1975. Canada remained the leading producer of nickel in the world and accounted for 32.6% of the total world mine production. The principal producers of nickel in Canada were INCO, Falconbridge International Ltd., and Sherritt Gordon Mines Ltd. Late in 1975, the provincial government of Ontario granted the mining industry a tax relief of between $8 and $10 million per year. Under the terms of the new concession, companies will be permitted to deduct foreign processing costs for tax purposes for a period of 5 years from the date the initial regulation on foreign processing was introduced.

INCO mined a total of 19.8 million tons of ore having an average nickel content of 1.41% in 1976, compared with 21.2 million tons having an average nickel content of 1.40% in 1975. Nickel production by INCO in 1976 was reported to be 231,000 tons, compared with 229,500 tons in 1975. Nickel production was somewhat less than expected as a result of two work stoppages at Thompson, totaling 14 days. The stoppages were in protest of the Anti-Inflation Board's rollback of wage increases granted under a collective bargaining agreement signed on February 25, 1976. INCO reported proven reserves in Canada of 412 million tons, containing 6.8 million tons of nickel and 4.4 million tons of copper. The company operated 15 mines during 1976, 12 in Ontario and 3 in Manitoba. Three mines were being maintained on a standby basis, two in Ontario and one in Manitoba. Mine development work continued during 1976 on the Levack East and the Clarabelle open pit extension. The Levack East mine is scheduled to begin production in 1983, while the Clarabelle, an extension of a mine that previously had been in production, was expected to be working again by 1978. The Victoria mine resumed production in April 1976. The small Kirkwood mine ceased production in March 1976 upon depletion of minable ore. Planning was completed at yearend on the construction of a $27 million ventilation system for the 75-year-old Creighton mine. At the Manitoba Division, development work continued on the three operating mines, Birchtree, Pipe, and Thompson. Construction on a new rolling mill in the Sudbury district of Ontario was started in March 1976 and was about 70% complete by yearend. The mill is scheduled to be in production by mid-1977. The rolling mill will direct-roll metal powders into nickel and cupronickel alloy strip for primary use as coinage. INCO's investment in the mill will be about $29 million. During 1976, INCO opened two water treatment plants in the Sudbury area. The two plants were constructed at a cost of $6 million as part of a new tailings disposal facility which will cost a reported $36 million. The combined capacity of the two treatment plants was reported as 67 million gallons per day. Reportedly, INCO's Ontario division uses recycled water for 87% of its requirements. Company officials reported that nickel inventories at yearend were equivalent to a 5 to 6 months' supply, compared with a normal level of 2 to 3 months' supply.

Falco and Sherritt Gordon remained the number 2 and 3 producers, respectively, of nickel in Canada in 1976. Falco continued a curtailment of nickel production throughout 1976 at its Sudbury operations. The East, Onaping, Fecunis, and Longvack South mines, the Fecunis mill, and one of two smelter blast furnaces remained idle throughout 1976. At yearend, work was started to reactivate the Longvack South mine. Ore deliveries to treatment plants from Falco's mines in the Sudbury area amounted to 3,219,000 tons in 1976, compared with 3,041,000 tons in 1975. The Manibridge mine in Manitoba produced 208,000 tons, compared with 189,000 tons the previous year. However, this mine will be closed during the first half of 1977 as the ore reserves become exhausted. The newly opened Lockerby property had reached 40% of capacity at yearend 1976. Falco's smelter operated one blast furnace and two converters throughout the year. Oxygen enrichment of the blast air was started in February in order to increase the throughput of the one furnace operation. The expansion program at the Strathcona mill was completed, raising the capacity to 8,500 tons per day. Work on the Fraser No. 1 shaft, which was halted on August 21, 1975, was resumed in August 1976. At yearend, the shaft was approximately 5,000 feet below the collar, and plans were underway for sinking a ventilation shaft. The $95 million Smelter Environmental Improvement Program at the Sudbury operations was restarted in August. At yearend, erection of steel for the new smelter building was essentially completed, the building was 50% closed in, and erection of vessels for the associated acid plant was 50% finished. Expenditures on this project at the end of 1976 totaled $31,751,000. The construction program is to be completed by the spring of 1978. Falco reported ore reserves as being 5,694,000 tons lower than at the end of 1975; however, there was a small increase in the grade. Reportedly, the loss of marginal ore from reserves reflected increased production costs which were not offset by a corresponding increase in the price of metals. Ore reserves in 1976 were reported as 83,405,000 tons grading 1.46% nickel (1,214,000 tons of nickel) compared with 89,099,000 tons grading of 1.43% nickel (1,279,000 tons of nickel) in 1975. The Dumbarton mine in the Bird River area of eastern Manitoba, 50% owned by Falco, was closed down in 1976. The underground operations were shut down several years ago, but the underground crushing facilities at the mine were used to reduce ore from the open pit nearby. Ore already mined was expected to be cleaned up by mid-1976. Some 600,000 tons of ore had been mined from the pit, averaging 1.17% nickel and 0.2% copper. Reportedly, Falco was exploring another nickel-copper occurrence some 8 miles northeast of the Dumbarton mine site.

Sherritt Gordon announced the planned shutdown of the Farley nickel-copper mine at Lynn Lake, Manitoba. Salvage work at the mine was estimated to require 6 months. The mill and surface plant were to be put on standby so that they could be reactivated if a new discovery was made within an economic distance of Lynn Lake. The major reason for the mine's unprofitability was that the tonnage and grade of ore were too low to generate sufficient revenues to cover escalating operating costs. The Farley mine had been operating since 1953 but recently was operating at about 1,200 tons per day, or one-third of its rated capacity. The closure will have some impact on the firm's Fort Saskatchewan nickel refinery, since concentrate from the mine would have provided about 15% of the refinery's feed for the next few years.

Production, as measured by sales and deliveries and reported by the three principal Canadian producers in 1976, follow:

Company	Type of operation	Thousand pounds
The International Nickel Co. of Canada, Ltd.	Delivery	409,830
Falconbridge Nickel Mines, Ltd.	do	83,615
Sherritt Gordon Mines, Ltd.	Sales	22,454

Teck Corp. reported a new nickel-copper discovery 35 miles northwest of Timmins, Ontario. Members of the exploration syndicate, each with a third working interest, were Teck Corp., Metallgesellschaft Canada Ltd., and Domik Exploration Ltd. of Japan. Thus far, nickel content of core samples has ranged from 0.6% to 2.8% with about 0.5% copper. An unusual find was announced in the Key Lake area of northern Saskatchewan by Uranerz Exploration and Mining Co., then a subsidiary of Uraniz-Bergbau GmbH of West Germany, Inexco Oil Co., Houston, Tex., and Saskatchewan Mining Development Corp., a provincial crown corporation. The ore body, which has been sampled with over 173 core holes, has shown an average grade of 3% U_3O_8 and 3.5% nickel. However, grades as high as 45% for both minerals have been recorded. A mine and mill are presently under consideration but will have to comply with the yet-to-be defined Provincial government requirements.

During the year, Boliden A.B. of Stockholm, Sweden, showed its faith in the Great Lakes nickel project by acquiring the largest single share in the company. Boliden bought an additional 22% of the shares in Great Lakes Nickel from the Canadian investment firm of 246057 Investments Ltd. Boliden expects to maintain the project on a standby basis until world demand and prices of nickel are right for its development.

Colombia.—The prospects for the 50-million-pound-per-year nickel project at Cerro Matoso starting up by 1980, appear to depend upon the world demand for nickel improving during the next few years. Pilot plant studies conducted at Riddle, Oreg., by Hanna have demonstrated the feasibility of using a rotary-kiln electric furnace process to produce ferronickel. Hanna is to be the manager and a co-owner of the nickel project for 25 years. A new Colombian corporation, Econiquel, would hold a one-third interest in the project, while Compania de Nicquel Colombiano S.A., a subsidiary of Conicol Ltd., a Delaware corporation controlled by Hanna, and the Chevron Corp. (20%) would control the remainder. Capital costs for the project are estimated at $300 million.

Cuba.—Construction and renovation of Cuba's Moa Bay and Nicaro nickel plants were underway in 1976. Current plans called for increasing the combined capacities of the two existing plants from 40,000 tons per year to 51,000 tons by 1980. Phase 2 would raise Cuba's nickel capacity to about 117,000 tons per year by 1985 with the addition of two new 33,000-ton plants. The addition of one or two more plants by 1990 could raise the nickel production capacity of Cuba to 165,000 tons. Reportedly, both phases 1 and 2 were underway during 1976. Phase 2 includes the construction of a 33,000-ton-per-year nickel-cobalt oxide plant at Punta Gorda, about 2 miles east of Moa Bay. A similar sized plant would be built 5 miles east of Moa Bay. Completion of the Punta Gorda facility is expected by 1982-83 and the second facility by 1985. Cubaniquel is currently selling 70% of the Nicaro oxide and sinter output to market economy countries; the balance and all of the Moa Bay sulfide output go to Comecon countries. The Cubans were reported to be building a 246-foot dam on the Boa River to ensure a steadier source of water for the plants. Each new plant was expected to employ about 5,000 mine and plant workers. The plants will use the same ammonium carbonate leaching process as used in the 32-year-old Nicaro plant, with some technological improvements. Recovery rates are expected to be more than 80%, compared with 76% at Nicaro.

Dominican Republic.—Falconbridge Dominicana, C. por A., shipped 28,236 tons of contained nickel in 1976, compared with 26,164 tons in 1975. The plant continued to operate satisfactorily, although at a reduced rate because of depressed nickel markets.

Metal output was about 10% below that of 1975. This allowed product inventories to be reduced to an acceptable level. Ore reserves at the end of 1976, on an undiluted in situ basis, were reported to be 72,500,000 tons grading 1.65% nickel. Improvements in ore reserves over those of 1975 resulted from development drilling programs on the major ore bodies, which included ore below the original open pit outline.

Greece.—Société Minière et Métallurgique de Larymna S.A. (LARCO) obtained, in March 1976, Government approval for a $50 million improvement and expansion of its facilities during the next 3 years. The expansion would increase production capacity from the present 15,000 tons to 27,000 tons of nickel per year and would double mine output. LARCO was also planning a subsequent $170 million investment to establish a second plant which will further increase the company's annual nickel production to 40,000 tons. Under the second stage of development, a completely new ferronickel plant on the island of Euboea is planned. Mine output will be increased to 5 million tons per year. Completion of the second stage is currently forecast for 48 months after the first stage of the program is completed.

Guatemala.—Construction of facilities for a lateritic nickel project near Lake Izabal, in eastern Guatemala by Exploraciones y Explotaciones Mineras Izabal, S.A. was nearly 95% complete at yearend 1976. Mining began in 1976, and the ore was stored for trial runs during the spring of 1977. Production of nickel matte was scheduled for the third quarter of 1977, and the plant was to reach the planned annual rate of 14,000 tons of nickel in matte in early 1978. The estimated cost of the project remained at $224 million. Financing arrangements were made during 1976 and were approved by the Guatemalan authorities. INCO is the majority shareholder and operator of the project; the government and Hanna also own shares in the company. Basic Resources International S.A. was considering developing nickel properties it holds in Guatemala. One of Basic's properties was adjacent to INCO's Lake Izabal property. According to company officials, discussions were held during 1976 on the possibility of developing a 30,000 ton-per-year operation in the country. The company stated a need for a partnership with a major nickel producer with expertise in smelting lateritic ores on a large scale.

Indonesia.—Construction of stage 1 of the lateritic nickel project of P. T. International Nickel Indonesia, a majority-owned INCO subsidiary, was completed at Soroako on the island of Sulawesi at yearend 1976. Nickel matte was scheduled for shipment during the summer of 1977. Production of the stage 1 unit was planned to be 17,500 tons of nickel in the form of matte. Stage 2 of the project included the construction of two additional process lines and a hydroelectric installation on the Larona River. These facilities were 40% completed at yearend 1976. Scheduled for production in 1978, the second stage will increase nickel production to 50,000 tons per year. The capital costs for the entire project, including a third 55 megawatt-generating unit at the Larona River hydroelectric plant, were reported as $850 million. Total electrical capacity will then be 165 megawatts.

P. T. Aneka Tambang's (ANEKA) newly constructed ferronickel smelter began production in March 1976. Japanese buyers agreed to purchase only a quarter of the output, contrary to earlier expectations that they would take all of it. The smelter will utilize ores that fall below export grade, thus prolonging the life of the mine for an indefinite period. The ferronickel will contain 20% to 25% nickel and cobalt. The smelter is capable of producing either a relatively expensive low-carbon ferronickel, which is difficult to produce; or a high-carbon product, for which buyers are harder to find. The plant cost $54.8 million and can process 350,000 tons per year of low-grade lateritic ore into 20,000 tons of ferronickel containing 4,000 to 4,250 tons of nickel. Operation of the plant will guarantee the survival of the nickel mines on Pomalaa, because the plant is based on using the lower grade ore that is not exportable. Officials of ANEKA were holding discussions at yearend 1976 with the Japanese in an attempt to conclude a contract for ferronickel imports during 1977.

A third project, P. T. Pacific Nikkel Indonesia, has the designed potential of producing 49,900 tons of metallic nickel annually, and the firm reportedly was making steady progress toward assembling financing for the project.

The Japanese-owned Indonesian Nickel Development Company (INDECO), with a Contract of Work on Gebe Island, informed Indonesian authorities that its findings do not show that a mining project there would be viable under economic conditions as they existed in 1976.

At mid-1976, the Mining Department of Indonesia announced that no further foreign investment would be permitted for nickel mining in Indonesia.

Japan.—The Nikko Nickel Cobalt Smelting Co., Ltd., established in September 1975, began commercial production of metallic cobalt and nickel at Hitachi, Ibaragi Prefecture, in 1976. The facilities are capable of producing 3,300 tons of nickel and 1,320 tons of metallic cobalt per year. The firm became the third largest producer of metallic nickel in Japan. Sumitomo Metal Mining Co., Ltd., began commercial production of nickel and cobalt at its Besshi plant, Ehime Prefecture, in 1976. The feed for the plant was from mixed sulfides imported from Marinduque Mining and Industrial Corp. in the Philippines. Plant capacity was reported as 2,770 tons of nickel and 1,760 tons of cobalt per year. Both companies use a solvent extraction process for separating cobalt and nickel from the mixed sulfides. Shimura Kako Co., Ltd., the second largest producer of electrolytic nickel in Japan (30% owned by INCO), announced plans in 1976 to build a new nickel electrolytic plant (capacity to be 11,000 tons), and a nickel sulfate plant (capacity of 1,100 tons contained nickel) at its Date plant in Hokkaido by the end of 1978. The company will close its Shimura plant (present capacity 8,000 tons of electrolytic nickel).

In March 1976, four Japanese ferronickel producers completed a $2 million, 2-year joint study on the production of ferronickel from laterites. The process includes pelletization of lateritic ore, followed by heating of the pellets in an annular vertical kiln prior to smelting to recover nickel. Although applicable to low-grade garnierite ore, the process has not been used in Japan. However, Pacific Metals planned to construct a ferronickel plant at Niigata, capable of producing 19,800 tons per year by 1978; the plant would have the largest electric furnace (60,000-kilovolt-amperes) in Japan. Reportedly, the company has invited the other four ferronickel producers to join in the project.

The Japanese Government imposed a 13% tariff on metallic nickel imports, unless the nickel was further refined. Nickel matte imported from Canada and Australia during the year contained about 25% sulfur and therefore definitely required refining. Consequently, no import duty would be applied under the regulations. However, the matte from Soroako, Indonesia, containing only 7% to 8% sulfur, could be used directly in making steel. Thus, the 13% tariff would be applicable to the low-sulfur matte, unless it was further refined.

New Caledonia.—Production of nickel ore in New Caledonia in 1976 was 12% less than that produced in 1975 and totaled 6.5 million tons. Nickel smelter production decreased 13% in 1976 from that of 1975 and totaled 68,245 tons. Ferronickel production decreased nearly 28% and totaled 42,044 tons, while matte production increased 30% over that of 1975. Exports of nickel ore to Japan increased 9% in 1976 compared with exports in 1975, reflecting a slight improvement in the world demand for nickel during 1976. Exported ore averaged 2.38% nickel plus cobalt.

During 1976, Société Métallurgique Le Nickel (SLN) played host to worldwide customers, Government officials, and journalists at the SLN facilities in New Caledonia and explained the firm's new projects and plans for meeting future demand for nickel. SLN had a capacity in 1976 to produce about 70,000 tons of nickel per year in the form of ferronickel and matte. SLN is to begin a $230 million expansion in 1977 that will eventually increase capacity of the Doniambo smelter to about 110,000 million tons. Ore production is to increase to about 1.3 million tons per year at Konaona and 2.2 million tons per year at Nepoui. The improvements at Doniambo will include ore preparation and calcination facilities. In addition to the New Caledonian improvements, the company will construct a new nickel refinery in the Sandouville-LeHarve industrial complex of France to produce 15,000 tons per year of high-purity nickel cathodes. Marketing of the high-purity nickel was scheduled for mid-1978.

Development of the large lateritic nickel deposits on the north side of New Caledonia (Poum and Tiebaghi deposits) moved forward during 1976 when Patino N.V. of the Netherlands agreed to sell to the French state-owned Bureau de Recherches Géologiques et Minières (BRGM) 90% of its share in Compagnie Française d'Entreprises Minières Métallurgiques et d'Investissements (COFREMMI). COFREMMI was to undertake the development of the deposits. Tentative plans called for the development of a 33,000- to 44,000-ton-per-year mining and metallurgy complex. The site would be at Koumac. Originally, BRGM was to complete previous studies begun by COFREMMI. Under BRGM's new approach, the firm will decide the final combination of possible processes, as submitted by companies interested in the project, to be used in conjunction with its own continuing studies. Reportedly, Amax and Péchiney Ugine Kuhlmann were interested in the deposits. INCO, which holds an option on a major share of the southeastern Goro deposits, reported it currently had no plans to join the study phase being conducted on the northern deposits.

Japanese smelter operators were able to secure a 3-month delay on a nickel ore price increase from SLN in October 1976.

Philippines.—Marinduque Mining and Industrial Corp. was still experiencing operating difficulties with its refinery on Nonoc Island during 1976. The refinery was shut down from February 16 until March 14 because of leaks in the waste-heat boiler of the gas plant. Other problem areas were in the reliability of services such as power, steam, hydrogen, and carbon dioxide gases; the training of personnel; roaster availability; materials and parts availability; the first-stage leach circuit cooling capacity; and excessive consumption of ammonia. However, average operating capacity for the first 9 months of 1976 was 48%. From November 14 through December 17, Marinduque shut the plant down for the purpose of installing a new boiler and for annual maintenance.

A joint nickel mining project between Rio Tuba Mining Corp. and Pacific Metals Co. of Japan, on the island of Palawan, was to be brought onstream late in 1976. Shipments of ore to Japan were to begin in January 1977. About 350,000 tons was to be shipped in 1977 and 500,000 tons in 1978. The ore would grade 2.2% nickel.

Rhodesia, Southern.—A $24.7 million expansion program by Rhodesia Nickel Corp. (Rhonickel) was completed in 1976. The Epoch mine started operations in January 1976, and the electric smelting furnace at Bindura was commissioned in November 1975. A new converter at Bindura was brought into operation in February 1976, and the entire expanded refinery was commissioned in mid-April. However, a slag runaway occured a week after the furnace was commissioned. The slag penetrated the main power station and caused a fire and subsequent loss of electrical power to the entire smelter complex. Ore grade from the Shangani mine north of Bulawayo was running less than originally expected due to oxidation in the upper levels of the orebody. The ore is currently being mined by open pit techniques. However, an incline is being sunk to exploit ore reserves below the level at which the open pit method is no longer economic. At yearend, Rhonickel requested permission to borrow an additional R$9 million to finance increased stocks of nickel.

South Africa, Republic of.—Nickel occurs with platinum in the Merensky Reef of the central Transvaal and is recovered by refining a nickel-copper matte at an approximate ratio of 1 ton of nickel to 55 ounces of platinum metal, indicating about 0.2% nickel per ton of ore. The two major producers were Rustenburg Platinum Mines Ltd. and Impala Platinum Ltd. A conservative estimate of nickel reserves in the Merensky Reef suggests a total of 200 million tons of ore containing 400,000 tons of nickel. Additional nickel is believed to be present in the Bushveld Igneous Complex and specifically the Vlakfontein deposit west of Pilanesburg.

Growth of nickel production in South Africa has been erratic owing primarily to its direct dependence upon platinum production. In 1975 22,800 tons of nickel was produced, compared with 24,200 tons in 1976. Data through September 1976 indicated that for 1976, 3,750 tons of nickel would be sold locally and 18,250 tons exported.

U.S.S.R.—Reportedly, equipment deliveries from Finland for the nickel smelter and sulfur plant at Norilsk began during the summer of 1976. Nine tons of engineering material were delivered by truck to Leningrad between March and April of 1976. Specialty equipment would not be delivered until the summer of 1978. The smelter will have a capacity to handle 550,000 tons of nickel concentrate per year.

TECHNOLOGY

Bureau of Mines scientists reported research results on the recovery of nickel, cobalt, and copper from domestic laterites.[2] The report described recent progress by Bureau of Mines scientists on their hydrometallurgical process. The process per-

[2]Siemens, R. E., and J. D. Corrick. Process for Recovery of Nickel, Cobalt and Copper From Domestic Laterites. Min. Cong. J., v. 63, No. 1, January 1977, pp. 29-34.

mits a high metal recovery (about 90%), relatively low energy requirements (for reduction, about 90 million Btu per ton of nickel recovered from laterite containing 1% nickel; and for electrowinning, 9.6 to 13.6 million Btu per ton of nickel) selectivity of metals of interest, no polluting discharges, efficiency of reagent utilization, and recovery of high-purity metals. The process is also applicable to a variety of nickel-, cobalt-, copper-, and zinc-bearing oxide and sulfide ores and secondary sources. Two Bureau of Mines investigative reports on Raney nickel were published during 1976. The first report dealt with investigation of the powder metallurgy of Raney nickel.[3] Factors studied included the typical angular particle shape in conjunction with aluminum present in a eutectic phase, its effect in facilitating the interlocking of particles, and the subsequent excellent green strength after compaction. The effect of compacting pressure on density and porosity was studied over a range of 37.5 to 207 meganewtons per square meter. Also studied was the effect of sintering in an inert atmosphere over the range of 575° to 850° C. A second Bureau report described the method employed to prepare supported Raney nickel catalysts by dip coating.[4] The studies were done in support of research to develop methanation catalysts for converting synthesis gas derived from coal to synthetic natural gas.

Scientists at four Bureau of Mines research centers continued to carry out nickel-related research during 1976. Research programs included studies to determine the potential of increasing domestic production of nickel by applying advanced technology to domestic nickel oxide and nickel-copper sulfide resources. Other areas of interest included nickel and cobalt recovery from Missouri lead ores (from both flotation concentrates and mattes and drosses), the recovery of nickel, cobalt, copper, and manganese from ocean nodules, and processing of the Duluth gabbro nickel-copper sulfide ores. The development of new nickel alloys and the discovery of possible new substitutes for nickel were also being investigated.

A new high-strength, copper-based alloy containing nickel was developed by the Ampco-Pittsburgh Corp.[5] The alloy, containing nickel, aluminum, and bronze, reportedly had greater tensile strength than other commercial copper alloys except for the high-beryllium-content coppers such as CA825 (2% Be). Present applications of the new alloy appear to be in the aerospace industry as bushings and bearings. Their greatest potential lies in alloys used to withstand the combined effect of corrosion and high mechanical demands. Other applications include aircraft landing gear components, hydraulic cylinder linkage bushings for utility trucks used for tree trimmings, valves for pumps used to inject corrosives into rock strata to enhance oil flow, and safety tools and machines used in explosive environments (tools made of this alloy are sparkless). Huntington Alloys, Inc., developed four new alloys for use by the aerospace industry.[6] Two of the alloys, Inconel MA754 and Inconel MA956E, are based on the new technology of mechanical alloying. A third alloy, 903, combines high strength and a low, constant coefficient of expansion. The fourth alloy, Inconel 617, combines high-temperature strength and oxidation-carburization resistance. According to a company spokesman, the new alloys will enable designers to achieve weight reductions and longer life in critical aerospace components. The alloys will probably find use in jet engines and the space shuttle. Another alloy introduced by Huntington, IN-939, is said to more than double the life of turbine blades used in industrial and marine turbines.[7] The alloy was expected to permit the use of cheaper, less refined fuel, and thus reduce operating costs. The advantages of a new range of nickel-based casting alloys, in which boron replaced carbon, were described, along with the production of wrought superalloys, their market, and their nuclear and chemical-petrochemical applications.[8] The effect of 2% cobalt, 1% nickel, and 1% chromium on the hot-rolled microstructure and properties of a bainitic steel containing 0.2% manganese, 1% silicon, 0.75% molybdenum, and 0.003% boron was described.[9] The results showed that nickel did not appear to influence the microstructure, when added

alone, but in combination with chromium, it enhanced the formation of the lower bainitic structure.

Yardney Electric Corp. stated that it was looking into development of a nickel-zinc battery for use in passenger cars.[10] The company hoped to expand the battery's range and acceleration capabilities with no increase in weight. Reportedly, the nickel-zinc battery had nearly double the energy density of a comparable lead-acid battery. Other companies exploring the potential of nickel-zinc batteries were General Motors Corp. and the National Aeronautics and Space Administration's Lewis Research Center in Cleveland.[11] Raney nickel has been used as a catalyst for hydrogen electrodes in alkaline hydrogen-oxygen fuel cells. Recent studies have shown that a titanium-containing Raney nickel was capable of significantly increasing the rate of anodic hydrogen conversion in these fuel cells.[12] The report described the properties of the catalyst powder, the effect of particle diameter, and the behavior of electrodes under load. Electrode kinetic parameters were determined for hydrogen and oxygen evolution at 80°, 150°, 208°, and 264° C on nickel electrodes in 50 weight-percent potassium hydroxide (KOH) solutions.[13] The results indicated that significant reductions in cell voltage for water electrolysis can be obtained at higher operating temperatures, and that at temperatures of about 150° C it should be possible to approach 100% energy efficiency.

Ford Motor Co. was exploring the development of the Stirling engine for use in powering its future cars. Reportedly, the materials and technology of the Stirling engine were outgrowths of Ford's turbine developments.[14] Because of the very high temperatures surrounding the combustion chamber, nickel-based alloys were being employed and evaluated.

What may be a significant technological development occurred with the patenting of a process for beneficiating low-grade laterites by a combination of segregation and either magnetic separation or froth flotation.[15] The process requires that a mixture of ground ore, calcium carbonate, calcium sulfate, and coke be sprayed with a solution of sodium chloride, the wet mass pelletized, and the pellets roasted for 90 minutes at a temperature not exceeding 1,050° C. This converts the nickel to a magnetic state. The roasted pellets are ground in a water medium, and the suspension is separated magnetically or by froth flotation to obtain a nickel-rich concentrate. A high level of industrial activity from previous years was again evident from the large number of patents issued during 1976. The patents ranged from mining through beneficiation to extractive metallurgy (both pyro- and hydrometallurgy).

Nitrogen

By Russell J. Foster[1]

Domestic production of fixed nitrogen in 1976 was 13.9 million tons, an increase of 2% over that of the previous year. Elemental nitrogen production rose 15% to 10.5 million tons. Exports of fixed nitrogen were up 3%; imports increased 9%. Domestic consumption, including net imports of 136,000 tons, rose 7%. Consumption of elemental nitrogen was considered equal to production.

Table 1.—Salient nitrogen statistics

(Thousand short tons of contained nitrogen)

	1972	1973	1974	1975	1976[p]
United States:

[1]Anhydrous ammonia and coke oven ammonium compounds.
[2]Converted from reported volume (at 70°F and 1 atmosphere pressure) at 27,605 cubic feet per short ton.
[3]Estimated, excludes elemental nitrogen.
[4]Includes producers' stock change in synthetic anhydrous ammonia and coke oven ammonium compounds; excludes elemental nitrogen.

Legislation and Government Programs.—After evaluating data submitted by nitrogen fertilizer producers, the Environmental Protection Agency (EPA) amended its effluent guidelines and standards for the fertilizer industry to allow limited discharges of nitric acid by manufacturers. The amended regulation set limitations in terms of pH, ammonia and nitrate in process waste water based upon data from all identified sources of discharge, and required pH control over noncontact cooling water. The need for a separate regulation for special discharges or for leaks and spills was deemed unnecessary.[2] EPA also proposed amendments to the effluent guidelines and standards for urea and ammonium nitrate.[3]

A committee of the National Research Council Assembly of Life Sciences was studying ammonia for its possible effects on public health. Major sources of ammonia in the atmosphere are natural processes, such as decomposition of organic matter and the release of ammonia from fertilizers. Like some other natural constituents of the atmosphere, ammonia appears hazardous only at high concentrations.[4]

DOMESTIC PRODUCTION

Domestic production of fixed nitrogen, primarily as anhydrous ammonia, increased 2% in 1976 to 13.9 million tons. Production of elemental nitrogen rose 15% to 10.5 million tons.

The Federal Power Commission (FPC) established new ceiling prices for interstate natural gas, effective at the beginning of 1976. The price of old gas, defined as gas flowing in interstate pipelines prior to January 1, 1973, was initially permitted to rise to 23.5 cents per 1,000 cubic feet, and on July 1, to 29.5 cents per 1,000 cubic feet. The ceiling price for new gas, that is, gas discovered or committed to interstate commerce after January 1, 1975, was increased by 1 cent to 52 cents per 1,000 cubic feet.[5] A second round of rate adjustments occurred in late July, as FPC raised the ceiling price of new gas to $1.42 per 1,000 cubic feet with a 4-cent annual escalation allowance. Gas discovered or committed to the interstate market after January 1, 1973, and before January 1, 1975, was permitted to go up to $1.01 per 1,000 cubic feet, and old gas could increase to 52 cents per 1,000 cubic feet as contracts expired.[6] The FPC rulings were upheld by a three-judge panel of the District of Columbia Court of Appeals on the condition that contracts include a refund provision.[7]

Canada announced a two-stage price increase of approximately 20% for natural gas exported to the United States. The first rise was implemented on September 1, 1976, lifting prices by 20 cents to $1.80 per 1,000 cubic feet. The second increase became effective at yearend.[8]

The National Weather Service forecasted colder-than-normal temperatures for the winter of 1976-77. A severe winter would necessitate greater demand for natural gas from residential users, and curtail supplies to industrial customers served by interstate pipelines. This could force shifts, where possible, to costlier alternate fuels, and also result in record losses of ammonia production.[9]

Georgia Pacific Corp. awarded a contract to Pullman Kellogg for construction of a 575-ton-per-day ammonia plant at Plaquemine, La. Completion of the $45 million facility was scheduled for late 1978. Byproduct hydrogen from the company's adjacent methanol and chlor-alkali plants will be combined with nitrogen for ammonia production. Utilization of the hydrogen will eliminate the high energy requirement for reforming the more traditional natural gas feedstock.[10]

Construction of a second ammonia plant for Agrico Chemical Co. was begun by Pullman Kellogg at Verdigris, Okla. The new 1,150-ton-per-day plant was scheduled onstream in 1977 adjacent to a recently completed fertilizer complex.[11]

American Cyanamid Co. will complete a new 245,000-ton-per-year ammonia plant at its Fortier, La., complex by mid-1979. The addition will bring capacity to 625,000 tons per year.[12]

A 68,000-ton-per-year ammonia plant was brought onstream by N-Ren Corp. at Carlsbad, N.M., and a 90,000-ton-per-year unit was started up at Taft, La., by Occidental Agricultural Chemical Co. Expansion of ammonia capacity by six other producers at existing plants totaled approximately 184,000 tons per year.[13]

Chevron Chemical Co. awarded a design contract to C & I/Girdler, Inc. for a second ammonium nitrate plant to be built at its Kennewick, Wash., facility, increasing total capacity from 100,000 tons per year to 233,000 tons per year.[14]

Farmland Industries, Inc. brought a 70,000-ton-per-year urea plant and an 80,000-ton-per-year ammonium nitrate unit onstream at Ft. Dodge, Iowa, and Dodge City, Kans., respectively.[15]

Existing urea capacity was increased by over 400,000 tons per year at the facilities of four producers. Ammonium nitrate capacity at two plants was expanded by nearly 100,000 tons per year, including the first commercial implementation of a pan granulation process by N-Ren Corp. at Pryor,

Okla.[16]

The modernization and expansion of nitric acid output at Kaiser Agricultural Chemicals Co.'s Savannah, Ga. complex was completed with the commissioning of a new 165,000-ton-per-year unit.[17] Mississippi Chemical Corp. commissioned a 300,000-ton-per-year nitric acid plant at Yazoo City, Miss.[18]

Hercules, Inc. sold its nitrogen products plant at Hercules, Calif., to Valley Nitrogen Producers, Inc., for $22 million.[19] Mobil Chemical Co. sold its 300,000-ton-per-year ammonia plant and downstream urea and ammonium nitrate units at Beaumont, Tex., to Swift Chemical Co.[20]

Air Products & Chemicals, Inc. began production of liquid nitrogen, oxygen, and argon at two new 300-ton-per-day facilities at LaSalle, Ill., and Conyers, Ga.[21] Air Products planned to bring two more 300-ton-per-day plants onstream at Pryor, Okla., in late 1977, and Greensboro, N.C., in 1978, and will increase the liquid industrial gases capacity of its plant at El Segundo, Calif., to 600 tons per day by mid-1978.[22] The company also announced the construction of a new unit at its LaPorte, Tex., chemical complex by 1979 to pipe 2,100 tons per day of nitrogen and oxygen to Syngas Co. of Deer Park, Tex., and provide 350 tons per day of liquid nitrogen, oxygen, and argon for sale in the Houston area.[23] In addition, Air Products arranged to deliver 300 tons of nitrogen and 250 tons of oxygen per day from a new facility to E. I. duPont de Nemours & Co.'s projected titanium dioxide plant at DeLisle, Miss., beginning in early 1979.[24]

Union Carbide Corp. planned to construct an air separation plant at Fife, Wash. Scheduled for completion in 1978, the new facility will produce 260 tons of liquid nitrogen, oxygen, and argon daily to meet growing demand in the Pacific Northwest.[25] The company brought onstream at Burns Harbor, Ind., the largest single-train air separation unit ever built. High purity gaseous nitrogen and argon will be produced in addition to 2,000 tons per day of oxygen for nearby steelmakers.[26]

The Pace Companies will engineer and construct three air separation plants with a combined value of $70 million for Big Three Industries, Inc. Two plants, at Plaquemine, La., and Channelview, Tex., will have combined capacity of 4,200 tons per day gaseous nitrogen, 1,950 tons per day gaseous oxygen, 300 tons per day liquid nitrogen and liquid oxygen, and 60 tons per day liquid argon. The same liquid nitrogen and oxygen capacity will be added to an existing gases plant at Bayport, Tex. All three projects were scheduled onstream by fall 1977. Big Three also announced plans to build an air separation plant at Etiwanda, Calif., to supply liquid nitrogen, oxygen, and argon for the industrial gas market of southern California, and oxygen for steel production.[27]

Liquid Air, Inc., announced plans to add nearly 400 tons per day of liquid nitrogen, oxygen, and argon capacity at their Union City, Calif., and Houston, Tex., plants. The $8 million project was scheduled for completion in late 1977.[28]

CONSUMPTION AND USES

Consumption of fixed nitrogen in the United States reached 13.9 million tons in 1976, an increase of 7%. Excellent spring weather and low prices created strong demand for nitrogenous fertilizers. Demand for other nitrogen-containing chemicals, such as acrylonitrile, increased also, reflecting the economic recovery from the slump in 1975. Elemental nitrogen consumption is assumed to be equal to production, since no statistics are collected on stocks, and international trade is negligible.

The primary use of fixed nitrogen was in fertilizers, which accounted for approximately three-fourths of production. Other uses included explosives, resins, fibers, plastics, and animal feeds. The two principal uses of elemental nitrogen were as a gas to exclude or purge air from such industrial processes as steelmaking, electronics, chemical manufacture, and glassmaking, and as a liquid to provide low temperatures in food processing and scientific applications.

PRICES

Spot market prices for anhydrous ammonia were well below list at the beginning of the year because of buyer resistance and growing inventories. Published list prices of agricultural-grade urea and diammonium phosphate were lowered substantially during the year. Prices paid by U.S. farmers for all nitrogenous fertilizers in 1976 continued to decrease from the peak attained in early 1975. The cost of anhydrous ammonia, ammonium nitrate, and urea at the farm level dropped an average of 29% from April 1975 to April 1976.[29]

The average price of elemental nitrogen as pipeline gas was $11.78 per ton in 1976, an increase of 6%. The price of elemental bulk liquid nitrogen dropped 1% to $57.49 per ton.[30] Airco, Inc., Air Products & Chemicals, Inc., and Union Carbide Corp. announced price increases of 4% to 10% for liquid, bulk, and compressed nitrogen and other industrial gases effective November and December 1976.[31]

[e]Estimate. [r]Revised.
[1]Less than 1/2 unit.

FOREIGN TRADE

Increased U.S. exports of ammonia and ammonium phosphates offset the reduced export levels of other nitrogenous fertilizers, as exports of contained nitrogen rose 3%. Substantial gains in imported urea, ammonium sulfate, and nitrogen solutions resulted in a 9% gain for fixed nitrogen imports. In terms of nitrogen content, the United States was a net importer of fixed nitrogen for the third consecutive year. Net imports amounted to 136,000 tons of nutrient, compared with 61,000 tons in 1975.

WORLD REVIEW

Large expansions of ammonia capacity have been scheduled in eastern Europe, the U.S.S.R., and a number of developing countries. Implementation of these projects could make inroads into the markets of traditional exporters of nitrogenous fertilizers. In addition, many importing nations have moved closer to self-sufficiency. Producers in Japan and western Europe lowered their output because of reductions in domestic purchases and exports. France and West Germany voiced disapproval of an influx of certain low-priced, nitrogenous fertilizers from eastern Europe. World fertilizer prices have declined sharply from the levels attained in spring 1975.

Albania.—A new urea plant with a capacity of 40,000 tons per year of contained nitrogen was completed at Fieri.[32]

Belgium.—Ste. Carbochimique, S.A. commissioned a new 236,000-ton-per-year nitric acid plant at Tertre in September.[33]

Brazil.—Pullman Kellogg was awarded a contract by Petrobras for the technology and design engineering of two 1,070-ton-per-day ammonia plants to be built at Laranjeiras and Norte Fluminense. The plants will be associated with two 1,200-ton-per-day urea units of Mitsui Toatsu technology.[34] A West German consortium received a contract for the construction of a 1,320-ton-per-day ammonia plant and a 1,650-ton-per-day urea unit at Araucaria. The facility will utilize heavy petroleum fractions as feedstock, and was scheduled for startup in 1978. Similar complexes were being planned at Paulinia and Aracaja.[35] The two 1,100-ton-per-day ammonia plants under construction at Camaçari were scheduled to come onstream at yearend 1977.[36]

Bulgaria.—A 200,000-ton-per-year ammonia plant and a 300,000-ton-per-year ammonium sulfate unit, both designed and constructed by Humphreys & Glasgow Ltd., started up at the Povelianovo Chemical Combine at Varna.[37]

Cameroon.—Ste. Cameroonaise des Engrais started up a 55,000-ton-per-year ammonium sulfate plant and a 30,000-ton-per-year complex fertilizer plant at Douala.[38]

Canada.—Canadian Fertilizers Ltd. brought the first of two 396,000-ton-per-year ammonia plants and a 495,000-ton-per-year urea unit onstream at Medicine Hat, Alberta, in the summer of 1976. Although the company announced in December that it had deferred the remainder of the project, financing has since been completed and construction was scheduled to proceed. The second plant was scheduled to come onstream in 1977. Production from both ammonia plants will be used for direct application and conversion to granular urea. The material will be earmarked for consumption in Canada and the United States.[39]

Pan Canadian Petroleum Ltd. announced at yearend that it will not proceed with an ammonia plant at Brooks, Alberta. Pan Canadian's partner in the venture, Tyler Corp., of Dallas, Tex., withdrew several months before. Sherritt Gordon Mines has also decided to shelve plans to expand its ammonia-urea complex at Fort Saskatchewan, Alberta.[40]

Genstar Chemical Co. commissioned a $9.5 million expansion of its nitric acid and

ammonium nitrate facilities at Maitland, Ontario.[41]

Union Carbide Canada announced plans for a 260-ton-per-day expansion of its air separation plants at Oakville, Ontario.[42] Air Products Ltd. scheduled the construction of an industrial gases plant with capacity of 400,000 tons per year at Nanticoke, Ontario. The plant will also produce 300 tons of liquid nitrogen, oxygen, and argon daily.[43] Liquid Air Corp. of North America began construction of a new air separation unit, the fourth at its Hamilton, Ontario, complex. The $15 million plant will supply an additional 250 tons of nitrogen and 600 tons of oxygen daily to Dominion Foundries & Steel Ltd. when it comes onstream early in 1979. Total daily production at the complex will then exceed 1,500 tons of nitrogen and 2,800 tons of oxygen[44]

Chile.—Petroquimica Chilena awarded a contract to Snamprogetti for a 1,485-ton-per-day ammonia plant and a 2,200- ton-per-day urea unit. The complex will be located by the Straits of Magellan in order to use the natural gas reserves in the area. A large percentage of the output from the facility is destined for export, primarily to Brazil and Argentina.[45]

China, People's Republic of.—Four ammonia-urea facilities went onstream in the provinces of Heilongkiang, Liaoning, Szechwan, and Hopei. Each facility included a 1,100-ton-per-day ammonia plant and a 1,780-ton-per-day urea unit of Kellogg design.[46] Although the country remains a large importer of nitrogenous fertilizers, imports have been steadily declining and domestic production has been increasing. Small-scale plants on the local level account for about one-half of total production. The nation should be self-sufficient in urea by the end of the decade.[47]

Denmark.—A new 165,000-ton-per-year nitric acid plant was commissioned by Superfos A/S at Fredericia.[48]

Egypt.—Three nitric acid plants with a combined capacity of 770 tons per day were brought onstream at Talkha. A fourth unit was scheduled for completion in 1978. In September nitrogenous fertilizer production began at the Talkha complex. Three Arab funds will provide financing for the second phase of the Talkha project, which includes a 359,000-ton-per-year ammonia plant and a 288,000-ton-per-year urea unit, due for completion in 1978. Feedstock is natural gas from the Abu Madi field in northern Egypt.[49]

France.—Friedrich Uhde GmbH was awarded a contract to build a 550-ton-per-day nitric acid plant at Lievin for Gardinier.[50] Air Products & Chemicals, Inc., began producing nitrogen, oxygen, and argon at a new 300-ton-per-day air separation plant at Beauvais.[51] An air separation plant with a capacity of 220 tons per day of liquid nitrogen, oxygen, and argon will be constructed near Lyons by Airgaz. Commissioning was slated for mid-1978.[52]

Germany, East.—The third 385,000-ton-per-year urea plant came onstream at Piesteritz.[53]

India.—The Fertilizer Association of India stated that the country must build five more nitrogenous fertilizer plants in addition to projects currently underway and the four presently approved in principle to bridge the gap between production and consumption by 1983-84.[54] The Fertilizer Corp. of India Ltd. commissioned a new naphtha-fed, ammonia-urea facility at Barauni in July. The capacities of the units are 220,000 tons of ammonia and 363,000 tons of urea per year.[55] Mangalore Chemicals and Fertilizers Ltd. commissioned a new urea plant at Mangalore with a capacity of 176,000 tons per year of nutrient.[56] Snamprogetti of Italy was awarded a contract by Gujarat State Fertilizers Co. Ltd. for a 1,980-ton-per-day urea plant to be built at Baroda.[57] Two ammonia-urea complexes

with daily capacities of 990 tons of ammonia and 1,700 tons of urea were scheduled onstream in 1978 at Bhatinda and Panipat.[58]

Indonesia.—Kellogg Overseas Corp. was named managing director for a grass-roots, ammonia-urea facility at Cikampek, West Java. The complex will consist of a 1,100-ton-per-day ammonia plant and a 1,900-ton-per-day urea unit. A major portion of the $200 million project will be financed by the Government of Iran. Plans to build the world's first floating fertilizer plant near gasfields off the coast of Kalimantan Province have been scrapped. A new plan calls for locating the plant on land, with daily capacities of 1,650 tons of ammonia and 1,100 tons of urea. The future of a proposed ammonia-urea facility at Aceh, North Sumatra, is uncertain. As the country's urea capacity climbs beyond 2 million tons per year, an exportable surplus should become available.[59]

Iran.—Construction of a new fertilizer complex using natural gas feedstock began at Shiraz for the Iran Fertilizer Co. The facilities were scheduled onstream in 1978 and will have annual capacities of 359,000 tons of ammonia, 248,000 tons of nutrient as urea, 76,000 tons of nutrient as ammonium nitrate, and 218,000 tons of nitric acid.[60]

Iraq.—The expansion at the Basrah fertilizer complex was completed by Mitsubishi Heavy Industries. The plant has a daily capacity of 880 tons of ammonia and 1,430 tons of urea. By 1982 ammonia capacity is scheduled to reach 1.5 million tons per year. At that point, Iraq's ammonia production could account for about one-third of the Middle East total.[61]

Italy.—Breda Cantiere Navale shipyards received a contract from Sudimport, the foreign trade organization of the U.S.S.R., to build three ammonia tankers.[62]

Japan.—A 91,000-ton-per-year nitric acid plant was completed by Mitsubishi Heavy Industries at Kurosaki.[63] Japanese urea exports declined sharply in 1976. As a result, ammonia and urea production have been running well below capacity. The industry, which is heavily dependent upon exports, urged the Government to offer tied loans and fertilizer supply arrangements as part of its economic aid program for Southeast Asian countries.[64]

Korea, North.—A $64 million complex was completed by West German and Austrian contractors at Nam Hung, the first large-scale chemical facility built in North Korea by Western contractors. Annual plant capacities were listed as 272,000 tons of ammonia and 400,000 tons of urea.[65]

Korea, Republic of.—Air Products & Chemicals, Inc., received a $20 million contract for design and construction of two 850-ton-per-day nitrogen, oxygen, argon plants for the Pohang Iron & Steel Co. Both plants were scheduled for completion in late 1978.[66] Yong-Nam Chemical Co. Ltd. completed an expansion project at its Ulsan complex. Total capacities were increased to more than 110,000 tons per year of ammonia and 132,000 tons per year of urea.[67]

Libya.—Libyan National Oil awarded a contract to Foster Wheeler Italiana for the construction of the country's first urea plant at Marsa el Brega by 1979. Ammonia feedstock for the 1,100-ton- per-day unit will be supplied by National Oil's adjacent plant which was due onstream in 1977.[68]

Mexico.—Guanos y Fertilizantes S.A. planned to construct two new urea plants. One of the units will be built at Coatzacoalcos with a capacity of 495,000 tons per year, and the other will be located near Salamanca with a capacity of 330,000 tons per year. The new production has been designated for both domestic consumption and export markets, since completion of the plants should result in self-sufficiency for the country in nitrogenous fertilizers.[69]

Poland.—Creusot-Loire Enterprises of France has contracted for the installation of a fertilizer complex at Police. The complex will comprise two 825-ton-per-day ammonia

plants, one 1,320-ton-per-day urea unit and mixed fertilizer facilities, with a projected startup date of late 1979.[70] Krupp Chemieanlagen of West Germany gained a contract for the construction of two coal gasification plants at a coal-based chemicals complex planned for Katowice. The complex will include a 550,000-ton-per-year ammonia plant and an 880,000-ton-per-year urea unit.[71]

Qatar.—Qatar Fertilizer Co. awarded a contract for the construction of a 1,000-ton-per-day ammonia plant at Umm Said, to be associated with a 1,100-ton-per-day urea plant. The complex was scheduled onstream in 1978.[72]

Spain.—Union Explosivos Rio Tinto commenced production at a 990-ton-per-day ammonia plant at Huelva. The plant uses naphtha as feedstock.[73] Local opposition to the construction of an ammonia plant by the fertilizer group Sefanitro at Bilbao led authorities to revoke the construction permit. Site preparation and equipment procurement for the plant were well advanced at the time. Sefanitro was seeking to form a partnership with one of several companies that would provide a new site.[74]

Syria.—Creusot-Loire Enterprises of France was awarded a turnkey contract by Unichem for a refinery and fertilizer complex at Homs. Naphtha from the refinery will be used as feedstock for a 363,000-ton-per-year ammonia plant with a downstream 400,000-ton-per-year urea unit.[75]

Turkey.—Kellogg International Corp. was awarded a contract by Azot Sanayii for a 314,000-ton-per-year ammonia plant at Gemlik. Part of the output from this naphtha-fed plant was slated for use in a new 172,000-ton-per-year ammonium nitrate unit.[76] Friedrich Uhde GmbH received a contract for construction of an 82,500-ton-per-year ammonium sulfate plant and other units at Bandirma by late 1978.[77]

U.S.S.R.—Toyo Engineering Corp. of Japan reached agreement with the U.S.S.R. to supply five more 1,500-ton-per-day ammonia plants using Pullman Kellogg technology at Kiev, Minsk, Kharkov, Moscow, and Perm. These plants are in addition to the deal concluded in 1975 for four identical plants.[78] Montedison of Italy contracted with Techmashimport to furnish two 1,650-ton-per-day urea plants at Kemerovo and Berezniki. Ammonia feedstocks will come from plants being constructed at the sites.[79] Technoexport Foreign Trade Co. Ltd. of Czechoslovakia agreed to construct and deliver three urea production lines, each with a capacity of 177,000 tons per year. Destinations are Grodno, Dneprodzherzhinsk, and Cherkassy in 1977-78.[80] New ammonium nitrate facilities came onstream at Berezniki, increasing downstream product capacity by 110,000 tons per year of contained nitrogen. Installed anhydrous ammonia capacity at the Severodonetsk complex reached 1.4 million tons with the completion of another 495,000-ton-per-year plant. A new urea plant was commissioned at Salavat bringing total urea capacity there to 540,000 tons per year.[81]

The first specific contract under the 1973 fertilizer agreement between Occidental Petroleum Corp. and the U.S.S.R. was signed in late November at Moscow. The contract called for the U.S.S.R. to supply Occidental with 3.5 million tons of ammonia over a 10-year period beginning in 1978. The company has been assisting the Soviets in the construction of ammonia pipeline and port facilities and arranging for new ammonia plants in the Soviet Union. Occidental is scheduled to deliver superphosphoric acid to the U.S.S.R. and receive ammonia, urea, and potash. Separate contracts still remain to be signed for the other components of the agreement.[82]

United Kingdom.—British Oxygen Corp. announced plans to expand production of industrial gases at its Brinsworth site near Rotherham. The new unit will produce 132 tons of nitrogen, 132 tons of oxygen, and 5 tons of argon daily. Construction was scheduled to start in January 1977 with an onstream target date of early 1979.[83] The Secretary of State for Scotland granted

approval for a Scandinavian chemicals group, Scanitro, to construct a 350,000-ton-per-year ammonia plant at Peterhead, Scotland. The $100 million facility will utilize natural gas feedstock from the North Sea. The plan must still receive the approval of local authorities. Scottish Agricultural Industries has contracted for an 88,000-ton-per-year prilled ammonium nitrate plant at Leith. The plant was scheduled onstream in 1978.[84]

Zambia.—Nitrogen Chemicals of Zambia was expanding its nitrogenous fertilizer complex at Kafue. The new coal-based ammonia plant will have a capacity of 85,000 tons per year, and was due onstream by July 1977.[85]

TECHNOLOGY

Higher energy costs and the rising demand for fertilizer have underscored the need for basic research into ways to increase nitrogen availability to agricultural plants. Research has focused on increasing the efficiency and amount of natural nitrogen fixation, introducing the process into plants in which it does not normally occur, and finding a low-energy industrial route that could replace the present energy-intensive process for making ammonia.[86]

A 5-year, $1.3 million United Nations research program to investigate natural nitrogen fixation will be implemented by the International Rice Research Institute in the Philippines, in collaboration with Cornell University and Boyce Thompson Institute in the United States. The new project will study rates of nitrogen fixation, the role of bacteria, and environmental factors.[87]

The Dow Chemical Co. brought onstream a facility to produce nitrapyrin, a nitrification inhibitor for use with anhydrous ammonia, urea, and ammoniacal-type fertilizers. The product stabilizes the fertilizers through its activity on specific bacteria that are responsible for rapid conversion of ammonium nitrogen in soil. The result is that more ammonium nitrogen is available for use by plant life and less is lost to nitrite and nitrate conversion and potential leaching from the soil.[88]

A high-priority project of the Tennessee Valley Authority (TVA) is reducing the fertilizer industry's dependence on natural gas as the hydrogen source for ammonia production. Accordingly, a prototype coal gasification plant under development is scheduled to be in operation in 2 to 3 years.[89]

TVA's new pipe-cross reactor process for the manufacture of ammonium phosphate eliminates the need for natural gas to dry the final product. Chemical heat produced by the reactants in the pipe-cross reactor is usually sufficient to completely dry the granular material. Elimination of drying equipment would also significantly reduce the cost of plants using the process.[90]

The Danish firm Haldor Topsoe introduced an improved design of its ammonia synthesis converter with a heat exchanger between the two radial flow catalyst beds. The new design provides ammonia conversion of 22% instead of 16%.[91]

A device that vaporizes fuel oil and thus will permit ammonia plant operators to use liquid fuels in furnaces fitted with natural gas burners has been developed by Allied Chemical Corp. The new system permits firing oil, gas, or any mixture of the two in existing burners, without making extensive modifications to piping.[92]

Production of ammonia from the exhaust gas of a stationary engine is possible with a new patented process developed by the Institute of Gas Technology. The major potential application is in converting irrigation pump exhaust gas into ammonia, which could be applied in the irrigation water. The process involves the reaction of carbon monoxide and water to form hydrogen, which reacts with nitric oxide to form ammonia.[93]

A new waste treatment plant due onstream in early 1978 at North Lake Tahoe, Calif., will incorporate an ammonia removal and recovery process to produce a 40% ammonium sulfate solution. Ammonium ions are absorbed in beds of the mineral clinoptilolite, which are regenerated by a concentrated sodium chloride solution. The ammonium sulfate solution will be suitable for application by farmers or for blending by fertilizer manufacturers. Sale of the fertilizer material should cut operating expenses of the plant by 60% compared with other tertiary treatment methods. However, the initial cost of the process amounts to 10% of the cost of the entire system.[94]

A report from the National Oceanic and Atmospheric Administration, based on a numerical model of the atmosphere, stated that nitrogen fertilizers are having little effect on the earth's ozone layer. The amount of fertilizer currently used adds only about 2 million tons of nitrous oxide to the estimated 1.4 billion tons already in the atmosphere. The study concluded that if nitrogen fertilizer use increased 6% annually until the year 2000 then leveled off, ozone would decrease somewhere between 1% and 10%.[95]

Skid-mounted stripping units that recover unreacted ammonia and urea can be added to existing urea plants to enable producers to meet EPA effluent standards. The stripping process recovers unreacted materials in the vapor phase at synthesis pressure and condenses them before they are returned to the reactor, thus cutting

energy costs by up to 15% and increasing yields.[96]

Gulf Oil Chemicals Co. has developed a catalytic process designed to be retrofitted to existing nitric acid plants. Nitrogen oxides in the stack gas are selectively reduced using an aluminosilicate, molecular-sieve catalyst. In operation, ammonia is mixed with the tail gas and is adsorbed preferentially along with nitrogen oxide molecules. They react to form nitrogen and water, which are then desorbed.[97]

Peat

By Donald P. Mickelsen[1]

U.S. peat production was up sharply in 1976 to 969,459 tons, 26% over 1975 production. This was principally due to an increase in the number of operations producing over 25,000 short tons annually. The number of active operations, however, decreased by seven, with several existing and planned operations being prevented from producing since they were unable to obtain environmental permits. Production in 1976 increased in eight States, with the largest production gains occurring in Pennsylvania, Indiana, and Michigan.

Commercial sales of peat also rose sharply, increasing to 947,462 tons, 27% above sales in 1975. The average value per ton of peat sold, f.o.b. plant, increased from $16.49 in 1975, to $18.04 in 1976; raising the total value of peat sold by 39% to $17.1 million.

Imports increased about 16% in 1976 and provided about 26% of the peat available for consumption in the United States. Canada provided 97% of the peat imported.

Estimated world production remained at 223 million tons, about 95% of which was in the U.S.S.R.

[1]Commercial sales plus imports.

DOMESTIC PRODUCTION

Peat is broadly classified in the United States as moss peat, reed-sedge peat, and humus, according to the type of plant matter from which it is formed and the degree of decomposition. Moss peat is a type that has been formed principally from sphagnum, hypnum, and/or other mosses; reed-sedge peat originated mainly from reeds, sedges, and other swamp plants; and humus peat is too decomposed for easy identification of its biological origin.

The 198,000-ton increase in 1976 production resulted from a larger output of humus peat in Pennsylvania and Indiana. Humus production was 92% greater than in 1975, owing to greatly increased output by several existing operations. Of the total peat production in 1976, 46% was reed-sedge peat, 32% was humus, and 22% was moss peat.

Peat was produced in 21 States in 1976. Michigan remained the largest producer, with 31% of the Nation's output. The next four largest producing States were Indiana, Pennsylvania, Illinois, and Florida.

Active operations in the United States decreased from 109 to 102, but the average output per plant increased greatly from

[1]Mineral specialist, Division of Coal.

7,080 tons in 1975 to 9,505 tons in 1976. Over three-fourths of the operations, however, had outputs below the average with only 32 plants producing more than 5,000 tons. The increase in average output, as well as the increase in the total U.S. peat production, can be attributed to the growth in the number and size of operations producing over 25,000 tons annually. These producers increased from five in 1975 to nine in 1976 and accounted for 63% of the total peat produced.

Production methods used in the United States varied with the size and conditions of the bog being worked. Almost all peat was harvested using conventional earthmoving and excavating machinery, or modified conventional machinery. Power shovels, bulldozers, and front-end loaders were used in drained bogs; draglines, clam shells, and dredges were used in submerged deposits.

Peat bogs are generally covered with water, tree trunks, limbs, and other debris and must be properly cleared and drained before harvesting. In most instances, the bog is drained by constructing a series of feeder ditches and collecting canals so that the prevailing water table can be lowered and controlled. Since the surface of a peat bog is unstable, roads are built across the bog to provide a firm surface for trucks to travel on. The use of special wide-track treads enables other machinery to operate upon the bog surface.

Various harvesting techniques are employed at domestic peat operations. Generally, the peat is harvested by first loosening the top layer of the bog to a depth of approximately one-half inch with a disk, spike, or spring harrow. The loosened peat is then scraped into piles alongside the roads with bulldozers and loaded into trucks with front-end loaders. Other production methods include the use of vacuum harvesters, snow-blowing machines, draglines, and dredges.

Peat is usually processed for sale by air drying, shredding, screening, and in a few instances, by artificial drying. Processing equipment consists of a variety of screens, shredders, grinders, hammer mills, and gas- and oil-fired dryers.

In 1976, 36% of the peat was sold as produced with no processing other than air drying. About 63% of the peat was shredded before sale, and only 1% was subjected to thermal drying.

CONSUMPTION AND USES

The amount of peat available for consumption in 1976 increased 24% over that in 1975. This was principally due to substantial increases in commercial sales of peat and peat imports.

Peat was used for a variety of purposes, but 86% of total commercial sales reported by producers were for general soil improvement. Among the principal markets for this peat were nurseries and greenhouses, which used peat as a mulch and as a medium for growing plants and shrubs; landscape gardeners and contractors, who used peat for building and maintaining lawns and golf-course greens and for transplanting trees and shrubs; and garden, hardware, and variety stores, which sold peat to homeowners for mulching and improving lawn and garden soils. The remaining 14% of the peat was sold principally for use in potting soils, a market that has grown greatly in the past few years along with the household plant industry. Other uses for peat were for packing flowers and shrubs for shipment, and for mushroom beds, earthworm culture, seed inoculant, and mixed fertilizers. About 69% of the peat sold commercially by producers was packaged, and this accounted for over 76% of the total value of sales. This was a 59% increase over packaged sales in 1975 and is a continuation of the industry trend in the past several years toward wider distribution and marketing, facilitated by the use of polyethylene bags.

Package sizes varied greatly, but most producers used 40-pound bags. Smaller bags have been used increasingly in the past several years for marketing both peat and potting soils. Five-, ten-, and twenty-pound bags of each have been commonly produced for household use. About 51% of the packaged peat sold in 1976 was of the reed-sedge type, 38% was humus, and 11% was moss peat.

States leading in sales of packaged peat in 1976 were Michigan, Pennsylvania, Indiana, and Illinois, in order of volume. Together, these States reported 84% of the total sales of packaged peat. Michigan, the largest producer, had 39% of the total sales.

Of the bulk peat sold in 1976, 62% was reportedly sold for general soil improvement. The remainder was sold mainly for use in potting soils, for packing flowers and shrubs, and in mixed fertilizers. States leading in sales of bulk peat were Florida, Indiana, and Michigan, in order of volume.

[1]Less than 1/2 unit.

PRICES AND SPECIFICATIONS

Prices of peat at individual operations varied greatly in 1976, with the price depending mainly upon the kind of peat sold, the amount of processing, and whether the peat was sold in bulk or package form.

The overall average value per ton, f.o.b. plant, for all peat sold in 1976 was $18.04, up from $16.49 in 1975. Most of the increase was attributed to higher average receipts for peat sold in 14 States, with significant price increases occurring in Minnesota, Ohio, Massachusetts, Pennsylvania, and Iowa.

The average value of bulk peat increased 15% to $13.78 per ton. Packaged prices decreased 1% to $19.94, probably owing to competition in the marketplace. Increased sales at higher prices by producers in Florida, Michigan, and Indiana contributed to the higher average price of bulk peat. The unit value of packaged peat was influenced mainly by packaged sales in Pennsylvania, Michigan, Minnesota, and Indiana.

In a few instances, when producers did not report the value of peat sold, the sales value was estimated based on the average value of a similar type of peat sold within the State.

Imported peat had a total value of $29.5 million in 1976. This value was 24% greater than in 1975, the average value per ton increased from $82.17 to $87.24.

Although the average value per ton of imported peat was four times that of domestically produced packaged peat, these values were not comparable because imported peat was less dense and of higher quality than domestic peat. Each 100 pounds of a typical air-dried imported peat measured approximately 12 bushels, whereas the same weight of a typical domestic peat measured only 3 or 4 bushels. The imported product was usually sold on a volume rather than a weight basis. A few domestic operations, in the northern latitudes, produced peat with properties similar to those of the imported kind.

FOREIGN TRADE

The quantity of peat imported into the United States in 1976 totaled 338,000 short tons. This tonnage was 16% greater than that imported in 1975 and represented a recovery from the previous year's depressed import market. Canada provided 97% of the peat imports. Most of the remaining imports of peat were supplied by Europe. European shipments to the United States increased 20% in 1976, in contrast to a 48% decrease in 1975.

Imported peat was classified according to use, either as poultry and stable grade or as fertilizer grade. Except for a duty of $0.50 per long ton levied on poultry and stable grade peat from countries with centrally controlled economies, there was no tariff on peat.

Foreign peat entered the United States through 28 customs districts in 1976, but 89% of the total was shipped through the customs districts of Buffalo, N.Y., Detroit, Mich., Ogdensburg, N.Y., Pembina, N.Dak., Portland, Maine, St. Albans, Vt., and Seattle, Wash. The largest quantity, 94,000 tons, was shipped through the Ogdensburg district.

WORLD REVIEW

World production of peat in 1976 was estimated at 223 million tons, practically the same as in 1975.

The U.S.S.R. was by far the largest peat producer, with an estimated 95% of world production. According to published U.S.S.R. figures, 145 million tons of peat was produced for agricultural use, and an estimated 66 million tons was used for fuel. Agricultural peat was used for general soil improvement and the manufacture of fertilizers, and fuel peat was used for generating electric power and for industrial and domestic heating.

Ireland ranked second in world peat production with an estimated 6.3 million tons, a 18% reduction from the 1975 output. Virtually all of Ireland's production was fuel peat used for generating electric power and for heating households. A small amount of agricultural peat was produced, principally for export.

West Germany was the third ranking country with 2.7 million tons, about the same output as in 1975. Most of this production was for agricultural use, with only 10% consumed as a fuel.

Other producers, in order of tonnage, were the United States, the Netherlands, Canada, and Finland. The combined output of these countries was about 1% of the world total. Although the United States was fourth in world production, it produced less than 0.5% of the world total.

[e]Estimate. [p]Preliminary. [r]Revised.
[1]In addition to the countries listed, Austria, Iceland and Italy produce negligible quanties of fuel peat, and East Germany is a major producer, but output is not officially reported and available information is inadequate for formulation of estimates of output levels.
[2]Sales.

TECHNOLOGY

Research conducted by the Department of Chemistry, University of Cincinnati, investigated the possible use of peat as a lightweight and inexpensive substitute for the XAD-2 polystyrene beads presently being used in shipboard filter cartridges.[2] These cartridges contain a filter agent which removes the oil from bilge water before it is discharged into waterways, in order to meet pollution laws. The filter materials coalesce the oil so that it can be separated by gravity. It was found that the coalescence capabilities of dried Irish peat and sulfuric-acid-treated Michigan peat when tested in distilled and synthetic seawater were comparable to that of the XAD-2 beads. Further research was required.

First Colony Farms, Inc., a large agricultural corporation, has been investigating peat as a source of fuel for electric-power generation.[3] Assisted by studies conducted by Ebasco, a private utilities consulting firm, First Colony estimated that the humus peat reserve on its land near Roper, N.C., could fuel a 1,600-megawatt powerplant for 35 years. First Colony purchased $300,000 worth of harvesting equipment from the U.S.S.R. to assist in harvesting the peat and planned to produce crops on the reclaimed land. There were, reportedly, environmental and political problems yet to be solved before the feasibility of the project could be evaluated.

The Institute of Gas Technology, Chicago, Ill., continued an Experimental Program for the Development of Peat Gasification for the Minnesota Gas Co. under contract with the U.S. Department of Energy.[4]. The first phase of the program consisted of deter-

[2]Smith, E.F. and H.B. Mark, Jr. The Use of Modified Forms of Peat as an Oil Coalescer. J. Environ. Sci. Health, v. A-11, Nov. 12, 1976, pp. 727-734.
[3]The News and Observer (Raleigh, N.C.). Peat Bogs May Yield New Fuel. July 19, 1977, p. 19.
[4]U.S. Energy Research and Development Agency. Experimental program for the Development of Peat Gasification. Fossil Energy Rept. FE-2469-8, Supp. Rept. 1, April 1977.

mining the chemical and physical characteristics of the different types of peat. It was found that reed-sedge peat had the most consistent content of nitrogen, oxygen, sulfur, and ash. The second phase investigated the gasification reactivity of peat using a series of thermobalance tests. It was found that although peat is two to four times as reactive as bituminous coal, the carbon-to-gas conversion efficiency was lower because of the low calorific value of peat and also because of production of liquid chemical byproducts. It was demonstrated that about 43% of the energy value in peat could be recovered in a high-Btu gas stream and that another 27% of this energy could be recovered in the chemical byproducts.

An economic evaluation was projected based on an extrapolated Hygas plant design using reed-sedge peat. It was estimated that investment in an 80-billion-Btu-per-day, peat-to-gas conversion plant would total $219 million. The production cost of the gas was estimated to be $2.14 per million Btu over a 20-year period, assuming a 90% steam factor and a delivered price of $5 per ton for peat. The major byproduct would be about 1 barrel of chemical byproducts, mostly benzene, naphthalene, and phenols, per 10,000 standard cubic feet of gas.

Perlite

By A. C. Meisinger[1]

Crude perlite production by the domestic industry in 1976 was the second highest on record for the quantity mined (727,000 tons) and for the quantity sold or used (553,000 tons) by crude ore producers for expanding. Value of crude perlite output was $9.4 million, or 29% greater than the previous record high set in 1975. New Mexico continued to be the major perlite-producing State with 86% of the total crude ore mined and established a record 481,368 tons sold or used from five mines, compared with the previous high of 480,024 tons in 1974.

Average value of crude perlite sold or used was $17 per ton or an increase of 19.5% over the previous record value in 1975.

Domestic perlite expanders set alltime highs in output of expanded perlite in 1976. The quantity produced was 438,000 tons compared with the previous high of 427,000 tons in 1972, and the quantity sold or used was 432,000 tons compared with the previous high of 421,000 tons in 1972. The value of expanded perlite sold or used was a new record of $41.0 million, compared with the old record of $34.3 million in 1975. Combined output of several new expanding plants contributed to the 1976 record total output. Illinois and Texas were the leading expanded perlite-producing States.

Table 1.—Crude and expanded perlite produced and sold or used by producers in the United States

(Thousand short tons and thousand dollars)

Year	Crude perlite						Expanded perlite		
	Quantity mined	Sold		Used at own plant to make expanded material		Total quantity sold and used	Quantity produced	Sold or used	
		Quantity	Value	Quantity	Value			Quantity	Value
1972	649	224	2,540	321	3,691	545	427	421	28,397
1973	759	238	2,771	306	2,819	544	424	418	28,005
1974	676	275	3,544	280	3,480	555	423	419	30,808
1975	706	239	3,407	273	3,874	512	401	394	34,258
1976	727	288	4,908	265	4,489	553	438	432	41,017

DOMESTIC PRODUCTION

The quantity of crude perlite produced by 11 companies at 12 mines in 6 States in 1976 was 727,000 tons, or 3% greater than that in 1975. New Mexico, with five mining operations, continued to be the principal source of crude perlite in the United States. New Mexico produced 86% of the mined ore in 1976, followed by Arizona, California, Colorado, Nevada, and Idaho in descending order of production. The quantity of crude perlite ore sold or used in New Mexico was a record high of 481,368 tons.

Crude perlite sold or used by producers totaled 553,000 tons valued at $9.4 million compared with 512,000 tons valued at $7.3

[1]Industry economist, Division of Nonmetallic Minerals.

million in 1975. The increase of 8% in quantity over that of 1975 was attributed in part to the opening in 1976 of the new mining and processing facilities of Grefco, Inc., at Socorro, N.Mex. The increase of 29% in value over that of 1975 established a new record in total sales value of crude perlite to expanding plants.

Producers of crude perlite during the year were Filters International, Inc., Harborlite Corp., and Guzman Construction Co. in Arizona; American Perlite Corp. in California; Persolite Products, Inc. in Colorado; Oneida Perlite Corp. in Idaho; Delamar-Mackie Perlite and United States Gypsum Co. in Nevada; and Grefco, Inc., Johns-Manville Sales Corp., Silbrico Corp., and United States Gypsum Co., all with operations in New Mexico.

The quantity of expanded perlite produced at 74 plants in 32 States totaled a record high of 438,000 tons, or 9% more than that produced at 69 plants in 29 States in 1975. The quantity (432,345 tons) and value ($41 million) of expanded perlite sold or used were alltime highs and represented increases of 10% in quantity and 20% in value compared with 1975 figures.

Leading States in descending order of expanded perlite production in 1976 were Illinois, Texas, Kentucky, Mississippi, Colorado, Pennsylvania, California, New Jersey, and Florida. California and Texas each had seven producing plants, followed by Illinois, Indiana, and Pennsylvania with five each. New expanding plants in operation in 1976 were located in California, Pennsylvania, Texas, Utah, Virginia, West Virginia, and Wyoming.

Table 2.—Expanded perlite produced and sold or used by producers in the United States

State	1975				1976			
	Quantity produced (short tons)	Sold or used			Quantity produced (short tons)	Sold or used		
		Quantity (short tons)	Value (thousands)	Average value per ton		Quantity (short tons)	Value (thousands)	Average Value per ton

Total	401,274	393,971	34,258	86.96	438,089	432,345	41,017	94.87

[1]Includes Colorado, Georgia, Idaho, Illinois, Iowa, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Mississippi, Nebraska (1975), Nevada, New Hampshire, New Jersey, North Carolina (1976), Oregon, Tennessee, Utah, Virginia (1976), West Virginia (1976), Wisconsin, and Wyoming (1976).

CONSUMPTION AND USES

Domestic consumption of expanded perlite increased 10% in quantity over that of 1975 and was an alltime high of 432,345 tons. A percent distribution by end use is shown in table 3. In descending order of quantity sold or used, the principal uses for expanded perlite in 1976 were roof insulation board, filter aids, acoustical tile, horticultural aggregate, concrete aggregate, and plaster aggregate. Expanded perlite sold or used for filter aids, acoustical tile, and insulation board combined, accounted for 291,000 tons or 67% of the total quantity and 57% of the total value of sales in 1976.

Compared with 1975, plaster aggregate use declined from 8% to 6%; concrete aggregate, from 8% to 7%; and formed products,

Table 3.—End use of expanded perlite

(Percent)

Use	1975	1976
Filter aid	21	21
Plaster aggregate	8	6
Concrete aggregate	8	7
Horticultural aggregate	8	9
Low-temperature insulation	1	2
Masonry and cavity fill insulation	3	3
Fillers	1	1
Formed products	11	10
Other[1]	39	41

[1]Includes insulation board.

from 11% to 10% of total consumption. End-use categories that remained unchanged in 1976 were filter aid (21%), masonry and cavity fill insulation (3%), and fillers (1%). Expanded perlite used as horticultural aggregates continued to increase in popularity (from 5% in 1973 to 9% in 1976) and accounted for nearly 36,900 tons in 1976 compared with 31,200 tons in 1975. Low-temperature insulation and various other uses increased modestly in 1976. The "Other" uses category included (other than insulation board and acoustical tile) such items as pipe insulation, foundry applications, paint texturizers, oil absorbent, fines, and specialty products.

PRICES

Processed (crushed, cleaned, and sized) crude perlite was sold by producers to expanders at an average price of $17.04 per ton, or an increase of $2.78 per ton over that in 1975. Crude perlite used by producers in their own expanding plants was valued at $16.94 per ton, or an increase of $2.75 per ton compared with that in 1975. The weighted average price of crude processed perlite was $16.99 per ton, or an increase of $2.77 per ton over that of 1975.

Expanded perlite sold or used, according to expanders, was valued at $94.87 per ton compared with $86.96 per ton in 1975. Average values for expanded perlite by States ranged from $40 to $167 per ton, compared with the 1975 range of $36 to $186 per ton. Average prices per end use in 1976 ranged from $37 per ton for acoustical tile to $240 per ton for low-temperature insulation.

WORLD REVIEW

Greece.—Preliminary figures for crude and processed perlite (for export) in 1976 indicated a significant increase over 1975 production. Production of perlite in Greece for the 1974-76 period is given in the following table, in short tons:

	1974	1975	1976[p]
Crude ore	[r]234,800	177,500	259,800
Processed ore (for export)	125,900	124,700	131,400

[p]Preliminary. [r]Revised.

General Enterprises Sarides, S.A. (formerly L. K. Sarides Mining Enterprises) of Piraeous, commenced construction of a new perlite processing plant on Milos. Crude ore from the company's open pit mine will be processed in the plant and classified into three grades ranging from 0.5 millimeter to 2.5 millimeters in size. The company has also started improvements in the docking facilities at the port of Adamas for handling larger shipments of perlite for export.

Mexico.— Production of crude perlite from Mexican operations in 1976 totaled 16,000 tons, or 5,000 tons under the 1975 output.

Philippines.—Crude perlite produced in 1976 increased substantially, from 733 tons in 1975 to 1,818 tons.

Grefco, Inc., Los Angeles, Calif., in association with local Philippine interests, started construction of a filter aid plant near Legaspi, Albay, on the Island of Luzon. The expanding plant, scheduled to be in operation by mid-1977, will help to supply perlite filter aid demand in the Philippines and certain market areas of the Far East.

South Africa, Republic of.—The perlite mining operation of Pratley Perlite Mining Co. (Pty.) Ltd. went on stream at yearend. The deposit is on the Nxwala Estate, Zululand. The crude ore will be transported to a processing plant at Krugersdorp.

A joint venture between Grefco, Inc., Los Angeles, and Chemical Holdings, Ltd. of Sandton, Transvaal, to construct a filter aid plant at Olifantsfontein near Johannesburg, was announced by Grefco.

Reflecting a moderate recovery in the economy coupled with an unusually severe winter, domestic demand[5] for petroleum products in 1976 increased sharply over 1975 and exceeded the previous high of 1973 by a slight margin. Sharp gains occurred in the demand for residual fuel oil and distillate fuel oil and moderate gains occurred in motor gasoline demand, as a result, overall domestic demand rose 6.9% to 17.5 million barrels per day (bpd) from 16.3 million bpd in 1975. Production of crude oil, lease condensate, and natural gas liquids continued to decline making it necessary to increase imports of crude oil and refined products significantly to have an adequate supply to meet demand.

[5]Certain terms as used in this chapter are more or less unique to the petroleum industry. Principal terms and their meanings are: *Total demand.*—A derived figure representing total new supply plus decreases or minus increases in reported stocks (because there are substantial consumers' stocks that are not reported to the Bureau of Mines, this figure varies considerably from consumption as reported by the Federal Highway Administration of the Department of Transportation); *Domestic demand.*—Total demand less exports; *New supply of all oils.*—The sum of crude oil production plus production of natural gas liquids, plus benzol (coke oven) used for motor fuel, hydrogen, and other hydrocarbons plus imports of crude oil and other petroleum products; *Transfers.*—Crude oil conveyed to fuel-oil stocks without processing, or reclassification of products from one product category to another; *All oils.*—Crude petroleum, natural gas liquids, and their derivatives; *Exports.*—Includes shipments to U.S. territories, possessions, and free trade zones; *Imports.*—Includes receipts from U.S. territories, possessions, and free trade zones.

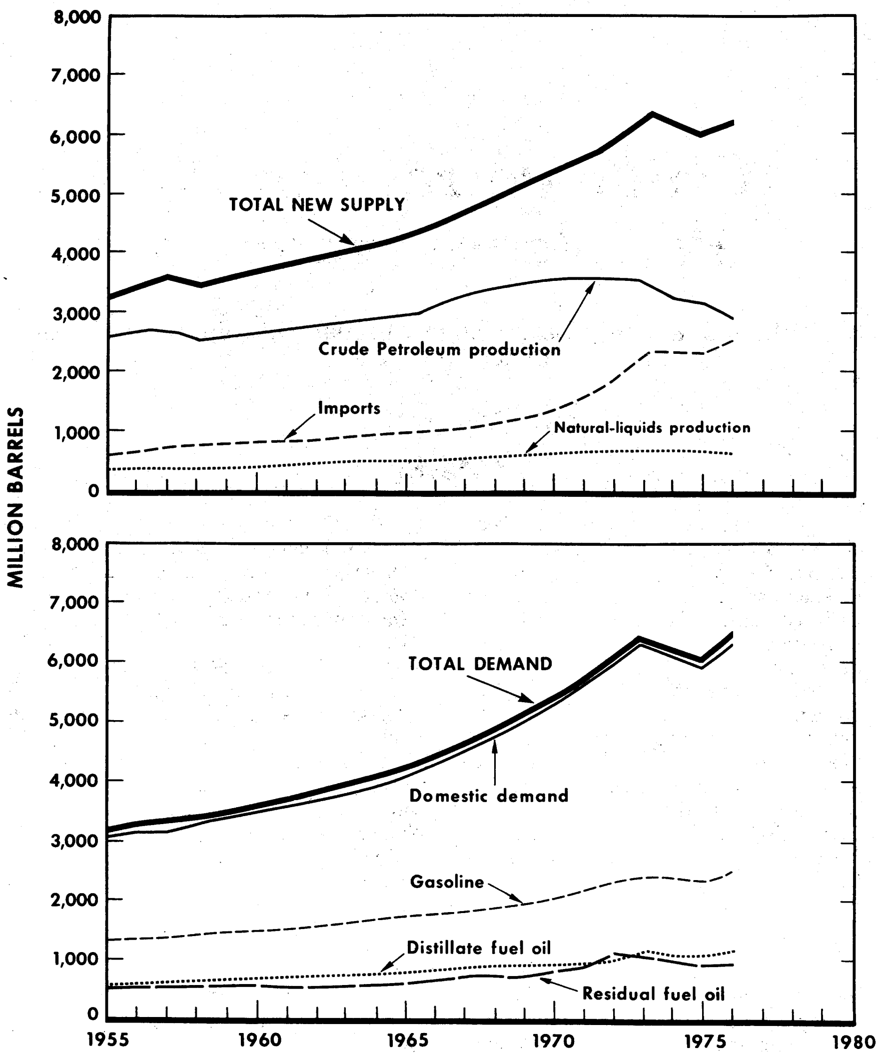

Figure 1.—Supply and demand of all oils in the United States.

New supply consists of domestic production of crude oil, lease condensate, natural gas plant liquids, and imports of crude oil and petroleum products. In 1976, imports supplied 42% of requirements compared with 37% in 1975. Imports of crude oil averaged nearly 5.3 million bpd in 1976, a 28.8% increase over the 4.1 million bpd average in 1975. Imports of products, such as increased receipts of residual fuel oil, more than offset declines in the imports of motor gasoline, jet fuels, and distillate fuel oil with a net result of an overall increase of 3% in 1976.

Refineries processed 4.9 billion barrels of oil in 1976, which is about 1 million bpd greater than in 1975. Foreign crude oil accounted for 39% of refinery input (table 18) compared with 33% in 1975. About 23% of the imported crude oil originated in Saudi Arabia in 1976 compared with 17% in 1975.

Construction of the 800-mile-long Trans-Alaska Pipeline was nearing completion. Oil was scheduled to start moving southward in late June 1977, filling the pipeline at about 300,000 bpd. Regular tanker loadings were expected to begin about mid-August 1977.

Table 1.—Salient statistics of crude petroleum, refined products, and natural gas liquids in the United States

(Thousand 42-gallon barrels unless otherwise indicated)

	1972	1973	1974	1975	1976[p]
Crude petroleum:					
Domestic production (including lease condensate)	3,455,368	3,360,903	3,202,585	3,056,779	2,976,180
World production	18,600,745	20,367,981	20,537,727	19,497,604	21,187,147

Exports	81,389	84,413	80,491	76,428	81,599
Total domestic demand for products (including crude-oil losses)	5,994,957	6,322,200	6,083,028	5,962,414	6,389,403

[p] Preliminary (except for crude production and value).
[1]U.S. Department of Commerce data.
[2]Reported to the Bureau of Mines.
[3]U.S. Department of Commerce, Oil Import Administration and Federal Energy Administration data, except for unfinished oils and plant condensate which are Bureau of Mines data.
[4]Stocks of refined products also include stocks of unfinished oils, natural gasoline, plant condensate and isopentane.

The Federal Government offered 536 tracts of land for lease on the Outer Continental Shelf (OCS), during 1976. Much of it (475 tracts) was in unexplored areas off Alaska, the Atlantic States, and the Gulf of Mexico. One of the OCS sales was a drainage sale (the sale of unleased tracts of land that offset producing tracts) in the Gulf of Mexico. The bids received and the parties bidding on the drainage sale tracts, reflect the continued interest in the Gulf of Mexico as a mature oil and gas producing province, as shown in the following tabulation:

Offshore location	Date	Offered		Leased		Total high-bid accepted million dollars
		Tracts	Acreage	Tracts	Acreage	
Gulf of Mexico	Feb. 18	132	688,063	34	161,286	$175
Gulf of Alaska	Apr. 13	189	1,008,500	81	432,214	572
Atlantic coast	Aug. 17	154	876,722	101	574,993	1,135
Gulf of Mexico	Nov. 16	61	347,274	48	273,364	318
Total		536	2,920,558	264	1,441,757	$2,200

Subsequently, the OCS sale of August 17, 1976 located off the Atlantic coast was declared void by a Federal Judge of the U. S. District Court. The Secretary of the Department of the Interior asked the Justice Department to appeal the decision on rescinding the sale of drilling rights off the Atlantic coast. On April 25, 1977, the appeal was heard by the U.S. Court of Appeals. The Appelate Court reversed the decision, ruling that the Department of the Interior environmental studies fully met all legal requirements.

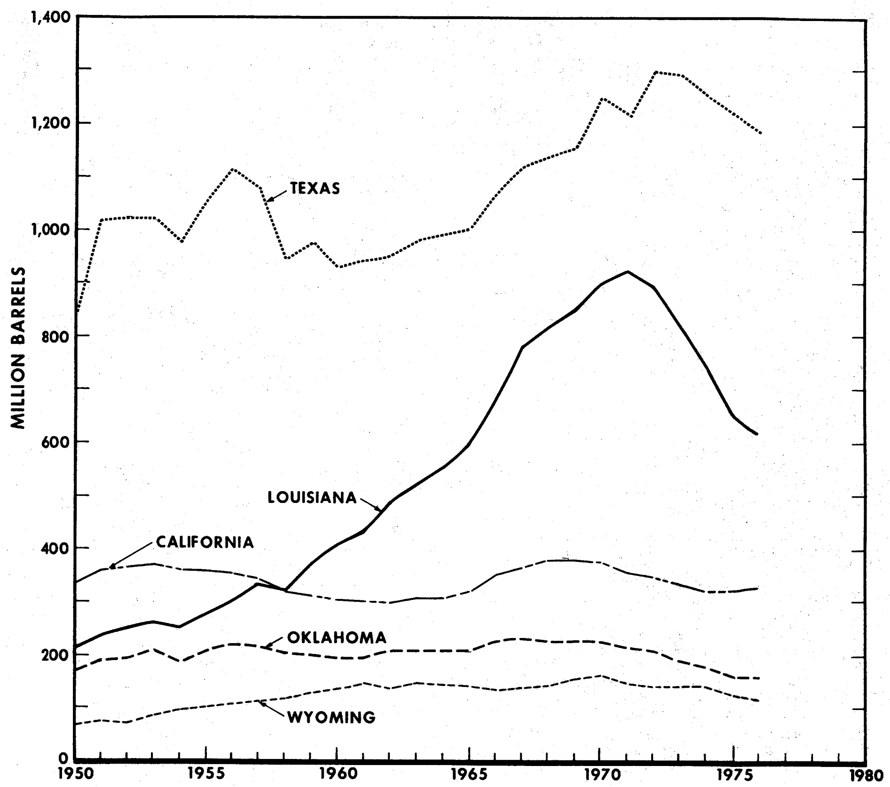

Figure 2.—Production of crude petroleum in the United States, by principal producing States.

CRUDE PETROLEUM

PRODUCTION

In 1976, production of crude oil, including lease condensate, continued the 6-year downtrend that began in 1970, but at a more moderate rate. In 1976, production totaled 2,976.2 million barrels which was 80.6 million barrels or 2.6% below that of 1975. In 1975, however, production was 145.8 million barrels or 4.6% below the 1974 level (table 1).

The largest declines in 1976 occurred in Louisiana, (44.3 million barrels) and Texas, (32.4 million barrels). These two States accounted for 95.2% of the decline, and there were declines of varying degrees in 17 other oil-producing States. Likewise, production increased in 13 oil-producing States, of which the most significant were, in millions of barrels, Michigan, 6.0, California, 3.8, Florida, 2.6, Arkansas, 2.0, North Dakota, 1.3, and Alabama, 1.3. A net increase of 3.8 million barrels in California reflected the opening of Elk Hills Naval Petroleum Reserve (NPR) No. 1 for exploration and development. Production in the East Central area of California, where NPR No. 1 is located, increased 18.4 million barrels in 1976 and more than offset the 14.6 million barrel decrease in other parts of the State. Other changes are shown in table 6.

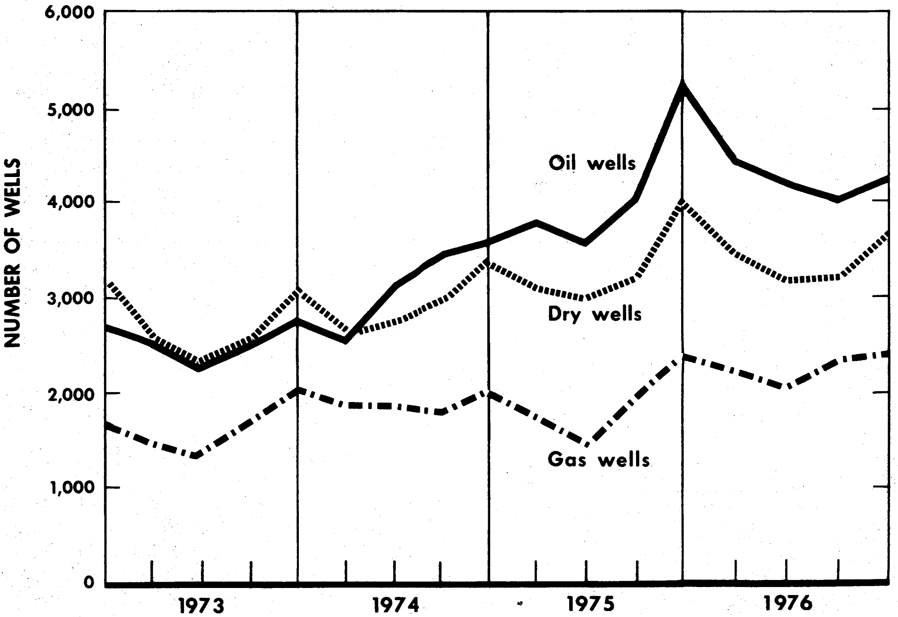

Figure 3.—Wells drilled for oil and natural gas in the United States, by quarter.

DRILLING ACTIVITY

There were 17,059 oil wells and 9,085 gas wells completed during 1976 in the United States, and 13,621 dry holes were drilled (excluding service and stratigraphic well core tests). This compared favorably with activities in 1975 when 16,408 oil wells and 7,580 gas wells were completed and 13,247 dry holes were drilled (table 8).

Total wells drilled relating to oil and gas exploration and production in 1976 were 41,455 totaling 185,344,695 feet. This was 2,358 more wells than the 39,097 wells and 178,505,507 footage drilled in 1975. The Hughes Tool Co. rig count reported a decline in the number of active rigs in operation; 1,808 during 1976 compared with 1,828 in 1975.

In early 1976 the decline in drilling rig activity was greater than the usual seasonal decline. The Federal Government removed crude oil produced from stripper well leases from price controls. A new classification of new oil as the amount of oil produced from the lease less the property's base production control level of oil produced in 1975, encouraged infill drilling. This resulted in the second half of 1976 rig activity rising to an average of 1,916 drilling rigs in operation, compared with the 1,707 average operating in the first half of the year. Infill drilling is development well drilling to expand the rate of production from the reservoir by increasing the number of producing wells. The lease holder must sell that amount of base production control oil at the lower tier price. Any production above the control level may be sold at the upper tier price.

A review of significant petroleum producing States showed that most States had increases in the number of rigs working. Texas, the most active State, averaged 654 rigs working during the year, up by nine units from 1975. Louisiana had an average of 242 rigs working during 1976, an increase of two units.

Other major States with higher activity included California, Mississippi, and Oklahoma. The major States that showed declines in activity were Colorado, Kansas, Michigan, New Mexico, Utah, and Wyoming.

Deep drilling is an indication of interest in a region to confirm hydrocarbon deposits, and stratigraphic test wells are drilled to obtain core samples and to accurately measure the subsurface for the petroleum potential. During 1976 deep drilling regional records were set; in the Texas Panhandle a well was drilled to 24,482 feet, Louisiana interests drilled a dry hole to 24,220 feet, and in Wyoming a well was drilled to 22,431 feet. The first well drilled offshore Massachusetts, the "Cost G-2" was drilled to 16,070 feet as a stratigraphic test. This well indicated the possibility of hydrocarbon generation from source beds that are present and abundant. Reservoir rocks throughout most of the geologic section have low permeability and porosity that range from 30% at the shallower depths to 10% at the deeper depths.

RESERVES

Based on the report of the Committee on Reserves of the American Petroleum Institute (API) proved reserves of crude oil as of December 31, 1976, were estimated at 30.9 billion barrels. Included in the reserve estimates are quantities of all liquids defined as crude oil, which geological and engineering data demonstrate with reasonable certainty to be recoverable under existing economic and operating conditions. Reserves at yearend 1976 were 1.7 billion barrels less than at yearend 1975, and continued the downtrend that began in 1971. Annual estimates by the API showed additions to reserves from new field discoveries, new reservoir discoveries, and extensions of old fields totaled 1.1 billion barrels. Domestic production of 2.8 billion barrels accounted for the 1.7-billion-barrel reduction in proved reserves (table 12).

The net change in proved reserves was positive for Indiana, Michigan, Nebraska, Ohio, Pennsylvania, and Tennessee, accounting for 1% of the proved reserves of 55 million barrels being added. The major producing States, Alaska, Texas, California, Louisiana, and Oklahoma, account for 88% of the United States proved reserves; these five States had a net reduction in proved reserves of 1.6 billion barrels. With this continued decline in proved reserves for the past 7 years, America has become dependent on foreign crude oil and petroleum products to meet the U.S. demand for petroleum and hydrocarbon products. In 1976, about 41% of domestic requirements was supplied from net imports of crude oil and petroleum products from foreign countries.

CRUDE SUPPLY

Total receipts of crude oil at refineries in 1976 were 4,920 million barrels, or 13.4 million bpd, an increase of 1.4 million bpd. Foreign receipts from overseas sources totaled 1.9 billion barrels, or nearly 5.3 million bpd, of which 72% originated from the Middle East and Africa. The Canadian Government continued to phase out its oil exports to the United States, while Mexico supplied the United States with 86,000 bpd in 1976, or 15,000 bpd more than in 1975.

CRUDE OIL CONSUMPTION

Oil refineries processed 4.9 billion barrels (13.4 million bpd), of which 61% was domestic crude oil and lease condensate and 39% originated in foreign countries. Based on operable refinery capacity at yearend 1976, refineries operated at 81% of distillation capacity of 16.4 million barrels per calendar day.

REFINING

Operable refinery capacity in the United States at yearend 1976 amounted to 16.4 million bpd, up 10% from yearend 1975. Refinery output averaged 13.4 million bpd during 1976, with motor gasoline accounting for nearly one-half of the production. Output of refined products from U.S. refineries accounted for only 80% of total demand for refined petroleum products in 1976, with the remainder supplied by imported products. About 50% of the residual fuel oil demand was met from domestic refinery output.

At yearend 1976, 291 petroleum refineries were dispersed across the country, with half of the operating capacity located in three States; California, Louisiana, and Texas. Expansion projects were planned or underway at numerous plants, and the largest refinery to be built in the United States in one phase was under construction at Caryville, La. The first units of that facility were started up during the fourth quarter of 1976, and the remaining construction projects at the 200,000-bpd refinery were scheduled to be completed early in 1977.

The Standard Oil Co. of California, Shell Oil Co., Standard Oil Co. (Indiana), Exxon Corp., and Texaco are the predominant refiners in the United States. Exxon's 510,000-bpd plant at Baton Rouge, La., was the largest in the country, and a 250,000-bpd expansion to Exxon's Baytown, Tex., plant under construction during 1976 and scheduled for completion in 1977, will expand that refinery to 640,000 bpd exceeded only by the Abadan refinery in Iran.

SUPPLY AND DEMAND

Demand for petroleum products in 1976 averaged 17.5 million bpd, a 6.9% increase over the 16.3 million bpd of 1975. The supply needed to meet this demand was derived in 1976 from production of crude oil and lease condensate averaging 8.1 million bpd plus production of natural gas liquids of 1.6 million bpd. This supply was supplemented with crude oil imports of 5.3 million bpd compared with 4.1 million bpd in 1975. Product imports in 1976 averaged 1.9 million bpd, which was about 67,000 bpd higher than 1975. A processing gain of 477,000 bpd filled the supply gap in 1976.

MOTOR GASOLINE

As a result of a moderate recovery in the economy, demand for motor gasoline in 1976 aggregated about 2.6 billion barrels or 7 million bpd, a 4% increase over 1975 (table 23). The Federal Highway Administration (FHA) of the Department of Transportation compiles data on motor gasoline use based on motor fuel tax reports filed with the States. Also, the FHA calculates data for highway and nonhighway use. The estimate of total usage 1976 averaged 7,133,000 bpd, or 4.9% above that of 1975.

Restrictions on motor gasoline by the Federal Energy Administration (FEA) under the Energy Policy and Conservation Act (EPCA) remained in full force and effect in 1976 and carried over into 1977.

Except for one premium gasoline marketed primarily on the east coast and in the south, all motor gasolines contained lead alkyl antiknock compounds until 1970 to increase octane quality. But with the agitation against the use of lead growing in intensity in 1971, automobile manufacturers in the United States began to build engines designed to operate on gasolines of nominal 91 Research Octane Number (RON). Unleaded and lowlead gasolines were introduced to supplement the conventional and well established gasolines such as premium and regular grades.

Since many motor vehicles in the United States, beginning with the 1975 model year, were equipped with catalytic converters, the Environmental Protection Agency (EPA) required most service stations, beginning in July 1974, to offer for sale at least one grade of 91 RON unleaded gasoline.

During 1976, tetraethyl lead was being phased out as the dominant motor gasoline octane booster, because the EPA considers the emissions from engines burning leaded fuels a health hazard. As a substitute for tetraethyl lead as an octane booster, domestic refiners used methylcyclopentadienyl manganese tricarbonly (MMT), produced by the Ethyl Corp., to produce large quantities of unleaded motor gasoline. Meanwhile, the EPA and domestic automobile manufacturers are pursuing investigations into the performance of MMT.

More than three-fourths of the motor gasoline sold in the United States during 1976 contained tetraethyl lead additives, but sales of unleaded fuels continued an upward trend. According to Ethyl Corp., sales of unleaded motor gasoline accounted for 17% of the total motor gasoline sales in January 1976, rose to 20% in June, and further increased to 23% in December.

During the year, the EPA issued regulations amending the schedule for phasing down the lead content in motor gasolines that requires refiners to meet average lead levels of 0.8 gram per gallon on January 1, 1978, and 0.5 gram per gallon on October 1, 1979. The Government revised the schedule in an effort to avoid possible shortages in gasoline supplies in 1977-78, while refiners installed the processing units necessary to produce unleaded fuel.[6]

AVIATION FUELS

Demand for aviation gasoline in 1976 totaled nearly 13.4 million barrels or about 5% less than in 1975 (table 25). From a peak of 38.1 million barrels in 1958, demand for aviation gasoline had shrunk to 13.3 million barrels by yearend 1976. Most of this reduction reflects the transition from the use of piston driven engines to the jet turbine types.

Aviation Gasoline.—Aviation gasoline, one of the most complex fuels produced, is subject to process control under ASTM-Specification D-910. In addition, there are other aviation gasoline specifications such as the U.S. Department of Defense (military specifications) and the British Ministry of Defense (D Eng RD specifications).

Jet Fuels.—The specification for aviation turbine fuels, ASTM D-1655, outlines requirements for three types of fuel: Jet A, a 40°C freeze point kerosine used within the

[6]Oil and Gas Journal. V. 74, No. 40, Oct. 4, 1976, p. 62.

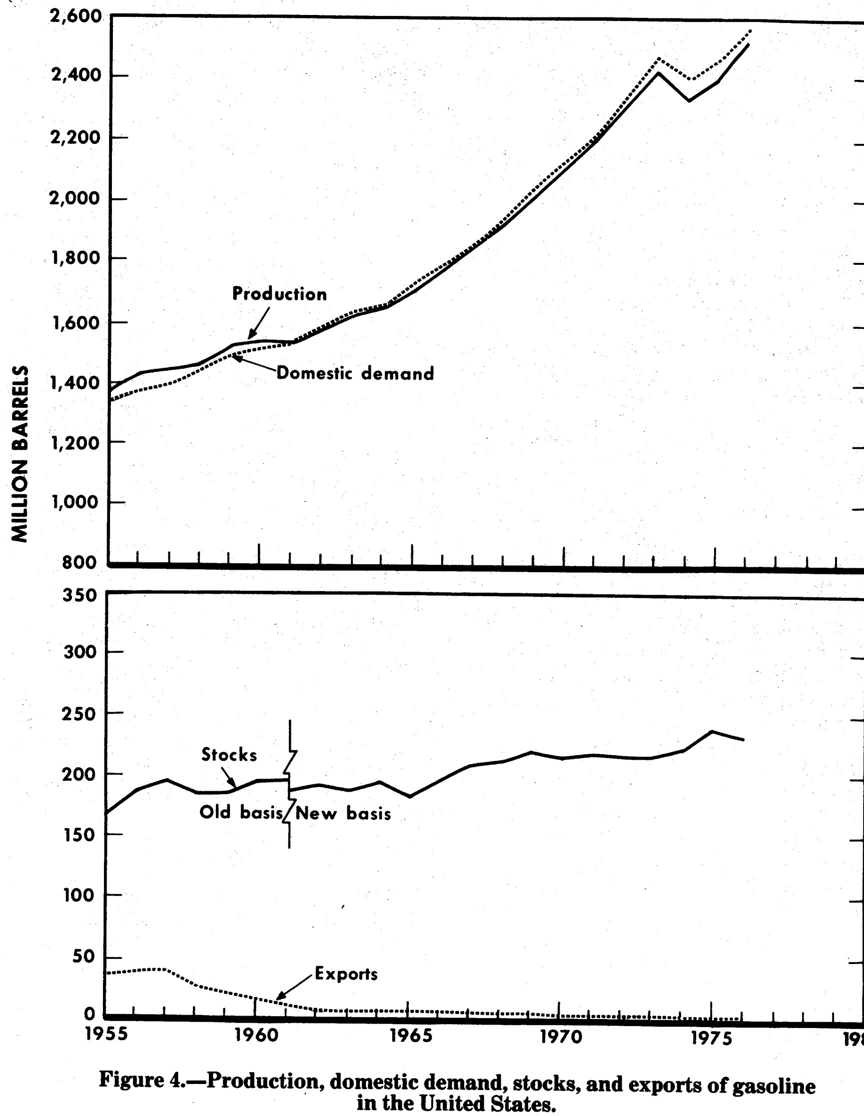

Figure 4.—Production, domestic demand, stocks, and exports of gasoline in the United States.

United States; Jet A-1, a 50° C freeze point kerosine which is the standard grade used for international flights; and Jet B, a widecut gasoline grade which at the present time is only in limited civil use.

Demand for kerosine-type jet fuel in 1976 averaged 789,000 bpd, which was slightly below the 1975 levels. Demand reached a peak of 842,000 bpd in 1973, and the subsequent reduction in fuel use reflects the impact of economies of operation adopted by the airlines. According to the Energy and Fuels Committee of the Air Transport Association (ATA), airlines have reduced the average number of flights by about 900 per day compared with 1973. At the same time, ATA estimated U.S. scheduled airlines in 1976 carried 223 million passengers, a 10.4% increase over the 1973 level. Over the same interval, kerosine-type jet fuel demand was 6.3% below that of 1973, as estimated by the Bureau of Mines.

Still another significant development was the expansion in production by refineries in the United States that resulted in a marked reduction in imports. From a peak of 176,000 bpd in 1973, imports have been in a downtrend. By 1976, imports shrunk to 61,000 bpd or 65.3% below the 176,000 bpd imported in 1973.

Naphtha-type jet fuel is used primarily by the military. In 1976, demand totaled 72.7 million barrels or 5% less than 1975.

Although FEA removed the allocation and price controls on naphtha-type jet fuels, controls on kerosine-type jet fuels and aviation gasoline remained in effect in 1976 and carried over into 1977.

LIQUEFIED GASES, ETHANE, AND ETHYLENE

Liquefied gases are derived from two sources; those produced at refineries are called liquefied refinery gases to distinguish them from liquefied petroleum gases obtained by processing natural gas. The liquefied petroleum gases (LPG) are all paraffins (propane, butane, and isobutane) and the standard specification is ASTM D-1835. The liquefied refinery gases (LRG) also contain paraffins but may also contain unsaturated hydrocarbons; such as the olefins (propylene, butylene, ethylene, etc.). The paraffins may be used as fuel (including as a blend with motor gasoline) or as feedstocks at petrochemical plants; the olefins are used primarily as petrochemical feedstocks.

Demand for ethane (including ethylene) rose 6.3% to 362,600 bpd in 1976 from 341,200 bpd in 1975. Ethane is used primarily to make ethylene, a building block for petrochemicals.

Domestic demand for LPG and LRG in 1976, excluding that blended into other products at refineries or terminals, increased 5.1% and exceeded 1 million bpd compared with 991,500 bpd in 1975. Propane accounted for 79.7% of liquefied gas demand in 1976, but if refinery propane and propylene is deducted from demand, the percentage shrinks to 577,800 bpd or 55.5%.

Propane was in strong demand during the heating season because of the impact of severe winter weather and a moderate recovery in the economy. As a result, with production down and demand up, stocks of plant propane totaled 69.7 million barrels at yearend, which was 8.4% below 1975. In 1976, the decrease in the production of propane and other natural gas liquids reflected the decline in natural gas production.[7]

Demand for plant propane rose 5.7% in 1976 to 830,200 bpd. Production at gas-processing plants in 1976 declined 5.5% and by yearend 1976 there was an 8.4% reduction in stocks to 69.7 million barrels from 76.1 million barrels at the end of 1975.

KEROSINE

The unusually severe weather east of the Mississippi River, particularly, helped lift demand for kerosine in 1976 to 61.9 million barrels, an increase of 169,200 bpd or 6.1%. Most of the increase in supply needs was met by imports and drawdowns on inventories. There was no noticable increase in refinery production of kerosine, but imports tripled and stocks at yearend 1976 were down 19.6% to 12.5 million barrels from the 15.6 million barrels of a year earlier (table 30). Nearly 80% of the domestic demand for kerosine (including range oil) is for space heating.

DISTILLATE FUEL OIL

Specifications for fuel oil are established by the ASTM Committee D-2 on Petroleum Products and Lubricants. The specification designation is ASTM D-396.

An extremely severe winter coupled with a mild recovery in general business resulted in a 9.8% increase in distillate demand in 1976, to 3.13 million bpd from 2.85 million bpd in 1975. Demand for distillate for heating rose about 3% to 1.38 million bpd from 1.34 million bpd in 1975. Severe and prolonged cold weather in the Midwest and on the eastern seaboard as far south as Florida boosted distillate demand sharply as reflected in the rise in the number of degree days. A degree day is defined as a unit of mean temperature representing 1° of difference from a standard temperature of 65°F used in calculating fuel consumption. If the mean temperature was 50°F then the calculation would be 15 degree days (65°-50°=15°).

Distillate oil heating degree days for the period July through December 1976 were 22% above normal and 35% above the level for the same period of 1975. Distillate oil heating degree days by PAD districts for the period July through December 1976 were as follows: PAD district I, 2,223.3 or 22% above

[7]Data are available for 1976 in the following Bureau of Mines Mineral Industry Surveys: Natural gas, Monthly; Natural gas Liquids, Monthly; and Petroleum Statement, Monthly; and also in the Bureau of Mines Minerals Yearbook 1976 Chapter on Natural Gas Liquids.

normal; PAD district II, 3,142.9 or 25% above normal; PAD district III 1,384.3 or 49% above normal; PAD district IV, 2,608.2 or 2% below normal; and PAD district V, 1,437.5 or 15% below normal.

RESIDUAL FUEL OIL

Reflecting needs accompanying a severe winter and a quickening in business activity, demand for residual fuel oil rose 13.5% in 1976 to 2.79 million bpd from 2.46 million bpd in 1975. The winter was the coldest in years. Most of the excess in degree days occurred in the final quarter of 1976 and in January 1977.

The use of residual fuel oil by utilities rose sharply in 1976 as the cold weather stimulated electric usage for heating. Increased demand for residual fuel oil also resulted from the movement of electricity generated from oil to normal coal generating areas with coal delivery problems. The shortage of hydropower is another contributing factor to increasing the demand for heavy fuel oil such as No. 5 and No. 6.

Domestic production of residual fuel oil increased 11.4% in 1976 to 1.38 million bpd from 1.24 million bpd in 1975. From a 30-year low of 706,000 bpd in 1970, production has been increasing steadily, and in 1976 established a new high. Nearly one-half of the 1976 production or 676,000 bpd was residual fuel oil of 1% or less sulfur content. In 1971, only 39% of production was 1% or less.

Imports in 1976 averaged 1.4 million bpd, a 14.3% increase over 1975. Some 658,000 bpd or 48.6% of imports were received into the States of Delaware, Maryland, New Jersey, Pennsylvania, and New York. About 472,000 bpd of imports had a sulfur content ranging from 0 to one-half (0.50%), and 262,000 bpd were destined for New York.

Although production and imports were up 13.2%, an increase in demand resulted in a moderate reduction in stocks to 72.3 million barrels by the end of 1976 compared with 74.1 million barrels at yearend 1975.

OTHER PRODUCTS

Petrochemical Feedstocks.—Some 164.4 million barrels of petrochemical feedstocks were produced by refineries in 1976, a 34.6% increase over the 1975 levels. Likewise, demand in 1976 rose 30.9% to 152.9 million barrels or 417,639 bpd. Naphtha-400° (less than 400° end point) accounted for 48% of demand, other feedstocks accounted for 40.6%, and still gas used for chemical or rubber manufacture, accounted for 11.4%.

Special Naphthas.—Special naphthas includes all finished products within the gasoline range that are specially refined to a specified flash point and boiling range for use as paint thinners, cleaners, and solvents. The special naphtha category also includes commercial hexane conforming with ASTM specification D-1836 and cleaning solvent conforming to ASTM specification D-484. Benezene, toluene, and xylene are considered in the special naphtha classification when they are blended into special naphtha stocks. Production in 1976 increased 19% to 89,200 bpd compared with 74,900 bpd in 1975. Exports in 1976 were double those of 1975, and domestic demand increased 9.5% in 1976.

Lubricants.—Demand for lubricants, after declining sharply in 1974-75, arrested the downtrend and increased 10.8% in 1976 to 152,273 bpd from 137,450 bpd in 1975. Exports in 1976 increased 4.2%. The 1976 production of 61.8 million barrels is 8.9 million barrels below 1974 (table 36).

There are 43 refineries in the United States with a finished lubricant manufacturing capacity of 226,900 bpd, according to a survey made by the National Petroleum Refiners Association. If the 168,861 bpd of production is equated against indicated capacity of 226,900 bpd, lubricant manufacturing facilities operated at 74.4% of capacity in 1976.

Waxes.—As a result of the pickup in economic activity, demand for waxes in 1976 increased 18.7% to 7.2 million barrels (19,700 bpd) from 6.1 million barrels (16,600 bpd) in 1975. There are 24 refineries in the United States with a finished wax capacity of 13,153 barrels per calendar day. In addition, these refineries and eight others have unfinished wax capacity of 12,089 bpd. During 1976, production of wax increased 23.7% to 7.0 million barrels of which fully-refined crystalline wax accounted for 45%; other crystalline accounted for 42%, and microcrystalline waxes accounted for 13%.

Wax is primarily a byproduct of lubricating oil manufacturing or at least of wax bearing crudes. Wax is found in varying amounts in crude oils. Paraffin base crudes and mixed base crudes, for example, contain both paraffins and naphthenes, they usually have a greater wax content than aromatic base crudes, and the type of wax recovered depends on the type of crude being refined. To improve the low-temperature pour point property of lubricating oils, the lubricant fraction of the crude is dewaxed and the byproduct from dewaxing is refined to obtain a finished wax. There are three broad classes of waxes: microcrystalline, fully-refined crystalline, and other crystalline (table 37).

Microcrystalline waxes are derived from the high-boiling lubricating oil fractions, and the other types are obtained from the intermediate boiling range lubricating oil fractions. Also, oil content is another characteristic. Fully-refined crystalline wax has an oil content of less than 0.5%. Microcrystalline waxes, because of their smaller crystal structure, have a greater affinity for oil than the crystalline type, and they are used extensively where there is a demand for tacky or ductile waxes such as for treating impregnating, coating, and filling electrical apparatus; and as a telephone cable filing compound.

Packaging provides the largest market for the crystalline waxes; important applications are hot melt coatings for frozen food overwraps, pouches, bags and envelopes; for coatings and impregnants for corrugated containers and folding cartons; and as coatings for paper cups. Nonpackaging uses are: Candles; crayons; floor, furniture, shoe, and automobile polishes; and cosmetics, pharmaceuticals, printing inks, explosives, carbon paper, and adhesives.

Petroleum Coke.—Petroleum coke is reported by the Bureau of Mines as catalyst coke and marketable coke. Catalyst coke is a noncommercial coke; it cannot be recovered commercially because it forms on the catalyst during the catalytic cracking of the charging stock in a refinery cracking unit. This carbon is burned off the catalyst in the regenerator section of a cracking unit, and the coke is used as a refinery fuel without ever being seen. However, production of catalyst coke is shown to complete a supply and demand balance for coke.

Production of both catalyst coke and marketable petroleum coke aggregated 130,145,000 barrels in 1976 or 1% above the 1975 volumes. About 52% of output was marketable coke and production in 1976 was 2% above 1975. Exports in 1976 were only nominally higher than in 1975 (table 38).

Only about one-third of exports is calcined coke and five countries, West Germany, Japan, the Netherlands, Norway, and Canada, accounted for 47% of the 12 million plus barrels exported. In the raw or green coke category, 25 million barrels were exported to foreign countries, and Japan and the Netherlands purchased more than half. There are three main outlets for marketable petroleum cokes; the domestic demand for raw coke as fuel, for calcined coke for the manufacture of carbon products such as electrodes and anodes, both baked and gravitized; for aluminum metallurgy, for brushes for electric motors and generators; and for specialties such as rings, seals and bearings, electronic, nuclear, and missile and jet propulsion parts. Coke can be gravitized by subjecting it to very high temperatures, and some refiners have developed premium automotive lubricating oils containing graphite made from petroleum coke. In 1976, total demand for marketable petroleum coke was 64,632,000 barrels. Of this, exports totaled 37,778,000 barrels and domestic demand accounted for the remaining 26,854,000 barrels. These data exclude 62,237,000 barrels of catalyst coke.

Asphalt and Road Oil.—A tapering off in the nationwide highway construction program, and a tightening in highway maintenance budgets of States, municipalities, and other political subdivisions affected demand adversely for asphalt and asphaltic products between 1973 and 1976. However, the decline curve appears to be flattening out; overall sales in 1976 of petroleum asphalt for consumption was less than 1% below the 1975 level, whereas in 1975 sales were 11.4% below the volumes sold in 1974.

Sales of asphalt paving products in 1976 were 21.5 million short tons or only about 118,000 short tons below 1975. Petroleum asphalt roofing product sales of 4,792,000 short tons in 1976 were a nominal 11,177 short tons less than in 1975. Likewise in 1976, similar small declines of 65,820 short tons occurred in sales of other products such as asphalts and fluxes.

Production of asphalt declined 3% in 1976 to 25.4 million short tons from 26.2 million in 1975, but with imports lower and demand down only about 1% it was necessary to drawdown on inventories. As a result, stocks at yearend 1976 were 3.5 million short tons or 15.0% below the 1975 yearend levels.

Road oil is a liquid asphalt of the slow-curing type and is classified by the ASTM as D-2026. Road oils may be derived from a blend of asphalt and oil which remain in a fractionator after the lighter ends such as naphtha, gasoline, kerosine, etc., are drawn off after straightrun distillation. Road oils, may be obtained, also, by blending asphalt cement with an oily fraction. In addition, there are two other types of liquid asphalt materials known as "cutback asphalts." The rapid-curing type (ASTM D-2028) is blended with naphtha and gasoline. The medium-curing type (ASTM D-2027) is blended with a lower vapor pressure material such as kerosine.

Still Gas.—Still gas is a mixture of extremely low-temperature boiling hydrocarbons produced during the distillation of crude oil and may be used as refinery fuel and/or as a petrochemical feedstock. During 1976, there were 180.7 million barrels used as fuel, a 3% increase from the 175.4 million barrels consumed in 1975. Consumption of still gas, used as a petrochemical feedstock, increased 11% in 1976 to 17.4 million barrels from 15.7 million barrels in 1975.

Miscellaneous Finished Oils.—The petroleum industry produces a variety of miscellaneous products that are sold directly to consumers or in bulk to specialty companies that package and distribute them under various trade names. Included in this category would be absorption oils, specialty oils such as hydraulic, insulating and medicinal oils, rust preventives, sand-frac, spray oils, and others. Also, synthetic natural gas (SNG) feedstock is included in this grouping. Production of miscellaneous finished oils in 1976 was about 47.2 million barrels, 46.5% over the 32.2 million barrels produced in 1975. Production of absorption oils decreased 8.3%, but the production of "other products" which includes SNG feedstocks, more than doubled from 11.1 million in 1975 to 25.4 million in 1976.[8]

Unfinished Oils.—Unfinished oils are oils that have been partly refined and will be further processed by refiners. Examples are: Naphtha, a light unfinished oil that is consumed primarily in the refinery itself to produce gasoline. About 90% of all naphtha use is in gasoline. Smaller amounts are used in the production of aromatics such as benzene, toluene, and xylenes. Also, small amounts are used in the production of specialty products such as hexane and special naphthas such as cleaners' solvents. In addition, small amounts are used as petrochemicals and synthetic gas feedstock. Gas oil, an unfinished oil, is heavier than naphtha and its major use is in the refinery to make middle distillate fuels (No. 294) and in the production of commercial jet fuel. Also small amounts are used in the production of lubricants and process oils. Aromatic gas oil, another unfinished oil, is a heavy residual oil derived from catalytic cracking of heavier oils for naphtha production. Its principal use is as carbon black feedstock. The rerun (net of unfinished oils) represents the receipts of domestic or foreign oil plus or minus changes in stocks (table 18).

TRANSPORTATION AND DISTRIBUTION

INTERDISTRICT MOVEMENTS

A vast transportation system consisting of pipelines, tankers, and barges and to a lesser degree, tank cars and tank trucks, move crude oil to refineries for processing into petroleum products. During 1976, refineries received 62.7% of their crude oil requirements by means of pipelines. Water transport, both tanker and barge, accounted for 35.7% and tank cars and trucks accounted for the remaining 1.6% (table 43).

Data collected on receipts of domestic and foreign crude petroleum at refineries in the United States show receipts from local production (intrastate), receipts from other States (interstate), and receipts of imported crude. These data, by method of transportation, indicate the final receipts by water, pipeline, tank car, and truck. Receipts of domestic crude by water usually are moved by pipeline from the point of production to the point of water shipment.

Refinery receipts of crude oil carried by tankers and barges totaled 1,758 million barrels or 4.8 million bpd in 1976. Some 84.6% of receipts by water was of foreign origin in 1976; in 1975 receipts were 78.3%. In 1972, foreign receipts accounted for 51.9%. A 5-year series of recipts is shown in table 43, and interdistrict movements by tanker and barge is provided in tables 44-45.

Domestic demand for petroleum products averaged 17.5 million bpd in 1976, a 6.9% increase over the 16.3 million bpd used in 1975. Demand in 1976 is broken down into PAD districts in table 14, and the 17 States comprising PAD district I accounted for 36.9% of domestic product demand. Foreign crude oil accounted for 89% of refinery output in district I. Of the remaining 11%, some 65,000 bpd were received primarily from district III (table 44).

[8]U.S. Bureau of Mines. Crude Petroleum, Petroleum Products, and Natural Gas Liquids, Mineral Industry Survey, April 1977, released September 1977, p.27.

There was a 47.7% increase in 1976 in the volume of foreign crude run by gulf coast refineries in district III. As a result, the volume of domestic crude run shrank to 69.2% from the 77.5% run in 1975 (table 20). However, gulf coast refineries continued to dominate, accounting for 42.6% of crude oil input to refineries in the entire United States.

A large part of refined product output by district III refineries is transported to other PAD districts and the interdistrict movement by tanker and barge of crude oil and major products, such as gasoline, jet fuel, distillate fuel oil, residual fuel oil, and other products such as lubricating oil, wax, and asphalt is shown in table 45. The magnitude of the tanker and barge movements of petroleum products from the gulf coast to the east coast in 1976 is indicated in table 45. The transportation of gasoline, jet fuels, kerosine, distillate fuel oil and natural gas liquids by pipelines between PAD districts is shown in table 46. During 1976, 1.6 million bpd or 69% of the motor gasoline output of refineries in district III was shipped to district I compared with 1.5 million bpd or 66% in 1975. Likewise, about two thirds of distillate fuel oil output in district III was used in district I in 1976.

Refined products produced at refineries in PAD district V in 1976 represented 88% of the domestic product demand for that district. Domestic crude oil, produced primarily in California, supplied 50% of refinery input and of the 50% of oil imported, 43% originated in Indonesia and 36% came from the Middle East, one-half of which came from Saudi Arabia. Canada, formerly an important supplier of crude oil for refineries in the Puget Sound area of Washington State, continues to phase out crude oil exports to the United States, as a result of actions taken by the Canadian National Energy Board (CNEB) in 1973. Imports of crude oil from Canada into district V in 1976 averaged 87,000 bpd compared with 163,000 bpd in 1975.

Under the original CNEB formula, crude oil exports to the United States would have been phased out by the end of 1981. But with the Sarnia-Montreal pipeline becoming operational Canadian crude oil exports to the United States except for heavy oil, will phase out by the late seventies. The Federal Government has indicated that for the next 5 years heavy oil production in excess of Canada's needs will be licensed for export.

The Canadian crude oil export phase out is having a drastic impact on "Northern Tier" refineries (those located in Washington, Montana, North Dakota, and Minnesota). This is discussed in another section of this chapter.

It is anticipated that the west coast will be unable to use all the oil available in PAD district V. This is understandable because Alaskan North Slope (ANS) oil is expected to be moving south through the Trans-Alaska pipeline to Valdez for tanker transport and become available for PAD district V by mid-1977. The pipeline is 800 miles long. Oil flow was at a rate of about 1.1 miles per hour so that the pipeline will be filled slowly at a rate of about 300,000 bpd. Providing there are no major complications, oil will arrive at the Valdez terminal by about the end of July 1977. Also, as a result of extensive drilling and development beginning in mid-1976, oil production from the naval petroleum reserve (NPR No. I), at Elk Hills, Calif., now exceeds 1 million barrels per month, and another source for oil over the longer term is the offshore fields in the Santa Barbara Channel. Both industry and Government estimates indicate that west coast refineries will be unable to absorb ANS production; therefore a sizeable surplus could develop by 1978, providing that Alaskan crude is not priced in such manner as to result in a shut-in of California production.

Although PAD district V could be a surplus area, there are crude oil deficient areas east of the Rocky Mountains in the Northern Tier States, the Midwest, midcontinent, and the gulf coast.

Two pipelines have been proposed to overcome these deficiencies. The first is the Long Beach to Midland, Tex., pipeline proposed by Sohio. Transportation Co. (Sohio). This line would run from a tanker unloading facility in the Port of Long Beach, Calif., across Southern California, Arizona, and New Mexico to Midland, Tex., and it would require about 250 miles of new pipeline and the conversion of a natural gas pipeline in California. In addition, about 670 miles of existing natural gas pipeline, owned by the El Paso Natural Gas Co. (EPNG), would be leased to Sohio and converted to transport crude oil eastward to Midland, Tex. From the Midland area, an extensive crude oil distribution system running north, east, and south is already in place aggregating a capacity of some 2 million bpd. Work on the Sohio project awaits the approval of the State of California.

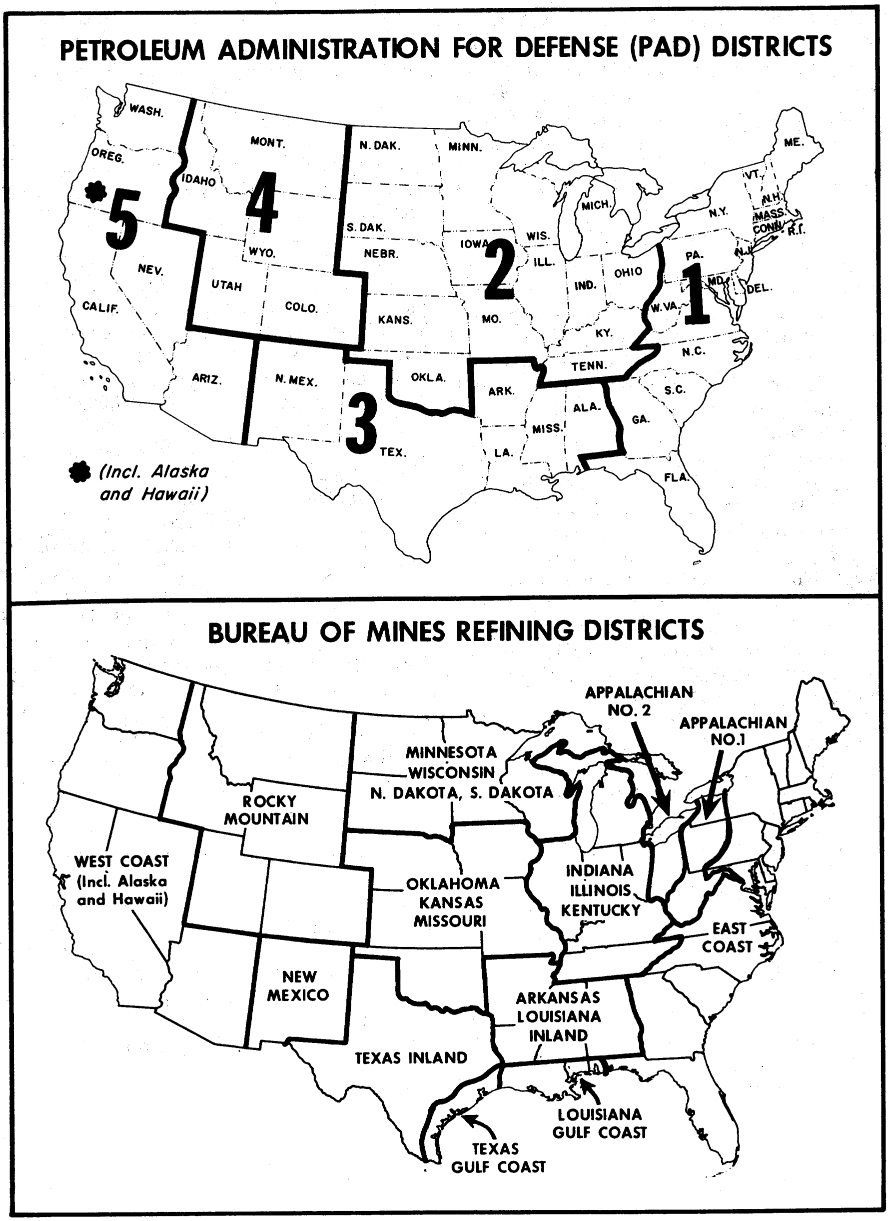

Figure 5.—Maps of Petroleum Administration for Defense (PAD) districts and Bureau of Mines refining districts.

Concern over the potential decrease in air quality in the Los Angeles, Calif., basin is the largest stumbling block to granting the permits needed to start work on this project.

The Northern Tier pipeline proposal would transport Alaskan oil by means of a 1,570-mile line from Port Angeles, Wash., to Clearbrook, Minn. The pipeline route from Port Angeles would skirt the Olympic National Park and pass through the Coeur d' Alene area of Idaho. In Montana, the route would run southeast to the Helena area, eastward into North Dakota, and on to Clearbrook, Minn. The proposed route has been selected for environmental acceptability. Also, more than one-fourth of the route would be over railroad rights-of-way.

Refineries in the six States which make up the Northern Tier have a crude oil throughput of about 840,000 bpd. Throughput of Washington refineries account for 285,000 bpd, and more than 200,000 bpd is foreign oil other than Canadian. Only about 60,000 bpd is imported to Washington refineries from Canada. Canadian oil imported in the other five States averaged about 280,000 bpd in 1976, and Minnesota accounted for one-half of that volume.

PIPELINES

Crude oil pipelines delivered 3,086 million barrels or 8,431,000 bpd to refineries in 1976, a slight increase from the 8,384,000 bpd in 1975 (table 43). Petroleum product pipelines delivered 3,662.1 million barrels, or an average of 10,005,737 bpd in 1976, compared with 3,272.2 million barrels, or 8,965,000 bpd in 1975. Transportation by pipeline of petroleum products between PAD districts is shown in table 46. Transportation and stocks in lines and working tanks is available in table 47; tariff rates are shown in table 48.

Pipeline Costs.—The Trans-Alaska pipeline was a major contributor to rising pipeline construction costs. Reasons for higher cost can be traced to new stronger stress-level codes requiring stronger pipe to meet more demanding specifications. The more expensive grades of steel and inspection cost are borne by the contractor and the company. Other items such as pumping units, both motor- and engine-driven power units, increased in cost during 1976. Actual construction and major cost items were up in 1976. The increase of the past 2 years, 1974 through 1975 was 22.9%, but between 1975 and 1976, the increase was only 5% according to the construction cost index of the Interstate Commerce Commission.

RAIL, TANK TRUCK, BARGE, AND TANKERS

The annual study of the Association of Oil Pipelines estimated that the total tonnage of crude oil and petroleum products carried was 1,831 million short tons in 1975. Of this, 48.02% was transported by pipelines, 22.06% by water carriers, 28.42% by motor carriers, and 1.5% by railroads. The overall volumes transported in 1975 were about 1% below that of 1974. Petroleum products accounted for two-thirds of the volume transported in 1975.

Product pipelines transport only the light products such as gasoline, light fuel oils, heating oils, LPG, kerosine, and jet fuel. These lines transported 424.7 million short tons or 34.8% of the total. Motor carriers transported some 444.4 million short tons or 36.4% of the petroleum products carried. In terms of billions of ton miles, the total aggregated was 846.7 billion, of which 59.9% was transported by pipelines, 35% by water carriers, 3.26% by motor carriers, and 1.66% by railroads. Total crude petroleum carried in domestic transportation, in billions of ton miles was 331.5 in 1975; pipelines accounted for 86.9% and water carriers accounted for 12.2%.

Deepwater Ports.—A tanker voyage from the Middle East to the U.S. east coast involves a 24,000-mile round trip, and many tankers in use today are very large crude carriers (VLCC's), and virtually all of these ships are unable to enter ports with depths under 75 feet. At present, there are no U.S. ports capable of accommodating VLCC's with capacities greater than 200,000 deadweight tons (dwt). The deepest ports in the United States are on the west coast and they can handle tankers up to 150,000 dwt. Most harbors in the United States are limited to ships with capacities ranging from 40,000 to 70,000 dwt.

The Deepwater Port Act of 1974, signed by the President in January 1975, provided for licensing and regulation of deepwater ports. The Secretary of Transportation is empowered to grant licenses for ownership, construction, and operation of deepwater-port facilities. At the same time, a Governor of an adjacent State could veto the project.

Two corporations, formed by groups of companies, proposed to construct two such ports: One 31 miles off the Louisiana coast at Grand Isle in water over 100 feet deep in the Gulf of Mexico, and the other off the Texas coast. In the Louisiana Offshore Oil Port (LOOP), the corporation proposes to store imported oil in the Clovelly salt dome near Galliano, La. The proposed storage capacity of this facility is expected to be about 56 million barrels of oil. The second deepwater terminal (Seadock) is to be constructed off the upper Texas gulf coast south of Freeport. The storage facilities for Seadock would be located 5 miles inland and would consist of 28 tanks with a storage capacity of 22.5 million barrels.

Oil off-loaded at such terminals would be transported by pipeline to shore thereby reducing the need to transfer oil cargoes from VLCC's to smaller vessels for transport to conventional terminals or refineries.

Both applications are being considered by the Department of Transportation (DOT), the agency authorized to issue licenses to build and operate deepwater terminals. If the permits are granted by mid-1977, the two terminals were expected to be online by 1980. Unlike LOOP, however, Seadock has run into difficulties. Four large participating oil companies have withdrawn from this project as the license provisions involving proposals by DOT, the antitrust division of the Department of Justice, and the Federal Trade Commission are considered to be too stringent and too restrictive.

Meanwhile, the Texas Legislature has enacted superport legislation that would enable the State of Texas to establish a terminal for large tankers off the Texas coast in the event the remaining Seadock project participants decide against obtaining a license. Under the bill, the State would finance the deepwater port by issuance of revenue bonds.

In addition to these offshore deepwater ports, the Port of Corpus Christi expects to bring into being the first onshore supertanker facility to the Gulf of Mexico. The U.S. Army Corps of Engineers is now completing work on an environmental impact study of the proposed facility.

TANKER RATES

Tanker charter rates, after reaching a peak late in 1973, have been in a downtrend. From $2.02 per barrel, charters in December 1973 for 34° crude oil for Large Range 2 tankers (from 80,000 to 159,999 dwt) by November 1975 dropped to $1.26 per barrel, for cargoes destined from Ras Tanura to New York by way of the Cape of Good Hope, rates firmed up during the severe 1975-76 winter, but at the end of 1976 the rate per barrel had declined to $1.18. Charters, same destination, for vessels of 16,000 to 24,999 dwt, which are classified as "general purpose" tankers, dropped over the same interval from $3.23 per barrel to $2.90 per barrel. By the end of 1976, the rate for the smaller tankers, however, had rebounded to $3.12 per barrel.

An oversaturation in tanker supply, particularly the larger tankers, has weakened tanker rates.

STOCKS

Stocks of crude oil, natural gas liquids and refined products have been expanding after reaching a low point of 866.9 million barrels in February 1973. Crude oil stocks, which were 242.5 million barrels at yearend 1973, had climbed to 285.5 million by yearend 1976, a 43-million-barrel or 17.7% difference. Stocks of refined products reflect the impact from the lack of natural gas and the substitution of fuel oils and liquefied petroleum gases for fuels. As a result, stocks at yearend 1976 were well below a year earlier (table 49).

As a result of very heavy drawdown of petroleum products such as distillate fuel oil and residual fuel oil, stocks of products at yearend 1976 were 707.7 million barrels, 40.1 million barrels or 5.4% below the December 1975 levels. However, stocks of crude oil and lease condensate at yearend 1976 were 285.5 million barrels or 5.2% higher than at yearend 1975 (table 50). Thus, continuing the growth from the 7-year low point of 235.4 million barrels at the end of February 1973.

STRATEGIC PETROLEUM RESERVES AND STORAGE SITES

The Strategic Petroleum Reserve plan has been setup to reduce the impact of an interruption of imports, if one occurs, such as the Arab Oil Embargo of 1973-74. Congress enacted legislation to establish a Stragegic Petroleum Reserve (SPR) in Title I, Part B of the Energy Policy and Conservation Act of 1975 (EPCA), Public Law 94-163.

Strategic Storage.—Under the initial phase of the SPR, referred to as the Early Storage Reserve (ESR), 150 million barrels of oil are to be stored by 1978, and storage will start initially at 40,000 to 50,000 bpd. Of the different storage sites picked, the one's to be used for the ESR are; Bryan Mound in Brazoria County, Tex.; West Hackberry in Cameron Parish, La.; and Bayou Choctaw in Iberville Parish, La.

Under the EPCA, the FEA is directed to pick eight sites for the SPR program. With the three sites previously listed, the other five sites are Cote Blanche Island mine, St. Mary's Parish, La.; Weeks Island mine, Iberia Parish, La.; Kleer salt mine, Van Zandt County, Tex.; Central Rock mine, Fayette County, Ky.; and Ironton mine, Lawrence County, Ohio.

The storage facilities sought are existing solution-mined salt dome cavities because of the relative low cost of bulk storage for petroleum and the extreme geological stability of the rock salt masses.

FEA had asked for a 500-million-barrel storage plan, but the President suggested that the reserve storage capacity be doubled to 1 billion barrels.

PRICES

Crude Oil.—The actual domestic average price of crude oil in the United States rose from $7.87 per barrel in February 1976, to $8.62 or a 9.5% increase according to the FEA. Prior to February 1976, the domestic crude petroleum wellhead price represented an estimate of the average of posted prices. After February 1976, however, the wellhead price represents an average of first-sale prices.

The average value of domestic crude oil at the wellhead, which was $3.39 per barrel in 1971-72, increased to $3.89 in 1973, $6.74 in 1974, $7.56 in 1975, and $8.18 in 1976. These increases, which began in 1973, were the result of an effort by the Cost of Living Council (CLC) to stimulate domestic crude oil production. On August 17, 1973, the CLC enacted a two-tier pricing system under phase 4 oil regulation. The system released from ceiling prices "new oil" (oil produced above 1972 levels) and made an adjustment for the remainder of current production. The price of new oil produced, which had not been covered by the price ceiling, rose steadily to market levels. The ceiling price for domestic crude was about $1 per barrel below the world price at the time phase 4 rules were issued on August 17, 1973. Since then, however, world prices have increased sharply and so have prices for upper tier domestic oil.

The price-regulating function of CLC was absorbed by the FEA in 1974. Between January and December 1974, the price per barrel rose 13% from $9.82 to $11.08. The price of old, or controlled, oil rose nearly 35% from $3.90 per barrel in August 1973 to $5.03 (revised) in December. Subsequently, the FEA revised its calculations and the price of old oil was reduced from $5.25 per barrel to $5.03 per barrel. The following tabulations show prices per barrel at the wellhead for old and new crude petroleum for the last month of each quarter in 1975. April 1977 prices are shown to illustrate the impact of EPCA after January 1976. Domestic crude petroleum prices per barrel have climbed from a 1975 average price of $7.67 to a 1976 average price of $8.14 or 6%.

	Old	New	Domestic average
1974:			
Average	5.03	10.13	6.87
1975:			
March	5.03	11.47	7.57
June	5.03	11.73	7.49
September	5.04	12.46	7.75
December	5.03	12.95	7.93
Average	5.03	12.03	7.67

	Lower tier	Upper tier	Stripper	Domestic average
1976:				
March	5.07	11.39	--	7.79
June	5.15	11.60	--	7.99
September	5.17	11.65	13.21	8.39
December	5.17	11.64	13.30	8.62
Average	5.13	11.69	13.29	8.18
1977:				
January	5.17	11.44	13.27	8.50
April	5.15	10.97	13.28	8.40

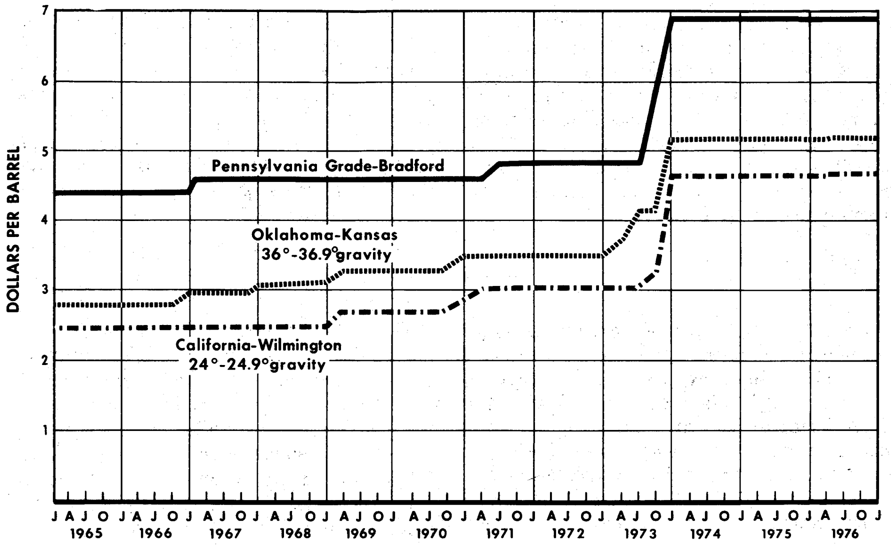

Figure 6.—Posted prices of selected grades of crude petroleum.

The FEA revised the designations used in pricing. The "old oil" title changed to "lower tier" and stripper well produced oil was released from price controls. "Upper tier" refers to the same oil as the former designation "new oil."

Crude oil imports supplied about 30% of crude oil requirements in 1976, and with prices climbing the refiners acquisition costs have followed suit. This cost to the refiner is the average of domestic and imported crude costs and represents the amount of crude cost which the FEA permits refiners to pass on to their customers.

A composite of refiner's acquisition costs of imported and domestic crude was $3.85 per barrel in May 1973, had climbed by December 1976 to $11.32 per barrel, nearly a threefold increase. The rise was due primarily to the increase in the cost of imported oil. The refiner's acquisition cost for imported oil rose from $3.92 per barrel in May 1973 to $13.71 per barrel by December 1976. That trend continues upward as evidenced in the tabulation for refiner's acquisition costs.

The following tabulation shows refiner's acquisition cost per barrel for imported oil, domestic oil, and a composite of both as maintained by FEA:

	Domestic	Imported	Composite
1974:

Entitlements.—Subsequent to adoption of the two-tier pricing system, in November 1974 FEA initiated the entitlements system under the Old Oil Allocation Program (CFR 211.67). Every refiner had to have an entitlement to process a barrel of old crude oil as a percentage of total crude processed (that is, the total runs to stills) of old oil, imported oil, and domestic exempted oil. The price of an entitlement fixed by FEA, is defined as the exact differential as reported for the month between the weighted average delivered cost per barrel to refiners of both imported crude oil and stripper crude oil, and the weighted average delivered cost per barrel to refiners of old oil, less 21 cents. Each month, FEA calculated the amount of old oil produced as a percentage of total crude oil processed. If, for example, the old oil ratio was 40% and a refiner's old oil ratio was 60%, this refiner would have to buy entitlements equal to 20% at prices set by FEA from those refiners with less than 40%. An entitlement purchased at $5.00 would entitle the purchaser to process 1 barrel of old oil at about $5.03 per barrel, so that the effective cost would be about $10.03 per barrel for the 20% over the old oil ratio.

The Energy Policy and Conservation Act (EPCA) amended the Emergency Petroleum Allocation Act of 1973 (EPAA) by adding a new section that setforth a "new" crude oil pricing policy, which required the President to adopt implementary regulations designed to result in the maximum weighted average first-sale price during the month of February 1976 of $7.66 per barrel, as stipulated in the EPCA. In subsequent months, the EPCA permitted adjustments in the first-sale price of domestic crude to take into account the impact of inflation and as a production incentive. For example, if current production from a property exceeds 1972 base production control levels (BPCL) for the property, the excess production qualifies under the new regulations as upper tier crude oil. In 1976, however, the FEA clamped ceilings on crude prices and the freeze continued into 1977. The impact of this freeze in 1976, is shown in table 55.

Data on prices of selected crude oils and products are given in tables 56-57.

In the United States, gasoline outweighs all other products in terms of volume produced and relative importance in the refinery mix. Prices of gasoline have continued upward along with rising crude oil prices. The average service station price of regular-grade gasoline (including taxes) has risen from 42.26 cents per gallon as of December 1, 1973, to 53.15 cents per gallon on December 1, 1974, to 59.42 cents per gallon on December 1, 1975, and to 60.61 cents per gallon on December 1, 1976, according to Platt's Oil Price Handbook and Oilmanac, 1976 edition.

Shown in the following tabulation (in dollars per 100 gallons) are some comparisons in selected cities of prices of No. 2 home-heating oil between the 1972 yearend and January 1977. These intervals indicate the impact of the pass-through policy on retail prices. Between January 1974 and January 1977 the U.S. average rose 38% from $32.89 to $45.42 per 100 gallons.

Standard metropolitan statistical area	December 1972	January 1974	January 1975	January 1976	January 1977
U.S. average	$19.72	$32.89	$37.84	$41.46	$45.42
Baltimore	19.33	31.18	36.60	41.02	45.12
Boston	20.40	32.90	40.06	42.49	45.06
Chicago and Northwestern Indiana	18.65	31.66	33.96	43.73	43.54
Detroit	18.62	30.35	35.75	39.68	44.75
Milwaukee	18.93	31.23	36.58	40.07	45.58
Minneapolis - St. Paul	18.06	34.74	35.72	40.13	44.91
New York and Northeastern New Jersey	20.40	36.90	40.04	34.82	47.71
Philadelphia	19.23	31.30	37.96	43.52	45.03
St. Louis	19.49	33.72	37.91	40.98	44.62
Washington, D.C	19.78	33.30	40.82	41.99	47.09
Seattle	22.17	33.50	38.20	44.93	47.32

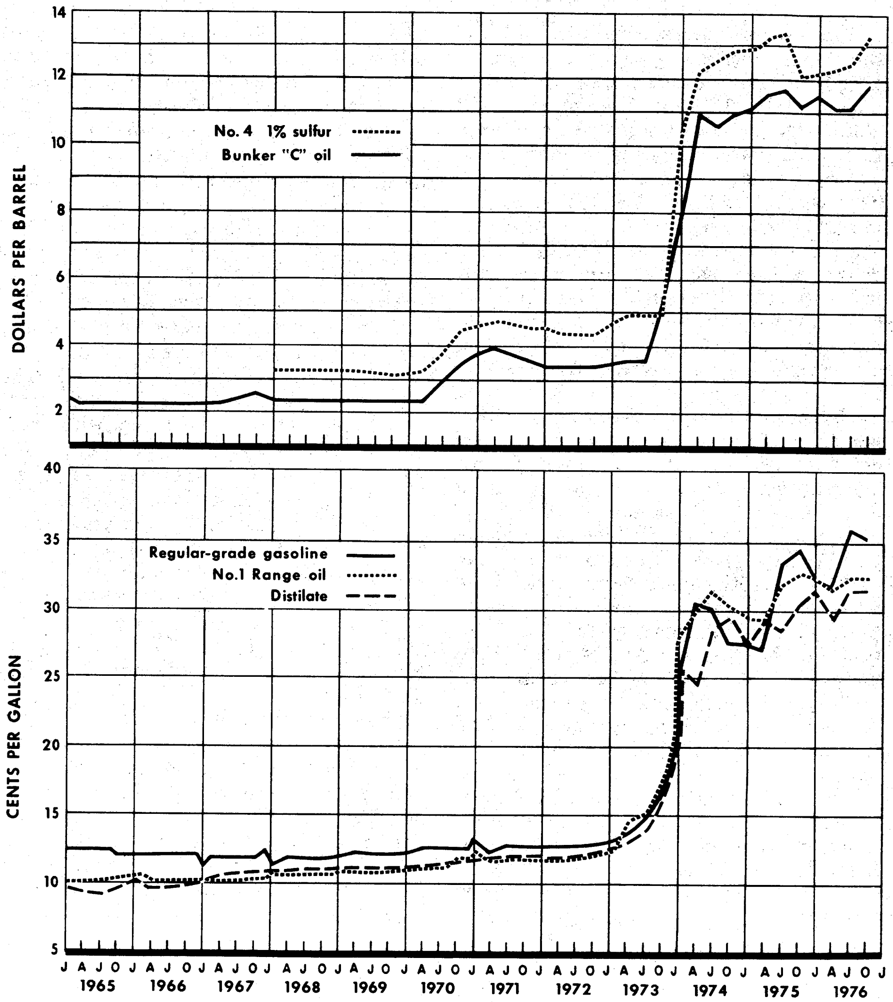

Figure 7.—Quarterly prices of Bunker "C" and No. 2 distillate fuel at New York Harbor, No. 1 range oil at Chicago district, and regular-grade gasoline at refineries in Oklahoma, by quarter.

Residual Fuel Oil Prices.—The price of Bunker "C" fuel oil at New York Harbor has been in an uptrend since 1972; from $3.45 per barrel at yearend 1972, to $5.42 per barrel by December 1973. By December 1976, the price was $11.85 per barrel. The trend of Bunker "C" prices for 1968-76, inclusive, is shown in figure 7.

Unlike the use of Bunker "C" fuel, use of No. 6 residual fuel oil is restricted to 0.3% sulfur in many communities along the eastern seaboard, New York City is an example. The average price per barrel for 0.3% sulfur No. 6 fuel oil high pour in the New York Harbor cargo market since 1972 follows:

1972	$3.33
1973	6.48
1974	14.60
1975	12.03
1976	12.49

The price at yearend 1976 was $14.35 per barrel for No. 6 high pour, 0.3% sulfur.

FOREIGN TRADE

Exports.—Exports, which comprise only 1.3% of total demand, totaled 81.6 million barrels in 1976 or an average of 223,000 bpd. This is an increase of 6.5% over 1975 when exports averaged 209,000 bpd. Virtually all of the 2.9 million barrels of crude exported was destined for Canada and Puerto Rico. In the products category, some 78.7 million barrels or 215,000 bpd were exported and petroleum coke accounted for 46% of petroleum exports. Coke, which is a surplus commodity in the United States, is sent primarily to Japan, the Netherlands, West Germany, and Canada where it is used extensively in the metallurgical industries of these countries.

Lubricants from the United States are shipped to virtually every country throughout the world, and in 1976 there were 9.5 million barrels exported from the United States. Lubricant exports from the United States, however, have been in a downtrend because new refineries constructed in foreign countries included facilities for the manufacture of lubricating oils and greases; hence, a shrinkage in the market for products from the United States. In 1967, for example, exports for lubricants averaged 50,866 bpd compared with 25,943 bpd in 1976.

Exports of petrochemical feedstocks in 1976 accounted for 11,144,000 barrels or 13.7% of shipments to foreign countries. Included in this category are carbon black feedstock oil, naphtha of less than 400° F end point, and many other unfinished hydrocarbons suitable for petrochemical manufacture. Exports of liquefied gases totaled nearly 9,000,000 barrels and were shipped primarily to Mexico from Texas by truck transports.

Imports.—Reflecting an increase in refining activity, imports of crude oil in 1976 rose 29.2% to 1.9 billion barrels or nearly 5.3 million bpd. In the products category, imports were lower for most products except kerosine, residual fuel, and butane and propane. An increase of 177,400 bpd in residual fuel oil imports more than offset sharp reductions in imports of gasoline and declines in imports of distillate fuel oil and jet juel. Saudi Arabia supplied more than 1.9 million bpd or 23% of crude imports, and Nigeria followed with about 1 million bpd or 19%. Indonesian oil ranked third with 536,000 bpd or 10%, and most of this oil was landed in 1976 in PAD district V for use by west coast refineries. About one-third of all crude oil imports or nearly 1.8 million bpd was received at gulf coast ports in PAD district III, and more than one-half of that crude oil was obtained from two countries; 542,600 bpd originated in Nigeria and another 456,400 bpd were imported from Saudi Arabia. Nearly 138,000 bpd were obtained from Algeria and imports from Libya into PAD district III averaged about 153,000 bpd.

Even more important to crude supply are imports of foreign crude into PAD district I. During 1976, imports of crude averaged 1.4 million bpd, a volume equivalent to 89.2% of the crude oil import to refineries in PAD district I in 1976. More than one-half of imports came from Saudi Arabia and Nigeria. Algeria and Venezuela supplied another 25% of the requirements.

Imports of petroleum products averaged 2 million bpd and residual fuel oil accounted for 1.4 million bpd or nearly 7 out of every 10 barrels of products imported. Venezuela supplied nearly one-third of the residual fuel oil imported into district I, and the Virgin Islands and the Netherlands Antilles combined imports supplied another 36%. Imports of residual fuel oil were received in district I from 37 countries of origin in 1976 and reflects the rising demand which accompanied the severe winter weather in the Midwest and the Northeast. Also, the lack of natural gas triggered increased use of fuel oils as a substitute fuel in 1976.

Some 49 million barrels of distillate fuel oil averaging 134,000 bpd were imported into district I, and 62% of this volume was received from the Virgin Islands. Likewise, of the 146,190 bpd of motor gasoline imported into district I, 60% came from the Virgin Islands and another 29% came from Puerto Rico.

In the aggregate, imports of both crude oil and products averaged 7,395,000 bpd in 1976. Of this volume 6,111,000 bpd was received from all Organization of Petroleum Exporting Countries (OPEC) sources, and 3,323,000 bpd was received from OPEC Middle East and North Africa as indicated in figure 8. It should be noted, however, that not all of these imports were received directly from OPEC. For example, in the petroleum products group some 1,050,000 bpd of petroleum products were derived from OPEC crude processed in refineries

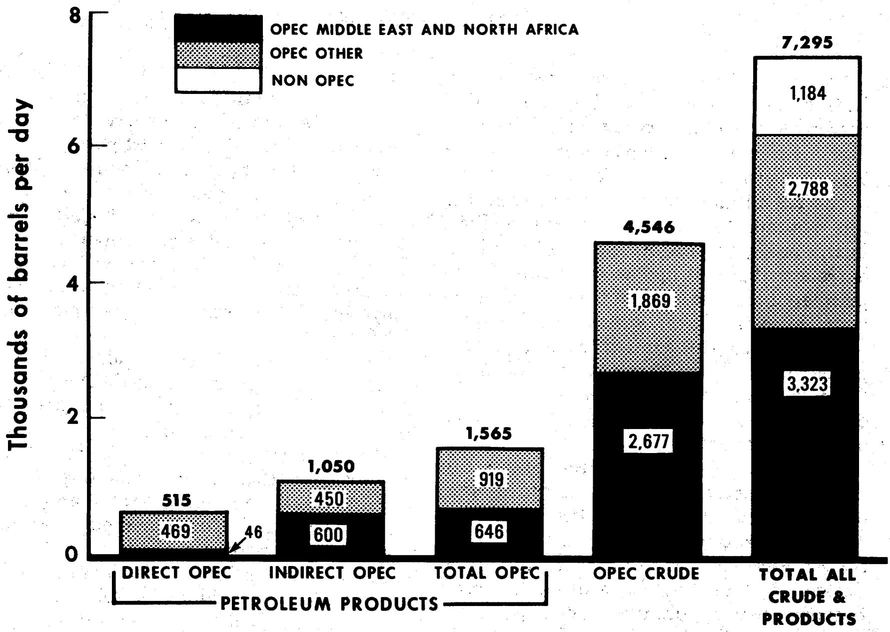

Figure 8.—Imports, direct and indirect, from OPEC Nations.

located primarily in the Virgin Islands and in Puerto Rico. Only 515,000 bpd of products were recovered directly from OPEC countries.

The OPEC consists of 13 countries, 6 of these are in the Middle East: Iran, Iraq, Kuwait, Qatar, Saudi Arabia, and the United Arab Emirates. Africa includes four countries: Algeria, Gabon, Libya, and Nigeria. Ecuador and Venezuela constitute the two countries in South America, and Indonesia in Asia completes the group.

Production of oil has been declining in the United States since 1970, creating a dwindling domestic supply. Meanwhile, demand continues to trend upward; hence, the need for greater imports. In 1976, imports equaled 41% of demand, whereas in 1970 when crude production peaked, imports accounted for only 24%. Furthermore, products made up more than one-half (57.9%) of total imports and residual fuel oil accounted for 77% of the products segment.

WORLD REVIEW

OPEC, which accounts for 90% of all crude oil in international trade, established the price of Arabian marker crude at $12.38 per barrel as the posted price[9] and $11.51 per barrel as the sales price in October 1975. These prices remained unchanged through yearend 1976. At the OPEC ministerial conference in December, price increases as high as 25% were proposed for January 1, 1977; however, Saudi Arabia, which currently produces about one-third of all OPEC output directed its influence in favor of price moderation. The Saudi Arabian Government declared its motive in adopting a price restraint policy as primarily an act of faith with the West to encourage their support in resolving the Arab-Israeli conflict.

The December OPEC meeting was finally concluded with the adoption of a two-tier structure of oil prices effective January 1, 1977. Eleven members of OPEC increased the price of marker crude by $1.19 per barrel or 10.3%, while Saudi Arabia and the United Arab Emirates raised the price of marker crude by $0.58 per barrel or 5%. Prior to this dispute, Saudi Arabia, as flexible producer, was able to minimize competition among OPEC members. When demand for OPEC crude was weak in the recession of 1974-75, Saudi Arabia made major cutbacks in oil production with the objective of preserving the cartel and maintaining high price levels. With revenue requirements far below receipts, the Nation could tolerate reduced exports. By the adoption of the lower tier price level, Saudi Arabia had reversed its role. Saudi Arabia announced plans to increase production and force the upper tier producers to cutback production in face of their market disadvantage. The longevity of the two-tier pricing structure is subject to the supply-demand outlook for OPEC oil in 1977 as well as the frequently shifting political climate.

Production.—World crude oil and field condensate production averaged 57.9 million bpd, a record level surpassing the previous high recorded in 1974 by 1.6 million bpd, and surpassing output in the deep recession year of 1975 by 4.5 million bpd. For the first 9 months of the year production averaged only 56.5 million bpd but surged to an average of 61.3 million bpd in the last quarter. Increased demand at yearend was prompted by stockpiling as buyers took advantage of the comparatively cheaper prices still in effect before the announced price increases of January 1, 1977.

The U.S.S.R. maintained its leading position among world producers accounting for 10.4 million bpd, followed by Saudi Arabia with its share of Neutral Zone production averaging a total of 8.6 million bpd, and the United States with production averaging 8.1 million bpd. For additional production figures on a country-by-country basis refer to table 62.

More than half of the world output was derived from the 13-member States of OPEC producing a combined average of 30.8 million bpd, for calendar year 1976 and surging to an average of 34.3 million bpd for the month of December, preceding the price increases of the new year.

Combined production from non-OPEC Nations averaged 27.1 million bpd an increase of 0.9 million bpd over 1975. While much of this increase in production was attributed to output from the U.S.S.R., production from the North Sea averaged over 0.5 million bpd in 1976, about 300,000 bpd over 1975 levels. By 1977, North Sea production should increase by approximately 1 million bpd over 1975 output leading the non-OPEC world in production growth by volume.

Crude Oil Movements.—Crude oil constitutes about 80% of all Western European petroleum imports, 88% of Japanese petroleum imports, and 75% of petroleum imports of the United States. Crude oil movements to these major markets totaled nearly 22 million bpd in 1976. Nearly 60% of these imports were obtained from the Middle East. Excluding intra-European shipments, Western European total crude imports averaged 12.1 million bpd with the Middle East supplying 71% or 8.6 million bpd. The Middle East supplied 79% of Japanese crude imports or more than 3.6 million bpd. United States crude petroleum imports approached 5.3 million bpd, about 35% or near 1.9 million bpd was supplied by the Middle East. Saudi Arabia supplied more than 1.2 million bpd. Other major U.S. crude suppliers were Nigeria with 1 million bpd and Indonesia at 0.5 million bpd.

[9]Price used for calculating producing companies' tax and royalty payments on equity oil.

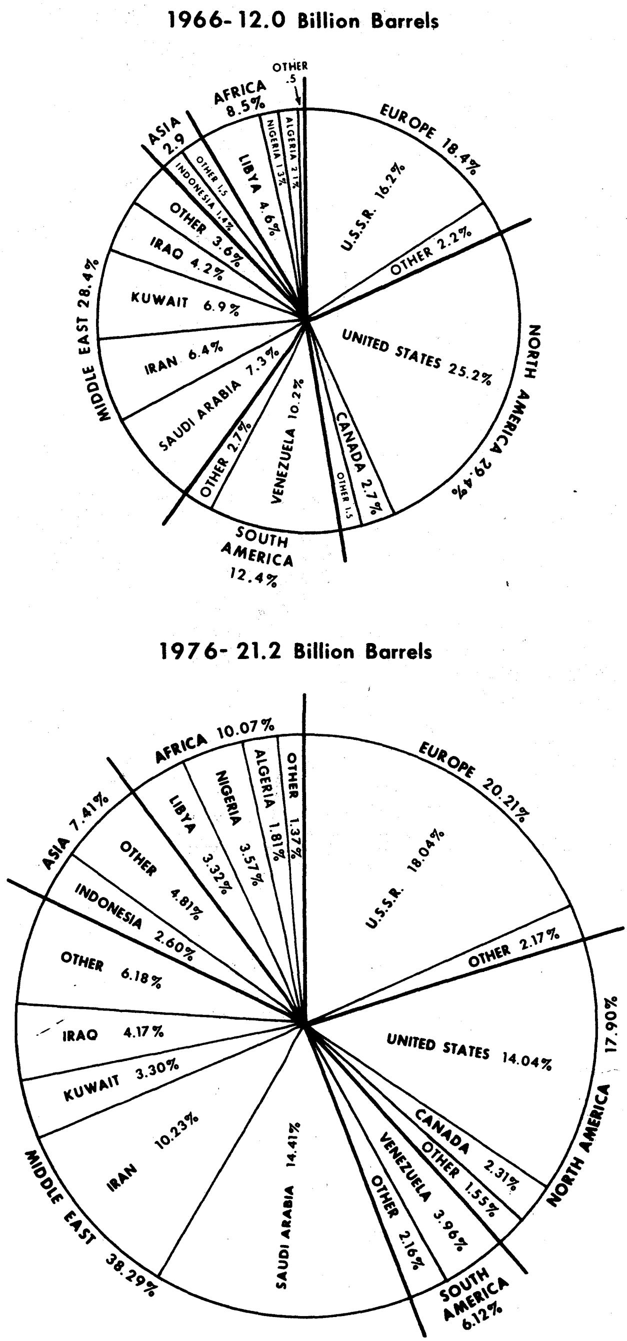

Figure 10.—World share of crude oil production, in 1966 and 1976.

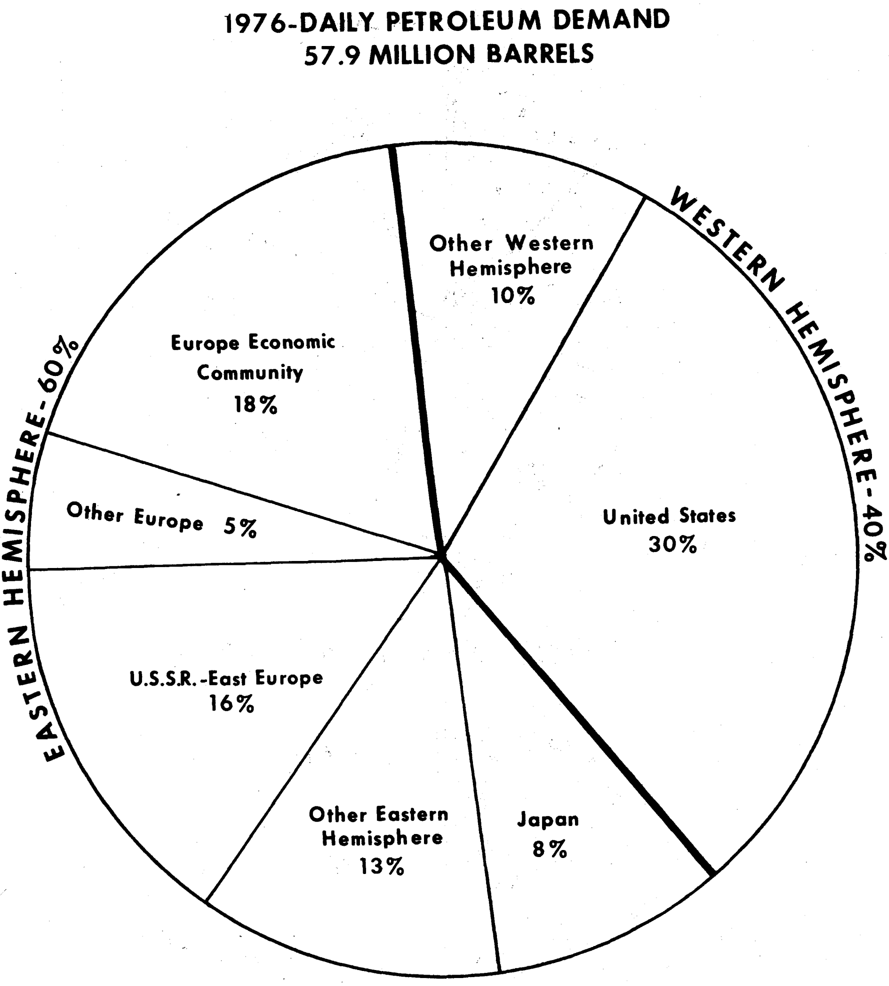

Figure 11.—World daily petroleum demand, 1976.

Transportation.—With the exclusion of nearly 46 million dwt in combined carriers, the world tanker fleet totaled 321 million dwt at yearend 1976 representing a net increase, after losses, scrappings, and conversions, of 29 million dwt over the previous year. Over 31% of the world tanker tonnage sails under the Liberian flag followed by registries in Japan and the United Kingdom, which account for 10% and 7%. Tankers over 200,000 dwt and up to 285,000-dwt capacity constitute 43% of the total tanker fleet. Since the closure of the Suez Canal in 1967, most of the new tankers under construction were in this capacity range. In 1976, however, of the 40.4 million dwt of newly commissioned tanker capacity, 13.5 million dwt was in the range of over 200,000 dwt and up to 285,000 dwt, while 14 million dwt was in the range of 285,000 dwt and over.

Voyages from the Middle East occupied 78% of the oceangoing fleet. Voyages from the Middle East to Europe alone occupied 41% of the total oceangoing fleet, while voyages between the Middle East and Japan occupied 11%, and voyages between the Middle East and the United States occupied 9%. Movements on the Mediterranean Sea were reduced when Iraq discontinued exports from Banias and Tripoli in April. The Saudi Arabian crude exports through the

Tapline terminal at Sidon had been discontinued in 1975 and were not renewed during 1976. Movement through the Suez Canal in 1976 was limited to laden tankers of no more than 70,000 dwt. Laden tankers transiting the Suez Canal totaled an estimated 35 million dwt in 1976. Tankers returning to the Persian Gulf in ballast totaled an estimated 100 million dwt in 1976.

Two new Middle Eastern pipelines should be operational in 1977; the Sumed pipeline connecting the Gulf of Suez with the Mediterranean Sea and the Iraq-Turkey pipeline connecting the Iraq oilfields to the Mediterranean outlet of Dortyal. When these pipelines are operational, Mediterranean tanker traffic will significantly increase. In 1977 the Trans-Alaska pipeline will be operational increasing tanker activity along the North American west coast and through the Panama Canal.

Five United States west coast ports can accomodate tankers of 100,000 dwt or better. The largest of these is at Ferndale, Wash., accomodating tankers up to 150,000 dwt. Most United States gulf coast and east coast ports, while serving the more heavily populated areas of the United States, can only accomodate tankers of 50,000 dwt or less. Without lightering and transshipment facilities, importers could not benefit from the economic advantages realized in using very large crude carriers for long distance hauls. Transshipment terminals, operating at Curacao and at the Grand Bahamas Island, were joined in 1976 by the new Bonaire terminal in the Netherlands Antilles. The construction of two superports off the gulf coast of the United States was under consideration in 1976.

Refining Capacity.—Total world crude oil refining capacity was estimated at 75.2 million bpd by yearend 1976 representing a 3.4 million bpd increase over 1975 levels. About 0.9 million bpd of new capacity is attributed to the United States, almost 0.4 million bpd to the People's Republic of China, about 0.3 million bpd to the U.S.S.R., and over 0.2 million bpd for both France and Italy. The Eastern Hemisphere, with major refining centers in the Common Market, in the U.S.S.R., and in Japan, accounted for 65% of total world refining capacity or 49.2 million bpd. Most Eastern Hemisphere refineries operated well below capacity. In the Common Market, where refining capacity totaled 17.3 million bpd, crude oil and blendstock throughput represented only 60% of capacity. Refining capacity of the U.S.S.R. is estimated at 9.5 million bpd, and capacity utilization is estimated at 90%. Japan, where refining capacity totals 5.5 million bpd, operated at 80% capacity. Refining capacity in the Western Hemisphere totaled 26 million bpd. Nearly 16 million bpd refining capacity is in the United States, over 2 million bpd in Canada, and nearly 1.5 million bpd in Venezuela; refineries operated at 85%, 80%, and 60% capacity, respectively.

Consumption.—World petroleum consumption increased by an estimated 4.9 million bpd, raising total consumption to 57.9 million bpd in 1976. Consumption levels in major industrial areas increased as the various economies adjusted to the petroleum price burden. Western European consumption increased by 127,000 bpd to 12.2 million bpd, and the United States increased by 940,000 bpd to 17.4 million bpd.

Australia.—Restrictions on foreign investments and a price ceiling of less than $3.00 per barrel on Australian crude resulted in a sharp decline in exploratory and development drilling. In 1972, a total of 139 exploratory and development wells were drilled. By 1976 drilling activity was reduced to 19 exploration wells and 14 development wells; consequently, crude reserves had dropped to 1.4 billion barrels, about 50% the 1972 reserve level. The Australian Government has reassessed its program and a more favorable investment climate is expected.

Australian crude production averaged 417,000 bpd, the bulk of which was derived from the Esso-Broken Hill Pty, Ltd. operations in Bass Strait where output from the Kingfish, Halibut, and Barracouta fields totaled an average of 385,000 bpd. Two new fields were under development in this area. The Mackerel field, with crude reserves of 200 million barrels, was scheduled to enter production in 1977; production at full development was estimated at 70,000 bpd. The Tuna field, with crude oil reserves of 40 million barrels and natural gas reserves of 500 billion cubic feet, was scheduled for production in 1978. It was reported that at full development, the field should produce 23,000 bpd.

France.—Domestic production averaged 21,000 bpd accounting for about 1% of France's petroleum consumption requirement.

Offshore exploration in the Mer d' Iroise proved promising, but further activity in this area has been suspended pending a decision by the International Arbitration Tribunal as to the median line between the

French Mer d' Iroise and the British Celtic Sea.

In January 1976 the French Government approved the merger of State-owned Enterprise de Recherches et d'Activités Pétrolières (ERAP) and Société National des Petroles d'Aquitaine. The new company is registered as Société Nationale Elf-Aquitaine (SNEA).

In mid-1976 Port Autonome du Havre opened its superport facilities at Antifer about 15 miles north of Le Havre. Antifer can accomodate tankers of 550,000-dwt capacity and can be made to accomodate tankers of 1,000,000-dwt capacity when the need arises. Tankers calling at Antifer offload petroleum for French consumption or use the facilities to transfer the petroleum to smaller tankers for delivery to other European ports of more limited tanker capacity.

India.—Production from the Bombay High offshore structure averaged 17,000 bpd for calendar year 1976 raising India's crude petroleum production to an average of 177,000 bpd for the year. By yearend, however, output from Bombay High approached 35,000 bpd, by yearend 1977 output should reach 80,000 bpd, and at full development in 1979, the field should average 200,000 bpd. The Bombay High structure contains proved reserves of 1.5 billion barrels or half of India's total proven crude petroleum reserve of 3 billion barrels.

The Indian Oil and Natural Gas Commission (ONGC) has reached agreement on the acquisition of the Caltex Oil Refining Co. and the marketing firm, Caltex (India) Ltd. for $14.6 million. Government policy favors discouraging foreign equity. The Caltex acquisition followed similar actions by ONGC in recent years with holdings of Esso Eastern Inc., Royal Dutch/Shell, and Burmah Oil Co., Ltd.

Indonesia.—Liquidity problems of the State oil and natural gas company, Pertamina, prompted the Government to seek a source for rapid cash receipt. One avenue was the renegotiation of long-standing contracts with foreign oil companies. Generally, the existing production sharing contracts designated 40% of production for investment recovery, 20% for delivery to Pertamina refineries at 20 cents above production cost, and divided the remaining production 65%/35% in favor of Pertamina. Revised contracts were signed in midyear and were retroactive to January 1, 1976. The new contracts essentially directed 89% of foreign company income to Pertamina. The new contract terms increased the Governments income by $640 million in 1976, but at the same time reduced the operators cash flow. As a result, exploration and development activity dropped significantly by yearend. During 1976 there were 142 exploratory well completions, a decline of 22% from 1975. Total footage drilled was 748,235 representing a 31% decline from 1975. In spite of reduced drilling activity, 43 new oil and gas wells were discovered for a success ratio of 1.3. Development drilling footage was reported at 1,549,699, also an appreciable drop from 1975 levels. Reduced exploration and development activity will probably continue in 1977, but a reversal might be anticipated by 1978, as the Indonesia Government announced that contract modifications allowing for exploration incentives would be forthcoming in 1977.

Indonesian crude oil production averaged over 1.5 million bpd, representing a 15% increase over the 1975 level. The adjustment of Indonesian crude prices to more competitive levels contributed signficantly to increased demand and the consequent increased production. Companies from the United States accounted for 85% of total production. Affiliates of Texaco, Inc. and Standard Oil of California alone accounted for 56% of total production.

Productive capacity of Indonesian fields approximated 1.75 million bpd in 1976, but should increase to 1.8 million bpd in 1977 when additional capacity becomes available from Cia. Française des Pétroles and Atlantic Richfield Co. operations in East Kalimantan, from Phillips Petroleum Co. operations in Irian Jaya, from Independent American Petroleum Co. operations in the Java Sea, and from Pertamina and Caltex Pacific Indonesia operations in Sumatra.

Crude petroleum exports were revitalized in 1976 averaging well over 1.2 million bpd. Japanese and U.S. markets absorbed 43% and 41%, respectively, of all Indonesian crude petroleum exports. Eight refineries with a combined capacity of 523,000 bpd are owned and operated by Pertamina, including the 100,000-bpd-capacity Cilacap refinery inaugurated in August 1976. Indonesia's only other refinery is the 4,000-bpd-capacity refinery at Cepu operated by the Oil and Gas Academy (Lemigos). Overall refinery output in 1976 averaged 310,650 bpd. This includes 83,000 bpd processed by two Singapore refineries under special arrangements with Pertamina. Petroleum product exports averaged 100,000 bpd. Product exports were almost entirely residual fuel processed from Minas Sumatran crude for direct-burning power generation in Japan.

Iran.—The petroleum industry is dedicated to sustaining high production levels for as long a period as possible, and to maximizing ultimate recovery by reservoir pressure maintenance. The goals were reinforced in 1976 as the initial phase of the $2.5 billion, 13,000 million-cubic-foot-per-day gas reinjection program was implemented. Four injection wells were drilled in the Haft Kel field where 400 MMcf per day of gas was injected. The gas was transported through a 24-inch pipeline connecting six wells in the Naft Safid field to the Haft Kel field. By yearend gas injection also commenced at Gachsaran and Agha Jari, Dome and associated gas from the Pozanan field was the supply source for gas injection programs in the Gachsaran and Aga Jari fields. A gas injection project was scheduled for the Pars field in 1977, gas was to be delivered by an extension of the Haft Kel 24-inch pipeline.

Crude oil production for 1976 averaged 5.9 million bpd; however, near capacity peak production levels were reached in the fourth quarter when output averaged 6.6 million bpd. Demand for crude registered a sharp rise at yearend as buyers attempted to stockpile as much crude as feasible in view of the announced January 1977 price increase. More than 90% of Iran's output comes from the Khuzestan fields in southwest Iran owned by the National Iranian Oil Co. (NIOC) and operated by the Oil Services Co. (OSCO). Among the larger fields in this area are the Marun field where production averaged 1,340,000 bpd in 1976, the Ahwaz field where production averaged 930,000 bpd, the Agha Jari field where production averaged 850,000 bpd, and the Gachsaran field where production averaged 620,000 bpd. Production from the last two fields reportedly would be appreciably increased in 1977 as a result of the gas injection program.

Of total Iranian crude production, at least 400,000 bpd was derived from offshore wells. NIOC has 50% interest in all offshore oil production. Companies producing in Iranian waters are Lavan Petroleum Co., Iranian Marine International Oil Co. , Iran Pan American Oil Co. and Société Irano-Italienne des Pétroles.

Crude exports averaged 5.2 million bpd in 1976. About 600,000 bpd was refined in Iran for domestic consumption. Iran's petroleum consumption growth rate was anticipated to be about 16% to 18% yearly for the next 5 years. In line with increased domestic consumption, the domestic refining capacity will be raised from 750,000 bpd in 1976 to 980,000 bpd in 1977, and to 1,450,000 bpd in 1981. Additional refinery capacity will emphasize production of middle distillates as this group represents 55% of Iran's consumption pattern.

Construction of the 80,000-bpd-capacity Tabriz refinery continued on schedule and completion was anticipated by April 1977. The refinery will process crude from the Ahwaz field for consumption in northwest Iran. In December 1977 ground breaking ceremonies launched construction of a 200,000-bpd-capacity refinery at Isfahan. The first of two 100,000-bpd-capacity distillation columns and supporting units will be operational in the spring of 1978, and the second will be operational in the fall of the same year. The Abadan refinery was under expansion raising capacity from 450,000 bpd to 600,000 bpd by 1977. A 300,000-bpd refinery is planned for completion by 1981. The location of this refinery has not yet been announced.

Iraq.—Production averaged 2,415,000 bpd for calendar year 1976; however, output in the last quarter surged averaging 3 million bpd in December. The bulk of crude output was derived from the Kirkuk complex followed by production from the Rumaila and Zubair fields. Three new fields, the Buzurgan, the Abu Ghirab, and the Fauqi, were under development in 1976. These fields are located in Southern Iraq near the Iranian border. The Buzurgan and Abu Ghirab fields entered production in October with crude oil averaging 23° API gravity and 3.7% sulfur. At yearend a commercial discovery was announced near Al-Qurnah. The new field, the Majnoon, has an estimated reserve of 2 billion barrels. Production capacity is estimated at 350,000 bpd.

In April, after a sustained dispute over transit fees and over prices on crude delivered to the Syrian Homs refinery, Iraq suspended shipments through pipeline from Northern Iraq across Syria to the Mediterranean terminals of Banias and Tripoli. Crude petroleum output was rerouted through a newly constructed 410-mile pipeline connecting the northern fields with Fao on the Gulf of Basrah. At Fao two submarine pipelines of 48-inch-diameter run a length of 25 miles to four offshore loading berths. Still another outlet for Iraqi crude exports should be available in 1977, when the 610-mile pipeline connecting Iraq fields to the Port of Dortyol, Turkey is operational.

Italy.—More than 50 Italian and foreign companies are exploring for oil and gas in Italy. Onshore concessions are concentrated in Italy near Tuscany, Lazio, and Abruzzi; while the offshore search is centered along the southern Adriatic Sea into the Ionian Sea and in the waters of Sicily and the smaller island groups between Italy and Tunisia. Italian reserves are estimated at 315 million barrels, no significant additions to reserves have been reported in 1976.

Italian refining centers have a rated capacity totaling well over 4 million bpd. Refineries continued to operate well below capacity as crude throughput, virtually all imports, averaged only 2.1 million bpd.

Kuwait.—Kuwait Law 10 of 1976 was ratified in March abolishing retroactively to March 1975 all previous oil concessions and participation agreements between the Government of Kuwait, the Gulf Oil Co., and British Petroleum Corp. (BP) in connection with the Kuwait Oil Co. (KOC) and its operations. The State assumed full control over the Nation's petroleum industry; however, both the Gulf Oil Co. and BP are under fee for technical assistance.

The KOC, now fully State-owned, accounted for all production in Kuwait, which averaged 1,912,569 bpd in 1976. The American Independent Oil Co. (Aminoil) accounted for all Kuwait onshore production in the Neutral Zone. Aminoil produced an average of 80,659 bpd in 1976. The Kuwait share of offshore operations in the Neutral Zone was 152,192 bpd. Offshore operations in the Neutral Zone are conducted by the Arabian Oil Co. (AOC) for both Kuwait and Saudi Arabia. The combined recovery from Kuwait and from that Nation's share of the Neutral Zone production averaged 2,147,000 bpd.

Nearly 1.8 million bpd, or more than 80% of the crude output was exported. The Far Eastern markets accounted for nearly half of the crude oil exports.

Mexico.—The State-owned company Pétroleos Mexicanos, S.A. (Pemex) announced a 6-year petroleum industry development program which would increase production from nearly 1 million bpd to 2.2 million bpd in the 1976-81 period. Pemex investment budget for this time frame provides $8.4 billion for exploration and development, $2.3 billion for refining expansion, $2.6 billion for petrochemical expansion, and $2.2 billion for transportation development.

During the 6-year period, Pemex plans to drill 1,324 exploratory wells and 2,152 development wells. Refinery capacity will be augmented by completing two new refineries with a combined capacity of 270,000 bpd, and by a 200,000-bpd expansion of both the Tula and the Salina Cruz refineries bringing total refinery capacity to 1.67 million bpd by 1981.

Petroleum exports, predominantly crude oil, averaged less than 100,000 bpd in 1976. Petroleum exports are planned at 1.1 million bpd in 1981, with products accounting for nearly two-thirds.

Nigeria.—Investment in exploration and development declined since 1974, when the Government acquired majority ownership in the producing companies. By yearend 1976 onshore rig count had dropped to 15 compared with 23 in operation in 1975.

The largest producer is the Petroleum Development Co., a joint venture between Royal Dutch/Shell and BP in which the Nigerian National Oil Co. (NNOC) recently acquired 55% equity. Shell/BP production averaged 1.23 million bpd from 75 onshore fields. Other major producers were Gulf Oil Co. averaging nearly 300,000 bpd, Mobil Oil Co. averaging 230,000 bpd, and ENI-Phillips averaging 186,000 bpd. The NNOC recently acquired 55% equity in the preceding companies as well.

Norway.—Crude oil production from the Ekofisk complex in the Norwegian Continental Shelf averaged 279,000 bpd in 1976. A deep trench along the coast of Norway renders a pipeline unfeasible; therefore, Norwegian offshore production was delivered to Teeside, England, for export or refining through a 34-inch-diameter, 200-mile pipeline of 1-million-bpd capacity. Terminal facilities at Teeside include stabilization units, tanker loading berths, and storage capacity for 7.5 million barrels.

In mid-1976, the Norwegian Parliament approved the development of the Statfjord field and requested that a 2-year testing program be launched in an effort to construct a pipeline across the Norwegian trench to connect this field with the Norwegian coast. The Statfjord field, discovered in 1974 by Mobil Oil Co., has an estimated recoverable reserve of 3.9 billion barrels of oil and 100 billion cubic meters of associated gas. Initial production from this field should be realized in 1979 at 60,000 bpd, and production at full development is anticipated at 900,000 bpd.

During 1976, two major discoveries on the Norwegian Continental Shelf were announced; Mobil Oil Co. announced a discovery in bloc 33/9 near Statfjord and Continental Oil Co. announced a discovery in bloc 7/12 near Cod.

Statoil, the Norwegian State oil company is at least a 50% partner in all petroleum exploration and development activity. On January 1, 1976, a State petroleum distribution company was formed under Norsk Olje (NOROL), following the Norwegian Government purchase of Norsk Braendselolje, Norske OK, and Norsk Hydro A/S.

Saudi Arabia.—The long pending takeover of the sole producing company in Saudi Arabia, the Arabian American Oil Co. (Aramco), had not materialized by yearend. Among the points still under negotiation were the details of the management contract.

Aramco reported the discovery of three new fields in 1976, located at Hasbah, Sharar, and Suban. Aramco's net addition to reserves at yearend were 2.3 billion barrels proved and 1.7 billion barrels probable. Aramco reported proved reserves at yearend at 110.2 billion barrels, and probable reserves at 177.5 billion barrels. These figures are for Saudi Arabian reserves and do not include about 3 billion barrels of the Saudi Arabian share from the Neutral Zone. The Government of Saudi Arabia has issued a less conservative estimate of proved reserves at 151.4 billion barrels.

Crude oil production from Saudi Arabia and from that Nation's share of Neutral Zone production averaged nearly 8.6 million bpd in 1976, a 21% increase over the 1975 average. Peak production level was achieved at 9.4 million bpd for the month of November as buyers accelerated crude oil purchases before the January price hike.

More than half of Saudi Arabia's 1976 production was derived from the giant Ghawar field which averaged 5.2 million bpd. Pressure maintenance techniques applied at Ghawar are the injection of saline aquifer water in the northern, eastern, and western perimeters, and the reinjection of gas in the northern dome. A massive seawater supply project is under construction to reduce dependence on aquifer water for pressure maintenance. The seawater will be collected just south of Dhahran and transported via a 65-mile long pipeline. The initial phase of the seawater pressure maintenance program will be in operation by 1978, when 4.2 million bpd of treated seawater will be available for injection. Future expansion to a 12-million-bpd capacity is programed.

At the December OPEC ministerial meeting, Saudi Arabia together with Abu Dhabi rejected the 10% price increase adopted by 11 other members of OPEC and launched a two-tier price system by adopting a 5% price increase effective January 1, 1977. At the same time Saudi Arabia announced its intention to increase production capacity from the 1976 level of nearly 12 million bpd to 16 million bpd by 1982.

U.S.S.R.—Production of crude oil and field condensate averaged 10.4 million bpd, maintaining the Nation's lead in world production of liquid hydrocarbons. The Urals-Volga region, which includes the major producing areas of Tataria, Bashkiriya, and Kuibyshev, accounted for nearly 4.5 million bpd. Production from Western Siberia followed with a reported output of 3.6 million bpd. The largest field in Western Siberia is Samotlor where output from more than 1,000 producing wells totaled an average of 2.2 million bpd in 1976. Soviet sources report the anticipated peak production of Samotlor at 2.7 million bpd in 1977 revising various earlier projections, while production at Samotlor rises to peak levels, development activity in Western Siberia continues. The following fields entered production in 1976: Kholmogorskoye, Severo-Vareganskoye, Lokoskovskoye, Yuzhno Balyskoye, Severo Pokurskoye, and Yuzhno Surgutskoye. Soviet production goals for Western Siberian fields are set at 6 million bpd by 1980, or nearly half of total Soviet projected output for that year.

Offshore production in the Soviet Union totaled 220,000 bpd of crude oil and field condensate, falling well below the 1976 planned goal. All Soviet offshore production is derived from Caspian Sea deposits, the largest of which is the Baku Archipelago, which accounted for 100,000 bpd or nearly half of the offshore output, followed by the Neftianye Kamni field, which yielded about 70,000 bpd.

Offshore drilling activity has been hampered by the lack of mobile drilling units often resulting in the time-consuming and costly construction of fixed platforms for wildcat drilling. The Soviet Union's mobile offshore drilling capability is limited to four jack-up rigs. The Apsheron rig is only capable of drilling in shallow waters not exceeding 50-foot depths with a total drilling depth capability of 5,900 feet. The Azerbaijan rig can operate in water depths up to 66 feet with total drilling depth at

10,000 feet. Recent additions to the Soviet mobile rig fleet are the Netherlands-built Khozar jack-up rig and the Soviet-built Baku jack-up rig; both rigs are capable of operating in 200 feet of water with a maximum drilling depth of 20,000 feet.[10] During the 1976-80 5-year plan, the Soviet Union intends to increase its mobile rig fleet to 12. The rigs will be employed on the Western and Eastern shelves of the Caspian Sea.

Offshore production goals for 1980 have been revised downward from 360,000 bpd to 275,000 bpd. During 1976, new discoveries were reported on the East Bank of the Caspian Sea near the Cheleken Peninsula, the Magyshlak Peninsula, and the Buzochi Peninsula. The development of these fields, as well as several shut-in fields, and the construction of adequate pipeline facilities have been incorporated in the Soviet Union's long-range plans which anticipate Caspian Sea production at 440,000 bpd in 1985.

Soviet sources report refining capacity at 9.5 million bpd. Total exports of crude petroleum and refined products averaged 3 million bpd. More than half of the petroleum exports or 1.7 million bpd were delivered to other centrally controlled economies, while shipments to Western Europe averaged nearly 1 million bpd.

United Kingdom.—Five new fields came onstream in the United Kingdom's section of the North Sea during 1976. The Auk field, owned by Shell U.K., Ltd. and Esso Petroleum Co., Ltd., entered production in February. Production at full development is estimated at 50,000 bpd. The Beryl field, owned by Mobil Producing North Sea, Ltd; Amerada Exploration Ltd.; Texas Eastern (UK), Ltd.; and the British Gas Corp., came onstream in June. Production at full development is estimated at 100,000 bpd by 1978. The Montrose field, owned by the British Gas Corp.; Amoco U.K. Petroleum, Ltd.; Amerada Exploration, Ltd.; and Texas Eastern U.K., Ltd., also came onstream in June. Production at full development is estimated at 60,000 bpd by 1978. The Brent field, owned by Shell UK, Ltd. and Esso Petroleum Co., Ltd., entered production in November. Production at full development will be 450,000 bpd. The Piper field, owned by Occidental Petroleum (UK), Ltd.; Getty Oil International (England), Ltd.; Allied Chemical (Great Britian), Ltd.; and Thomson North Sea, Ltd., came onstream in December. Production from the Piper field is anticipated at 250,000 bpd by yearend 1977. Combined U.K. production from the North Sea averaged 230,000 bpd in 1976. This includes output from the five fields which entered production in 1976 as well as output from the Argyll and Forties fields which have been onstream since 1975. By yearend 1976, daily production from these seven fields in the North Sea was averaging 500,000 barrels. The rate of production should continue to climb through 1977 reaching a daily average well in excess of 800,000 barrels, or about half of the U.K. consumption requirement. Two additional fields, Thistle and the Claymore, were scheduled to come onstream late in 1977.

Other significant developments in 1976 include the conclusion of agreements on State participation which in effect gave the British National Oil Co. the right to buy nearly 1.3 million bpd by 1980 at the prevailing price, and the discovery of 12 new oil and 2 gasfields bringing total discoveries to 73 since offshore exploration began in 1964.

Venezuela.—Nationalization of the petroleum industry was in effect as of January 1, 1976, and compensation to foreign companies and subsidiaries was $1.1 billion. The transfer involved 5.4 million acres of concession holdings over 18 billion barrels of proved reserves well over 7,000 producing wells, 1.5 million bpd in refining capacity, over 6,000 miles of pipelines, as well as tankers, terminals, and other facilities.

Petróleos de Venezuela (Petroven) is the State holding company for 14 new operating companies. Production averaged 2.2 million bpd, and oil sales were reported at $8.84 billion. The Venezuelan Treasury's share of net sales totaled $6.77 billion. Capital investment in the oil industry was $375 million in 1976 and scheduled to increase to $700 million in 1977.

TECHNOLOGY

During 1976, technological development in production, refining, transportation, storage, and marketing have contributed to the efficient use of energy. The decrease in the time used in drilling the well helped to advance production. Refineries are using new procedures and processes to refine less desirable oil into desired products; some products in demand, like gasoline, are being extended by adding methanol. Heat energy is being contained as tanks, which store petroleum, are being insulated to prevent heat loss. A fuel oil additive to improve combustion and reduce pollution is being marketed. The private individual can buy an oil filter with additives for the oil to increase the effectiveness of the oil.

Domestic production is dependent on the addition of new producing wells. The new technological developments allow these wells to be drilled fast and in deep water in the Outer Continental Shelf.

Computer assisted drilling technology is being developed by Baroid Research to provide the drilling rig operator with computerized well control. Applied drilling technology (ADT) service by Baroid is designed to help operators drill wells with optimum efficiency and minimum hazards, through accurate formation pressure control. The data recorded are utilized for normalized drilling rates, total mud and mud weight available, continuous gas in mud, pump pressure, casing pressure, mud viscosity, and normalized shale density for variations in mineral composition. With these observations mud properties can be established to control formation pressure during trips, prevent gas kicks and their control, while not exceeding the fracture gradient causing loss circulation problems. Functions monitored by nondigital instrumentation and manually monitored include formation density, penetration rate, formation drill ability, cost per foot, lagged mud temperature and resistivity, and formation pore pressure.

Computerized drilling permits optimization of the drilling process through rapid data acquisition and analysis. Drilling costs are minimized by optimum bit weight and rotary speed for best bearing load and tooth wear. Hydraulics are continuously optimized by computer to determine slip velocities, critical velocities, equivalent circulating density, pressure drops, and hydraulic horsepower for best hole cleanout and mud circulation.[11]

The U.S. Energy Research and Development Administration (ERDA)[12] and private companies tested downhole engines (electrical motors or turbines) to drive the drill bit. The method tested was an electrical motor for offshore directional drilling. The downhole and surface electronic package was built to combine directional control with the ability to sense downhole parameters in realtime so drilling procedures change as downhole conditions change. These attempts to improve the speed and accuracy of drilling by putting the drill-turning motor near the drill bit instead of imparting motion to the entire string of drill pipe is done as an economic basis.[13]

Stratapax is a polycrystalline diamond blank for drill bits, which is supplied by General Electric Co. to drill bit fabricators. Blanks made of Stratapax have proved higher impact and abrasion resistant for longer bit life. The high abrasion resistance is due to the polycrystalline structure which has no cleavage planes but many tiny, randomly oriented crystals bonded to each other. The drill bits made with Stratapax blanks can double the penetration rates of conventional bits in soft and medium-hard stratas, but drilling problems in hard or abrasive formations have not been solved.[14]

Exxon Corp. installed a production and drilling platform in the Hondo field. The platform, set in 850 feet of water off California, has a total height of 945 feet, is in the Santa Yves unit with plans to drill 28 development wells to a depth of 11,000 feet. Estimated production in 1978 from this field is 60,000 barrels of oil daily and 77 million cubic feet of gas daily from three platforms.

Numerous technological advancements were realized in refining during 1976. Gulf Oil Corp. and Mobil Oil Corp. developed technology which they claim would permit refiners to produce larger amounts of gasoline and middle distillates from crude oil by means of hydrotreating and fluid catalytic cracking.[15]

Chevron Research Co. developed a process for catalytically reforming naphthas into

motor gasoline blending stocks and aromatic chemicals. A bimetallic catalyst utilizes platinum and rhenium on alumina and results in lower fouling rates and lower catalyst costs.

A new process developed by Mobil Oil Corp. reportedly yields 75% to 80% high-quality 90-100 RON gasoline in a single pass of methanol through a pilot reactor using a zeolite catalyst. The company states that the yield can be boosted to 90% of the input by using a secondary process. Mobil researchers estimated the production cost of gasoline from coal-derived methanol is 5 cents per gallon.[16]

Advanced air emissions and water control systems, installed at the Amoco Oil Co.'s petroleum refinery at Texas City, Tex., resulted in a reduction in pollution from the plant. Electrostatic precipitators on the catalytic cracking units contributed to a 92% drop in particulate emissions from the refinery over a 2-year period. The plant's storm and waste water processing system likewise resulted in a significant decrease in pollutants discharged from the refinery.[17]

In France, a new technique called hydropyrolysis was developed for cracking gas oil and naphtha feedstocks at high temperatures and pressures to produce large yields of ethylene.[18]

Several new catalysts were developed for use in petroleum refining during the year. Nitto Chemical Industry Co., Ltd. of Japan and Standard Oil Co. of Ohio (Sohio) announced a new catalyst for Sohio's acrylonitrile process.

In West Germany, an automobile fuel of 85% gasoline and 15% methanol has been tested.

Energy efficiency is being extended to the tank farms at refineries by application of insulation to petroleum storage tanks. Several domestic companies gained experience during the year in applying glass, polyurethane, and other foam insulation to petroleum storage tanks. It is reported that a significant energy savings was realized on heated tanks at which foam insulation had been installed.[19]

Two new products now available to the public and industry are a time release additive system to fortify an automobile's engine lubricating oil, and a fuel oil additive to improve combustion and reduce visible smoke pollution.

Monroe Auto Equipment Co. developed a time-release additive system packaged with an oil filter that would extend the life of automobile engine lubricating oils. While Monroe's new filter cleans the oil, antioxidants, antiwear agents, and viscosity improvers are released in the oil.[20]

Drew Chemical Corp. began marketing a new blend of combustion catalysts, solvents, dispersants, and water-emulsifying agents to be added to fuel oil in industrial boilers. Use of the product reportedly improves combustion resulting in reduced fuel consumption, reduced corrosion and slag deposits in boilers, and reduces noxious and visible smoke pollution.[21]

NATIVE ASPHALT

Bituminous Limestone, Sandstone, and Gilsonite.— Natural rock asphalt and limestone rock asphalt were produced in Alabama, Missouri, and Texas, and were used for roadbuilding material. Gilsonite was produced in Utah. The total production of native asphalts and related bitumens in 1976 was 2,011,500 short tons with a value of $17,647,000.

Stocks of all oils:					
Crude oil and lease condensate	246,395	242,478	265,020	271,354	285,471
Unfinished oils	94,761	99,154	106,031	106,352	110,488
Natural gasoline[5]	4,802	6,160	6,480	6,217	6,649
Refined products	611,748	658,840	695,045	747,867	707,723
Plant condensate	1,273	1,675	1,070	1,165	1,479
Total	958,979	1,008,307	1,073,646	1,132,955	1,111,810

[p]Preliminary (except for crude oil and lease condensate production).
[1]U. S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U. S. Department of Commerce and Federal Energy Administration data for all other imports. Imports of crude oil include some Athabasca hydrocarbons.
[2]Represents the difference between total disposition and the indicated demand for crude petroleum.
[3]U. S. Department of Commerce data.
[4]Produced at petroleum refineries. Demand for ethane and liquefied gases used for petrochemical feedstocks are excluded. Demand data for these products for petrochemical feedstocks used are included under the items "Ethane" and "Liquefied Gases."
[5]Includes isopentane.

[p]Preliminary.
[1]U.S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U.S. Department of Commmerce and Federal Energy Administration data for all other imports. Imports of crude oil include some Athabasca hydrocarbons.
[2]Represents the difference between total disposition and the indicated demand for crude petroleum.
[3]Minus sign represents withdrawal from stock, which is added to total disposition; plus sign represents stocks increase, which is subtracted from total disposition.
[4]U.S. Department of Commerce data.
[5]Liquefied refinery gases.
[6]Liquefied petroleum gas.
[7]Produced at petroleum refineries. Demand for ethane and liquefied gases used for petrochemical feedstocks are excluded. Demand data for these products for petrochemical feedstocks used are included under items"Ethane" and "Liquefied gases."
[8]Includes isopentane.

[p]Preliminary except for crude petroleum production.
[1]Reported to the Bureau of Mines. Imports of crude oil include some Athabasca hydrocarbons.
[2]Represents the difference between supply and indicated demand for crude petroleum.
[3]U.S. Department of Commerce.

[p]Preliminary.
[1]Includes some Athabasca hydrocarbons.
[2]"Other hydrocarbons and hydrogen" is defined as including all hydrogen, process natural gas, tar sand bitumen, gilsonite, shale oil, and other naturally occurring hydrocarbon mixtures consumed as raw materials in the production of finished products.
[3]Production at gas-processing plants shown as direct transfers and omitted from the input and output at refineries.

Table 19.—Percentage yields of refined petroleum products from crude oil in the United States[1]

Finished products	1972	1973	1974	1975	1976[p]

Imports	--	655	2,340	720
Exports	1,187	1,207	1,124	1,112
Domestic demand	18,934	24,263	32,674	47,464
Unfinished oils (net):				
Input (+) Output (-)	+45,768	+37,351	+12,664	+7,599
Stocks, end of year	99,154	106,031	106,352	110,488
Imports	50,161	44,228	12,985	11,735

[p]Preliminary.

[1]Includes underground stocks at plants and refineries in thousand barrels. At plants: Ethane, 1975, 5,549; 1976, 11,180; propane, 1975, 68,765; 1976, 50,560; butane, 1975, 17,778; 1976, 12,100; butane-propane mixture, 1975, 162; 1976, 159; and isobutane, 1975, 6,891; 1976, 5,054. At refineries, (includes LRG): Propane, 1975, 4,822; 1976, 3,014; butane, 1975, 2,417; 1976, 2,260; butane-propane mixtures, 1975, 1; 1976, less than 1; and isobutane, 1975, 628; 1976, 103.

[2]Includes No.4 fuel oil, in thousand barrels: 1973, 3,499; 1974, 4,116; 1975, 5,035; 1976, 4,821.

[3]Includes foreign crude oil to be burned as fuel, in thousand barrels: 1973, 19,105; 1974, 7,508; 1975, 13,559; 1976, 5,553.

[4]Produced at petroleum refineries. Data for LRG petrochemical feedstocks are included with those for "Liquefied gases."

Note: "Stocks at refineries" include stocks at refineries and bulk terminals operated by refining and products pipeline companies including pipeline fill, and stocks at independent bulk terminals. "Stocks at plants" include stocks at plants and terminals operated by natural gas processing companies and natural gas liquids stocks at terminals of pipeline companies, including pipeline fill.

[1]Excludes direct imports by the military of naphtha-type jet into: P.A.D. I, 8,721,000 barrels; P.A.D. V, 1,506,000 barrels. Also excludes direct imports by the military of kerosine-type jet into: P.A.D. I, 100,000 barrels; P.A.D. V, 44,000 barrels.

[2]Includes 3,175,000 barrels sold to electric utilities, and 1,763,000 barrels sold as jet-grade kerosine.

[3]Excludes direct imports by the military of naphtha-type jet fuel into: P.A.D. I, 3,424,000 barrels; P.A.D. V, 1,795,000 barrels. Also excludes direct imports by the military of kerosine-type jet into: P.A.D. V, 904,000 barrels.

[4]Includes 4,234,000 barrels sold to electric utilities, and 651,000 barrels sold as jet-grade kerosine.

Definitions of terms used in this table:

Aviation gasoline—Any fuel in the gasoline boiling range for use in a piston-type aviation engine.

Jet fuel—Any fuel for use in an aviation turbine engine.

Airline—Sales to U.S. certified air carriers, including air freight carriers, and international air carriers (if delivery is made in the United States), and to such other air carriers as supplemental or non-scheduled carriers, air taxi, etc.

Factory—Direct sales to airframe and engine manufacturers. Does not include aviation fuels supplied to these accounts for the Defense Fuel Supply Center (DFSC).

General aviation—All nonmilitary sales which are not classified as airline or factory. Primarily made up of sales to distributors and airport dealers.

Military—Sales to Defense Fuel Supply Center and to other military agencies of the Government.

Nonaviation—Sales for use in turbine engines other than aviation turbine engines. Sales to electric utilities are included in this category.

Table 31.—Sales of distillate fuel oil[1] in the United States in 1972-76, by use

(Million barrels)

Use	1972	1973	1974	1975	1976
Heating[2]	543.3	536.9	493.2	488.4	544.3
Industrial (excluding oil-company use)	60.4	67.3	64.0	64.0	79.5
Oil-company use	13.4	14.9	13.8	13.6	13.5
Electric utility companies	68.3	77.9	84.7	[3]63.4	[4]60.5
Railroads	97.0	102.8	103.0	93.2	99.9
Vessels	22.2	26.8	24.8	26.1	27.0
Military	20.2	19.6	17.8	18.0	17.6
On-highway diesel	189.1	221.4	221.0	217.9	242.8
Off-highway diesel	50.2	55.5	48.7	49.0	54.4
All other	10.8	11.9	10.1	10.1	11.4
Total	1,074.9	1,135.0	1,081.1	1,043.7	1,150.9

[1]Includes diesel fuel.

[2]Includes range oil.

[3]Includes 19.7 million barrels of distillate No. 2, 2.5 million barrels of distillate No. 4 fuel oil used at steam-electric plants, and 3.2 million barrels of kerosine-type jet fuel used by electric utility companies.

[4]Includes 22.4 million barrels of distillate No. 2, 2.2 million barrels of distillate No. 4 fuel oil used at steam-electric plants, and 4.2 million barrels of kerosine-type jet fuel used by electric utility companies.

[P]Preliminary.
[1]Represents crude oil used as fuel on pipelines, which is considered part of the demand for distillate.
[2]No. 4 fuel oil, in thousands of barrels: PAD district I, 1975, 3,911; 1976, 3,935; PAD district II, 1975, 83; 1976, 59; PAD district III, 1975, 376; 1976, 594; PAD district IV, 1975, 9; PAD distric V, 1975, 656; 1976, 224.

[p]Preliminary.
[1]Represents crude oil used as fuel on leases and for general industrial purposes.
[2]Sulfur content in thousands of barrels: 0-0.50%, 1975: 108,943; 1976: 128,396, 0.51%-1.00%, 1975: 111,516; 1976: 118,951, 1.01%-2.00%, 1975: 123,469; 1976: 127,949, over 2.00%, 1975: 107,029; 1976: 128,657.
[3]Sulfur content in thousands of barrels: 0-0.50%, 1975: 173,760; 1976: 172,771, 0.51%-1.00%, 1975: 68,778; 1976: 106,898, 1.01%-2.00%, 1975: 67,511; 1976: 70,257, over 2.00%, 1975: 114,674; 1976: 146,475.
[4]Includes foreign crude oil to be burned as fuel, in thousands of barrels. District I: 6,588; District II: 6,312; District V: 659.
[5]Includes foreign crude oil to be burned as fuels, in thousands of barrels. District II: 5,553.

[p]Preliminary.
[1]Imports for onshore use of military jet fuel, distillate and residual fuel oils, and receipts from Puerto Rico, the Virgin Islands, and Guam included in these data are based on figures reported to the U.S. Department of the Interior. All other import figures are compiled from U.S. Department of Commerce data.

[p]Preliminary.
[1]Imports of crude oil, unfinished oils, and plant condensate are reported to the Bureau of Mines. All other import data are compiled from U.S. Department of Commerce and Federal Energy Administration data.
[2]Includes quantities imported duty-free for supply of vessels and aircraft engaged in foreign trade.

Phosphate Rock

By W. F. Stowasser[1]

The average unit value of marketable phosphate rock decreased from $22.99 per ton, f.o.b. plant in 1975 to $19.28 per ton, f.o.b. plant in 1976. Although the apparent consumption in 1976 was similar to that of 1975, international trade remained depressed and international prices declined, continuing the trend established in 1975. International prices were not published in 1976. Prices were established by negotiation in a highly competitive market and declined throughout the year.

It became apparent that in the United States and in the world phosphate rock was in more than adequate supply. Stocks in all producing countries increased, particularly in the uncontrolled and competitive industry in the United States. Although exports of phosphate rock declined from 1975 levels, integrated phosphate fertilizer producers in the United States continued, as they did in 1975, to export phosphate intermediates and concentrated phosphate fertilizer.

The price of phosphoric acid, triple superphosphate, and diammonium phosphate in the export market reached levels of $450 per ton, $350 per ton, and $400 per ton, respectively, f.o.b. U.S. gulf ports in 1974. Prices declined sharply in 1975 and, by mid-1976, the export price of phosphoric acid was down to the order of $175 per ton, triple superphosphate declined to $80 per ton, and diammonium phosphate sold for about $100 per ton, f.o.b. gulf ports. Integrated fertilizer producing firms in the United States exported at these price levels into Western Europe and Asian markets. Fertilizer producers in Western Europe and Japan were frequently unable to compete with imported products from countries with a raw material base because both phosphate rock import costs as well as energy costs were much greater than pre-1974 costs.

Estimated world production of phosphate rock in 1976 was 117.9 million short tons, about the same as the 118.3 million short tons produced in 1975.

Although Morocco acquired the phosphate mines in the Spanish Sahara in 1975, production from the Bu Craa mine was not a factor in world supply in 1976. The conveyor belt was damaged and truck transportation from the mine to the port of El Aaiún limited operations. It is estimated that Morocco exported from 15.5 to 16.0 million short tons of phosphate rock in 1976, an improvement over the 14.5 million short tons exported in 1975.

Legislation and Government Programs.—Environmental regulations enacted since 1969 have had a signficant impact on the phosphate industry. The National Environmental Policy Act (NEPA) of 1969 requires that a Federal agency prepare an Environmental Impact Statement (EIS) prior to taking any action that affects the environment such as granting preference right mining permits or leasing land for mining and processing purposes. It is common practice for the company requesting a permit to furnish all the information as a draft EIS. This is a major expense for a phosphate company and will require 2 to 4 years to produce, to pass through a review process, and to obtain approval. During this time, the changing costs and selling prices in the marketplace can reduce the economic incentives for the company to proceed with a mine and plant. This appears to be the situation that has developed during the past several years. Changing economics and shifts in the supply and demand for phosphate rock have made it likely that firms that initiated applications for permits to mine phosphate rock on

public or private land 2 or 3 years ago would not proceed if the permits were granted.

Applications to mine phosphate rock in the Los Padres National Forest of California, the Caribou National Forest in Idaho, and the Osceola National Forest in northern Florida, that have been pending for many years were not granted in 1976. A task force under the direction of the U.S. Geological Survey completed an EIS on developing phosphate resources in southeastern Idaho. A final EIS on mining phosphate rock in the Los Padres National Forest was completed in 1976. A 2-year study to determine the effects of potential phosphate mines in the Osceola National Forest on the aquifer's ability to supply water and the water demands of the two logical mining units was started in 1976. In North Carolina, the Corps of Engineers has delayed North Carolina Phosphate Corp.'s plans to develop a new mine and plant in order to study the issuance of dredge and fill permits for South Creek, a tributary of the Pamlico River.

In central Florida, phosphate rock was mined prior to 1976 only in Polk County. Two mines were permitted to be constructed in Hillsborough County and one of these was near completion at the end of 1976. Development of Regional Impact (DRI) statements, similar documents to EIS, were submitted for mines in Manatee and Hardee Counties, permits were not granted in 1976. The delay in permitting new mines in central Florida was further extended when, in May, President Ford ordered the Council on Environmental Quality to prepare an EIS on central Florida that established a moratorium on new mine development in this area.

Because of rapid population growth in Florida, high water demand from communities and industries, falling ground water levels, and deterioration of water quality, the State has developed one of the most comprehensive sets of laws and regulations to control development of resources. Regulatory power is distributed between local and State governments and special districts. The practical effect of this State legislation is that the phosphate industry must deal with a complex set of governmental regulations, including the Florida State Comprehensive Planning Act of 1972 and the Florida Environmental Land and Water Management Act of 1972. Policies affecting surface mining are established by these Acts. To strengthen the powers of local governments, the Local Government Comprehensive Planning Act of 1975 requires municipalities and counties to prepare and adopt plans to guide development. The Florida Water Resources Act of 1972 established State and regional programs to manage water resources and related land resources, including issuing permits for water used in mining. Florida has 67 counties and several hundred municipalities. By statutory authority, the local level of government can be a decisive factor in influencing the use of land and resources. Some counties have little or no land planning programs, some have adopted many types of land use control devices, and most have some type of planning and regulation. Analysis of local government involvement is discussed in a Geological Survey open file report.[2]

DOMESTIC PRODUCTION

Marketable phosphate rock production was 49,241,000 tons, an increase of 425,000 tons or 1% over that of 1975. The value of the marketable rock was $949,365,000, a decrease of 15.4% from that of 1975. The average grade of ore mined in the United States was 11.8% P_2O_5, and the average grade of marketable rock was 30.7% P_2O_5, about the same as that of 1975. The average weight recovery of concentrate and rock marketable as mined was 28.9%, an improvement over the 26.0% weight recovery in 1975. The average P_2O_5 recovery was 75.4% in 1976, considerably more than the 64% in 1975. In the United States, Florida and North Carolina produced 41,554,000 tons (84.4%) of the total marketable phosphate rock, the Western States produced 5,886,000 tons (11.9%), and Tennessee produced 1,801,000 tons (3.7%).

Florida and North Carolina.—Production of marketable phosphate rock was 41,554,000 tons, an increase of 2.1% over that of 1975. The value of marketable rock was $867,092,000, a decrease of $133,260,000 or 13.3% less than that of 1975.

The average grade of phosphate ore mined was 11% P_2O_5, somewhat less than the average grade of 11.8% P_2O_5 ore mined in 1975. The average grade of marketable rock was 31.3% P_2O_5, the same as the average grade produced in 1975.

The average weight recovery of concentrates and rock marketable as mined was 26.4%, an improvement over the average weight recovery of 23.4% in 1975. The average P_2O_5 recovery was 75%, a significant increase over the P_2O_5 recovery of 62.2% achieved in 1975. The improvement in weight and P_2O_5 recovery was attributed to normal operations in 1976 of mines that were started in 1975 and that stockpiled concentrate feed for processing in 1976.

Agrico Chemical Co.; Borden, Inc.; Brewster Phosphates; Florida Agglite Corp.; Gardinier, Inc.; W. R. Grace & Co.; International Minerals & Chemical Corp.; T. A. Minerals Corp.; Mobil Oil Corp.; Occidental Petroleum Corp.; Swift Agricultural Chemicals Corp.; and U.S.S. Agri-Chemicals, Inc., produced marketable phosphate rock from the Bone Valley Formation in central Florida and a similar matrix in northern Florida. Howard Phosphate Co.; Kellogg Co.; Loncala Phosphate Co.; and Manko Co., Inc. mined 29,000 tons of soft rock, a waste from nonoperating hard rock mines, in central Florida.

In North Carolina, Texasgulf, Inc. increased mining capacity with the addition of a 30-inch electric hydraulic dredge to strip the top 40 feet of overburden from the phosphate deposit and a 45-cubic-yard dragline. The mine, washer, and flotation plant capacity was increased to 5 million tons per year of product if operated in a single float mode. North Carolina Phosphate Corp., jointly owned by Agrico Chemical Co. and Kennecott Copper Corp., continued permitting procedures. All permits were issued except for a dredge and fill permit from the Corps of Engineers to deepen South Creek to prepare for barge traffic from the plant to Morehead City, the deepwater port on Pamlico Sound.

In northern Florida, Occidental Chemical Co., a division of Occidental Petroleum Corp,. opened the Swift Creek mine in early 1976, and after a temporary shutdown in

[2]Imhoff, E. A. An Analysis of Selected Laws and Governmental Programs in Florida, as Related to Mineral Resource Management and Surface Mining. U. S. Geological Survey Open File Rept. 76-648, 1976.

midyear, finally closed the mine at yearend as demand declined for phosphate rock. Occidental continued to operate the nearby Suwanee River mine.

In central Florida, Agrico Chemical Co. completed the first full year of operating the Fort Green mine and closed the Palmetto mine because reserves were exhausted. Construction continued on Brewster Phosphates' Fort Lonesome mine and Borden, Inc.'s Big Four mine in Hillsborough County. The Fort Lonesome mine is scheduled to start producing in early 1977, and the Big Four mine is planned to replace the Tenoroc mine in Polk County that is scheduled to be phased out in late 1977 or early 1978 as this reserve is depleted. C.F. Industries, Inc. purchased 19,555 acres of land in Hardee County for $101,547,592. The firm plans to initially produce 2 million tons per year of phosphate rock for its chemical plants at Bartow and Plant City, Fla. Farmland Industries purchased about 7,000 acres in Hardee County for $33.3 million. Plans are to mine the reserve in the 1980's. Freeport Phosphate Mining Co. announced a lease agreement with Limestone Land Co. to mine 6,200 acres in Hardee County. W.R. Grace completed construction of a new beneficiation plant near Bradley Junction, Fla. The Hooker Prairie deposit will be mined and treated at this new plant. In addition to the noted land acquisitions, Gardinier, Inc.; Mississippi Chemical Co.; Mobil Chemical Co.; United States Steel Corp. and International Minerals & Chemical Corp., all purchased substantial acres of phosphate land in Hardee County.

Western States.—Production of marketable phosphate rock was 5,886,000 tons, similar to the 5,825,000 tons produced in 1975.

The value of marketable rock decreased to $67,746,000, 27.2% less than the value in 1975. The average grade of mined phosphate ore was 22.3% P_2O_5. The average grade of mined phosphate rock used without beneficiation was 26.2% P_2O_5. The average grade of beneficiated rock was 31.8% P_2O_5. The average grade of all marketable rock was 28.1% P_2O_5. Of the total phosphate rock produced in the Western States, 65.9% was used directly and the balance, 34.1%, was beneficiated product. The weight recovery of the combined beneficiated concentrates and rock used as mined was 64.6% and P_2O_5 recovery was 81.1%.

Beker Industries Corp., Monsanto Co., J.R. Simplot Co., and Stauffer Chemical Co. mined and processed phosphate rock in Idaho. In Montana, Cominco American, Inc., recovered phosphate rock from underground mines near Garrision. Stauffer Chemical Co. mined phosphate rock in Wyoming and in two areas in Utah. Jon-T Phosphates, Inc. mined some phosphate rock in Van Buren County, Ark. Meramec Mining Co., Sullivan, Mo., recovered apatite concentrate from Pea Ridge iron ore mine tailings.

During the year, Beker Industries Corp.'s Maybie Canyon mine and fertilizer complex at Conda, Idaho, was closed when demand for fertilizer in the Western States declined in June of 1976. Jon-T Phosphates, Inc. also suspended production indefinitely when demand for phosphate rock slumped. A draft EIS, "Development of Phosphate Resources in Southeastern Idaho," prepared jointly by the U.S. Department of the Interior and the U.S. Department of Agriculture, presented an analysis of the broad cumulative impacts of existing and proposed phosphate resource development in southeastern Idaho, as well as an analysis of specific applications pending before the Federal Government. The final EIS had not been issued by the close of the year. No new mines were developed in the Western States in 1976.

Tennessee.—Production of marketable phosphate rock was 1,801,000 tons, a decrease of 490,000 tons or 21.4% less than reported in 1975. The value of the marketable rock decreased from $28,803,000 in 1975 to $14,527,000 in 1976, a decrease of 49.6%.

The average grade of mined ore was 20.4% P_2O_5, the average weight recovery of concentrates was 54.1%, and the recovery of P_2O_5 was 68.1%. A small quantity of phosphate rock was used in electric furnaces without beneficiation. The average grade of phosphate rock that was beneficiated and used directly was 25.8% P_2O_5.

Hooker Chemical Co.; M.C. West, Inc.; Monsanto Industrial Chemicals Co.; and Stauffer Chemical Co., mined and processed phosphate rock in Tennessee for reduction in electric furnaces to elemental phosphorus. The Tennessee Valley Authority closed its phosphate mines in Tennessee and its electric furnaces at Muscle Shoals, Ala.

[1]Includes Arkansas, California, Idaho, Missouri, Montana, Utah, and Wyoming.
[2]Data may not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Apparent consumption of marketable phosphate rock, defined as the quantity sold or used plus imports minus exports, increased only 125,000 tons to 34,328,000 tons in 1976. According to producers' reports, the quantity of phosphate rock sold or used in 1976 was 44,677,000 tons, a considerable reduction from the 46,439,000 tons sold or used in 1975. Of the total sold or used in 1976, 76.7% was consumed domestically and 23.3% was exported.

The consumption pattern as reported by producers is shown in table 3. Of the total sold or used, including both domestic and export markets, the distribution pattern in 1976 for the domestic segment was wet-process phosphoric acid 58.3%, normal superphosphate 2.6%, triple superphosphate

3.4%, defluorinated rock 0.7%, direct applications 0.1%, elemental phosphorus 11.1%, and ferrophosphorus 0.5%, for a total of 76.7% or 34,277,000 tons.

The percent distribution by grade of marketable phosphate rock consumed in the United States and sold in the export market in 1976 is compared with the distribution patterns in 1974 and 1975 in the following tabulation:

Grade, percent BPL[1] content	Distribution (percent)		
	1974	1975	1976
Less than 60	5.6	9.4	7.8
60 to 66	20.8	14.7	14.6
66 to 70	42.0	48.4	53.8
70 to 72	12.2	10.8	9.4
72 to 74	11.6	10.7	8.3
Over 74	7.8	6.0	6.1

[1]1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Florida and North Carolina.—The quantity of phosphate rock sold or used decreased from 37,921,272 tons in 1975 to 37,392,197 tons in 1976. Of the total sold or used in 1976, 74.1% was consumed domestically and 25.9% was exported. Of that consumed domestically, 24,311,000 tons (87.8%) was used to produce wet-process phosphoric acid, 1,141,000 tons (4.1%) for normal superphosphate, 1,450,000 tons (5.2%) for triple superphosphate, 319,000 tons (1.2%) for defluorinated rock, 38,000 tons (0.1%) for direct applications, and 451,000 tons (1.6%) for elemental phosphorus and ferrophosphorus.

The percent distribution by grade of the marketable rock sold or used from Florida and North Carolina in 1974, 1975, and 1976 is shown in the following tabulation. Exports are included in this distribution pattern:

Grade, percent BPL[1] content	Distribution (percent)		
	1974	1975	1976
Less than 60	0.2	0.1	0.2
60 to 66	17.0	14.8	13.4
66 to 70	47.2	55.0	60.2
70 to 72	14.3	11.2	11.2
72 to 74	11.9	11.5	7.7
Over 74	9.4	7.4	7.3

[1]1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Western States.—The quantity of marketable phosphate rock sold or used decreased from 6,124,140 tons in 1975 to 5,376,922 tons in 1976. Of the total sold or used in 1976, 86.6% was consumed in the United States and 13.4% was exported.

Of that consumed in the United States, expressed as a percent of the total sold or used from the Western States, 1,718,768 tons (32.0%) was used for wet-process phosphoric acid, 41,000 tons (0.8%) was used for normal superphosphate, 53,000 tons (1.0%) was used for triple superphosphate, 6,000 tons (0.1%) was used for direct applications, 2,754,299 tons (51.2%) was used to produce elemental phosphorus, and 85,185 tons (1.6%) was collected in ferrophosphorus.

The percent distribution by grade of marketable rock sold or used from the Western States in 1974, 1975, and 1976 is shown in the following tabulation:

Grade, percent BPL[1] content	Distribution (percent)		
	1974	1975	1976
Less than 60	35.8	38.8	37.7
60 to 66	22.5	13.2	18.5
66 to 70	23.5	25.9	28.5
70 to 72	3.5	12.2	--
72 to 74	14.3	9.9	15.3
Over 74	0.4	--	--

[1]1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Tennessee.—The quantity of marketable phosphate rock sold or used declined from 2,393,000 tons in 1975 to 1,908,000 tons in 1976. All of the rock was used in electric furnaces to produce elemental phosphorus and industrial chemicals. Most of the elemental phosphorus was converted into phosphoric acid, the base for sodium and calcium phosphates and anhydrous derivatives.

The percent distribution by grade of marketable rock sold or used in Tennessee in 1974, 1975, and 1976 is compared in the following tabulation:

Grade, percent BPL[1] content	Distribution (percent) 1974	1975	1976
Less than 60	19.7	80.9	72.1
60-66	75.6	17.5	26.8
66-70	4.7	1.6	1.1
70-72	--	--	--
72-74	--	--	--
Over 74	--	--	--

[1]1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

1974	2,607	708	20,594	7.90
1975	2,393	617	29,921	12.50
1976	1,908	494	15,326	8.03

STOCKS

Stocks of marketable phosphate rock in the United States increased from 9,946,045 tons at the beginning of the year to 15,181,760 tons at yearend. At the end of 1976, inventories reported were larger than in prior years. It was the second consecutive year of a significant increase in inventory levels.

In Florida and North Carolina, stocks increased from 8,533,323 tons at the beginning of the year to 13,296,312 tons at yearend. In Tennessee, stocks declined from 307,364 tons to 280,567 tons during the year. Stocks in the Western States increased from 1,105,358 tons to 1,604,881 tons during the year.

PRICES

The prices of phosphate rock sold in either the domestic or export markets were not published. The selling price, negotiated between the producer and consumer, is not public information. Although some producers publish price lists, contractual prices are not required to follow published prices. An indication of domestic price levels for phosphate rock was published in the Chemical Marketing Reporter. Table 8 shows prices for Florida land-pebble phosphate rock at the end of 1976.

A similar price tabulation was not available for phosphate rock produced in other parts of the country. Phosphate rock in Tennessee is normally used in local electric furnaces as is a large part of the production from the Western States. Some phosphate rock from the Western States enters the merchant rock market but not in quantities comparable with those from Florida. Most of the production in North Carolina is captively consumed by Texasgulf, Inc. and converted into higher value products.

The producing companies report the grade and value[3] of marketable phosphate rock semiannually to the Bureau of Mines. The average 1976 unit value of marketable rock reported by producers, and estimated if unspecified, was $19.28 per ton f.o.b plant, 16.1% less than the $22.99 per ton value reported in 1975. The average unit value of land-pebble rock reported sold or used in the domestic and export market from Florida and North Carolina decreased from $24.46 per ton in 1975 to $20.73 per ton in 1976. The average value of all marketable rock sold or used from Florida and North Carolina, including soft rock was also $20.73 per ton. In the Western States, the unit value of marketable rock sold or used decreased from $15.64 per ton in 1975 to $12.42 per ton in 1976. The unit value of marketable rock sold in Tennessee declined from $12.50 per ton in 1975 to $8.03 per ton in 1976.

The average unit value of phosphate rock exported from the United States decreased from $34.98 per ton in 1975 to $26.23 per ton in 1976, a 25% decrease. The unit value of marketable rock exported from Florida and North Carolina decreased from $36.57 per ton in 1975 to $26.34 per ton in 1976. The unit value of phosphate rock exported from the Western States increased from $19.32 per ton in 1975 to $24.84 per ton in 1976. Tennessee rock was not exported.

The Phosphate Rock Export Association published an export price schedule effective January 1, 1976. This schedule is shown in table 9. Although the Phosphate Rock Export Association did not publish new price schedules during the year, price reductions were made in April and December 1976. Estimates of the price schedules are also shown in table 9. Price estimates are averages as each contract is independently negotiated between buyer and seller and adjustments for factors other than grade are normal.

Early in 1976, the Office Cherifien des Phosphates of Morocco published phosphate rock price schedules that were to be effective as of January 1976. These are shown in table 10. International phosphate rock price erosion that began in 1975 continued into 1976 and, as the year progressed, Moroccan export prices declined to the estimated levels shown in table 10 at yearend.

At the end of 1976, international demand for phosphate rock was weak and a further decline in prices appeared certain early in 1977.

FOREIGN TRADE

Phosphate rock producers reported 10,400,000 tons were exported in 1976, a decline of 15.3% from the 12,272,000 tons exported in 1975. Of the total exported in 1976, 93.1% was shipped from Florida and North Carolina and 6.9% originated in the Western States. Exports of phosphate rock from Florida declined, phosphate rock exports from North Carolina are either small tonnages or not a factor in this market, and exports from the Western States declined 36.8% compared with exports in 1975.

The average calculated unit value of exported phosphate rock in 1976 was $26.23 per ton, a significant reduction from the comparable value of $34.98 per ton calculated from reported tons and value in 1975.

The United States imported 51,000 tons of phosphate rock in 1976, somewhat more than the 37,000 tons imported in 1975. The unit values in 1976 and 1975 were $43.59 and $43.83 per ton, respectively. Most of the phosphate rock was imported from the Netherlands Antilles.

WORLD REVIEW

Phosphate rock producing countries have developed beneficiation systems for their particular type of phosphate deposits to raise the P_2O_5 content of the concentrate to levels acceptable for production of phosphoric acid and conversion into fertilizer end products. Dried concentrates were exported from producing countries to support fertilizer industries in areas that do not have phosphate deposits of commercial value. This pattern of production and distribution appeared to be changing as producing companies and countries were increasingly processing the concentrates into phosphoric acid, which can be exported, or utilizing the phosphoric acid to produce monoammonium phosphate, diammonium phosphates, or granular mixed fertilizers for export. The vertical integration of phosphate rock producers, as typified in the United States, was expanding into other phosphate producing countries. Tunisia was the first North African country to produce phosphoric acid at Gabes. Other producers that have traditionally exported phosphate rock planned to establish fertilizer plants; these included Algeria, Morocco, Jordan, and the Republic of South Africa. It now appears that the past practice of processing phosphate rock into fertilizer close to the consuming market in industrialized countries is changing to increased vertical integration of the industry in the countries with a raw material base.

Australia.—BH South Ltd., has outlined phosphate reserves in northwest Queensland totaling over 2 billion tons of phosphate rock with an average 17.1% P_2O_5 content. The deposits are all located in the Georgian Basin. The southern most deposits at Duchess and Ardmore are of immediate interest and Queensland Phosphate Ltd., a wholly-owned subsidiary of BH South Ltd. mined direct shipping ores from the Duchess deposit. The central reserves of the Lady Annie and Lady Jane deposits are north of Mount Isa, and further north are smaller reserves of Highland Plains, Babbling Brooke Hill, Mount O'Conner, Mount Jennifer, Phantom Hills, and Riversleigh.

With completion of the 42-mile railroad extension to the Duchess deposit, shipments from the mine to Townsville were expected to attain a rate of 1 million tons per year in 1976 and 2 million tons per year by 1978. It is not likely that the Lady Annie or Lady Jane deposits will be developed until the early or mid-1980's.[4]

Brazil.—Industrial production of phosphate rock is presently limited to the Serrana S.A. de Mineração installation at the Jacupiranga mine and the Camig plant close to Araxá. Only at the Jacupiranga mine, 250,000 tons per year, is a concentrate suitable for production of phosphoric acid produced. From the Barreiro mine in Araxá rock is ground for direct application, 40,000 tons per year, and the balance, 30,000 tons per year, is sold for reduction in an electric furnace. The following new projects were reported by World Mining.[5] From the Araxá-Barreiro mine, Arafertil-Araxá S.A. Fertilizantes e Productos Quimicos has a lease and plans to produce 550,000 tons per year of 34% P_2O_5 concentrates that will be used in an integrated acid and fertilizer plant. Production is scheduled for 1977. The

5Abib, P. Brazil's Busy Phosphate Industry. World Min., v. 30, No.2, February 1977, pp. 46-49.

Catalão-Metago mine owned by Metais de Goias S.A. is planning to produce from 400,000 to 600,000 tons of 34% P_2O_5 concentrate per year starting in 1978. From the Tapira-Valep mine, Cia. Vale do Rio Paranaiba S.A. intends to produce 1,000,000 tons per year of 36% P_2O_5 concentrate. It is scheduled to start producing in 1978. Preliminary plans are being made by Serrana to develop the Ipanema deposit and others are investigating the potential at Patos de Minas and the northern Pernambuco deposit.

Canada.—In August 1975, International Minerals & Chemical Corp. (Canada) Ltd., reported a phosphate deposit in a carbonatite complex in Cargill Township, Ontario. Drilling and trenching programs were conducted in 1976 to define the orebody.

Egypt.—Phosphate rock production has declined from about 1.6 million tons in 1968 to 559,000 tons in 1974 as the ore deposits at Kusair and Sofaga on the Red Sea were depleted. A new phosphate mine and plant started in February 1976 at Hamrawein and was expected to raise production to pre-1968 levels.[6] Another major event was the completion of a contract to study the feasibility of mining, processing, and shipping phosphates from the Abu Tartur deposits in the south-central part of Egypt west of the Nile River. The deposit, although large, contains, unfortunately, high concentrations of iron, alumina, and clay, and unless procedures are developed to eliminate these problem materials the viability of the deposit remains in doubt.

Greece.—The Institute of Geological and Mineral Research located commercial phosphate rock deposits at Epirus in Northern Greece. The deposit is located about 37 miles north-northwest of Ioannia and preliminary investigations indicate the reserve is 10 million tons of 15% P_2O_5 ore that can be upgraded to plus 30% P_2O_5.[7]

India.—India's first phosphate beneficiation plant at Udaipur went onstream. The plant is designed to process about 660 tons per day of 20% P_2O_5 ore to a product grading 34% P_2O_5. The concentrates will be used to produce phosphoric acid and superphosphates.[8]

Iraq.—Plans to exploit the phosphate rock deposits at Akashat have been made. Work on the mine to produce 3.7 million tons per year of phosphate rock started in 1976. Concurrently, an associated fertilizer complex reportedly will be constructed. Both the mine and initial fertilizer complex are scheduled to start up in mid-1980.[9]

Israel.—Negev Phosphate Co. Ltd. was granted a loan from the Export Import Bank of the United States to assist in financing the expansion of the phosphate mine and beneficiation plant at Nahal Zin. Production will be doubled to 2 million tons per year of concentrates.[10]

Jordan.—The Jordanian Phosphate mines plan to increase phosphate rock production to about 5 million tons per year by expansion of the El-Hassa mine and by opening a new mine at Al-Sheidieh.[11]

Mexico.—Press reports that began in 1974, describing the discovery of a phosphate rock reserve in the Baja California peninsula of Mexico, have continued through 1976. The most recent report indicated the reserve may be 100 million tons. An experimental pilot plant is scheduled to start in 1977 to process rock from the Baja peninsula deposit.[12]

Morocco.—The Office Cherifien des Phosphates has plans to develop a series of new phosphate rock mines, plants, and new port facilities to handle future exports of phosphate rock and solid and liquid phosphate intermediates.

The Khouribga mines are located on the Oulad Abdoun Plateau, between Khouribga and Oued Zem. The two principal open pit mines are Sidi Daoui and Mera el Arech. A new open pit mine, Recette IV, located between Sidi Daoui and Mera el Arech, is being developed. About 30% of Khouribga's production was from underground mines. A new drying plant, similar to the Beni Idir drying plant, was under construction at Oued Zem and will treat the production from Recette IV.

The Youssoufia underground mines are located on the Ganntour plateau. Approximately 70% of the ore was from underground mines and 30% was recovered from surface contour mines. Plans to continue mining the white ore above the water table will continue; however, an increasing quantity of black ore, unoxidized and relatively high in hydrocarbon content, from below the water table will be mined in the future. The black ore will be calcined in fluid bed reactors. The first reactor is scheduled to operate for a full year in 1977.

[12]Industrial Minerals, No. 110, November 1976, p. 42.

A new mine, Benguerir, is scheduled to start production in 1978 or 1979. Initial production will be 2.9 million tons per year. Ultimately, the mine is expected to produce from 10 to 12 million tons per year. The ore from this open pit will be shipped about 56 miles to a beneficiation plant, located on the hill behind the chemical plant, Maroc Phosphore II, near the port of Safi. Salt water will be used to wash the ore. The grade will be increased from 64% bone phosphate of lime (BPL) to 67% BPL with reductions in iron, aluminum, and magnesium oxide content before it is used to produce phosphoric acid.

A new port is to be developed south of Casablanca at Jorf Lasfar to break the shipping bottlenecks that have developed at Casablanca and Safi. These bottlenecks are expected to worsen as production from new mines increases in the next decades. A beneficiation plant is planned at Jorf Lasfar to treat ore mined at Sidi Hajjaj in the early 1980's.

Pakistan.—The Hazara phosphate deposits situated near Abbotabad were drilled and mapped by a British company in 1976. The survey, expected to be completed in 1978, will cover an area of 60 square miles. An appraisal of these deposits will be completed before the design, construction, and training programs for mines and plants are initiated.[13]

Peru.—According to a press release published in Lima on December 17, 1976, Minero Perú and the National Institute of Industry in Spain, through the Empresa Nacional Adaro de Investigaciones Mineras S.A. (ENANDINSA) signed an agreement for the exploitation of the Bayovar phosphate deposit. ENANDINSA will finance and perform the feasibility study over a 10-month period. When the study is completed, a mining company will be formed with Minero Perú on a 49% to 51% basis to develop the deposit. The Spanish will finance the project. The initial production will be 850,000 tons per year of concentrates. A construction schedule of from 3 to 4 years is contemplated.[14]

South Africa, Republic of.—The Phosphate Development Corp. Ltd. (Foskor), commissioned two phosphoric acid facilities which will use phosphate rock from the Phalaborwa deposits. The Federale Kunsmis phosphoric acid plant, an extension of the Bosveld Kunsmis fertilizer complex, started producing in late 1976. The plant capacity is 300,000 tons per year of acid. The Triomf Fertilizer's phosphoric acid plant at Richards Bay went into full production at the end of the year. The capacity is 750,000 tons per year of acid.[15]

Spanish Sahara.—It was reported in midyear that the Office Cherifien des Phosphates made the decision to move phosphate rock from the Bu Craa mine to the port of El Aaiun by trucks after the 62-mile-long conveyor belt was damaged by guerilla attacks. The tonnage moved by trucks was not reported. It was not clear if this effort to replace stocks at El Aaiun was continued for the balance of the year. With only a moderate demand for phosphate rock in 1976, Morocco was able to ship phosphate rock from Casablanca and Safi to meet the commitments for Bu Craa phosphate rock.

Syria.—From a production level of 20,000 tons in 1971, Syria produced 857,000 tons in 1975, but short of the Government's goal of 1.3 million tons. By 1980, Syria plans to produce at the rate of 3 million tons per year. Production was from three plants with a combined capacity of 2 million tons per year. All are located near Palmyra in central Syria. Concentrates are trucked to the port of Tartous and this will continue until a railway is completed in 1978.[16]

Tunisia.—The capacity of Tunisian phosphate mines is projected to increase from a level of 4 million tons per year in 1977 to 6.3 million tons per year in 1980, and 7 million tons per year in 1981. Most of the additional production to achieve the planned increases will come from the underground Sehib mine and Kef Schfair, an open pit mine. Some additional capacity will be created by mechanization of mining systems in the underground mines of Metloui, M'Dilla, Redeyef, M'rata, Moulares, and Kalaa Djerda.

U.S.S.R.—To meet the demand forecast in 1980 for chemical fertilizers and mineral feed supplements, the U.S.S.R. plans to increase production of phosphorus bearing raw materials according to an article by L. Kostandov, the Minister of Chemical Industry of the Soviet Union, published in the weekly paper, Economicheskaya Gazeta, in January 1976. Information about the supply of phosphate rock in the U.S.S.R. is meager; however, from available information, it appears that the Soviet Union will find it increasingly difficult to meet its own phos-

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Belgium, Indonesia, and Tanzania may have continued to produce phosphate rock, and South West Africa produced guano, but output is not officially reported and available information is inadequate for formulation of reliable estimates of output levels.

[2]Less than 1/2 unit.

[3]Revised to none.

[4]Estimate by International Superphosphate Manufacturer's Association on the basis of a marketable product averaging 34.8% P_2O_5; differs with data reported in the U.S.S.R. chapter of Volume III of the Minerals Yearbook which are reported in terms of two products of differing grade.

[5]Exports.

[6]Local sales and exports of phosphate concentrate and direct-sale ore.

phate rock demands. Production from the Kola Apatite Combine, an 86% BPL rock, was equally divided between domestic and export markets. Exports reached a peak of about 7.3 million tons in 1973, and declined in 1974 and 1975. The production target for the Kola Apatite Combine was about 16.9 million tons and, if achieved, was an increase of 4.4 million tons more than was produced in 1970. The target for 1980 is about 20 million tons, an increase of 3.0 million tons over that of 1975. Other sources of phosphate rock will be required to satisfy the demands of the fertilizer industry in the U.S.S.R. It was estimated that 9.7 million tons were produced from the Kara Tau phosphate mines in 1975 and if the U.S.S.R.'s goal of meeting a demand of 37 million tons in 1980 is to be realized, Kara Tau phosphate mines will have to produce an additional 7.9 million tons. Unlike the Kola concentrates that are high-grade and have exceptionally low iron and magnesium oxide analysis, Kara Tau mines supply a low-grade phosphate rock, 28% P_2O_5, that contains 2.2% MgO and 1.5% Fe_2O_3. The low-grade and undesirable impurities are especially troublesome when phosphoric acid is produced and fertilizers manufactured.

TECHNOLOGY

The Albany Metallurgy Research Center of the Federal Bureau of Mines, Albany, Org., conducted programs to improve the recovery of phosphate and byproducts such as fluorine, vanadium, and chromium from phosphate deposits in the Western States. Operating companies in the Western States furnished samples to the Center and these were characterized for potential beneficiation procedures. The samples from nine locations varied in composition and were characterized as low-grade, carbonaceous, and weathered; weathered carbonaceous phosphate shale, partially weathered with interbedded limestone; a pelletal phosphate in a weathered siliceous matrix; and a hard partially liberated, high CaO and MgO content, with carbon ranging from 4% to 14%. A beneficiation process was selected for each sample to obtain an indication of the concentrate grade and recovery from the selected process. The processes ranged from scrubbing and sizing to calcining, grinding, and flotation. A 60-pound-per-hour flotation circuit was set up to develop a combination carbonate-silica flotation process. Methods to improve the liberation of phosphate minerals from unweathered phosphate bearing rock were studied. These included preliminary studies of the effect of leaching and attrition grinding prior to flotation.

The Center also produced feed-grade monocalcium phosphate from Western phosphate concentrates, determined that fluorine retention in triple superphosphate was affected by the iron and aluminum levels in phosphoric acid, and separated vanadium from Western phosphate slime tailings by selective leaching.

Studies to determine the feasibility of producing phosphoric acid from Florida unbeneficiated land-pebble matrix by digesting with sulfuric acid continued. The objective was to minimize phosphate losses and produce a waste product that could be easily used in land reclamation programs and that would not require the impoundment procedures needed to hold waste slimes from Florida washing plants. During the year, filtration rates of matrix-derived phosphoric acid and gypsum residue were progressively improved and approached industry filtration rates normal for acid produced from phosphate concentrates. Excessive aluminum content of matrix-derived phosphoric acid was lowered to levels normally found in commercial acid by liquid-liquid extraction with octyl phenyl phosphoric acid. It was found that iron was concurrently reduced.

The study to determine the effects of reagent additions to high-grade attapulgite slime from the Florida phosphate field was continued at the Tuscaloosa, Ala. Metallurgy Research Center. Organic, inorganic, and commercial reagents were tested. The viscosity, conductivity, and pH of the reagent slime mixtures were measured at different reagent concentrations. After adjustment to different pH levels, the mixtures were centrifuged to simulate a 30-day settling test. The results of these tests were not encouraging as the dewatering rates did not significantly improve. One reagent, polyethylene oxide, was superior when used to flocculate and dewater high-grade attapulgite and montmorillonite slimes as well as Florida phosphate plant slimes. Favorable results were obtained from tests to develop a continuous process to dewater slimes using polyethylene oxide. A phosphate slime of 5% solids and the flocculant solution were combined in a launder, additionally mixed in a low pressure cyclone-type apparatus and fed to a rotating trommel. The flocculated material dewatered rapidly, forming rolls and balls as the material moved down the trommel. The trommel was equipped with a 10-mesh screen to separate the water from the agglomerates that were 25% to 30% solids. At slime feed rates of 1.5 and 3.0 liters per minute, reagent consumption was approximately 1 and 2 kilograms per metric ton respectively. Successful continuous dewatering treatment depends on adequately mixing reagent and slimes and then immediately separating released water from the dewatered solid fraction.

The Center developed a filtration procedure to evaluate the effect of reagents on the settling behavior and mineral composition of slimes. Investigations on static filtration, wicking, and compaction systems to dewater phosphate slimes were continued with emphasis on movement of slimes through a stationary screen barrier.

Characterization studies of the phosphate-bearing Hawthorn Formation limestone continued at the Tuscaloosa Center in cooperation with the Florida State Bureau of Geology. Beneficiation studies of grab samples that contained at least 5% P_2O_5 were made by grinding, scrubbing, and desliming prior to flotation. Acceptable phosphate-grade and recoveries were obtained on some samples with single-stage flotation after dolomite removal.

Platinum-Group Metals

By W. C. Butterman[1]

World mine production of platinum-group metals increased 4% in 1976 compared with that of 1975, to 6 million troy ounces. As in past years, three countries accounted for 99% of the entire output - the Republic of South Africa, the U.S.S.R., and Canada. World demand for platinum-group metals partially recovered from the depressed level of 1975, owing largely to increased demand in the United States, where apparent consumption including industry stock changes rose 24%, to 2.1 million troy ounces. Consumption in Japan remained at about the 1975 level of 1.9 million troy ounces.

In the United States, mine production dropped 68% compared with that of 1975, to 6,116 troy ounces; refinery production, derived almost entirely from secondary materials, and including both toll and nontoll metal, decreased 16%, to 1.09 million troy ounces. Imports increased 47%, to 2.7 million troy ounces, while exports fell 22%, to 0.5 million troy ounces. Sales of metal and metal products to industry increased 22% over those of 1975, to 1.6 million troy ounces, and industry stocks rose 28%, to 1.1 million troy ounces.

[1]Physical scientist, Division of Nonferrous Metals.

rRevised.
[1]The platinum group comprises six metals: Platinum, palladium, iridium, osmium, rhodium, and ruthenium.
[2]Recovered from platinum placers and as byproducts of copper refining.

Legislation and Government Programs.— In 1976, as in previous years, U.S. Government inventories of platinum, palladium, and iridium remained unchanged. All three metals were in excess of stockpile goals established in 1973. In October, the Federal Preparedness Agency published revised goals for stockpiled platinum-group metals. The new goals (1,314,000 troy ounces of platinum, 2,450,000 ounces of palladium, and 97,761 ounces of iridium) were several times larger than the pre-October goals, and substantially larger than the inventories.

U.S. motor vehicle emissions standards, as provided for in the Clean Air Act of 1970, have a direct bearing on the amounts of platinum-group metals used as emissions-control catalysts, and even on the combinations of metals used; for example, rhodium may displace palladium in the catalysts if more stringent emissions standards require the use of so-called three-way catalytic converters. Thus, the platinum metals industry followed with interest the months-long debate in the U.S. Congress about future emission standards. Congress adjourned in early October without having amended the Clean Air Act; as the matter stood at yearend 1978 model automobiles will be required to meet emission standards considerably more stringent than those set for the 1977 models.

Table 2.—U.S. Government inventory of platinum-group metals, December 31, 1976

(Troy ounces)

	Platinum	Palladium	Iridium
National stockpile	[1]402,646	[2]507,314	[3]17,002
Supplemental stockpile	49,999	747,680	--
Total	452,645	1,254,994	17,002

[1]Includes 13,043 troy ounces nonstockpile-grade material.
[2]Includes 2,204 troy ounces nonstockpile-grade material.
[3]Includes 12 troy ounces nonstockpile-grade material.

DOMESTIC PRODUCTION

Domestic mine production of platinum-group metals, largely a byproduct of copper mining, decreased 68% in 1976, to 6,116 ounces. The Goodnews Bay Mining Co. placer platinum mine in Alaska, the only domestic deposit mined principally for the platinum-group metals, was shut down early in the year. The Johns-Manville Corp. studied the feasibility of mining its claims in the Beartooth Mountains of southern Montana, but at yearend had not announced whether mine development would proceed. Grade of ore in the mineralized horizon, which had been traced over 24 miles, averaged 0.43 to 0.46 troy ounce of platinum plus palladium per ton, with 0.15% copper plus nickel. The platinum-to-palladium ratio in samples was 1 to 3.5.

U.S. refinery production, including toll-refined metal, fell 16%, to 1.09 million troy ounces; 98% of this was secondary metal. Secondary metal refined on a nontoll basis fell 20%, to 215,355 ounces; toll-refined secondary metal dropped 14% to 859,432 ounces. Refined primary metal totaled 17,333 ounces, most of which was of domestic origin.

Table 3.—Platinum-group metals refined in the United States

CONSUMPTION AND USES

Sales of platinum-group metals to domestic industries increased 22% over those of 1975, to 1.6 million troy ounces. Sales of five of the six metals increased by the following percentages: Platinum, 22%; palladium, 21%; iridium, 11%; rhodium, 11%; and ruthenium, 100%. Osmium sales declined 26%. Of particular importance were sales of platinum and palladium to the automotive industry for use in emission-control catalysts; these were nearly double the 1975 level, owing partly to an increase in automobile production and partly to the depletion of the large inventories of platinum and palladium held by the automobile manufacturers in early 1975. The automotive industry accounted for more than 50% of platinum sales, and more than 25% of palladium sales; thus, for the third consecutive year, it was the largest domestic purchaser of platinum-group metals, accounting for 42% of total sales. It was followed, in order of importance, by the electrical industry (18%), the chemical industry (15%), the dental-medical industry (10%), the petroleum refining industry (4%), and other industries (11%). Platinum sales comprised 53% of total sales, followed by palladium (41%), rhodium (3%), ruthenium (3%), iridium (less than 1%), and osmium (less than 1%).

The uses of the platinum-group metals in 1976 were related to their outstanding catalytic properties, refractoriness, and resistance to chemical corrosion. The patterns of usage of the two principal metals, shown in figure 1, were similar to the patterns of recent years, except that catalyst use of palladium displaced electrical use as the most important end use of that metal.

r Revised.
[1] Comprises primary and nontoll refined secondary metals.
[2] Revised to zero.

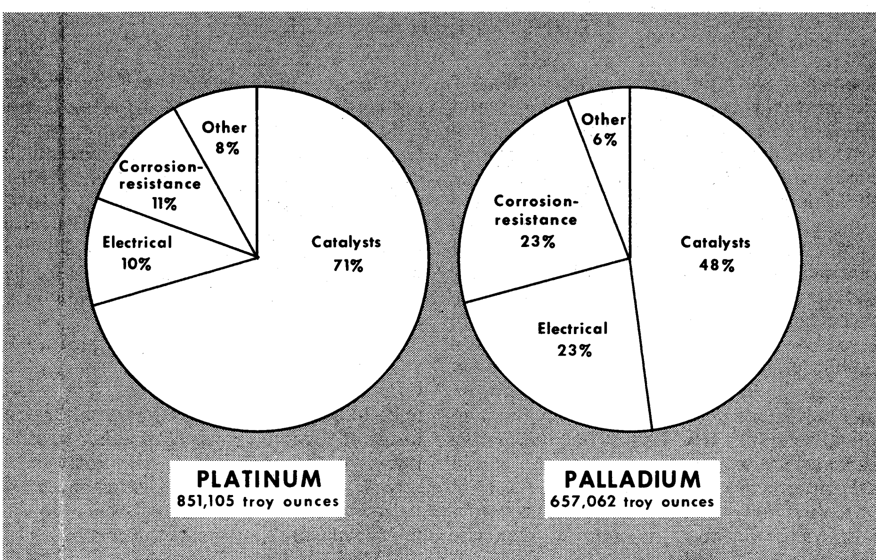

Figure 1.—Uses of platinum and palladium in 1976.

STOCKS

Stocks of platinum-group metals held by refiners, importers, and dealers increased 28% in 1976 compared with those of 1975. Rhodium stocks fell 11% and osmium stocks fell 30%, but stocks of the other four metals increased, as follows: Platinum (27%); Palladium (37%); iridium (11%); ruthenium (5%). It should be noted that these are partial industry stocks, since the Bureau of Mines does not collect inventory data from end users of the platinum-group metals, some of whom may hold sizable inventories. In addition, there were the Government stockpiles of platinum, palladium, and iridium.

Table 5.—Refiner, importer, and dealer stocks of platinum-group metals in the United States, December 31[1]

Year	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total
1972	426,611	405,793	14,987	82	56,967	26,413	930,853
1973	446,522	493,078	14,813	327	51,504	26,880	1,033,124
1974	532,675	478,210	18,159	869	55,791	36,102	1,121,806
1975	420,770	335,621	18,276	627	53,847	20,069	849,210
1976	536,318	459,765	20,318	439	47,769	21,094	1,085,703

[1]Includes metal in depositories of the New York Mercantile Exchange; on Dec. 30, 1976, this comprised 172,100 troy ounces of platinum and 20,500 troy ounces of palladium.

PRICES

The producers' price for platinum was quoted at the beginning of the year at $155 per troy ounce, was raised to $165 in June, to $170 in July, and then lowered to $162 at the beginning of November. The producers' palladium price began the year at $50 per troy ounce, was lowered to $40 in April, raised to $45 in May, and to $55 in June. The rhodium price at the beginning of the year was $300 per troy ounce, and was increased to $350 at the beginning of July, and to $400 on July 20. The iridium price went from $400 per troy ounce to $300 at the beginning of April. Producers' ruthenium and osmium prices remained unchanged throughout the year at $60 and $200 per troy ounce, respectively.

Dealers' prices for platinum and palladium remained below producers' prices, except for a few weeks near midyear. Dealers' prices for rhodium and iridium, which began the year far below producers' prices, began to rise in the second quarter and were above producers' prices in the third quarter before falling below producers' prices again in the fourth quarter. Dealers' prices for ruthenium and osmium remained, as in recent years, below producers' prices all year. Average prices for the year, calculated at the low ends of the ranges of weekly averages published by Metals Week, follow:

	Producer (per troy ounce)	Dealer (per troy ounce)
Platinum	$161.73	$153.38
Palladium	50.93	47.29
Iridium	325.00	271.09
Osmium	200.00	129.42
Rhodium	347.50	309.68
Ruthenium	60.00	36.55

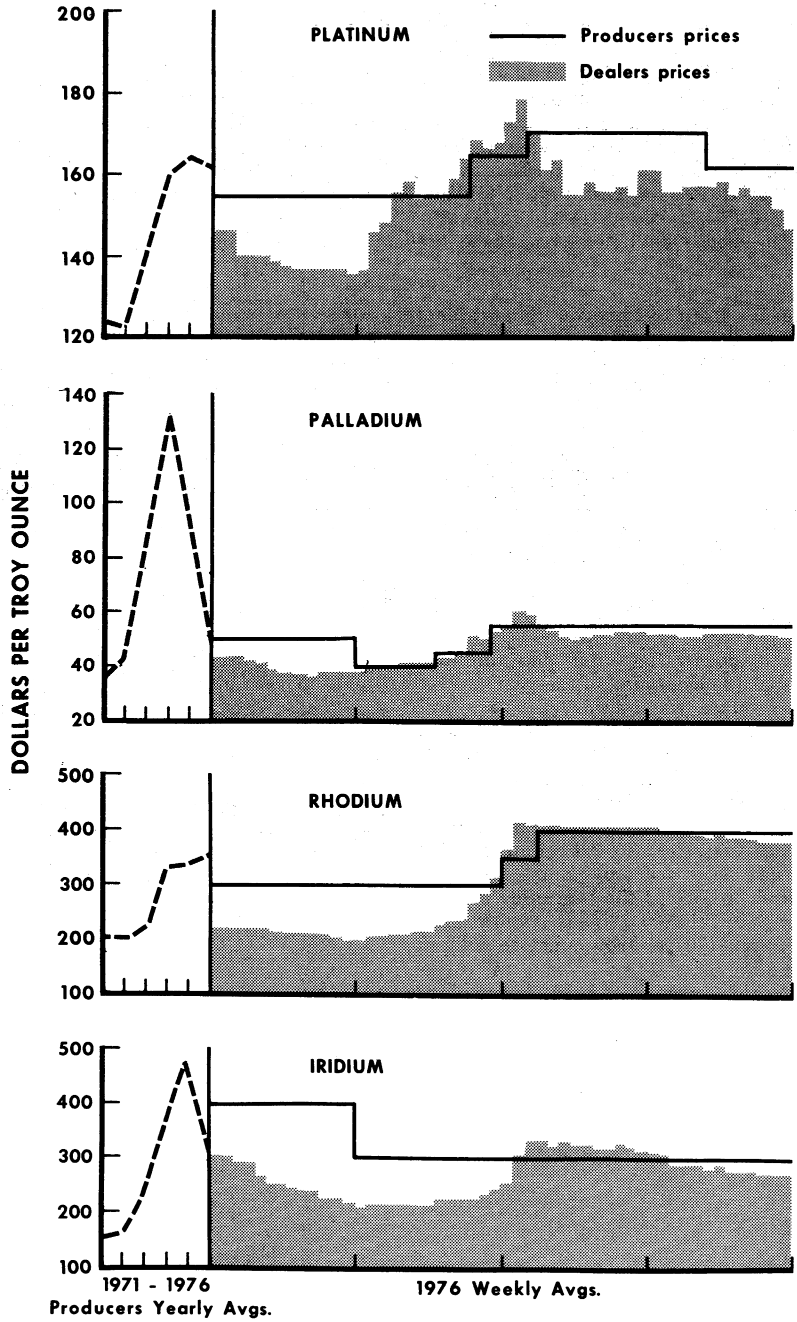

Figure 2.—Prices of four platinum-group metals.

FOREIGN TRADE

Exports of unwrought and semimanufactured platinum-group metals decreased 22% in 1976, to 512,407 troy ounces; about 225,000 troy ounces of this, or 44%, was platinum. Valued at $53 million, exports went mainly to the United Kingdom (26%), Japan (23%), and West Germany (15%).

Imports, on the other hand, increased 47% in 1976, to 2.7 million troy ounces, valued at $292 million. Of total imports, including estimates of metal in composite import classes, 44% was platinum and 48% was palladium. Compared with 1975 levels, Platinum imports increased 16% and palladium imports nearly doubled. The principal sources of platinum-group imports were the Republic of South Africa, which supplied 47% of the imports directly and originated a substantial part of the 17% of imports that came from the United Kingdom; and the U.S.S.R., which supplied 24% of the imports directly and an unknown additional quantity via European countries. Imports of each metal were estimated as follows:

	Thousand troy ounces
Platinum	1,185
Palladium	1,284
Iridium	31
Osmium	4
Rhodium	74
Ruthenium	89
Total	2,667

WORLD REVIEW

World mine production of the platinum-group metals increased about 4% in 1976, to 6 million troy ounces. The U.S.S.R. mined 2.8 million troy ounces and the Republic of South Africa mined 2.7 million troy ounces; together they accounted for 92% of world output. Canada mined 430,000 troy ounces, or 7% of the world total. The United States and six other countries accounted for the remaining 1% of world production.

U.S. mine production, largely as a byproduct of copper mining, was 6,116 troy ounces in 1976, compared with 18,920 troy ounces in 1975. The output of Colombia's river placers was 26,000 troy ounces, and small quantities of platinum-group metals were derived from placer mining in Ethiopia, and as byproducts of copper and nickel mining in Japan, Finland, the Philippines, and Australia.

Canada.—Canadian output of platinum-group metals increased 8%, to 430,000 troy ounces. The metals were byproducts of nickel-copper mining in Ontario and Manitoba, and were produced by Inco, Ltd., and Falconbridge Nickel Mines, Ltd. Texasgulf, Inc., after considerable exploratory drilling, dropped its option on the Lac des Iles platinum-group metals prospect near Thunder Bay, Ontario. However, drilling was resumed late in the year by the owner of the property, Boston Bay Mines, Ltd.[2]

South Africa, The Republic of.—The Republic of South Africa produced 2.7 million troy ounces of platinum-group metals in 1976, including about 61% of the world's newly-mined platinum, 27% of its palladium, 58% of its rhodium, 35% of its iridium, 46% of its ruthenium, and a substantial part of its osmium. Except for small quantities of osmiridium recovered as a byproduct of gold mining, all of the platinum-group metals were mined as principal products from several mines in the Merensky Reef, an extensive horizon in Transvaal Province containing more than half of the world's resources of platinum-group metals. Estimated production of the four companies that mined the Reef are as follows: Rustenburg Platinum Mines, Ltd., 1,550,000 troy ounces; Impala Platinum, Ltd., 1,000,000 troy ounces; Western Platinum, Ltd., 130,000 troy ounces; Atok Platinum Mines, Pty., Ltd., 30,000 troy ounces. The two largest companies decreased production in early 1975, to adjust to a sluggish market in that year, but by about mid-1976, both companies began to increase production. As a result, South African production in 1976 was modestly higher than in the preceding year.

U.S.S.R.—The U.S.S.R. produced an estimated 2.8 million troy ounces of platinum-group metals in 1976, accounting for 31% of the world's platinum, 66% of its palladium, 34% of its rhodium, 55% of its iridium, and 44% of its ruthenium. A small fraction of the metal came from gold-platinum placer deposits in the central Urals, but most was a byproduct of nickel-copper mining in the Norilsk-Talnakh region of northwestern Siberia, and the Petsamo-Monchegorsk region of the Kola Peninsula.

Table 9.—Platinum-group metals: World production by country[1]

(Troy ounces)

Country	1974	1975	1976[p]
Australia:			
Palladium, metal content, from nickel ore[e]	860	1,400	1,500
Platinum, metal content, from nickel ore[e]	260	[r]430	470
Canada: Platinum-group metals from nickel ore	384,618	399,218	429,999
Colombia: Placer platinum	21,094	22,114	26,000
Ethiopia: Placer platinum	230	162	[e]200
Finland: Platinum-group metals from copper ore[e]	650	600	640
Japan[2]:			
Palladium from nickel and copper ores	11,104	13,915	18,089
Platinum from nickel and copper ores	4,101	5,486	8,706
Philippines:			
Palladium from nickel/cobalt ores	2,315	836	--
Platinum from nickel/cobalt ores	1,350	579	--
South Africa, Republic of: Platinum group metals from platinum ores[e] [3]	[r]2,830,000	[r]2,600,000	2,700,000
U.S.S.R.: Placer platinum and platinum-group metals recovered from nickel/copper ores[e]	2,500,000	2,650,000	2,800,000
United States: Placer platinum and platinum-group metals from gold and copper ores	12,657	18,920	6,116
Total[4]	[r]5,769,239	5,713,660	5,991,720

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Excludes metal refined in Norway and the United Kingdom derived from Canadian and South African ores.
[2]Japanese figures exclude metal recovered from Philippine ores.
[3]Includes osmiridium from gold ores estimated at 2,500 troy ounces annually.
[4]Total excludes metal refined in West Germany and which is believed to be derived from imported ores. Production is as follows in troy ounces: 1974—4,115; 1975—3,601; 1976—2,283.

TECHNOLOGY

Research continued on automotive emission-control devices in 1976, although on a smaller scale than in previous years, it appeared that the U.S. Congress would amend the automotive emissions standards. The new standards were expected to result in the use of the three-way converter, which employs a platinum-rhodium catalyst to act simultaneously on carbon monoxide, unburned hydrocarbons, and nitrogen oxides. The major domestic and foreign automobile companies tested various models of the three-way converter, and limited numbers were installed on production cars sold in California. Much of the research was aimed at reducing the rhodium content of the catalyst; unless the rhodium-platinum ratio in the catalyst could be brought down to the rhodium-platinum ratio in South African ores, it would be difficult to obtain enough rhodium to equip all American cars with three-way converters.

Higher numbers of automobiles equipped with catalytic converters necessitate the increased production of unleaded gasoline. This requires the achievement of higher unleaded (clear) octane numbers, a process in which catalytic reforming plays an important part. However, yield of gasoline and octane rating are inversely related in reforming. Operating at low pressures lessens the dropoff in yield, but it also increases the coking rate of the catalyst. One solution to the problem of maintaining catalyst activity in an economic, uninterrupted fashion was reported by UOP Inc. In UOP's Continuous Platforming system, small quantities of catalyst are removed from the reactor, reactivated, and returned to the reactor in an essentially continuous manner. Continuous platformers have been in operation since 1971, and by 1976, six units were onstream. Several dozen more were in various stages of design and construction.[3]

Certain water-insoluble organic ruthenium complexes were found to be effective, on a laboratory scale, in splitting water through a photoinduced electron-transfer mechanism. The work was of considerable interest as a potential means of using solar energy to produce a highly desirable fuel, hydrogen. The reaction was believed to be truly catalytic, with an overall efficiency somewhere between 10% and 50%.[4]

Platinum metal catalysts, designed to support the thermal combustion of a variety of fuels, such as low-Btu gas, were announced. They were considered to be of potential use in transportation, home heating, power generation, and other stationary and mobile applications.

Printed thermocouples, formed by applying newly developed precious metal inks

[3]Pollitzer, E.C. Continuous Platforming. Platinum Metals Rev., v. 20, No. 1, January 1976, pp. 2-6.
[4]Chemical & Engineering News. Ruthenium Complexes Aid Hydrogen Process. V. 54, No. 23, May 31, 1976, pp. 17-21.

to ceramic substrates, were developed. The gold-palladium:platinum-palladium thermocouples are usable in air up to 850°C, and are similar to Chromel:Alumel wire thermocouples in electromotive force output. They were said to be rugged, to give rapid response, and to have excellent long-term stability. Continued development of other temperature-measuring devices resulted in new rhodium-iridium thermocouples that are accurate to 2100°C; in other thermocouple alloys of platinum, palladium, iridium, and gold, designed to replace base metal thermocouples in the temperature ranges up to 120°C; and in a new rhodium versus 0.5% iron resistance thermometer wire which extends the measurement of cryogenic temperatures down to 0.35°K.[5]

The platinum-rhodium gauzes that catalyze the oxidation of ammonia to nitric acid in modern nitric acid plants ordinarily remain in service several months. Occasionally, however, a gauze pack becomes inactive prematurely, and cannot be reactivated by cleaning in solvents or acid. A study of normal and inactive gauzes by scanning electron microscopy and X-ray diffraction, reported in 1976, showed that the surfaces of inactive gauzes were covered with crystalline rhodium oxide. It was inferred, from earlier work, that gauzes become passivated by a rhodium oxide layer when, because of error in temperature control or calibration, they are operated below design temperature.[6]

An account was published of experimental studies confirming that reduction of refractory metal oxides by carbon monoxide, hydrogen, carbon, and organic vapors is promoted by the presence of platinum-group metals, especially platinum and palladium. These reactions are of importance in industrial situations where platinum metals and refractory oxides are in close proximity or physical contact at high temperatures; under these circumstances, accidental or temporary exposure to reducing flames or organic impurities can lead to rapid destruction of the platinum metal and refractory material. The studies yielded thermodynamic data on the reduction reactions, and suggested the possibility of brazing other metals to refractory oxides by use of a platinum-containing brazing alloy.[7]

The unmanned Viking lander that reached Mars in July contained a small gas chromatograph/mass spectrometer for analyzing the gases emitted by pyrolyzed samples of Martian soil. An important component of the instrument was a unique electrolytic pump used to remove the hydrogen carrier gas from the sample gases before their entry into the spectrometer. The pump was essentially an electrolytic cell consisting of palladium-silver alloy tubing immersed in molten sodium hydroxide electrolyte. Hydrogen was ionized in the anodic coil, after which it diffused through the palladium-silver wall into the electrolyte, and flowed to the cathodic coil, where, after reduction, it diffused into the tubing and was discharged to the atmosphere as molecular hydrogen.[8]

The rate at which sputtered coatings of the platinum metals may be satisfactorily deposited reportedly was increased more than an order of magnitude by the invention of a new system that employs a magnetic field to trap secondary electrons emitted from the target. The entrapment increases the sputtering rate by preventing secondary electrons from bombarding, and thus heating, the substrate. At the same time, it uses the secondary electrons to enhance ionization in the sputtering gas.[9]

Potash

By Richard H. Singleton[1]

Apparent consumption of potash in the United States increased 20% in 1976 to 6.15 million tons of K_2O equivalent. The increased demand was met primarily by a 21% increase in imports, to 4.59 million tons of K_2O, 97% of which came from Canada. Domestic production continued to decline, decreasing 4% in 1976 to 2.40 million tons and producers' inventories decreased by 0.10 million tons to 0.52 million tons of K_2O. Sales by domestic producers increased 19% in volume to 2.5 million tons of K_2O and 8% in value to $203 million. Exports increased 21% to 0.95 million tons.

U.S. consumption was stimulated by price reductions which occurred during the summer months. The average 1976 price for domestic potash, f.o.b. mine, based on actual sales, was about 10% lower than in 1975.

Sulfates of potash, including purchased muriate that was converted to sulfate, comprised 16% of total U.S. production on a K_2O basis, compared with 15% in 1975. The average 1976 price, based on actual sales, for sulfate of potash was about 9% higher than the 1975 price.

Total sales of potash to U.S. customers by North American producers increased 24% to about 6.0 million tons of K_2O. Sales of granular grade increased 38% to 1.64 million tons, sales of coarse grade increased 25% to 2.27 million tons, and sales of standard grade increased only 10% to 1.17 million tons.

Modest capacity expansions by three producers and a contraction of capacity by one producer in the Carlsbad, N. Mex., area were reported. One mine in the Carlsbad

[4]U.S. customs value.
[5]Measured by sales plus imports minus exports.

area was opened and another was closed. Two producers announced increases in sylvite ore reserves, both in zone 1 of the Carlsbad deposits. Two organizations began exploratory drilling in Montana and North Dakota, and a preliminary evaluation indicated that solution mining at depths of 7,000 to 9,000 feet was technically feasible. A U.S. potash producer began exploratory drilling in Utah with an intent of solution mining at depths of around 6,000 feet.

Five U.S. producers were indicted by the U.S. Department of Justice for allegedly restricting potash trade and production and fixing prices. The trial was scheduled to begin in January 1977.

Exploratory drillings were made in the Carlsbad area to evaluate mineral resources in the region of a potential salt-bed repository for nuclear reactor wastes. An economic-engineering analysis was begun in late 1976 by the Federal Bureau of Mines to determine whether the repository would significantly reduce reserves of potash in the area.

Potash production in Canada, all muriate, decreased to 5.51 million tons and producers' inventories also decreased. Overseas exports decreased to 0.99 million tons whereas exports to the United States increased to 4.44 million tons. Domestic consumption in Canada increased to approximately 0.27 million tons. The government of the Province of Saskatchewan began acquisition of the Province's potash industry by purchase of a mine and mill from Duval Corp. of Canada. Appraisal of two other mine-mill units was completed, and appraisal of a third began. The government's announced intention was to acquire control of 50% of Saskatchewan's potash industry by 1979. Litigation continued in Saskatchewan courts regarding the legality of the Province's reserve tax and other Provincial taxes.

World production of potash decreased 2% to 26.9 million tons of K_2O equivalent. Production decreases in North America and in Western Europe were not quite counteracted by production increases in Eastern Europe. Producers' inventories remained high in much of Western Europe because demand was lower than anticipated.

The Bureau of Mines continued potash beneficiation experiments aimed primarily at improving potash recoveries from high-clay sylvite ores.

DOMESTIC PRODUCTION

U.S. production of marketable potash salts decreased 4% to 2.40 million tons of K_2O equivalent. Sulfates of potash, including purchased muriate that was converted to sulfate, comprised 16% of total production compared with 15% in 1975. Production of standard-grade muriate decreased 8% to 0.99 million tons of K_2O, whereas output of coarse grade increased 10%. Production of granular grade remained constant.

In New Mexico, the source of 83% of U.S. production in 1976, nine underground mines were operated near Carlsbad by AMAX Chemical Corp., Duval Corp. (two mines), International Minerals & Chemical Corp., Kerr-McGee Chemical Corp., Mississippi Chemical Corp., National Potash Co. (two mines), and Potash Co. of America. The average K_2O content of ores mined in New Mexico declined to 14.8% in 1976 from 15.2% in 1975. These ores had contained an average of 17.5% K_2O in 1966.

Three companies produced potash in Utah: Texasgulf, Inc., working an old room-and-pillar mine near Moab by solution mining; Great Salt Lake Minerals & Chemicals Corp., producing potassium sulfate from brines from the Great Salt Lake; and Kaiser Aluminum & Chemical Corp., treating near-surface brines near Wendover. In California, potash continued to be produced from Searles Lake brines by the Kerr-McGee Chemical Corp.

AMAX Chemical Corp. undertook capital programs at its New Mexico facility to somewhat expand ore reserves and increase production capacity.

Duval Corp. opened its North mine in New Mexico in March and thereby planned to increase total muriate production capacity to 210,000 tons of K_2O equivalent by late 1977.

Great Salt Lake Minerals & Chemicals Corp. developed a proprietary process for converting purchased muriate of potash into sulfate of potash; this was one of the steps taken to reduce dependency of output on Utah weather. Wet weather, which had diluted brine in the Great Salt Lake and in the solar evaporation ponds, abated in 1976. A unique commercial flotation process for concentrating schoenite, prior to conversion to sulfate of potash, went onstream in January 1976.

[2]Includes sulfate of potassium produced by conversion of purchased muriate of potassium.

International Minerals & Chemical Corp. leased acreage in northern Montana where supposed deposits of potash may have solution-mining potential.

Kaiser Chemicals announced construction by 1979 of an 8,000-acre, $3 million solar evaporation system to replace the old system at Wendover, Utah. The new system was scheduled to operate until 1995.

Mississippi Chemical Corp. began modernization and expansion of its flotation plant in New Mexico during late summer. The plant was closed approximately 4 months during the second half of 1976 and remained closed at yearend. Planned annual capacity of the renovated plant was approximately 180,000 tons of K_2O equivalent. The product, all muriate of potash, was to be used exclusively to manufacture fertilizer mixtures made in captive plants and marketed by Mississippi Chemical Corp.

National Potash Co. closed its Eddy County mine near Carlsbad in November when recovery of all available ore was completed. All future mining and milling was to be done at the Lea County mine site at a reduced annual capacity of near 240,000 tons of K_2O equivalent. Sylvinite ore from the Lea County mine, which had been opened in 1974, was leaner than that from the Eddy County mine.

The potash reserve in Potash Co. of America's New Mexico mine was increased by about one-half to 5.5 million tons of K_2O equivalent, all as muriate. The increase resulted largely from planned use of secondary mining techniques and newly defined ore body limits. The new reserve estimate allowed planned mining of this rich (25% K_2O) deposit to be extended into the late 1980's.

Texasgulf, Inc., determined that the remaining reserve in its Cane Creek mine in Utah is sufficient to allow potash recovery by solution mining for about 10 years at current rates of removal. Solution mining experimentation continued in new wells near Moab. A substantial resource of potash was indicated by the U.S. Geological Survey[2] in the Paradox Basin in Utah. The deposit occurs over a depth range of 5,000 to

[2]Hite, R. J. A Potential Target for Potash Solution Mining in Cycle 13, Paradox Member, Near Moab, Utah. U.S. Geol. Survey Open-File Rept. 76-755, 1976, 5 pp.

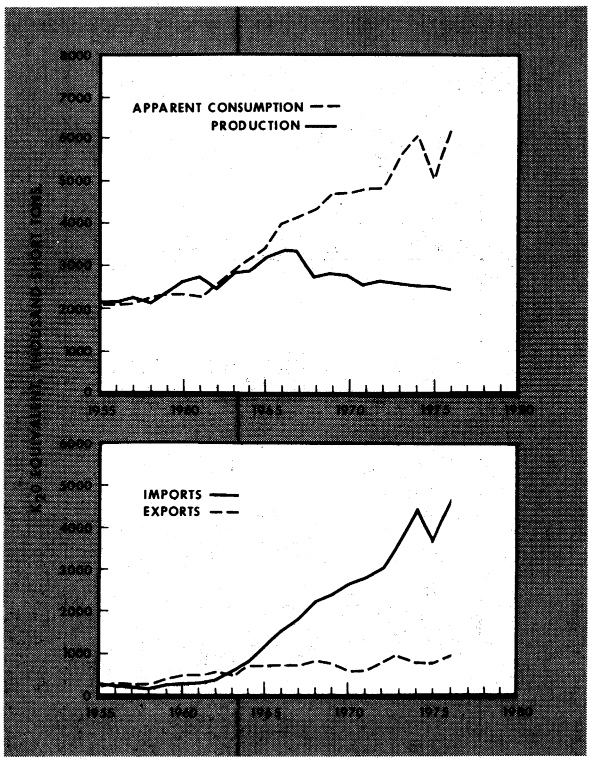

Figure 1.—Marketable production, apparent consumption, exports, and imports of potash measured in K_2O equivalent.

6,500 feet and has potential as a solution-mining target.

An indictment was filed on June 29 by the Antitrust Division of the U.S. Department of Justice in U.S. District Court, Northern District of Illinois, charging five U.S. producers with restricting trade by curbing U.S. production and stabilizing U.S. prices at noncompetitive levels and conspiring to coordinate U.S. and Canadian production and prices for potash; they were also indicted for coordinating exports of potash from the United States and imports of offshore potash into the United States. The case related to the prorationing system enforced by the Provincial government on the potash industry in Saskatchewan, Canada, from 1970 to 1974 and covered only that period of time. The criminal trial was scheduled to begin in January 1977. The potential fine was $50,000 per producer. The States of Illinois and Connecticut and some 30 other potash users filed class-action civil suits, mostly in the same Illinois court, seeking damages from the potash producers for the higher prices paid for potash during prorationing.

Leasing of Federal land near Carlsbad was renewed at mid-1976 after a 2-year moratorium caused by environmental considerations.

Exploratory drilling began on a southern extension of the Williston basin, in the Montana-North Dakota area near the Saskatchewan border, by two parties, Kalium Chemicals, a division of PPG Industries, Inc., and Farmers Potash Co., a combine of Burlington Northern, Inc. and C. F. Industries, Inc. Land leasing had begun in 1975. Five holes had been drilled by yearend at a cost of about $3 million in Burke and Bottineau Counties in North Dakota and in Daniels and Sheridan Counties in Montana. Preliminary data indicated that solution mining is technically feasible at depths of 7,000 to 9,000 feet. Engineering evaluations for commercial development were expected to be completed in 1977. Local lignite would be used for this energy-intensive operation. Immediate construction of pilot wells and mills was indicated, the main scheduling deterrent being local environmental considerations. Unit size for a commercial solution-mining operation would be about 1

million tons of K_2O equivalent at a capital cost of about $300 million. Estimated resources were sufficient to satisfy U.S. demand for centuries.

Exploratory drilling was completed for evaluating potash resources in a 29.6-square-mile area 35 miles east of Carlsbad, N. Mex. This area had been selected by the U.S. Energy Research and Development Administration (ERDA) as the prime candidate for its nuclear Waste Isolation Pilot Plant (WIPP) project. Storage would be realized by about 1983 in a 2,000-foot-thick halite bed at a depth of about one-half mile if the area was determined to be geologically, ecologically, and economically suitable. Two potash-mining leases would be affected. In late 1976, the Federal Bureau of Mines began an engineering-economic study to determine the potential potash reserves that would be removed by construction of WIPP. The Bureau's reserve estimate, based on 21 exploratory holes drilled for ERDA and on previous drillings, was expected during 1977.

CONSUMPTION AND USES

Apparent domestic consumption of potash increased 20% to 6.15 million tons of K_2O equivalent; approximately 95% of this was used in the fertilizer industry and the balance in chemicals manufacture, mainly in production of caustic potash. Consumption was stimulated by price reductions during the summer.

The north-central States of Illinois, Indiana, Iowa, Ohio, Minnesota, and Wisconsin purchased 52% of all agricultural potash, compared with 53% in 1975.

Total sales in the United States of muriate of potash for agricultural purposes follow: Standard grade, up 10% to 1.17 million tons K_2O, coarse grade, up 25% to 2.27 million tons K_2O, granular grade, up 38% to 1.64 million tons K_2O; and soluble grade, up 33% to 0.40 million tons K_2O, according to the Potash Institute.

Apparent consumption of potassium sulfate and potassium magnesium sulfate combined increased 16% to 0.28 million tons of K_2O, according to the Potash Institute. However, 1975 apparent consumption had dropped 15% compared with that of 1974.

STOCKS

Domestic producers' inventories decreased during 1976 by 0.10 million tons to 0.52 million tons of K_2O equivalent; most of this decrease occurred during the first half of the year. These stockpiles had increased in 1975 by 0.41 million tons. Producers' inventories of sulfates of potash decreased 10% in 1976 to 0.08 million tons of K_2O.

PRICES

Domestic prices for muriate of potash decreased significantly below the 1975 highs, particularly during the latter half of 1976, when the average price for the three common grades of muriate dropped to $59.93 per ton of K_2O equivalent, or 21% below the 1975 average. The price of standard muriate was particularly depressed because of lack of demand in the domestic market. Sulfate of potash prices continued to climb significantly.

[3]Average price includes price of sulfate produced by conversion of purchased muriate.

FOREIGN TRADE

Total U.S. exports[3] of potash increased 21% to 0.95 million tons of K_2O equivalent. Areas receiving these exports were Latin America, 55%, Oceania, 21%, Asia, 17%, and other, mainly Western Europe, 7%. Exports of sulfates of potash increased 9% to 0.12 million tons of K_2O. Exports of potash to Brazil, the main recipient country, increased 34% to 0.38 million tons of K_2O. New Zealand became the second largest importer of U.S. potash; exports to that country approximately doubled to 0.16 million tons of K_2O. Japan remained the largest importer of U.S. sulfates of potash.

Potash imports, 97% from Canada, increased 21% to 4.59 million tons of K_2O equivalent. Muriate of potash comprised 99% of these imports. Israel remained the second-place supplier, providing nearly 2% of U.S. imports in 1976. Imports from centrally controlled economy countries more than doubled but remained below 0.03 million tons of K_2O.

[3]Salient U.S. trade data includes only muriate, sulfate, nitrate, and potassium magnesium sulfate.

WORLD REVIEW

Potash production in 1976 continued to rise in Eastern Europe, although at a slower rate than in previous years, and continued to decrease in the Western World. Eastern European production increased 5% to 12.6 million tons of K_2O equivalent; production in Western Europe, including Israel and the People's Republic of the Congo,[4] and North America decreased 8% and 7% to 5.8 and 7.9 million tons of K_2O, respectively.

The apportionment of world production was Eastern Europe, 47%, North America, 29%, Western Europe, including Israel and the People's Republic of the Congo, 22%, and others, mainly the People's Republic of China, 2%. The U.S.S.R. and Canada continued as the first and second largest producers, with 34% and 21% of the world's 1976 output, respectively.

The only significant capacity increases during 1976 were in Eastern Europe, particularly in the U.S.S.R. where export markets including Western markets were sought.

The only significant expansion that occurred in Western Europe in the 1970's was the construction of the Boulby mine in the United Kingdom which was expected to produce at about one-half capacity in 1977; reported capacity was 0.55 million short tons of K_2O per year.

Each of the three major potash-producing world blocs, North America, Western Europe, and Eastern Europe, remained self-sufficient in potash. North American net export decreased 3% in 1976 to 1.76 million tons of K_2O. Net export from Eastern Europe increased 2% to 1.71 million tons. West European net imports increased 4% to 0.13 million tons in 1976. Approximately 60% of world consumption was in producing countries. Total world demand increased about 10% to approximately 26 million tons of K_2O indicating a cessation of the previous rapid buildup of producers' inventories.

An anticipated increase in Western European consumption in 1976 was not realized, partly because of a drought; consequently, producers' inventories remained high.

Combined exports in 1976 of the two Eastern European producers, the U.S.S.R. and East Germany, remained at about 5.1 million tons, equaling about 40% of 1976 production. Areas receiving these exports were other Eastern European countries, 66%; Western Europe, 20%; Asia, 8%; and Latin America, 6%. Eastern European exports to Latin America increased 85% to 0.33 million tons.

Total exports from Western European primary-producing countries, which included, in order of production volume, West Germany, France, Israel, Spain, the People's Republic of the Congo, and Italy, decreased 3% to 2.08 million tons of K_2O. Areas receiving these exports were Western Europe, 58%; Asia, 15%; Africa, 13%; Latin America, 9%; North America, 5%; and Eastern Europe, 2%.

A new trade organization, Austria, Kali-Export GmbH based in Vienna, was formed to administer export trade by West Germany, France and the People's Republic of the Congo, Israel, and the United Kingdom.

Total overseas exports from North America decreased 10% to 1.90 million tons. Areas receiving these exports were Asia, mainly Japan, 46%; Latin America, mainly Brazil, 36%; Oceania, 13%; Western Europe, 4%; and others, 1%.

Total world shipments to nonproducing nations decreased 2% to 8.54 million tons; receiving areas were, in order of volume, Eastern Europe, mainly Poland and Hungary, 39%; Western Europe, mainly Belgium and the United Kingdom, 21%; Asia, mainly Japan and India, 19%; Latin America, mainly Brazil, 14%; Africa, mainly the Republic of South Africa, 4%; and Oceania, 3%. Major suppliers were East Germany and the U.S.S.R. to Eastern Europe; Canada, East Germany, the U.S.S.R., West Germany, the United States, and Israel, in order of volume, to Asia; and the United States, East Germany, Canada, the U.S.S.R. and West Germany, in order of volume, to Latin America. Imports into Brazil, the market-economy world's largest nonproducing importer, increased 46% to 0.83 million tons. Imports into Japan, the second

[4]Israel and the People's Republic of the Congo are included in Western Europe because they were in the same trading block.

largest nonproducing importer in the market-economy world, decreased 29% in 1976 to 0.70 million tons of K_2O. Large user inventories were reported in Asia.

Total 1976 exports of potassium sulfates from Western European producing countries increased 4% to 0.56 million tons of K_2O. Of this, 50% was shipped to nonproducing Western European countries. East Germany, the only other sulfates exporter except for the United States, increased sulfate exports by about 50% to approximately 0.10 million tons of K_2O. Of this, about 80% was shipped to Eastern European countries.

Brazil.—A consortium of government and private concerns was formed to undertake a feasibility study and build a pilot plant to exploit the carnallite and sylvinite deposits in the Sergipe Basin. Reserves and resources of potash in Brazil were estimated to be 60 million and 300 million tons of K_2O equivalent, respectively.

Brazilian consumption of potash increased 40% in 1976 to 0.78 million short tons of K_2O, all of which was imported.

Canada.—Production remained at little more than 50% of capacity during the first 6 months because of lagging U.S. demand at the farm level, lower overseas sales, and high producers' inventories.[5] Substantial price cuts during the summer increased sales greatly in the second half of the year. However, total 1976 production decreased 8% to 5.51 million tons. Producers' inventories decreased by only 0.21 million tons to 0.88 million tons of K_2O equivalent; of this, 49% was standard grade muriate or finer. Overseas exports decreased 27% to 0.99 million tons reflecting both decreased demand and increased competition abroad. Areas receiving these exports during 1976 were Asia, 73%; Latin America, 17%; and others, mainly Oceania, 10%.

Exports to the United States increased 27% to 4.44 million tons of K_2O. Domestic consumption in Canada increased by about 9% to approximately 0.27 million tons of K_2O. Imports, mostly sulfates of potash from the United States, remained at about 19,000 tons of K_2O.

International Minerals & Chemical Corp. (Canada). closed their K-2 mine at Esterhazy in January for an indefinite period; however, it was reopened in September because of the improved market. A new heavy-media circuit was put onstream in September. Effective total annual capacity at Esterhazy was increased 16% to about 2.7 million tons of K_2O by yearend.

Sylvite of Canada, Ltd. purchased a third Marietta continuous miner in 1976. Alwinsal Potash of Canada, Ltd., ordered a new continuous miner; the firm's facility was shut down for part of 1976 because of major storm damage. Several facilities added more compaction presses for conversion of standard-grade muriate into coarser fertilizer–blending grades. Many producers stated that further capacity expansions were inhibited by the high level of Provincial taxation, which, combined with Federal taxes, prevented realization of a reasonable return on their investment. Provincial taxes alone averaged about $20 per ton of K_2O for Saskatchewan fiscal year 1976.

The government of the Province of Saskatchewan began acquisition of the Province's potash industry by the purchase in October of Duval Corp. of Canada's mine and mill near Saskatchewan. Legislation enabling expropriation had been passed by the Saskatchewan government in January, although the government reportedly planned to acquire the properties by negotiation. Near yearend the government announced plans to expand its newly acquired facility, renamed Cory Limited, by 25% to an annual capacity of about 0.9 million tons of K_2O; this included procurement of a new continuous miner. The Potash Corp. of Saskat-

[5]Data on Canadian production, inventory, and overseas exports were supplied by the Potash Institute, Atlanta, Ga.

chewan, the government-owned operator of government-acquired mines, completed appraisal of two more mines, owned by Sylvite of Canada, Ltd., and Alwinsal Potash of Canada, Ltd., respectively, and negotiations for acquisition of the Sylvite facility were progressing by yearend. Government appraisal of Central Canada Potash Ltd.'s mine was begun, and plans for appraisal of the Allan mine owned by A.P.M. Operators Ltd. were announced at yearend. A Saskatchewan government representative announced that acquisition of 50% or more of the Saskatchewan potash industry would be completed by 1979. The main sales office of the Potash Corp. of Saskatchewan was established in Atlanta, Ga., and the government-owned firm became a member of the Potash Institute.

Kalium Chemicals Ltd., Amax Chemical Corp., and Potash Co. of America Ltd. withdrew their membership from Canpotex Ltd., the Canadian export association. The Potash Corp. of Saskatchewan joined Canpotex.

Nine potash producers filed, in May 1976, an action in the Court of Queen's Bench in Regina, alleging breach of contract by the Saskatchewan government in connection with the reserve tax and prorationing fees. Under an agreement signed in 1960, the government had agreed not to increase royalties or royalty-like charges for a period of 21 years. Both this suit and those filed by industry in 1975, maintaining that the reserves tax and the prorationing fee are unconstitutional, were pending at yearend. Industry claimed that the heavy tax structure was excessive and prohibited expansion. The Provincial government refused to modify the tax structure and continued to recommend expansion. The Canadian Potash Producers' Association pledged to continue to seek tax reform.

The Supreme Court of Canada ruled on October 5, 1976, that, in the event the reserves tax and the prorationing fee were declared *ultra vires*, producers could recover all back reserve taxes paid to the Saskatchewan government. That government had legislated that retroactive taxes did not have to be returned to the producers; subsequently, 11 potash producers had filed suit alleging that enactment of this legislation exceeded the power of the Province. As a result of the Supreme Court decision, most of the reserve taxes that had been withheld by the producers were relinquished to the government.

The Saskatchewan Court of Queen's Bench had ruled in May 1975 that the prorationing legislation enacted by the Saskatchewan government in 1969 was unconstitutional. The suit had been filed by Central Canada Potash Ltd., later joined by the Attorney General of Canada. After this ruling, most producers withheld payment of the prorationing fee, $1.20 per ton. However, the Saskatchewan Court of Appeal overturned this ruling on January 11, 1977, declaring that the prorationing legislation was constitutional. Central Canada Potash Ltd. then filed an appeal on January 20, 1977, with the Supreme Court of Canada.

Promising potash exploration continued in New Brunswick, Canada. Drilling by International Minerals & Chemical Corp. outlined a rich sylvinite deposit averaging 29% K_2O in a 70-foot-thick bed within a 2-square-mile area near Salt Springs in Kings County. Ten holes were drilled in 1976. On the basis of seven holes that intersected the deposit, bed thickness and grade were found to be variable. The bed was located on one side of an anticline, and faulting was indicated. Bed depth ranged from 2,000 to 3,400 feet. The bed was underlain with a thick deposit of 98% halite. The intent was to combine halite and potash mining at the same location. Exploratory drilling was expected to continue throughout most of 1977. The company had been licensed by the Province of New Brunswick to explore a 77-square-mile area.

The Potash Co. of America continued exploration of a sylvinite potash deposit near Sussex, Kings County, New Brunswick. Exploratory drilling was terminated in August; nearly 30 exploratory holes had been drilled over a 3-year period. This deposit was found to be folded and to contain, reportedly, some carnallite. The company notified the New Brunswick government in October that they would submit a plan for commercial development within 1 year.

The Province of New Brunswick passed legislation in late 1976 fixing the royalty on mineral products at 6.5% of the average world market price for the first 15 years of plant production.

It appeared that commercial development of the New Brunswick deposits is technically feasible although overall production costs would likely be higher than in Saskatchewan. An indicated advantage was that the New Brunswick deposits are near an Atlantic port.

XX Not applicable.
[1]Data on U.S. exports supplied by the Potash Institute; data on exports from other countries supplied by ISMA, Ltd., Paris, France.
[2]Includes potassium sulfate and potassium magnesium sulfate.

Congo, People's Republic of the.— Production of potash from sylvinite beds continued to become increasingly less competitive and profitable because of technical and political problems. The beds were folded and irregular in thickness. Production fell by approximately 10% in 1976 to about 0.28 million tons of K_2O equivalent. Compagnie des Potasses du Congo was searching for new investors to develop the extensive and potentially more profitable Congolese carnallite deposits. The French Government attempted, without success, to disengage itself from the Congolese potash production industry in 1976.

France.—The 1975 downtrend in French potash production continued into 1976 because of high French inventories and continuing low demand in Western Europe. Production decreased 16% to 1.77 million tons of K_2O equivalent. Producers' inventories decreased 14% to 0.33 million tons of K_2O. However, an encouraging revival in the domestic market occurred near yearend.

Combined exports from France and the People's Republic of the Congo, 60% of which went to Western Europe, decreased 13% to 0.52 million tons of K_2O.

An agreement to control discharge by the Alsatian potash industry of byproduct salt into the Rhine River was reached by France, West Germany, Luxembourg, the Netherlands, and Switzerland. Discharge from the French mines was to be limited immediately to 130 kilograms of chloride ion per second, and this pollution was to be reduced, in three stages, by nearly 50% over a 6-year period. The cost of the first stage, about $25 million, was to be borne mainly by the Netherlands, France, and West Germany.

The Bollwiller mine, smallest of the four French potash mines, was closed in 1976.

Germany, East— Production and exports of potash continued to increase moderately; production increased 5% to about 3.5 million tons of K_2O equivalent, and total exports increased 6% to 2.54 million tons of K_2O. Export distribution was 60% to Eastern Europe, mostly Poland and Czechoslovakia, 22% to Western Europe, 9% to Asia, and the balance to Latin America. Exports to Latin America increased 80%, compared with that of 1975. About 4%, on a K_2O basis, of the total exports was sulfate of potash.

Muriate grade had improved since 1970 so that three-quarters of 1975 production was 60% K_2O quality. It was realized that production of coarser grades of muriate must increase in order to penetrate the U.S. market. Potassium sulfate comprised only 2% of production. Projected 1980 potash production was about 4.0 million tons.

Germany, West—The 1975 downtrend in West German potash production continued into 1976 because of continuing low demand in Western Europe. Production, 14% as sulfates and the balance as muriate, decreased 8% to 2.24 million tons of K_2O equivalent. Fifty-six percent of the muriate produced was premium 60% K_2O material; the balance contained less than 60% K_2O. Potash producers' stocks were controlled and held at a near normal level. Domestic consumption increased 6% to 1.28 million tons of K_2O; 10% was used in the chemical and related industries, and the balance was used for agricultural purposes. Exports, 24% of which was sulfates, decreased 13% to 0.86 million tons of K_2O; the export breakdown by world area was 58% to Western Europe, 20% to Asia, 10% to Latin America, and 12% to other.

Kali und Saltz G.m.b.H., the major producer in West Germany, drilled one borehole on the northern shore of Steinhuder Meer, west of Hannover, with the view of exploiting the potash deposit there.

The Ronnenberg mine near Hannover, with a reported annual capacity of 150,000 tons of K_2O, was closed permanently because of flooding.

Israel.—Exports, the main outlet for Israeli potash, continued to decline, decreasing 7% in 1976 to 0.38 million tons of K_2O equivalent. Producers' inventories continued to increase despite a decrease in production late in 1976. Total potash production, all muriate, decreased 2% to 0.75 million tons of K_2O in 1976 after having increased 15% in 1975.

Haifa Chemicals completed an expansion of its plant in Haifa, which produced a pure grade of potassium nitrate from potassium chloride. The new capacity was reportedly 240,000 tons per year, equivalent to approximately 110,000 tons of K_2O per year. Most of this increased production was destined for export.

Italy.—Italy continued to rely on imports for most of its potash supply. Net imports increased 18% to 0.18 million short tons of K_2O equivalent. Potash production decreased 8% to 0.15 million tons.

Laos.—Before being evicted from Laos, the U.S. Agency for International Development outlined a sylvinite bed 10 to 15 feet thick in a deposit along the Mekong River flats near Vientiane. The depth of the bed ranged from 300 to 1,400 feet. Reserves and resources were estimated to be 21 and 44 million short tons of K_2O equivalent, respectively.

Peru.—The Government of Peru was reportedly undertaking pilot plant tests for extraction of potassium chloride from brine deposits in the western half of the Sechura Desert. Estimated reserves were reported to be about 10 million tons of K_2O equivalent.

Spain.—Spanish potash production continued to increase in 1976, rising 14% to 0.58 million tons of K_2O equivalent or near full capacity. About one-sixth of this production was potassium sulfates. Exports, 63% to Western Europe, about tripled to 0.26 million tons of K_2O.

Thailand.—A 145-foot-thick bed of high-grade carnallite was outlined in northeastern Thailand near the Laos border. No significant quantities of sylvinite had been located, although its presence was inferred. The Thailand Department of Mineral Resources partially completed a program for exploration drilling. Outside investment was sought for commercial development of these resources. Total reserves and resources of potash in Thailand were estimated to be 60 million and 10 billion tons of K_2O equivalent, respectively.

U.S.S.R.—Both production and exports of potash reportedly increased sharply over the period 1970 to 1975; annual increases averaged 16% for production and 14% for exports. Production increases were below target in 1976; producton rose only 4% to 9.1 million tons of K_2O equivalent, reportedly because of overestimated demand in the U.S.S.R. grainbelt. Reported exports for 1976 decreased 7% to 2.54 million tons of K_2O. Export distribution was 71% to Eastern Europe, mostly Poland, 17% to Western Europe, 7% to Asia, and 5% to other areas.

Although 28% of potash production was exported, additional foreign markets were being sought, particularly where U.S.S.R. potash could be exchanged for phosphate fertilizers. Major facility expansions were underway in the Uralkali Combine. Two complexes, Berezniki 4 and Novosolikamsk, each with a nameplate capacity of 3.2 million short tons K_2O, were scheduled to go onstream by the end of 1977 and 1978, respectively. Production forecast for 1980 was reported to be near 13 million tons of K_2O.

The U.S.S.R. was reportedly procuring 16 large compacting presses, with a total capacity of about 1 million tons of K_2O, for conversion of standard muriate into granular muriate of potash to enhance its salability in Western markets. Granular muriate was being offered in the international market by the end of 1976.

Longwall mining was used in some of the mines in the Starobinsk deposit at Soligorsk. Mineral recovery in this rich sylvinite deposit was increased, as a result of this longwalling, from 45% to 70%, and the average K_2O content of the ore was increased from 26% to 36% K_2O.

A pilot solution-mining plant began operation at Gaurdak in Turkmenistan.

TECHNOLOGY

Research continued by the Federal Bureau of Mines and industry on removal of insoluble slimes from high-clay Carlsbad sylvinite ores prior to froth flotation of muriate of potash from halite. Bureau studies indicated that removal of insolubles by a selective flocculation-flotation procedure should be an improvement over standard mechanical desliming techniques; potash loss in the clay-slime tailings was decreased significantly.

Pumice and Volcanic Cinder

By A. C. Meisinger[1]

A record high quantity of 4.13 million tons of pumiceous materials (pumice, pumicite, volcanic cinder, and scoria) was produced in the United States in 1976. Value of production was $10.5 million, the second highest value on record, compared with $11.2 million in 1975. More crude material was sold or used at a lower unit value per ton to partially account for the 7% decrease in total value compared with that of 1975.

Three States— Arizona, California, and Oregon— accounted for 64% of the total U.S. production of pumiceous materials. California led all producing States with 95 active operations. Volcanic cinder, including scoria, comprised 78% of the domestic output of pumiceous materials in 1976, and was produced in 10 of the 11 producing States. Combined use of pumiceous materials for road construction and concrete aggregate and admixtures comprised 79% of U.S. consumption (excluding imports) compared with 84% in 1975.

Exports of domestic pumice and pumicite declined for the third consecutive year, but only 19% in quantity compared with 57% in 1975. The principal export destination was Canada (53%), followed by West Germany and Israel.

Imports of pumice in 1976, primarily from Italy and Greece, totaled 81,401 tons, the lowest figure since 1962, and represented a 44% decrease compared with 1975 imports. Pumice imported for use in manufacturing concrete masonry products decreased 46% and was the primary factor for the overall decline in U.S. imports for the second consecutive year.

DOMESTIC PRODUCTION

Production of pumiceous materials in 1976 totaled 4.13 million tons valued at $10.5 million, compared with 3.89 million tons valued at $11.2 million in 1975. The record high quantity in 1976 (previous record high was 3.94 million tons in 1974) was attributed to increased production of pumice and pumicite (15% over that of 1975) and a record high of 3.2 million tons of volcanic cinder mined.

Although total production of pumiceous materials increased 6% in quantity over that of 1975, the value declined nearly 7% from the record high value of $11.2 million established in 1975. The decrease in total value was due, in part, to an increase in use of crude pumiceous materials at a lower unit price per ton and a subsequent decrease in prepared material at a lower unit price. Volcanic cinder and scoria comprised 78% of the domestic output of pumiceous materials, compared with 80% in 1975.

Domestic output in 1976 came from 93 individuals, firms, and governmental agencies producing from 259 operations in 11 States, compared with 91 producers and 267 operations in 11 States in 1975. California led all the producing States in number of active operations with 95, followed by Oregon with 68, and Arizona with 40. The combined output of pumiceous materials (primarily volcanic cinder) in Arizona, California, and Oregon in 1976 was 2.6 million tons, or 64% of the national total. Other States with significant output levels of pumiceous materials were Hawaii, Nevada, and New Mexico. Volcanic cinder, including scoria, was produced in 10 of the 11 States and in American Samoa.

[1]Industry economist, Division of Nonmetallic Minerals.

CONSUMPTION AND USES

The combined use of domestic pumiceous materials for road construction and concrete admixtures and aggregates accounted for 79% of U.S. consumption compared with 84% in 1975. End uses for the remaining 21% were railroad ballast (8%), landscaping (7%), and other uses including abrasives (6%). Pumiceous materials used as roofing granules accounted for 38% of the total quantity and 49% of the total value of "Other uses" shown in table 3.

The quantity of pumiceous materials used for various abrasive applications increased from 19,000 tons in 1975 to 29,000 tons in 1976, or 53%; that used in landscaping, 84%; in concrete admixtures and aggregates, 12%; and in "Other uses", 83%. Although railroad ballast use remained steady at 310,000 tons in 1976, road construction use decreased 7%. Of the total domestic quantity of pumiceous materials used for road construction, surfacing, and repair, 49% was used by the U.S. Forest Service for road maintenance in National Forests in Arizona, California, New Mexico, and Oregon.

[2] Data do not add to total shown because of independent rounding.

PRICES

The weighted average value of pumiceous materials produced domestically in 1976 was $2.53 per ton, a 12% decrease compared with that of 1975. The average value for crude material declined from $1.31 per ton to $1.20 per ton, and that for prepared material declined from $4.36 per ton to $4.15 per ton.

Average prices per ton for pumiceous materials in all major uses were lower in 1976 compared with those of 1975. The average price of pumiceous materials used for abrasives (including cleaning and scouring compounds) was $24.34 per ton, a $6.08 decrease; for concrete aggregate and admixtures, $2.63, a $0.24 decrease; for landscaping, $4.44, a $3.22 decrease; for railroad ballast, $1.36, an $0.11 decrease; for road construction material, $1.58, a $0.58 decrease; and for other uses, $6.74, a $1.66 decrease.

According to trade publications, 1976 prices for pumice remained unchanged compared with 1975. Quoted prices in American Paint and Coatings Journal at yearend, per pound, bagged f.o.b. New York or Chicago, were $0.0445 to $0.08 for powdered pumice, and $0.0665 to $0.09 for lump pumice. Quoted prices in Chemical Marketing Reporter at yearend were as follows for domestic grades, bagged in 1-ton lots: Fine, $0.0765 to $0.1140 per pound; medium, $0.1160 per pound; and coarse, $0.094 per pound. Prices from the same source for imported (Italian) silk-screened pumice, bagged in 1-ton lots, were as follows: Fine, $138 per ton; medium, $150 per ton; and coarse, $140 per ton. The price of imported small-lump and large-lump pumice was quoted at $275 per ton.

FOREIGN TRADE

Exports of pumice materials continued to decline from the record high set in 1973 (3,095 tons). Compared with those of 1975, exports decreased 19% in quantity and 74% in value. Exports totaled 1,011 tons in 1976, and went primarily to Canada (53%), West Germany (27%), and Israel (16%).

A substantial decrease in the quantity of pumice imports for the second straight year resulted in the lowest amount (81,401 tons) imported since 1962 (86,504 tons). Compared with that of 1975, the quantity of pumice imports, excluding manufactured, n.s.p.f., decreased 44%, although the value increased 9%. Imports of crude or unmanufactured pumice and wholly or partly manufactured pumice imported, each increased in quantity compared with those of 1975, but that imported for use in the manufacture of concrete masonry products declined 46%, offsetting the gains shown in quantity for the other import classes. Italy and Greece continued to be the major import sources.

Table 4.—U.S. exports of pumice

Year	Quantity (short tons)	Value (thousands)
1973	3,095	$765
1974	2,911	1,211
1975	1,252	1,027
1976	1,011	271

Pumice stone, TSUS No. 519.05, for use in concrete products, continued to be admitted into the United States duty-free. Duty rates (unchanged from 1975) for other pumice products at yearend were as follows: TSUS No. 519.11, crude or crushed, valued not over $15 per ton, 0.02 cent per pound; TSUS No. 519.14, crude or crushed, valued over $15 per ton, 0.04 cent per pound; TSUS No. 519.31, in grains or ground, pulverized or refined, 0.17 cent per pound; and TSUS No. 519.93, millstones, abrasive wheels, and abrasive articles, n.s.p.f., and 523.61 articles, n.s.p.f., 7% ad valorem.

WORLD REVIEW

Portugal.—A geological survey on the Island of São Miguel in the Azores has indicated approximately 10 million tons of pumice located on the mountainous southern slopes of a volcanic crater near the village of Sete Cidades. Plans were reportedly underway for commercial development of the deposits.

United Kingdom.—A significant increase in imports of pumice by the United Kingdom from Italy, Greece, and West Germany was achieved in 1976 to meet the growing demand for pumiceous construction material. Pumice imports increased 145% (about 307,000 tons) compared with those of 1975. Italy and Greece supplied nearly 97%.

Rare-Earth Minerals and Metals

By Martha L. Kahn[1]

Production of rare-earth oxide (REO) contained in bastnäsite and monazite concentrates decreased about 13% in 1976; however, apparent domestic consumption of rare earths in most industries increased. The overall end-use consumption pattern remained similar to that of 1975. Petroleum catalysts continued to be the major consumer, with metallurgical applications second. The ceramic and glass industries were also major consumers.

Molycorp, Inc., and the Davison Div. of W. R. Grace & Co. continued to be the major processors of rare earths. Production of rare-earth compounds and metals was adequate to meet market demand. There was a slight increase in industrial stocks during the year.

U.S. exports of rare earths increased in 1976, but total REO imported decreased from the 1975 level. Monazite was imported from Malaysia; compounds and metals were imported mostly from Australia, Austria, Brazil, France, Japan, West Germany, and the United Kingdom; and yttrium concentrate was imported mostly from Canada.

Legislation and Government Programs.—At yearend 1976, a total of 7,174 short tons REO equivalent was held in the General Services Administration (GSA) stockpile. Disposals for the year totaled 55 tons REO equivalent. Government stocks of yttrium oxide (Y_2O_3) remained unchanged at 237 pounds.

DOMESTIC PRODUCTION

Concentrate.—Domestic production of REO in bastnäsite and monazite concentrates decreased about 13% in 1976 from the 1975 level. Bastnäsite continued to be the major source of rare earths; the remainder, less than 10%, was produced from monazite.

According to Molycorp's annual report, its Mountain Pass, Calif., operation produced 14,500 short tons of REO contained in bastnäsite concentrate during 1976; 1975 production was 16,500 tons.

Titanium Enterprises, owned jointly by American Cyanamid Co. and Union Camp Corp., recovered monazite as a byproduct of mining a beach sand deposit for titanium minerals and zircon, near Green Cove Springs, Fla. During 1976, monazite production increased substantially.

The only other domestic producer of monazite was Humphreys Mining Co. Again monazite was recovered as a byproduct of heavy-mineral beach sand mining. The dredging operation was located near Hilliard, Fla., and the titanium concentrates were trucked to the company dry plant at

[1]Physical scientist, Division of Nonferrous Metals.

Folkston, Ga., for processing. Monazite production decreased in 1976 from the 1975 level, due to the mining of titanium sands of lower monazite content.

Significant concentrations of rare earths, associated with uranium and thorium in the mineral allanite were discovered[2] on Seward Peninsula in Western Alaska by a U.S. Geological Survey field party. Samples of the mineralized rock, which was associated with alkaline dikes in a 100-square-mile area contained over 2% rare-earth elements.

Buttes Gas and Oil Co. continued feasibility and pilot-plant studies of its southwestern Colorado titanium prospect.[3] The ore mineral, perovskite, contained significant amounts of rare-earth elements that could be recovered. Kerr-McGee Chemical Corp. reported 74,000 tons of indicated recoverable monazite contained in its heavy-mineral sand deposit in Benton County, Tenn.

Compounds and Metals.—In 1976, there were two major processors and producers of rare-earth compounds, Molycorp and the Davison Div. of W. R. Grace & Co., Chattanooga, Tenn. Molycorp, with processing plants at Mountain Pass, Calif., Louviers, Colo., and York, Pa., continued to be the principal domestic producer. Molycorp's sales increased significantly to $27.2 million, compared with $18.9 million in 1975.[4]

A 3-year program to expand mill and chemical-plant production capacities at Mountain Pass was completed at yearend 1975. The new 200-ton-per-day bastnäsite thickening, filtering, and drying section at the mill began processing material in January 1976. A lanthanum concentrate dryer at the chemical plant also became fully operational in early 1976. The new capacity of the mill and chemical plant was 60 million and 30 million pounds, respectively, of rare-earth oxide.

Producers of high-purity rare-earth oxides and compounds were Molycorp; W. R. Grace & Co.; the Research Chemicals Div. of Nucor Corp., Phoenix, Ariz.; Atomergic Chemetals Corp., Plainview, N.Y.; and Transelco Inc., Penn Yan, N.Y.

Mischmetal production increased about 23% in 1976 from the 1975 level. Mischmetal shipments from primary producers also increased. Three domestic companies that produced mischmetal during 1976 were as follows: Ronson Metals Corp., Newark, N.J.; Reactive Metals and Alloys Corp., (REMACOR), West Pittsburgh, Pa.; and Rare Earth Metals Co. of America, (REMCOA), owned jointly by Aluminum Co. of America and Molycorp., Arnold, Pa. REMCOA produced mischmetal from its 125-ton-per-year demonstration unit at the beginning of the year.

Rare-earth ferrosilicon alloys were produced by three companies: Foote Mineral Co., Exton, Pa.; Ohio Ferro-Alloys Corp., Canton, Ohio; and Union Carbide Corp., Alloy, W. Va.

Nucor was the major producer of high-purity rare-earth metals, and Molycorp was the predominate producer of yttrium compounds. The yttrium was processed from yttrium rare-earth concentrates imported from Canada.

CONSUMPTION AND USES

Domestic rare-earth processors consumed an estimated 14,200 tons of REO contained in raw materials in 1976. Consumption of bastnäsite decreased about 17%; however, consumption of monazite increased more than 100%. Shipments of rare earth and yttrium products from primary processing plants to domestic end-use consumers were about 9,700 tons contained REO, valued at about $37 million.

The approximate distribution of rare earth and yttrium consumption by end use, based on information supplied by primary processors and certain consumers, was as follows: Petroleum cracking catalysts, 43%; metallurgical, including nodular iron and steel, other alloys and mischmetal, 35%; ceramics and glass, 14%; and miscellaneous, including electrical, arc carbons, and research 8%. High-purity rare earth and yttrium oxides and metals represented less than 2% of the total weight of shipments; however, such materials comprised a much larger proportion of the value of total shipments.

Domestic yttrium processors consumed an estimated 120 tons of Y_2O_3 contained in raw materials in 1976, compared with 95 tons in 1975. This increase was attributed to

[2]Miller, T. P., R. L. Elliot, W. I. Finch, and R. A. Brooks. Preliminary Report on Uranium, Thorium and Rare-Earth-Bearing Rocks Near Golovin, Alaska. U.S. Geol. Survey Open File Rept. 76-710, Sept. 27, 1976, 13 pp.

[3]Engineering and Mining Journal. International Directory Mining Activity Digest. New Development Highlight. V. 2, No. 10, Mar. 12, 1976, p. 1.

[4]Molycorp Inc. 1976 Annual Report, p. 5.

greater demand by manufacturers of color television phosphors.

The use of rare-earth zeolites in cracking catalysts to increase gasoline yields from petroleum feedstocks continued to be the single largest use of rare earths. Metallurgical usage of rare-earth elements, mostly as additives to ductile iron and steel, was stable. Rare-earth elements are added to high-strength low-alloy (HSLA) steels in mischmetal or rare-earth silicides.

The production of lighter and striker flints continued to be a major consumer of mischmetal. Other rare-earth alloys and metals were used in the production of high-temperature alloys and superalloys.

The glass industry continued to be a major consumer of rare-earth compounds, particularly cerium oxide. The established uses of cerium oxide are as an abrasive for polishing glass; an additive in eyeglasses, television tubes, and camera lenses; and as a decolorizing agent in refining clear glass. Other rare-earth oxides of praseodymium, erbium, holmium, and neodymium, were used as colorants in glass. Lanthanum oxide was used to improve the refractive quality of camera lenses.

The use of rare earths in X-ray phosphors increased in 1976. Terbium-activated gadolinium or lanthanum oxysulfide phosphors were used to intensify X-ray screen images. Because of the effectiveness of these phosphors, they allowed speedup of X-ray film exposure, which reduced patient X-ray dosages by as much as 80%.

Yttrium and europium oxide were consumed as key constituents of the red phosphor in color television tubes.

Synthetic garnets composed of yttrium-aluminum (YAG), yttrium-iron (YIG), gadolinium-aluminum (GAG), and gadolinium-iron (GIG). were used as microwave filters and control devices, as simulated diamonds, and, when doped with neodymium or erbium, in lasers. Minor quantities of gadolinium-gallium garnets (GGG) in thin-film, magnetic-bubble memory systems were used in communication and computer systems, including a 100-million-bit-capacity data recorder being built by the Autonetics Division of Rockwell International, and a recorded message machine at one of Michigan Bell Telephone Co.'s Detroit switching offices.

Significant quantities of rare-earth oxides and fluorides were used in carbon-arc lamps, which emit a high-intensity white light used in searchlights and the motion picture industry.

The consumption of rare-earth-cobalt alloys in permanent magnets continued to expand. These high-energy magnets, which are two to three times more powerful than conventional permanent magnets, are used mainly in small electric motors and generators, electric wrist watches, and electronic tubes. Samarium and rare-earth alloys were predominately combined with cobalt for magnet production. A new use of rare earths in 1976 was as phosphors in fluorescent lamps, which emit white light made up of only three narrow spectral bands (blue, green, and red). The blue phosphor is strontium chlorapatite-europium, and the red phosphor is yttrium oxide-europium. The new lamps were reported to offer about 30% more light output, greater brightness and visual clarity, and better color rendition than other fluorescent lamps.[5] It was estimated [6] that if this new lamp were to capture only 10% of the fluorescent bulb market, it would create a demand for high-purity rare-earth oxides roughly equivalent to that of the color television industry.

STOCKS

Stocks of rare earths in all forms, held by 15 rare-earth producing, processing, or consuming companies increased slightly during 1976.

At yearend 1976, bastnäsite concentrate stocks held by the principal producer and three other chemical processors increased by about 18% compared with the levels at the beginning of the year. Monazite stocks decreased 35% during the year. Stocks of compounds and mixtures of rare earths held by 10 companies increased about 6% during 1976. Mischmetal stocks increased about 16% during 1976. Stocks of high-purity metals held by three companies decreased about 46% in 1976.

[5]Cannon, J. G . Rare Earths - '76 Was Slow; Pickup Seen for '77. Eng. & Min. J., v. 178, No. 3, March 1977, pp. 183-188.

[6]The Value Line Investment Survey. Arnold Bernhard & Co., Inc. Pt. 3, 4th ed., Jan. 28, 1977, p. 587.

PRICES

Prices for domestic monazite increased about 25% during 1976. The average declared value of imported monazite, all from Malaysia, decreased slightly to $205 per short ton from $207 per short ton in 1975. The average price per metric ton of Australian monazite (minimum 60% REO plus ThO_2) as quoted in Metal Bulletin (London) remained constant during 1976 at $A170 to $A185 However, the price of Australian monazite in U.S. dollars decreased about 17% in December 1976 because of the devaluation of Australian currency. Quoted prices for Malaysian xenotime concentrate containing a minimum of 25% Y_2O_3 remained at the 1975 level of $2 to $3 per pound c.i.f.

Prices for unleached, leached, and calcined bastnäsite containing 55% to 60%, 68% to 72%, and 85% to 90% REO, respectively, were increased by yearend from 45, 50, and 60 cents, respectively, to 50, 58, and 68 cents per pound REO, respectively, f.o.b. Mountain Pass or Nipton, Calif., in 100-pound paper bags or 55-gallon steel drums in truckload or carload lots.

Prices of rare-earth compounds and metals remained at about the 1975 level. Most prices of rare-earth products were negotiable if purchased in large quantities. A sampling of quoted prices at yearend of rare-earth compounds, per pound f.o.b. plant were as follows: Lanthanum-rare-earth hydrate, 75% REO, $0.75; rare-earth chloride, 46% REO, $0.55; rare-earth carbonate, 65% REO, $1.30; and cerium fluoride, 62% REO, $1.55.

Prices quoted in the American Metal Market for 1-pound ingots in 50- to 100-pound lots of 97% didymium and cerium-free mischmetal were $15 and $12, respectively, f.o.b. plant. Mischmetal, 99.8%, was quoted at $3.45 per pound same basis. Quoted prices, in dollars per pound, of rare-earth metals for magnet use remained at the 1975 level: Cerium, $18; lanthanum, $27.50; praseodymium, $62.50; and samarium, $75 (all 99% purity and in 10- to 100-pound amounts).

Table 1.—Prices of high-purity rare-earth oxides, salts, and metals in 1976 [1]

(Dollars per pound)

Element	Oxide[2]	Salts[3]	Metal[4]

[2]Minimum 99.9% purity, more than 1 pound.
[3]Minimum 99.9% purity, more than 1 pound; includes chlorides, nitrates, sulfates, oxalates, and acetates.
[4]Minimum 1 pound, ingot form.

FOREIGN TRADE

Exports of bastnäsite concentrates contained about 2,700 tons of REO, according to Molycorp, the sole producer. Exports of ferrocerium and other pyrophoric alloys to the Republic of Korea, Canada, and 28 other countries increased 19% to 119,792 pounds valued at $334,973. The average unit value was $2.80 per pound. Shipments of compounds and mixtures of rare-earth metals, including yttrium and scandium, went to 33 countries. Japan and West Germany received about 56% of the 631,593 pounds, valued at $5,015,239. This was a 57% decrease in shipments from 1975.

Monazite imports (table 2), all from Malaysia, decreased to 2,103 tons with an average unit value of $205 per ton. Imports of cerium oxide, predominately from France, increased to 814 pounds valued at $6,713 in 1976 compared with 624 pounds valued at $5,216 in 1975. The average unit value was $8.25 per pound. Imports of cerium chloride, from West Germany, totaled 4,409 pounds, with an average unit price of 72 cents per pound. Imports of other cerium compounds, predominately from France, totaled 13,055 pounds valued at $57,178. The unit value ranged from $3.93 (France) to $154.69 (West Germany) per pound.

Rare-earth metals, scandium, and yttrium imports for consumption totaled 74 pounds valued at $9,131. In addition, there were general imports of rare-earth metals, scandium, and yttrium from the U.S.S.R. totaling 4,483 pounds valued at $141,132.

Imports of ferrocerium and other pyrophoric alloys increased 19% to 40,259 pounds valued at $166,978. Japan supplied 79% of the total valued at $118,824, followed by France with 14% valued at $33,589. Other suppliers were the United Kingdom, India, Austria, and Switzerland. Imports of rare-earth metals and alloys, predominately from Australia and Brazil, increased 123% to 43,509 pounds valued at $70,612. The average unit value decreased from $5.73 per pound in 1975 to $1.62 per pound in 1976 owing to increased mischmetal imports from Australia. Imports of other rare-earth-metal alloys, entirely from West Germany, totaled 1,044 pounds valued at $3,387.

WORLD REVIEW

The major world sources of rare earths were bastnäsite, which accounted for about 68% of world mine production in 1976, and monazite. Separated compounds and metals of lanthanum through europium were derived mainly from bastnäsite. Separated compounds and metals of the other rare-earth elements and yttrium were derived mainly from monozite. Many countries had limited rare-earth-processing capacity; however, only five countries—France, the United Kingdom, Japan, U.S.S.R., and the United States—produced a full range of rare-earth compounds and metals in commercial quantities.

Table 4.—Monazite concentrates: World production, by country

(Short tons)

Country[1]	1974	1975	1976[p]

[1]In addition to the countries listed, Indonesia and North Korea may produce monazite, but information is inadequate to make reliable estimates of output levels.
[2]Exports.

Australia.—According to the Rutile & Zircon Development Assoc., Ltd., the 1976 production of monazite by member companies was as follows, in tons:

State	1974	1975	1976
New South Wales	1,071	1,207	1,089
Queensland	30	685	227
Western Australia	2,550	3,252	3,698
Total	3,651	5,114	5,014

Mary Kathleen Uranium, Ltd., continued work on a pilot plant to recover rare earths from uranium processing operations.[7] Metals Exploration Ltd. and Alliance Oil Development Australia NL announced the discovery of mineral sands containing 800,000 tons of heavy minerals at Cataby, about 90 miles north of Perth.[8] The heavy minerals contain about 1.5% monazite. Associated Minerals Consolidated Ltd. and Western Titanium Ltd., announced merger plans. The two companies produced 2,095 tons of byproduct monazite in 1976.[9] Westralian Sands Ltd., a producer of byproduct monazite, resumed full-scale mining operations at Yoganup.[10] The mine and treatment plant had been on a care and maintenance level due to low demand for ilmenite.

Canada.—Denison Mines, Ltd., reported production of 58,000 pounds of yttrium oxide contained in yttrium-rare-earth concentrate in 1976; all production was exported. This was a 25% decline in production from that in 1975 and was mainly a result of labor problems during 1976. Since the start of operations 17 years ago, a total of 702,000 pounds of yttrium oxide has been produced.[11] The yttrium-rare-earth concentrate, which is a byproduct of uranium mining, contained about as much REO as Y_2O_3.

Germany, West.—Th. Goldschmidt AG of Essen increased its capacity to produce powder form rare-earth cobalt alloys to 50 tons per year. [12] The alloys were for use in permanent magnets.

India.—About 500,000 tons of monazite was estimated to occur in a 15-mile belt in coastal sands in the Ganjam and Puri districts, Orissa State.[13]

Separation of byproduct monazite, by electromagnetic and electrostatic mineral separation techniques, from ilmenite deposits in the Chavara beach sands of Kerala, was under consideration by Kerala Minerals and Metals Ltd.[14]

Source: Japan Metal Journal. Demand Prospects of Rare-Earths. V. 7, No. 16, April 18, 1977, p. 7.

Japan.—In 1976, rare-earth demand increased significantly over that of 1975, owing mainly to increased demand for color television sets and transceivers.[15] The United States provided about one-fourth of the total Japanese imports of rare-earth metals and compounds. Rare-earth consumption in Japan for 1975, 1976, and the estimated demand for 1977 is given in table 5.

Malaysia.—Malaysian Rare Earth Corp. (MAREC), a joint venture of Mitsubishi Chemical Industries Ltd., of Japan and Beh Minerals Sendirian Berhad of Ipoh, Perak State, Malaysia, in 1976 became the first chemical company in Malaysia to upgrade locally produced zenotime.[16] The plant's trial run and commissioning occurred in November, and the first overseas shipment took place on November 11, 1976. MAREC planned to produce about 130 tons of a 50% yttrium concentrate per year.

South Africa, Republic of.—The proposed heavy mineral operation north of Richards Bay on the east coast by two companies, Tisand (Pty.) Ltd., and Richards Bay Iron and Titanium (Pty.) Ltd., was scheduled to proceed as soon as financial arrangements were completed. The proposed mining area will be approximately 11 miles long and 2 miles wide. Monazite could be recovered as a byproduct of rutile and zircon mining.

Yemen.—Hunting Geology & Geophysics Ltd., was investigating heavy minerals in beach sands as part of a larger study being performed for the Government.[17] A 2-year program was anticipated.

TECHNOLOGY

Research continued on rare-earth X-ray screen film systems.[18] Compared with systems that do not contain rare-earth elements, rare-earth systems were up to 13 times faster, resulted in less patient exposure, and improved operational parameters. Rare-earth magnet research continued in areas as diverse as magnets in dentures to keep teeth in place, and the use of high-speed (about 190 miles per hour) magnetically levitated vehicles, which have been built and tested in West Germany and Japan.[19] Magnetic bearings with zero friction and the use of rare-earth-cobalt magnets in ironless armature torque motors were also studied.

Research continued on the development of a rare-earth auto-emission-control catalyst that tolerates leaded gasoline.[20] $LaCoO_3$ was found to be an inexpensive material that was not poisoned by tetraethyl lead or lead dibromide or ethylene dibromide, and retained its catalytic activity after exposure to high-temperature surges simulating backfire.

A relatively inexpensive crystalline alloy, containing lanthanum, neodymium, praseodymium, and nickel was found to be capable of adsorbing six atoms of hydrogen per molecule. It was suggested that such hydrogen adsorbers could be used in solar heating and cooling of homes, leveling peak-load demands at electric utility companies, for advanced compressor and nonpolluting engine design, safer hydrogen storage at petrochemical, synthetic fuel, and chemical-processing plants, and in offgas purification systems.[21]

Research on rare-earth lasers continued in 1976, with emphasis on nuclear fusion applications.[22] The largest neodymium glass laser in the world was being built. It was to contain 1,000 liters of rare-earth-doped material.[23] The University of Rochester's Laboratory for Laser Energetics launched a 5-year, $46.5 million program to build and test a 10-Kilojoule neodymium glass laser system, which will have a peak power of 20 to 40 terawatts.[24] KMS Fusion continued the only laser fusion research effort by a private company and planned to expand the power of its neodymium glass laser system in 1977 to 4 or 5 terawatts.

The U.S. Air Force manufactured rods as long as 4 inches of anisotropic yttrium aluminate doped with neodymium.[25] These rods are potential replacements for neodymium-doped yttrium-aluminum-garnet (YAG) in solid-state lasers.

Two rare-earth laser devices were on the Industrial Research list of 100 top products of 1976.[26] One of the top products was a new laser ion-host system, consisting of lanthanum beryllate single crystals doped with neodymium, which had advantages over conventional YAG doped with neodymium. The other laser device was an yttrium lithium fluoride crystal doped with holmium used as a pulsed or continuous source of 2-micron laser radiation.

A patent was issued for the extraction of columbium, rare earths, and thorium from pyrochlore.[27] A patent was issued [28] for a method of purifying an atmosphere containing carbon monoxide by passage through a catalyst bed of terbium oxide, in which the carbon monoxide is oxidized to carbon dioxide. The use of a rare-earth catalyst to convert nitrogen and sulfur compounds, created during the dosposal of dynamite-manufacturing wastes, to oxides was under consideration.[29]

A new alloying method, mechanical alloying, in which rare-earth elements can be used was discussed.[30] The base metal and alloying metals are combined in a high-energy ball mill in a nitrogen or inert gas atmosphere, with no lubricant. Mechanical alloying has led to the development of an alloy that combines the moderate-temperature properties of nickel-base alloys with the high-temperature properties of nickel strengthened by a dispersion of very small particles of thorium or yttrium oxide.

Mechanically alloyed nickel-20 weight-percent chromium alloys containing dispersed Y_2O_3 and/or La_2O_3 were compared with a commercial alloy and a mechanically alloyed material not containing rare-earth elements.[31] It was found that less than 0.1% La_2O_3 or Y_2O_3 improved the oxidation resistance of the nickel-chromium matrix compared with the commercial alloy. The rare-earth-doped alloys also exhibited better scale adhesion.

Crucibles made with yttrium oxide were found to successfully contain new titanium alloys with minimal interaction between the crucible and the molten titanium.[32] The crucibles, with compositions Y_2O_3-15%Ti and Y_2O_3 with a Y_2O_3-K_2SiO_3 face coat, resulted in typical casting contamination levels of 0.2%-0.49% oxygen and 0.2%-0.5% yttrium. These crucible materials could be used in the development of a low-cost-investment casting process for producing titanium alloys.

The use of the rare-earth ions Ho^{3+},

Er^{3+}, Tm^{3+}, and Yb^{3+} in anti-Stokes phosphors was studied.[33] Anti-Stokes phosphors, or up-converters, adsorb infrared photons and combine their energies in multiples of two or three to emit new photons in the visible or ultraviolet region. These anti-Stokes phosphors could be used for large area displays in place of conventional light-emitting diodes.

A psoriasis treatment using a dysprosium gas-discharge lamp was developed.[34] The treatment reportedly avoided the risk of toxic side effects sometimes associated with oral treatment.

Rare-earth research continued at Bureau of Mines metallurgy research laboratories on a number of projects: The use of rare-earth oxides as additives in high-temperature ceramics, determining optimum composition and conditions required to fabricate mischmetal-cobalt magnets, improving methods of production of rare-earth silicide, and the use of rare-earth transition metal catalysts for methanation of CO and H_2 during synthetic natural gas production and for liquid-phase catalytic reactions.

Rhenium

By Larry J. Alverson[1]

Domestic mine production of rhenium increased substantially in 1976, yet the industry was still operating 70% below full capacity level, or at about 80% of the average production level of the past several years. Consumption increased 38% over that of 1975 to a record 8,300 pounds. Imports of ammonium perrhenate also reached a record high of approximately 4,000 pounds, as prices for both metal powder and compounds continued to decline. Bimetallic platinum-rhenium catalysts used in petroleum refining continued to be the major use for rhenium, accounting for about 90% of consumption.

Table 1.—Salient rhenium statistics

[e]Estimate.

DOMESTIC PRODUCTION

Production of rhenium, as a byproduct of molybdenite (MoS_2) from various sources, increased in 1976 to 4,400 pounds contained in ammonium perrhenate (NH_4ReO_4) from 2,000 pounds in 1975. Shattuck Chemical Co., a subsidiary of Engelhard Minerals & Chemicals Corp., was the leading producer in the United States. Shattuck processed MoS_2 concentrate from the United States and Canada at its Denver, Colo., molybdenite roasting facility. Rhenium was recovered as ammonium perrhenate, from which the company made a variety of rhenium products.

M&R Refractory Metals, Inc., at its Winslow, N.J. plant, produced ammonium perrhenate for Engelhard Minerals & Chemicals Corp., and for Utah International, Inc. (UI) on a toll (contract) conversion basis. Production at the plant, halted by a fire in late 1975, was not resumed until the spring of 1976. In prior years, Molycorp, Inc., produced ammonium perrhenate from byproduct MoS_2 concentrate from western U.S. porphyry copper ores. However, in 1976 the rhenium production facility at Washington, Pa., was inactive. Kennecott Copper Corp.'s recovery operation at Garfield, Utah, remained closed during the year, although a subsidiary, Cleveland Refractory Metals, remained active in the domestic and international rhenium market, operating primarily from accumulated stocks.

The United States operated at about 30% of rhenium mine production capacity (byproduct) in 1976.

[1]Industry economist, Division of Ferrous Metals.

CONSUMPTION AND USES

Estimated 1976 consumption of rhenium was about 8,300 pounds, an increase of 38% from that of 1975. Increased usage took place in all sectors of the market, with the largest percentage increase in the flashbulb area. However, bimetallic platinum-rhenium catalysts used in petroleum refining represented about 90% of total rhenium consumption.

Of the three types of bimetallic catalytic reformers, semiregenerative units accounted for 49.4% of reforming capacity compared with 38.6% in 1975 and 27.6% in 1971. Cyclic and other bimetallic units combined, decreased in total capacity from that of 1975. However, the combined capacity of all three types was at an all-time high of over 60% of total U.S. reforming capacity, an increase of about 20% over that of 1975. Platinum-rhenium's share of total bimetallic catalyst capacity was about 65% to 75%, or about 40% to 45% of total domestic reforming capacity. Indications are that U.S. refiners are focusing on catalytic reforming and other octane improvement processes to cope with rising demand for unleaded gasoline and the tetraethyl lead gasoline phasedown.

The excellent activity and yield stability of Chevron Oil Co.'s platinum-rhenium catalysts reduce the necessity for more expensive cyclic or continuous reforming. The activity stability of these platinum-rhenium catalysts permits commercial, long-cycle, semiregenerative Rheniforming at a pressure of 125 pounds per square inch, gage. This operating pressure is as low as any achieved by other commercial cyclic and continuous reformers using bimetallic catalysts and is much lower than pressures used in cyclic reformers with monometallic platinum catalysts.

Numerous conversions to bimetallic reforming catalysts took place during the year; most were in the smaller refineries (2,000 to 8,000 barrels per stream-day).

The remaining 8% of estimated domestic rhenium consumption was used in X-ray tubes and targets, high-temperature thermocouples, electrical contacts, electronic devices, vacuum tube and flashbulb filaments, heating elements, metallic coatings, electromagnets, and high-temperature alloys in research and development work.

A new method for dating the universe was disclosed during the year; it is based on the decay of the radioactive isotope rhenium 187 to the stable isotope osmium 187. Use of this rhenium-osmium "clock" was proposed to be theoretically sounder than the other principal nuclear dating technique which is based on radioactive decay of uranium to thorium. One reason is that the half-life of rhenium-osmium decay, 44 billion years, is substantially longer than the generally accepted age of the universe. Therefore, calculations should be less susceptible to errors from uncertainties in details of the stellar processes involved than they would be using the shorter lived uranium-thorium decay process.[2]

The most widely used tungsten-rhenium (W-Re) thermocouple alloy combinations are W versus W-26% Re, W-5% Re versus W-26% Re, and W-3% Re versus W-25% Re. Because of the inherent brittleness of unalloyed tungsten, the W versus W-26% Re thermocouple wire is more difficult to handle than the other two. The average electromotive force of W-3% Re versus W-25% Re is slightly less than that of W vs W-26% Re and slightly more than that of W-5% Re versus W-26% Re. The ductility of W-3% Re is about equal to that of W-5% Re but much superior to that of unalloyed tungsten. All three combinations can be used to 2,760°C in hydrogen or inert gas atmospheres and in vacuum but undergo rapid deterioration under oxidizing conditions.

Research continued on rhenium's use in nickel-base high-temperature alloys. Rhenium was used in some cobalt-base alloys for high-temperature space applications and in some nickel-base alloys used in jet engine turbine blades. The cobalt-base alloy contains 2% rhenium, and the nickel-base alloy contains 0.5% rhenium.

---

[2]Chemical& Engineering News. Method Dates Universe at 20 Billion Years. V. 54, No. 29, July 12, 1976, pp. 4-5.

PRICES

Prices paid for rhenium metal powder, perrhenic acid, and ammonium perrhenate during the year reportedly were below those quoted in most domestic trade journals. The price for metal powder ranged from $500 to $650 per pound, dependent upon grade and quantity. The prices for perrhenic acid and ammonium perrhenate, both of which are compounds of rhenium, ranged from less than $400 to more than $600 per pound. Some buyers paid prices outside these ranges, depending on their own situations. However, the general trend of prices continued downward, as it has in the past several years, reflecting the inactivity in new petroleum refinery construction.

Prices quoted by Cannon-Muskegon Corp., for W-Re thermocouple wire, ranging in size from .003 inch to .020 inch, were $3.50 to $21.00 per double foot of W versus W-26% Re. Prices for W-5% Re versus W-26% Re were $5.00 to $30.00 per double foot for similar sizes.

FOREIGN TRADE

Imports for consumption of ammonium perrhenate increased sharply during the year to a record high of 4,047 pounds of contained rhenium valued at $1,407,000. All the material came from Chile and West Germany. The Chilean material was withdrawn from bonded warehouses, while the West German material was directly imported. Imports increased partly in response to increased demand from nearly all sectors of the rhenium market.

Imports for consumption of rhenium metal and waste and scrap increased to 82 pounds from 59 pounds in 1975. This remains insignificant compared with the record high of 1,437 pounds in 1973. However, the disparity has been more than accounted for by increased ammonium perrhenate imports, which have a more favorable duty status and are more easily obtained.

The duty on imports of ammonium perrhenate from market economy countries was 4% ad valorem, while the duty on that from the central economy countries was 25% ad valorem. The import duty on rhenium metal from market economy countries remained at the January 1, 1972, rates of 5% ad valorem for unwrought rhenium metal and 9% ad valorem for wrought rhenium metal. Wrought metal items are, however, seldom imported to the United States. The duty on wrought and unwrought rhenium metal from central economy countries remained unchanged at 45% and 25% ad valorem, respectively. The rhenium content of imported molybdenite concentrate was not taxed. The duty on rhenium waste and scrap was suspended indefinitely in 1975.

WORLD REVIEW

World production of rhenium totaled 14,200 pounds, compared with a total world potential capacity of 27,300 pounds, according to a report in the German trade journal Handelsblatt. Western European production reportedly was 3,300 pounds from a capacity of 5,700 pounds.

Porphyry copper deposits in Canada, Chile, Peru, and the United States were the major worldwide sources of rhenium. Rhenium recovery facilities outside the United States exist in Chile, Belgium, Bulgaria, East and West Germany, France, Sweden, the United Kingdom, and the U.S.S.R.

Canada.—All Canadian rhenium production was by UI's Island Copper mine on Vancouver Island, British Columbia. In 1976, shipments of molybdenite concentrate to the United States and Europe totaled about 2,400 tons containing approximately 4,500 pounds of rhenium. Companies in the United States and Europe toll-processed the MoS_2 concentrate for UI and returned the rhenium as ammonium perrhenate and perrhenic acid for subsequent sale. The mine has one of the richest concentrations of rhenium in the world.

Chile.—Production of rhenium in Chile in 1976 totaled 3,000 pounds contained in 4,350 pounds of ammonium perrhenate. Expansion of molybdenum output, and hence rhenium production capability, continued during the year. A new molybdenum plant at Saladillo was being built in 1976 to extract molybdenum from the Government-owned Andina copper mine's copper-molybdenum ore. The rhenium content averages 350 parts per million (ppm) in the molybdenite concentrate.

The firm Molibdenos y Metales, S.A. (MOLYMET) was created at the end of 1975. It will be responsible for producing and marketing molybdenum and rhenium products, which were formerly handled by Carburo y Metalurgia S.A. (Carbomet), a rhenium producer since 1971.

Germany, West.—Western Europe's newest petroleum refinery, near Wilhelmshaven, came onstream in December 1975. The refinery, owned by Mobil Oil AG, utilizes a catalytic reformer of Mobil design. It is a semiregenerative unit employing a platinum-rhenium catalyst, designed to operate under the most severe conditions for 6 months before regeneration. Several other bimetallic catalyst reforming units in Germany were scheduled for completion in 1977 and 1978. One such unit of Oberrheinische Mineralölwerke GmbH, located at Karlsruhe, will employ a 16,000 barrel-per-day (b/d) Platformer to make lead-free gasoline.

United Kingdom.—Small amounts of residues containing rhenium were recovered from roasting molybdenite concentrates by three companies: Murex, Ltd., at Reinham, Essex; High Speed Steel Alloys Ltd. at Widnes; and Minworth Metals Ltd., at Stowmarket. The residues were processed for rhenium recovery by Johnson Mathey and Co., and New Metals & Chemicals Ltd.

U.S.S.R.—The first Soviet rhenium recovery operation was put onstream in 1948 at the Balkhash plant in Kazakhstan. Rhenium was recovered from solutions derived from liquors used to leach low-grade molybdenite concentrate. The liquors were upgraded by evaporation, and metal was recovered from solution by cementation with metallic iron. Presently, the same plant treats flue dusts of copper, lead, and zinc smelters as well as solutions from molybdenite leaching. The plant employs up-to-date technology for the recovery of rhenium.

Since porphyry copper deposits are not abundant in the USSR, the Soviets rely on a number of sources for rhenium supply. Therefore, a number of processes that recover rhenium from flue dust of various nonferrous metal smelters as well as from molybdenite concentrate have been developed. The dusts average between 200 and 700 ppm rhenium and require hydrometallurgical treatment to recover the rhenium.

One source of rhenium is the Dzhezkazgan porphyry copper mine where the rhenium concentration ranges from 10 to 100 ppm. It is highest in the bornite mineralization and falls to about 40 ppm in chalcopyrite and sphalerite mineralization. Galena mineralization contains about 20 ppm rhenium. The oxidized cap contains only 0.04 ppm rhenium.[3]

TECHNOLOGY

The Bureau of Mines demonstrated an electrooxidation-solvent extraction-carbon adsorption process for recovering molybdenum and rhenium from low-grade molybdenite concentrate at a commercial operation. The equipment used was a prototype of a commercial size, 125-kilovoltampere, 41-electrode cell operating at 1,000 amperes. The flow sequence consisted of dissolution of metal values by electrooxidation, liquid-solid separation by thickening and filtering, acidification, and chlorate ion removal by sulfur dioxide treatment. This was followed by concentration of molybdenum and rhenium by solvent extraction, separation of molybdenum and rhenium by carbon adsorption, and metal value recovery by crystallization. The rhenium was recovered as ammonium perrhenate. The electrooxidation process in the pilot plant resulted in dissolution of 99.1% of the rhenium with an energy consumption of 13.7 kilowatt-hours per pound of molybdenum extracted.[4]

The Bureau published results of a study on the thermodynamic properties of high-purity rhenium oxides. Prior to this investigation, high-temperature enthalpy or Gibbs energy of formation data were not available for the three stable oxides of rhenium - ReO_2(s), ReO_3(s), and Re_2O_7(s,l). The temperature range of the heat capacity measurements was 5° to 310°K for ReO_2, and 8° to 309°K for ReO_3. High-temperature enthalpy measurements alone were determined for pure Re_2O_7(s,l).[5]

Activated sintering was shown by Soviet scientists in 1976 to be synonymous with "activated alloying" as applied to the powder metallurgy of molybdenum- and tungsten-base alloys. Thus, the use of small additions of palladium or nickel to powder mixtures of tungsten and rhenium or tungsten and chromium effectively promoted alloying during sintering for 1 to 2 hours at 1200° to 1250° C.

A patent was issued for the recovery of rhenium from molybdenite or copper sulfide ore roaster gases. Dust-free roaster gas was wet-filtered, and the rhenium-bearing liquor was recycled to upgrade the rhenium concentration. The rhenium-bearing liquor from the first scrubbing step was added to the second scrubbing step, and the excess accumulated liquor was drawn off for conventional processing for extraction of the rhenium values.[6]

Salt

By Russell J. Foster[1]

Salt production in the United States rose 5% in 1976 to 43,801,000 tons. The amount of salt sold or used by domestic producers was up 8%, mostly owing to greater chlorine-caustic soda production and increased use of salt on highways. Solar, rock, and brine salt exhibited the most substantial gains. Prices of all forms of salt advanced. The largest price increases occurred in evaporated salt. Imports reached a record 4.4 million tons.

Legislation and Government Programs.—The Energy Policy and Conservation Act of 1975 authorized the creation of a strategic petroleum reserve consistent with a plan developed by the Federal Energy Administration (FEA). In 1976 FEA submitted for Congressional approval a plan that called for the storage of 500 million barrels of crude oil by December 1982 in underground salt domes, salt mines, or rock caverns, which are readily accessible to tankers or major crude oil pipelines, or both. Capacity for storing approximately 240 million barrels will be developed for an early storage reserve, and FEA will endeavor to fill this capacity to 150 million barrels by December 1978. The reserve will cost $7.5 to $8.0 billion to design, construct, fill, and maintain through 1982. Underground storage will minimize cost and environmental problems while maximizing security. Existing caverns are available and new ones can be formed efficiently. Six of eight candidate sites for storage of the reserve are salt deposits in Louisiana and Texas. Rock salt has several characteristics that make it attractive for cavern construction and storage. When relatively pure, it is generally impervious to liquid and gas, has high compression strength, exhibits plasticity to seal incipient fractures, and can easily be solution-mined. The feasibility of using salt caverns for storage has been previously demonstrated in Europe and the United States.[2]

Returning to its original position, the Federal Government announced plans to dispose of radioactive wastes by storing them in stable geologic formations, such as salt deposits, under the continental United States. The Energy Research and Development Administration proposed to construct

a waste isolation pilot plant in the bedded salt and potash of southeastern New Mexico. The main purpose of the facility would be to test and demonstrate the operational and technical principles of a permanent repository.[3]

DOMESTIC PRODUCTION

The amount of salt sold or used by domestic producers increased nearly 8% in 1976. Solar salt showed the largest gain, 11%. Rock salt and salt in brine were also up significantly. In 1976, 55 salt-producing companies operated 99 plants in 16 States and Puerto Rico. Twelve of the companies produced over 1 million tons each, accounting for 87% of U.S. salt production. The five leading States in the amount of salt sold or used follow:

State	Percent of total
Louisiana	30
Texas	22
New York	15
Ohio	11
Michigan	10
Total	88

The percentage of salt sold or used by domestic producers in 1976 by type follow:

	Percent
Salt in brine	52
Mined rock salt	35
Vacuum-pan salt	8
Solar-evaporated salt	4
Grainer or open-pan salt	1

The water in the Great Salt Lake continued to rise in 1976, reaching its highest level in 50 years. To prevent further damage to dikes around salt operations and other lakeshore industries, the Great Salt Lake Division of Utah's Department of Natural Resources was considering a proposal to pump a large amount of the water to a nearby desert area, creating a new lake.[4]

The final phase of 9 years of litigation concluded in June 1976, when the U.S. Supreme Court ruled that Utah also held title to all relict shorelands of the Great Salt Lake, thus granting total ownership of the lake and its mineral content to the State. The shorelands had been covered by water at the time of Utah's statehood, but became exposed when the shorelines receded. Morton Salt Co. had been the largest single private landowner of lakeshore prior to the decision.[5]

In March 1976, Morton Salt Co. announced the closing of its salt mine at Seneca Lake, N.Y., owing to high operating costs and an oversupply of rock salt in the market area.[6] Cargill, Inc., acquired majority ownership in Watkins Salt Co., an evaporated salt producer located at Watkins Glen, N.Y.[7]

STOCKS

Total salt stocks at yearend 1976 as reported by producers amounted to 2.3 million tons, or 5% of production. Over 56% was in the form of rock salt and 35% was solar salt. Solar salt had the greatest share of its production in stocks, 46%. Rock salt stocks were 8% of production, and the amounts of open-pan and vacuum-pan salt production in stocks were 3% and 2%, respectively. Brine inventory at yearend was small.

CONSUMPTION AND USES

A resurgent U.S. chemical industry increased its consumption of salt in 1976. The amount of salt sold or used by domestic producers for the production of chlorine-caustic soda rose 2 million tons. Synthetic soda ash production consumed less salt because of reduced capacity, but salt usage in the syntheses of other chemicals was up. Nearly 59% of all salt sold or used by domestic producers was raw material for the manufacture of chemicals.

Weather conditions across the nation necessitated a large increase in the use of salt on highways. Most other categories of distribution also showed gains over 1975, particularly the textile, metals, oil, and pulp and paper industries. The only area besides soda ash production in which salt consumption dropped notably was the rubber industry.

W Withheld to avoid disclosing individual company confidential data; included with "Other."
[1]Less than 1/2 unit.
[2]Includes shipments to overseas areas administered by the United States, Puerto Rico, exports, some shipments to unspecified destinations, and States indicated by symbol W.
[3]Data may not add to totals shown because of independent rounding.
[4]Differs from totals in tables 2, 4, and 5 because of changes in inventory.
[5]Differs from totals in tables 1, 11, 12, and 13 because of incomplete data on the distribution of imported salt.

PRICES

The following salt prices were quoted at yearend 1976 in Chemical Marketing Reporter:[8]

	Per 100 pounds
Salt, evaporated, common, 100-pound bags, carlots or trucklots, works	$1.99
Salt, chemical-grade, same basis	2.23
Salt, rock, medium coarse, same basis	1.35
Salt, rock, extra coarse, same basis	1.40

The average values of different classes of salt in bulk, f.o.b. works, as reported by producers follow:

	Per ton	
	1975	1976
Evaporated:		
Open pans or grainers	$43.02	$51.67
Vacuum pans	43.01	50.56
Solar	12.01	14.36
Pressed blocks, all sources	41.42	45.51
Rock salt, bulk	7.34	7.82
Salt in brine	3.75	3.80

The weighted average price increase for all salt was 5%. Open-pan salt displayed the largest rise in price, 20%. The smallest increase occurred in brine at slightly more than 1%.

In October 1976 four major salt companies, Cargill Inc., Diamond Crystal Salt Co., International Salt Co., and Morton Salt Co., announced price increases ranging from 8% to 12% for rock and evaporated salt, effective in late 1976 and early 1977. Increased costs of energy, labor, packaging, and distribution were the factors cited.[9]

[8]Chemical Marketing Reporter. Current Prices of Chemicals and Related Materials. V. 210, No. 26, Dec. 27, 1976, p. 39.

[9]Wall Street Journal. Two More Processors Set Price Increases on Salt of at Least 8%. V. 188, No. 82, Oct. 26, 1976, p. 40.

FOREIGN TRADE

In 1976 exports of salt from the United States declined 24%, to 1 million tons. Canada received 95% of exported U.S. salt.

The United States imported a record 4.4 million tons of salt, an increase of 35%. Canada regained its position as the principal foreign source of salt for the United States with 38% of the total. The Bahamas provided 32% and Mexico 16% of salt imports. Net imports of salt claimed 7% of apparent consumption.

Table 9.—Salt shipped to the Commonwealth of Puerto Rico and overseas areas administered by the United States

Area	1975		1976	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)
American Samoa	210	$17	[1]213	[1]$11
Puerto Rico	19,375	2,261	17,106	2,197
Virgin Islands	[2]219	26	398	22

[1]Effective August 1976, data on shipments from the United States to American Samoa were no longer compiled by the Bureau of the Census owing to elimination of the requirement for filing export declarations for such shipments. The 1976 figure, therefore, reflects only the months January through July.
[2]Adjusted by the Bureau of Mines.

[1]Disagreement with totals in tables 1, 11, 12, and 13 is because of incomplete data on the uses of imported salt.

WORLD REVIEW

World salt production in 1976 was estimated at 183 million tons. Distribution of the production by continent follows:

	Million tons	Percent
Europe	66.9	37
North America	57.6	31
Asia	44.8	25
Oceania	5.9	3
South America	5.9	3
Africa	2.2	1

The 12 principal salt-producing nations, which together accounted for 81% of the world's salt, are as follows:

	Percent
United States	24
People's Republic of China	18
U.S.S.R.	8
United Kingdom	5
Germany, West	4
France	4
Poland	3
Australia	3
Canada	3
Mexico	3
India	3
Romania	3

Algeria.—A contract was awarded to Tecnosel of Milan, Italy, for a technical and economic feasibility study of a 500,000-ton-per-year solar salt operation.[10]

[10]European Chemical News. Tecnosel Wins Algerian Solar Salt Study. V. 29, No. 761, Nov. 12, 1976, p. 48.

Australia.—In March, following Japanese acceptance of a 40% increase in the price of Mexican salt, the Australian Government raised the minimum price for salt exports to Japan by 33%. An interim increase of 24% had been agreed upon at the beginning of 1976.[11]

Canada.—Soquem, the crown-owned Quebec mining exploration company, announced plans to produce 1 million tons of salt per year by 1980 from deposits on the Magdalen Islands in the Gulf of St. Lawrence. In addition to mine development work, construction of a $20 million port for shipping the salt to the mainland was scheduled. Initially, total salt production has been designated for deicing the roads of Quebec.[12]

International Minerals & Chemical Corp. (Canada) Ltd. signed an agreement with the Government of New Brunswick to explore and develop a potash and salt prospect in a 77-square-mile area near Salt Springs. The initial exploration work could lead to development of a mine and plant by 1982, in which case the agreement would commit the company to produce and market a minimum tonnage within a specified time and to pay provincial royalties on the products.[13]

Germany, West.—Salzgewinnungsgesellschaft of Westfalen began drilling for brine in the Gronau area near the German-Dutch border. Plans call for the drilling of 15 new holes by 1978. The brine will be pumped through a pipeline to electrolysis plants at Rheinberg and Marl.[14]

Greece.—Bertzeletos & Bros. and the Dutch firm Akzo Zout Chemie Nederland BV have formed a joint venture called Greek Salt for the purification, drying, and packaging of solar salt. The new facility, near Soussaki on the Gulf of Corinth, was scheduled to go onstream in October 1976 with a production of 24,000 tons per year[15]

Hellenic Industrial and Mining Investment Co. was investigating the possible expansion and modernization of the solar salt works at Messolonghi in western Greece. An increase in capacity from the present 110,000 tons to 550,000 tons would cover the requirements of a proposed chlorine-caustic soda plant near Kavala, and a soda ash facility at Messolonghi.[16]

Iran.—The construction of a $10 million salt operation with a production capacity of 550,000 tons per year was completed near Bandar Shahpur. About 80% of the salt was slated for use in chlorine-caustic soda plants of a planned petrochemical complex. The remaining salt was designated for sale within Iran.[17]

Italy.—Montedison and the Sicilian Mining Board, which runs all the rock salt mines in Sicily through a subsidiary, have established Soc. Salitaliana to coordinate mining from all sources and improve the efficiency of domestic and foreign rock salt marketing. Montedison has a 990,000-ton-per-year salt operation at Ciro Marina.[18]

Libya.—A West German group headed by Salzgitter Industriebau announced plans to construct a $540 million petrochemical complex for the Libyan Government at Abu Kammash. The principal unit, scheduled to go onstream in 1980, will utilize Libyan salt in a polyvinyl chloride plant.[19]

Mexico.—The Mexican Government announced its intention to increase its 25% share to a majority holding in Exportadora de Sal, the salt-mining complex 75% owned by Mitsubishi of Japan. The Government's effort to obtain more control over its raw material resources followed a long-running dispute with Japan over salt prices, which culminated in the temporary suspension of Mitsubishi's salt-mining activities in 1975. Most of the production of the Baja California mine has been exported to Japan and the United States. Nationalization of the salt operation, coupled with a projected increase in production to 7.7 million tons per year, was intended to place more emphasis on domestic consumption.[20]

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Salt is produced in many other countries, but quantities are relatively insignificant or reliable production data is not available.
[2]Less than 1/2 unit.
[3]Series revised to include byproduct output from potash works, not previously included.
[4]Includes an average annual production in the Canary Islands of about 13,000 short tons of marine salt.
[5]Year beginning March 21 of that stated.
[6]Quantity shown is for 12 months ending June 30th of the year stated.

Saudi Arabia.—After a review of the country's second 5-year industrial development plan, the Saudi Arabian Government canceled Japanese contracts for two sea-water desalination plants at Jidda and Al Jubayl.[21]

Yemen Arab Republic.—The U.S.S.R. agreed to purchase Yemeni rock salt, part of which will be considered repayment of Soviet loans. With aid from Kuwait, the capacity of the As-Salif saltworks has been expanded to 500,000 tons per year.[22]

TECHNOLOGY

Researchers at the University of Delaware College of Marine Studies have been studying plants that thrive in saline soils to determine which are edible, their nutritional value, and the extent of irrigation they require. Many experts have noted that salt marsh production exceeds that of cultivated land, and coastal waters and marshes do not require the fertilization and energy that must go into cultivating most land.[23] Scientists at the University of California, Davis, have been engaged in an effort to find strains of crop plants that are able to tolerate salty environments. They have attempted to create, through selection and breeding, crop plants that can be grown in soil irrigated with brackish or salt water taken directly from the ocean or other sources. The use of water from saline sources could turn agriculturally useless land into productive areas.[24]

In Japan the first commercial reverse-osmosis, sea-water desalination plant was commissioned by Ohte Engineering. Developmental work had been undertaken by Envirogenics Co., a subsidiary of U.S. Aerojet General Corp. The concentration of sea-water salts in the processed water is below 300 parts per million (ppm).[25]

Imperial Chemical Industries Australia Ltd. started up the first full-size plant using a desalting process developed by them and Australia's Commonwealth Scientific and Industrial Research Organization. The process features ion-exchange resins that adsorb salts at a relatively low temperature of 20° to 30°C and that can be regenerated by washing with 90°C water. This method avoids the cost and environmental concerns of acid or alkali regeneration. Although it does not handle seawater, the system can accept brackish streams of up to 3,000 ppm salt, turning out water for drinking or industrial use.[26]

The U.S. Department of the Interior's Office of Water Research and Technology awarded an $85,000 contract to Gulf South Research Institute to develop new materials and techniques for desalting seawater.[27]

New scale-preventive chemical additives that have undergone successful testing in high-temperature multistage flash distillation units were presented at the 5th International Symposium on Fresh Water from the Sea. The established method of avoiding calcium carbonate and magnesium hydroxide scale on heat transfer surfaces of sea-water distillation plants has been by acid dosing with sulfuric acid. However, this measure can itself cause corrosion damage. To avoid acid, many plants have been designed for low-temperature, chemical-additive-dosed operation. However, the lower operating temperature results in reduced output compared with an acid-dosed plant. The new additives, therefore, combine the dual benefits of high-temperature, scale-free operation without acid.[28]

The Agricultural Research Service of the U.S. Department of Agriculture conducted experiments in which hides were preserved for as long as 28 days using acetic acid and sodium sulfite in place of salt. The researchers estimated that if U.S. leather processors used acid-sulfite curing on all hides stored less than 28 days, salt usage for domestic hide production could decline by 50%.[29]

Sand and Gravel

By James R. Evans[1]

In 1976, a total of 885 million tons of sand and gravel was reported sold or used in the United States. The f.o.b. value was $1.774 billion. Of these totals, construction sand and gravel was 855 million tons, with a value of $1.604 billion, and industrial sand and gravel was 30 million tons, with a value of $170 million.

Environmental Factors.—Environmental and reclamation factors continued to be of major concern to the sand and gravel industry throughout the United States.

Guidelines for limitations on existing

sources of wastewater discharges from sand and gravel operations into navigable water of the United States were published by the Environmental Protection Agency (EPA) in the Federal Register of June 10, 1976. These limitations are to be achieved by industry by July 1, 1977. Those who had existing permits from EPA, or from a State agency whose program was approved by EPA, could continue under the conditions of that permit until it expired. The 1977 limitations are defined as those achievable through application of the Best Practicable Control Technology currently available (BPT).

Possible environmental effects of sand and gravel mining in arctic and subarctic streams in Alaska were analyzed by Woodward-Clyde and Associates for the U.S. Fish and Wildlife Service. Thirty-one mining sites were examined in order to determine whether any relationship exists between sand and gravel extraction, the geomorphic characteristics of stream channels, and water quality and biological characteristics of the streams. The report, when completed in 1978, will be of great interest because of the increasing importance of sand and gravel in Alaska. Construction of the Trans-Alaska pipeline has resulted in the use of millions of tons of sand and gravel and has made Alaska the second largest producer in the United States from 1974 through 1976. Future similar projects in Alaska may result in a continuing large demand for Alaska's sand and gravel.

A new Michigan State law signed April 1, 1976, will require mining companies to obtain permits to mine dune sand within 1.5 miles of the lakeshore of Lake Michigan. In addition, an advance mining plan must be filed and land must be reclaimed after mining is complete. There are 6 mining companies working in at least 10 areas that will be affected by the new law. A royalty of 1 cent per ton must be paid by companies in order to finance the legislation.

River Rock Products Co.'s asphalt plant area, Fresno, Calif., won the 1976 first place Ecological Award given by the National Asphalt Pavement Association. This clean operation is on a 20-acre site that includes a three-hole golf course, lawns, landscaped drives, groves of more than 300 trees, flower borders, and a lake. Extensive ongoing maintenance is required to maintain the beauty of the site.

DOMESTIC PRODUCTION

The Pacific geographic region led the Nation in construction sand and gravel tonnage with 207 million, 24% of the national total (Figure 2, and tables 2 and 3). Next was the East North Central geographic region with 169 million tons, followed by the West North Central geographic region with 101 million tons. In industrial sand and gravel, the East North Central geographic region led the Nation with 12.5 million tons; 42% of the national total, and three times the tonnage of the second-place Middle Atlantic geographic region.

On a State basis, California led the Nation in construction sand and gravel sold or used, and in f.o.b. value (Table 4). Next, in order, were Alaska, Texas, Michigan, and Ohio. Collectively, these five States made up about 35% of the national total tonnage. The four leading States for industrial sand and gravel, in order, were Michigan, Illinois, New Jersey, and California. Their combined tonnage made up about 50% of the national total.

Sales and use of sand and gravel were reported from 7,599 deposits. Construction materials were extracted from 7,396 deposits; industrial materials, from 127; and both construction and industrial materials, from 76. Most of the tonnage came from deposits producing construction sand and gravel. More specifically, most of the tonnage came from deposits with sales and use levels over 200,000 tons (Table 11). Of the 7,396 construction sand deposits, only 1,023 were over the 200,000-ton level, but they accounted for 62% of the total tonnage.

There were 6,162 sand and gravel processing plants reported in operation. Of these, 5,593 plants were associated with extraction areas on land, and 569 plants were associated with dredging operations.

Most of the sand and gravel tonnages reported to the Bureau of Mines is that sold or used and not necessarily produced. Some companies produced more than they sold on the market, or sold to themselves as a user. Other companies, because of stockpiles, sold or used more than they produced. Over a period of a few years most companies' production would match their material sold or used.

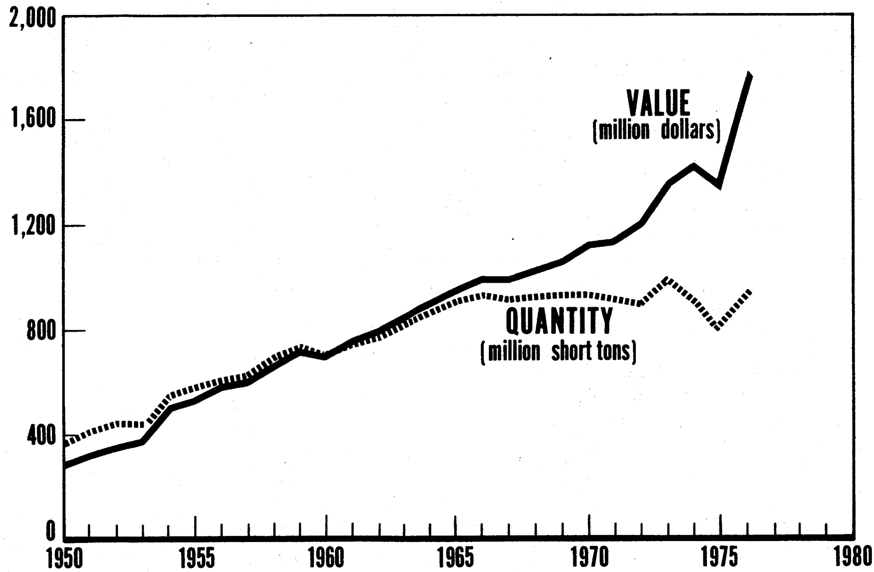

Figure 1.—Sand and gravel, quantity sold or used and value in the United States.

CONSUMPTION AND USES

The U.S. consumption of construction sand and gravel was equivalent to sales or use and was 855,242,000 tons, nearly 97% of all sand and gravel consumption. Of this total, about 33% went into concrete aggregates for use in residential and nonresidential buildings, and engineered construction such as highways, bridges, dams, waterworks, and airports. About 9% went into concrete products such as cement blocks, bricks, and pipe; 15% into asphaltic concrete aggregates and other bituminous mixtures, and 24% into roadbases and coverings for construction and repair of highways and roads. Nearly 16% went into fills and 3% into other unspecified uses (Table 5).

Table 6 shows the use pattern for construction sand and gravel by geographic region in the United States. The data indicates great differences between use categories and between certain geographic regions. For example, the Pacific geographic region leads the Nation in total construction sand and gravel, but the East North Central geographic region leads the Pacific in tons of concrete aggregates and concrete products sold or used. The Pacific geographic region, however, leads the Nation in tons of roadbases and coverings and fill. Table 7, which is based on data from table 6, shows a percentage breakdown by major use categories by geographic region. It aids in quickly determining the relative proportions of construction sand and gravel sold or used by major use category and geographic region.

Table 8 shows the major use categories for construction sand and gravel and tonnages sold or used. The top 10 States in this category are as follows, in thousand tons sold or used: California, 94,765; Alaska, 74,208; Texas, 46,571; Michigan, 42,067; Ohio, 37,790; Illinois, 34,300; Minnesota, 33,486; Wisconsin, 29,630; New York, 27,725, and Indiana, 25,518. These States made up 52% of the total national consumption.

Consumption of industrial sand and gravel in the United States was 29,914,000 tons. The top six States in this category are as follows, in thousand tons sold or used: Michigan, 5,336; Illinois, 4,484; New Jersey, 2,819; California, 1,827; and Texas and Oklahoma tied with 1,277 each. These States made up 57% of the total national consumption. Table 10 shows the major use categories for industrial sand and gravel. The three main uses (glassmaking, molding sand, and metal manufacture) accounted for 69% of the national total.

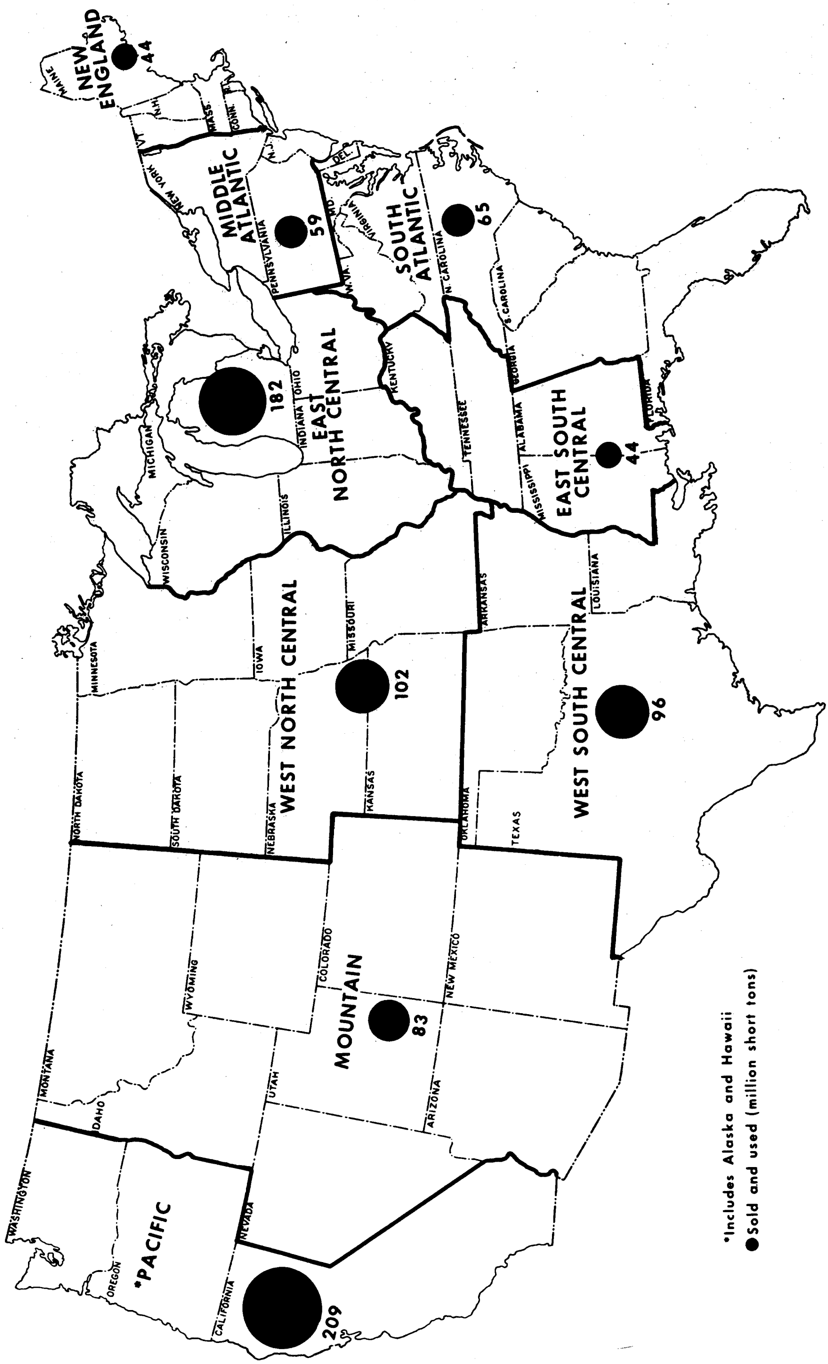

Figure 2.—Sand and gravel sold or used by geographic region.

PRICES

For purposes of this chapter, price means f.o.b. value of sand and gravel at the first point of sale or self-use. This value does not reflect any needed transportation from the plant, yard, or deposit to the consumer. It does, however, reflect those transportation costs needed to bring sand and gravel to the first point of sale or self-use by a company.

Based on this canvass, the national value per ton of construction sand was $1.56; gravel, $2.17; and sand and gravel $1.88. Industrial sand was $5.70; gravel, $4.39; and sand and gravel, $5.69. For all sand and gravel the national value per ton was $2.00.

Values per ton for major use categories for construction sand and gravel by State and for the United States are given in table 9. A significant difference in values between States and geographic regions as well as between major use categories is evident. Concrete products and concrete aggregates generally have the highest value per ton, at $2.11 and $2.08 respectively. Asphaltic concrete aggregates are close behind at $1.97; roadbases and coverings and fill follow at $1.69 and $1.58, respectively.

Values per ton for industrial sand and gravel were significantly higher than construction sand and gravel values: unground sand for glass, $5.72; metallurgical sand, $3.43; and foundry sand, $4.86 (table 10).

FOREIGN TRADE

Gravel, construction sand, and industrial sand were exported from the United States in 1976. As in 1975, nearly all of the materials went to Canada, with most of the remainder to Mexico and France.

Gravel exports were 579,359 short tons valued at $1,098,731 (f.a.s.), compared with 537,290 tons and $863,821 (f.a.s.) in 1975: 91% went to Canada, 1% to Mexico, and the remainder to 15 other countries. Construction sand exports were 558,733 tons valued at $1,336,721 (f.a.s.), compared with 510,859 tons and $1,111,410 (f.a.s.) in 1975: 97% went to Canada, 2% to Mexico, and the remainder to 27 other countries. Industrial sand exports were 2,533,475 tons valued at $17,079,590 (f.a.s.), compared with 2,171,109 tons and $13,071,346 (f.a.s.) in 1975: 63% went to Canada, 23% to France, 12% to Mexico, and the remainder to 62 other countries.

Construction sand and gravel and industrial sand were imported to the United States in 1976. The pattern was nearly the same as for 1975, with Canada and Australia the main import countries. Total tonnage of imports of construction sand and gravel was down about 11% from the 1975 level, and industrial sand was up about 35% from the 1975 level.

Construction sand and gravel imports totaled 292,112 tons valued at $424,764 (customs import value) and $624,377 (c.i.f. value). Slightly less than 99% of these imports came from Canada, 0.65% from West Germany, and the remainder from other countries.

Industrial sand imports totaled 60,670 tons, valued at $483,522 (customs import value) and $1,042,531 (c.i.f. value). Almost 97% of these imports came from Australia, 2.3% from Canada, and the remainder from six other countries.

WORLD REVIEW

Nearly all countries in the world use or produce sand and gravel of some kind. However, specific data for most countries is not available. The United States, Canada, the U.S.S.R., People's Republic of China, Mexico, Australia, France, West Germany, and the United Kingdom each consume more than 100 million tons annually. Probably the United States is the leading producer and consumer.

An important report on aggregates in the United Kingdom was published in 1976.[2] The report was prepared because of the crucial confrontation between the planning units of government and those in the industry who supply aggregates for construction. It was reported that in the southeast of England, where there is great concern for the environment, the sand and gravel industry has only about 15 years of

[2] Advisory Committee on Aggregates, Aggregates: The Way Ahead. Department of the Environment, Scottish Development Department, Welsh Office, Great Britain, 1976, p. 118.

life. Six important aspects of the problem with which the report dealt are as follows: (1) Extension of rail facilities for transportation of aggregates, (2) the possibility of restoring high-quality land, (3) reduction of constraints on marine dredging for sand and gravel, (4) more use of lightweight aggregates and slag and other waste materials, (5) the possibility of mining underground for aggregates, and (6) the creation of super quarries in granite rocks in the northern part of the United Kingdom for production of aggregates to be shipped by sea to the southeast of England.

A two-part perspective article on silica and silica sands was published in 1976. Production, consumption, and trade of silica in the United Kingdom, Europe, and Scandinavia were discussed in Part 1.[3] In Part 2, the same subject matter was treated for North and South America, Canada, Oceania, the Middle and Far East, and Africa.[4]

In Europe, the main deposits of silica sand are the Mol District of Belgium and the Fontainebleau region of France. West Germany and the Netherlands are also important silica-sand-producing countries. All of these countries export silica sand, which goes almost entirely to neighboring European countries. Lump silica for silicon and ferrosilicon production largely comes from Italy, Yugoslavia, Spain, and Portugal. These countries provide almost all of the needs of other European countries with the exception of France.

In North America, there is extensive cross trading between the United States and Canada of both silica sand and lump silica. Australia is self-sufficient in silica products and largely supplies the extensive South-East Asian market, particulary Japan.

TECHNOLOGY

During 1976 many reports were published concerning construction sand and gravel and industrial sand and gravel extraction and processing, and the use of waste material for aggregates. A brief description of some of the more significant publications follow.

Construction Sand and Gravel.—A map showing the sand and gravel and stone extraction areas in Fairfax County, Va., and their relation to geologic rock units was prepared by the U.S. Geological Survey.[5] The availability of construction materials and the urgency for local and regional planning to insure adequate future needs is described in a short text on the map sheet. Another similiar map published by the U.S. Geological Survey contained information concerning sand and gravel and other minerals in Prince Georges County, Md.[6]

Lone Star Industries, Inc., started construction on its new $12 million sand and gravel facility at Rancho Cordova, Sacramento County, Calif.[7] The deposit is in the flood plain of the American River. As at its former nearby facility in Fair Oaks, Lone Star mines rows of old gold dredge tailings. About 45 million tons or a 30-year supply is available. The processing plant will be able to produce a complete spectrum of construction aggregates. A concrete ready-mix plant and an asphaltic concrete hot-mix plant will also be built onsite. Stringent environmental controls are required, and the use permit has 22 separate operating conditions. Before construction begins, a 15-foot-high earth berm planted with trees will be built to screen the sand and gravel operation.

Columbia Sand and Gravel, a subsidiary of Columbia Consolidated Corp., Tucson, Ariz., opened a new sand and gravel pit.[8] A newly built plant, rated at 400 tons per hour on the dry circuit and 350 tons per hour on the wet circuit, produces pea gravel, roadbases, concrete sand, mortar sand, and block sand. Another Arizona company, Arizona Sand and Rock, opened a new operation on the Salt River (dry bed) near Mesa.[9] The site is leased from the Pima and

Maricopa Indian Tribes. A new 500-ton-per-hour plant supplies material to the adjacent concrete ready-mix and hot-mix asphalt plants. Knox County Sand and Gravel Co., Vincennes, Ind., built a 400-ton-per-hour processing plant to replace its old smaller capacity plant.[10] Ample reserves and an increasing demand indicated that the new plant was necessary. The new plant can deliver two gravel gradations and four sand gradations. Gifford-Hill and Co. put a new dredging system into operation that has resulted in greater production and less pump maintenance costs.[11] The deposit and plant are near Eagle Lake, Tex., along the banks of the Colorado River. The new system involves the use of two dredges, one as a digging dredge and the other a nearshore booster dredge to dig and transport material to the dewatering plant at about 475 tons per hour. This operation, which is the company's largest, produces about 1.8 million tons of sand and gravel per year. Owl Rock Co.'s Star operation near Anaheim, Calif., has been beset with raw-material-gathering problems.[12] A new wheel loader-conveyor combination, however, has solved the problems. Coherent conglomerate of tertiary age is blasted and moved down a steep slope by two track dozers and a backhoe equipped with a chisel instead of a bucket. Material has not moved properly downslope to the loading hopper. Therefore, it was necessary to excavate a bench about one-third of the way down slope from the mining area. Three 100-foot portable conveyors were set up on the bench to haul material across the bench to a dropoff point where it is then transferred to the delivery conveyor to the crushing plant. A 10-cubic-yard wheel loader feeds the portable conveyor system by dumping into a hopper.

Resurfacing of the five-lane upper deck of the San Francisco-Oakland Bay Bridge was accomplished by using a special 3/4-inch-thick layer of epoxy asphalt containing aggregate composed of a very hard metamorphosed sandstone.[13] The mixture provides a surface with increased skid-resistance and durability that traffic wear does not polish.

Two important reports were published by the Transportation Research Board. One had eight papers dealing with asphalts, aggregates, mixes, and stress-absorbing membranes.[14] The other report deals with procedures and criteria for setting density standards to control compaction during construction of granular base and subbase courses.[15]

Industrial Sand and Gravel.—Ford Glass Division's new Tulsa, Okla., plant is now operating with a second line. The two lines can produce about 1 million square feet of architectural and auto glass daily. Employment is 720 and the workers come from a 100-mile radius.[16]

Many foundries are now using reclaimed sand because transportation and/or purchase prices of new sand have risen significantly.[17] Cost saving can be significant since reclaimed sand makes better molds and cores and because grain size is more consistent, grains are rounder than for new sand, and many contaminants are removed. Consistent high-quality sand is provided for by reclamation, resulting in optimum binder use and production of a high-quality casting.

Waste Materials.—The Transportation Research Board published the results of a comprehensive survey of the technical and economic potential for employing waste materials in aggregates used in highway construction and maintenance.[18] There were two main objectives of the survey: (1) to inventory types, sources, and quantities of solid wastes potentially suitable for production of aggregates, and (2) to assess prospects for the practical use of such aggregates in highways, particularly when conventional aggregates are in short supply.

a new fusion process has been developed in which municipal refuse is incinerated into highway paving material.[19] The Refuse Residue Fusion Process is a five-step operation that starts with screening, includes firing at 1,800°F, and finally involves crushing and sizing to produce a product called eco-rock (ecologically sound, economical to

produce). Twenty-seven tons (before crushing) of eco-rock was produced in a pilot plant in 1976. The product is reported to have excellent skid resistance. It will be tested for this and other properties in a wearing coarse at a site yet to be determined by the U.S. Department of Transportation.

The San Diego Division of California's Department of Transportation is substituting freeway sweepings for sand used in maintenance work and saving $2.50 per cubic yard in the process.[20] By 1975 500 cubic yards had been processed and plans are to increase output to 3,000 cubic yards per year in the greater San Diego area.

In northwestern Iowa rubble from old concrete pavement was used as aggregate for replacement pavements in an experimental program.[21] About 15,000 tons of rubble was processed to produce 5,500 tons of coarse crushed material that met specifications for paving about 2 miles of approaches to two replacement bridges on U.S. 75 south of Rock Rapids. Problems experienced were the peeling off of the asphalt overlay to eliminate bituminous material from rubble, control of fines in rubble, traffic control, setting up detours around the work areas, and scheduling for an independent contractor to haul off the broken pavement.

Silicon

By Frederick J. Schottman[1]

Production and consumption of most silicon materials increased in 1976 over the depressed levels of 1975, and silicon metal production reached record high levels. Supplies were adequate, and while ferrosilicon prices were raised at midyear, silicon metal prices were unchanged, despite rising production costs. The relatively strong U.S. market attracted increased imports of ferrosilicon as worldwide industrial activity remained well below capacity.

Domestic producers continued construction programs intended to increase capacity and to meet environmental protection requirements. Foreign producers were also adding new capacity, much of it located in countries which had not previously been major producers of silicon materials.

DOMESTIC PRODUCTION

Production of silicon materials followed the general improvement in economic activity. Particularly large increases were made for silicon metal and miscellaneous silicon alloys.

Overall, production of ferrosilicon increased over the levels of 1975, but did not match those of 1973 and 1974. Production of 25% to 55% ferrosilicon was up 13% and shipments were up 29%. Shipments of 56% to 95% ferrosilicon increased 20%, but production increased only slightly. However, a significant portion of the production of 56% to 95% ferrosilicon in 1975 had gone into building up stocks, while 1976 production was more in balance with shipments. Since 1974, there was a shift from high-silicon-content ferrosilicon by domestic producers. On the basis of silicon content, about two-fifths of ferrosilicon alloys produced in 1974 were in the 56% to 95% class, compared with about one-fourth in 1976.

Production and shipments of silicon metal reached the highest levels ever with increases of 37% and 47%, respectively. Miscellaneous alloys showed increases of 15% in production and 28% in shipments. About three-fourths of the material in this class is magnesium ferrosilicon. Among other alloys included are calcium-silicon, silicon-manganese-zirconium, and rare-earth silicides.

Except for silicon metal stocks, which increased 34%, producers' stocks were little changed from the beginning of the year.

Several new plants and modernization projects were completed or under construction during the year. The new construction included both addition to capacity and replacement of obsolescent furnaces by more efficient and environmentally cleaner modern furnaces.

Ohio Ferro-Alloys Corp. completed a new silicon metal plant at Montgomery, Ala. The plant has three 20-megawatt (MW) furnaces with a capacity of 36,000 tons per year (tpy). A new 24-MW ferrosilicon furnace was completed by Airco, Inc., at its Niagara Falls, N.Y., plant. The Addy, Wash., plant of Northwest Alloys, Inc., a subsidiary of Aluminum Co. of America, began limited production in 1976. The plant is designed for a capacity of 16,000 tpy of silicon metal and 24,000 tpy of magnesium. The magnesium is produced using ferrosilicon smelted at the plant. A new ferrosilicon plant with a

[1]Physical scientist, Division of Ferrous Metals.

40-MW furnace was under construction by Tennessee Alloys Co. (TAC) at Bridgeport, Ala., with startup planned in 1977. The project is a joint venture between International Minerals & Chemical Corp., with a 75% interest, and Allegheny Ludlum Steel Corp. The new furnace will replace the three furnaces in the old TAC plant at Bridgeport and will result in a net increase in capacity of 50% to 75,000 tpy of 50% ferrosilicon.

In May 1976, the U.S. Environmental Protection Agency issued standards of performance for air pollution control systems for ferroalloy submerged arc furnaces, constructed or modified since October 1974. The standards set limits on the emission of particulates and carbon monoxide.

CONSUMPTION AND USES

Reported consumption of silicon materials increased in 1976, compared with 1975 use. The increase followed closely the production trends for end uses such as cast iron and aluminum castings.

Consumption of 25% to 55% ferrosilicon

Table 3.—Consumption, by major end use, and stocks of silicon alloys and metal in the United States in 1976

(Short tons, gross weight except as noted)

End use	Silvery pig iron	Ferrosilicon[1]				Silicon metal	Miscellaneous silicon alloys[2]	Total silicon content[3]

increased 19% while that of 71% to 80% ferrosilicon, the other major grade, decreased slightly. Consumption of 56% to 70% and 81% to 95% ferrosilicon increased in 1976, but these grades remained a small part of the total ferrosilicon used. Since 1974, the data indicate a change away from the use of the higher grades of ferrosilicon toward the use of the 25% to 55% grade.

Cast iron remained the largest end use for ferrosilicon in 1976, and accounted for most of the reported increase in consumption. Steel, the other major end use, showed little change.

Silicon metal consumption increased 41%. For the two major end uses, which together accounted for over nine-tenths of the total, consumption in alloys (principally aluminum base alloys) and in silicones increased 37% and 57%, respectively. Silicones accounted for about two-fifths of the total. An important, but relatively low tonnage, application for silicon metal is as the raw material for the production of semiconductor silicon. This material is the basis for most semiconductor devices now produced. Advances in electronic device technology reduced the amount of silicon required to perform a function, but these same advances opened up new uses. Applications expanded rapidly, both in new products and as replacements for mechanical and electromechanical systems.

Yearend consumer stocks for all classes of materials were little changed from the beginning of the year.

PRICES

Prices for silicon materials were relatively steady in 1976. Supplies were adequate as demand recovered moderately from 1975 and new production capacity came onstream.

Domestic producers raised ferrosilicon

prices in June. On the basis of contained silicon, the price of 50% ferrosilicon was raised 2 cents to 34.5 cents per pound, and the price of 75% ferrosilicon was raised 0.5 cent to 37.0 cents per pound for standard grades, f.o.b. shipping point. The f.o.b. warehouse price of imported 75% ferrosilicon, as quoted in Metals Week, bottomed out at 28 to 30.5 cents per pound early in the year, after declining steeply in 1975, and rose to 30 to 31.5 cents per pound at yearend.

Prices for domestic silicon metal were unchanged during the year at 42.25 and 46.4 cents per pound for the 1% and the 0.35% maximum iron grades, respectively. Quoted prices for imported silicon metal declined from 42.5-44.5 cents per pound to 40-41 cents per pound.

FOREIGN TRADE

Exports of ferrosilicon were down 68% in quantity and 51% in value from 1975. Approximately 68% of the exports were to Canada which received 8,498 tons. Other major recipient nations were Brazil, with 1,349 tons, and Mexico, with 563 tons.

Ferrosilicon imports increased by 40% in quantity on a gross weight basis but decreased 5% in value. The quantity of 8% to 60% ferrosilicon doubled, with the increase coming from Canada, which provided 84% of the imports in 1976. Imports of 60% to 80% ferrosilicon rose 23% in quantity. Norway continued to supply the largest portion with 40% of the total. Other major suppliers were France (9%), India (9%), the Republic of South Africa (8%), Yugoslavia (8%), and Brazil (8%). Japan, which in earlier years had been an important source of both 8% to 60% and 60% to 80% ferrosilicon, shipped lower amounts to the United States in 1976. Shipments of 60% to 80% ferrosilicon to the United States from Taiwan and Canada also decreased significantly.

As in 1975, Norway, the Republic of South Africa, and Yugoslavia were the major sources of imported silicon metal, with 35%, 33%, and 22% of the total, respectively. West Germany and Japan supplied nearly all of the imported high-purity semiconductor grade silicon, which is included in the over 99.7% silicon import class.

Ferrosilicon containing 60% to 80% silicon and silicon metal with 99.0% to 99.7% silicon were among the materials from certain developing countries granted duty-free entry to the United States under the Generalized System of Preferences (GSP) starting January 1, 1976. During the year, the Office of the Special Representative for Trade Negotiations rejected a petition from the Ferroalloys Association that the treatment of ferroalloys under GSP be modified.

WORLD REVIEW

Australia.—A new 45-million-volt-ampere (MVA) ferrosilicon furnace was commissioned by the Tasmanian Electrometallurgical Co. Pty. Ltd. (TEMCO), a subsidiary of Broken Hill Proprietary Co. Ltd. The furnace, located at Bell Bay, Tasmania, has a capacity of 28,000 tpy of 75% ferrosilicon.

Brazil.—Several companies are planning or installing additional ferrosilicon capacity totaling about 110,000 tpy. The companies include Alcan Alumínio do Brasil S.A., Cia. Paulista de Ferro-Ligas, Cia. Brasileira Carbureto de Calcio, Electrometalur SA, Italmagnesio SA, Ligas de Alumínio S.A. (Liasa), and Productos Metalurgicos Sampaio Lara Ltda.

Canada.—Production began at the Becancour, Quebec, plant of SKW Electro-Metallurgy Canada Ltd. The plant includes a 30-MW furnace and two 20-MW furnaces, and has a capacity of 25,000 tpy of 75% ferrosilicon and 25,000 tpy of silicon metal.

Iceland.—Elkem-Spigerverket A/S took over Union Carbide Corp.'s former interest in Icelandic Alloys Ltd. The Icelandic Government holds 55% interest in the company. Startup of the first furnace at the ferrosilicon plant under construction in 1976 is expected in 1978, with a second furnace due later.

Japan.—A 19,000 tpy ferrosilicon furnace was started at the Wakagawa plant of Japan Metals and Chemicals Co. Ltd., giving the company a capacity of 72,000 tpy.

Korea, Republic of.—Sam Chok Industrial Co. Ltd. began testing the furnace at its new silicon metal plant.

Venezuela.—Hornos Electricos de Venezuela S.A. (HEVENSA) installed two new furnaces to raise its capacity to 12,000 tpy of ferrosilicon.

Silver

By Harold J. Drake[1]

Domestic mine production of silver in 1976 totaled 34.3 million ounces,[2] a level of 2% below that of 1975. The decline in output was mainly attributed to a labor strike that shut down the Sunshine mine in Idaho for most of the year and the closure of several mines in Nevada. Refinery output in 1976 from domestic and foreign ores, coins, and old scrap totaled 104.6 million ounces compared with 111.2 million ounces in 1975. Most of the decline occurred in output of silver from foreign ores and concentrates and old scrap other than coins. Imports totaled 88.4 million ounces and exports totaled 14.6 million ounces. The excess of imports over exports was 73.8 million ounces compared with 57.8 million ounces in 1975. The general decline in the price of silver that began in the second half of 1975 was halted on January 26, 1976, when the average daily price per ounce reached 381.5 cents, the low for the year. The high for the year, 510.0 cents, was reached on July 6 with the price declining thereafter. The average daily price was 424.0 cents on January 5, 437.5 on December 30, and 435.4 cents for the year. The average monthly price followed an upward trend from 406 cents per ounce in January to 481 cents per ounce in June but declined rapidly thereafter and remained near 435 cents per ounce for the rest of the year.

Industrial consumption totaled 170.6 million ounces, an increase of 8% over that of 1975. An additional 1.3 million ounces was used in coinage. Significant increases were recorded for electroplated ware, photographic materials, mirrors, contacts and conductors, catalysts, and coins, medallions, and commemorative objects. Significant declines were recorded for sterling ware, jewelry, brazing alloys and solders, and batteries.

Private stocks of silver at yearend totaled 146.4 million ounces, down 11.9 million ounces from 1975. Government stocks, at 186.8 million ounces, were down 1.7 million ounces from the preceding year. Industrial stocks fell 4 million ounces to 30.6 million ounces and trading stocks at various commodity trading centers fell 8.4 million ounces to 115.8 million ounces. Treasury bullion stocks in the Bureau of the Mint were 39.7 million ounces at yearend, a level only slightly below that of yearend 1975. Silver available to defense contractors from the Department of Defense stocks totaled 7.6 million ounces at yearend. These stocks consisted of fine silver recovered from old scrap items collected mostly from various U.S. military services branches. The total amount of silver in the national stockpile remained at 139.5 million ounces, the same as at yearend 1975. On October 1, 1976, the Federal Preparedness Agency of the General Services Administration (GSA) issued new goals with the goal for silver set at zero. As a result, the 139.5 million ounces in the stockpile was surplus but congressional approval for disposal had not been given by yearend 1976.

Trading volume on the New York Commodity Exchange (COMEX) was 18.5 billion ounces in 1976 compared with 14.5 billion ounces in 1975. Trading volume on the Chicago Board of Trade (CBT) totaled 10.1 billion ounces compared with 9.8 billion ounces in 1975. COMEX warehouse stocks at the end of 1976 stood at 54.8 million ounces compared with 85.7 million ounces at yearend 1975. CBT stocks at yearend 1976 were 61.0 million ounces compared with 38.5 million ounces at yearend 1975.

Legislation and Government Programs.—Legislation was introduced in Con-

[1]Physical scientist, Division of Nonferrous Metals.
[2]Ounce as used throughout this chapter refers to the troy ounce.

gress, but not enacted, to authorize the disposal of approximately 118 million ounces of excess silver in the national stockpile. During 1976, GSA offered and sold by bid 696,205 ounces of silver reclaimed by various Federal agencies. The Bureau of the Mint struck the last of the 45 million 40% silver Bicentennial coins ordered by Congress.

DOMESTIC PRODUCTION

Domestic mine production of recoverable silver decreased slightly to 34.3 million ounces equivalent to 20% of U.S. demand in 1976. Idaho accounted for 34% of the output, Arizona 22%, and Colorado 12%. Missouri, Montana, Utah, New Mexico, and Nevada, in the aggregate, accounted for 30% and eight other States accounted for the remainder. About 39% of the silver came from copper mining operations, 30% from silver ore, 14% from lead ore, and 13% from complex copper-lead-zinc ores. The remainder came from ores of gold, gold-silver, zinc, and from old tailings.

Refinery output of marketable silver totaled 104.6 million ounces, 52% of which came from concentrates and ores, both foreign and domestic, with the remainder coming from old scrap. Recovery from domestic ores and concentrates rose about 4%, whereas recovery from imported ores and concentrates continued to decline dropping by 26%. Production of silver from coins more than doubled which nearly offset a 22% decrease in output from other old scrap, and therefore. the amount of silver extracted from old scrap declined only 2% to 50.2 million ounces. Production of new scrap, 53.1 million ounces, was 5% above that of 1975.

The 25 leading silver producers (table 3) accounted for 81% of domestic production. Six of the leading producers mined silver ores while most of the remainder mined copper, lead, and zinc ores. Twelve of the leading mines produced in excess of 1 million ounces during 1976.

The largest silver mining district in the United States, Coeur d'Alene, Idaho, was reviewed in detail.[3] Major subjects of the review were the complex geology of the area and mining and metallurgical methods at the principal silver mines. Another report detailed the efficient mining operations at the Black Pine silver mine near Philips-

[3]Carters, R. A., and T. Li. Idaho's Coeur d'Alene District Sets Sights on Record Production. Min. Eng., v. 28, No. 7, July 1976, pp. 49-64.

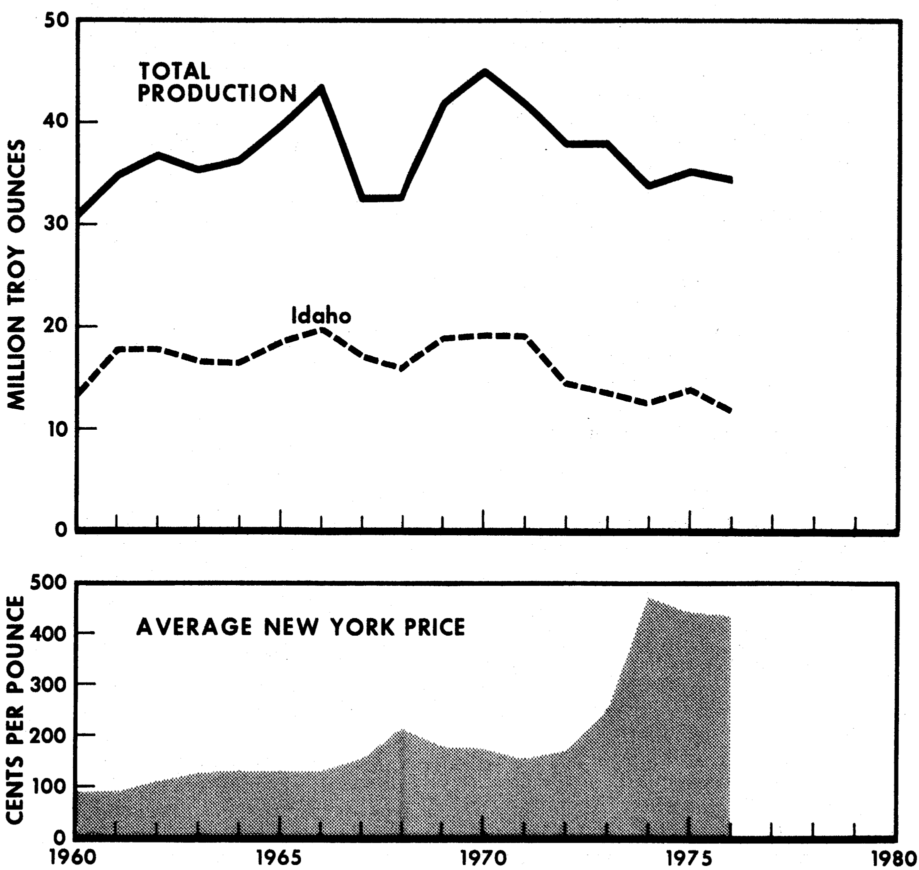

Figure 1.—Silver production in the United States and Idaho and price per ounce.

burgh, Montana.[4] The Black Pine mine produced 300 tons per day of ore with a per ton grade of 7.2 ounces of silver, 0.01 ounce of gold, and about 11 pounds of copper.

ASARCO Inc. reported that production of silver totaled 3.42 million ounces from its Galena mine, 0.67 million ounces from its share of the Coeur mine, and 0.22 million ounces from the Park City mine.[5] ASARCO continued to evaluate the Troy project, a copper-silver deposit in Montana, with a potential annual output of 4.2 million ounces of silver. The new Coeur mine went onstream in June and by yearend was operating at its design capacity of 2.2 million ounces of silver per year. Also in June, the company brought into commercial production a new copper refinery at Amarillo, Tex., with an annual capacity of 60 million troy ounces of silver.

Day Mines Inc. (DMI), Wallace, Idaho, reported a sharp increase in silver production to 1.95 million ounces in 1976.[6] DMI's Sherman mine in Colorado produced 53,514 tons of ore averaging 24.51 ounces of silver per ton. Other mines contributing to DMI's increased output were the Galena and Coeur mines in Idaho in which DMI has interests.

Earth Resources Co. (ERC) continued construction of the De Lamar silver mine in Idaho which was expected to be in operation by April 1977.[7] Exploration by ERC during 1976 more than doubled reserves thereby extending the estimated life of the mine from 10 years to more than 20 years.

Hecla Mining Co., Wallace, Idaho, reported a 1-million-ounce decline in production to 3.2 million ounces of silver in metallic concentrates in 1976.[8] The sharp decline in

[4] White, L. Trackless Mining on a Small Scale: Inspiration's Black Pine Silver Mine. Eng. Min. J., v. 177, No. 9, September 1976, pp. 98-100.

[8] Hecla Mining Co. 1976 Annual Report. 28 pp.

production resulted from a nearby yearlong strike at the Sunshine mine which reduced considerably its output and, consequently, Hecla's share of that output. Hecla's Lucky Friday mine accounted for 82% of Hecla's output, the company's share of the Sunshine Unit area for 10% and, its share of the Star-Morning Unit area, for 7%. The remainder came as Hecla's share of the output from the Lakeshore mine. The Lucky Friday mine produced 2.64 million ounces of silver from 186,520 tons of ore for an average recovery of 14.16 ounces per ton. Tonnage was higher but grade was lower in 1976 than in 1975. Hecla's share of the Sunshine Unit area totaled 0.31 million ounces from 13,447 tons of ore averaging 23.05 ounces of silver per ton.

Production of silver by The Bunker Hill Co., Kellog, Idaho, a subsidiary of Gulf Resources & Chemical Corp., rose 12% to 7.79 million ounces.[9] Most of the silver came from the Bunker Hill mine in Idaho, which at yearend, contained 2.3 million tons of proven ore averaging 1.4 ounces per ton. An additional 0.78 million tons of the same grade was classed as probable ore. Bunker Hill's interest in the Star mine consisted of 0.51 million tons of proven ore and 0.19 million tons of probable ore, both of which averaged 4.0 ounces of silver per ton. Exploration at the company-owned Crescent mine resulted in the discovery of a new area of silver mineralization, the size of which had not been delineated by yearend.

Homestake Mining Co., reported silver production from its Bulldog mine in Colorado totaled 1.6 million ounces in 1976, up slightly compared with 1975.[10] The average grade of the 117,783 tons of ore mined in 1976 was 18.1 ounces per ton. Ore reserves of all types at yearend were 791,375 tons averaging 19.9 ounces of silver per ton.

CONSUMPTION AND USES

Industrial consumption of silver rose 8% to 170.6 million ounces in 1976. An additional 1.3 million ounces was used for coinage purposes, a level half that of 1975. Use in photographic materials, which accounted for one-third of consumption in 1976, rose 21% to 55.5 million ounces. Use in contacts and conductors, the second largest use category, rose 19% to 32.3 million ounces, whereas, the third largest use, sterling ware, declined 16%. In the aggregate, these three uses accounted for 63% of total industrial consumption in 1976. Use of silver in catalysts continued to increase and recorded a 40% gain to 12.3 million ounces. Use in electroplated ware rose 9% to 9.5 million ounces and use in coins, medallions, and commemorative objects rose 15% to 8.2 million ounces. Use in mirrors rose 47% to 4.6 million ounces and use in dental and medical supplies rose 29% to 1.9 million ounces. Declines in consumption were recorded for brazing alloys and solders, down 18% to 11.2 million ounces; jewelry, down 14% to 11 million ounces; and batteries, down 18% to 3.5 million ounces.

Certain applications appear to have excellent potential for an increased rate of growth in demand. The use of silver in solar energy applications was expanding. In this application, pure metallic silver is used in mirrors for collecting and concentrating the sun's rays which are then focused on boilers or other receivers used to generate electricity. Use of silver to purify water is growing because it can effectively control bacteria and other organisms found in water. Major applications includes swimming pool filters and filters that purify drinking water. Silver is being used to prevent buildup of static electricity in carpets and other types of woven material. In such applications silver is precipitated on a fiber which is eventually included with other fibers used to make the antistatic product.

STOCKS

Total accountable stocks at yearend were 333.2 million ounces. These consisted of 30.6 million ounces in industry stocks, 39.7 million ounces in Treasury stocks, 7.6 million ounces in Department of Defense stocks, 139.5 million ounces in the strategic stockpile, and 115.8 million ounces in COMEX and CBT registered vaults. COMEX warehouse stocks decreased 30.9 million ounces to 54.8 million ounces while CBT stocks rose 22.5 million ounces to 61.0 million ounces. Compared with total stocks at yearend 1975, a decrease of 14.1 million ounces was registered in 1976.

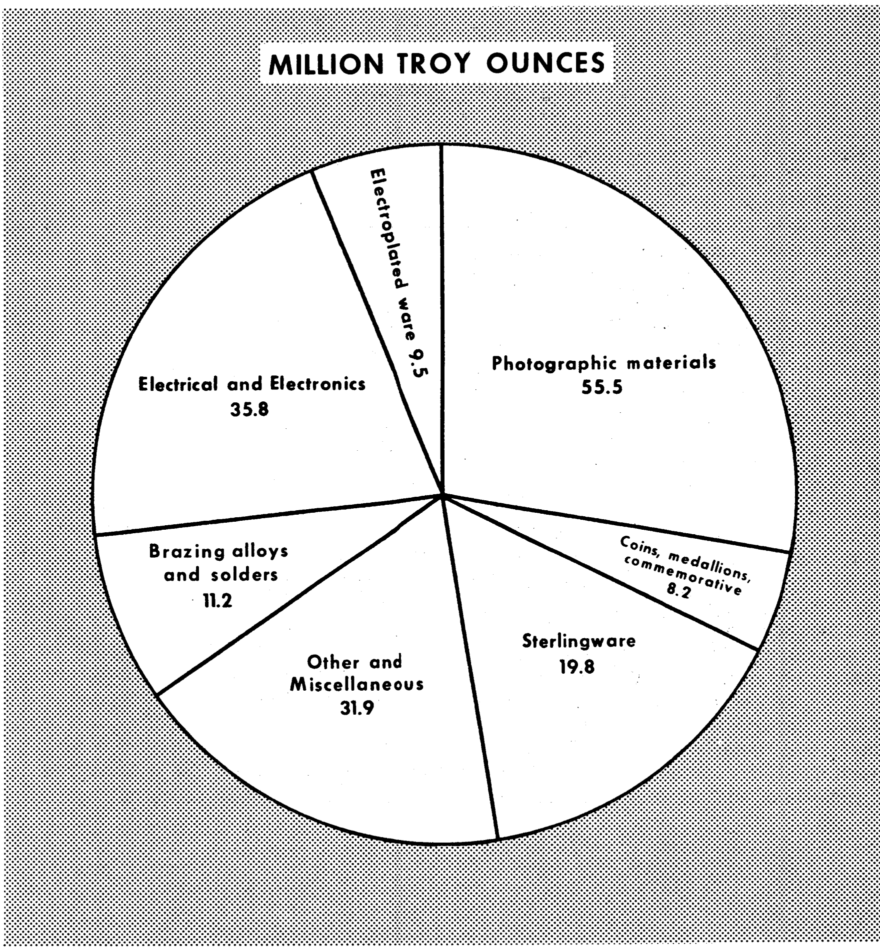

Figure 2.—Silver consumption in the United States, 1976.

PRICES

The price of silver fluctuated somewhat during 1976, rising in the first half then falling rather rapidly for the next few months. The price then rose slightly and remained fairly steady for the remainder of the year. The average daily price in cents per ounce of silver, as quoted by Handy and Harman, New York, began the year at 416.5, reached a low of 381.5 on January 26, a high of 510.0 on July 6, and finished the year at 437.5 on December 30. The gain in the average daily price in 1976 was 21.0 cents. The average monthly price was 406.3 cents per troy ounce in January, rose to 481.2 in June and 477.9 in July, and then declined sharply to 423.7 cents in August. A slight increase was then recorded in the final months to about 435.0. The average monthly price for the year was 435.4 cents per troy ounce compared with 441.8 cents in 1975.

Prices on the London Metal Exchange ranged from a low of 389.5 cents per ounce to a high of 507.6 cents per ounce (U.S. equivalent). The average for 1976 was 434.9 cents.

Trading volume on the COMEX was 18.5 billion ounces during 1976, an increase of 4.0 billion ounces over 1975. The CBT trading volume was 10.1 billion ounces, a gain of 0.3 billion ounces over that in 1975.

FOREIGN TRADE

Exports of silver fell 55% to 14.6 million ounces. Refined bullion, which accounted for 52% of total exports, totaled 7.6 million ounces, a level one-third that of 1975. Exports of waste, scrap, and sweepings declined 31% to 6.8 million ounces which was equivalent to 47% of total exports. Ore and concentrates, the remainder of the exports, totaled 0.16 million ounces. Japan, the principal foreign market in 1976 for exported material received 49% of the total; the United Kingdom, 20%; Belgium-Luxembourg, 11%; Taiwan, 4%; Spain, 3%; and Brazil and Switzerland 2% each. The remaining 9% went to about 10 countries. Bullion was shipped mainly to Japan, with significantly smaller amounts to Canada, Taiwan, and Brazil. Waste, scrap, and sweepings were sent to the United Kingdom, Belgium-Luxembourg, Japan, Spain, and Switzerland among others.

Imports of silver totaled 88.4 million ounces compared with 90.4 million ounces in 1975. Refined bullion accounted for 76% of total imports; ore and concentrates, 19%; waste and sweepings, 4%; and doré and precipitates the remainder. A 9% increase in imports of bullion to 67.2 million ounces was not enough to offset a 21% decrease in imports of ore and concentrates to 16.7 million ounces, a 40% decrease in imports of waste and sweepings to 3.3 million ounces, and a 45% decrease in imports of doré and precipitates to 1.2 million ounces.

The principal source for imported silver in 1976 was Canada which supplied 40.6 million ounces equivalent to 46% of total imports. Mexico supplied 18.4 million ounces or 21% of total imports, Peru 11.3 million ounces or 13%, and the United Kingdom 6.0 million ounces or 7%. Honduras, India, Japan, and Yugoslavia, in the aggregate, supplied 9.1 million ounces or 10% of total imports. The remaining 3% was supplied by a number of countries including Australia, Chile, Territory of South-West Africa, Italy, and the Philippines.

Most of the bullion imported in 1976 came from Canada, Mexico, Peru, and the United Kingdom. Ore and concentrates came mainly from Canada, Australia, Honduras, Mexico, Peru, Philippines, and South-West Africa. Canada accounted for most of the imports of waste and sweepings.

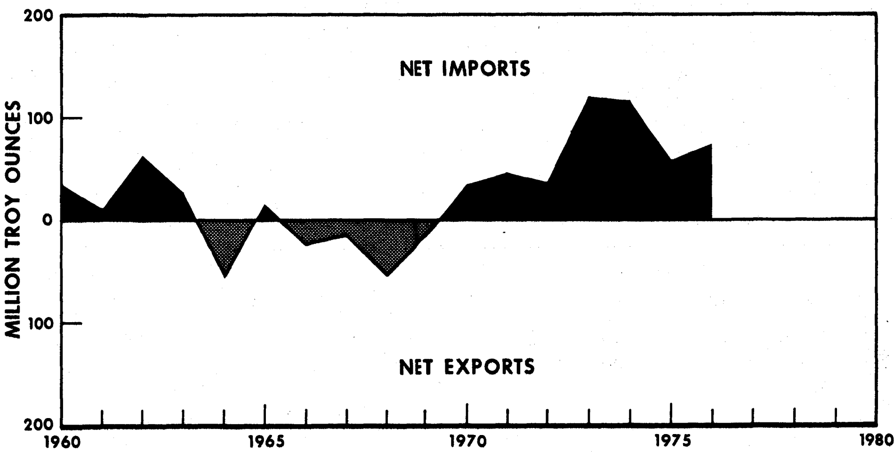

Figure 3.—Net exports or imports of silver, 1960-76.

WORLD REVIEW

World mine production of silver in 1976, including centrally planned economy countries, increased 2% to 305.0 million ounces. The United States, Canada, Mexico, and Peru accounted for 50% of world output.

World consumption of silver in 1976 for industrial and coinage uses, exclusive of centrally planned economy countries, totaled 422.0 million ounces compared with 394.5 million ounces in 1975.[11] A 19% increase in industrial use, which accounted for 94% of total use in 1976, was more than enough to offset an 8% decrease in use of silver in coinage. Total consumption by market economy countries exceeded newly mined supply by 178.0 million ounces according to Handy & Harman estimates. Secondary production supplied 40% of the difference, outflow from Indian stocks, 31%; demonetized coin, 28%; and U.S. and foreign Government stocks the remainder. West Germany was reported to have supplied an unusually high 28 million ounces of silver in 1976 reclaimed from official coins that had been retrieved by that Government.

Australia.—Production of silver rose 7% to 25.1 million ounces. An agreement was reached between Australian Mining & Smelting Ltd., St. Joe Minerals Corp., and Phelps Dodge Corp., to develop the Woodlawn lead-zinc-copper-silver deposits in New South Wales. The deposit contained about 11 million tons of proven reserves containing about 22 million ounces of silver in addition to other metals. An open pit mine was planned to be operational in about 2 years. The agreement calls for continued exploration around the Woodlawn ore body, particularly of sulfide occurrences similar to the main deposit. Western Selcast (Pty.) Ltd. and MIM Holdings Ltd. continued to explore the massive sulfide zone at their Teutonic Bore property in Western Australia. By yearend, several million tons of ore containing as yet unknown quantities of silver, copper, and zinc had been outlined. Diamond drilling of the deposit and metallurgical testing of the ore were continuing. Aquitaine Australia Minerals Pty. Ltd. and Serem Australia Pty. Ltd. continued to explore a major silver, lead, and zinc prospect near the town of Kunununa, in Western Australia.

Canada.—Mine production of silver in 1976 increased 3% to 40.9 million ounces.

[11]Handy & Harman. The Silver Market, 1976. 61st Annual Review, 1976, 22 pp.

Production of silver at the Kidd Creek mine of Texasgulf Canada Ltd. totaled 10.4 million ounces, about 13% above that of 1975.[12] At yearend, the mine contained a 205-million-ounce silver reserve above the 2,800-foot level. Exploration below this level continued to find ore so that the ultimate depth of the deposit had not been delineated at yearend. Texasgulf Inc. continued diamond drilling its large base metal sulfide deposits at Izok Lake and Hood River, Northwest Territories. At yearend, the exploration has delineated ore reserves containing 25 million ounces of silver at Izok Lake and about 1.0 million ounces at Hood River. Further drilling was planned to determine the extent of the deposits.

Mine production of silver by United Keno Hill Mines, Ltd. declined 19% to 2.4 million ounces.[13] Ore reserves declined from 208,000 tons averaging 37 ounces of silver per ton to 182,000 tons averaging 43 ounces per ton. Silver production at the Sturgeon Lake mine, a joint venture between Sturgeon Lake Mines, Ltd. and Falconbridge Copper Ltd., was 1.1 million ounces, a level only slightly above that of 1975.[14] Reserves at yearend 1976 totaled 1.4 million tons averaging 5.47 ounces of silver per ton.

Noranda Mines Ltd. reported silver production from the No. 12 and No. 6 mines of Brunswick Mining & Smelting Corp., Ltd. totaling 3.0 million ounces in 1976 compared with 4.4 million ounces in 1975.[15] Reserves at both mines at yearend totaled about 100 million tons containing 300 million ounces of silver. Noranda Mines Ltd. has a 64.1% interest in Brunswick Mining & Smelting Corp. Ltd. Noranda's Geco Div. reported production of 1.6 million ounces of silver in 1976 from an ore reserve that contained 41.0 million ounces at yearend. Production of silver by Mattagami Lake Mines Ltd. and Mattabi Mines Ltd. totaled 2.5 million ounces in 1976. Ore reserves of the two mines totaled 26.1 million ounces at yearend 1976. Noranda Mines Ltd. has operating interests in these mines.

Canex Placer Ltd., a subsidiary of Placer Development Ltd., was planning a mine-mill complex to exploit the Sam Goosley silver-gold-copper property located at Houston, British Columbia. The property was estimated to contain 43.5 million tons of ore containing 2.78 ounces of silver per ton. The Ruth Vermont silver-lead-zinc mine near Golden, British Columbia, began operating at near capacity from an ore reserve that contained an estimated 4 million ounces of silver.

Dominican Republic.—Rosario Dominicana, S.A. a subsidiary of Rosario Resources Corp., operated its new Pueblo Viejo base metal mine near capacity in 1976.[16] Production of doré bullion included 907,318 ounces of silver and 413,739 ounces of gold. Reserves of oxide ore totaled 25.8 million tons containing 18 million ounces of silver and 3 million ounces of gold. A sulfide ore reserve contained 19.5 million ounces of silver and 2.6 million ounces of gold. At yearend, a satisfactory metallurgical process to treat the sulfide ore had not been developed.

Honduras.—Production of silver in 1976 at the El Mochito mine of Rosario Resources Corp. totaled 3.2 million ounces. Ore reserves decreased during the year to 6.2 million tons containing 31.7 million ounces of silver and 12,340 ounces of gold, in addition to lead, zinc, and copper.

Japan.—Production (primary and secondary) and consumption of silver in 1976 totaled 37.9 million ounces and 57.0 million ounces, respectively. The supply deficiency was made up by imports of bullion and stock withdrawals. The principal uses were photography (which accounted for 45% of total consumption), contacts and conductors (12%), fabricated products (10%), and brazing alloys (8%).

Mexico.—Mine production of silver in 1976 totaled 42.6 million ounces. The extensive expansion of silver mines and plants of recent years did not result in the sharply increased output expected in 1976. However, production was still expected to increase by about 20 million ounces by the end of 1978.

Lacana Mining Corp., formed in 1975 through the merger of Lacanex Mining Co. Ltd., Pure Silver Mines Ltd., and Tormex Mining Developers Ltd., completed its first full year of operation in 1976.[17] The company has a 30% interest in Las Torres silver-gold mining complex in Guanajuato and a 40% interest in La Encantada silver-lead mine in Coahuila. It also has mining operations outside Mexico. Silver production at Las Torres complex in 1976 totaled 4.1 million ounces from an ore reserve that at yearend 1976 contained 46 million ounces of silver. When operating at full capacity, annual production at Las

[12]Texasgulf Inc. 1976 Annual Report. 48 pp.

[15]Noranda Mines, Ltd. 1976 Annual Report. 40 pp.
[16]Rosario Resources Corp. 1976 Annual Report. 32 pp.
[17]Lacana Mining Corp. 1976 Annual Report. 22 pp.

Torres should total 7.2 million ounces of silver. Silver production at the Encantado mine in 1976 totaled 1 million ounces. At yearend, silver reserves totaled 38 million ounces. Annual production at the La Encantada mine is expected to be 3.2 million ounces when operated at full capacity.

Expansion of the Huautla silver-lead mine in Morelos by Rosario Mexico, S.A. de C.V. continued in 1976.[18] Completion of the new crushing plant, which will increase the production rate from 140 tons of ore to 300 tons per day, was delayed until early in 1977. Silver production in 1976 totaled 546,817 ounces. At yearend, silver reserves stood at 8.0 million ounces.

Placer Development Ltd. Canada, continued to study its Real de Angeles silver property in Zacatecas. Diamond drilling in prior years outlined a deposit containing 43 million tons of ore averaging 2.5 million ounces of silver per ton. Plans in 1976 called for an open pit mine capable of producing 6 million ounces of silver per year to be in full production in 1979.

Production of silver at the Real del Monte mine, Hildago, was 4.0 million ounces in 1976.[19] Reserves were estimated at yearend to be about 30 million ounces.

Nicaragua.—Rosario Mining of Nicaragua, Inc., a subsidiary of Rosario Resources Corp. continued to explore the area around the Rosita mine and a large low-grade deposit of silver and gold in the Coco River area.[20] Mine and reserve development took precedence over production and as a result the mill at Rosita was not operated in 1976.

Peru.—Mine production of silver in 1976 totaled 35.6 million ounces compared with 37.5 million ounces in the preceding year. Partial financing for the planned expansion of the mining industry was extended to Empresa Minera del Centro del Peru, a wholly-owned subsidiary of Minero Peru, the Government-owned mining enterprise. Under the plan, the Cabriza copper-silver mine will expand annual output from 0.7 million tons of ore to 3.5 million tons of ore containing approximately 1.3 million ounces of silver. The Cuajone copper project began operating in late November 1976 with a rated mill capacity of 45,000 tons per day from a deposit grading 1% copper. In addition to primary copper, significant quantities of byproduct silver will be produced.

TECHNOLOGY

Researchers at the Bureau of Mines Reno, Nev. Metallurgy Research Center continued studies to develop economic methods for recovering silver and associated metals from low-grade or refractory ores. Much of the research dealt with heap leaching, activated carbon gold-silver recovery methods, and elevated-temperature pressurized stripping of gold and silver loaded carbon. Preliminary chemical refining tests were conducted on a silver sulfide precipitate to determine the feasibility of producing pure silver by a leaching-electrowinnning sequence. Research on the selective extraction of silver and copper from a complex sulfide concentrate from an antimony leach plant was continued. The concentrate was treated with an alkali sulfation roast followed by a sulfuric acid leach that resulted in the extraction of 99.5% of the silver and 99.7% of the copper. Refractory oxide silver ore was subjected to beneficiation tests to produce a silver-enriched limonite product for an acid-brine leach and a separate calcareous tailing. Results of the tests were inconclusive.

A rockburst monitoring system developed by the Bureau of Mines to warn of impending outbursts of rock was ready for commercial use.[21] The sensing elements of the monitoring system are geophones, extremely sensitive microphone-like instruments for detecting vibrations in rock. Strategically arrayed groups of geophones are linked to a computer that has been programed to pinpoint the origin of small-scale displacements, or microseismic events, that create minute noises the intensity and frequency of which can signal dangerously high stress. The monitoring system identifies zones where high stresses, that cause dangerous

[18]Page 9 of reference cited in footnote 16.

rockbursts, can be relieved by detonating explosive charges in strategic locations. Such controlled blasts help prevent the rockbursts. A rockburst monitoring system designed by the Bureau of Mines is in use at ASARCO's Galena silver mine near Wallace, Idaho, and similar systems have been installed in the Lucky Friday silver mine and the Star silver mine both of which are adjacent to the Galena mine.

A study of energy use patterns in the production of silver was published.[22] The report detailed energy consumption in each operation in the production of metallic silver and concluded that total consumption of energy per ton of metallic silver amounted to 1.5 billion Btu's.

Innovative drilling and blasting techniques were developed at Texasgulf Canada, Ltd's, Kidd Creek base metal mine near Timmins, Ontario.[23] The underground operation utilizes a unique sublevel open stope method developed using large diameter blastholes bored with rotary drills.

Worldwide research on silver technology was reviewed.[24]

A method was developed for recovering silver adsorbed as a cyanide complex on activated charcoal.[25] Loaded charcoal is treated with sodium carbonate or potassium carbonate and then washed with deionized or softened water to dissolve the silver. Silver was removed from some ores using a flame formed by reacting hydrogen and chlorine, which volatilized the silver. The metal was then recovered by condensation and leaching.[26]

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Recoverable content of ores and concentrates produced unless otherwise noted.
[2]In addition to the countries listed Ghana, Thailand, and Turkey produce silver, but information is inadequate to make reliable estimates of output levels.
[3]Revised to none.
[4]Includes production by the State mining company (COMIBOL) plus the exports of medium and small (private sector) mines.
[5]Smelter and/or refinery production.
[6]Output by Inyati mine only.
[7]Data include estimate of silver production from Klein Aub Koper Maatskappy Ltd. copper mines.
[8]Less than 1/2 unit.
[9]Refined silver and silver contained in blister copper and refinery muds.

Slag—Iron and Steel

By James R. Evans[1]

Combined sales and usage of iron and steel slags in 1976, at 32.6 million tons, remained fairly constant compared to those of 1975. Total sales value, however, showed about a 10% increase from that of 1975 to $79.7 million— the highest total sales value ever recorded.

During 1976 Vulcan Materials Co. placed an air-cooled iron blast-furnace slag plant onstream in the Chicago area.

DOMESTIC PRODUCTION

Iron slags sold or used in 1976 totaled 26.0 million tons, a slight increase from that of 1975 and near the level of 1970 (fig. 1 and 2). The total sales value for 1976, however, reached $70.0 million—the highest ever recorded. The quantity and sales value of iron slags by major process type are shown in table 1.

Steel slags sold or used in 1976 totaled only 6.6 million tons, the lowest in 7 years. The total sales value, however, of $9.7 million exceeded the 1975 value by $0.8 million.

Slags of all types were processed at 101 major iron and steel furnace slag plants (table 3). There are an undetermined number of smaller plants in the United States that are not shown in table 3. The geographic distribution of slag plants by State is shown in figure 3.

Iron blast-furnace slags were processed in 14 States (table 2). Ohio and Pennsylvania accounted for 46% of the total. Ohio and Pennsylvania plus Illinois, Indiana, and Michigan accounted for 69% of the domestic total.

About 70% of iron slag products in the United States were shipped to markets by truck. Rail shipments composed 26%, and waterway shipments, 4% (table 3). Data for shipments of steel slags were not available.

CONSUMPTION AND USES

Because there were no imports and negligible exports of iron slag products in 1976, production or processing essentially equaled consumption in the United States. As in the past, nearly all of the slag consumed in the United States was in the construction industry.

Iron slag is a waste or byproduct of pig iron production, and the amount of iron slag available each year is controlled by the production of pig iron. It appears that nearly all of the iron slag products made from newly processed material are consumed in the marketplace each year. Steel slags are less available for marketing because each year since 1972 an increasing amount of steel slag has been returned to the blast furnaces as part of the charge. This is done to recover metallic iron. Also, steel slags cannot be used for all purposes for which iron slags are used.

Air-cooled iron blast-furnace slag continued to be the most important slag product in terms of both tons processed and range of applications. Locally, they are competitive with natural aggregates such as crushed stone and sand and gravel. This type of slag shows excellent bonding characteristics when mixed with portland cement to make concrete. It also shows high stability when

used in asphaltic concretes and high skid resistance when used in bituminous road surfacing. Consumption was up slightly from that of 1975 to 22.9 million tons. The use pattern and tonnage by uses were about the same as those in 1975.

Granulated iron-blast furnace slag consumption was down slightly from 1975 to 1.6 million tons (table 6). The major use of granulated slag was in highway construction; consumption was up about 250,000 tons from that of 1975 to 1.2 million tons. Because granulated slag shows natural hydraulic properties, its main use is in highway construction as bases, subbases, and fill. When compacted damp, this type of slag will slowly set into a hard dense mass and assure little overall settlement to pavement or other overlays. Uses other than in highway construction were minor but do show, except for agricultural liming, that consumption in 1976 was down from that of 1975.

Nearly all of the expanded iron-blast furnace slag goes into aggregates for concrete-block manufacture (table 6). This slag is lightweight and shows high fire resistance and low shrinkage properties, which makes it very desirable for lightweight concrete blocks. Consumption for this use was up about 300,000 tons from that of 1975 to 1.4 million tons.

Steel slags are used mainly for unconfined bases, fill, and highway shoulders (table 7). Because steel slags can exhibit uncontrolled expansion, a result of hydration of free lime, and marked variations in chemical composition and physical properties, uses for steel slags are limited. Aging for a period of at least 6 months has proved useful in controlling expansion. In 1976 total consumption was down about 700,000 tons from that of 1975 to 6.6 million tons.

PRICES

Average selling prices of slags at the plant for all major uses were higher in 1976. The average prices given in table 8 were derived from the total values and quantities shown in tables 5, 6, and 7. Data given in the range column of table 8 reflect the highest and lowest known selling prices of material that went into the use categories. Extreme higher prices in the use categories indicate that some users required demanding specifications, which necessitated more than normal processing. In some geographic areas overall construction as well as other costs are higher, resulting in higher prices for processed materials.

FOREIGN TRADE

There were no known imports of slags in 1976. Approximately 46,000 tons of iron blast-furnace slag were exported to Canada from the Buffalo, N.Y., and Detroit, Mich., areas.

WORLD REVIEW

The steel industry in Japan generated about 40 million tons of slag in 1976, which created environmental and disposal problems.[2] Nihon Cement Co. and the second ranked steel producer in Japan, Nippon Kokan, began a study on the possibility of using slag in cement and/or concrete aggregates. The study should be completed in 1977.

TECHNOLOGY

Fourteen technical papers on slag were presented in the October 1976 at the International Slag Conference at Mons, France. A wide variety of subject matter was treated, including blast furnace slags in vitroceramics, steel slag application in highway construction, relation between strength of slag cement and properties of slag, and studies of ferroalloy slags.

Laboratory studies on the use of fine-grained, self-cementing pelletized blast furnace slag in stabilized base construction were conducted at McMaster University, Hamilton, Ontario, Canada.[3] The finer portions of the minus 200-mesh portion of the ground pelletized slag showed cementing properties, and a satisfactory base mix of 70% crusher run slag and 30% ground pellets was developed. It was reported that ground pelletized blast furnace slag can offer, in many cases, a viable alternative to the use of asphaltic or portland cements, with an attendant saving in energy.

Sodium and Sodium Compounds

By Russell J. Foster[1]

The general economic upturn in 1976 prompted increased production in the chemical, glass, and pulp and paper industries, resulting in greater consumption of sodium compounds compared with the amounts used in 1975. The quantity and value of sodium compounds and metallic sodium produced in 1976 follow:

	Production (thousand short tons)	Value (thousand dollars)
Soda ash	5,216	259,253
Sodium sulfate	663	32,655
Metallic sodium	146	[e]71,754

[e]Estimate.

Natural soda ash production increased 21%, but output of synthetic material decreased 16%. One Solvay soda ash plant closed in 1976, but a new natural facility came onstream, and two other producers of natural ash were in the process of adding capacity. Production of both natural and synthetic sodium sulfate remained virtually unchanged. One producer of natural sodium sulfate had an expansion under construction. Exports of soda ash reached 9% of production. Net sodium sulfate imports totaled 17% of apparent consumption.

DOMESTIC PRODUCTION

The total amount of soda ash produced in 1976 was 7,560,000 tons, a 6% increase over that of 1975. Production of natural soda ash derived from trona or brine increased 21%, but synthetic ash declined 16%. The natural material claimed 69% of total production. Table 2 illustrates the continuing trend away from Solvay, toward natural ash.

[1]Physical scientist, Division of Nonmetallic Minerals.

Table 1.—Manufactured and natural sodium carbonates produced in the United States

1973	3,813	50.6	3,722	49.4
1974	3,507	46.4	4,059	53.6
1975	2,802	39.3	4,328	60.7
1976	2,344	31.0	5,216	69.0

Diamond Shamrock closed its 800,000-ton-per-year synthetic soda ash plant at Painesville, Ohio, at yearend 1976. Only three synthetic plants with a total capacity of about 2 million tons remain in the United States—Allied Chemical Corp. at Syracuse, N.Y., BASF-Wyandotte at Wyandotte, Mich., and PPG Industries at Corpus Christi, Tex.[2]

Texasgulf, Inc., became the fifth producer of natural soda ash in the United States when its 1-million-ton-per-year operation came onstream at Granger, Wyo., in October 1976. The capacity of the $150 million, coal-fired facility reportedly can be doubled with a minimum of inconvenience.[3]

The completion of a 750,000-ton-per-year expansion project at yearend 1975 brought the capacity of FMC Corp.'s natural soda ash plant in Wyoming up to 2.5 million tons per year.[4] Stauffer Chemical Co. was enlarging the capacity of its Wyoming plant by 200,000 tons per year. Completion was scheduled for early 1977.[5] Construction continued on the expansion of Kerr-McGee Chemical Corp.'s soda ash plant at Trona, Calif. The project will raise the capacity to 1.3 million tons per year by February, 1978. The boilers of the new facility were designed to burn solid, gaseous, or liquid fuels.[6]

Total production of sodium sulfate in 1976 was 1,232,000 tons. Production of both natural and byproduct material was essentially unchanged from that of the previous year. Nearly 54% of the total sodium sulfate was the natural compound, produced by three companies operating five plants in California, Texas, and Utah. Kerr-McGee Chemical Corp. was increasing natural sodium sulfate capacity by 150,000 tons per year at Trona, Calif., with startup slated for February, 1978.[7]

[e]Estimate. [r]Revised.

CONSUMPTION AND USES

Estimated industrial demand for soda ash and sodium sulfate is tabulated below:[8]

Industry	Percent of demand	
	Soda ash	Sodium sulfate
Pulp and paper	7	70
Glass	47	--
Detergents	6	20
Chemicals	25	--
Water treatment	3	--
Other and exports	12	10

Apparent consumption of sodium carbonate and sodium sulfate rose in 1976, reflecting recovery from the 1975 economic slump. Total production of chemicals and related products increased. Greater demand for chlorine made coproduct caustic soda increasingly available to compete with soda ash in certain processes.

The glass industry exhibited growth in all major areas— containers, fibers, and especially flat glass. Production of pulp, paper, and board products rose 9% to 14%. Increased demand for gasoline antiknock additives contributed to a 1% increase in metallic sodium production.

———. Soda Ash. V. 208, No. 8, Aug. 25, 1975, p. 9.

PRICES

The prices of natural soda ash and natural sodium sulfate, f.o.b. mine or plant, as reported by producers were as follows:

	Value, dollars per short ton		Change, percent
	1975	1976	
Bulk soda ash	42.20	49.70	+18
Bulk sodium sulfate	41.48	49.25	+19

Yearend prices of metallic sodium and sodium compounds quoted by Chemical Marketing Reporter follow:

		1975[1]	1976[1]
Sodium carbonate (soda ash):			
Light, paper bags, carlots, works	per ton	\$57.00 -71.00	\$57.00 -71.00
Light, bulk, carlots, works	do	57.00 -64.00	57.00 -64.00
Dense, paper bags, carlots, works	do	57.00 -71.00	57.00 -71.00
Dense, bulk, carlots, works	do	47.00 -49.00	47.00 -49.00
Sodium sulfate (100% Na_2SO_4):			
Technical detergent, rayon-grade, bags, carlots	do	60.00 -65.00	70.00 -72.00
Technical detergent, rayon-grade, bulk, works	do	55.00	55.00
Domestic salt cake, bulk, works[2]	do	60.00	60.00
National Formulary (N.F. XII), drums	per pound	.235	.235
Metallic sodium:			
Bricks, carlots, works	do	.30	.29
Fused, lots 18,000 pounds and more, works	do	.265- .275	.265- .29
Bulk, tank, works	do	.225	.225

FOREIGN TRADE

In 1976 U.S. exports of soda ash reached 645,000 tons, or 9% of total production, and imports were negligible. More than 36% of the exported soda ash went to other countries in North America, 30% to South America, 23% to Asia and Oceania, and 11% to Africa.

Imports of sodium sulfate amounted to 316,000 tons. Half of the imported material came from Canada, and 44% was shipped from Belgium. Sodium sulfate exports totaled 57,000 tons, or 5% of production. The principal destinations for exported sodium sulfate were Oceania, 57%, and Canada, 33%. The total value of exported sodium compounds exceeded the value of imports by over \$37 million.

Table 5.—U.S. exports of sodium carbonate and sodium sulfate

(Thousand short tons and thousand dollars)

WORLD REVIEW

World production of soda ash and sodium sulfate, by country, is listed in tables 8 and 9. Only 22% of the world's soda ash was derived from natural sources in 1976, and the United States produced 98% of that quantity. The five top-ranking nations in the production of soda ash were the United States, the U.S.S.R., West Germany, France, and Japan.

Natural sodium sulfate provided 50% of the world's supply, and the United States and Canada combined produced 56% of the natural material. The top five sodium sulfate producing countries in the world were the United States, the U.S.S.R., Canada, Japan, and Spain.

Bulgaria.—Plans were announced for increasing the capacity of the mineral fertilizer and soda ash plant at Devnya.[9]

Colombia.—The state-owned Cia. Colombiana de Alcalis revealed plans for a $12 million expansion of its 308,000-ton-per-year soda ash production facilities.[10]

India.—By 1979-80 India expects to increase production of soda ash to nearly 1.2 million tons per year. This will be accomplished by commissioning three new units at Tarapore, Haldia and Tuticorin, and the expansion of two existing plants at Mithapur and Porbandar.[11]

United Kingdom.—Imperial Chemical Industries, Ltd., allotted a total of $30 million over the next 2 years to modernize its synthetic soda ash complex in Cheshire. An extra 8,000 tons of capacity is scheduled, which would bring ICI Mond Div.'s soda ash capacity in the United Kingdom to about 1,925,000 tons per year.[12]

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, the People's Republic of China, Poland, Romania, and the United Kingdom are assumed to have produced manufactured sodium sulfate, and other unlisted countries may have produced this commodity, but production figures are not reported and available general information is inadequate for the formulation of reliable estimates of output levels.

[2]Natural mine output, excluding byproduct output from the nitrate industry, which is reported separately under manufactured.

[3]Conjectural estimates based on 1968 information on natural sodium sulfate and general economic conditions.

[4]Byproduct of nitrate industry.

[5]Quantities of manufactured sodium sulfate credited to Spain are reported in official sources in such a way as to indicate that they are in addition to the quantities reported as mined (reported in this table under natural), but some duplication may exist.

[6]Derived figure; data presented are the difference between reported total sodium sulfate production (natural and manufactured, undifferentiated) and reported natural sodium sulfate production (reported under natural in this table).

TECHNOLOGY

The need for conservation of energy resources has prompted increased funding for battery systems that weigh less and store more energy than present models, and that can compete with gasoline power on a cost basis. Among the high-storage-density batteries currently under development is the molten sodium-sulfur system, which consists of a reservoir of molten sodium metal separated from a supply of molten sulfur by a solid electrolyte that conducts sodium ions. The system has a very high energy density and operates at 300° to 350°C. What makes the sodium-sulfur batteries attractive for electric vehicles is their low potential cost and lower operating temperatures than competitive lithium versions.[13]

The Superior Oil Co. reportedly has perfected a multimineral process to extract soda ash, nahcolite (sodium bicarbonate), alumina, and oil from deposits containing oil shale, nahcolite, and dawsonite in Colorado's Piceance Basin. The modular plant separates nahcolite from the shale by friability difference, and recovers oil by use of a circular-grate retort. Dawsonite and any remaining nahcolite are dissolved in alkali to yield a solution of sodium aluminate and sodium carbonate. Aluminum hydroxide is crystallized, filtered, and calcined into cell-grade alumina. Sodium carbonate is recovered using triple-effect evaporation and centrifugation. Spent shale is returned to the mine.[14]

Stone

By Avery H. Reed[1]

The stone industry leveled off and operated at about the same rate as in 1975. Output of dimension stone was 1.40 million tons valued at $104.4 million, 27% below 1974 production. Output of crushed stone was 900 million tons valued at $2.12 billion, 15% below the 1973 record production.

Stone was produced in every State except Delaware and North Dakota. There were 2,188 companies, operating 5,665 quarries. Average output per company was 412,000 tons. Average output per quarry was 159,000 tons. More than half the stone was produced at quarries producing more than 500,000 tons each. Most of the stone was hauled by truck.

Leading stone producers were Vulcan Materials Co., 86 quarries, Martin Marietta Corp., 112 quarries; United States Steel Corp., 14 quarries; Medusa Corp., 50 quarries; Koppers Co., 45 quarries; Lone Star Industries, Inc., 24 quarries; U.S. Forest Service, 534 quarries; General Dynamics Corp., 7 quarries; Ashland Oil Corp., 34 quarries; and the Flintkot Co., 20 quarries. With 926 quarries, these 10 operators accounted for 24% of the total production of stone.

Classification.—The Bureau of Mines classifies stone into two categories (crushed and dimension) and into nine kinds (granite, limestone, marble, marl, sandstone, shell, slate, traprock, and miscellaneous).

The category classifications are not exact; some crushed stone may be in large pieces, such as riprap, and some dimension stone may be in small pieces, such as art objects or carvings. The dimension stone industry is concerned with cutting or shaping stone to a certain size, and waste or scrap from processing dimension stone may be a part of the crushed stone industry.

Classification by kind is also difficult. Granite may include metamorphic gneisses or syenites. Limestone may be pure calcium carbonate, but may be bituminous, dolomitic, or siliceous. Marble may include any calcareous rock that will polish. Marl may range from low to high in shale or clay content. Sandstone may be calcareous, quartz or quartzite, silt, or conglomerate. Miscellaneous stone includes aa, lava, schist, and any other stone not included in the aforementioned categories.

Imports for consumption (value)	$43,436	$48,678	$51,631	$46,137	$46,211

rRevised.
[1]Data may not add to totals shown because of independent rounding.

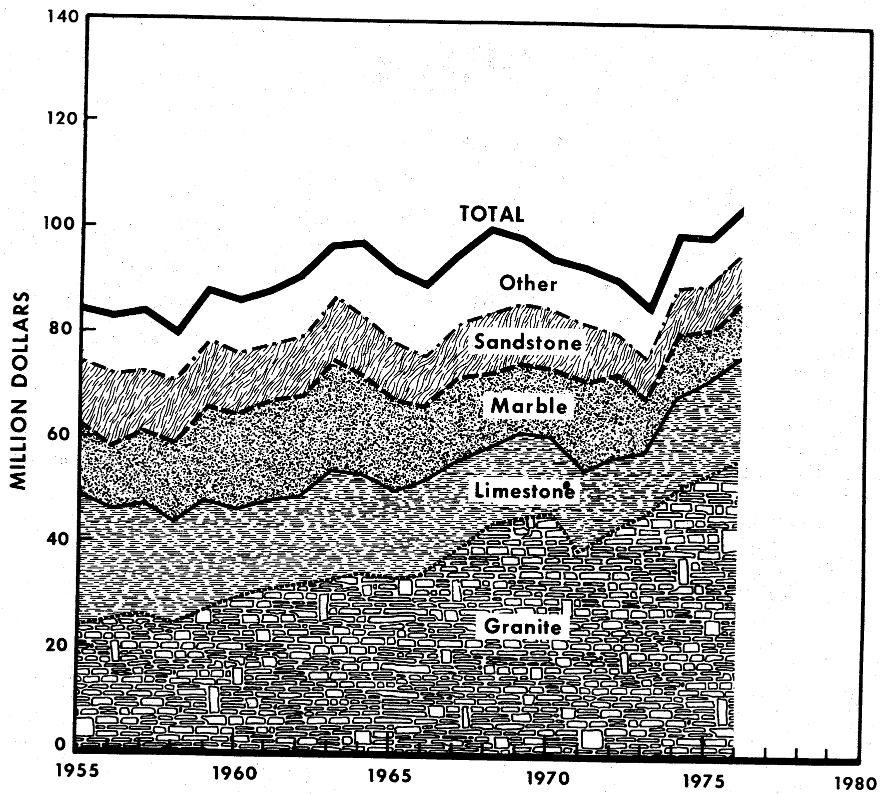

Figure 1.—Value of dimension stone sold or used by producers in the United States, by kind.

The Bureau of Mines generally accepts the classification reported by producers.

Deposits of unconsolidated materials, including beach sands, are generally classified as sand and gravel, regardless of chemical content. However, many deposits of stone are relatively soft and may be mined without blasting. Natural sand deposits are classified as sand and gravel, but manufactured sand (stone sand) is classified as stone.

The Bureau of Mines canvass of dimension stone does not include processors of purchased rough stone. All producers are covered; if the producer sells rough stone to a processor, it is tabulated as rough stone; if the producer processes finished stone, only the finished stone is tabulated, and the rough stone is deducted.

Capacity figures and stocks are not available. Inventories on hand at quarries and plants are estimated at about 1 month's supply, or 100 million tons.

DOMESTIC PRODUCTION

Dimension Stone.—Dimension stone was produced at 450 quarries in 44 States. Leading States were Indiana, Georgia, Vermont, Ohio, and Massachusetts, which accounted for 56% of the total output of dimension stone. Of the total production, 41% was granite, 30% was limestone, 19% was sandstone, 4% was slate, 4% was marble, and 2% was miscellaneous stone. Leading companies were Coggins Granite Industries, Inc., and Rock of Ages Corp. There were 303 companies, and average output per company was 4,600 tons valued at $345,000. Total output of dimension stone was about the same as in 1975, 1.40 million tons valued at $104.4 million.

Crushed Stone.—Crushed stone was produced at 5,214 quarries, in every State except Delaware and North Dakota. Leading States were Pennsylvania, Illinois, Texas, Missouri, and Ohio, which accounted for 30% of the total output of crushed stone. Of the total production, 74% was limestone, 11% was granite, 8% was traprock, 3% was sandstone, 2% was miscellaneous stone, and 2% was shell. There were 1,936 companies, and average output per company was 465,000 tons valued at $1.09 million. Total output of crushed stone was about the same as in 1975, 900 million tons valued at $2.12 billion. Leading companies were Vulcan Materials Co. and Martin Marietta Corp.

LIMESTONE

Dimension.—Dimension limestone was produced by 66 companies in 18 States. Leading States were Indiana, Wisconsin, Kansas, Minnesota, and Alabama, which accounted for 88% of the total output of dimension limestone. Leading companies were Victor Oolitic Stone Co. and Indiana Limestone Co. Total output of dimension limestone decreased 1% to 414,000 tons valued at $19.8 million. Average production per company was 6,300 tons valued at $300,000.

Crushed.—Crushed limestone was produced by 1,307 companies in 46 States. Leading States were Illinois, Texas, Pennsylvania, Missouri, and Ohio, which accounted for 38% of the total output of crushed limestone. Leading companies were Vulcan Materials Co. and Martin Marietta Corp. Total output of crushed limestone was about the same as in 1975, 663 million tons valued at $1.50 billion. Average production per company was 507,000 tons valued at $1.14 million. The States with no crushed limestone output were Delaware, Louisiana, New Hampshire, and North Dakota.

GRANITE

Dimension.—Dimension granite was produced by 86 companies in 21 States. Leading States were Georgia (34%), Vermont, Massachusetts (14%), New Hampshire (11%), and South Dakota (6%). Leading companies were Coggins Granite Industries and Rock of Ages Corp. Total production of dimension granite decreased 5% to 574,000 tons valued at $55.9 million. Average output per company was 6,700 tons valued at $650,000.

Crushed.—Crushed granite was produced by 150 companies in 31 States. Leading States were Georgia, North Carolina, Virginia, South Carolina, and Arkansas, which accounted for 79% of the total output of crushed granite. Leading producers were Vulcan Materials Co. and Martin Marietta Corp. Total output of crushed granite increased 4% to 98.3 million tons valued at $240 million. Average production per company was 656,000 tons valued at $1.60 million.

TRAPROCK

Dimension.—Dimension traprock was produced by three companies in Hawaii, Washington, and California. Leading companies were J. W. Glover Ltd. and Heatherstone Inc. Output decreased 5% to 1,160 tons valued at $14,300. Average production per company was only 390 tons valued at $4,800.

Crushed.—Crushed traprock was produced by 298 companies in 25 States. The five leading States—Oregon, New Jersey, Washington, Massachusetts, and Connecticut—accounted for 59% of the total output of crushed traprock. Leading producers were the U.S. Forest Service and Ashland Oil Inc. Total output decreased 4% to 75.2 million tons valued at $193 million. Average production per company was 252,000 tons valued at $647,000.

SANDSTONE

Dimension.—Dimension sandstone was produced by 91 companies in 27 States. Leading States were Ohio, Pennsylvania, New York, Georgia, and Maryland, which accounted for 60% of the total output of dimension sandstone. Leading producers were Standard Slag Co. and Briar Hill Stone Co. Output was 272,000 tons valued at $10.2 million. Average production per company was 3,000 tons valued at $112,000.

Crushed.—Crushed sandstone was produced by 199 companies in 33 States. Leading States were Pennsylvania, Arkansas, California, and Ohio, which accounted for 51% of the total output of crushed sandstone. Leading producers were Ashland Oil Co. and Ottawa Silica Co. Output decreased 1% to 26.7 million tons valued at $78.5 million. Average production per company was 134,000 tons valued at $395,000.

MARBLE

Dimension.—Dimension marble was produced by 15 companies in 12 States. Leading States were Vermont, Georgia, Tennessee, Montana, and Alabama, which accounted for 87% of the total output of dimension marble. Leading producers were Georgia Marble Co. and Vermont Marble Co. Output expanded 12% to 56,000 tons valued at $10.3 million. Average output per company was 3,700 tons valued at $688,000.

Crushed.—Crushed marble was produced by 20 companies in 13 States. Leading States were Alabama, Georgia, North Caro-

lina, Texas, and Wyoming, which accounted for 91% of the total production of crushed marble. Leading producers were Georgia Marble Co. and Thompson-Weinman & Co. Output was about the same as in 1975, 1.46 million tons valued at $20.6 million. Average production per company was 72,800 tons valued at $1.03 million.

SLATE

Dimension.—Dimension slate was produced by 29 companies in 6 States. Leading States were Pennsylvania and Vermont, which accounted for 76% of the total output of dimension slate. Other States were Virginia, New York, North Carolina, and California. Leading companies were A. Dalley & Sons Inc. and Stoddard Slate Co., Inc. Output decreased 6% to 58,000 tons valued at $7.26 million. Average production per company was 2,000 tons valued at $250,000.

Crushed.—Crushed slate was produced by eight companies in Virginia, Georgia, Arkansas, and New York. Leading producers were Hercules Inc. and Georgia Lightweight Aggregate Co. Output expanded 16% to 879,000 tons valued at $5.81 million. Average output per company was 110,000 tons valued at $726,000.

SHELL

Crushed shell was produced by 13 companies in Louisiana (68%), Texas, Alabama, Florida (4%), South Carolina, California, and Virginia. Leading companies were Radcliff Materials, Inc., and Parker Bros. & Co., Inc. Output declined 11% to 13.8 million tons valued at $37.4 million. Average production per company was 1.06 million tons valued at $2.88 million.

CALCAREOUS MARL

Crushed marl was produced by 31 companies in 8 States. Leading States were South Carolina, Texas, and Mississippi, which accounted for 92% of the total output of crushed marl. Leading producers were Santee Portland Cement Co. and Giant Portland Cement Co. Output decreased 4% to 3.37 million tons valued at $4.45 million. Average production per company was 109,000 tons valued at $143,000.

MISCELLANEOUS STONE

Dimension.—Other kinds of dimension stone were produced by 22 companies in 11 States. Leading States were Maryland, Pennsylvania, California, and Oregon, which accounted for 87% of the total output of other dimension stone. Other States were Arizona, New Mexico, Virginia, Washington, North Carolina, and Hawaii. Leading producers were Stoneyhurst Quarries and Tri State Stone Co. Output declined 32% to 25,000 tons valued at $911,000. Average production per company was only 1,100 tons valued at $41,400.

Crushed.—Other crushed stone was produced by 84 companies in 26 States. Leading States were Pennsylvania, California, North Carolina, Alaska, and Washington, which accounted for 79% of the total output of other crushed stone. Leading producers were the U.S. Forest Service and Eureka Stone Quarry Inc. Output expanded 25% to 17.7 million tons valued at $41.1 million. Average production per company was 210,000 tons valued at $489,000.

CONSUMPTION AND USES

Stone was consumed in every State. Dimension stone was marketed over wide areas to meet specific requirements. Crushed stone was generally marketed in a limited area, usually in the State where produced. Although large stockpiles may exist, output during the year is considered to equal consumption.

Dimension.—Dimension stone was used for building stone (32%), monuments (24%), rough blocks (19%), and for other uses. Output of rough monumental stone decreased 3% to 271,500 tons valued at $15.2 million. Production of rough blocks decreased 8% to 271,400 tons valued at $9.1 million. Output of cut building stone decreased 5% to 120,800 tons valued at $24 million. Production of rough construction stone increased 19% to 119,000 tons valued at $3.2 million. Output of curbing decreased 4% to 118,500 tons valued at $8.0 million. These five uses accounted for 64% of the total production of dimension stone.

Crushed.—Crushed stone was used for roadstone (55%), concrete (13%), cement (11%), and many other uses. Output of roadbase aggregate declined 12% to 191.2 million tons valued at $401.7 million. Production of other aggregate and roadstone expanded 12% to 131.2 million tons valued at $299.9 million. Output of concrete aggregate decreased 3% to 116.0 million tons valued at $270.6 million. Stone used in cement increased 4% to 99.2 million tons valued at $177.1 million. Production of bituminous aggregate decreased 3% to 86.6 million tons valued at $225.3 million. These five uses accounted for 69% of the total production of crushed stone.

LIMESTONE

Dimension.—Dimension limestone was used for building stone (48%), as rough blocks (33%), for rubble (13%), and for other purposes. Output of rough blocks declined 15% to 137,600 tons valued at $3.7 million. Production of cut building stone increased 8% to 58,700 tons valued at $8.7 million. Output of house stone veneer increased 4% to 57,800 tons valued at $2.3 million. Production of rubble expanded 51% to 55,400 tons valued at $610,000. Output of sawed building stone declined 12% to 47,800 tons valued at $3.1 million. These five uses accounted for 86% of the total production of dimension limestone.

Crushed.—Crushed limestone was used for roadstone (50%), cement (14%), concrete aggregate (14%), and many other purposes. Output of roadbase aggregate declined 10% to 136.2 million tons valued at $272.1 million. Production of stone for cement increased 6% to 93.4 million tons valued at $166.3 million. Output of concrete aggregate decreased 4% to 90.6 million tons valued at $203.1 million. Production of other aggregate and roadstone expanded 10% to 80.5 million tons valued at $175.9 million. Output of bituminous aggregate declined 10% to 52.0 million tons valued at $127.2 million. These five uses accounted for 67% of the total production of crushed limestone.

A study was made of the output of agricultural and industrial limestone during the period 1940-76. Output of stone for cement more than tripled from 34.0 million tons in 1940 to a record 106.9 million tons in 1973. Output of stone for lime (including dead-burned dolomite, alkalies, and sugar) more than doubled, from 16.0 million tons in 1940 to a record 40.1 million tons in 1973. Output of aglime expanded more than four times, from 8.7 million tons in 1940 to a record 39.8 million tons. Output of flux stone expanded from 22.9 million tons in 1940 to a record 40.9 million tons in 1953; since 1953 output has declined 45% to 22.5 million tons. Output of stone for fillers (whiting, asphalt filler, and other fillers) expanded from 856,000 tons in 1940 to a record 4.8 million tons in 1962; since 1962, output has declined 32% to 3.3 million tons. Output of stone for glass expanded seven times, from 301,000 tons in 1940 to 2.1 million tons. Output of stone for mineral food expanded 16 times, from 132,000 tons in 1940 to a record 2.1 million tons in 1974. Output of stone used as rock dust in coal mines expanded 14 times, from 99,000 tons in 1940 to 1.4 million tons. Output of stone for other industrial and agricultural uses expanded eight times, from 414,000 tons in 1940 to 3.4 million tons. Total output for these uses more than doubled, from 83.5 million tons in 1940 to 204.8 million tons.

W Withheld to avoid disclosing individual company confidential data; included with "Other States" and with "Other uses."
[1]Includes dead-burned dolomite, alkalies, and sugar.
[2]Includes concealed uses and other uses.
[3]Data may not add to totals shown because of independent rounding.
[4]Includes New Jersey, Oregon, Rhode Island, and States indicated by symbol W.
[5]Includes other uses only: Railroad ballast, glass, mineral food, other filler, fill, rock dust for coal mines, other chemicals, ferrosilicon, whiting, sulfur dioxide removal from stack gases, asphalt filler, filter stone, roofing granules, soil conditioning, waste material, drain fields, terrazzo, magnesium metal, paper, building products, bedding material, refractory stone, acid neutilization, abrasives, stucco, disinfectant, and other uses.
[6]Concealed States only.

GRANITE

Dimension.—Dimension granite was used for monuments (56%), curbing (21%), building stone (13%), and other purposes. Output of rough monumental stone decreased 5% to 266,500 tons valued at $14.9 million. Production of curbing decreased 4% to 118,000 tons valued at $8.0 million. Output of dressed monumental stone expanded 18% to 54,700 tons valued at $18.1 million. Production of rough blocks declined 48% to 31,500 tons valued at $1.1 million. Output of cut building stone declined 24% to 29,300 tons valued at $10.3 million. These five uses accounted for 87% of the total production of dimension granite.

Crushed.—Crushed granite was used for roadstone (63%), concrete (17%), and other purposes. Output of roadbase aggregate declined 24% to 22.8 million tons valued at $53.0 million. Production of other aggregates and roadstone expanded 43% to 17.8 million tons valued at $43.8 million. Output of concrete aggregates increased 8% to 17.2 million tons valued at $43.3 million. Production of bituminous aggregate increased 7% to 16.2 million tons valued at $42.8 million. Output of railroad ballast expanded 22% to 9.1 million tons valued at $20.6 million. These five uses accounted for 84% of the total production of crushed granite.

TRAPROCK

Dimension.—Dimension traprock was used for rubble, rough blocks, and rough construction stone

Crushed.—Crushed traprock was used for roadstone (77%), and other purposes. Output of other aggregates and roadstone increased 7% to 18.5 million tons valued at $48.9 million. Production of roadbase aggregate declined 15% to 16.3 million tons valued at $38.7 million. Output of bituminous aggregate decreased 6% to 11.8 million tons valued at $33.9 million. Production of surface treatment aggregate expanded 30% to 9.6 million tons valued at $21.8 million. Output of concrete aggregate declined 25% to 5.1 million tons valued at $15.4 million. These five uses accounted for 82% of the total production of crushed traprock.

SANDSTONE

Dimension.—Dimension sandstone was used for building stone (48%), other rough stone (18%), rough blocks (12%), rubble (10%), and other purposes. Output of rough construction stone decreased 3% to 50,100 tons valued at $1.1 million. Output of other rough stone was 48,300 tons valued at $1.6 million. Production of sawed building stone expanded 72% to 34,700 tons valued at $1.7 million. Production of rough blocks declined 26% to 32,500 tons valued at $550,000. Output of rubble declined 20% to 28,300 tons valued at $370,000. These five uses accounted for 71% of the total production of dimension sandstone.

Crushed.—Crushed sandstone was used for roadstone (61%), concrete aggreate (8%), and other purposes. Output of roadbase aggregate increased 6% to 6.8 million tons valued at $14.9 million. Production of other aggregate and roadstone declined 13% to 4.9 million tons valued at $10.9 million. Output of bituminous aggregate expanded 31% to 3.1 million tons valued at $8.1 million. Production of concrete aggregate increased 2% to 2.2 million tons valued at $6.6 million. Output of riprap declined 13% to 1.6 million tons valued at $3.8 million. These five uses accounted for 69% of the total production of crushed sandstone.

MARBLE

Dimension.—Dimension marble was used for rough blocks (41%), monuments, building stone, and other purposes. Output of rough blocks declined 10% to 23,200 tons valued at $2.2 million. Production of dressed monumental stone was 11,100 tons valued at $3.9 million. Output of cut building stone expanded 40% to 6,800 tons valued at $2.8 million. Production of rough construction stone was 3,958 tons valued at $116,000. These four uses accounted for 80% of the total production of dimension marble.

Crushed.—Crushed marble was used for fillers, terrazzo (12%), roadstone, and other purposes. Output of stone for other fillers expanded 22% to 920,000 tons valued at $14.4 million. Production of terrazzo declined 27% to 170,000 tons valued at $3.6 million. Output of other aggregates and roadstone was 152,000 tons valued at $322,000. These three uses accounted for 85% of the total production of crushed marble.

SLATE

Dimension.—Dimension slate was used for flagging (44%), structural shapes (17%), roofing (17%), flooring (11%), and other purposes. Output of flagging increased 1% to 25,500 tons valued at $1.1 million. Production of structural shapes declined 15% to 10,000 tons valued at $2.4 million. Output of roofing declined 10% to 10,000 tons valued at $2.0 million. Production of flooring decreased 1% to 6,200 tons valued at $1.0 million. These four uses accounted for 89% of the total production of dimension slate.

Crushed.—Crushed slate was used for lightweight aggregate (59%), roadstone, roofing granules, and other purposes. Total output expanded 16% to 879,000 tons valued at $5.81 million.

SHELL

Crushed shell was used for roadstone, cement (15%), and other purposes. Output of other aggregate and roadstone declined 21% to 4.9 million tons valued at $10.8 million. Production of roadbase aggregate decreased 4% to 3.4 million tons valued at $9.7 million. Output of shell for cement declined 43% to 2.1 million tons valued at $5.9 million. These three uses accounted for 75% of the total production of crushed shell.

CALCAREOUS MARL

Crushed marl was used for cement (87%), roadstone, agstone, and fill. Output of marl for cement increased 8% to 2.92 million tons valued at $3.53 million. Total production of marl decreased 4% to 3.37 million tons valued at $4.45 million.

MISCELLANEOUS STONE

Dimension.—Other dimension stone was used for construction, rubble (20%), and other purposes. Output of rough construction stone declined 15% to 13,800 tons valued at $360,000. Production of rubble declined 58% to 5,000 tons valued at $95,000. These two uses accounted for 75% of the total production of other dimension stone.

Crushed.—Other crushed stone was used for roadstone (78%), and other purposes. Output of roadbase aggregate decreased 4% to 5.4 million tons valued at $12.8 million. Production of other aggregate and roadstone expanded 79% to 4.4 million tons valued at $9.1 million. Output of bituminous aggregate expanded 44% to 2.4 million tons valued at $7.4 million. These three uses accounted for 69% of the total production of other crushed stone.

PRICES

Values are the company-reported average selling prices f.o.b. quarry or plant, and do not include transportation away from the plant.

Unit values for dimension stone ranged from $11.83 per ton for rubble to $521.53 for slate used for blackboards and averaged $74.55, an increase of 6% over the 1975 average. Values, per cubic foot, were $5.38 for rough monumental stone, $2.62 for rough blocks, $15.47 for cut building stone, $2.14 for rough construction stone, and $5.76 for curbing, averaging $6.16 per cubic foot.

Unit values for crushed stone ranged from $1.25 per ton for waste material to $20.22 for whiting and averaged $2.35 per ton, an increase of 4% over the 1975 average. Values included $2.10 per ton for roadbase aggregate, $2.29 for other aggregate and roadstone, $2.33 for concrete aggregate, $1.78 for stone used in cement, and $2.60 for bituminous aggregate.

Unit values for dimension limestone averaged $47.81 per ton, or $3.60 per cubic foot; crushed limestone averaged $2.26 per ton. Values for dimension granite averaged $97.39 per ton, or $8.84 per cubic foot; crushed granite averaged $2.44 per ton. Values for dimension traprock averaged $12.31 per ton, or $1.05 per cubic foot; crushed traprock averaged $2.56 per ton. Values for dimension sandstone averaged $37.44, per ton or $2.89 per cubic foot; crushed sandstone averaged $2.94 per ton. Values for dimension marble averaged

$184.32 per ton, or $16.18 per cubic foot; crushed marble averaged $14.14 per ton. Values for dimension slate averaged $125.01 per ton, or $11.05 per cubic foot; crushed slate averaged $6.60 per ton. Shell sold for $2.72 per ton and marl for $1.32. Values for miscellaneous dimension stone averaged $36.45 per ton, or $3.01 per cubic foot; other crushed stone averaged $2.33 per ton.

Table 33.—Unit values of stone sold or used by producers in the United States

Stone	1975			1976		
	Dimension stone		Crushed stone, per ton	Dimension stone		Crushed stone, per ton

FOREIGN TRADE

Dimension stone was exported all over the world, but mainly to Canada. Exports included 63,000 tons of dimension limestone valued at $1.49 million and 120,000 tons of other dimension stone valued at $2.60 million.

Crushed stone was exported to many countries, mainly to Canada. Exports included 3.19 million tons of crushed limestone valued at $10.5 million and 1.2 million tons of other crushed stone valued at $9.35 million.

Stone was imported from many countries; total value of stone imported was $46.2 million, about the same as in 1975. Imports of dimension stone included 5,000 tons of limestone from Mexico valued at $176,000 82,000 tons of granite, mainly from Canada, Mexico, Taiwan, and Italy, valued at $9.88 million; 258,000 tons of marble, all from Italy, valued at $20.2 million; and 49,000 tons of slate, mainly from Italy and Portugal, valued at $5.88 million.

Imports of crushed stone included 3.60 million tons of limestone, mainly from Canada, Bahamas, and the Dominican Republic, valued at $9.08 million; 11,000 tons of granite from the Republic of South Africa valued at $194,000; and 2,500 tons of marble from Canada valued at $86,000. Total crushed stone imports were 3.69 million tons valued at $10.1 million.

WORLD REVIEW

Stone occurs all over the world. Resources are virtually unlimited, but shortages of stone for certain uses exist. Most stone is produced in the heavily industrialized countries. World output of stone in 1976 was estimated at about 5 billion tons, including 2 billion from Europe, 1.5 billion from Asia, and 1 billion from North America.

Canada.—Production of stone in 1975 was 97 million tons valued at $171 million. Exports of stone, mainly to the United States, were 1.7 million tons valued at $6.1 million. The stone was used for roadmetal (34%), concrete aggregate (19%), asphalt aggregate (7%), railroad ballast (5%), and many other uses. Of the total, 78% was limestone and 15% was granite. Leading Provinces were Quebec (55%) and Ontario (35%).

France.—France ranked behind Italy in output of dimension stone. Production of crushed stone was about 200 million tons, 4%, of the world's output.

Germany, West.—Production of stone in West Germany was estimated at about 250 million tons, 5% of the world total.

Italy.—Italy ranked first in output of dimension stone. Output of crushed stone was estimated at about 100 million tons, 2% of the world total.

Japan.—Japan produced about 180 million tons of stone, 4% of the world total.

U.S.S.R.—The Soviet Union ranked second behind the United States in stone production. Output was estimated at about 500 million tons, 10% of the world's supply of stone.

Sulfur and Pyrites

By John E. Shelton[1]

There was a slight increase in sulfur prices in 1976 compared with those in 1975. The average net shipment value f.o.b. mine/plant for Frasch and recovered elemental sulfur increased 2% from $45.63 per long ton in 1975 to $46.45 per ton in 1976. Both export and import prices decreased. The yearend price for Frasch sulfur was $61 per ton Gulf Ports.

Production of sulfur in all forms in 1976 decreased 4.9% below that of 1975. For the first time in 8 years, production did not equal apparent domestic consumption. Sulfur was produced by 69 companies at 182 operations in 32 States, with 10 companies having 57 operations accounting for 75% of the output. Distribution of production was Frasch sulfur 59%, recovered elemental sulfur 29%, and the contained sulfur in other production 12%. Production was concentrated in Texas and Louisiana. Together, these two States accounted for 68% of the total output.

[1]Supervisory physical scientist, Division of Nonmetallic Minerals.

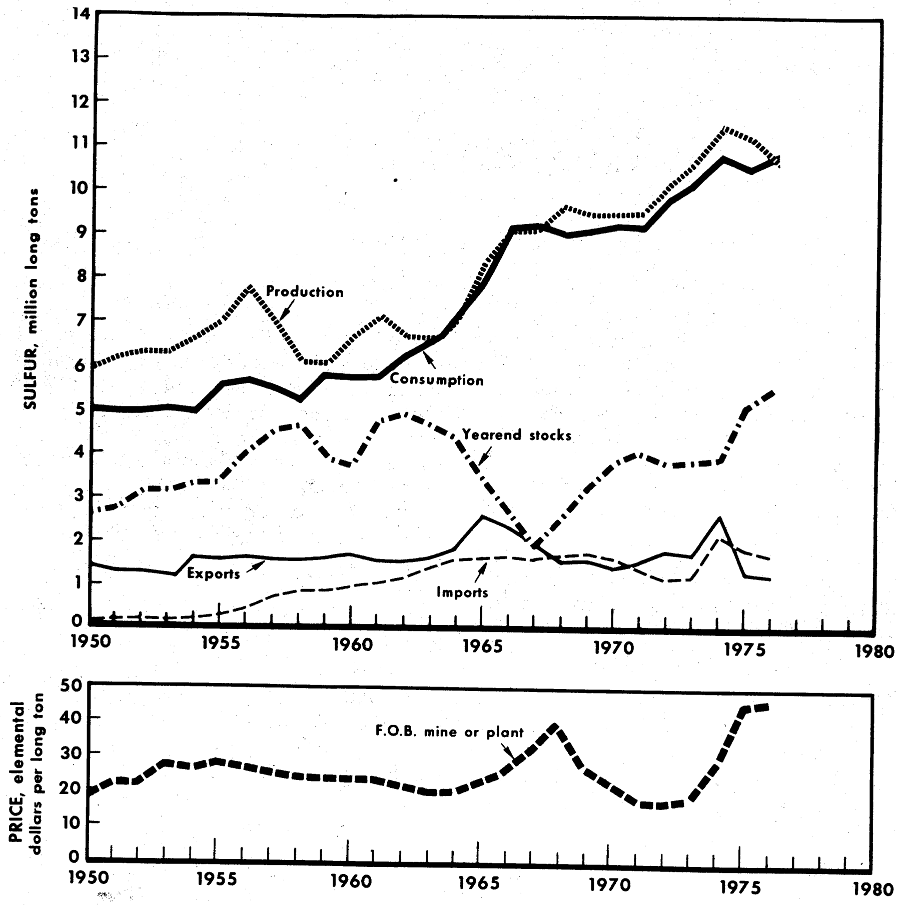

Figure 1.—Trends in the sulfur industry in the United States.

Shipments of sulfur in all forms to domestic and export markets increased 3% above those in 1975. Frasch and elemental sulfur accounted for 87% of the total shipments of sulfur in all forms in 1976. The total value of shipments f.o.b. mine/plant was $477.4 million in 1976 as compared with $459.8 million in 1975, an increase of 4%. Eighty-eight percent of the shipments was for domestic consumption and 12% for export. Shipments of sulfur in all forms in 1976 were 4% less than the quantity produced. Producers' yearend stocks of Frasch and recovered elemental sulfur were almost 9% greater than those at yearend 1975.

The apparent domestic consumption of sulfur in all forms increased 2% over that of 1975. Sulfur for domestic consumption was obtained mainly from domestic sources: Frasch 43%, recovered elemental 29%, and sulfur in other forms 12%. The remaining 16% of the sulfur was obtained by imports of Frasch and recovered elemental sulfur.

The United States was a net importer again in 1976. Exports of sulfur in all forms decreased 6% from 1975. Imports of sulfur in all forms in 1976 were 9% less than in 1975.

DOMESTIC PRODUCTION

Frasch Sulfur.—Output of Frasch sulfur was 59% of the domestic production of sulfur in all forms in 1976 compared with 64% in 1975.

In 1976, there were 12 Frasch mines, all in Texas and Louisiana. Producers and mines in Louisiana were Freeport Minerals Co. at Garden Island Bay, Grand Isle and Grand Ecaille, and Texasgulf, Inc., at Bully Camp. Producers and mines in Texas were Farmland Industries, Inc., who purchased the Atlantic Richfield Co. mine at Fort Stockton on November 1; Duval Corp. at Culberson; Jefferson Lake Sulfur Company at Long Point Dome; and Texasgulf, Inc.at Boling Dome, Fannett Dome, Moss Bluff Dome, Spindletop Dome, and the new mine at Comanche Creek. With the opening of the Comanche Creek mine, capacity to produce sulfur in West Texas will be more than 3 million tons per year.[2]

The ten mines operated by Duval Corp., Freeport Minerals Co., and Texasgulf, Inc., accounted for most of the Frasch sulfur production. A relatively small portion of the output was from the other two producers operating one mine each.

Production was again concentrated in the larger low-cost mines to counteract increasing production costs. The five largest mines, with four having a production rate in excess of one-half million tons per year each, accounted for 82% of the total Frasch sulfur production compared with 84% in 1975. These mines also accounted for 48% of the total output of sulfur in all forms in 1976 compared with 54% in 1975.

Producers' shipments of Frasch sulfur were 4% less than in 1975. Approximately 20% of the total shipments were for export and 80% were for the domestic market compared with 21% and 79%, respectively, in 1975. Because production was greater than shipments, producers' reported stocks after inventory adjustments were 9% greater than at yearend 1975.

Primarily because of the decrease in the quantity of Frasch sulfur shipped, the total value of shipments, f.o.b. mine, decreased almost 2% below that of the alltime reported high of $305 million in 1975.

Recovered Sulfur.—Production of recovered elemental sulfur, a nondiscretionary byproduct from natural gas and petroleum refinery operations, accounted for 29% of the total domestic production of sulfur in all forms compared with 26% in 1975. Production and shipments reached an alltime high with increases of 6% and 8%, respectively, over those of 1975, indicating the continuing increase in importance of recovered sulfur as a source of domestic supply. This type of sulfur was produced by 51 companies at 137 plants in 27 States, 2 plants in Puerto Rico, and 1 in the Virgin Islands. Most of the plants were of relatively small size, with only four reporting an annual production exceeding 100,000 tons. The 10 largest plants accounted for 37% of the output, and the combined production from the 5 leading States was 66% of the total. By source, 59% was produced by 38 companies at 79 refineries or satellite plants treating refinery gases, and 1 coking operation, and 41% was produced by 24 companies at 57 natural gas treatment plants. The five largest recovered elemental sulfur producers were Chevron, U.S.A., Inc., Exxon Co., U.S.A., Getty Oil Co., Shell Oil Co., and Standard Oil Co. (Indiana). Together, their 41 plants accounted for 53% of recovered elemental sulfur production in 1976.

The total value of shipments of recovered elemental sulfur in 1976 increased 13% to an alltime high of almost $118 million.

The leading States in production of recovered elemental sulfur were Texas, California, Florida, Mississippi, and Alabama.

W Withheld to avoid disclosing individual company confidential data; included with "Other States."
[1]Less than 1/2 unit.
[2]Combined to avoid disclosing individual company confidential data; includes Colorado (1975), Delaware, Missouri, Montana, New York, North Dakota, Utah, Virginia, Washington, Virgin Islands, and Puerto Rico.
[3]Data may not add to totals shown because of independent rounding.

Together these States contributed 66% of the total 1976 output. Production in 1976 increased compared with 1975 by 9% each in California and Texas and 8% in Florida. The production rate in Alabama was essentially unchanged whereas it dropped 21% in Mississippi. Recovery of sulfur in Alabama, Florida, and Mississippi was mainly from the treatment of dry sour natural gas and sour natural gas associated with petroleum in the deep Jurassic formations. Indications were of further increases in sulfur recovery in future years.

Byproduct Sulfuric Acid.—Sulfur contained in byproduct sulfuric acid produced at copper, lead, and zinc smelters and roasters during 1976 was 9% of the total domestic production of sulfur in all forms compared with 7% in 1975. The total output and value reached an alltime high in 1976. In

[1]Includes acid from foreign materials.
[2]Excludes acid made from pyrites concentrates.
[3]Excludes acid made from native sulfur.

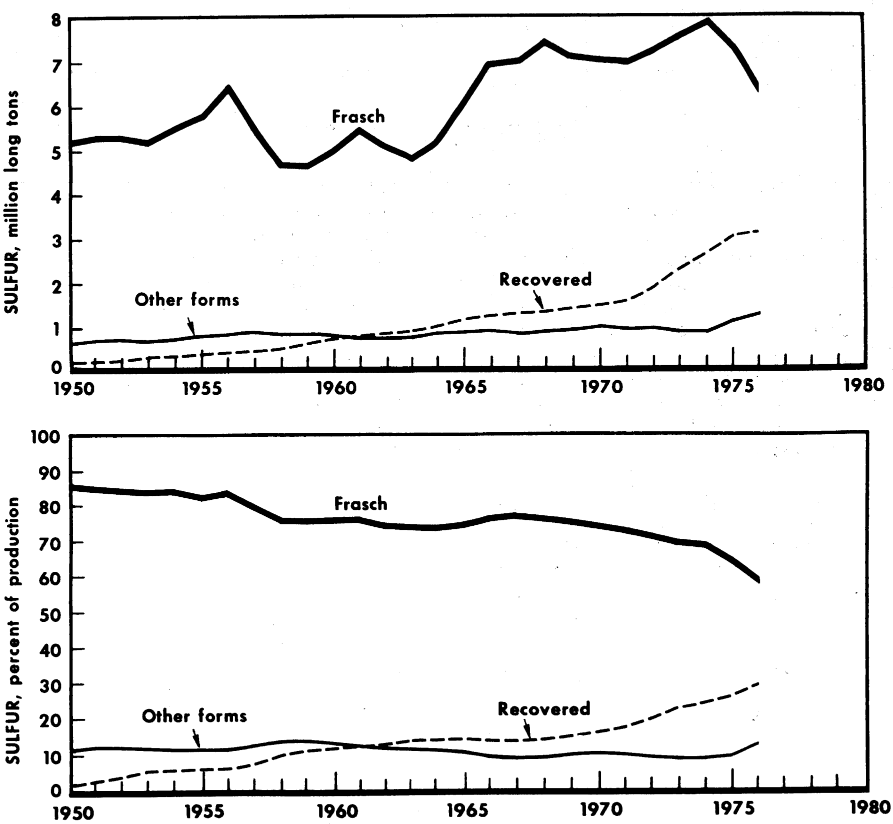

Figure 2.—Trends in the production of sulfur in the United States.

1976, output was 23% higher and total value was 8% higher than in 1975. Byproduct sulfuric acid was produced by 13 companies at 24 plants in 13 States. Fourteen acid plants operated in conjunction with copper smelters and 10 plants were accessories to lead and zinc roasting and smelting operations. The five largest acid plants accounted for 44% of the output, and production in five States was 79% of the total. The five largest producers of byproduct sulfuric acid were ASARCO Incorporated, Magma Copper Co., Kennecott Copper Corp., Phelps Dodge Corp., and St. Joe Minerals Corp., whose 14 plants produced 71% of the byproduct sulfuric acid in 1976.

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.— Sulfur contained in pyrites, hydrogen sulfide, and sulfur dioxide represented 3% of the total production of sulfur, unchanged from 1975. The total sulfur content in these products was 16% more than that of 1975, and the value of shipments was 81% higher. Pyrites was produced by three companies at three mines in three States, hydrogen sulfide by three companies at four plants in three States; and sulfur dioxide by two companies at two plants in two States. The three largest producers of these products were Cities Service Co., (pyrites, and sulfur dioxide), ASARCO Incorporated (sulfur dioxide), and Shell Oil Co. (hydrogen sulfide). These companies combined, at one mine and four plants, accounted for 94% of the contained sulfur produced in the form of these products.

1974	162	70	232	6,052
1975	237	75	312	7,097
1976	286	77	363	12,869

CONSUMPTION AND USES

In 1976, apparent domestic consumption of sulfur in all forms was 10.8 million tons, 2% greater than in 1975. Eighty-four percent of this consumption was from domestic sources compared with 82% in 1975. The supply sources of sulfur were domestic Frasch sulfur 43% compared with 45% in 1975, domestic recovered elemental sulfur 29% compared with 27% in 1975 and combined domestic byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide 12% compared with 10% in 1975. The remaining 16% of the sulfur was from imports of Frasch and recovered elemental sulfur compared with 18% in 1975.

The apparent sales of domestic Frasch sulfur to domestic consumers decreased by 120,000 tons, or 3% below shipments in 1975. Apparent shipments of recovered elemental sulfur for domestic consumption increased by 229,000 tons, or 8% over those in 1975. Reported sales of the sulfur content of byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide increased 226,000 tons or 21% above those in 1975. Total supplies of domestic sulfur in all forms to the domestic market increased by 335,000 tons. Imports of Frasch and recovered elemental sulfur decreased 170,000 tons or 9% below those of 1975. By source, imports of Frasch sulfur from Mexico decreased 236,000 tons; while imports of recovered elemental sulfur from Canada increased 39,000 tons and from other countries by almost 27,000 tons.

The Bureau of Mines initiated a survey to collect data on the end uses of sulfur and sulfuric acid by Standard Industrial Classification (SIC) of industrial activities. Canvass forms were sent to producers for data on shipments by end uses. In 1975 and 1976, 58 elemental sulfur and 77 sulfuric acid producing companies responded to the canvass. Of the above companies 17 reported shipments of both sulfur and sulfuric acid.

Producers of sulfur who responded to the canvass reported shipments of 10.6 million long tons of sulfur in 1975 and 10.5 million long tons in 1976. Of these reported shipments 1.2 million tons each year were for export. The largest use was 7.6 million tons in 1975 and 7.9 million tons in 1976 for sulfuric acid. This represented 81% and 84%, respectively, of shipments for domestic consumption in 1975 and 1976. Other reported end uses for elemental sulfur were industrial inorganic chemicals; synthetic rubber, cellulosic fibers and other plastic products; paints and allied products, explosives, industrial organic chemicals and other chemical products; petroleum refining and petroleum and coal products; pulp and paper products and agricultural chemicals which showed little change as a percentage of total domestic uses. Some companies did not identify shipments by end use. Some identified end uses were tabulated in the unidentified uses because of company confidentiality.

Of the reported shipments of 32.8 million short tons in 1975 and 33.6 million short tons in 1976 of 100% sulfuric acid, the largest end use was for phosphatic fertilizers. Shipments were 19 million tons or 58% of the total in 1975 and 19.7 million tons or 59% of the total in 1976. Shipments for other chemical products were 2.9 million tons or 9% of the total in both years. Petroleum refining and other petroleum and coal production received 2 million tons of acid or 6% in each year. The petroleum refining industry was a net user of about 700,000 tons of sulfuric acid however, since 1.3 million tons of spent acid were returned each year for reclaiming.

Usage of acid for copper ore leaching increased from 1.4 million tons in 1975 to 1.8 million tons in 1976, 4% and 5%, respectively, each year of the total shipments. Shipments for other categories are shown in table 10. Several end uses for sulfuric acid such as food products, automotive, electrical equipment, rubber and metal fabrication were tabulated in "Unidentified" because of confidentiality.

Of the total of 2.1 million short tons in 1975 and 2.4 million short tons in 1976 of spent acid returned for reclaiming, 175,000 tons or 9% in 1975 and 186,000 tons or 8% in 1976 were from the production of industrial organic chemicals. Petroleum refineries accounted for 61% in 1975 and 54% in 1976 of the total spent acid returned for reclaiming. The remaining reclaimed acid was from production of plastic materials, nonferrous metals, phosphatic fertilizers, paints and allied products, other chemical products, inorganic pigments, soaps and detergents, explosives, other agricultural chemicals, and organic chemicals.

Table 11 shows the total domestic use of sulfur including the sulfur content of sulfuric acid. The largest identified end use for sulfur (mostly as sulfuric acid) was the 49% in 1975 and 51% in 1976 for phosphatic fertilizers. Other uses were for other chemical products, 8% each year, petroleum refining and other petroleum and coal products, 6% each year and other inorganic chemicals, 5% each year. Sulfur used for copper ore processing (as sulfuric acid) increased 35% from 396,000 tons, 3% of the total in 1975 to 533,000 tons, 5% of the total in 1976.

[1]Does not include elemental sulfur used for production of sulfuric acid.
[2]Includes explosives (1975), and industrial organic chemicals (1976).
[3]Included in "Unidentified."

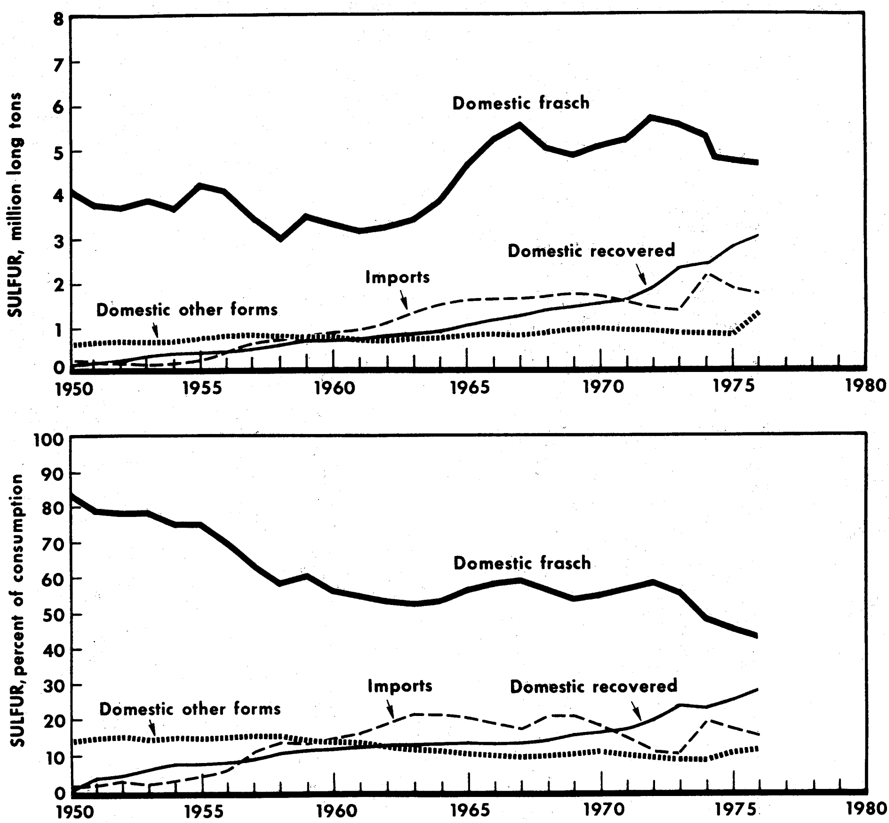

Figure 3.—Trends in the consumption of sulfur in the United States.

STOCKS

Producers' stocks of Frasch plus recovered elemental sulfur, after inventory adjustments, increased 9% over inventories at yearend 1975. Frasch sulfur stocks increased 9%; whereas recovered elemental sulfur stocks decreased 1%. The combined yearend stocks amounted to approximately 7.4 months supply based on 1976 domestic and export demands for domestically produced Frasch and recovered elemental sulfur.

Table 12.—Producers' yearend stocks

(Thousand long tons)

Year	Frasch	Recovered	Total
1972	3,665	131	3,796
1973	3,816	111	3,927
1974	3,744	213	3,957
1975	4,857	269	5,126
1976	5,297	266	5,563

PRICES

The quoted price for liquid sulfur exterminal Tampa, Fla., was $61 to $65 per long ton at yearend 1976 compared with $65 per ton at yearend 1975. There were price decreases in other markets.

On the basis of shipments and total value reported to the Bureau of Mines, the average value of shipments of Frasch sulfur f.o.b. mine for both domestic consumption and exports during 1976 rose to $51.19 per ton compared with $50.16 per ton in 1975 an increase of 2%. The recovered elemental sulfur industry was in a less favorable marketing position to obtain full benefit of the higher sulfur prices. This market was subject to regional competitive forces. Also, as a nondiscretionary byproduct there was a general tendency to sell sulfur in local markets. Sales were more dependent upon the industrial sector of the market. Shipment values varied widely in different regions; lowest in the West, somewhat higher in the midcontinent, and near the values for Frasch sulfur in the East and South. Overall, the reported unit shipment values f.o.b. plant in 1976 were $37.61 per ton, up 4% from $36.14 per ton in 1975.

Marketing sulfur produced in other than the elemental form reflected competitive positions in the limited regional markets for these products. In 1976, shipments of sulfur contained in byproduct sulfuric acid decreased $6.99 per ton of contained sulfur or 12%; whereas, the unit value for sulfur contained in pyrites, hydrogen sulfide, and sulfur dioxide increased $12.70 or 56% compared with 1975.

Table 13.—Reported sales values of shipments of elemental sulfur, f.o.b. mine or plant

(Dollars per long ton)

Year	Frasch	Recovered	Total
1972	17.39	15.60	17.03
1973	18.63	15.45	17.84
1974	30.52	23.79	28.88
1975	50.16	36.14	45.63
1976	51.19	37.61	46.45

FOREIGN TRADE

The United States was a net importer of sulfur in 1976, for the second year. Exports were down 6% to less than 1.3 million tons. Imports in the form of elemental sulfur decreased 9% to 1.7 million tons. The net import balance in 1976 was 457,000 tons compared with a net import of 545,000 tons in 1975.

Exports from the United States were almost entirely in the form of Frasch sulfur. The tonnage of crude sulfur exported in 1976 was 8% less than in 1975. Exports of refined sulfur more than doubled. The total value of exports declined 11% below that of 1975. The reported average export value was $53.08 per ton in 1976 compared with $55.44 in 1975 a decrease of 4%. Belgium-Luxembourg and the Netherlands received 75% of the exports, mainly for transshipment to other European Community Countries. Brazil was the third largest customer, receiving 10% of the exports. Not included in the above were exports from the Virgin Islands which were 72,000 tons valued at $3.5 million in 1976.

Imports of Frasch sulfur from Mexico decreased from 967,000 tons in 1975 to 731,000 tons in 1976. Imports of recovered elemental sulfur mostly from Canada increased 7%. Imports from Canada totaled 969,000 tons and imports from Japan were 26,000 tons. The unit value of imports of sulfur from Canada declined $4.71 to $18.30, whereas imports from Mexico increased $5.50 to $56.60 in 1976.

WORLD REVIEW

World production of sulfur decreased slightly in 1976. Following the pattern for the past several years, production of sulfur in all forms continued to exceed demand. World producers' stocks increased more than 3 million tons, primarily in Canada where stocks increased about 2.5 million tons.

Canada.—Production of sulfur in all forms totaled 7.2 million tons in 1976, down from 7.4 million tons in 1975. Recovered elemental sulfur produced at sour natural gas plants, refineries and tar-sand operations represented 89%. Sulfur contained in byproduct sulfuric acid produced at nonferrous metal smelters accounted for the remaining 11%.

In 1976, 45 sour natural gas plants, 42 in Alberta, 2 in British Columbia, and 1 in Saskatchewan were operated with a combined capacity of 9.5 million tons. Production from smelter gases was 767,000 tons of contained sulfur in sulfuric acid, an increase of 12% from 1975. Smelter gases will continue to increase as a source of sulfur, likely doubling by 1985.[3]

Production of sulfur from the Province of Alberta declined 2% to 6.3 million tons in 1976. Shipments increased from 3.8 million tons to 3.9 million tons in 1976. Of these shipments 2.4 million tons was to offshore foreign markets other than the United States, up from 2.2 million tons in 1975. Producers' stocks rose to 18.5 million tons at the end of 1976 up from 16.1 million tons at the end of 1975.

The value of marketed sulfur f.o.b. plant was $16.21 in December 1976 down from $19.24 in December 1975.[4]

A sulfur slating facility, with an annual capacity of 1.2 million tons, was opened by Shell Canada at the Waterton gas processing plant.

The Athabasca tar sands in Alberta, Canada, have been estimated to contain 300 million tons of economically exploitable reserves of sulfur if the tar sands are mined by open pit techniques.[5]

Cyprus.—Production of pyrite in Cyprus was 97,000 tons (sulfur content) in 1975, and about 93,000 tons in 1976. Exports in 1975 were 98,000 tons.

France.—Production of sulfuric acid increased about 8% in 1976.

Production of sulfur from the sour natural gas at the Lacq deposit has placed France among the major world sulfur producers. Annual production of 1.7 to 1.8 million tons are from reserves of recoverable sulfur estimated at 60 million tons in 1970.[6]

Japan.—Capacity to produce recovered elemental sulfur from imported oil increased from 900,000 long tons in 1971 to 1.9 million tons in 1975. During the same period production increased from 305,000 tons to 775,000 tons. Since demand for elemental sulfur is less than production, a storage problem has resulted which has created a problem for Japanese producers who are not permitted to store sulfur in bulk form. Therefore Japanese producers have been searching for export markets.[7]

Elemental sulfur recovered at petroleum refineries was 980,000 long tons in 1976. Sulfur content of pyrite and pyrrhotite ores and concentrates produced in 1976 was 463,000 tons.

Mexico.—Production of Frasch sulfur was 2.0 million tons in 1976 about the same as in 1975. Output of recovered elemental sulfur was 95,000 tons in 1976.

Poland.—Exports of Polish sulfur to market economy countries increased slightly to about 1.6 million tons. Exports to the rest of the world increased about 25% to 1.9 million tons, as European sulfuric acid markets improved.

U.S.S.R.—Production of sulfuric acid increased about 8% to 19.7 million long tons.

Gypsum	[r]150	142	87

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, a number of nations may produce limited quantities of sulfur, either in the elemental state or as a compound (chiefly H_2S or SO_2), as a byproduct of petroleum and natural gas operations, and/or metallurgical operations, but output, if any, is not quantitatively reported, and no basis is available for the formulation of reliable estimates of output levels. Countries not listed in the body of the table which may have byproduct sulfur recovery from oil refining include: Albania, Bangladesh, Brunei, Burma, Costa Rica, Guatemala, Honduras, Jamaica, Malaysia, Nicaragua, Paraguay, People's Democratic Republic of Yemen, and Sri Lanka. Albania and Burma may also produce byproduct sulfur from crude oil and natural gas extractions. No complete listing of other nations which may produce byproduct sulfur in any form from metallurgical operations (including processing of coal for metallurgical use) can be compiled, but the total of such output is considered as small. Nations listed in the table which may have production from sources other than those listed are identified by individual footnotes.

[2]The term "source" reflects both the means of collecting sulfur and the type of raw material. Sources listed include the following: 1) Frasch recovery; 2) native, comprising all production of elemental sulfur by traditional mining methods (thereby excluding Frasch process recovery); 3) pyrite (whether or not the sulfur is recovered in the elemental form or as acid); 4) byproduct recovery, either as elemental sulfur or as sulfur compounds (chiefly H_2S and H_2SO_4) from a) coal gasification, b) metallurgical operations including associated coal processing, c) crude oil extraction, d) natural gas extraction, e) petroleum refining, f) tar sand cleaning, g) processing of spent oxide from stack-gas scrubbers; and 5) recovery from the processing of mined gypsum. Recovery of sulfur in the form of sulfuric acid from artificial gypsum produced as a byproduct of phosphatic fertilizer production is excluded because to include it would result in double counting. It should be noted that production of Frasch sulfur, other native sulfur, pyrite derived sulfur, mined gypsum derived sulfur, byproduct sulfur from extraction of crude oil and natural gas, and recovery from tar sands are all credited to the country of origin of the extracted raw material; in contrast, byproduct recovery from metallurgical operations, petroleum refineries, and spent oxides are credited to the nation where the recovery takes place, which in some instances is not the original source country of the crude product from which the sulfur is extracted.

[3]Revised to zero.

[4]In addition may produce limited quantities of byproduct sulfur from natural gas.

[5]Excluding sulfur content of auriferous pyrites, for which data are not available.

[6]Excluding sulfur recovered, if any, from processing copper concentrates.

[7]Includes the following quantities recovered in elemental form in thousand long tons: 1974—26; 1975—24; 1976—59.

[8]In addition, may produce limited quantities of byproduct sulfur from crude oil and natural gas and/or from petroleum refining.

[9]Exports; regarded as tantamount to production owing to minimal domestic consumption levels.

[10]In addition, may produce limited quantities of byproduct sulfur from metallurgical operations and/or coal processing.

[11]Data represent only the sulfur content of pyrite and pyrite sands produced, and for 1975 excludes relatively small quantities of sulfur content of pyrite sands produced by Kampia Mines Ltd. from copper-zinc-iron sulfide ore; additional substantial quantities of sulfur are contained in copper concentrates exported for processing to metal , but are not reported under Cyprus because recovery of sulfur from such ores is presumably included among byproduct metallurgical recovery in the nations processing such concentrates.

[12]In addition, may produce limited quantities of byproduct sulfur from oil refining.

[13]Less than 1/2 unit.

[14]Data appearing under this heading in previous editions of this table are not native sulfur, but rather are elemental byproduct sulfur derived from metallurgical operations and as such have been included with byproduct metallurgical output.

[15]Elemental byproduct recovered sulfur only; sulfur recovered as SO_2, H_2S and/or other compounds are included under unspecified.

[16]Comprises all byproduct sulfur recovered in the form of compounds including that, if any, recovered from petroleum and natural gas operations, as well as total recovery from metallurgical operations.

[17]Official East German sources record the production of elemental sulfur as follows in thousand long tons: 1974—88; 1975—84; 1976—78. Presumably the differences between these figures and quantities listed in the body of the table represent recovery in the form of compounds.

[18]Includes only the elemental sulfur equivalent of sulfuric acid produced as a byproduct from metallurgical furnaces; additional output may be included under undifferentiated.

[19]Figure represents pyrite concentrate production; may exclude small quantities of direct-shipping grade pyrite ores.

[20]Includes recovery from gypsum, if any.

[21]Presumably includes sulfur recovered from coals processed to coke at metallurgical facilities, and excludes sulfur, if any, recovered by metallurgical facilities in elemental form.

[22]Includes sulfur recovered in the form of acid from coal, heavy oil and other unspecified sources, as well as sulfur, if any, recovered by metallurgical facilities in elemental form.

[23]Official Polish sources report the nation's total mined elemental sulfur output annually; this figure has been divided between Frasch and other native sulfur on the basis of information obtained from supplementary sources. Therefore, although both of these number are estimates, their total is not an estimate. Estimates for production of byproduct and gypsum-derived sulfur are based on officially published data on sulfuric acid production and additional information from unofficial sources.

[24]Estimates reported under the heading "Metallurgy" represent byproduct recovery in the form of compounds (principally sulfuric acid) from all sources (including coal and fertilizer plants); estimates reported under the heading "Petroleum" represent only elemental sulfur recovery from petroleum, with any recovery in the form of compounds included under the heading "Metallurgy."

[25]Elemental sulfur only.

[1]In addition to the countries listed, Chile produces a small quantity of byproduct pyrite, but insufficient data exists for the formulation of reliable estimates of gross production.
[2]Sold or used by producers.
[3]May exclude small quantities of direct-shipping grade pyrite ore.
[4]Revised to zero.
[5]Excludes relatively small quantity of pyrite sands produced by Kampia Mines, Ltd., from copper-zinc-iron sulfide ore.
[6]Excludes production of auriferous pyrites, which is not available.

TECHNOLOGY

Polish sulfur deposits have been geologically classified as evaporite deposits, resulting from the concentration and deposition of marine salts by evaporation in shallow bays. Most geologists consider the sulfur to have been formed epigenetically, by alteration of sulfate rocks in the presence of bitumen.[8]

Laboratory tests were made on borehole samples from the Mishraq sulfur deposit to determine the effects on sulfur extraction by different hydraulic parameters and to determine a technique to estimate sulfur recovery.[9]

A number of processes are being tried to pelletize sulfur for shipment to avoid dust loss, and reduce risk of fire or explosions. One process involving water quenching to produce spherical pellets is being pilot tested in Canada. A process to form sulfur prills by air quenching has been developed in Poland.[10]

[10]Leszczynska, Halina. Sulphur Forming-the Polish Experience. Sulphur (London), No. 123, March-April 1976, pp. 44-46.

Work under a cost sharing agreement with the Bureau of Mines was initiated by St. Joe Minerals Corp. to demonstrate the citrate process SO_2 removal system at a coal burning powerplant. A study was made to evaluate the potential marketing of abatement acid and sulfur from fossil-fuel-fired powerplant sources.[11]

A method was demonstrated to recover sulfur from stack gases by scrubbing with ammonia liquor followed by conversion to elemental sulfur and ammonia for recycling.[12]

Sulfur dioxide emissions at Japanese copper smelters is recovered as readily marketable products such as sulfuric acid, gypsum, and sodium salts.[13]

Several processes for removal of sulfur oxides from waste gases were selected for review and evaluation of status.[14]

The substitution of sulfur for asphalt in road paving has been tested in several countries. Test sections constructed in roads and highways have indicated use of up to 13% sulfur in asphaltic paving provides an acceptable surface.[15]

Sulfur was added to improve compression, flexural, and tensile strength of concretes.[16]

A sulfur coating material was applied to a variety of surfaces such as concrete, earth, and wood. Tests indicate improved resistance to corrosion and damage due to winter temperatures.[17]

Talc and Pyrophyllite

by Robert A. Clifton[1]

The partial recovery from the economic recession of 1975 gave rise to a 13% increase in total domestic production of talc and pyrophyllite. Domestic production of both talc and pyrophyllite increased: world production of both was up 10%. Soapstone data is included with that of talc.

The apparent 90% increase in value of the talc minerals sold is due more to statistical technique changes than to market changes. Apparent consumption decreased 11%.

The Johns-Manville Corp. closed both its Los Angeles mill and its Warm Springs, Calif., mine. This corporation also announced the start of production at a talc mine near Timmins, Ontario, Canada.

Cyprus Industrial Minerals Co. restructured its operations into two separate divisions, talc and clay, and named an executive vice-president to head each. Tredmont, Inc., purchased the Boren and Harvey pyrophyl-

lite properties in North Carolina late in 1976.

Legislation and Government Programs.—Congress enacted Public Law 94-420 effective in September 1976, which closed Death Valley National Monument, among others, to mineral entry and location, imposed a 4-year moratorium on mineral exploration and development, and restricted surface disturbance to those areas where minerals had been extracted prior to February 29, 1976. Continued extraction was limited to the average annual rate of 1973, 1974, and 1975.

The General Services Administration reported that the national stockpile inventory of talc consisted of 1,119 short tons of steatite, block or lump, and 2,916 short tons of ground steatite. This represented a 30-ton drop in the block inventory and a static powder inventory. The block steatite was sold for $290 per ton.

The Office of Minerals Exploration, Geological Survey, offered to grant loans of up to 50% of approved exploration costs for eligible deposits of block steatite talc, but no loans for that purpose were made in 1976. The allowable depletion rates for talc, established by the Tax Reform Act of 1969 and unchanged through 1976, were 22% on production of block steatite talc of domestic origin and 14% on foreign production of the same material, which rate applied also to production of all other classes of talc from all sources.

DOMESTIC PRODUCTION

Talc.—Production from United States talc mines in 1976 was up over that of 1975 but still below that of the record high established in 1974. The value of the mine production, however, established a new record dollar high, 19% over the 1974 high.

Talc (including soapstone) was produced at 36 mines in 12 States in 1976, with California having by far the largest number of active mines at 10. Mines in four States produced 90% of the tonnage and 75% of the value of talc in 1976, and the production in eight other States accounted for the rest. The highest producing States in decreasing order are Vermont, Montana, New York, and Texas. Montana led all the States in the value of the talc produced. Every State, with the exception of Nevada, that mined talc had one or more mills to process the ore.

The seven largest domestic producers of talc in 1976, listed alphabetically, were Cyprus Industrial Minerals Co., with mines in California, Montana, and Texas; Eastern Magnesia Talc Co. in Vermont; Pfizer Inc., Minerals, Pigments & Metals Div., in California and Montana; Southern Clay Products, Inc., in Texas; R. T. Vanderbilt Co., Inc., in New York; and Windsor Minerals, Inc., in Vermont. Those firms supplied 96% of the 1976 tonnage, and the combined output of about 15 smaller producers made up the remainder.

Pyrophyllite.—Pyrophyllite is a natural hydrous aluminum silicate whose empirical chemical formula is $Al_2Si_4O_{10}(OH)_2$. Because of some properties similar to talc, some shared markets, and a degree of substitutability, it has long been associated with this mineral and some of the data concerning both is obscured by the combination of the two. The end uses of the twominerals are showing some divergence because of their differing chemistry and high temperature characteristics.

Pyrophyllite production in 1976 was above that of 1975 and established a new record high year. The lack of production at the Interpace Corp.'s mine in California left North Carolina as the only State producing pyrophyllite in 1976. Four companies operated six mines during the year.

Table 2.—Talc and pyrophyllite produced in the United States, by State

(Short tons and thousand dollars)

State	1975 Quantity	1975 Value	1976 Quantity	1976 Value
California (talc)	152,978	1,598	56,871	1,513

rRevised. W Withheld to avoid disclosing individual company confidential data.
[1]Talc and pyrophyllite produced.
[2]Includes Alabama (1975), Arkansas, Georgia (1976), Montana (1975), Nevada, New York, Oregon, Virginia, and Washington.

CONSUMPTION AND USES

The apparent domestic consumption of talc and pyrophyllite in 1976 decreased 11% from that in 1975 and was just 69% of the 1973 record high. The $34 million sales value was a new record high.

The 1976 end-use distribution showed 33% of the ground talc used in ceramics, 24% in paint, about 8% each in paper and plastics, 7% in roofing, more than 5% in cosmetics, 3% in insecticides, 2% in rubber, 1% in refractories, and the remainder in other uses.

The largest portion (50%) of pyrophyllite was used in refractories, 20% in ceramics, 16% in insecticides, and 14% in other uses.

Table 3.—End uses for ground talc and pyrophyllite, 1976

(Short tons)

Use	Talc	Pyrophyllite	Total
Ceramics	258,840	21,473	280,313
Cosmetics[1]	36,788	50	36,838
Insecticides	23,268	17,100	40,368
Paint	188,952	2,149	191,101
Paper	60,212	--	60,212
Plastics	59,767	--	59,767
Refractories	8,717	53,334	62,051
Roofing	52,471	629	53,100
Rubber	18,443	239	18,682
Other uses[2]	86,298	12,326	98,624
Total	793,756	107,300	901,056

[1]Incomplete data. Some cosmetic talc known to be included in "Other."
[2]Includes art sculpture, asphalt filler, crayons, floor tile, foundry facings, rice polishing, stucco, and other uses not specified.

PRICES

Engineering and Mining Journal, December 1976, quoted prices for domestic talc, ground, in carload lots, f.o.b. mine or mill, containers included, per short ton, as follows:

Vermont:	
98% through 325 mesh, bulk	$38.00-$47.00
99.99% through 325 mesh, bags:	
Dry processed	75.00- 84.00
Water beneficiated	122.00-140.00
New York:	
96% through 200 mesh	36.00- 38.00
98 to 99.25% through 325 mesh	48.00
100% through 325 mesh, fluid energy ground	75.00-105.00
California:	
Standard	69.50
Fractionated	37.00- 71.00
Micronized	62.00-104.00
Cosmetic steatite	44.00- 65.00
Georgia:	
98% through 200 mesh	20.00
99% through 325 mesh	35.00
100% through 325 mesh, fluid energy ground	85.00

American Paint and Coatings Journal, January 3, 1977, listed the following prices per ton for paint-grade talcs in carload lots:

California:	
325 mesh, bags, mill:	
Fibrous, white, high oil absorption	$34.00-$37.00
Semifibrous, medium oil absorption	32.00- 73.95
Montana: Ultrafine grind, f.o.b. mill	70.00
New York:	
Nonfibrous, bags, mill:	
98% through 325 mesh	46.50- 50.50
99.4% through 325 mesh	55.50
Trace retained on 325 mesh	105.00
Fine micron talcs (origin not specified)	68.00-111.50

The approximate equivalents, in dollars per short ton, of the price ranges quoted in Industrial Minerals (London), December 1976, for steatite talc, c.i.f., main European port, were as follows:

Norwegian:	
Ground (ex store)	$45.00-$47.00
Micronized (ex store)	72.00-106.00
French, fine ground	61.00-136.00
Italian, cosmetic grade	136.00-167.00
Chinese	106.00-122.00

FOREIGN TRADE

Exports.—The quantity of talc exported from the United States during 1976 exceeded that of 1975 by 34% and that of the previous record high year (1974) by 16%. The value of the exports exceeded that of 1975 by 43% and that of the previous record high year (1974) by 35%.

Mexico was the destination of 55% of the exports at an average value of $18.21 per ton. Canada's 19% of the exports averaged $64.78 per ton; Belgium's 10%, $52.12 per ton; Japan's 6%, $54.70 per ton; and Venezuela's 3%, $128.92 per ton. The remaining 7% went to 51 countries. The average value of all exports was $42.54 per ton.

Imports.—The quantity of talc imported for consumption continued to decline from the 1974 high. The 1976 imports were 87% of those in 1975 and 67% of those in 1974. The value of the 1976 imports, however, rose 27% over that of 1975.

Table 4.—U.S. exports of talc, crude and ground

(Thousand short tons and thousand dollars)

Year	Quantity	Value
1974	183	6,711
1975	158	6,338
1976	212	9,034

WORLD REVIEW

Australia.—Roughly half of Australia's talc production comes from the open pit mine of Three Springs Talc, Pty. Ltd., near the town of Three Springs about 211 miles north of Perth. Drilling and blasting give a product that has a ratio of waste and substandard talc to the first grade talc of about 4.5:1. The company has a 220-short-ton-per-day treatment plant.

Canada.—Canadian Johns-Manville Corp. brought onstream Canada's fourth talc mining operation in July. The mine is located in Penhorwood Township, 45 miles southwest of Timmins in Northern Ontario. It will have an estimated capacity of 20,000 to 30,000 tons per year and the ore will be flotation concentrated at mine-site. Drying and milling will occur at a facility in Timmins.

China, People's Republic of.—China's exports of talc nearly tripled in the 10-year period 1965-74 from 91,000 to 259,000 short tons. The value of these exports more than quadrupled in those years from $2.4 to $11.1 million.

Finland.—A talc-magnesite deposit at Polvijarvi, 15 miles from Outokumpu in Eastern Finland, will be exploited in a joint venture by Oy Lohja A. B. and Outokumpu Oy. The ore, 60% talc, 40% magnesite, and 0.18% nickel, will be processed by flotation for separation of the talc and nickel constituents. The talc plant, scheduled for August 1977 startup, will be near the town of Joensuu. Initial capacity is planned to be 150,000 tons per year of micronized talc of 90% brightness for the Scandinavian paper industry.

India.—The Indian Bureau of Mines reported that of the 15 million tons of talc reserves in the country, 55% are in Maharashtra and 42% in Rajasthan. The paper

[e]Estimate. [p]Preliminary. [r]Revised.
[1]In addition to the countries listed, Southern Rhodesia is believed to produce talc, but available information is inadequate to make reliable estimates of output levels.
[2]Includes talc and wonderstone (pyrophyllite).
[3]Data are for calendar year beginning March 20 of that stated.
[4]Includes talc and pyrophyllite; in addition, pyrophyllite clay is produced as follows in short tons: 1974—466,030; 1975—483,857; 1976—Not available.
[5]Data based on Nepalese fiscal year, beginning mid-July of year stated.

industry uses 53% of the domestic consumption; insecticides and pesticides, 30%; cosmetics, 5%; and ceramics, 3%.

Japan.—The Japanese refractories industry consumed 380,000 short tons of pyrophyllite (including some diaspore) in 1965 and had increases practically every year until it reached 771,000 short tons in 1973, the peak year. The next 2 years saw a decline in consumption with just 558,000 short tons used in 1975.

Japanese imports of talc were 329,603 short tons in 1974 and 260,359 short tons in 1975. The People's Republic of China was by far the biggest supplier with 53% of the 2-year total.

Spain.—Spanish apparent consumption of talc grew dramatically in 1974. Domestic production, a nominal 40,000 tons per year, rose to 61,000 tons that year and imports doubled from 5,000 to 10,000 tons. Talc is produced near Bonar in Leon Province, around Figueras in Gerona Province, and near Fuengirola in Malaga Province.

Turkey.—Reported mineral reserves found in Eskisehir Province of Turkey include 400,000 tons of talc.

• TECHNOLOGY

The existence at Pambula in Southeastern Australia of a pyrophyllite deposit with an inferred 30 million short tons of ore belonging to Pyrophyllite Corp. Ltd., has prompted the Australian Commonwealth Scientific and Industrial Research Organization (CSIRO) to initiate market development research. The CSIRO reported that experimental pyrophyllite bricks lining steel production ladles have doubled the pour life for such bricks. Pyrophyllite and zircon bricks tripled the pour life. CSIRO scientists say that the addition of pyrophyllite to road surfacing materials not only toughens the surface and extends the useful life of the materials, but imparts a soft glow to the surface, making night driving safer.

Alfred University's Research Foundation was the recipient of a grant from Windsor Minerals, Inc. The research covered by the grant is aimed at reclamation and utilization of talc mining waste residues.

The Cosmetic, Toiletry and Fragrance Association announced an industry-wide review of cosmetic product ingredients. The multi-year project will gather health effects data for presentation to the Food and Drug Administration.

An international trade magazine[2] reported that talc filler is upgrading the properties of engineering plastics in several areas. Talc-filled polypropylene in new "esthetic" grades that overcome the former limitations of whitening and dull appearance are now available. They retain the desirable properties of higher stiffness and better resistance to warping and sink marks that characterized the older talc-filled polypropylene.

Cyprus Mines Corp. patented its process for separating molybdenum and talc. In this process the talc is depressed and higher concentrations of molybdenum recovered. A high energy using oxidizing roast of the ore was eliminated using the new process.

The Joseph Dixon Crucible Co. is now producing processed soapstone for use by welders. The pressed talc soapstone, formed in either flat, round or square crayons, is uniform without the hard spots or flaws of the natural product and is less brittle.

Thorium

By Martha L. Kahn[1]

Thorium was an unused coproduct of mine production during 1976, and demand for thorium was not the decisive factor in determining its supply. Monazite, the principal source of thorium, continued to be a byproduct of titanium and tin mining and was recovered for its rare-earth content. Byproduct monazite was recovered in Florida by Humphreys Mining Co. and Titanium Enterprises. Thorium-containing residues remaining after extraction of rare earths from monazite were stored for future use. Practically all thorium compounds used by the domestic industry during 1976 came from previous company stocks or imports.

Several occurrences of thorium of potential economic significance were described in 1976. These included new occurrences in Alaska and South Dakota, as well as deposits in Colorado and Tennessee that were under study by mining companies to determine economic feasibility.

No major developments occurred in the nonenergy uses of thorium, which included mantles for incandescent lamps, hardeners in magnesium alloys, refractories, and electronic and chemical applications.

The future prospects for thorium's use in nuclear fuels remained uncertain in 1976. The only commercial thorium-fueled, high-temperature, gas-cooled reactor (HTGR), located at Fort St. Vrain, Colo., with a capacity of 330 megawatts (MW), began commercial operation in December 1976 and was expected to reach full power in late 1977.

DOMESTIC PRODUCTION

Exploration.—Significant concentrations of thorium, associated with uranium and rare-earth elements, were discovered on Seward Peninsula in western Alaska.[2] Samples of the mineralized rock, which occurs along alkaline dikes in a 100-square-mile area, contained as much as 1.05% thorite. Uranium- and thorium-bearing parts of the Precambrian Estes Conglomerate were found in Lawrence County, S. Dak.[3] Samples from deeply weathered surface exposures contained as much as 800 parts per million thorium. Thorium occurrences in the Upper Peninsula of Michigan and northern Wisconsin were described.[4]

A report on thorium resources of the United States in 1974 was made available to the public in 1976.[5] The report indicated that thorium reserves are in beach placers, and most identified resources are in veins, carbonatites, and stream placers.

Buttes Gas and Oil Co. continued feasibility and pilot-plant studies of its southwestern Colorado titanium prospect.[6] The ore mineral perovskite reportedly contains significant amounts of thorium that could be recovered. Kerr-McGee Chemical Corp. reported 74,000 short tons of indicated recoverable monazite contained in its heavy-mineral sands deposit in Benton County, Tenn.

Mine Production.—Monazite, a thorium-containing rare-earth phosphate mineral,

was produced as a byproduct of processing beach sands for titanium minerals in 1976. Two mines in Florida, Humphreys Mining Co., near Hilliard, and Titanium Enterprises, near Green Cove Springs, were the only domestic producers of monazite. Humphreys Mining Co. continued to truck wet titanium concentrates from its mine in Florida to the company's dry plant at Folkston, Ga. U.S. mine production of thorium in 1976 was less than the 1975 production.

Refinery Production.—In 1976 there was only one domestic firm, W. R. Grace & Co., Davison Chemical Division, at Chattanooga, Tenn., with facilities for processing large tonnages of monazite. Although Grace did not produce any thorium compounds from monazite for sale, thorium was extracted from monazite during the refining of rare-earth elements and stored. Practically all thorium compounds used by the domestic industry during 1976 came from previous company stocks or imports.

Table 1.—Companies with thorium processing and fabricating capacity

Company	Plant location	Operations and products
Atomergic Chemetals Corp	Plainview, N.Y.	Processes oxide, fluoride, and metal.
Consolidated Aluminum Corp	Madison, Ill	Magnesium-thorium alloy.
Controlled Castings Corp	Plainview, N.Y	Do.

Ventron Corp.,Alfa Div	Danvers, Mass	Metallic thorium.
Westinghouse Electric Corp	Bloomfield, N.J	Processes compounds; produces metallic thorium.
Do	Columbia, S.C	Nuclear fuels.

CONSUMPTION AND USES

Based on domestic mine production, releases from the Government stockpile, and foreign trade, the estimated apparent domestic consumption of thorium contained in monazite and thorium compounds for 1976 was 236 short tons of ThO_2 equivalent. However, monazite was processed mainly for its rare-earth content, and the thorium residues were stockpiled. The actual industrial demand for thorium was about 45 tons of ThO_2 equivalent, based mainly on shipments from processors. This was below the 1975 consumption level of 50 tons. The decline in consumption during 1976 was mainly due to low demand in energy applications.

Nonenergy uses consumed about 35 tons of ThO_2. The principal application was as a constituent in mantles for Welsbach incandescent lamps (estimated to be around 18 tons). Other nonenergy uses were as follows: As a hardener in magnesium-thorium alloys (4 tons); in refractories (4 tons); in electronic and chemical applications, plus other applications and research (9 tons).

The 330-megawatt HTGR at Fort St. Vrain, Colo., began producing electricity on December 11, 1976, and was up to 21% of electrical capacity by the end of 1976. The core of the reactor contains about 22 tons of thorium. A reload section containing about 3 tons of thorium was scheduled to be added annually.

Development of a thorium-fueled, light-water breeder reactor (LWBR) continued at Shippingport, Pa. Initial loading of about 46 tons of thorium was expected to take place in 1977, with power production scheduled for 1978.

STOCKS

On December 31, 1976, the General Services Administration (GSA) stockpile inventory totaled 7,265,004 pounds of thorium nitrate (1,680 short tons ThO_2 equivalent). On October 1, 1976, the thorium nitrate stockpile goal was set at 1,800,000 pounds (418 short tons ThO_2 equivalent).

The Energy Research and Development Administration (ERDA) inventory as of December 31, 1976, was 1,068 short tons of thorium. About 149 tons of this material was being utilized in research and development.

Industrial stocks of thorium at the end of 1976 were less than at the end of 1975. Estimated industrial stocks at yearend in terms of ThO_2 equivalent were as follows: Monazite, 98 tons; and in compounds and metal, 355 tons.

PRICES

Prices for domestic monazite containing approximately 4% ThO_2 rose about 25% in 1976. The average declared value of imported monazite (all from Malaysia) decreased slightly to $205 per short ton from $207 in 1975. The average price per short ton of Australian monazite quoted in Metal Bulletin (London) remained constant during 1976 at A$170 to A$185. However, the price of Australian monazite in U.S. dollars fell about 17% in December 1976 owing to the devaluation of Australian currency.

Prices for thorium compounds varied depending upon purity and quantity. Thorium nitrate, mantle grade, was quoted at $3 per pound; thorium oxide, ceramic grade, $5.80 to $10 per pound; thorium metal in pellets, $15 per pound; and metal powder, $65 per pound.

FOREIGN TRADE

During 1976, no thorium concentrates or ores were exported. Other thorium export data were combined with those for uranium. Although these two elements were not statistically differentiated, it was believed that the amount of thorium exported was minor.

Monazite containing about 6% thorium was imported from Malaysia for its rare-earth content. In 1976, imports of gas mantles and thorium compounds decreased.

Table 2.—U.S. foreign trade in thorium and thorium-bearing materials

(Quantity in pounds unless otherwise specified)

[1]Includes uranium; thorium and uranium are undifferentiated in official statistics.
[2]Based on the manufacture of 1,000 gas mantles per pound ThO_2.

WORLD REVIEW

The predominate source of the world's thorium is monazite, a byproduct of titanium and tin mining. Australia, India, Malaysia, Brazil, and the United States continued to be the leading monazite producers among market-economy countries. The small world demand for thorium, however, is not reflected by the quantity of this production, since monazite is processed mainly for its rare-earth element content.

Table 3.—Monazite concentrate: World production, by country

(Short tons)

Country[1]	1974	1975	1976[p]
Australia	[r]3,943	4,968	5,016

[e]Estimate. [p]Preliminary. [r]Revised. W Withheld to avoid disclosing individual company confidential data.
[1]In addition to the countries listed, Indonesia and North Korea may produce monazite, but information is inadequate to make reliable estimates of output levels.
[2]Exports.

Australia.—According to the Rutile & Zircon Development Association, Ltd., 1976 monazite production by member companies, by state was as follows: New South Wales, 1,089 short tons; Queensland, 227 short tons, and Western Australia, 3,698 short tons.

Metals Exploration Ltd. and Alliance Oil Development Australia NL announced the discovery of mineral sands containing about 800,000 short tons of heavy minerals at Cataby, 93 miles north of Perth.[7] The heavy minerals contain about 1.5% monazite. Westralian Sands Ltd., a producer of byproduct monazite, resumed full scale mining operations at Yoganup.[8] The mine and treatment plant had been on a care and maintanence basis due to low demand for ilmenite.

Canada.—Research continued on a thorium cycle for the Canadian-deuterium-uranium (CANDU) reactor. Studies indicated that thorium could probably be burned in combination with enriched uranium or plutonium in the CANDU with minor if any changes. However, since the CANDU presently uses only unenriched uranium, an advanced fuel technology must be developed before the thorium cycle could be implemented.

Germany, West.—Construction of the 300 megawatt pebble-bed thorium high-temperature reactor (THTR) at the Hamm-Uentrop station of Vereinigte Elektrizitaetswerke Westfalen AG continued. Completion of the THTR developed by Hochtemperatur-Reaktorbau GmbH was rescheduled for mid-1978.[9]

General Atomic Co. (San Diego) has joined four German and four Swiss firms in developing a gas turbine HTGR.[10] The gas turbine powerplant would not require cooling water since waste heat would be released to the air.

India.—An estimated 500,000 tons of monazite sands found in a 16 mile belt in the coastal areas of Ganjam and Puri districts in Orissa State was reported by the Minister for Mining and Geology.[11]

TECHNOLOGY

A patent was issued for the extraction of columbium, rare-earths, and thorium from pyrochlore.[12] Thorium has never been commercially produced from pyrochlore, which is a major source of columbium.

A thorium-containing personnel neutron dosimeter, to be worn as a monitoring device for recording radiation exposure, was developed.[13] When a fast neutron hits the thorium target, the fission fragments given off are recorded on a detector foil that can be periodically removed for analysis. This new dosimeter was reportedly insensitive to gamma rays and X-rays and relatively insensitive to light, temperature, and humidity compared with some conventional dosimeters. The Nuclear Regulatory Commission was expected to grant a licensing exemption for personnel dosimeters containing not more than 50 milligrams of thorium.

A 2-year occupational health study to determine possible effects of thorium on the human body was begun by the Argonne National Laboratory of ERDA.[14] The study was to involve over one hundred former employees of the now-closed Lindsay Light and Chemical Co., a former thorium processor.

Research continued on the thorium fuel cycle in several different reactors, including the HTGR, LWBR, CANDU, light-water reactor, liquid-metal fast-breeder reactor, and gas-cooled fast-breeder reactor (GCFR). Large-scale development of any of these reactors could substantially increase the consumption of thorium.

General Atomic Co. (GA) developed unit processes and equipment for reprocessing HTGR fuel and designed and developed an integrated line to demonstrate the head end of HTGR reprocessing using unirradiated fuel materials. Trade-off studies were also made concerning the required design of facilities for large-scale recycling of HTGR fuels, in order to guide the development activities for recycling HTGR fuel.[15] ERDA and GA also studied the gas turbine HTGR and the HTGR steam cycle. The gas turbine HTGR was of particular interest since it would require no cooling water, could be used in arid regions, and would still reach thermal efficiencies of over 40% under these conditions.

Research on the use of thorium-fuel in a GCFR nuclear power system were still underway by ERDA. The GCFR utilizes the coolant and nonnuclear component technology of the conventional HTGR. GA expected the GCFR, under steady-state conditions, would produce enough fuel for four thermal reactors.

ERDA was expected to load the Shippingport LWBR with thorium-containing fuel in 1977. Successful operation of the Shippingport LWBR might permit conversion of operating or presently planned pressurized-water reactors to thorium-containing LWBR cores.

A comprehensive study of the thorium fuel cycle in power reactors was conducted[16] by ERDA during 1976; results were published in early 1977. Initial findings indicated that the use of the thorium-fuel cycle in thermal reactors would result in better uranium utilization, and in some cases, better economic performance, as well as add flexibility to the nuclear industry in case of delays in development of fast-breeder reactors. A mixed uranium/thorium fuel cycle would have the added advantage of permitting a "denaturing" of recycled fissile fuels, since U_{233} can be diluted with U_{238}.

Tin

By Keith L. Harris[1]

As the world economy recovered from the 1975 recession, tin demand increased, resulting in higher prices and higher world tin mine production. At the end of June, 15 months after initiation, export controls were removed from member producing nations by the International Tin Council (ITC). The ITC price range was revised upwards a record three times during the year, providing 19% and 20% rises in the floor and ceiling prices, respectively. Over 19,000 metric tons[2] of the ITC buffer stock was sold during the year in an effort to defend the ceiling price.

U.S. consumption of primary and secondary tin increased 13% in 1976 to 62,928 tons. The major uses for tin were in tinplate, 33%; solder, 28%; bronze and brass, 12%; chemicals, 9%; and babbitt, 4%. Most of the Nation's tin, in the form of slabs, bars, and ingots, was imported from Malaysia, Bolivia, and Thailand. Less than 100 tons of tin came from mines in Colorado and New Mexico. About 18% of the tin consumed in the United States in 1976 was reclaimed from scrap.

The only primary tin smelter-refinery operating in the United States in 1976 was the Texas City, Tex., facility of Gulf Chemical & Metallurgical Co. (GCMC). The major feed to the smelter was tin concentrate from Bolivia's state-owned Corporación Minera de Bolivia (COMIBOL).

The average price of Straits (Malaysian) tin for New York delivery in 1976 was 379.82 cents per pound, 40 cents above the 1975 level. The Bureau of Mines changed to a composite price[3] in 1976, so the two annual averages are not directly comparable.

On September 15 the U. S. Senate ratified the treaty authorizing U.S. membership in the Fifth International Tin Agreement (ITA). The United States signed the Agree-

ment on October 28, marking the first time the United States had joined a metal commodity agreement.

Legislation and Government Programs.— The General Services Administration (GSA) continued commercial sales of tin during the year. Sales totaled 3,643 tons, while shipments totaled 2,638 tons. The stockpile goal was lowered during the year from 41,150 tons to 33,021 tons. At yearend, there was an excess of 173,529 tons, of which 2,704 tons was authorized for sale by Congress. Several bills were introduced in Congress to authorize additional tin disposal from the Government stockpile, but none was enacted.

The depletion allowance for tin remained 22% for domestic deposits and 14% for foreign deposits.

Maine and Michigan passed legislation during the year that imposed deposits on disposable containers sold in those States. Oregon and Vermont were the only other States that had similar legislation. The legislation could decrease the use of disposable tinplate cans for beverages.

DOMESTIC PRODUCTION

PRIMARY TIN

Mine Production.— Domestic production of tin in 1976 was less than 100 tons. Most of the year's output came from Colorado as a byproduct of molybdenum mining. Some tin concentrate was produced at a placer operation in New Mexico.

Smelter Production.— The only domestic tin smelter, GCMC, received 5,733 tons of tin-in-concentrate from Bolivia, which formed the base feed together with domestic tin concentrate and secondary tin-bearing materials. Tin production was estimated at 5,700 tons.

SECONDARY TIN

The United States is the world's largest producer of recycled, or secondary, tin. Secondary tin furnishes about a quarter of the total U.S. supply each year. In 1976, secondary tin production increased 4% from the 1975 level to 16,446 tons. Of the tin recycled in 1976, 91% was as an alloy constituent of reclaimed bronzes, brasses, solders, and bearing and type metals, or as an element in chemical compounds. Only 9% of the recycled tin, mostly from new tinplate scrap, was reclaimed as metal.

[1]Brass-mill stocks include home scrap, and purchased-scrap consumption is assumed equal to receipts; therefore, lines and total in brass-mill section do not balance.

[2]Omits "machine-shop scrap."

CONSUMPTION

Tin consumption recovered 13% from the abnormally low level in 1975 to 62,928 tons, but was still at its lowest level since 1938, excluding 1975. Primary consumption increased 19%, while secondary consumption decreased 8%. Consumption was up in most sectors, but declines were reported for babbitt, terne metal, type metal, and miscellaneous alloys. The largest increases were recorded in the consumption of tin in solder, up 2,653 tons; tinplate, up 1,897 tons; and chemicals, up 1,623 tons. U.S. brass mills consumed 751 tons of primary tin and 233 tons of secondary tin, compared with 1975 levels of 481 tons and 244 tons, respectively.

[1]Includes secondary pig tin and tin acquired in chemicals.
[2]Includes pewter, britannia metal, and jewelers' metal.

STOCKS

Plant stocks of pig tin declined 7% to 6,856 tons, or about a month-and-a-half supply. As the price of tin increased during the year, companies cut back inventories and purchased tin when the market price temporarily dropped. Plant stocks were highest in July at 7,435 tons. Tinplate mills held 60% of the plant pig tin stocks at yearend.

PRICES

The price of tin during the year was influenced by ITC-imposed export controls, buffer stock purchases and sales, speculation, currency hedge buying, and a slowly increasing world demand. Definite rises in the price occurred in anticipation of price level increases at the May, October, and December ITC meetings; after the ITC revealed that the buffer stock contained only 2,820 tons on June 30; during the suspension of buffer stock operations from June 30 to July 7 as the Fifth ITA entered provisionally into force; and on December 28 when the Bolivian Government announced it would not ratify the Fifth ITA.

The average annual price increased substantially from the depressed prices of 1975 as the world economy recovered from the recession. The average U.S. price of Straits tin for New York delivery was 379.82 cents per pound, compared with 339.82 cents per pound in 1975. The average Penang price for ex-works Straits tin was M$1,146.56 per picul[4] (338.94 cents per pound) compared with M$963.79 per picul (303.55 cents per pound) in 1975. The average price for cash tin, standard grade, on the London Metal Exchange (LME) was £4,242.40 per metric ton (347.42 cents per pound). All averages, except the U.S. average, were the highest ever recorded.

The Penang market started the year at M$957 per picul (283 cents per pound). Buffer stock purchases and export controls were necessary to support the price until late January when dealers, covering their short positions, initiated an upward trend that peaked at the high for the year of M$1,320 per picul (390 cents per pound) on July 8. Consumer and speculative demand was evident during the rise, necessitating the sale, through July, of over 17,000 tons of tin from the buffer stock in an unsuccessful defense of the ceiling price. After July, the price declined and remained in the upper sector of the ITC price range for several months. In November, prices began moving upward, possibly in anticipation of a higher ITC price range, which came into effect on December 9. The price then stabilized around M$1,250 per picul (370 cents per pound) until word of Bolivia's decision not to ratify the Fifth ITA moved the price at yearend up to M$1,318 per picul (390 cents per pound).

Beginning in 1976, Metals Week, the source of the Bureau of Mines U.S. tin price, discontinued quoting a daily New York spot price and initiated a composite price. The composite price represents a replacement cost to the consumer and not a spot price as had been previously quoted with the daily New York Metals Week price. The Metals Week annual New York spot price for tin was 30.5 cents less than the composite price in 1976.

Table 10.—Monthly prices of Straits tin for delivery in New York

(Cents per pound)

Month	1975			1976		
	High	Low	Average	High	Low	Average

FOREIGN TRADE

Exports of tin declined 35% from the 1975 level to 2,338 tons, a more normal level than that existing since 1973 when GSA commenced tin sales. Reexports continued to be larger than exports, as has been the case since 1975.

Imports of tin-in-concentrate, all from Bolivia, declined 11% as Bolivian labor problems caused a drop in shipments during the first quarter of the year.

Tin metal imports have always been the predominant portion of U.S. supply and 1976 was no exception. Of the 45,055 tons of tin metal imported, Malaysia supplied 60%; Thailand, 15%; Indonesia, 11%; and Bolivia, 4%. Imports of tin from the People's Republic of China dropped substantially from the

[4]One picul = 133.33 pounds. One ringget (M$) = US$0.39414 in 1976, US$0.4200 in 1975.

[2]Less than 1/2 unit.

1975 level of 6,378 tons to 1,727 tons in 1976. A downward trend in imports from the People's Republic of China was expected as the internal demand of a new tinplate line lowered the tin available for export.

Small tonnages of secondary tin enter the United States as alloy constituents in recyclable solders or other alloys, or as tinplate or other scrap, dross, skimmings, and residues. These imports are included in secondary production figures and account in part for the differences encountered between U.S. production and consumption of secondary tin. Imports and exports of tin in alloy such as babbitt, solder, type metal, and bronze are shown in the Minerals Yearbook chapters on copper and lead. Ferrous scrap exports, including those of tinplate and terneplate scrap, are not classified separately.

WORLD REVIEW

INTERNATIONAL TIN AGREEMENT

During the year the ITC used all resources available to it in an effort to obtain market stabilization. Export controls had been imposed on member producing nations on April 18, 1975, and remained in effect until mid-1976. The buffer stock held 20,071 tons on December 31, 1975, and purchases continued through January 1976.

By the March quarterly meeting, the tin price had moved into the upper sector of the price range in response to increased demand and general optimism evident in all nonferrous metal markets. Because of increased mining costs, producers initiated and received an increase in the floor price of M$50 as of March 12. Export controls were not removed. By April 22, pressure on the ceiling price caused the ITC to schedule a special May session.

Meanwhile, Bolivia decided not to ratify the Fifth ITA by the April 30 deadline, claiming the ITC price range for tin was not high enough to cover Bolivian mining costs. A delegation headed by the ITC chairman went to Bolivia and persuaded the Government to announce its intent to ratify the agreement by April 30.

At the special May session, the price range was raised for the second time in the year, and the export quota for the second quarter was increased from 35,000 to 40,000 tons.

Export controls were removed June 30 during the June ITC meeting. The ITC revealed that the buffer stock held only 2,820 tons on June 30 and suspended its operations until a buffer stock was reestablished under the Fifth ITA. Consequently the price of tin penetrated the ceiling to reach its high for the year.

Since Bolivia had not ratified the Fifth ITA by the deadline date, it went provisionally into force July 1. The United States became a member for the first time. The buffer stock manager was released from his obligation to sell tin at the ceiling price and was authorized to operate at his discretion when the tin price was above the ceiling.

In October, the price issue was raised again by the producers, but the council deferred a decision until cost data were provided by the producers. The data were submitted, and a price rise was granted on December 9, although the United States voted against it. A comparison of the ranges at the beginning and end of the year follows:

	Jan. 1, 1976		Dec. 31, 1976	
	M$ per picul	U.S. equivalent cents per pound	M$ per picul	U.S. equivalent cents per pound
Floor price	900	266	1,075	318
Lower sector	900-980	266-290	1,075-1,150	318-340
Middle sector	980-1,040	290-307	1,150-1,250	340-370
Upper sector	1,040-1,100	307-325	1,250-1,325	370-392
Ceiling price	1,100	325	1,325	392

Bolivia did not ratify the Fifth ITA during the year. The agreement could be provisional for only 1 year before it must be renegotiated. Definitive entry into force of the Fifth ITA required the signature of at least six producing nations that held over 950 of the 1,000 producer votes in the Fourth ITA. Bolivia held 179 votes.

Australia.— Tin production, up for the first time since 1972, totaled 10,364 tons for the year. Increased output by Australia's two largest producers, Renison Ltd., up 750 tons over that of 1975 to 4,533 tons, and Abminco N.L., up 321 tons to 1,691 tons, ended the downward trend.

Renison, a subsidiary of Consolidated Gold Fields Australia Ltd., mined 505,703 tons of ore and treated 494,339 tons of ore containing 1.24% tin during the year ending June 30. Recovery of metal dropped to 65.3% from 68.8% in the previous year because of the higher proportion of refractory ore in the concentrator feed. Proven and probable reserves increased 839,000 tons to 9.9 million tons, but the average grade decreased from 1.34% to 1.24%. Additional diamond drilling was planned in the Mount Lindsay, Tasmania, joint venture area. Results from the first five holes were encouraging. Renison joined with other companies to explore the Doradilla tin prospects, southwest of Bourke, New South Wales, and the Mount Moss tin prospect, northwest of Townsville, Queensland. A feasibility study by Mitsubishi Metals Corp. was commissioned by Renison for a 7,000-ton-per-year tin smelter to be located in Tasmania. The study will be concluded in 1977.

During the year the Aberfoyle Group reorganized, with Aberfoyle Tin Ltd. transferring all operating interests to Abminco (formerly Cleveland Tin N.L.) in exchange for shares in that company. As a result, Abminco N.L. became owner of the Ardlethan tin mine at Ardlethan, New South Wales, the Aberfoyle mines in northeastern Tasmania, and the Cleveland tin-copper mine at Luina, Tasmania, while Aberfoyle Ltd. became a holding company with a 61.06% interest in Abminco N.L.

The Cleveland mine returned to a 7-day workweek at the end of June when ITC export controls were removed. The mine treated 363,036 tons of ore with a 0.73% head grade of tin and a recovery of 56.95%. Reserves were down 175,000 tons to 1.7 million tons, and the average grade dropped to 0.79% from 0.82% in the previous year. Ardlethan mine production declined 130 tons to 1,180 tons during the year ending November 23, 1976. Ore reserves were down 10% to 1.8 million tons, but the grade increased to 0.59%. The company operated at a loss during the year.

Bolivia.— Tin mine production increased 4% over the 1975 level to 29,812 tons. Production by COMIBOL, at 20,540 tons, was down slightly, but medium and small mine production increased 15% and 32%, respectively, to 6,665 tons and 2,607 tons. Tin exports totaled 30,355 tons, 15% above 1975 exports. The tin exports, valued at $227.9 million, accounted for 37% of the value of total Bolivian exports and 60% of the value of mineral exports.

Bolivia announced a major capital investment program for the minerals sector. Investments totaling $621 million over the next 5 years were planned in mining and metal processing. By 1980, domestic tin-smelting capacity was expected to be 32,500 tons, and tin mine output to be 35,000 tons.

COMIBOL experienced a miners' strike in June, and settlement required a 30% wage increase to all employees. Also included was a $136 million social amenities and housing program. Although COMIBOL's reported costs to produce and market tin increased 25% to $3.80 per pound during 1976, profits reached $3 million on sales of $255.3 million compared with losses of $10.7 million on sales of $211.3 million in 1975.

The Catavi mine, the world's largest underground tin mine, produced 5,418 tons of tin. Golder Associates, Inc. completed a geological and prefeasibility study for conversion of the Catavi mine to an open pit operation. The preliminary study delineated 80 million tons of ore grading 0.3% tin, sufficient for 25 years of operation with a mill recovering 4,500 tons of tin per year in a 52% concentrate.

The Huanuni mine, COMIBOL's most profitable mine, produced 4,486 tons of tin during the year. Huanuni, located 50 kilometers southeast of Oruro, is next to the Playa Verde alluvial tin deposit, which will be jointly exploited by COMIBOL and London Tin (Malaysia) Bhd. in a $10 million dredging project.

The Caracoles mill was modernized to treat 8,500 tons of ore per month with a mill head of 1.8% tin. Production totaled 1,745 tons of tin-in-concentrate in 1976. Additional investment in mine extensions and mechanization was scheduled to increase production 40% over the next 2 years.

The Empresa Nacional de Fundiciones (ENAF) smelter produced 9,185 tons of tin metal during the year and exported 9,211 tons. Increased production at the Vinto smelter was the result of an increase in capacity from 7,500 tons per year to 11,500 tons per year beginning in January. Additional expansion to 20,000 tons per year was expected by April 1977. Work was started on a smelter to be located next to the Vinto high-grade smelter to treat 10,000 to 12,500 tons per year of low-grade tin ore.

China, People's Republic of.— Tin reserves in the People's Republic of China (PRC) were estimated to be 2.2 million tons.[5] Tin deposits occur in six of the PRC's Provinces, but the PRC has published quantities for only the Haifeng and Chaoan districts in Kwangtung. Each district was estimated to have reserves of more than 200,000 tons of tin metal. Exports of tin, at 6,458 tons, declined 50% from the 1975 level. The PRC has exported an average of 7,500 tons per year over the past 10 years. The new 100,000-ton electrolytic tinplate line at Wuhan, to be commissioned in 1977, will divert some of the exports to internal consumption.

Germany, East.— East Germany will expand its tin production by nearly 45% by 1980 through the use of the Soviet-developed Kivcet process. The electrothermic process may improve recoveries to as much as 70% of the tin content of the high-sulfide ores mined in the Erzgebirge region.

Indonesia.— Indonesia established new regulations for negotiating mining contracts, replacing those rescinded in 1972. No contracts had been signed in more than 4 years. The regulations provided for duty-free imports of equipment and materials, a corporate income tax of 35% for the first 10 years and 45% for the following 20 years, an additional 5% annual deduction for capital investment expenditures for the first 4 years of production, a 10% export tax, decreasing in relation to the amount of ore processed in Indonesia, and supervision by Bank Negara Indonesia of foreign exchange earnings from mining exports.

Perusahaan Negara Tambang Timah (P.N. Timah), Indonesia's State-owned tin mining enterprise, was restructured into a limited company called Perusahaan Terbatas Tambang Timah (P.T. Timah) to allow it greater autonomy of operation.

P.T. Timah awarded the design contract for a new seagoing bucket dredge, the *Bangka II*, to F.W. Payne & Son Ltd. The dredge, to be equipped with 0.62-cubic-meter buckets with a maximum dredging depth of 50 meters and annual throughput of 5.3 million cubic meters, was scheduled to be in operation by 1979. The dredge will produce about 1,500 tons of tin-in-concentrate per year.

Timah's Peltim smelter at Mentok, Bangka, began smelting all of Indonesia's tin mine production in April. Capacity expansion from 18,000 to 33,000 tons, completed in 1975, precluded the necessity of exporting concentrates to Malaysia for smelting.

P.T. Koba Tin, a joint venture owned 25% by the Indonesian Government and 75% by three Australian firms, operated three gravel pump mines in the southeast Bangka district. About 1,000 tons of tin-in-concentrate was produced in 1976. Two small 0.08-cubic-meter bucket dredges under construction in Malaysia were expected to begin operation in 1977. Reserves of 36,000 tons of tin have been blocked out at the property.

Billiton Exploratie Maatschappij Indonesia, B.V. (BEMI) ordered a $25 million, 0.85-cubic-meter bucket dredge to exploit its concession in the Pulau Tudjuh area. The dredge, designed by Mining & Transport Engineering B.V. and built by Jurong Shipyard Ltd., will begin operations late in 1978 and recover about 1,700 tons of tin per year.

P. T. Broken Hill Pty. Indonesia (BHP) completed the final stage of development at the Kelapa Kampit lode mine on Bilitung Island. Dewatering was completed, the underground workings were partially rehabilitated, and exploration for additional reserves continued. A feasibility study was to be completed for presentation to the Indonesian Government in 1977.

Malaysia.— Tin production was at its lowest level since 1964. A total of 63,401 tons was mined, 1% below the 1975 level. The State licensing policy and high taxation reportedly were the main factors in the continuing decline in Malaysia's tin output. At yearend there were 51 tin dredges, 724

---

[5]Ikonnikov, A.B. Mineral Resources of China. Geol. Soc. of America, Boulder, Colo., 1976, 500 pp.

gravel pump mines, and 36 opencast, underground, and other miscellaneous mines in operation, reflecting an 11% decrease in total active mines from yearend 1975 levels. Gravel pump operations accounted for 50% of the concentrate produced; dredging, 36%; opencast mining, 4%; underground mining, 3%; and miscellaneous sources, 7%. The tin-mining labor force declined 7% to 36,828 workers at yearend.

Metal production, at 78,017 tons, was 6% below the 1975 level. Exports of metal increased to 82,164 tons over the 77,635 tons in 1975. Imports of tin-in-concentrate totaled 8,156 tons, down 56% from those of 1975 because of decreased imports from Burma and Indonesia.

Industry officials expressed concern over problems that curtailed prospecting activity and created a poor investment climate. Heavy taxation was a substantial deterrent. The tin industry, the most heavily taxed industry in Malaysia, paid export duties, export surcharges, and taxes on tin profits, development, and income. In some cases, these taxes were over 70% of gross mining profits. Delays in processing applications for mining leases and the possible rejection of lease renewal applications have been major contributors to declining production over the past 4 years. Streamlining the application process and reduced taxation have been recommended. Also, the new economic policy of 30% Malaysian participation in the national economy was reported to have had a negative effect on tin productivity.

A $6 million aerial and geochemical survey was to be conducted over 30,000 square kilometers in Kelantan and Pahang to locate new sources of tin and other minerals. The program, to be financed by the Canadian Government, will take about 3 years to complete.

Perbadanan Nasional Bhd.'s (Pernas) subsidiary, Pernas Securities (the Malaysian Government investment branch), through an expenditure of $68 million, became the major owner of the London Tin Corporation (LTC), the world's largest tin investment group and the largest holder of Malaysian tin mines. Pernas Securities established New Tradewinds (NTW) as a holding company to buy LTC. NTW exchanged shares with Charter Consolidated Ltd. for Charter's Malaysian interests. As a result, Pernas held 71.35% of NTW, and Charter held 28.65%. NTW has interests in 18 mining companies, mostly in Malaysia, but also in Thailand and Nigeria, that produced 27,322 tons of 70% to 75% tin concentrate in 1976, or about 8.5% of the world tin mine production. The LTC purchase was a major step in furthering the Malaysian Government's new economic policy of 70% domestic private ownership in the tin industry by 1990.

Ayer Hitam Tin Dredging Ltd. displaced Berjuntai Tin Dredging Bhd. as Malaysia's largest tin-producing company. Ayer Hitam's No. 2 dredge worked very rich deep ground for several months, thereby more than doubling production to 5,923 tons of tin concentrate in 1976. This was the highest tin production by any private tin-mining company in the world since nationalization of the large Bolivian tin-mining companies in 1952.

Berjuntai's production increased 8% to 4,215 tons of tin concentrate. The company's new No. 8 dredge began production in September. Both the No. 8 and the No. 7 dredges were working areas that have reserves for 18 years of production. Nos. 2 and 3 dredging areas have reserves for 12 years; No. 4, about 16 years; No. 5, 3.5 years; and No. 6, 23 years.

Malaysian Tin Dredging Ltd. produced 2,895 tons of tin concentrate in 1976, 4% above that of 1975. The Perak State Government approved the diversion of the Kinta River, which will result in a 140-hectare addition to the mining area. The additional reserves will increase the life of four of the company's five dredges to more than 10 years. Reserves for the other dredges were sufficient for 8 years of operation.

Southern Malaysian Tin Dredging Ltd., with production of 2,403 tons of tin concentrate during the year, completed the diversion of the Chenderiang River to limit flooding and to fulfill a condition of the mining lease for the Degong Road property. The ITC tin export control period required cutbacks of 84 dredging days at the Tanjong Tualong property and 43 days at the Degong Road property.

Austral Amalgamated Tin Bhd.'s production declined 16% from the 1975 level to 1,290 tons of tin concentrate owing to the closing of one of its three dredges after exhaustion of reserves. Kuala Kampar Tin Fields Bhd. was also forced to close one of its dredges when operations became uneconomic.

Although Pacific Tin Consolidated Corp., the only U.S. company mining tin in Malaysia, decreased tin production slightly in 1976, income before taxes increased 68% because of increased tin prices.

The Selangor State Development Corp.'s (SSDC) mining subsidiary, Syarikat Timah Langat, began trial operations of its first dredge. The 0.7-cubic-meter, $5 million dredge operated at a concession of 800 hectares at Dengkil in the Kuala Langat forest reserve.

Charter and its subsidiary company, Tronoh Mines Ltd., stopped exploration at its Kuala Langat concession joint venture with the SSDC after SSDC notified Charter it did not have funds to reimburse Charter for its share of the development costs. Political uncertainty and equity apportioning of the 55% SSDC-36% Charter-9% Tronoh joint venture were contributing factors in the cessation of operations.

Conzinc Riotinto Malaysian Sdn. Bhd. recovered 1,079 tons of tin at its single-dredge operation on a 550 hectare Kuala Langat concession. It joined with the Pahang Tenggara Developent Authority in a 30%-70% joint venture to explore for tin and other metals in Pahang Tenggara.

Nigeria.— Tin production continued to decline for the eigth consecutive year to 3,710 tons in 1976, the lowest level since the Bureau of Mines began publishing world production data in 1921. Increased costs for fuel, power, and labor continued to plague the Nigerian tin industry.

Forty percent of Amalgamated Tin Mines of Nigeria (Holdings) Ltd. (ATMN), Nigeria's largest tin-mining company, was sold to the state-owned Nigerian Mining Corporation (NMC). The acquisition was aimed at giving Nigeria a voice in the exploitation and expansion of mining operations. Although ATMN reported an increase in production of 156 tons from the previous fiscal year, the proceeds in terms of Nigerian currency were considerably lower. Work began in mid-November on ATMN's Sabon Gida tinfield. Due to the depth of the deposit and the time needed to move the overburden, tin production was not expected until mid-1977.

Gold & Base Metal Mines of Nigeria Ltd., continued development at its Liruie prospect in Kano State at a reduced level while an agreement was reached on the formation of a new company, Ririwai Mines Ltd. NMC was the major shareholder, with Gold & Base retaining 20%. A mine is to be established with a treatment plant capable of processing 900 tons of ore per day. Production was expected to start in 1979.

South Africa, Republic of.— The country's three tin producers continued to mine tin at about the same rate as in 1975. Rooiberg Minerals Development Co. Ltd. operated four mines at the Rooiberg tin field 56 kilometers west of Warmbaths that produced 3,710 tons of tin concentrate. The decreasing grade of ore mined at the Hartebeestfontein mine ("A" mine) was offset by an increase in grade of ore treated at the Leeuwpoort mine ("C" mine). Surface drilling at the "A" mine delineated a new medium grade area that may be amenable to open pit mining.

Union Tin Mines Ltd. produced 1,619 tons of concentrate during the year, up 2% over the 1975 level. Underground reserves were estimated to provide another year of production, depending upon the tin price, but reworking of the tailings dam may extend the mine's life into 1978.

Zaaiplaats Tin Mining Co. Ltd., South Africa's smallest tin producer, was installing a small ball mill to increase milling capacity. Production was down slightly to 303 tons of tin concentrate in 1976.

Thailand.— Illegal mining by suction boat operations became less of a problem in 1976 after the Government allowed the boats to operate in the near-shore portion of the concessions of the nationalized Thailand Exploration and Mining Co., Ltd. (Temco). The independent miners were required to register their operations and sell their output to the Government. Thailand's official production increased 4,000 tons over the 1975 level to 20,453 tons, with the suction boat operations producing 4,683 tons.

After numerous false starts and frequent changes in political leadership, the Thai Government and Billiton reached a production-sharing agreement over the nationalized Temco concessions. The 5-year agreement, with provisions for an extension, allows a 69% Billiton - 31% Thai Government split of profits on production under 1,300 tons per year, a 50%/50% split of profits on production over 1,500 tons per year, and a 40%/60% split of profits on production over 1,700 tons per year.

Aokam Tin Bhd., Southern Kinta Consolidated Ltd., and Tongkah Harbour Tin Dredging Bhd., all owned by LTC, were closed by illegal strikes late in January. Operations at Aokam and Tongkah Harbour resumed in April after a new agreement was negotiated with the labor union. Southern Kinta did not resume operations during the year owing to lease difficulties. Aokam, the largest tin producer, mined 2,441 tons of tin concentrate in 1975 but only 1,490 tons in 1976. Combined production of Southern Kinta and Tongkah Harbour was only 448 tons of concentrate in 1976, compared with 1,337 tons in 1975.

United Kingdom.— Although mine production declined 7 tons from the 1975 level to 3,323 tons in 1976, the outlook for the United Kingdom's tin mining industry improved as a result of higher tin prices. Domestic tin production accounted for 25% of the country's primary demand. The Cornish Chamber of Mines felt production could increase if the Government initiated mineral rights legislation enabling mining companies to prospect or mine in Cornwall.

At St. Piram Ltd.'s South Crofty mine, the country's largest tin mine, a $1.4 million investment program neared completion. An underground haulage system was installed, and a second underground crusher was installed at the 658-meter level. The Dolcoath North lode was opened up on four levels, adding to ore reserves. Continued development work was expected to bring production up to 2,800 tons in 2 years. The Simms shaft at St. Piram's Pendarves mine was deepened, and cross-cutting to the Tryphena lode started. Development continued to improve mine ventilation. Production at both of St. Piram's Cornwall mines totaled 1,541 tons of tin-in-concentrate.

Wheal Jane Ltd.'s production continued to decline, with output of tin-in-concentrate down 11% from that of 1975. Low tin prices in 1975 limited cash flow, thereby interrupt-

ing Wheal Jane's development program and resulting in the lower output. The company obtained a loan of $6.8 million, 60% of which was provided interest-free by the Government, to finance a 3-year development for driving additional access tunnels and improving the efficiency of the concentrator.

Geevor Tin Mines Ltd. obtained a $900,000 low-interest loan to continue its 5-year expansion plan. Geevor mined 110,354 tons of ore during the year, recovering 948 tons of 65% tin concentrate.

Production began in February at the Mount Wellington mine of Cornwall Tin & Mining Ltd., but the mine operated only at about 30% of capacity during the year owing to water seepage and labor problems. Ore reserves were over 1 million tons with a tin content of 1.35%. The capacity of the mill was 200,000 tons of ore per year, yielding 1,600 tons of tin per year.

Zaire.— The final phase of company mergers in the Kivu Province took place in February. Cobelmine-Zaire and Syndicat Minière de l'Etain (Symetain) combined to form Société Minière et Industrielle du Kivu (Sominki). The Zairian Government held a 20% interest in the company. Sominki produced 3,315 tons of tin in concentrate in 1976.

[7]Includes small production of tin from smelter in Singapore.

TECHNOLOGY

The Institution of Mining and Metallurgy sponsored a meeting in London on tin technology and economics.[6] Papers were presented on surface and underground production, tin ore treatment, smelting, refining, marketing, and uses of tin, impact of substitution, and tin supply and demand.

A process was developed for recovering underground sulfidic or oxidic ores of tin in metallic form.[7] Electric induction heating by alternating current was used to melt and break the ore, yielding metal which was pneumatically pumped to the surface.

A sled for recovering sedimentary tin from the ocean floor was developed.[8] The sled incorporated a bucket elevator mechanism that was loaded from a concentrate collector on the sled and emptied onto a surface vessel.

Continued research on froth flotation beneficiation of tin yielded several patentable processes.[9] One process, requiring relatively low-cost reagents, uses a coarser feed than usual and has increased yield. Flotation can take place between pH 2.0 and 8.0 in the presence of alcohols and/or oils as frothers and sodium hexafluorosilicate or sodium silicate as a suppressant. Another method uses a cyanide reducing agent to lower the valence state of the tin-containing particles, improving their floatability in the presence of an olefin alcohol or propargyl carbinol collector agent.

Australia's Commonwealth Scientific & Industrial Research Organization (CSIRO) developed a highly efficient method of processing low grade (20% to 30%) tin concentrates.[10] The submerged combustion process uses a double tubed lance to inject reductants and air below the surface of the molten concentrate. CSIRO claimed the process is at least 20 times faster and more energy efficient than conventional melting techniques.

The International Tin Research Council sponsored the First International Conference on Tinplate.[11] Papers on marketing, production, canmaking, can performance, lacquering, quality control, and metals reclamation were presented.

Bethlehem Steel Corp. developed an organic-coated blackplate.[12] It was stated that although the process was not competitive with 0.25-pound-per-base-box tinplate when coated at a toll coater's facility, it was competitive when coated at the end users inhouse facility. A single-side organic-coated blackplate would offer a savings over the 0.25-pound-per-base-box tinplate whether coated inhouse or by a toll coater.

A new miticide based on bis (trineophyltin) oxide for controlling a wide range of plant-feeding mites became commercially available.[13] Research on lead-calcium-tin alloys for use in maintenance-free batteries was summarized, and commercial applications of such alloys were discussed.[14] Lead-copper-tin batteries offer prolonged shelf life, and reduced battery failure due to positive grid oxidation. They require no water additions in normal circumstances.

Titanium

By Langtry E. Lynd[1]

U.S. production of titanium sponge metal in 1976 was 41% less than in 1975. Consumption of sponge metal was 13,315 tons, down 24% from that of 1975. Ingot production and consumption were each about 21,000 tons in 1976 or about 15% less than in 1975. Sponge inventories dropped from 5,669 tons to 3,617 tons, and scrap metal consumption increased from 8,316 tons in 1975 to 9,211 tons in 1976. Titanium dioxide pigment production was about 713,000 tons, 18% higher than in 1975. Pigment imports increased to about 70,000 tons from about 16,000 tons in 1975, probably due to larger imports by NL Industries, Inc., from its European subsidiaries to offset limited production at Sayreville, N.J.

Domestic ilmenite production declined during 1976 for the third consecutive year to 652,404 tons, down 9% from 1975 production. However, imports of ilmenite, natural rutile, and synthetic rutile increased 38%, 18%, and 48%, respectively. Titanium slag imports were 19% below the 1975 level.

The main price changes during 1976 were a decrease in the price of rutile to $A230 to $A240 per metric ton ($244 to $254 per short ton) f.o.b. Australian ports; an increase in the price of QIT slag to $90 per long ton f.o.b. Sorel, Quebec; a 3-cent-per-pound increase in the price of titanium dioxide pigments to 46.5 cents per pound for rutile and 41 cents per pound for anatase; and a decrease in the price of imported sponge from about $2.70 to $2.45-$2.50 per pound.

Legislation and Government Programs.—In June, the Federal Preparedness Agency, General Services Administration, reinstated a stockpile objective for titanium sponge metal at 32,329 short tons. In October, the Agency recommended a new stockpile goal of 131,503 tons, based on 3-year

rRevised.
[1]Excludes U.S. production data in order to avoid disclosing individual company confidential data.

war criteria for establishing stockpile objectives. The quantity of specification titanium sponge metal in the Government stockpile in December 1976 was 27,853 tons. In addition, there was 4,476 tons of nonspecification material.

In October, the Government stockpile goal for rutile ore was set at 173,928 tons and total rutile stockpile inventory in December 1976 was 39,186 tons.

In December 1976, the Antitrust Division, U.S. Department of Justice, began an investigation of price fixing in the titanium metal industry, following voluntary disclosure by NL Industries, Inc., that certain employees of its affiliate, Titanium Metals Corporation of America (TMCA), had discussed titanium pricing with competitors during the period 1971 to early 1976.

Plans for the proposed B-1 strategic bomber raised expectations that titanium metal demand would increase significantly, because each of the planned 241 aircraft would require about 175,000 pounds of titanium. The whole B-1 program would probably require over 20,000 tons of ingot and would consume about 5% to 10% of annual U.S. mill product production for several years.

DOMESTIC PRODUCTION

Concentrates.—Production and shipments of ilmenite concentrate decreased 9% and 12%, respectively, in 1976, the third consecutive yearly decline for both categories. Titanium dioxide contained in concentrates shipped was 7% less than in 1975, although the average TiO_2 content increased from 57.6% in 1975 to 60.7% in 1976. A 98% increase in production at the Titanium Enterprises mine, Green Cove Springs, Fla., and increases of 9% and 45% from the mines of ASARCO Incorporated and SCM Corp., Glidden-Durkee Div., both near Lakehurst, N.J., were insufficient to offset decreases at the mines of NL Industries, Inc., Tahawus, N.Y., and Humphreys Mining Co., Boulogne, Fla. Production at the E. I. du Pont de Nemours & Co., Inc., mines, Starke and Highland, Fla., increased about 3%. The large decrease in production at Tahawus resulted mainly from reduced demand because of the prolonged strike at the Sayreville, N.J. pigment plant.

Kerr-McGee Chemical Corp. completed construction of its synthetic rutile plant at Mobile, Ala., which has a reported production capacity of 110,000 tons per year. This plant was to provide feed material for a proposed new pigment plant to be built at Mobile with a capacity of 50,000 tons per year of titanium dioxide pigment and for a similar 10-year old pigment plant in Hamilton, Miss. The synthetic rutile plant was to initially consume ilmenite from Australia and employ the Benilite Cyclic Process, which involves partial reduction of ilmenite, leaching of the reduced ore with 18% to 20% hydrochloric acid to remove iron, and recovery of the acid from the spent liquor.

The U.S. Geological Survey announced discovery of a sand deposit of glacial origin, containing 31 million tons of ilmenite and a smaller quantity of rutile. However, the ilmenite occurs mainly in mixed grains, intergrown with silicate minerals and probably could not be recovered profitably under present economic conditions.[2]

A perovskite deposit in southwestern Colorado owned by Buttes Gas & Oil Co. was estimated to contain about 50 million tons

[2]New York Times. Titaniferous Ores Found on Adirondack Fringe. V. 125, No. 43,197, May 1, 1976, p. 40.
U.S. Geological Survey. Titanium Minerals Found in Upstate New York Sand Deposits. U.S. Geol. Survey News Release, Apr. 27, 1976, 2 pp.

Table 2.—Production and mine shipments of ilmenite concentrates[1] from domestic ores in the United States

Year	Production (short tons, gross weight)	Shipments		
		Short tons (gross weight)	TiO_2 content (short tons)	Value (thousands)
1972	677,944	739,801	417,553	16,739
1973	776,013	804,355	458,541	20,128
1974	744,571	755,338	434,605	22,715
1975	717,281	702,252	404,269	26,946
1976	652,404	617,896	374,989	27,578

[1]Includes a mixed product containing rutile, leucoxene, and altered ilmenite.

of TiO_2.[3] The deposit was also reported to contain a significant quantity of columbium, thorium, rare-earth elements, and apatite. Processes to convert the perovskite to titanium dioxide were being investigated and economic feasibility studies were being carried out.

Ferrotitanium.—Ferrotitanium was produced by Shieldalloy Corp. at Newfield, N.J., and by Reactive Metals and Alloys Corp. West Pittsburgh, Pa. As in the years prior to 1976, most of the production contained 40% titanium or higher.

Metal.—Production of titanium sponge metal in 1976 was 41% lower than in 1975. Ingot production was down about 15% from the 1975 levels.

Sponge producing companies were TMCA, Henderson, Nev., jointly owned by NL Industries, Inc., and Allegheny-Ludlum Steel Corp.; RMI Co., Ashtabula, Ohio, owned by National Distillers & Chemical Corp. and United States Steel Corp.; and Oregon Metallurgical Corp., Albany, Oreg., owned by Armco Steel Corp. and Ladish Corp., which resumed production late in 1976. The following 11 companies produced titanium ingot:

Company	Plant location
American Welding & Manufacturing Co	Warren, Ohio
Crucible, Inc., Colt Industries	Midland, Pa.
Howmet Corp.,[1] Alloy Division	Whitehall, Mich.
Lawrence Aviation Industries, Inc	Port Jefferson, N.Y.
Martin Marietta Aluminum, Inc	Torrance, Calif.
Oregon Metallurgical Corp	Albany, Oreg.
RMI Co	Niles, Ohio
Teledyne Allvac	Monroe, N.C.
Titanium Metals Corp. of America	Henderson, Nev.
Titanium West, Inc	Reno, Nev.
TiTech International, Inc	Pomona, Calif.

[1]Now a subsidiary of Pechiney Ugine Kuhlmann Corp.

Titanium West ceased production during 1976. American Welding and Lawrence Aviation began ingot production in 1976 and 1975, respectively.

Pigment.—Pigment production was 18% higher than in 1975. Shipments were up 24% and the value of shipments increased 40%. Rutile pigment accounted for 75% of total production and was produced by 6 manufacturers. Five companies produced anatase pigment. Companies producing titanium dioxide pigment during the year with plant location and nominal capacity in tons per year were as follows:

Company and plant location	Pigment capacity (tons per year)	
	Sulfate process	Chloride process
American Cyanamid Co., Savannah, Ga	50,000	50,000
E. I. du Pont de Nemours & Co., Inc.:		
Antioch, Calif	--	30,000
Edge Moor, Del	--	160,000
New Johnsonville, Tenn	--	235,000
Kerr-McGee Chemical Co., Hamilton, Miss	--	50,000
NL Industries, Inc.:		
St. Louis, Mo	100,000	--
Sayreville, N.J	125,000	--
New Jersey Zinc Co.:		
Gloucester City, N.J	42,000	--
Ashtabula, Ohio	--	30,000
SCM Corp., Glidden-Durkee Div.:		
Baltimore, Md	55,000	30,000
Ashtabula, Ohio	--	30,000
Total	372,000	615,000

Capital allocations of $40 million were made by Du Pont for preliminary work on a new chloride process pigment plant to be built at De Lisle, Miss. The plant was reported to have a planned capacity of 150,000 tons per year and was expected to be completed in 1979 at a cost of about $150

million. Du Pont's production of upgraded ferric chloride as a byproduct of pigment production at its Edge Moor, Del., plant was expected to reach close to its 150,000-ton-per-year ferric chloride capacity by the end of 1976. The company was reported to be upgrading and selling about 20% of its waste ferric chloride in solution form early in 1976 and planned to be selling around 80% of it by 1979. Ferric chloride is used in water purification.

NL Industries was planning to build a 100,000-ton-per-year pigment plant using its own chloride process which can utilize lower grade feed materials such as beneficiated ilmenite as well as rutile. A site in the Southeastern United States near the company's raw material sources was being considered. Start of construction was planned for 1979, following anticipated completion of a 40,000-ton-per-year chloride process plant at Leverkusen, West Germany, where NL also operates a sulfate process plant.

The strike at the NL Industries Sayreville, N.J., plant, which began in early February, was settled in December, but production was not resumed until mid-1977. The plant was operated by management and technical personnel at somewhat less than 50% of capacity until September 1976.

Kerr-McKee Chemical Co. planned to build a chloride process plant of 50,000 tons annual capacity at Mobile, Ala. The plant was to be supplied with feed material from the company's rutile plant that was completed at Mobile in 1976.

American Cyanamid Co. appealed a decision by a special hearing officer of the State of Georgia that the company could be fined up to $300,000 for continued pollution of the Savannah River by effluent from its Savannah, Ga., pigment plant. A State antipollution deadline had been set for December 31, 1972. The company claimed it was impossible to build a new waste treatment plant by the deadline. American Cyanamid did open a new waste treatment plant in August 1975, but had operational problems with the process that converts pigment plant waste into gypsum and a nonpolluting liquid effluent. In September 1977, the Georgia Supreme Court upheld a lower court decision overturning the fine that had been levied against the company.

CONSUMPTION AND USES

Concentrates.—Consumption of ilmenite, rutile, and titanium slag increased 10%, 3%, and 38%, respectively, from 1975 levels.

Metal.—Consumption of titanium sponge and ingot decreased 24% and 14%, respectively; scrap metal consumption increased 11%. Net shipments of mill products decreased 7% from the 1975 level, but the amount of castings shipped increased 7% to 257 tons. The quantity of pipe and tubing shipped, including other extrusions, increased 16% to about 2,800 tons. The most significant declines were in rod and bar shipments, off 22% at about 1,300 tons, and flat rolled products, down 15% to about 3,700 tons. Forging and extrusion billet shipments amounted to about 6,500 tons, down 7% from the 1975 level.

Aerospace applications, both military and commercial, continued to dominate the market for titanium metal with production of the McDonnell Douglas F-15 accounting for a substantial portion of mill product shipments. The use of titanium in chemical processing and other industrial applications continued to grow, but did not increase sufficiently to offset the decline in requirements of titanium for aerospace applications.

A major industrial use of titanium in 1976 was for powerplant surface condenser tubing, although growth in this area was slowed somewhat by cancellation or delay of construction of several nuclear power generating plants. Other industrial applications expected to continue to grow steadily include the use of titanium cathodes as starter sheets in the electrolytic refining of copper and use in other situations requiring high corrosion resistance; for example, pulp and paper industries, petrochemical and chemical industries, for storage tanks, reaction vessels, valves, pumps, and piping.

Pigment.—Preliminary figures showed a 24% increase in pigment shipments in 1976, recovering most of the decrease that occurred in 1975. Shortages, which might have developed because of low inventories, increased demand, and the strike at the NL Industries plant at Sayreville, N.J., were

[4]Includes ceramics, chemicals, glass fibers, and titanium metal.

averted by increased imports from NL's European and Canadian subsidiaries and by increased production rates in the rest of the industry. Excluding NL, the industry's operating rate was estimated at close to 85%.

Ferrotitanium.—The amount of ferrotitanium and titanium metal scrap used in steelmaking increased 38% from 2,759 tons in 1975 to 3,802 tons in 1976. The use of these materials in stainless and heat-resisting steels increased 80% to 2,008 tons. Most of this increase was caused by larger amounts of titanium being used in steels for automobile mufflers built to accommodate catalytic convertors.

Ferrotitanium is the main form in which titanium is added to steel or other alloys; however, scrap titanium is used to make some of the ferrotitanium and for direct additions to the alloy melt. The following table shows the amount of ferrotitanium plus titanium scrap used for steel and other alloys in 1973 through 1976. Ferrotitanium is used in 30%, 40%, or 70% titanium grades; information on the amount of each grade used is not available.

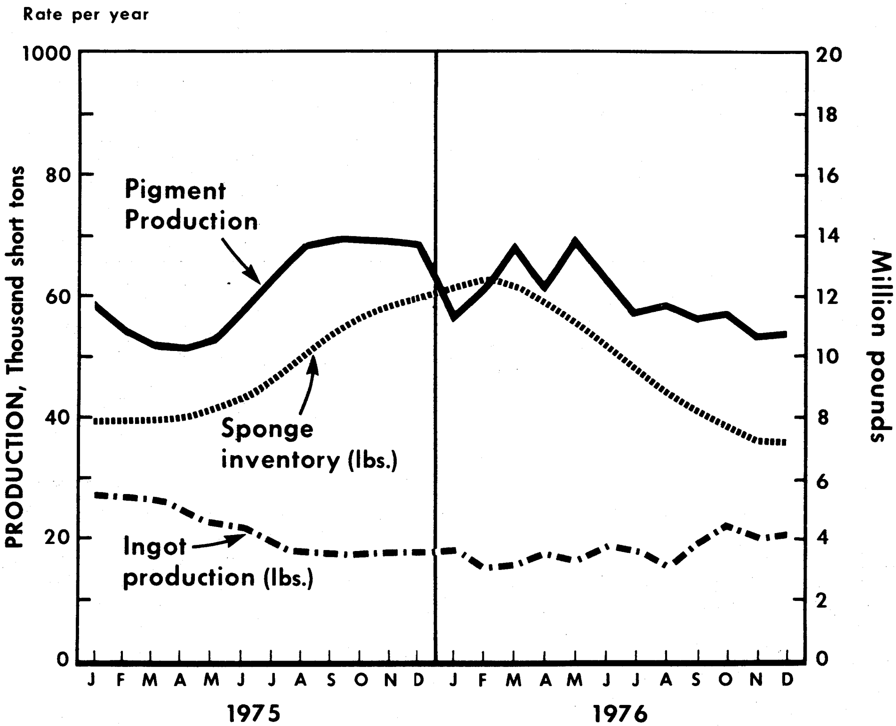

Figure 1.—Salient trends of titanium products, 1975-76.

STOCKS

During 1976, inventories of ilmenite, titanium slag, and rutile increased 11%, 13%, and 9%, respectively. Stocks of titanium sponge increased in the first quarter of 1976, then decreased for the rest of the year, and at yearend were 36% below the December 1975 level. Scrap inventories decreased 6% during 1976. Industry stocks of various grades of titanium pigment were 71,556 tons at the end of 1976, down 17% from the corresponding 1975 figure.

PRICES

Concentrates.—Price quotations for ilmenite (imported, 54% TiO_2) in domestic markets remained at $55 per long ton throughout the year. Australian ilmenite prices remained at $A15 to $A18 per metric ton f.o.b. Australian ports. Indian concentrates (58% to 60% TiO_2) were steady at $23 per long ton f.o.b. Indian ports.

Rutile spot prices bulk, f.o.b. cars at Atlantic, Gulf, and Great Lakes ports were quoted at $710 per ton in January and at $510 in February and for the remainder of the year. Long-term contracts presumably were concluded at somewhat lower figures. Published prices f.o.b. Australian ports began the year at $A240 to $A250 per metric ton, decreasing to $A230 to $A235 in the third quarter. Declared valuations of shipments entering U.S. ports were in the range of $138 to $551 per short ton in January and $128 to $276 per short ton in December 1976. Declared valuations of synthetic rutile shipments entering U.S. ports averaged $150 per short ton for the year, and c.i.f. value averaged $190 per short ton.

Titanium slag f.o.b. Sorel, Quebec, increased to $90 per long ton on January 1, 1976, and remained at that level throughout the year.

Metal.—Domestic titanium sponge was quoted at $2.70 to $2.75 per pound throughout the year. Published prices for Japanese sponge were $2.65 to $2.70 per pound early in the year, but dropped in June to $2.45 to $2.50 per pound and remained there for the rest of the year. Quotations for mill products throughout the year were as follows: Bar, $7.48; billet, $4.86; plate, $6.50; and sheet and strip, $11.90 per pound.

Pigment.—The price of titanium dioxide pigment in carload lots increased during the first half of 1976 to 46.5 cents per pound for rutile and 41 cents per pound for anatase, and remained at these levels for the rest of the year.

FOREIGN TRADE

Titanium dioxide exports in 1976 amounted to 20,580 tons, 30% above the 1975 total. Of the 1976 total, Canada received 18%, Venezuela 16%, Brazil 12%, other Latin American and West Indian countries 15%, Western Europe 12%, Republic of Korea 11%, Japan 7%, other Far Eastern nations 6%, and other countries 3%.

Exports of unwrought, waste, and scrap titanium were 42% higher than in 1975; 51% went to the United Kingdom, 23% to Belgium, 11% to Italy, and 4% to Spain. The average valuation was 70 cents per pound, 18 cents per pound less than in 1975. Exports of intermediate mill shapes and mill products were 44% lower than in the previous year.

Imports of ilmenite from Australia in 1976 were 71% greater than in 1975. Imports of Sorelslag were 19% less than in 1975. Imports of natural rutile were 18% higher and imports of synthetic rutile were 48% higher than in 1975.

Imports of unwrought, waste, and scrap titanium were 28% less than those of 1975. Of the 1976 total, 1,778 tons was sponge, which came from Japan (1,360 tons), the U.S.S.R. (256 tons), and the United Kingdom (162 tons). The sponge shipments from Japan, the U.S.S.R., and the United Kingdom had an average declared valuation of $2.01, $1.78, and $1.91 per pound, respectively.

Imports of pigment totaled 68,497 tons during the year and constituted 9.6% of domestic consumption.

WORLD REVIEW

Australia.—Australia continued to dominate world markets in mineral sands, particularly ilmenite, rutile, and zircon. In 1976, ilmenite production was 1,104,300 short tons including an estimated 18,740 short tons of leucoxene, about the same as in 1975. Rutile production was 435,791 tons, 15% higher than in 1975. Exports of ilmenite were 1,063,373 tons, up 77% from those of 1975, and rutile exports were 382,346 tons, 9% higher than in 1975. Ilmenite exports went mainly to the United States,

[e]Estimate. [p]Preliminary. [r]Revised. W Withheld to avoid disclosing individual company confidential data.
[1]In addition to the countries listed, the Republic of South Africa may also produce titanium concentrates, but available information is inadequate to make reliable estimates of output levels.
[2]Ilmenite is also produced in Canada and reported separately in Canadian sources but is not included here because it is almost entirely used in slag production (see titaniferous slag).
[3]Includes leucoxene as follows in short tons: 1974—16,924; 1975—18,629; 1976—[e]18,740.
[4]Exports.
[5]Includes a mixed product containing ilmenite, leucoxene, and rutile.
[6]Does not contain U.S. production in order to avoid disclosing individual company confidential data.
[7]Contains 70% to 72% TiO_2.

the United Kingdom, Japan, France, and Brazil, with rutile going mostly to the United States, the United Kingdom, the Netherlands, Japan, and West Germany.

Beach sand minerals supply was reportedly exceeding demand as producers were completing expansion plans started during high price periods in 1973-74. Also contributing to the outlook for a continued oversupply situation was the imminent addition of new capacity elsewhere, as at Richards Bay, Republic of South Africa, and in Sierra Leone. Factors tending to decrease supply were the shrinking reserves on the east coast of Australia and some reduction of rutile production there for environmental reasons.

Early in 1976 the Australian Government sharply reduced the minimum permissible export price for mineral sand concentrates. Late in the year, the Australian Government issued an order withdrawing all export licenses for mineral concentrates extracted from Fraser Island, Queensland, sands effective December 31, 1976. Prime Minister Malcolm Fraser said that this decision was taken to protect the environment of Fraser Island, the largest sand island in the world, following recommendations from a special environmental commission. Fraser Island was described by the commission as being of international environmental significance, with beach sand mining producing permanent and irreversible environmental harm.

Two companies were affected by the Fraser Island action: Queensland Titanium Mines Pty., Ltd. (owned by NL Industries subsidiaries) and D. M. Minerals, Ltd. (a partnership between Dillingham Construction Pty., Ltd., and Murphyores Inc. Pty., Ltd.) Their operations on Fraser Island were said to represent about 14% of Australia's installed productive capacity for rutile. Reserves on the island were placed at 874,000 tons of rutile, 917,000 tons of zircon, and smaller quantities of ilmenite and monazite. The Environmental Minister of Australia stated that compensation for the mining companies involved would be considered.

Mineral Deposits, Ltd., was considering development of a sand deposit at Agnes Water, 80 miles south of Gladstone, Queensland. Cost to bring the project into production was estimated at $A14 million, with annual production of 132,000 tons of ilmenite and 22,000 tons of rutile, over a 10-year period.

Western Titanium Ltd.'s mineral sands mining and concentrating complex near Eneabba, Western Australia, was completed, and shipments of concentrates were to start in October. The cost of the plant, port installation, and housing was estimated at $A18.5 million. A merger was announced between Western Titanium and Associated Minerals Consolidated, Ltd., both members of the Consolidated Gold Fields Australia Ltd. group. With Western Titanium's Eneabba operations expected to be in full production during 1977, the combined companies were expected to have an annual production capacity of 440,000 to 550,000 tons of ilmenite, 143,000 of tons rutile, 50,000 tons of beneficiated ilmenite, and 187,000 tons of zircon.

Westralian Sands was expanding its operations at Yoganup, Western Australia, to increase ilmenite capacity to 550,000 metric tons per year. Instead of rutile and leucoxene, production was to include 55,000 tons per year of "HYTI 93" (minimum 93% TiO_2) and "HYTI 68" (minimum 68% TiO_2). The full increase in ilmenite production was to await construction of a proposed plant that would produce 110,000 tons per year of synthetic rutile from ilmenite.

Western Mining Corp. purchased the Jurien Bay project, near the end of 1975, not far from the Eneabba area, from Black Sands Pty. Ltd. for about $A13 million; in early 1976 it was building toward full production planned at 33,000 tons per year of rutile and 33,000 tons per year of zircon. The company's reserves at Jurien were stated as 3.5 million tons of heavy minerals, with comparable additional reserves at nearby partially explored Cooljarloo.

Alliance Oil Development Australia NL and Metals Exploration Ltd. announced the discovery of mineral sands deposits at Cataby, 93 miles north of Perth. Drilling so far has indicated the presence of about 770,000 tons of heavy minerals in 10 million tons of sand. The heavy minerals consist of about 70% ilmenite, 7% rutile, 12% zircon, and 1.5% monazite.

Brazil.—The New Jersey Zinc Co. made an agreement with Mineração Vale do Paranaiba, South America, (VALEP) and Cia. Vale do Rio Doce (CVRD) to develop a process for producing upgraded ilmenite and titanium dioxide from complex ores containing anatase. Estimates of reserves have ranged from 132 million tons of ore averaging 21.6% TiO_2 up to 1,600 million tons of ore containing 10% TiO_2, near Tapira and Salitre, Minas Gerais. The ore occurs in carbonatite rocks containing the primary titanium minerals perovskite, ilmenite, magnetite, and rarely rutile, associated with apatite and pyrochlore. The bulk of the titanium reserves are anatase and leucoxene, weathering products of the primary minerals. Plans were being made to recover phosphate, columbium, rare-earth elements, and titanium. Production was scheduled to start in May 1978.

Nearly 94 million tons of titanium ore reportedly have been discovered near Campo Alegre de Lourdes, 500 miles northwest of Salvador, Bahia. The deposits were reported to contain 20.6 million tons of TiO_2 in the form of ilmenite.

Titanium Fabrication Corp. (Ti-Fab) of Fairfield, N.J., was reported to be setting up a fabrication and service organization to make titanium metal products in Brazil to satisfy what the company referred to as a substantial market in that country. A long range goal was to establish a primary titanium metal extraction facility in Brazil, utilizing Brazilian ore sources and employing electrolytic processing rather than the Kroll process for reduction to metal.

Canada.—Demand for Quebec Iron and Titanium Corp. (QIT) Sorelslag was above production capacity in 1976 when QIT produced 907,193 tons of Sorelslag (70% to 72% TiO_2); 604,796 tons of Sorelmetal (a low manganese pig iron); and 156,799 tons of Sorelflux (ilmenite ore used as a flux in electric steel furnaces). Although demand for Sorelslag has been increasing, inventories of Sorelmetal had built up to 425,598 tons by September 1976, and recovery in demand for this coproduct was very slow.

Most of the Sorelslag was exported to the United Kingdom, Western Europe, and the United States, with about 13% sold to the two Canadian producers of pigments: Canadian Titanium Pigments, Ltd., Varennes, Quebec, a subsidiary of NL Industries, and Tioxide of Canada Ltd., Tracy, Quebec, a subsidiary of BTP Tioxide, Ltd., United Kingdom. The combined capacities of the two Canadian producers, both of which use the sulfate process, total about 76,000 tons per year.

An agreement was made between Laurentian Titanium Mines and Inco Limited for Inco to provide funds for exploration of

Laurentian's titaniferous magnetite deposit about 47 miles northeast of Montreal. Inco could eventually become the owner of the deposit, which has estimated reserves of 124 million tons of titaniferous magnetite and 16 million tons of ilmenite.

European Economic Community (EEC).—Common Market ministers reportedly postponed until 1977 proposals for standards to regulate the disposal of wastes from titanium dioxide plants. The ministers failed to agree on a single set of disposal standards that would have required 90% reduction of these wastes by 1985. Instead, they appeared to prefer a British proposal that producers be allowed to continue ocean discharge to the extent that plant wastes can be absorbed by the surrounding environment.

Germany, West.—Du Pont reportedly gave up its 26% ownership of Pigment Chemie, with Metallgesellschaft gaining control of the company. Pigment Chemie operates a 55,000-ton-per-year titanium dioxide pigment plant at Duisberg.

Italy.—Montedison, S.p.A., announced plans to phase out the older of its two plants at Spinetta Marengo, southwest of Milan, since treatment and waste disposal costs did not permit profitable operation. The company plans to build a chloride process facility at Crotone in Calabria, with production planned for 1979. Montedison is said to be subject to the most stringent pollution controls in Europe, and the Italian Government has supported Montedison in its efforts to persuade the EEC commission that all European titanium dioxide producers should be governed by the same effluent controls.

Society Mineraria Italiana confirmed discovery of a deposit of rutile in Savona with reserves of 31 million tons of ore containing 6% TiO_2. Open pit mining was planned at a rate of 1 million tons ore per year, using a patented upgrading process to yield 20,000 tons per year of concentrate containing 95% TiO_2.

Norway.—Producton of ilmenite concentrate in 1976 was 845,244 tons.

Spain.—Titanio S.A. reportedly started up a 50,000-ton-per-year pigment plant at Huelva, using Tioxide International's sulfate process technology. Titanio is owned 55% by Esplosivos Rio Tinto S.A. and 45% by Tioxide Group, Ltd. The plant was said to be using both the sulfate and chloride pigment processes.

United Kingdom.—The Tioxide Group, Ltd., was planning extensive improvements and modifications of the BTP Tioxide, Ltd., chloride process plant at Teeside, England, including replacing original chlorination units with a newly developed chlorination plant and installating of the most recent design of vapor-phase oxidation equipment in place of the existing units.

The Tioxide Group reported a marked improvement in sales and profits during the first half of 1976, compared with the depressed levels of 1975. Capacity utilization was considerably above the 60% level average for 1975.

Wogen Resources started a new company, Wogen Titanium Ltd., which began construction of a 3,000- to 3,500-ton-per-year ferrotitanium plant. Production was expected to begin in the first half of 1977.

Imperial Metal Industries Ltd. (IMI), Britain's only titanium mill products producer, began a campaign in August 1976 against what it called unfair competition in the international titanium market. In complaints to the EEC and the United Kingdom Government, IMI claimed that Japanese titanium was flooding the United Kingdom market at prices as much as 55% below the Japanese domestic prices. It also stated that the EEC common external tariff of 6% to 8% was hurting its business since United States and Japanese import tariffs were 18% and 12%, respectively. In November 1976, there were similar complaints about price cutting by the Soviet Union.

India.—Ilmenite deposits reportedly have been found in seabed sediments around Ratnagiri in Maharashtra State by the National Institute of Oceanography. The deposits may contain several million tons of ilmenite.

Work on a titanium dioxide pigment complex for the State of Kerala was scheduled to begin early in 1977. Plans were for a production rate of 24,000 tons per year, starting in 1980, with expansion later to about 100,000 tons per year. Total cost of the project, to be located near Quilon, is estimated at about $90 to $110 million, with the first stage costing about $55 million.

Japan.—Toho Titanium Co., Ltd., and Osaka Titanium Co., Ltd., produced 6,996 tons of sponge metal in 1976, a decrease of 16% from 1975 production. Exports of sponge and fabricated products in 1976 were 1,799 tons and 963 tons, respectively; the United States received 75% of the sponge; while the Netherlands, West Germany

France, and the United Kingdom received over 24%. Domestic sales and internal plant consumption increased 16% to 4,755 tons.

Three Mitsubishi-group companies made a contract for a 1-year option on the use of Du Pont technology for chlorinating higher grade concentrates. Formal licensing was not yet effected but seemed probable. Mitsubishi Metal and Mitsubishi Chemical are believed to have developed a new form of synthetic rutile. The third company, Asahi Glass, is a large producer of chlorine. These and other factors suggest that the companies were seriously considering a new large scale chloride process project, aimed at replacing existing sulfate plants that have pressing pollution problems.

Malagasy.—Montedison of Italy completed exploration and test work directed toward exploiting ilmenite deposits near Tamatave on the east coast of Madagascar. Montedison announced its acceptance of 51% State ownership of the proposed ilmenite mining venture. Montedison was reportedly proceeding with plans for a plant to produce 200,000 tons per year of ilmenite and 28,000 tons of zircon.

Malaysia.—Malaysian Titanium Corp. began operation of a synthetic rutile plant at Ipoh, with expected production of 4,000 tons in 1976, 50,000 tons in 1977, and capacity production of 100,000 tons in 1980. Malaysian Titanium Corp. is a joint venture of Straits Trading Co., Ltd., Pernas Mining, Empat Nombor Ekor, Malaysian Tin Smelting, and Benilite Corp. of America. Raw material used is ilmenite in tin tailings from the area around tin mines in Lahat, 4.5 miles from Ipoh.

New Zealand.—New Zealand Steel Mining Co. was reported to have offered to sell an additional 1 to 1.5 million tons per year of titaniferous ironsand to Japanese steel firms starting in 1977 in addition to fulfilling an existing contract for 1.3 million tons per year from the Taharoa sand mines. Waipipi Iron Sands Ltd. was also a major producer at Waipipi.

Titanomagnetite ores in New Zealand also provide the basis for a local steel industry, utilizing the a solid fuel direct-reduction process.

Sierra Leone.—It was reported by Bethlehem Steel Corp. and Nord Resources that the Export-Import Bank agreed to lend an additional $9 million to finance their rutile mining venture in Sierra Leone. Bethelehem holds an 85% interest in Sierra Rutile Ltd., with Nord holding 15%. It had been estimated that the cost of the project would be about $28 million. Initial production of rutile was still planned for late 1978 with an eventual annual rate of about 100,000 tons of concentrate from a deposit containing about 3 million tons of rutile.

South Africa, Republic of.—Development of the titanium deposit at Richards Bay in Natal was proceeding on schedule. Mining was expected to begin in late 1977 with smelting to start in early 1978. The planned annual production rate was about 440,000 tons of 85% TiO_2 slag, 62,000 tons of rutile, 127,000 tons of zircon, and 239,000 tons of low-manganese pig iron. About 1 million tons per year of ilmenite was to be produced and smelted in electric furnaces to make the high-TiO_2 slag using Quebec Iron and Titanium Corp. technology. The ore occurs in dune deposits estimated to contain over 770 million tons of heavy-mineral-bearing sand.

Because of its high TiO_2 content and low magnesium content, the Richards Bay (RB) slag will be competitive for use in the chloride pigment process as well as the sulfate process. Japan's five titanium pigment producers were reported to have concluded a long-term agreement to import RB slag at an annual rate between 70,000 and 100,000 tons. Partners in the $320-million Richards Bay project include Quebec Iron and Titanium Corp. (40%), Union Corp. (project manager with 30% interest), Industrial Development Corp. of South Africa (20%), and the South African Mutual Life Assurance Society (10%).

Tanzania.—It was reported that titanium deposits have been found near Mtwara on the southeast Tanzanian coast and that feasibility studies on exploiting the deposits had begun.

U.S.S.R.—The Soviet Union was reportedly planning to exploit rich reserves of titanium ore found in the Yaregsk region of the northern Ural Mountains. The reserves are said to be extensive and higher in grade than any previously found in the U.S.S.R. Beneficiation methods were being investigated.

Production of titanium metal in the U.S.S.R. was estimated at 35,000 tons, 7% higher than in 1975. Development of the titanium industry continued to be based mainly on Ukranian and Siberian ilmenite and rutile. Reports indicated that a titaniferous slag containing 83% TiO_2 was being produced at the Zaporozhye plant in the Ukraine. Production of titanium was planned to be 39,000 tons in 1977 and 46,000 tons in 1980, with exports of titanium sponge to be increased significantly.

The Soviet Union reportedly was planning to build a 110,000-ton-per-year titanium dioxide plant at Armansk, using the sulfate process, at a cost of about $170 million. Armansk is the site of an existing 30,000-ton-per-year TiO_2 plant built using technology supplied by Montedison. Possible sources of technology said to be under consideration by the Soviet Union include American Cyanamid, Du Pont, and Kronos Titan in West Germany.

TECHNOLOGY

The U.S. Geological Survey published a series of papers on the geology and resources of titanium, covering titanium partitioning in rocks, source rocks of titanium placer deposits, the types of deposits associated with various rocks, and describing some alluvial ilmenite placer deposits in central Virginia.[4] A separate publication reported on heavy mineral resources in the Port Leyden area of New York State.[5]

A review of ore dressing investigations on Canadian titaniferous ores was published.[6] Aside from the Allard Lake area in Quebec, deposits with the best potential include the 140-million-ton magnetite-ilmenite deposit in the Temagami area of Ontario, containing 38.5% Fe and 18.7% TiO_2, with combined concentrates assaying about 48% Fe and 21.5% TiO_2. Less well-known deposits in the Lanark and Leeds areas of Ontario yield magnetite concentrates containing about 0.24% TiO_2 and might be exploitable if the present specification of 0.1% TiO_2 in iron concentrate is increased to 0.3% TiO_2.

At the Third International Conference on Titanium held in Moscow in May 1976, emphasis was on improving properties in existing alloys such as fracture toughness, fatigue, and notch strength as opposed to developing new alloys with higher tensile strength. There were papers on processing techniques that make more efficient use of titanium such as casting, forging, superplasticity, and powder metallurgy. It was disclosed that the Soviet titanium industry uses hard rock ilmenite as a basic feed material, smelting it to obtain a slag for chlorination containing 88% to 90% TiO_2. Japanese titanium producers were reportedly using combinations of rutile and sand ilmenite (converted to synthetic rutile), or rutile and titanium slag. In the United States, nearly all the feed material for titanium metal manufacture was Australian rutile. All titanium-producing countries except the Soviet Union were showing increasing consumption of titanium for commercial applications such as utility surface condensers, reaction vessels, and dimensionally stable anodes.

In the United States, research is continuing to determine the range of thermomechanical variables under which titanium alloys can be processed to achieve maximum material utilization with satisfactory product properties. Procedures being investigated include hot die-forging processes,[7] impact forming, diffusion bonding,[8] and superplastic forming, all of which are cost cutting alternatives to machining.[9]

A titanium scrap reclamation process used by Teledyne Allvac was selected by the Air Force Materials Laboratory as the only reliable way to recycle aerospace machine shop chips and turnings. The problem of removing particles of tungsten carbide cutting tools was solved by melting the scrap metal using a rotating nonconsumable copper electrode. The rotating electrode avoids tip erosion, and the cutting tool fragments settle to the bottom of the furnace allowing the molten titanium to be poured off to form either a consumable electrode or a remelt ingot.[10]

Papers were published describing the BCA Cyclic Process[11] and the Ishihara process[12] for making a rutile substitute from ilmenite. Both processes are being utilized commercially.

Bureau of Mines research related to titanium included studies on methods of recovering titanium from ilmenite[13], recovery of chlorine and iron oxide from ferric chloride[14], soda ash smelting-leaching procedure for preparing sodium titanate from domestic ilmenite[15], electrodeposition of titanium boride coatings on various metals[16], reflectance and emittance of thin film absorber stacks containing zirconium or titanium compound thin films[17], the use of titanium carbide as a deoxidizer in electric furnace steelmaking[18], and a process for chlorination of titanium bearing materials and for dechlorination of iron chloride[19]. A patent was obtained on a process for production of synthetic rutile from slag[20].

Tungsten

By Ben A. Kornhauser[1]

Domestic production increased 4% over that of 1975, and consumption rose 15%. Production and consumption in 1976 were 5.8 and 16.1 million pounds of contained tungsten, respectively. Essentially all domestic production came from two mining operations, one in California and one in Colorado. Production of ammonium paratungstate (APT) increased 25%, and production of tungsten products rose 44%; consumption of APT increased 54%, and consumption of tungsten products rose 30%. Imports for consumption of tungsten in concentrate decreased 19% to 5.3 million pounds, while exports of tungsten concentrate increased 31% to 1.7 million pounds of contained tungsten.

The reported unit value of tungsten concentrate shipments in 1976, f.o.b. domestic mines and custom mills, increased 20% when compared with that of 1975, and averaged $100 per short ton unit.

Legislation and Government Programs.—The Office of Stockpile Disposal, General Services Administration (GSA) continued to sell excess stockpiled tungsten

concentrate on the basis of monthly sealed bids. The excess concentrate was offered on a regular monthly basis at the disposal rate of 500,000 pounds of contained tungsten, of which 375,000 pounds was for domestic use only and 125,000 pounds was for export only. Occasionally, supplemental offerings also were made. These offerings resulted in concentrate sales of 3,708,407 pounds of contained tungsten, of which 1,844,935 pounds was for domestic use and 1,863,472 pounds was for export. The material released for domestic use was sold at prices, ex-duty, that ranged from $81.74 to $127.07 per short ton unit. Material released for export was sold at prices, ex-duty, that ranged from $78.87 to $127.00 per short ton unit. However, actual deliveries of concentrates for domestic use and export in 1976 were 4,003,767 pounds of contained tungsten.

On October 1, 1976, the material stockpile goals (formerly termed objectives) were revised by the Federal Preparedness Agency of GSA. These goals were to be updated as necessary in the future. U.S. Government tungsten stockpile materials, inventories, and goals are presented in table 2.

Executive Order No. 11888, dated November 24, 1975, modified the Tariff Schedules of the United States to implement the Generalized System of Preferences (GSP) authorized by Title V of the Trade Act of 1974. The Executive order designated beneficiary countries and eligible articles for the GSP. Since the implementation of GSP, it has been modified by various Executive orders. Products that are eligible articles and meet the conditions stipulated in the act are duty-free, if imported into the United States directly from a beneficiary country on or after January 1, 1976. Countries eligible under section 504 (c) of the Trade Act to export tungsten ores and concentrates to the United States, duty-free, are noted in table 13. Withdrawal of GSP eligibility from a country for duty-free treatment would occur if the GSP beneficiary country, in any one year, exported more than $29.9 million of tungsten or more than 50% of the total U.S. tungsten imports. The program will expire on January 4, 1985.

Table 2.—U.S. Government tungsten stockpile materials, inventories, and goals

(Thousand pounds of contained tungsten)

Material	Goals[1]	Inventory by program, Dec. 31, 1976

[1]Goals established Oct. 1, 1976.
[2]Defense Production Act (DPA).
[3]Data may not add to totals shown because of independent rounding.
[4]Includes hydrogen- and carbon-reduced tungsten metal powder, formerly reported separately.

DOMESTIC PRODUCTION

Domestic mine production of tungsten concentrate increased 4% over that of 1975 and totaled 5.8 million pounds of contained tungsten for the year; mine shipments increased 7% to 5.9 million pounds. Forty-nine mines in 9 Western States reported production, but only 46 mines reported concentrate shipments. However, only two mines essentially operated continuously throughout 1976; these were the Pine Creek mine and mill of the Metals Div., Union Carbide Corp. (UCC), northwest of Bishop, Inyo County, Calif., and the Climax mine and mill of Climax Molybdenum Co., a division of AMAX, Inc., at Climax, Lake County, Colo. The major mineral value recovered at Pine Creek continued to be tungsten, with minor amounts of byproduct molybdenum, copper, gold, and silver. UCC processed ore directly into (APT), an intermediate tungsten product suitable for conversion to tungsten powder.

The major mineral value recovered at Climax was molybdenum. Concentrates of tungsten, tin, and pyrite were recovered as coproducts, which depend upon the rate of molybdenum production. At Climax, the maximum annual production capacity for tungsten concentrate is about 2.5 million pounds of contained tungsten.

Intermittent tungsten concentrate production and/or shipments also were reported from Pima County, Ariz.; Fresno, Inyo, Kern, Los Angeles, Madera, San Bernardino, San Diego, and Tulare Counties, Calif.; Boulder County, Colo.; Custer and Valley Counties, Idaho; Granite County, Mont.; Churchill, Elko, Esmeralda, Nye, Pershing, and White Pine Counties, Nev.; Baker County, Oreg.; Box Elder and Tooele Counties, Utah; and Stevens County, Wash. The Tungsten Queen mine and mill of Ranchers Exploration & Development Corp., near Townsville in Vance County, N.C., remained on standby status for the entire year. UCC development of the Tempiute mine and mill in southern Nevada was delayed, with completion and startup rescheduled for mid-1977. When operating at designed capacity, this facility expects to produce 2 million pounds of tungsten annually, plus a byproduct zinc concentrate. Tempiute will process the scheelite ore to a tungsten semiconcentrate for conversion to APT at UCC's Pine Creek, Calif., facilities. Eighteen mines were considered discontinued in 1976 based on submitted information and unclaimed reporting forms.

Table 3.—Tungsten concentrate shipped from mines in the United States

Year	Quantity			Reported value, f.o.b. mine[1]		
	Short tons 60% WO_3 basis[2]	Short ton units WO_3[3]	Tungsten content (thousand pounds)	Total (thousands)	Average per unit of WO_3	Average per pound of tungsten
1972	7,401	444,145	7,045	$18,104	$40.77	$2.56
1973	7,418	445,051	7,059	19,154	43.04	2.71
1974	8,233	494,012	7,836	37,413	75.73	4.77
1975	5,769	346,112	5,490	29,090	84.05	5.30
1976	6,168	370,069	5,869	37,266	100.70	6.35

[1]Values apply to finished concentrate and are in some instances f.o.b. custom mill.
[2]A short ton of 60% tungsten trioxide (WO_3) contains 951.6 pounds of tungsten.
[3]A short ton unit equals 20 pounds of tungsten trioxide (WO_3) and contains 15.86 pounds of tungsten.

CONSUMPTION AND USES

Reported domestic consumption and stocks of tungsten products, by end use during 1976, are given in table 6. Cutting and wear-resisting materials continued to be the major end use of tungsten, primarily as tungsten carbide (WC). This end use accounted for 68% of total tungsten product consumption, of which 62% was used as WC in cutting and wear-resisting materials and 7% was consumed in hard-facing rods and materials. Total tungsten product consumption increased 30% to 16.8 million pounds of contained tungsten for the year. Other major end-use categories were mill products, 14%; specialty steels (tool, stainless, and alloy), 9%; superalloys, 3%; and chemicals, 4%.

The major consumption distribution of intermediate tungsten products used to make end-use items in 1976 follows: Tungsten carbide (including cemented, crushed and cast, and crystalline), 39%; tungsten metal powder, 41%; ferrotungsten, 6%; and scrap, 9%.

Domestic shipments, imports, consumption, and the average price of tungsten concentrate are presented graphically in figure 1. The production, disposition, and stocks of tungsten products in the United States during 1976 are presented in table 5, and the major domestic companies engaged in tungsten operations during 1976 are listed in table 4.

Figure 2 is a simplified tungsten flow diagram showing the major process flow of intermediate tungsten products and major end-use items involved in the tungsten processing industry.

The use of coated tungsten carbides and other coated materials for cutting tools increased approximately 25% during 1976, according to Bureau of Mines data and as noted by Metcut Research Associates, Cincinnati, Ohio.[2]

[3]Less than 1/2 unit.

STOCKS

At yearend 1976 producer-held stocks of tungsten concentrate at domestic mines decreased 72% and consumer-held stocks of tungsten concentrate decreased 49%, compared with stocks held at yearend 1975. Producers' and consumers' stocks of APT decreased 16% from those of 1975. Producers' stocks of intermediate tungsten products decreased 15%, while consumers' stocks of intermediate products remained virtually the same, as indicated in tables 5 and 6.

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."
[1]Includes melting base self-reducing tungsten.
[2]Includes both carbon-reduced and hydrogen-reduced tungsten metal powder.
[3]Includes tungsten chemicals, natural and synthetic scheelite, tungsten scrap and other.
[4]Includes welding and hard-facing rods and materials and nonferrous alloys.

PRICES AND SPECIFICATIONS

In 1976, the average value of tungsten concentrate shipped from domestic mines and mills, as reported to the Bureau of Mines, increased 20% to $100.70 per short ton unit of WO_3, when compared with the 1975 value. During 1976, GSA sold excess tungsten concentrate for domestic use at prices, ex-duty, ranging from $81.74 to $127.07 per short ton unit. GSA sales of excess tungsten concentrate for export ranged from $78.87 to $127 per short ton unit.

The European price of tungsten concentrate, as quoted in the Metal Bulletin (London), reported in Metals Week, and shown in table 7, increased steadily each month from a low of £42 per metric ton unit (about $76.31 per short ton unit) in January to a high of £90 per metric ton unit (about $135.94 per short ton unit) at yearend. The increase in average price per short ton unit of WO_3 was 25% over the average price of $83.19 per short ton unit of 1975.

The price of APT delivered to large-volume contract customers was $106 per short ton unit at the beginning of the year. This low price for the year was maintained

Table 7.—Monthly price quotations of tungsten concentrate in 1976

Month	Wolfram and scheelite; London market, pounds sterling per metric ton unit of WO_3, 65% basis		Equivalent quotations, dollars per short ton unit of WO_3, 65% basis[1]		
	Low	High	Low	High	Average[2]
January	£42.00	£45.00	$76.31	$82.77	$79.57
February	43.50	46.00	80.11	84.70	82.59
March	45.00	51.75	82.71	90.30	86.64
April	51.00	58.50	86.52	97.07	91.06

September	71.00	75.00	112.52	118.33	115.70
October	74.25	81.50	111.82	121.74	116.13
November	83.50	90.00	118.66	135.94	128.13
December	[3]85.50	[3]88.20	130.18	134.26	132.16

[1]Equivalent high and low quotations as reported in Metals Week from biweekly Metal Bulletin (London) data; price dependent upon the prevailing rate of currency exchange.
[2]Arithmetic average of weekly quotations. The equivalent 1976 average price, excluding duty, was $103.68 per short ton unit.
[3]In December, due to new Bank of England Exchange control regulations, the Metal Bulletin (London) quotations were changed to U.S. dollars per metric ton unit and ranged from $143.50 to $148.00 per metric ton unit. The December 1976 foreign exchange average of $1.678 for the pound sterling was used in making the conversion.

until August 1976, when it was increased to $135 per short ton unit. The price of "Blue Oxide" (W_2O_5) remained at $2 per short ton unit above the APT price plus a 1% surcharge to cover processing losses.

The conversion fee of $18.50 per short ton unit in effect on January 1976 was maintained throughout 1976 for toll-processing tungsten concentrate to APT at a recovery rate of approximately 96%.

The price of hydrogen-reduced tungsten metal powder (99.99% purity), f.o.b. shipping point, as quoted in Metals Week, was $10.21 to $12.01 per pound of contained tungsten from January to October 1. In October, the price range increased to $10 to $13. Within these ranges, the price depended primarily on the tungsten powder particle size (Fisher number).

UCAR ferrotungsten is a proprietary high-purity ferroalloy containing 90% tungsten. In January, its price was quoted at $7.75 per pound of contained tungsten, rising to $7.95 on June 1, to $8.40 on August 1, and to $9.25 on November 1.

The price of scheelite concentrate (calcium tungstate) for direct addition to steel melts was believed to be comparable to the prices reported in table 7.

FOREIGN TRADE

Exports.—During 1976, tungsten concentrate exports continued to represent excess materials purchased from GSA stockpiles and increased 31% to 1.7 million pounds of tungsten in concentrate. There were no exports of ferrotungsten during 1976. On the other hand, APT exports increased 41% to 188,360 pounds of contained tungsten with the United Kingdom as the principal recipient. In 1976, exports of WC powder increased 58% to 1.3 million pounds of contained tungsten. Mexico (26%), Canada (24%), West Germany (11%), Sweden (6%), and Iran (6%), received 73% of the exports.

Exports of unwrought tungsten metal and alloys in crude form including waste and scrap increased 27% to 1,099,169 pounds gross weight, valued at $3,260,499 and were shipped primarily to West Germany (65%), the United Kingdom (12%), and Belgium-Luxembourg (10%). Exports of tungsten and tungsten alloy powder decreased 3% to 610,858 pounds of contained tungsten valued at $3,836,671. The principal recipients were Israel (60%), the United Kingdom (13%), Canada (9%), and Austria (5%).

Exports of tungsten and tungsten alloy wire increased 22% to 194,718 pounds, gross weight, valued at $6,219,902, and were received mainly by Canada (27%), West Germany (12%), Brazil (11%), Israel (6%), Japan (6%), Mexico (6%), Italy (5%), and the U.S.S.R. (5%). Exported wrought tungsten and tungsten alloys increased 5% to 241,727 pounds, gross weight, valued at $3,637,310. These materials were shipped mainly to West Germany (35%), Canada (14%), Sweden (14%), the United Kingdom (12%), and Mexico (7%).

[1]Data are "general imports", that is, they include tungsten imported for immediate consumption plus material entering warehouses.

Imports.—Tungsten concentrate imported in 1976 for consumption decreased 19% from that imported in 1975 to 5.3 million pounds of contained tungsten. The major suppliers were Canada (25%), Peru (16%), Thailand (11%), and Bolivia (11%).

Tungsten carbide imports for the year increased 19% over those of 1975 to 194,432 pounds of contained tungsten valued at $2,184,376 and came primarily from West Germany (70%), France (12%), and Sweden (11%). Imports of tungsten waste and scrap containing over 50% tungsten increased 117% to 149,794 pounds of contained tungsten valued at $694,269. The imports came primarily from Israel (53%), Singapore (17%), Japan (10%), and Mexico (9%). Imports of unwrought tungsten (except alloys) in lump, grain, and powder forms increased 87% to 377,153 pounds of contained tungsten valued at $2,600,338 and were received mainly from West Germany (52%), France (14%), and Singapore (9%). Wrought tungsten imports increased 237% to 42,893 pounds, gross weight, valued at $1,966,446, and were supplied primarily by Canada (51%), Japan (27%), and Austria (15%).

Imports of tungsten material classified as "metal-bearing materials in chief value of tungsten" increased 433% to 378,528 pounds of contained tungsten valued at $2,224,743. The imports were received solely from Bolivia and are believed to be mostly synthetic scheelite. Ammonium tungstate imports decreased 30% to 582,622 pounds of contained tungsten valued at $3,699,178 and were supplied by the Republic of Korea (71%) and Japan (29%). Imports of calcium tungstate and sodium tungstate dropped to relatively insignificant quantities of 19,014 and 20,131 pounds of contained tungsten, respectively.

WORLD REVIEW

In two meetings of the United Nations Committee on Tungsten in 1976, discussions were continued on methods to stabilize tungsten prices. At the first meeting in January producers and consumers only agreed that a concentrate containing 65% WO_3 would be the basis for any price stabilization measures. At the second meeting in November, the producers, led by Bolivia, urged the establishment of a group of experts (producer and consumer) to draft a formal price stabilization agreement. The meeting ended without an agreement, and further negotiations were put off until after a special United Nations Conference On Trade and Development (UNCTAD) board session in 1977. The proposed agreement, outlined at the November 1976 meeting of UNCTAD, suggested establishing a system of maximum and minimum prices that would be supported at appropriate times by coordinated nationally held stockpiles and be combined with restrictions on both imports and exports.

Australia.—The King Island Scheelite Mine Division, Peko-Wallsend Ltd., the major producer of tungsten in Australia, developed the Bold Head and Dolphin mines so that 386,000 short tons per year of ore could be produced from underground operations, with the potential of 440,000 tons per year. In 1976, 329,350 tons of ore, averaging 0.77% WO_3, was treated to produce 2,600 tons of concentrate, averaging 72.7% WO_3.

A decision was made to install an artificial scheelite plant to produce a molybdenum-free calcium tungstate product from the flotation concentrate. The plant was scheduled to be completed in early 1978.[3]

Austria.—The Miltersill scheelite mine of Wolfram-Bergbau and Hüttengesellschaft mbH, Metallgesellschaft AG, and Teledyne Inc. began production in late August. The concentrate was sold while the processing plant was under construction. When the processing plant is completed in early 1977, it will become part of the second integrated tungsten production facility in Europe, and the fourth in the world. The plant's production capacity will be 1,490 tons of contained tungsten per year. The tungsten will be sold in a variety of forms: Carbide powder, pure tungsten powder, blue oxide, APT, and tungsten concentrate. When operational, the plant is expected to meet 10% of Western Europe's demand for tungsten. Reserves were estimated at 3.1 million tons, containing 0.7% to 1% WO_3. The mine has an estimated life of 8 to 10 years, based on proven reserves.

Bolivia.—Bolivian tungsten is primarily in wolframite, ranging between huebnerite and ferberite. The Corporacíon Minera de Bolivia (COMIBOL) accounts for most of the tungsten production. The tungsten mineralization belt extends along the general line of the Eastern Cordillera of the Andes from Peru to Argentina. In the north, mineralization follows closely the tin deposits related to granitic batholiths of the Cordillera Real and Quimsa Cruz. In the south, mineralization is related closely to deposits of antimony, zinc, and silver.

International Mining Co. (IMCO), a subsidiary of Estalsa S.A., planned to expand the capacity of its Chojlla mine and mill. A new beneficiation plant reportedly will be installed to treat tailing dumps containing 0.22% tin and tungsten (about 50% of each). The plant would have a capacity to process 4,410 tons per day. Tailing processing should increase the company's output of tungsten contained in WO_3 by 358 tons per year, and operations will begin in early 1977.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Conversion factors: WO_3 to W, multiply by 0.7931; 60% WO_3 to W, multiply by 0.4758.

[2]Producer's shipments; actual production data are not officially reported, but available company figures indicate a substantial difference between actual output and shipments in some years.

[3]Data presented are sum of production reported by COMIBOL and exports credited to medium and small mines and other unspecified exporters (including COMIBOL). Total national output is not reported.

[4]Actual recorded total national output. Not available for prior years.

[5]Less than 1/2 unit.

[6]Production of Beardmore mine only.

[7]Production of Brandberg West mine of South West Africa Company, Ltd. only. Data are for calendar years.

[8]Revised to zero.

COMIBOL tungsten reserves were estimated as follows: Bolsa Negra, 442,000 tons at 1% WO_3; Kami, 100,000 tons at 0.98% WO_3; Viloco, 2,210 tons at 0.98% WO_3; Esmoraca, 1,990 tons at 1.8% WO_3. IMCO reserves were estimated as follows: Chojlla, 2,210,000 tons at 1% WO_3; Chambillaya, 496,000 tons at 1% WO_3; Enrramada, 551,000 tons at 1% WO_3; San José Bergue, 55,100 tons at 1% WO_3; Santa Isabel, 11,000 tons at 1% WO_3. Various small mines had reserves estimated at 160,000 tons averaging 1.05% WO_3.[4]

Brazil.—A new tungsten company, Brejui Mineração e Metallurgia S.A., was established by Nittetsu Mining Co., Kanematsu-Gosho Ltd., and a local company Mineração Tomaz Salustino S.A. The new company will produce 130 tons per year of synthetic scheelite from tailings in the Currais Novos region. A pilot plant for the production of 70% to 75% scheelite concentrate from 0.2% ore also was scheduled for construction in 1977, at the site of the large Brejui tungsten mine.

Union Carbide Corp. brought its new tungsten mine and mill in Boca DeLage onstream in December 1976. The operation is scheduled to produce 1 million pounds per

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Bulgaria, Denmark, Finland, Israel, Norway, Romania, Switzerland, and Yugoslavia may consume tungsten concentrate, but consumption levels are not reported and available general information is inadequate to permit formulation of reliable estimates of consumption levels.

[2]Estimated by U.S. Bureau of Mines. (All estimates not so footnoted are reported in the primary source.)

[3]Production plus imports minus exports.

[4]Data represents tungsten content of concentrate consumed to make ammonium paratungstate at APT plant adjacent to Sangdong mine and mill.

year of tungsten in concentrate. The output will be marketed by UCORE Ltd., London, a trading company wholly owned by Union Carbide.

Canada.—Canada Tungsten Mining Corp. Ltd. (CTMC) planned to double the mill capacity at its Flat River mine in the Northwest Territories to 1,000 tons of ore per day. Construction of additional facilities was planned for the summer of 1977. CTMC's mill treated 188,934 tons of scheelite ore, averaging 1.55% WO_3, during the year. Total production was 238,998 short ton units of WO_3, an increase of 33% over that of 1975. Mill recovery was 81.6% in 1976, compared with 71.1% in 1975. The concentrator operated at a rate of 523 tons per day with an overall efficiency of 97.8%. Minable ore reserves at yearend were estimated to be 4,190,000 tons of ore, grading 1.55% WO_3. Exploration, development, and diamond drilling added about 857,000 tons, averaging 1.65% WO_3, to the ore reserve in 1976.[5]

India.—Production of tungsten concentrate from two mines totaled 97,372 pounds, an increase of 18% over that of 1975. Over 80% of this production was from Rajasthan, with the remainder coming from West Bengal. Imports of tungsten concentrate into India totaled 828,937 pounds valued at $2.4 million, Thailand and Bolivia were the major suppliers.

Korea, Republic of.—The Ministry of Commerce and Industry reported that 5,138 tons of tungsten in concentrate was produced in Korea during 1976 by the following companies:

Company	Short tons of contained tungsten
Chungyang Mining Co., Ltd.	160
Korea Tungsten Mining Co., Ltd.	4,619
Okbang Mining Co., Ltd.	71
Other companies	288
Total	5,138

Korea Tungsten Mining Co., Ltd., 8.7% owned by the Republic of Korea, increased production by 86% and accounted for al-

[5]Canada Tungsten Mining Corp. Ltd., (Toronto, Canada). 1976 Annual Report. 9 pp.

most 90% of the country's tungsten output. The Economic Planning Board reported that stocks on hand at yearend 1976 were 540 tons.

Rwanda.—The larger of two competing wolframite mining operations was absorbed by Société Minière du Rwanda (SOMIRWA), which in 1976 mined over 93% of Rwanda's yearly output. Concentrate output is relatively high grade, containing about 70% WO_3, and was sold directly through GEOMINES, a Brussels-based company.

Thailand.—Production of tungsten concentrate in 1976 totaled 4,384 tons, averaging 65% WO_3, an increase of 25% over that of 1975.

Turkey.—Etibank's new Uludas tungsten mine and mill was nearly ready for inauguration by yearend. The deposit is near the near the summit of Uludas Mountain and is in two sections. The upper section is low grade and garnetiferous, while the lower section is granitic and averages about 0.4% WO_3. Mining is by underground methods, and the concentrator, employing magnetic separation and tabling, has a capacity of about 3,300 tons of concentrate per year at about 65% WO_3. The mine is owned and operated by the Turkish State mining enterprise Etibank, and the cost of development was reportedly about $90 million.

United Kingdom.—An extensive drilling program was underway at the Hemerdom tungsten-tin and kaolin mine near Plymouth to prove the extent of mineralization. Tungsten mineralization averages 0.29% WO_3, and it was hoped that an orebody of 50 million tons could be proved. The old mine was operated underground, but any new venture would use open pit methods.[6]

Weco Development Corp. of the United States announced that it granted a 1-year option, beginning September 1, 1976, to the Carrock Fell Mining Company Ltd. (part of the Amalgamated Industrials Ltd. in the United Kingdom) and to Robertson Research International Ltd., an international engineering-consulting firm, to reopen Weco's Carrock Fell tungsten mine. This consortium intends to undertake a development and evaluation program and to modify and improve the mill. If the new operators exercise their option to place the mine into production on a continuing basis, Weco will retain a 31.5% interest in the mine and mill, including 3,500 acres of land.

TECHNOLOGY

Bureau of Mines researchers successfully coated two large steel valve seats with an adherent deposit of tungsten for test in an experimental coal gasifier to determine their ability to withstand wear, abrasion, and corrosion at temperatures up to 1000°C. Approximately 0.6 pound of metallic tungsten was deposited on each seat by a chemical vapor deposition technique. Advantages gained by this method were the ease of application and the requirement of only moderate temperatures during application.

Studies were continued during the year by Bureau of Mines research metallurgists to develop a process to recover tungsten economically from the low-grade brine deposits of Searles Lake, Calif. These deposits contain about 35 million pounds of tungsten.

According to manufacturers, cutting tools made by the particle metallurgy process are replacing carbide and high-speed-steel products. The process is especially useful in blended alloys of cobalt and tungsten. Unlike the powder metallurgy process, in which powder is compacted under high pressure, particle metallurgy involves heating the particles to a molten temperature and then cooling the material in a vacuum.

Industrial research was reported on coatings, such as titanium and hafnium nitrides and alumina, and tungsten carbide cutting tools as well as changes in tool shapes such as fluting and layer webs.[7] Coated tools combine the strength of the tungsten substrate with the hardness and reduced friction of coatings that minimize cratering. In particular, the coated tools are excellent for roughing steel, whereas a solid tungsten carbide tool is excellent for finishing operations on medium steels at lighter feeds and speeds. The latest coating development uses a tungsten carbide substrate with triple-phase coatings of which the first layer is titanium carbide, the second layer is titanium carbonitride, and the outside coating is titanium nitride. The titanium carbonitride provides a better bond between the coatings.[8]

Field tests were conducted by Teledyne Firth Sterling on tungsten carbide tools coated with hafnium nitride (0.002 inch thick). The coated tools have a higher

[8]Work cited in footnote 2.

temperature hardness since the hafnium nitride has more lubricity than hafnium carbide, thereby reducing the cratering problem. These coated tools perform best on highly alloyed steels that generate a strong chip.[9]

General Electric Co.'s Carboloy Systems Department introduced a line of tungsten carbide disposable inserts coated with alumina for cutting metal in applications where cutting speeds are beyond the capabilities of tungsten carbide tools coated with titanium carbide and where solid oxide tools tend to break. The chemical inertness of alumina makes it an excellent material for high-speed machining (above 500 surface feet per minute). Below 500 surface feet per minute, titanium carbide is more resistive to abrasive wear, the primary cause of insert failure in that speed range.[10].

An entirely different design of a carbide cutter tool, the Dust Hog, was introduced by Mining Tools Inc. and is claimed to have substantially better performance characteristics than conventional mining bits. The new drilling bit features layer webs and places the dust holes closer to the tungsten carbide cutting edge for more efficient drilling and dust collection. The tool is claimed to run cooler, to provide 55% faster penetration, and to have 50% longer life in dry drilling applications. The design change includes a hexagonal coupling between the bit and steel chuck that is more rigid, is almost impossible to break, and produces straighter holes by eliminating bit wobble.[11]

General Electric researchers completed a project for the Marshall Space Flight Center to improve the service properties of tungsten for uses such as X-ray targets. The researchers designed and tested a facility which permits the levitation melting of tungsten through electromagnetic levitation with electron-beam heating. Not only does this process provide a means of growing tungsten crystals for the production of X-ray targets, but it also can deposit tungsten onto molybdenum by vapor deposition from a superheated melt. Several advantages were claimed for the process in that the targets produced were reported to have a greater exposure life, greater strength, and enhanced room temperature ductility.[12]

Several patents were issued during the year relating to tungsten recovery. One patent concerned the separation of tungsten and molybdenum when the two metals occur together in solution.[13] A second patent related to the extraction of tungsten from solutions containing the metal. The solvent extraction occurs by utilizing ammonium hydroxide and about 36% silica by weight to convert the tungsten to soluble ammonium metatungstate.[14]

Uranium

By James H. Jolly[1]

The search for uranium continued to accelerate worldwide in 1976, owing to high uranium prices and expanding nuclear power programs. Both U.S. and world uranium reserves increased significantly. U.S. reserves at forward costs to $30 per pound of U_3O_8 were estimated at 680,000 tons of U_3O_8, a 40,000-ton increase, and world reserves at $30, exclusive of central economy countries, were estimated at 2.4 million tons of U_3O_8.

In the United States, most States had some level of uranium exploration activity. The Energy Research and Development Administration (ERDA) continued to expand its uranium reconnaissance activities under the National Uranium Resource Evaluation (NURE) program. Interest in low-grade uranium resources increased. Land acquisition and exploration drilling were at alltime highs. Mining activity continued high, and the gross tonnage of ore mined exceeded last year's record. The number of producing mines increased dramatically over that of 1975. In 1976, underground mines totaled 209, open pit mines 44, and other sources 28, compared with 121 underground mines, 23 open pits, and 25 other sources producing in 1975. More ore was milled in 1976 than during any previous year. Although milled ore increased almost 19%, uranium production increased only about 10% owing to lower ore grades and poorer mill recoveries. The millfeed grade averaged 0.15% U_3O_8 in 1976, down from 0.16% in 1975 and 0.17% in 1974. Sixteen conventional mills and two plants that recover uranium from in situ leaching solutions operated in 1976. Uranium recovery from phosphate rock was hampered by technical problems.

Uranium production was expected to increase rapidly in the next few years. A number of major new mines and associated mills were nearing startup, under construction, or planned. New developments were primarily underway in New Mexico and Wyoming. Increased emphasis was placed on recovery of uranium by solution mining, primarily in Texas and Wyoming, where a number of operations were starting up and planned. In Florida and Louisiana, increased production of uranium from phosphate rock was also anticipated.

In other sectors of the nuclear fuel cycle, legislation to aid the development of private uranium enrichment facilities was not approved making the future uncertain for proposals by four private groups. Programs to increase capacity at three Government enrichment plants continued, and plans to build an additional enrichment plant moved forward. A nuclear-fuel-reprocessing facility in South Carolina was almost completed; however, licensing problems and political decisions related to plutonium, proliferation, and waste management were delaying startup. In October, the President put a 3-year de facto moratorium on commercial fuel reprocessing and plutonium recycle. Waste management was a major concern. Long-term storage in stable geological formations continued to be the favored means of disposal.

Shortages of investment capital, concern for reactor safety, plutonium, radioactive waste, nuclear weapons proliferation, and reduced electricity demand continued to delay commercial nuclear power development. Problems related to nuclear proliferation, terrorism, and theft became major issues in 1976. Although public concern over nuclear power increased in 1976, voters in seven States voted down propositions designed to limit or stop construction of all future nuclear powerplants. The Price-Anderson Act, which provides financial protection to the public against losses

[1]Physical scientist, Division of Nonferrous Metals.

resulting from a nuclear accident, was extended for 10 years but was modified to enable the Government's indemnity to be phased out.

Seven new nuclear power plants became operable in 1976; however, there were orders for only three new plants, resulting in the smallest total megawatts ordered since 1965. At yearend, 65 plants were operable and 172 were under construction or planned. Nuclear powerplants generated 9.4% of the Nation's electrical energy in 1976, up from 8.9% in 1975. Overall, nuclear power supplied 2.8% of the Nation's total energy needs in 1976.

In the rest of the world, nuclear power development continued at a strong pace, and by mid-1977 the rest of the world's total on-line nuclear megawatt capacity was expected to exceed that of the United States. At yearend, exclusive of the United States, there were 111 nuclear plants operable in 18 countries and 187 under construction or planned in 30 countries.

Exploration and Reserves.—According to an ERDA survey,[2] 108 companies reported expenditures of $171 million on uranium exploration activities in 1976, compared with expenditures of $122 million in 1975. Foreign interests in 15 companies accounted for $13 million, or about 8% of total exploration expenditures. At yearend, 96 companies reported uranium exploration holdings of almost 15 million acres, 26% more than in 1975. During 1976, 4.75 million acres were acquired at a cost of $14 million. The cost per acre ranged from less than 10 cents to more than $200, averaging $2.92, down from $4.80 in 1975.

In 1976, more than 67,000 surface holes were drilled by 113 companies using an estimated 200 drill rigs. Total exploration and development drilling footage was a record 34.8 million feet, 37% more than in 1975. Exploration costs, including drilling, access roads, site preparation, geologic and technical work, sampling, and logging, ranged from $1 to $25 per foot, averaging $3.13 per foot, an 8% increase over costs in 1975.

Ten companies reported 350,000 feet of surface drilling exclusively for solution mining production in 1976 at a cost of $1.83 million, averaging $5.23 per foot drilled.

[2]Energy Research and Development Administration, Grand Junction (Colo.) Office. Uranium Exploration Expenditures in 1976 and Plans in 1977-78. GJO - 103, 1977, 10 pp.

Table 2.—Surface drilling for uranium

[1]Includes Alaska, Arizona, California, Idaho, Nevada, Nebraska, North Dakota, Oregon, Oklahoma, South Dakota, Washington, and Eastern United States.

Source: Energy Research and Development Administration.

New Mexico and Wyoming continued to be the leading States in uranium reserves with a combined total of 86% of the $10 reserves and 83% of the $15 reserves. ERDA estimates of yearend reserves by State at a cost of $30 per pound of U_3O_8 were:

State	Tons of ore (millions)	Grade (percent U_3O_8)	Tons of U_3O_8	Percent of total tons of U_3O_8
New Mexico	328	0.11	357,000	52
Wyoming	308	.07	[1]216,000	32
Texas	87	.05	[1]44,000	7

[2]California, Idaho, Montana, Nevada, North Dakota, Oregon, South Dakota, and Washington.

Source: Energy Research and Development Administration.

ERDA reported increases in overall domestic uranium reserves in 1976, but estimates of reserves recoverable at a cost of $10 or less per pound of U_3O_8 declined significantly owing to the effects of inflation and to reevaluation of data for certain deposits. There were 526 properties having reserves at $10 per pound of U_3O_8 and 1,801 properties having reserves at $30.

ERDA continued to expand its NURE program to assess the potential uranium resources of the United States, including Alaska, by 1981.[3] Nearly 80,000 miles of aerial radiometric reconnaissance surveys were flown in 1976 using computerized, high-sensitivity, gamma-ray spectrometers and magnetic detectors. The resource program also included hydrogeochemical studies and the sampling of alluvial sediments. Participants included ERDA's national laboratories, private companies, universities, State agencies, and the U.S. Geological Survey. Data on the airborne and geochemical studies were placed on open file following completion of each survey. To meet the expanding program, NURE funds were increased from $14 million in fiscal 1975 to $21 million in fiscal 1976. NURE funds for fiscal 1977 were $50 million.

DOMESTIC PRODUCTION

Mine.—Gross uranium ore output was 25% higher than that of 1975, but the average ore grade and mill recovery were lower. Domestic ores mined in 1976 graded an average of 0.15% U_3O_8, down from 0.16% in 1975 and 0.17% in 1974. ERDA data indicated production, by State, as follows:

State	Mine production[1]	
	Ore (thousand tons)	U_3O_8 content (tons)
New Mexico	3,401	6,500
Wyoming	3,315	4,400
Other[2]	2,482	3,100
Total	9,198	14,000

[1]Does not include output of approximately 200 tons of U_3O_8 from mine waters, leaching operations, and recovery from phosphate rock processing.
[2]Colorado, Texas, Utah, and Washington; combined to avoid disclosing individual company confidential data.

About 48% of the total production of 14,000 tons of U_3O_8 was from open pit mines, 48% from underground mines, and 4% from other sources. There were 209 underground mines, 44 open pits, and 28 miscellaneous sources in 1976, compared with 121 underground mines, 23 open pits, and 25 miscellaneous operations in 1975.

In 1976, many new mines, mainly in New Mexico and Wyoming, were either brought into production, under development, or planned. The Johnny M mine in New Mexico, a joint venture of Ranchers Exploration & Development Corp. (RED) and HNG Oil Co., began production from Section 7 in late 1976, after being delayed almost a year by startup problems. Full production of about 600 tons of ore per day is anticipated in early 1977 following development of the Section 18 ore body. RED and Chaco Energy Co. were developing the Hope mine near Grants, N. Mex. for ore production of 6,000 tons per month in1977. A 465-foot shaft was completed in September. Ore reserves, estimated at 224,000 tons containing 826,000 pounds of recoverable U_3O_8 were adequate for about a 3-year operation.

Phillips Petroleum Co. announced plans for the development of its Nose Rock deposit near Crownpoint, N. Mex.[4] Plans called for the sinking of four 3,400-foot shafts, two for production and two for ventilation, be-

[4]Phillips Petroleum Co. 1976 Annual Report. P. 16.

ginning in 1977. Production of about 3,000 tons of ore per day was expected in the early 1980's. Mill construction was planned for 1978. The deposit was estimated to contain reserves of about 25 million pounds U_3O_8.

The L-Bar mine and mill complex in the Laguna District, New Mexico, jointly owned by Sohio Petroleum Co. and Reserve Oil & Minerals Corp. (ROM), began uranium production in August. The only operating mine of the complex, the J. J. Number One mine, was expected to attain full production of 1,500 tons per day by mid-1977. Aggregate reserves in three deposits on the property totaled 17.4 million pounds of U_3O_8. The mill, which was completed by Fluor Utah, Inc. in July, was approaching rated design capacity, 1,600 tons per day, at yearend. Much of the ore being milled, however, was from the nearby, recently opened St. Anthony open pit mine of United Nuclear Corp. (UNC). UNC planned a yearly production of 500,000 pounds of U_3O_8. Recent drilling and mine development indicated that the St. Anthony mine's U_3O_8 reserves were substantially higher than the 7.9 million pounds initially thought to be present.

UNC continued development at its largest ore-producing mine located near Church Rock, N. Mex. A second 1,760-foot production shaft was completed in late 1976. Annual production of the mine was anticipated to be about 3 million pounds of U_3O_8 when the new shaft is operational in 1977. Construction of a 3,000-ton-per-day mill was on schedule, and the mill was expected to be completed in June 1977.

Gulf Mineral Resources Co. (GMR), a division of Gulf Oil Corp., continued development on the largest and deepest uranium mine in the United States, near Mount Taylor in New Mexico. The ore body, which lies at a depth of 3,500 feet, was estimated to have reserves exceeding 100 million pounds of U_3O_8. At yearend, both the 24-foot main shaft and the 14-foot service shaft were sunk to a depth of about 1,000 feet. Shaft sinking was expected to be completed in 1979, with commercial production scheduled for 1981.

Kerr McGee Corp. (KMC) continued uranium ore production from seven mines in the Ambrosia Lake region near Grants, N. Mex., and from its new Church Rock No. 1 mine, which was expected to attain full capacity in 1977. KMC planned three additional mines in New Mexico: A second mine at Church Rock and mines at Roca Honda in eastern Ambrosia Lake and at Rio Puerco between Grants and Albuquerque. The Rio Puerco mine was expected to begin production in early 1977.

The Section 21 (Ruby) mine at Smith Lake, N. Mex., operated by Western Nuclear, Inc. (WNI), began ore production in mid-1976 at a rate of about 15,000 tons per month. The ore was being toll-milled milled at Ambrosia Lake. WNI, which has additional reserves at Smith Lake, was planning a second mine in the area.

Mining operations at Homestake Mining Co.'s (HMC) F-33 mine near Grants were terminated late in 1976. To meet its contract commitments, HMC was increasing production at the four United Nuclear-Homestake Partners (UNHP) mines in the Grants area and planned to bring onstream a fifth UNHP mine in the latter half of 1977. Production from the new mine was expected to be about 200,000 pounds of U_3O_8 per year.

In Colorado, HMC continued development of the Pitch open pit mine near Gunnison. Production, expected in 1977, was to be toll-processed through the UNHP mill in New Mexico prior to the startup of the Pitch mill, scheduled for operation in 1979. Plans called for mine production of 150,000 tons of ore per year with a mill output of 600,000 pounds of U_3O_8 yearly. Reserves were estimated to exceed 10 million pounds of U_3O_8.

In December, Utah International Inc. (UI), a large producer of uranium in Wyoming, merged with General Electric Co. (GE), with GE as the surviving company. UI's uranium operations were transferred to a new wholly owned subsidiary, the Lucky Mc Uranium Corp. Under terms of the merger, Lucky Mc will not be able to sell uranium to GE until the year 2000.

Lucky Mc planned to develop nine uranium pits on its Green Mountain uranium property, located 15 miles southeast of Jeffrey City, Wyo. The company began stripping operations and mine construction in 1976. Development of the pits, which involves the removal of about 100 million cubic yards of overburden, was not expected to be completed until the mid-1980's. Mineral Exploration Co., a subsidiary of Union Oil Co., and Silver Bell Industries planned a mining operation to produce about 15 million pounds of U_3O_8 from a property near Rawlins, Wyo.[5] Construction of a $45 million mine-mill complex was expected to begin in 1977 with a 3,000-ton-per-day mill scheduled for startup in late 1978.

[5]Mining Journal (London). Uranium Mine Near Rawlins. V. 287, No. 7367, Oct. 29, 1976, p. 342.

Rocky Mountain Energy Co., a joint venture of Union Pacific Corp. and Mono Power Co., was constructing a $50 million mine-mill complex at Bear Creek, 65 miles northeast of Casper, Wyo. Construction of a 1,000-ton-per-day mill began in 1976, and the mill was expected onstream in late 1977. A 12-year operation was envisioned.

The Cleveland-Cliffs Iron Co., Getty Oil Co., Skelly Oil Co., and Nuclear Resources Inc., a unit of Commonwealth Edison Co. of Chicago, were planning to develop reserves containing 12 million to 18 million pounds of U_3O_8 in the North Butte area of the Powder River basin in Wyoming. A full-scale mining and milling operation was envisioned in 1982.[6]

KMC signed a uranium sales contract with Public Service Electric and Gas Co. of New Jersey, calling for the delivery of 20 million pounds of uranium between 1980 and 1995.[7] The uranium is scheduled to be mined from KMC's reserves in the South Powder River basin in Wyoming. The project, as planned, required the opening of three underground and several open pit mines and construction of a uranium mill. KMC planned to start production from the Bill Smith mine, its first mine in the basin, in 1977. The production shaft and haulage development of the Bill Smith mine were nearly complete at yearend.

The Morton Ranch property in Wyoming, a joint venture of the Tennessee Valley Authority and UNC, was expected to begin production in 1977. Stripping operations on a 32-acre area began in December. Startup of a 1,000-ton-per-day mill was scheduled for 1979. Ore reserves containing 11.4 million pounds of U_3O_8, were expected to be exhausted in about 10 years.

WNI, which received approval in October from the U.S. Department of the Interior, planned to proceed with its $50 million Sherwood uranium project on the Spokane Indian Reservation near Wellpinit, Wash. Development of the mine and construction of a 2,000-ton-per-day mill were to begin in January 1977, with completion scheduled for mid-1978. Reserves were estimated to be about 12.5 million pounds of U_3O_8.

Standard Oil of California planned to begin construction in 1977 on a $40 million mining and milling operation in south Texas near Panna Maria, where the company has reserves of about 5.5 million pounds of U_3O_8. Open pit mining and ore processing were expected in 1979; eventual capacity was anticipated at 2,000 tons of ore per day.[8]

The establishment of uranium-ore-buying stations in Colorado and Utah by private companies resulted in the opening of many small independent mines. GE was planning to increase ore buying at its Naturita, Colo., buying station from less than 10,000 tons per month in 1976 to 20,000 tons per month in 1977. Energy Fuels Ltd. (EFL) was establishing ore-buying stations at Hanksville and Blanding in southern Utah. In December, EFL owned, leased, or held production rights of 30 small, active mines. The company, which anticipates bringing in about 1 million pounds of U_3O_8 in ore per year, was studying proposals on whether or not to establish mills near the buying sites.

UOCO, Inc., established a buying station in Salt Lake City in July and was buying ore from independent and widely scattered producers. Plans called for the arranging of toll milling and supplying of yellowcake to utility clients.

Solution Mining.—Niagara Mohawk Utilities (NMU) and U.S. Steel Corp. (USS) bought out the interest of Atlantic Richfield Co. (ARCO) and Dalco Oil Co. in two in situ producing properties in the Clay-West uranium field in Live Oak County, Tex. The sale of ARCO's interest in the uranium properties reportedly was to help lessen antitrust objections to the planned acquisition of The Anaconda Company by ARCO. Production capacities of the two properties were rated at 150,000 and 250,000 pounds of U_3O_8 per year in 1976. Facilities at both properties were undergoing expansion and were expected to have capacities of 500,000 and 1 million pounds of U_3O_8 by 1978.

Intercontinental Energy Corp. (IEC) planned to start production at a 150,000-pound-per-year in situ facility on its Pawnee and Sparkman properties in Bee and Live Oak Counties, Tex., in early 1977 to fulfill a uranium contract with Virginia Electric Power Co. IEC concluded another sales contract in December that will require the startup in early 1978 of a 300,000-pound-U_3O_8-per-year in situ leaching operation on its Zamzow site, also in Live Oak County. The Zamzow site was reported to have uranium reserves of 1.3 million pounds of U_3O_8.

Wyoming Minerals Corp. (WMC), which has several in situ operations, began production at its Bruni, Tex., site (250,000

pounds per year capacity) in 1976 after startup problems were resolved. WMC was also planning to bring its Lamprecht lease in Texas into production in 1977 at a rate of 500,000 pounds of U_3O_8 per year. In Wyoming, WMC was constructing a solution-mining facility at its Irigaray property, 40 miles southeast of Buffalo. Plans called for a facility able to produce 500,000 pounds of U_3O_8 per year, to be operational in early 1978.

Other companies operating pilot solution mining operations in 1976 in Texas and Wyoming included KMC, Union Carbide Corp. (UCC), and Mobil Oil Co. Mobil's efforts in Webb County, Tex., reportedly may result in the country's largest in situ leaching operation.

Byproduct Uranium.—About 200 tons of byproduct uranium was produced in 1976 from mine waters, percolation leaching of ore in piles or vats, and wet-process phosphoric acid. Production of uranium from mine waters accounted for about half of the byproduct total. The only major heap-leaching operation in 1976 was a short campaign at UCC's Maybell, Colo., site.

RED acquired about 2 million tons of mill tailings at Naturita and Durango, Colo., from Foote Mineral Co. for solution recovery of uranium.[9] Tests indicated that 1.7 million pounds of U_3O_8, or about half of the uranium content, as well as substantial quantities of vanadium, were recoverable by acid leaching in impervious earthen tanks.

WMC and Kennecott Copper Corp. (KCC) were planning to construct a $6 million commercial facility to recover uranium from copper dump leach solution at KCC's Bingham Canyon, Utah, copper mine.[10] The installation will comprise two units, each processing 3,350 gallons of solution per minute through a continuous-ion-exchange loop. Production of 143,000 pounds of U_3O_8 per year is envisioned beginning in late 1977.

Production of uranium from wet-process phosphoric acid, although small in 1976, was expected to increase rapidly in the next few years and was projected to account for about 5% of domestic production in 1979.[11] The Uranium Recovery Corp. (URC), a subsidiary of UNC, was expected to begin commercial recovery of uranium in the latter half of 1977 at the W. R. Grace & Co. (WRG) phosphoric acid facility near Barstow, Fla. Startup of the uranium recovery module was delayed for more than a year owing to testing additional equipment and making process modifications. URC was planning to construct three additional modules beginning in 1977. When these four units are operational, URC will have the capacity to produce 1.3 million pounds of U_3O_8 per year.

Freeport Minerals Co. planned to construct a $32 million facility for the extraction of uranium at its wet-process phosphoric acid plant at Uncle Sam, La. The facility, which has a design capacity to produce 690,000 pounds of U_3O_8 per year, was expected to be ready for initial production in late 1978.

Gulf Oil and Minerals Corp. and WMC continued with pilot programs to recover uranium from wet-process phosphoric acid operations. Late in the year WMC announced that it was planning to build a 400,000-pound-per-year uranium recovery plant at the Farmland Industries Corp.'s phosphoric acid production facility near Barstow, Fla. Startup was expected in 1978 with commercial operation in 1979.

Mill.—Output of U_3O_8 in concentrate was 12,700 tons, about 10% higher than in 1975, owing mainly to a 19% increase in mill throughput. The mill feed grade continued to drop, averaging 0.154% U_3O_8 in 1976, down from 0.164% in 1975 and 0.174% in 1974. Sixteen conventional mills, one more than in 1975, plus two additional processing plants were operating at the end of 1976. The 16 mills operated at the highest average rate per mill ever attained (1,500 tons of ore per day), and the total tons of ore processed (8.9 million) exceeded that of the record years of 1960 and 1961 when more than 25 mills were processing ore. The mills operated at about 77% of capacity, and mill recovery decreased marginally, averaging slightly less than 93%. At yearend, total operable milling capacity was 31,160 tons of ore per day, an increase of 2,710 tons from 1975.

Source: Energy Research and Development Administration.

The Anaconda Company planned a $20 million expansion of its Blue Water uranium mill near Grants, N. Mex. The expansion, scheduled for completion in late 1977, would increase mill capacity from 3,000 to 6,000 tons per day and was expected to allow the processing of lower grade ores without affecting uranium output. Additional ore requirements were expected to come from the Jackpile-Pugate open pit mine at Laguna.

Getty Oil Co. and Skelly Oil Co. planned to reopen the Petrotomics mill in the Shirley Basin, Wyo., in late 1977 or early 1978. The mill, which has a capacity of 1,500 tons per day, was undergoing reconditioning plus process improvements in anticipation of processing ore from Getty's UJV properties in the Shirley Basin. Overburden removal from the UJV deposit began in early 1976, and mining was scheduled to commence in 1977.

Cotter Corp., a subsidiary of Commonwealth Edison of Chicago, announced plans for a $23 million expansion of its uranium mill at Canon City, Colo.[12] The expansion, which is designed to boost milling capacity from 450 tons per day to 1,000 tons per day, was expected to require the reopening of five mines on the Colorado Plateau, as well as increased ore production from the company's Schwartzwalder mine.

Uranium Hexafluoride (UF_6).—Two commercial operations—the Allied Chemical Corp. plant at Metropolis, Ill., and the Kerr McGee Corp. (KMC) plant at Sequoyah, Okla.—produced UF_6 during 1976. The conversion capacities of the two plants were 14,000 and 5,000 tons, respectively, of uranium as UF_6. KMC's program to double conversion capacity by early 1978 was on schedule. According to ERDA, the available annual conversion capacity of 26,450 short tons of uranium after the KMC expansion will be sufficient until about 1979.

Beker Industries Corp. delayed plans to build a plant at Carlsbad, N. Mex., for the conversion of uranium to UF_6. The company was, however, continuing feasibility studies on a plant expected to cost $100 million and have a capacity of 23,500 tons of UF_6 per year.

Enriched Uranium.—ERDA reported enrichment revenues of $588 million in 1976 for separative work furnished under enrichment contracts. A total of 9.6 million separative work units (SWU)[13] was carried out for 26 domestic and 17 foreign customers. At yearend ERDA held longterm enrichment services contracts covering 329,000 electrical megawatts of nuclear power. Of the total, 208,000 megawatts represented domestic nuclear powerplants and 121,000 megawatts represented foreign plants. Throughout 1976 the transacting tails assay continued at 0.20% U-235 and operating tails at 0.25% U-235.

The ongoing ERDA Cascade Improvement Program (CIP) and Cascade Uprating Program (CUP) were expected to increase the annual SWU capacity of the Government's three enrichment plants from 17.2 million to 27.7 million by 1981. These programs, costing about $1.5 billion, were on schedule in 1976. The additional separative work gain installed in CIP at yearend was about 1.3 million SWU per year; by October 1977, the gain was expected to total about 2.5 million SWU.

ERDA obtained preliminary approval to build an additional gaseous diffusion enrichment plant at Portsmouth, Ohio. Plans called for initial production from this plant in 1984 with full production in 1986. The plant, which has an estimated cost of $4.4 billion, was expected to add 8.75 million SWU capacity to the present enrichment plant complex. The plant is anticipated to allow continued enrichment operations, to have nearly optimum nuclear fuel production economics, and to permit the offering of new enrichment services contracts.

A proposed bill, the Nuclear Fuel Assurance Act, which would allow private industry to enter the enrichment field, failed to obtain congressional approval in 1976. As a result, the plans of four private groups proposing construction of enrichment facilities were uncertain at yearend. The Goodyear Tire & Rubber Co. dropped out of Uranium Enrichment Associates (UEA), the only company completely shelving its plans, and ARCO withdrew from CENTAR Associates. CENTAR, Exxon Nuclear Co., Inc. (ENC), and Garrett Nuclear Corp., each of which has proposals for 3-million-SWU-per-year gas centrifuge enrichment plants, have delayed their programs awaiting Government action.

In March, ENC and Avco Corp. applied for a license to operate a facility to test the enrichment of uranium by laser technology. A facility to be located at Richland, Wash., was scheduled for startup in 1978. Power consumption of a commercial laser enrichment plant was anticipated to be about 20% less than that of a gas centrifuge plant, and a laser plant was expected to require about half the acreage of a gas centrifuge plant.

Fuel Fabrication.—Fuel fabrication orders continued to increase in 1976, despite deferrals and rescheduling of nuclear powerplants by electric utilities. ENC completed the doubling of fuel fabrication facilities at its Richland, Wash., plant. Babcock & Wilcox Co. won a $21 million order for 34,000 fuel pins to be used in the Fast Flux Test Facility being constructed at ERDA's Hanford, Wash., complex. The fuel, which is in addition to 18,000 pins previously supplied, was to be fabricated at the company's Parks Township, Pa., facility.

In October, the Nuclear Regulatory Commission (NRC) reported its findings in the final environmental impact statement (EIS) on the use of recycled plutonium in light water reactors (LWR). The study indicated that the potential hazards to the public from the use of mixed-oxide fuel in LWRs was about the same as that from uranium alone.[14] An NRC decision on whether to permit wide-scale use of mixed-oxide fuel was to be based on the final generic environmental statement on mixed-oxide fuel (GESMO), expected in 1978.

Fuel Reprocessing.—Commercial fuels reprocessing continued in abeyance awaiting resolution of political and regulatory problems related to safeguards of plutonium, mixed-oxide fuel usage, and waste disposal. Nuclear Fuel Services, Inc. (NSF) announced that its West Valley, N.Y., nuclear-fuels-reprocessing plant, the only reprocessing plant ever to operate commercially in the United States, would not be renovated and reopened because of rapidly increasing costs.[15] NFS estimated that modifications to the plant required by new regulations and seismic criteria would cost $600 million, contrasted with the $15 million originally estimated in 1972 when the plant suspended operations to double capacity and improve efficiency. Disposition of about 600,000 gallons of radioactive reprocessing waste at the plant remained undetermined.

Allied General Nuclear Services Inc. (AGNS) completed the uranium separation and UF_6 facilities at its fuels-reprocessing plant at Barnwell, S.C., but was unable to proceed with design of the plutonium processing and waste solidification facilities because the standards had not been determined. Because of anticipated continuing delays in licensing, early utilization of AGNS's plant was expected to be related to implementation of an ERDA demonstration program for waste- and plutonium-processing facilities.

ENC planned a $1 billion complex at Oak Ridge, Tenn., for storing and reprocessing used nuclear fuel. The first phase of the project involved the building of a $300 million fuel storage facility that could hold fuel from 25 nuclear powerplants for 10 years; construction was proposed to begin in 1979 if NRC approval is obtained. The second phase entailed construction of a fuel-reprocessing center in the 1980's capable of reprocessing up to 2,100 tons of used fuel per year, enough to meet the needs of 40 nuclear powerplants.

A study by ERDA showed that recycling of LWR nuclear fuels has economic advantages over disposal of fuel elements after one use.[16] Other advantages of recycle were increased uranium availability and natural resource conservation.

Waste Management.—ERDA continued research on the terminal storage of high-level radioactive waste and was preparing a generic statement on the management of commercially generated radioactive waste. ERDA was expected to announce in 1978 a decision on waste forms, storage modes, and packaging criteria to be used as a basis for designing one or more terminal storage

[14]Nuclear News. NRC's Final EIS Supports Pu Recycle. V. 19, No. 13, October 1976, p. 33.

facilities. Also in 1978, the Environmental Protection Agency and NRC were expected to announce general environmental standards applicable to high-level waste management and storage. As part of the management program, the United States was appraising salt deposits in several sections of the country to identify sites suitable for an ERDA underground storage pilot program, expected to be in operation by 1985. Facilities equipped to receive solidified high-level radioactive waste were to be included in the pilot underground waste disposal program.

Low-level commercial wastes were buried at six sites in the States of Kentucky, Nevada, South Carolina, Illinois, New York, and Washington in 1976. About 2 million cubic feet of waste was added to these sites in 1976, increasing the total to about 16 million cubic feet. These sites were estimated to have the capacity to handle low-level wastes until the mid-1990's. ERDA operated large land burial sites at five principal facilities for ERDA-generated waste. These sites contained about 45 million cubic feet of radioactive waste, exclusive of classified waste. About 1.3 million cubic feet was added in 1976.

CONSUMPTION AND USES

Domestic nuclear reactor orders totaled three in 1976, the lowest megawatt amount ordered since reactor units became commercially available in 1965. The three orders (3,720 megawatts), all obtained by Babcock & Wilcox Co., were reorders of reactors that were canceled in 1975.

The nuclear industry continued to encounter many environmental and regulatory problems, as well as reduced electrical load growth. As a result, utilities continued to defer, delay, or cancel nuclear reactor programs. Projections of nuclear power growth were also reduced. The number of nuclear units expected to be in commercial operation in 1985 was 178, compared with a 1975 estimate of 184.

Seven power-generating units (6,796 megawatts electric) were licensed to operate, and 10 were expected to come onstream in 1977. Domestic reactor status at yearend follows:

Status	Number of instal-lations	Capacity (megawatts electric)
Operable	[1]65	46,391
Under construction	90	95,195
Planned	82	94,878
Total[2]	237	236,464

[1]Includes two ERDA-owned plants.
[2]This compares with 238 units and 236,728 megawatts electric at yearend 1975.

About 10% of the total U.S. electrical power generation capability was nuclear based in 1976. Nuclear power supplied 191 billion net kilowatt-hours or 9.4%, of the Nation's electricity in 1976, compared with 170 billion kilowatt-hours or 8.9%, in 1975. According to an Atomic Industrial Forum survey, nuclear-generated electricity based on total generating costs averaged 1.5 cents per kilowatt-hour, compared with 1.8 cents per kilowatt-hour for coal and 3.5 cents per kilowatt-hour for oil.

An ERDA survey of uranium producers, utility companies, and reactor manufacturers indicated that uranium supply arrangements for planned U.S. nuclear fuel capacity improved considerably in 1976.[17] Domestic uranium-buying activity reached its highest level, resulting in additional procurement of 83,400 tons of U_3O_8 in concentrate. This total exceeded the previous high of 45,800 tons in 1973 and was over 5 times higher than the 16,200 tons added in 1975. Buyers were becoming directly involved in U_3O_8 production to obtain their fuel supplies. Twenty-five utilities were participating in uranium raw materials activities in one stage or another. About half of additional 1976 supply was scheduled to come from mine production controlled by uranium buyers.

Table 9.—Current and projected domestic U_3O_8 demand[1]

(Short tons)

Year	Demand	
	Annual	Cumulative
1976	10,700	10,700
1977	12,300	23,000
1978	19,800	42,800
1979	24,400	67,200
1980	28,600	95,800
1985	39,900	280,900
1990	45,100	499,300

STOCKS

Uranium concentrate stocks held by the producers or by milling companies were reduced during 1976, whereas those held by the consuming industry increased by 3,200 tons of U_3O_8, as indicated in the following data provided by ERDA (in tons of U_3O_8):

	Jan. 1, 1976	Dec. 31, 1976
In ore at mills	200	300
In process at mills	400	600
In concentrate at mills	2,700	2,500
In concentrate held by utility companies, reactor manufacturers, and agents (including equivalent U_3O_8 in UF_6)	22,600	25,800
Total	25,900	29,200

[17]Energy Research and Development Administration. Survey of United States Uranium Marketing Activity. ERDA 7-46, April 1976. 28 pp.

A 3,500-ton inventory of foreign U_3O_8 was also reported at yearend 1976, compared with 1,100 tons one year earlier. Overall, domestic stocks were an estimated 32,700 tons of U_3O_8, up 5,700 tons from 1975.

The stockpile of depleted uranium continued to grow as a result of large-scale enrichment services provided for domestic and foreign customers. The ERDA tailings stockpile contained about 235,000 tons of uranium in the form of UF_6 at yearend 1976.

PRICES

The price for spot sales and future deliveries of U_3O_8 in concentrate continued to rise during 1976. The strong sellers' market that developed in 1974 continued to be reflected in newly negotiated 1976 contracts, many of which called for prepayments, price adjustments, or payments based on prices prevailing at the time of delivery. According to the Nuclear Exchange Corp. (Nuexco), the spot bid price increased from \$35 per pound of U_3O_8 for delivery in January to \$41 at yearend. During this period, the bid price for delivery in 1980 increased from \$47.35 to \$53.85.[18]

An ERDA survey indicated significantly lower average U_3O_8 prices paid by reactor manufacturer and utility companies having long-term contracts.[19] According to the survey, contract prices representing 91% of commitments ranged from \$6 to \$43 per pound of U_3O_8, averaging \$16.10. In 1975 the average price per pound of U_3O_8 was \$10.50. An average price of \$18 per pound of U_3O_8 was indicated by the survey in 1980.

Uranium ore was purchased at the GE ore-buying station at Naturita, Colo., for 95% of one-half the listed spot price per pound of contained U_3O_8. A minimum of 2 pounds of U_3O_8 per ton of ore was required for purchase.

The costs for enrichment services continued to rise because of increasing operating expenses at ERDA's three enrichment facilities. In April, fixed-commitment contract holders were paying \$59.05 per SWU, an increase of \$5.70. Customers with requirements-type contracts began paying \$67.25 per SWU in August. The previous price was \$60.95 per SWU.

Depleted uranium metal in 300-pound ingots (Derby metal) was priced at \$2 per pound.

FOREIGN TRADE

Uranium imports were largely in the form of U_3O_8 concentrate and UF_6. Most imports were for enrichment services rather than for domestic consumption. Since imports are not differentiated in official statistics, precise figures on uranium imports for domestic consumption are not available. According to data compiled by ERDA, uranium imports amounted to 2,900 tons of U_3O_8 in 1976, 1,800 tons more than in 1975. In 1976, an additional 1,800 tons of foreign U_3O_8 was contracted for by the domestic industry bringing the total foreign procurement for future delivery to 43,200 tons.

Restrictions on the enrichment of foreign uranium for domestic use continued to yearend 1976. Beginning in 1977, the enrichment of up to 10% of a utility's uranium requirements could come from foreign sources. The allowable percentage was to be

increased each year until 1984, when 100% of a utility's uranium requirements could come from imported material. Commitments by domestic uranium producers to sell uranium to foreign buyers increased by 2,600 tons of U_3O_8 during 1976, raising the total forward commitment to 5,500 tons. ERDA reported that 600 tons of U_3O_8 was delivered to foreign buyers in 1976.

The worldwide spread of nuclear technology, relative to the prevention of proliferation of nuclear weapons, gained increasing attention in 1976. Bills were introduced in Congress that would limit or halt exports of U.S.-enriched uranium and technology and would restrict other countries.

In October, the President called for a 3-year international moratorium on exports of reprocessing and enrichment facilities to prevent nuclear proliferation. There were objections by Western European countries, Japan, and many developing countries, primarily because they lack suitable energy alternatives and view nuclear power and the breeder reactor as their future sources of energy. Legislative action on the proliferation policy was expected in 1977.

WORLD REVIEW

Uranium exploration continued to expand on a worldwide scale. Many countries had some form of exploration program underway or planned in 1976. Few major deposits were discovered; however, uranium reserves increased significantly. Estimated world uranium reserves to $30 per pound of U_3O_8 were about 2.4 million tons of U_3O_8. An additional 2.1 million tons of U_3O_8 of resources was indicated.

Forecasts for nuclear power growth outside the United States continued to decline, mainly because of 2 years of poor economic growth and diminishing growth rates for electricity consumption. Public opposition was also rising. Projections by ERDA indicated that the world's nuclear generating capacity was expected to grow from the 1976 level of about 86 gigawatts to over 1,500 gigawatts by the year 2000. 2000.[20] Foreign growth was expected to occur largely in Western Europe and Japan to the year 2000; significant growth in the developing countries was anticipated after 1990. At yearend, the European Economic Community (EEC) Commission projected that installed nuclear capacity by 1985 in EEC countries would be about 125 gigawatts, about 50 gigawatts less than projected 2 years earlier.

Despite lower forecasts, nuclear power continued to be the fastest growing electrical energy form, and worldwide, operable capacity increased from 75,103 megawatts in 1975 to 86,657 megawatts in 1976.

According to yearend data compiled by the American Nuclear Society, 111 plants

outside the United States were operable in 18 countries and 187 nuclear units were planned in 30 countries. This compares with 104 plants operable in 18 countries and 168 units planned in 29 countries at the end of 1975. Most of the planned units were scheduled for completion by 1985. Tables 15 and 16 indicate the foreign nations having operable or planned nuclear powerplants at the end of 1976.

[1]Under construction or ordered as of Dec. 31, 1976.

Source: American Nuclear Society.

Western Europe and Japan continued to rely on enrichment services from the United States, but the Europeans planned to become self-sufficient in enrichment in the mid-1980's. Urenco Ltd., a tripartite organization of the Netherlands, the United Kingdom, and West Germany, was commissioning commercial gas-centrifuge enrichment plants at Almelo, Netherlands, and at Capenhurst, United Kingdom. The first sections of both full-scale production plants, having capacities of 200,000 SWU, were completed in late 1976. Plans called for Urenco capacity to reach 2 million SWU annually by 1982 and 10 million SWU annually by 1985. Deliveries of enriched uranium reportedly were made from Urenco's two 50,000-SWU-per-year-capacity pilot enrichment plants. Eurodif, a five-nation consortium comprising France, Belgium, Iran, Italy, and Spain, continued construction of a gaseous diffusion enrichment plant at Tricastin, France. The plant was expected to have a 2.3-million-SWU capacity by 1979, increasing to 10.8 million SWU per year by 1982. Another group, Coredif, a joint venture of the Eurodif partners, was planning to construct a similar-sized, diffusion-enrichment facility, to meet projected shortfalls in enrichment capacity in the mid-1980's.[21] Although the site for the Coredif plant was undecided, the first stage, having a 5-million-SWU-per-year capacity, was anticipated to be onstream in 1985 with full production in 1988.

Other countries were also building or planning to build enrichment pilot plants. Japan's Power Reactor and Nuclear Fuel Development Corp. (PRF) was proceeding with the construction and operation of a 50,000-SWU-capacity pilot centrifuge enrichment plant. PRF proposed building a 500,000-SWU demonstration plant by 1984, followed by a 1-million-SWU-capacity commercial plant by 1988, and increasing overall capacity to 4 million SWU by 1995. The Uranium Enrichment Corp. (UCOR) of the Republic of South Africa completed its pilot plant at Valindaba and tested the feasibility of its stationary-wall centrifuge technique. UCOR planned to proceed with a commercial-scale plant, estimated to have a

[21]Nuclear News. Nuclear News Briefs. V. 19, No. 13, October 1976, p. 97.

5-million-SWU annual capacity. Initial production was planned for 1984, followed by full output in 1986. West Germany's plans to build a 180,000-SWU-per-year demonstration enrichment plant in Brazil using an advanced nozzle-enrichment method were delayed awaiting clarification of the West German Government's proliferation policy. A large-scale commercial plant with a capacity of 1 to 2 million SWU per year was envisioned if the program is carried out.

Progress continued toward solving problems in the back end of the fuel cycle. Research programs dealing with spent fuel storage, reprocessing, and waste management continued in those countries having large nuclear programs. British Nuclear Fuels Ltd. (BNFL) planned to spend $1.8 billion over the next 5 years at the Windscale site to provide greatly increased reprocessing and waste treatment capacity. A 1,300-ton thermal oxide reprocessing plant was proposed, based mainly on the need to reprocess fuel from the United Kingdom's Magnox program and on fuel-reprocessing contracts from Japanese utilities.

La Compagnie General des Matieres Nucleaires (Cogema), the French Government fuels-reprocessing company, also planned to greatly increase reprocessing capacity. Cogema began oxide reprocessing in May at its plant at La Hague. The facility, which will primarily be devoted to the processing of imported fuels, was scheduled to have a capacity of 800 tons per year by 1980. A consortium of Japanese companies was planning to establish a fuels-reprocessing company to process all nuclear fuels used by utilities in Japan. Plans called for the establishment of a 1,500-ton-per-year facility by 1987. Most Japanese fuels were scheduled to be reprocessed by BNFL and Cogema in Europe prior to full development of the reprocessing industry in Japan. A small (40-ton-per-year) reprocessing plant owned by the Power Reactor and Nuclear Fuel Development Corp. (PNC) at Tokai Muri had difficulties in 1976 and was not expected to be commissioned until late 1977.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed Brazil, Czechoslovakia, Finland, East Germany, West Germany, Hungary, India, Israel, Japan, the People's Republic of China, and the U.S.S.R. are believed to have produced uranium oxide, but information is inadequate to make reliable estimates of output levels.

[2]Data represent shipments. Official production was reported as follows in short tons: 1975—[r]4,565; 1976—6,252.

Argentina.—A 600-ton-per-year uranium mine-mill complex was planned at Comision Nacional de Energia Atomica's (CNEA) uranium deposit at Sierra Pintala in Mendoza Province, 500 miles west of Buenos Aires. CNEA projected that this operation, expected to start in mid-1979, could supply the country's uranium needs for 15 years.

A new mill at Los Adobes in Cherbut Province started up in June and was expected to produce about 6 tons of yellowcake per month beginning in 1977. CNEA was expecting the country's uranium output to exceed 130 tons in 1977 as a result of the new operation; 1976 output was about 44 tons.

Australia.—Uranium exploration, after several years of intense effort, was at reduced levels in 1976, as companies waited for clarification of Government policy on production and exports. The first Fox Commission report endorsed uranium mining and milling; however, development of uranium deposits in the Northern Territories was not to be allowed until a second Fox report on the Ranger deposit was issued. An interim report released in October indicated that development might be limited in 1977.

In November the Government granted export permits for earlier uranium sales contracts for Mary Kathleen Uranium Ltd. (MKU), Queensland Mines Ltd. (QM), and the Ranger deposit of Electrolytic Zinc Co. of Australasia Ltd. and Peko-Wallsend Mines Ltd. Because production from QM or Ranger was not expected for a few years, deliveries from government stocks were to be permitted to meet early delivery commitments.

The Government was dropping out of active uranium exploration and selling its participation in uranium mining ventures. Government policy requiring 75% Australian ownership in uranium projects before production begins, however, was continued.

In June, the South Australian Government announced that a 2-year feasibility study of a proposed $1.6 billion uranium gas-centrifuge enrichment plant would be carried out. The proposed plant, which would include a hexafluoride conversion facility, was to be sited at Redcliffe near Port Augusta.

Australia's reasonably assured uranium resources recoverable at less than $15 per pound of U_3O_8 in June totaled 250,000 tons, an increase of almost 48,000 tons over the $10 reserves estimated 1 year earlier.[22] The addition was due primarily to a substantial increase in the reserves at the Jabiluka 2 deposit in the Northern Territory.

MKU resumed operations in May at the Mary Kathleen mine in Queensland producing at a rate of about 1,000-tons of U_3O_8 per year. Reserves at the mine were sufficient for about 8 years' operation. Shipments of concentrate, all for export, were delayed for much of the year owing to strikes by the transportation unions.

Western Mining Corp. Ltd. planned to build a $15 million alkali-leach pilot plant as part of the development of the Yeelirrie uranium deposit in Western Australia. Commercial development was, however, dependent on Government approval of export contracts.

[22]Australian Atomic Energy Commission. Twenty-Fourth Annual Report. 1975-76, 135 pp.

Brazil.—Empresas Nucleares Brazileiras S.A. (Nuclebras), a Government agency, spent about $20 million on uranium exploration in 1976. Extensive uranium reserves were reportedly found in Goías State near Amarinopolis, 300 miles southeast of Brasilia.[23] A new company, Nuclebras Auxiliar de Mineração (Nuclam), owned 51% by Nuclebras and 49% by West Germany's Urangesellschaft MbH, began uranium exploration programs in the States of Paraíba and Santa Catarina. This company was the first of a group of nuclear ventures to be established under a nuclear cooperation agreement signed in July 1975.

According to Nuclebras, Brazilian uranium reserves totaled about 29,000 tons of U_3O_8. The principal deposits and estimated tonnage follow:

Deposit	Tons of U_3O_8
Pocos de Caldas (Minas Gerais)	15,300
Figueira (Parana)	5,300
Quadrilatera Ferrifero (Minas Gerais)	4,500
Amarinopolis (Goias)	3,300
Campos Belos (Goias)	600
Total	29,000

Nuclebras planned a $30 million mine-mill facility at Poços de Caldas. Production was scheduled to start in 1979 at a rate of 500 tons of U_3O_8 per year.

Canada.—Uranium production, 6,252 tons of U_3O_8 in 1976, was 37% higher than in 1975. One new mine was brought into production and established producers were well advanced with expansion programs.[24]

Exploration activity continued to increase, and significant mineralization was found in several areas, most notably at Key Lake in Saskatchewan.

The Canadian Government continued its Uranium Reconnaissance Program, which is similar to ERDA's NURE program but smaller in scope. During 1976, the program covered approximately 214,000 square miles including 174,000 by airborne gamma spectrometry and 85,000 by regional geochemistry.

In late December, the Dominion Government announced that exports of uranium and Canadian nuclear reactors will be allowed only to countries that ratify the Non-Proliferation Treaty or otherwise accept international safeguards for their nuclear programs. The new policy became effective on January 1, 1977.

Canada's national uranium policy, enacted late in 1974, requires at least a 30-year reserve for nuclear fuel for existing, committed, and planned reactors in any 10-year forward period. Allocations amounting to 21% of each producer's reserves have been applied to provide for the 30-year fueling requirements of about 90,000 tons of U_3O_8 for the 16,240 megawatts of nuclear capacity expected to be operating in Canada by 1987. As of June 1976, uranium producers had export commitments of about 110,000 tons of U_3O_8 and domestic commitments of 33,000 tons of U_3O_8. Production was expected to increase significantly in the next 10 years to meet contract commitments and anticipated demand for uranium. Uranium output was expected to reach 10,300 tons of U_3O_8 in 1980 and 16,200 tons in 1984.[25]

Government estimates of Canada's recoverable uranium resources in short tons follow:

Minable	Measured	Indicated	Inferred
Up to $40 per pound of U_3O_8	103,000	115,000	309,000
Up to $60 per pound of U_3O_8	5,000	14,000	90,000
Total	108,000	129,000	399,000

Uranium production in 1976 came from five operations—Denison Mines Ltd., Rio Algom Ltd., and Madawaska Mines Ltd., in Ontario, and Eldorado Nuclear Ltd. (ENL) and Gulf Minerals Canada Ltd./Uranerz Canada Ltd. in northern Saskatchewan. Shipments from these operations totaled 6,678 tons of U_3O_8, an increase of 595 tons over those of 1975.

Denison Mines Ltd. reported increased uranium output for the third successive year, reaching 1,556 tons of U_3O_8, about 7% higher than in 1975. Mill throughput was up 13.6% to about 1.7 million tons, but ore grade decreased from 2.30 pounds of U_3O_8 per ton to 2.16 pounds. The mill expansion to 7,100 tons of ore per day was completed

[23] American Metal Market. Brazilian Geologists Discover Extensive Uranium Reserves. V. 83, No. 146, July 20, 1976, p. 8.

[24] Williams, R. M. Uranium. Can. Min. J., v. 98, No. 2, February 1977, pp. 145-160.

[25] Canadian Department of Energy, Mines and Resources. 1976 Assessment of Canada's Uranium Supply and Demand. Report EP 77-3, June 1977, 19 pp.

in early 1976, and the company was increasing ore output to run the mill at capacity. Ore-handling capacity was to be increased, and the No. 1 shaft was being rehabilitated for use as a production shaft.

In October, Rio Algom announced plans to reactivate the Panel mine and mill which are east of the company's Quirke mine.[26] The project, expected to cost about $100 million, was to be completed in 1980. Initial mill capacity was planned at 3,000 tons per day. Rio Algom was also well along with its $76 million expansion of the Quirke complex. The expansion of mill capacity from 4,500 tons per day to 7,000 tons per day was expected to be completed in 1978.

ENL continued a 5-year, $44 million program to increase uranium production at the Beaverlodge mine and mill in Saskatchewan. Plans called for increasing output to 1.5 million pounds of U_3O_8 by yearend 1977 and to 2 million pounds of U_3O_8 by 1979. Production in 1976 was 1,187,846 pounds of U_3O_8.

The Gulf/Uranerz uranium operation, which began production at Rabbit Lake, Saskatchewan, in late 1975, reached full capacity in the third quarter of 1976. The company, which has a mill designed to process 1,800 tons of ore per day, anticipated an annual production of about 2,200 tons of U_3O_8.

Madawaska Mines Ltd., a joint venture of Federal Resources Ltd. (51%) and Consolidated Canadian Faraday Ltd. (49%), reopened the Faraday mine and mill and began ore production at a daily rate of 750 tons in August.[27] Full capacity, 1,500 tons of ore daily, was expected in early 1977. Amok Ltd., owned entirely by French interests (Compagnie de Mokta, Cie. Française des Minerais d'Uranium, Péchiney Ugine Kuhlmann, and Commissariat à l'Energie Atomique), planned to bring its Cluff Lake deposit in northern Saskatchewan into production in 1977. A two-phase operation was envisioned, at a total cost of $133 million. The first phase involved the mining and milling of high-grade ore from the D-ore body at a rate of about 80 tons per day in 1979, followed by a second-phase mill with a milling rate of 1,200 to 1,500 tons per day in 1981 or 1982 for an annual output of 1,700 tons of U_3O_8. Amok's development program could be significantly delayed, however, owing to a yearend announcement by the Saskatchewan Government that it planned to hold hearings relative to the Cluff Lake operation. Agnew Lake Mines Ltd. (ALM) completed a $3 million program, begun in 1974, to test large-scale leaching of uranium from broken ore both on surface and underground. In March, ALM announced a $37 million project designed to produce 1 million pounds of U_3O_8 per year.[28] The mine, near Espanola, Ontario, was dewatered, and underground development was in progress.

France.— COGEMA, a new group formed by the Commissariat à l'Energie Atomique, was the major uranium producer with a mine output from three operations of 2,258 tons of U_3O_8 in 1976, or almost 84% of total production. Production from France's eight active uranium mines, in tons in 1976 follows:

Mine	Ore production	U_3O_8 content
Limousin	377,000	963
Vendée	384,000	697
Forez	139,000	598
Lozere	151,000	211
Creuse	16,000	65
Morbihan	8,000	47
Corrèze	8,000	35
Cantal/Creuse	36,000	84
Total	1,119,000	2,700

Uranium concentrate output was 3,144 tons of U_3O_8, of which 788 tons was derived from preconcentrated material imported from Gabon.[29]

Italy.—AGIP Mineraria planned to develop uranium deposits near Novazza in Bergamo Province. Mining operations were expected to begin in 1979 and to continue for about 10 years.[30] Mineralization occurs in small separate deposits, the largest of which contains about 1,650 tons of U_3O_8.

Mexico.—The Institute Nacional de Energia Nuclear (INEN) increased its efforts to provide the uranium necessary to sustain Mexico's nuclear power program, projected to be 15,000 megawatts electric by 1990. The program was estimated to require 250 million pounds of U_3O_8. Exploration activity was centered in the States of Chihuahua and Tamaulipas, where significant deposits have been found. The major deposits were Las Margaritas, with reserves of 9 million

[30]Mining Magazine. Italian Uranium. V. 135, No. 5, November 1976, p. 475.

pounds of U_3O_8 and Nopal with reserves of 2 million pounds of U_3O_8, in Chihuahua State, and LaComa and Buenavista with reserves of about 6 million pounds of U_3O_8 in Tamaulipas State.

Niger.—The Arlit mine of Sociètè des Mines de L'Air (SOMAIR), an international consortium composed of Niger, French, Italian, and West German interests, was the only uranium producer in 1976. Production was 1,898 tons of U_3O_8 in 1976, compared with 1,820 tons in 1975. Another international consortium (Niger, French, Japanese, and Spanish), the Compagnie Miniere d'Akouta, was developing the Akouta uranium mine 5 miles south of the Arlit mine. The Akouta mining complex, which will cost $200 million, was expected to begin production in 1978 and reach an output level of 2,200 tons of U_3O_8 annually by 1980.

At Imouraren, a joint venture composed of Niger's Uraniger (30%), Continental Oil Co. (35%), and the French Commissariat à l'Energie Atomique (35%) expected to complete the drilling of 500 exploratory holes by mid-1977. Results have been favorable, and production might be possible by 1981.

Major exploration for uranium was carried out by several foreign companies in 1976. Most efforts were centered in 10 concession areas largely in the north-central and northeast parts of Niger.

South Africa, Republic of.—In 1976, uranium output, as a byproduct and coproduct from eight gold mines and one copper mine, totaled 3,587 tons of U_3O_8, an increase of 353 tons over that of 1975. The uranium content in gold ore processed continued to decline, decreasing from 0.454 pound of U_3O_8 per metric ton in 1974 to 0.417 pound in 1975 and to 0.397 pound in 1976. Production by gold mines in 1976 follows:

Mine	Pounds of U_3O_8
Blyvooruitzicht	288,996
Buffelsfontein	1,337,994
Harmony	1,096,344
Hartebeestfontein	768,734
Vaal Reefs	2,233,658
West Driefontein	500,945
Western Deep Levels	308,702
West Rand Consolidated	325,189
Total	6,860,562

Palabora Mining Co. reported a 1976 production of 315,926 pounds of U_3O_8 in calcine, an increase of about 40,000 pounds over 1975.

Government estimates indicated that expected uranium oxide output for South Africa and South-West Africa would be about 10,000 tons by 1978. The Anglo American Corp. of South Africa Ltd. opened its large-scale coproduct complex at its President Brand mine in the Orange Free State in August. The complex and beneficiation plants are designed to process tailings slime from seven area mines—President Brand, President Steyn, Free State Geduld, Welkom, Western Holdings, Free State Saayplaas, and Freddies. Principal products expected to be produced were pyrite for sulfuric acid production, gold, and uranium. When fully operational, annual uranium oxide output was projected to be about 1.3 million pounds.

East Rand Gold and Uranium Co. Ltd. planned to extract uranium, gold, and pyrite from 19 slimes dams containing about 415 million tons of slime at an overall grade of 0.015 troy ounce of gold, 1.16 pounds of uranium, and about 21 pounds of sulfur per ton of slime. Commissioning of the various plants was planned for late 1977 with production starting in early 1978. Annual production, after a few months' buildup period, was expected to be 7.7 tons of gold, 220 tons of uranium, and 580,000 tons of sulfuric acid.

Vaal Reefs Exploration and Mining Co., Ltd., and Randfontein Gold Mines, Ltd., were both expanding their uranium plants. West Rand Consolidated, Ltd., a nonproducer of uranium in 1975, owing to modernization and expansion of its uranium plant, resumed uranium production in 1976. The upgraded plant has an annual capacity of about 1 million pounds of U_3O_8.

South-West Africa, Territory of.—In October, Rossing Uranium Ltd. announced that full production would be delayed 18 months to 1978 owing to the need for ore-processing equipment replacement and mechanical changes to rectify construction faults. Estimated uranium output in 1976 was 770 tons of U_3O_8. Production was expected to reach half the ultimate production level, 5,000 tons U_3O_8 annually, by mid-1977.

General Mining and Finance Corp. Ltd. reported the finding of a large calcrete-type uranium deposit at Langchenrich in the Swakopmund district. Metallurgical problems were delaying development of the deposits.

Sweden.—Luossavaara-Kiirunavaara Aktiebolag planned to develop a small uranium mine at Pleutajokk in Lappland to supplement production from the Ranstad mine in southern Sweden. Plans called for the mining of 200 tons of ore per day beginning in 1980. The Pleutajokk deposit was estimated to have 2,200 tons of U_3O_8 reserves. Planned expansion of the Ranstad mine was postponed because of environmental problems.

TECHNOLOGY

ERDA continued to enlarge its NURE program, stepping up both airborne radiometric and geochemical surveys and developing new technologies to improve uranium exploration mining and extraction.[31] Many reports and maps resulting from the program were published in 1976.[32] In June, ERDA issued the preliminary NURE report.[33]

The U.S. Geological Survey and ERDA continued development of automated delayed neutron activation analysis and design, and tested a downhole californium-252 neutron-generating probe capable of detecting uranium concentrations as low as 0.01%. In the United Kingdom, a towed seabed spectrometer, used for continuous seabed surveys, was developed.[34] The device has operated at depths up to 1,000 feet. The alphameter, an instrument that measures alpha particles emitted by radon, reportedly was easier to use, cheaper, and more reliable than older uranium emanometer prospecting methods.[35]

A rapid procedure for measuring uranium in natural waters using thermal neutron activation and anion-exchange separation of uranium was reported to have a detection limit of 0.05 part per billion.[36] A comparison of analytical methods to determine uranium in granitic rocks was made.[37] A combination of delayed-neutron determinations for uranium and gamma ray spectrometric analyses of radium equivalent uranium, thorium, and potassium provided the best data base for geochemical prospecting.

Increasing demand and high uranium prices continued to stimulate Government and industry interest in solution mining as a means to reduce investment and construction lead times, to produce from low-grade ore bodies, and to minimize environmental problems. A generalized cost model for current solution mining practices was developed.[38] Operating costs accounted for 60% of total costs and capital costs for about 40%. Estimated costs per pound of production ranged from $13.94 for a 1-million-pound-of-U_3O_8-per-year operation to $17.19 for a 250,000-pound operation.

The Bureau of Mines expanded its research and development work on processing technology for recovering uranium from low-grade and refractory ores. Beneficiation and leaching of granites from Wyoming and Vermont were studied. Also investigated in 1976 were ores resistant to acid leaching; these ores proved to be readily leachable after they were subjected to autoclave oxidation or to roasting.

The South African National Institute for Metallurgy was developing and pilot-plant-testing a lower cost continuous-ion-exchange (CIX) process for uranium extraction.[39] Capital costs of a uranium plant using the CIX process were estimated to be 20% lower than costs of one using the Purlex process. Resin use was also cutto one-third to one-half that of fixed-bed ion exchange, and unlike Purlex, CIX operated satisfactorily in solutions containing suspended solids. The process reportedly was particularly well suited to in situ and heap leaching solutions.

Another process similar to the CIX process was undergoing pilot plant tests to extract uranium at Elliott Lake, Canada. The first full-scale installation was to commence operation at a new Canadian uranium mill in 1977.[40]

[40] Mining Journal (London). Ion Exchange Technique Used for Uranium Extraction in Canada. V. 287, No. 7354, July 30, 1976, p. 82.

Research continued on novel uranium-enrichment methods.[41] A variation of the West German nozzle process using a higher percentage of carrier gas was believed to accelerate the lighter uranium isotopes. The technique is called "seeded beam separation." Asahi Chemical Industry Co., Ltd., in Japan reported that it had successfully developed a technique combining chromatography and ion-exchange resin for enriching uranium.[42] Power consumption was estimated at half that required by gas centrifuge methods. TRW, Inc. was developing a method of uranium isotope separation by a plasma-electromagnetic effect, known as the Dawson separation process.[43] In the Dawson process, natural uranium is introduced into a plasma and subjected to magnetic and radio frequency fields. The U-235 nuclei resonate to different fields than other uranium isotopes and then can be isolated.

NRC continued efforts to improve LWR safety. Research was directed toward developing methods of calculating the course of events if an accident should begin. To assist this effort, NRC conducted tests at the Power Burst Facility (PBF) at the Idaho National Engineering Laboratory to provide data to define the behavior of nuclear fuels under abnormal and hypothetical accident conditions. The Loss-of-Fluid-Test program (LOFT), NRC's largest experimental facility, was completed, and the first experiments were conducted in 1976. The LOFT facility was designed to provide verification of analytical methods used for prediction of integrated system behavior in a loss-of-coolant accident.

ERDA continued its basic research and development program on four breeder concepts—the liquid metal fast breeder reactor (LMFBR), the light water breeder, the gas-cooled breeder, and the molten-salt breeder. Reference designs, work schedules, and cost data were established for the demonstration Clinch River LMFBR in Tennessee. ERDA planned to have the facility completed in 1983; however, late in the year the President indicated that he would recommend delaying the development of the breeder reactor. The Flux Test Facility for testing breeder fuels and materials, and for safety and reactor development experience, was expected to be completed in 1977. Progress was made in studies on advanced oxide fuels and higher breeding mixed uranium-plutonium carbide and nitride fuels.

Development of the Actinide Nitride-Fueled (ANF) reactor was proposed as a possible means to recycle nuclear waste, sharply reduce problems of environmental safety and radioactive waste storage, and minimize the risks of theft or attack by terrorists.[44] The recycling aspects of the system reportedly would permit almost 90% cost savings over presently accepted methods.

Research directed toward preventing theft of weapons-grade uranium and plutonium increased substantially in 1976. Plant security improved, and proposals for international fuel fabrication and reprocessing centers were advanced. ERDA proposed co-processing of uranium and plutonium in mixed oxide fuels in order to prevent plutonium from existing as a separate entity anywhere in the fuel cycle. Battelle Columbus Laboratories was studying the addition of long-lived actinides to fuel elements, which would make the fuel elements so radioactive that remote control equipment is required, thereby making theft difficult. Similarly, irradiation of fuel elements to make them too radioactive to handle was proposed.

Conversion to a thorium fuel cycle was advanced as a means to help prevent worldwide proliferation since very little plutonium is created in the cycle and the bred U-233 can only be separated from the other uranium isotopes present by enrichment techniques.[45]

Vanadium

By Grace N. Broderick[1]

Consumption of vanadium in 1976 in the United States was 14% less than in 1975, and 34% less than the alltime high of 7,200 short tons of contained vanadium reported in 1974. Domestic production of vanadium oxide, however, was considerably higher than in 1975. Arkansas, for the fifth consecutive year, was the leading vanadium-producing State. Both exports and imports of ferrovanadium increased in 1976. Exports classified as ores, concentrates, oxides, and vanadates were at a much lower level than in 1975. Vanadium pentoxide imports, which until 1974 were insignificant, accounted for about 16% of total vanadium imports for consumption in 1976. U.S. price quotations for the principal vanadium materials, which remained stable in 1975, increased about 10% in mid-1976.

Requests for high-purity vanadium metal continued to be received by the Bureau of Mines; a total of 16 pounds was supplied to the Oak Ridge National Laboratory and to the University of Illinois for research purposes.

[1]Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

[2]Produced directly from all domestic sources and includes metavanadates.

[3]Less than 1/2 unit.

Legislation and Government Programs.—As of December 31, 1976, the physical inventory of the U.S. Government stockpile remained at 540 tons of vanadium, all in the form of vanadium pentoxide. New stockpile goals for strategic and critical minerals were announced by the General Services Administration on October 1; those for vanadium were 10,095 tons of ferrovanadium and 2,576 tons of vanadium pentoxide.

[1]Physical scientist, Division of Ferrous Metals.

DOMESTIC PRODUCTION

Four mills produced vanadium pentoxide from domestic sources in the United States during the year. Union Carbide Corp. continued to operate both its Uravan-Rifle mill complex in Colorado, and its Hot Springs, Ark., mill; Kerr-McGee Corp. operated its Soda Springs, Idaho, plant; and Atlas Corp., Moab, Utah, began recovering vanadium early in 1976. Colorado Plateau uranium-vanadium ores, Arkansas vanadium ore, and Idaho ferrophosphorus constituted the domestic raw materials that were run through the mills. Other sources included vanadium-bearing slags from Chile, •the U.S.S.R., and the Republic of South Africa and spent catalysts and powerplant residues from U.S. and Caribbean sources. Vanadium recovered from imported vanadium-bearing materials was not included in any of the production figures shown in the tables, nor was the vanadium recovered directly from slags or residues as ferrovanadium or similar products.

The Cotter Corp., a wholly-owned subsidiary of Commonwealth Edison Co., Inc. of Chicago, awarded a contract for the design and construction of a $26.1 million uranium-vanadium processing facility at Canon City, Colo. In addition to a new ($23.5 million) mill that will process 1,000 tons of ore per day, the facility will include a plant ($2.6 million) for recovery of vanadium, molybdenum, nickel, cobalt, and tungsten from spent catalysts. Startup of the mill is not expected until 1978 or early 1979.

Ranchers Exploration and Development Corp. planned to rework, for its residual uranium-vanadium content, tailing remnants of uranium-vanadium milling operations conducted in 1943-63 at Naturita and Durango, Colo., by Vanadium Corp. of America. The tailings totaled around 2 million tons; about 600,000 tons of this is located at Naturita, and 1.5 million tons is at Durango. The tailings will be removed from their present sites to locations where they can be leached and processed by solvent extraction. It has been reported that about 1,100 pounds of U_3O_8 and 4,000 pounds of V_2O_5 per day are expected to be produced. Production from the Naturita tailings pile is to begin in late November 1977 and continue for approximately 16 months; production from the Durango tailings is projected to begin in mid-1979 and to continue for about 32 months.

Long Island Lighting Co. (LILCO) reported that sales of vanadium produced as a byproduct of the burning of Venezuelan oil in its power-generating operations over the past 12 years have produced more than $5 million in revenues.

Table 2.—Mine Production and recoverable vanadium of domestic origin produced in the United States

(Short tons of contained vanadium)

Year	Mine production[1]	Recoverable vanadium[2]
1972	4,699	4,887
1973	4,117	4,377
1974	5,240	4,870
1975	5,213	4,743
1976	8,076	7,376

[1]Measured by receipts of uranium and vanadium ores and concentrates at mills, vanadium content.
[2]Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

Table 3.—Production of vanadium oxides in the United States[1]

(Short tons)

Year	Gross weight	Oxide content[2]
1972	10,410	9,367
1973	8,226	8,683
1974	9,304	9,583
1975	8,597	8,674
1976	10,836	11,063

[1]Produced directly from all domestic sources; includes metavanadates.
[2]Expressed as equivalent V_2O_5.

CONSUMPTION AND USES

Domestic consumption of vanadium, reported by type of material in table 4 and by end-use category in table 5, decreased 14% in 1976 from that of 1975 and 34% from the alltime record high of 7,200 tons established in 1974. Decreases occurred in nearly all end-use categories, tool steel being the one noteworthy exception as it increased 37% over that of 1975. Stainless and heat-resisting steel and full-alloy steel remained at about the same level of consumption as in 1975. Reduced activity in aircraft construction and less demand for carbon steel and high-strength low-alloy steel contributed significantly to the drop in consumption.

Eighty-eight percent of the vanadium was consumed as ferrovanadium and associated proprietary vanadium-iron-carbon materials. Compared with data for 1975, ferrovanadium (including proprietary materials) consumption fell 12% and oxide consumption declined 19%. Consumption of ammonium metavanadate, however, increased 58%. Consumption of other vanadium materials, consisting principally of vanadium-aluminum alloys and small quantities of other vanadium alloys, was 35% below that of 1975.

Table 4.—Consumption and consumer stocks of vanadium materials in the United States

(Short tons of contained vanadium)

Type of material	1975		1976	
	Consumption	Ending stocks	Consumption	Ending stocks
Ferrovanadium[1]	4,703	868	4,144	924
Oxide	216	56	175	50

Miscellaneous and unspecified	57
Total	4,720

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."
[1]Includes magnetic alloys.
[2]Includes pigments.

STOCKS

In addition to the consumers' stocks shown in table 4, producers' stocks of vanadium as fused oxide, precipitated oxide, metavanadate, metal, alloys, and chemicals totaled 3,018 tons of contained vanadium at yearend 1976, compared with 3,375 tons at yearend 1975.

PRICES

Prices in the United States for the principal vanadium materials increased about 10% at midyear. The price for domestic 98% fused vanadium pentoxide, as quoted by Metals Week, began the year as a dual quotation of $2.45 and $3.06 per pound of contained V_2O_5 and increased to $2.75 and $3.35. Prices for technical-grade air-dried vanadium pentoxide per pound of contained V_2O_5 were raised from $2.45 to $2.75 on August 1, 1976, by Kerr-McGee Corp. and from $3.06 to $3.35 on July 1, 1976, by Union Carbide Corp.; Foote Mineral Co.'s air-dried vanadium pentoxide price has been posted at $3.54 per pound of contained V_2O_5 since January 10, 1975.

Metals Week, as of midyear, no longer published a price quotation for U.S. standard grade (70% to 75% vanadium) ferrovanadium, which had been quoted at $6.35 per pound of contained vanadium since November 1974. It began publishing, effective July 1, a new price quotation of $6.10 per pound of contained vanadium for U.S. producer 80% vanadium grade ferrovanadium. The price per pound of contained vanadium for both Carvan and Ferovan, effective July 1, rose from $5.10 to $5.60.

Metal Bulletin's United Kingdom price for ferrovanadium containing 50% to 60% vanadium was quoted as £5.30 to £5.40 at the beginning of the year and ended the year at £7.30 to £7.60.

FOREIGN TRADE

Exports of ferrovanadium were up about 19% in 1976. Exports of ores, concentrates, and oxides, however, were at a much lower level than in 1975, declining by 54%. Average declared value for exports of ores, concentrates, and technical-grade oxides remained about the same, $2.11 per pound of contained vanadium pentoxide in 1976, compared with $2.12 per pound in 1975. The average declared value for exports of ferrovanadium was $3.79 per pound of alloy in 1976, compared with $3.91 in 1975.

No imports classified as vanadium ore and concentrate were received in 1976. Imports classified as vanadium carbide totaled 525 pounds (gross weight), all of which came from West Germany. Imports of vanadium-bearing materials (such as ashes and slags) totaled 6.0 million pounds of contained vanadium, compared with 5.8 million pounds of contained vanadium in 1975. In both years, the Republic of South Africa, the U.S.S.R., and Chile were the major sources of this supply. Vanadium pentoxide (anhydride) imports decreased significantly from those of 1975, with imports for consumption in 1976 totaling 2,184,241 pounds (gross weight) valued at $3,481,047, compared with 4,297,303 pounds (gross weight) valued at $7,873,796 in 1975. Ferrovanadium imports in 1976, shown in table 7, came largely from West Germany and Norway; in terms of the vanadium content, they were about double the 1975 ferrovanadium imports.

WORLD REVIEW

In addition to the nations listed in table 9, some others had relatively small vanadium production from secondary, waste, or byproduct sources. Japan and West Germany produced vanadium from several such sources. Pipeline production continued to be a major factor in world demand.

Australia.—Western Mining Corp. Ltd.'s prospective uranium mine at Yeelirrie, Western Australia, may also produce byproduct vanadium pentoxide. Annual output would start around 1982 and would be about 1,000 tons of V_2O_5 per year.

Bolivia.—Construction of a ferroalloys plant in Bolivia, which was to have begun in January 1977, was postponed by Empresa Nacional de Fundaciones (ENAF). Marketing and financial considerations were given as factors in delaying the project for 1 year. In addition to producing 500 tons annually of ferrotungsten from Bolivia's tungsten concentrates, the planned facility would have capacity to produce ferrovanadium. The latter production would be from imported concentrates because Bolivia does not produce vanadium.

Table 9.—Vanadium: World production from ores and concentrates, by country

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Based on U.S. imports.
[2]The Republic of South Africa officially reports the undistributed total production of vanadium in pentoxides and vanadate products as well as in vanadium bearing slags. Data on vanadium content of vanadium slag are estimated on the basis of a reported tonnage of vanadium bearing slag (gross weight) multiplied by an assumed grade of 14% vanadium. Vanadium content of pentoxide and vanadate products represents the difference between the reported total and the calculated estimate for vanadium in slag.
[3]Data represent output of South West Africa Co. Ltd. for the years ending June 30 of that stated.

Finland.—According to Finnish trade statistics, Finland exported 2,653 tons of vanadium compounds[2] in 1975, compared with 2,955 tons in 1974. Of the 2,653 tons, 672 tons went to France, 590 tons to Sweden, 450 tons to West Germany, 364 tons to Great Britain, 331 tons to the U.S.S.R., 165 tons to Czechoslovakia, 46 tons to Brazil, 23 tons to the United States, 12 tons to Mexico, and negligible amounts to Spain and Italy.

Rautaruukki Oy reported an output of 2,854 tons (gross weight) of vanadium pentoxide in 1976, of which 2,424 tons came from the Otanmäki mine and 430 tons from the Mustavaara mine. Production at the Mustavaara mine began in May 1976; because most of the year was consumed by trial runs of the various processes and repairing faults discovered, only minor quantities of vanadium pentoxide could be obtained from this mine.

Germany, West.—According to official trade statistics, West Germany imported 22,602 tons (gross weight) of vanadium-containing ashes, residues, and slag in 1976, compared with 29,674 tons (gross weight) in 1975.

India.—Ferrovanadium production was 58 tons in 1976, compared with 55 tons in 1975 and 72 tons in 1974.

Yearly production of vanadium sludge was reported to be around 1,760 tons from two alumina plants— the Bharat Aluminium Co.'s (BALCO) plant at Korba in Madhya Pradesh, with a capacity of about 880 tons of sludge per year; and Hindustan Aluminium Corp. Ltd's (HINDALCO) plant at Renukoot in Uttar Pradesh, also with an annual capacity of about 880 tons. HINDALCO was in the process of increasing its capacity to 1,320 tons of sludge per year. Indian Aluminium Co. Ltd. (INDALCO) was examining the feasibility of vanadium recovery from sludge in a pilot project at its Muri (Bihar) alumina plant, and eventually expects to recover about 330 tons of sludge per year from each of its two alumina plants at Muri (Bihar) and Belgaum (Karnataka).

Philippines.—Filmag (Philippines) Inc., the second largest iron sand processor in the Philippines, was reportedly constructing, in cooperation with Japan's Mitsubishi Corp., a 4,400-ton-per-year ferrovanadium plant at Luzon. They also have planned to build in 1978 a 6,000-ton-per-month pig iron plant (using Lingayen iron sand), which also would produce a 15% vanadium slag.

Sweden.—MX-Processor AB, Mölndal, Sweden, has developed a new process for recovering vanadium from flue dust produced at heavy-oil-fired power stations. Plans call for building a large pilot plant adjacent to the Stenungsund power station. The plant would be capable of recovering about 100 tons per year of vanadium worth about $660,000 with startup expected in 1978.

South Africa, Republic of.—South Africa continued to be the world's leading vanadium-producing country. Vanadium statistics published by the South African Government's Department of Mines were for the combined forms— slag, polyvanadate and metavanadate, and fused pentoxide as V_2O_5. In this combined form, production in 1976 totaled 19,431 tons, compared with 20,946 tons in 1975.

Production of vanadium-bearing slag by Highveld Steel and Vanadium Corp. Ltd.—South Africa's and the world's leading producer of vanadium—totaled 49,671 tons (gross weight) in the fiscal year ending June 30, 1976, compared with 45,955 tons (gross weight) in the previous fiscal year. Highveld's ore originates from the Steelpoort Roosenekal area of the Transvaal. It is smelted at Witbank, where a sixth kiln was commissioned in October and major overhauls and uprating were carried out on the original four. The company's Vantra Division, which produces fused vanadium pentoxide, took its small kilns out of operation in December 1975 for major repairs and modifications and recommissioned them in April 1976.

TECHNOLOGY

Aspects of the geology of vanadium as a framework for appraising resources of this commodity in the light of present-day technology, economics, and geologic knowledge were discussed in a report by the U.S. Geological Survey. Geologic habits of base-metal vanadates and of titaniferous magnetite deposits were described; maps showing world distribution of these deposits were included.[3]

[2]Although the title of the export class is "vanadium compounds," the material is almost all vanadium pentoxide.

[3]Fischer, R. P. Geology and Resources of Base-Metal Vanadate Deposits. U.S. Geol. Survey Prof. Paper 926-A, 1975, 14 pp.

——. Vanadium Resources in Titaniferous Magnetite Deposits. U.S. Geol. Survey Prof. Paper 926-B, 1975, 10 pp.

Hot-rolling behavior of austenite microalloyed with vanadium and nitrogen was investigated. The addition of vanadium and nitrogen to an aluminum-killed carbon-manganese-silicon steel altered the behavior of austenite during both deformation and holding subsequent to hot rolling in five different ways. The net result of the changes increased the number of heterogeneities present in the austenite prior to transformation. This caused an increase in the number of sites for the heterogeneous nucleation of ferrite and a concomitant decrease in the grain size of the transformation product.[4]

A new superconducting magnet system installed at the Japanese National Research Institute for Metals was developed through the combined use of columbium-tin superconductor tape manufactured by Intermagnetics General Corp. of the United States and vanadium-gallium superconductor tape developed by Vacuum Metallurgical Co. Ltd. of Japan. The magnet has produced a record magnetic field of 175,000 gauss.[5]

A patent was issued on a process for producing carbide addition agents including a new steel addition agent marketed as Ferrovanadium Carbide. This product, which contains about 70% vanadium and approximately equal percentages of carbon and iron, was introduced in the second half of 1976 by Reading Alloys, Inc., of Robesonia, Pa.[6]

A vanadium sludge, suitable for processing into vanadium metal, can be recovered from digestion solutions obtained in the processing of vanadium-containing bauxite or alunite into aluminum metal. The caustic solution is cooled to 40° to 65° C., and maintained at that temperature until a precipitate forms. The precipitate is removed, and the liquor is further cooled to 20° to 30° C. A precipitate of vanadium compounds is formed, the liquor is settled, and the second precipitate is separated as a sludge.[7]

The Vanadium International Technical Committee (Vanitec) continued to sponsor research projects on vanadium applications in 1976. Development of high-performance steels having high strength and impact resistance has been a major emphasis.

Vermiculite

By Stanley K. Haines[1]

Domestic production of crude vermiculite declined 8% from the 1975 level to 304,000 short tons. Output of exfoliated vermiculite remained the same as in 1975 at 235,000 short tons. The average value per ton of exfoliated vermiculite increased 5% to $161.82. Exfoliating plants processed both domestic and South African crude. The principal end uses were concrete aggregate; as premixes for acoustic, fireproofing, and other applications; and as loose-fill and block insulation. World production of crude vermiculite was 565,866 tons, a decrease of 2% from 1975.

rRevised.

DOMESTIC PRODUCTION

Crude Vermiculite.—Output of vermiculite concentrate, commonly called crude, decreased from 330,000 tons in 1975 to 304,000 tons in 1976. The principal mining operations were W. R. Grace & Co.'s mine, in Libby, Mont., and beneficiation plants in Libby, Mont., and Enoree, S.C. In addition, Patterson Vermiculite Co. produced a small tonnage at Lanford, S.C.

Progress has been made by Virginia Vermiculite Co. in its efforts to begin mining in Louisa County, Va. In the latter part of 1976 the circuit court of Louisa County, Va., upheld the right of the board of supervisors to rezone the tracts of land containing vermiculite to allow mining. This decision is under appeal. The principal disputed issues are the damage mining would cause to the land (sight pollution) in light of the area's rural national historic landmark designation and the possible adverse effects caused by the presence of asbestos fibers in the ore.

Exfoliated Vermiculite.—The tonnage of exfoliated vermiculite sold or used remained about the same as in 1975. The five leading producing States were California, Florida, New Jersey, South Carolina, and Texas. W. R. Grace & Co., Construction Products Div., the principal producer of crude and exfoliated vermiculite, operated 30 exfoliating plants in 24 States. Crude vermiculite imported from the Republic of South Africa was exfoliated at 10 domestic

[1]Physical scientist, Division of Nonmetallic Minerals.

plants. The sources of crude for domestic exfoliated vermiculite sold or used were Libby, Mont., 62%; South Carolina, 26%; and the Republic of South Africa, 12%.

CONSUMPTION AND USES

Only minor changes in the end-use pattern occurred from 1975 to 1976. The principal end-use categories follow: Aggregates, 47%; insulation, 33%; agriculture, 17%; and miscellaneous, 3%. Additionally, 15,000 tons of crude vermiculite was consumed for various end uses without exfoliation.

PRICES

According to the Bureau of Mines canvass, the average value of domestic crude vermiculite increased from $41.70 per ton in 1975 to $46.16 per ton in 1976. The average value of exfoliated vermiculite increased 5% to $161.82. These values are f.o.b. mine or plant.

Engineering and Mining Journal quoted nominal yearend prices for crude vermiculite as follows: Per short ton, f.o.b. mine, domestic crude, $38 to $68, and c.i.f. Atlantic ports, Republic of South Africa crude, $60 to $80.

FOREIGN TRADE

Approximately 40,000 tons of crude vermiculite was imported duty-free into the United States from the Republic of South Africa, a 21% increase over that imported in 1975. A total of 40,850 tons of crude vermiculite was exported to Canada, principally from Libby, Mont.

WORLD REVIEW

Canada.—A total of 62,856 tons of crude vermiculite was imported in 1976, from the United States and the Republic of South Africa. The end-use pattern in 1975 follows: Loose insulation, 77%; insulating concrete, 4%; insulating plaster, 1%; agriculture, 9%; and miscellaneous (including fireproofing, underground pipe insulation, and barbecue base), 9%.[2]

South Africa, Republic of.—Total production of crude vermiculite increased over 7% in 1976 to 244,798 tons.

Zinc

By V. Anthony Cammarota, Jr.[1]

As the rate of economic activity rose during 1976, mine and smelter production and imports of metal increased to satisfy a 23% increase in slab zinc consumption. Imports of slab zinc supplied about three-fifths of metal consumption. Imports of ores and concentrates fell, continuing the decline of 1975. Producer and consumer stocks at yearend 1976 were higher than at yearend 1975.

Mine production increased 3% compared with that of 1975, to 484,513 tons of recoverable zinc. Tennessee, Missouri, New York, Colorado, and Idaho accounted for 70% of the output. Eleven States showed increases and eight registered declines. Exploration activities were high in Tennessee and in Wisconsin, where Exxon Corp. announced the discovery of a massive sulfide deposit that could increase U.S. zinc reserves about 10%.

U.S. primary smelters operated at slightly more than 80% capacity in 1976 to produce 536,479 tons of slab zinc, a 13% increase compared with 1975 production. At yearend, National Zinc Co. started up a new electrolytic zinc plant to replace its horizontal retort plant. AMAX Inc. completed an extensive rehabilitation program at its electrolytic zinc plant. The New Jersey Zinc Co. broke ground for a 90,000-ton-per-year electrolytic zinc plant in Tennessee, which is expected to be operational in 1979. The Bunker Hill Co. completed construction of a 600-foot stack at its zinc plant in Idaho to meet pollution requirements.

Consumption of slab zinc increased to 1,134,141 tons. Increases in automobile production and housing starts of 27% and 25%, respectively, contributed to the recovery in consumption. A 3-month strike in the tire industry reduced consumption of zinc oxide.

Producer and consumer stocks were 181,952 tons on January 1, and after falling to 164,889 tons in March, the level gradually increased to finish the year at 215,047 tons.

In January, the price of Prime Western zinc was reduced 2 cents, to 37 cents per pound. In August, the producers raised the price to 39 to 40 cents per pound, but in October the companies rescinded the price increase. The 1976 average price was 37 cents per pound. The European producer price remained at 36.1 cents per pound. On the London Metal Exchange (LME), equivalent prices climbed in the first half of the year to an average of 35.9 cents per pound in June, but then underwent a steady decline to end the year at under 30 cents per pound.

On October 1, the Federal Preparedness Agency (FPA) approved a new goal for zinc of 1.313 million tons. The previous goal was 374,830 tons set in June. Achievement of the goal was to be a long-term program requiring a number of years.

With the exception of 1974, general imports of zinc in ores and concentrates have declined since 1970. In 1976, such imports were 97,115 tons, a 33% drop from those of 1975. General imports of slab zinc reached 714,489 tons in 1976, the highest level on record. Canada supplied 44% and Mexico, 9%. Major suppliers, who more than doubled shipments to the U.S. market compared with those of 1975, included Italy, Mexico, Yugoslavia, and Zaire. The People's Republic of China shipped 2,532 tons. The European Economic Community provided 19% of U.S. imports of zinc metal, compared with 17% in 1975.

Legislation and Government Programs.—On June 28, FPA raised the stockpile goal for zinc to 374,830 tons, which was the total uncommitted inventory at the time of the announcement. The previous goal was 202,700 tons. This action elimina-

[1]Physical scientist, Division of Nonferrous Metals.

ted the excess of 172,130 tons of zinc that the General Services Administration (GSA) previously had available for disposal. In addition, GSA cancelled its agreement to sell zinc under long-term contracts with the producers. On October 1, FPA announced a new goal of 1,313,000 tons. At the end of the fiscal year, total inventory was 385,171 tons; uncommitted inventory was 374,830 tons, and 10,341 tons was committed to various Government agencies. The Director of FPA stated that stockpile planning was based on a 3-year emergency and that civilian needs were considered in the program.

The Environmental Protection Agency (EPA) suspended the daily average effluent limitation of 0.5 milligram of zinc per liter for ore mining and dressing facilities until April 30, 1977, to study additional data.[2]

A bill, H.R. 12883, was introduced in Congress on March 30 to suspend for a 2-year period the duty on zinc slab, but it did not pass.

Public Law 94-413, Electric and Hybrid Vehicles Research, Development, and Demonstration Act of 1976 was passed, the objective of which was to advance the technology of battery systems for electric vehicles through research and grants by the Energy Research and Development Administration (ERDA). Batteries using zinc have shown promise as practical high energy-density batteries for electric vehicles.

The International Lead and Zinc Study Group (ILZSG) held its 20th session in Geneva, Switzerland, November 4-12, to review developments in lead and zinc and consider projections for 1977. Producers curtailed zinc metal production in 1976, and were expected to continue to do so into 1977 in an attempt to avoid stock increases. Because France, Japan, and the United States have national stockpile policies, the need to review the impact of stockpiles on the market was expressed.

DOMESTIC PRODUCTION

MINE PRODUCTION

U.S. mine production from 19 States was 484,513 tons, a 3% increase over that of 1975. The major producing States were Missouri and Tennessee, 17% each; New York, 15%; and Colorado and Idaho, 10% each. All of the major producing States, except New York and Tennessee, showed higher production than in 1975.

Table 5 shows sources of zinc production in 1976 according to ore type. Zinc ore accounted for 53% of the total zinc production, followed by zinc-lead ore, 21%; lead ore, 18%; copper-zinc and copper-lead-zinc ores, 7%; and other ores, 1%.

Table 6 shows the 25 leading U.S. zinc mines, which accounted for 89% of the recoverable domestic zinc mined in 1976. The five leading mines accounted for 41% of the total U.S. mine production.

Tennessee zinc mine production dropped 1% from that of 1975. Seven mines produced zinc from zinc ores, and one mine, Copperhill, produced zinc from copper-zinc ore. Jersey Minière Zinc Co., a 60-40 joint venture of The New Jersey Zinc Co. and Union Minière, S.A., continued development of the Gordonsville and Stonewall mines; New Jersey Zinc developed the Beaver Creek mine. The Elmwood mine attained full production status in 1976.

In east Tennessee, ASARCO Incorporated operated its zinc mines below design capacity throughout the year.[3] Production from the four mines was 42,700 tons of zinc, compared with 47,900 tons in 1975 and 56,400 tons in 1974. The zinc concentrate is used mainly for the production of zinc oxide at ASARCO's own plants in Ohio and Illinois. At the Young mill, construction began on a new ore concentrate drying and loading facility.

St. Joe Minerals Corp. formed a joint venture with a subsidiary of Freeport Minerals Co., for a 3-year, $5 million exploration and development project for zinc near Carthage, Tenn. ASARCO, Cominco American Inc., and NL Industries Inc. formed a joint venture to explore for zinc near Burkesville, Ky.

Zinc production as a coproduct from eight lead mines in Missouri increased 12% over that of 1975, as the State regained its position as the leading zinc producer. The Buick mine, owned 50% each by Homestake Mining Co. and AMAX Inc., mined 1,614,028 tons of ore with a lead content of 9.9% and zinc content of 3.9%. Ore reserves were given as 55 million tons assaying 7% lead and 2% zinc.[4] A program was begun to increase mine production to 1.8 million tons annually through improved techniques.

Production of zinc decreased 4% in New York, where St. Joe Minerals Corp. operated the Balmat and Edwards mines with a total capacity of 4,900 tons of ore per day. The Balmat mine retained its position as the Nation's largest zinc producer. The company stated that the decline in production resulted from mining lower grade ore.

[3] ASARCO Incorporated. 1976 Annual Report. Pp. 11, 18.
[4] Homestake Mining Co. 1976 Annual Report. P. 17.

In Colorado, zinc production from 13 mines was 50,621 tons, up 4% compared with that of 1975. Idarado Mining Co., owned 80.1% by Newmont Mining Co., treated 361,000 tons of ore grading 3.83% zinc, 2.40% lead, 0.49% copper, and 0.03 and 1.37 ounces of gold and silver per ton, respectively. Ore reserves were 3.5 million tons grading about 4.4% zinc. Resurrection Mining Co., wholly owned by Newmont Mining Corp., milled 200,000 tons of ore grading 9.26% zinc from the Leadville mine, which is managed by ASARCO. Ore reserves were 2 million tons grading 9.94% zinc.[5] Minerals Engineering Co. closed its Creede lead-zinc mine because of poor ore grade. Standard Metals Corp. increased mill capacity at its Sunnyside mine at Silverton to 1,000 tons of ore per day.

Zinc mine production was reported from 17 mines in Idaho, where production increased 14% over that of 1975. The Bunker Hill Co., a wholly owned subsidiary of Gulf Resources & Chemical Corp., increased production 10% at its Bunker Hill mine; production from the Star mine, owned 30% by Hecla Mining Co., remained unchanged. Proven and probable reserves of lead-zinc ore at these mines were 4.1 million tons containing 4.5% zinc and 3.3% lead.[6] Ore grade of the Star mine averaged 6.05% zinc, 5.61% lead, and 2.98 ounces of silver per ton, all of which were higher than 1975 levels.[7] Several veins contributed significantly to overall mine production and the preparation of new stoping areas assured adequate production for the next year. Most of the lateral development was at the 7,900-foot level, but the No. 4 shaft was deepened to the 8,100-foot level. Hecla's Lucky Friday mine produced 186,520 tons of ore, up 8% over 1975 production. Ore grade was 1.47% zinc, 10.91% lead, and 14.41 ounces of silver per ton. Operating costs increased about 5%, but were partially offset by improvements in productivity. Stope preparation on the 4,250-foot level was completed, along with station work on the 4,450-foot level, deepening of the main shaft to the 4,660-foot level, and installation of hoisting facilities. Ore reserves at yearend were 475,000 tons compared with 505,000 tons in 1975. Intermountain Mining Engineers, with 50% participation by U.S. Antimony Corp., rehabilitated the Nabob mine in the Pine Creek area of the Coeur d'Alene mining district and produced a small quantity of zinc.

Utah production of zinc from three mines was 22,481 tons, a 14% increase over that of 1975. Park City Ventures, a joint venture owned 60% by The Anaconda Company and 40% by ASARCO, mined 174,888 tons of ore at its leased lead-zinc-silver Ontario mine. In addition, Park City purchased 12,437 tons of ore from the Bingham district for milling. The milled ore contained 7.4% zinc, 5.2% lead, and 3.3 ounces of silver per ton. A 5-year development and exploration program was underway.[8]

Production was reported from one mine in Virginia, where production dropped 26%. Piedmont Mineral Associates, a joint venture of Callahan Mining Corp. (49%) and The New Jersey Zinc Co. (51%), suspended its underground drifting and drilling program at the Cofer mine at Mineral, Va. The company believes that high mining costs may make the deposit uneconomical.

Washington reported a significant increase in production compared with that of 1975 from its four mines. Ore production at the Pend Oreille mine increased about 25% over that of 1975. Exploration for additional reserves continued.[9]

In Maine, the Blue Hill joint venture, 60% owned by Kerr Addison, Ltd., and 40% by Kerramerican, Inc., was the only zinc producer. Mine production of recoverable zinc was 7,810 tons, a 6% decline from that of 1975. Total ore mined was 176,100 tons grading 1.2% copper and 5.1% zinc.[10] Because of zinc smelter cutbacks, 10,700 tons of concentrate was stockpiled. Minable ore reserves of 219,000 tons grading 3.2% zinc were down 58% from those of 1975. About 186,000 tons of ore reserves in the Carlton area, which were included in the 1975 figure, were deleted from the reserves figure given in 1976, because they were considered uneconomic.

Mine production of zinc from two mines in Southwest Wisconsin increased slightly compared with that of 1975. Exxon Company, U.S.A., a division of Exxon Corp., announced the discovery of a massive sulfide deposit near Crandon in northern Wisconsin containing 70 million tons of ore grading 5% zinc, 1% copper, and lesser amounts of lead, gold, and silver.

Arizona zinc production from nine mines was 9,501 tons, up 10% over that of 1975. Cyprus Mines Corp. produced 90,278 tons of ore grading 13% zinc and 3.54% copper

from its Cyprus Bruce mine. Proven reserves were established at 128,000 tons. Exploratory underground drilling uncovered no significant mineralization.[11]

Production in Nevada declined 74% with the closing of the Pan American mine near Pioche early in the year. Later, The Bunker Hill Co. acquired an interest in the mine and Caselton concentrator 16 miles away. If exploration and development work proved sufficient reserves, full-scale mining operations were to begin in 1977.

SMELTER AND REFINERY PRODUCTION

U.S. slab zinc production at 6 primary plants and 13 secondary plants was 562,410 tons in 1976, an increase of 13% over that of 1975. Primary and secondary metal production at primary plants was 536,479 tons, for a capacity utilization of slightly more than 80%. The portion of domestic slab zinc production from domestic ores was 68%; from foreign ore, 21%; and scrap, 11%. Zinc produced from foreign ore decreased 10% from that of 1975, while production from domestic ore increased 24%, and from scrap, 10%. Producer stocks at the smelter increased from 74,676 tons to 93,893 tons during the year.

Primary slab zinc produced at electrolytic refineries increased 11% compared with that of 1975 and was 46% of the total slab zinc produced. Zinc produced at retort plants was up 17% and comprised 43% of the total. Redistilled slab zinc from secondary materials produced at primary smelters increased 8% and contributed 7% of the total, and redistilled slab zinc at secondary smelters increased 13% and comprised 4% of the total. Distribution of slab zinc production, by grades was Prime Western, 48%; Special High Grade, 42%; High Grade, 5%; Intermediate, 4%; and Brass Special, 1%.

The new 350-ton-per-day acid plant at ASARCO's Corpus Christi, Tex., electrolytic zinc plant was almost completed by yearend. The company planned to modernize the leaching and electrolyte purification systems, which would lead to increased capacity and operating efficiency. ASARCO's plans for a 180,000-ton-per-year zinc plant in Kentucky advanced when M.I.M. Holdings Ltd. of Australia, owned 49% by ASARCO, agreed to participate in the venture and supply concentrates in proportion to its ownership interest.

National Zinc Co. completed construction of its Bartlesville, Okla., electrolytic plant in mid-1976. The new $40 million plant, rated at an annual capacity of 56,000 tons of slab zinc, replaced the old horizontal retort smelter of similar capacity at the same location. However, a 3-month strike delayed startup until December. The new facility makes use of the existing roaster and sulfuric acid plant. The company intends to debase its Special High Grade zinc product to Prime Western and Continuous Galvanizing Grade. The plant was expected to meet air and water pollution standards that were a major factor in the decision to replace the retort smelter.

AMAX Zinc co., Inc., completed modernization of its Sauget, Ill., electrolytic zinc plant with the installation of a new water treatment facility. The plant produced 70,031 tons of zinc compared with 58,060 tons in 1975.[12]

Bunker Hill produced 100,000 tons of slab zinc, a 7,000-ton increase compared with 1975 production. The company filed a petition in late 1975 for a judicial review of the EPA decision to disapprove the Idaho plan for control of sulfur dioxide emissions. Bunker Hill began a long term program of revegetation of 18,000 acres near the Kellogg plant.[13] Bunker Hill and NL Industries Inc. terminated their toll agreement on December 31, 1975, and Bunker Hill Sales Co., Inc., was formed in January to handle sales of zinc metal from the Kellogg plant.

The New Jersey Zinc Co. and Union Minière, S.A., of Belgium, broke ground for a $97 million, 90,000-ton-per-year zinc plant at Clarksville, Tenn., scheduled for completion in early 1979. Concentrate from the Tennessee mines being developed by the partnership will be transported to the plant by river barge.

St. Joe Minerals Corp. was building a zinc dust facility at its Monaca, Pa., smelter that will have an initial capacity of 6,000 tons per year.[14] In addition, the company planned to spend about $50 million for pollution control at the zinc smelter. Zinc concentrates from the Balmat and Edwards mines comprise about one-half of the smelter feed,

[12]AMAX Inc. 1976 Annual Report. P. 19.
[13]Pages 11-13 of work cited in footnote 6.
[14]St. Joe Minerals Corp. 1976 Annual Report. Pp. 10, 19.

with the balance being obtained from other domestic and foreign suppliers. The company stated that energy costs for producing zinc had increased 145% since 1974.

A contract was awarded to St. Joe for the design, construction, and operation of a facility to test the U.S. Bureau of Mines citrate process for removing sulfur from stack emissions. The test facility will be built at the powerplant that supplies electricity to its electrothermic smelter. St. Joe owns the coal mines which supply the powerplant.

Secondary Zinc Smelters.—Zinc recovered from zinc-bearing scrap was 372,891 tons in 1976, a 32% increase compared with that recovered in 1975. Zinc-base scrap accounted for 59% of the total compared with 58% in 1975, while zinc recovered from copper-base scrap was 41%, the same as in 1975. Recovery from both new and old scrap was higher than that in 1975, with old scrap accounting for 26% in 1976 of the total zinc recovered from scrap, compared with 27% in 1975. Of the total zinc recovered from scrap, 29% was recovered as zinc metal, 58% as alloys, mostly brass and bronze, and 13% as compounds, mostly zinc oxide.

Slag-Fuming Plants.—Hot and cold lead blast furnace slags and residues were processed by slag-fuming plants to produce zinc oxide fume. The oxide was either sold and used as oxide or sent to smelters and refineries for processing into metallic zinc. Three plants operated in 1976 as in 1975: ASARCO at El Paso, Tex., and East Helena, Mont., and Bunker Hill, at Kellogg, Idaho.

Byproduct Sulfuric Acid.—In 1976, seven plants roasted zinc sulfide concentrates and produced sulfuric acid, with one plant operating solely to produce calcine for processing to zinc oxide or slab zinc. In 1976, production of byproduct sulfuric acid from zinc plants was 799,773 tons, up from 711,769 tons produced in 1975.

Zinc Dust.—Production of zinc dust increased 10% over that of 1975 to 46,358 tons in 1976. Zinc dust from distilled scrap accounted for 40,471 tons.

CONSUMPTION AND USES

In 1976, slab zinc consumption increased 23% over that of 1975 as a result of the economic recovery. Domestic consumption of slab zinc was 1,134,141 tons in 1976. The zinc content of the ore used directly in galvanizing or compounds was 101,241 tons, up from 82,732 tons in 1975. The zinc content of secondary materials to make alloys, zinc dust, and compounds was 306,508 tons, up from 223,753 tons in 1975. Total consumption of zinc for all classes was 1,541,890 tons, an increase of 25% over that of 1975.

Slab zinc used for galvanizing accounted for 433,083 tons (38%); zinc-base alloys, 427,031 tons (38%); brass products, 166,244 tons (15%); zinc oxide, 39,027 tons (3%); rolled zinc, 29,859 tons (3%); and other, 38,897 tons (3%).

Slab zinc consumption distributed by grade was Special High Grade, 551,270 tons (49%); High Grade, 111,407 tons (10%); Intermediate, 23,204 tons (2%); Brass Special, 104,460 tons (9%); Prime Western, 342,538 tons (30%); and Remelt, 1,262 tons (0.1%). Consumption of all grades of slab zinc increased over that of 1975. The most significant increases were 34% for High Grade and 26% for Special High Grade zinc, while the gain for Prime Western was 11%.

Slab zinc consumed at rolling mills was 29,859 tons in 1976, an increase of 9% over that of 1975. Production of rolled zinc products increased 13% to 29,874 tons. Strip and foil accounted for 75%. Exports of wrought zinc increased 39% to 2,271 tons and imports decreased from 236 tons to 209 tons. Production of rolled zinc from scrap was 24,630 tons in 1976, yielding a total of 54,504 tons of rolled zinc during the year, compared with 49,878 tons in 1975.

The leading zinc-consuming States in 1976 were Illinois with 155,357 tons (14%); Ohio, 152,814 tons (13%); Pennsylvania, 124,991 tons (11%); New York, 119,542 tons, (11%); Indiana, 117,070 tons (10%); and Michigan, 113,882 tons (10%). These six States accounted for 69% of the slab zinc consumed, excluding remelt zinc. Ohio ranked highest in galvanizing and Michigan was the leader in diecasting.

The Zinc Institute Inc. conducted a survey of 446 diecasters to determine the market distribution of the 416,450 tons of zinc consumed by these companies in 1976. The results showed that automotive components accounted for 49.6% of the total; builders' hardware, 21%; domestic appliances, 7.3%; industrial, agricultural, and commercial machinery, 5.7%; electrical components, 8.9%; sporting goods and toys, 2.4%; scientific and professional equipment, 1.3%; sound and television equipment, 1.2% and miscellaneous, 2.6%.

ZINC PIGMENTS AND SALTS

Production.—Production of zinc oxide in 1976, at 194,481 tons, increased 18% compared with that of 1975. Shipments were 2% higher than production. The source of domestic zinc oxide production was 59% from ore and concentrate (American process), 24% from slab zinc (French process), and 17% from secondary material. Total French process zinc oxide, including that from remelt and scrap, was 31% of the total. Lead-free zinc oxide was produced at 13 plants in the United States and leaded zinc oxide was produced at 1 plant.

Zinc sulfate production, at 34,681 tons from nine companies, showed an increase of 48% as Madison Industries Inc. became a significant supplier of zinc chemicals. Zinc sulfate production came from secondary material and from ore or intermediate products. Zinc chloride production from five companies was 15,241 tons, 11,457 tons of which was shipped.

St. Joe Minerals produced 52,246 tons of zinc oxide, up 11% over that of 1975, and ASARCO, with plants at Columbus, Ohio, and Hillsboro, Ill., produced 34,100 tons, up 34% over 1975. New Jersey Zinc also produced zinc oxide from ores or concentrates. Other major zinc oxide producers, such as the Eagle-Picher Industries, Inc., Hillsboro, Ill., plant and the Sherwin-Williams Co., Coffeyville, Kans., plant, used calcines, fume, and secondary materials as raw materials. ASARCO, New Jersey Zinc, and St. Joe were the three producers of French process zinc oxide from primary slab zinc.

Consumption and Uses.—The apparent consumption of zinc oxide increased 18% in 1976 to about 213,000 tons. Analysis of domestic shipments by industry usage showed the largest consumers to be the rubber industry with 53% of the total; chemicals, 17%; photocopying, 12%; and paints, 8%. The use of zinc oxide increased in all categories except photocopying, which declined 2% and other, down 29%. Among miscellaneous uses, zinc oxide was used in floor coverings, fabrics, lubricants, plastics, and rayon manufacturing. Agriculture was the chief use for zinc sulfate with lesser amounts assigned to rayon, flotation reagents, and chemicals. Leaded zinc oxide was used in rubber, and lithopone was used mainly in paints. Most of the zinc chloride was used in soldering fluxes and batteries.

Prices.—Effective January 5, U.S. producers lowered prices 1 cent per pound for zinc oxide. Prices quoted were 39 to 40 cents per pound for American process zinc oxide, 40.5 cents for French process, 43 to 44 cents for electrophotographic grade, and 35.5 cents for leaded zinc oxide. St. Joe increased prices 3 cents per pound in July to 42 cents for American process and 43.5 cents for French process. The price for electrophotographic grade climbed to 45 to 46 cents per pound and leaded zinc oxide was quoted at 39 cents. New Jersey Zinc also increased its zinc oxide prices to the same level, citing higher labor, production, and energy costs as the reason. On October 13, with the reduction in the price of zinc, the prices of various grades of zinc oxide were also reduced. List prices were 40 cents per pound for American process, lead-free, pigment grade, 41.5 cents for French process, regular, 43 to 44 cents for electrophotographic grade, and 38 cents for zinc oxide, leaded, 12%. The price of zinc sulfate, granular monohydrate industrial, 36% zinc, bags in car load lots, was reported as $24.00 to $26.50 per 100 pounds in December, unchanged from a year earlier. The price of technical grade zinc chloride, 50% solution, in tank car quantities, was $15.25 per 100 pounds during the year.

Foreign Trade.—Exports of zinc oxide increased 56% over those of 1975 to 4,838 tons, of which 4,261 tons was pigment grade. Canada and Mexico received 70% of the total. Lithopone exports decreased by 15% to 779 tons. Imports of all classes of zinc compounds increased in 1976 to a total of 27,969 tons, a 52% gain. As in 1975, zinc oxide was the major component of imports of zinc compounds. Mexico and Canada supplied 94% of the zinc oxide; other European Economic Community countries contributed most of the remainder.

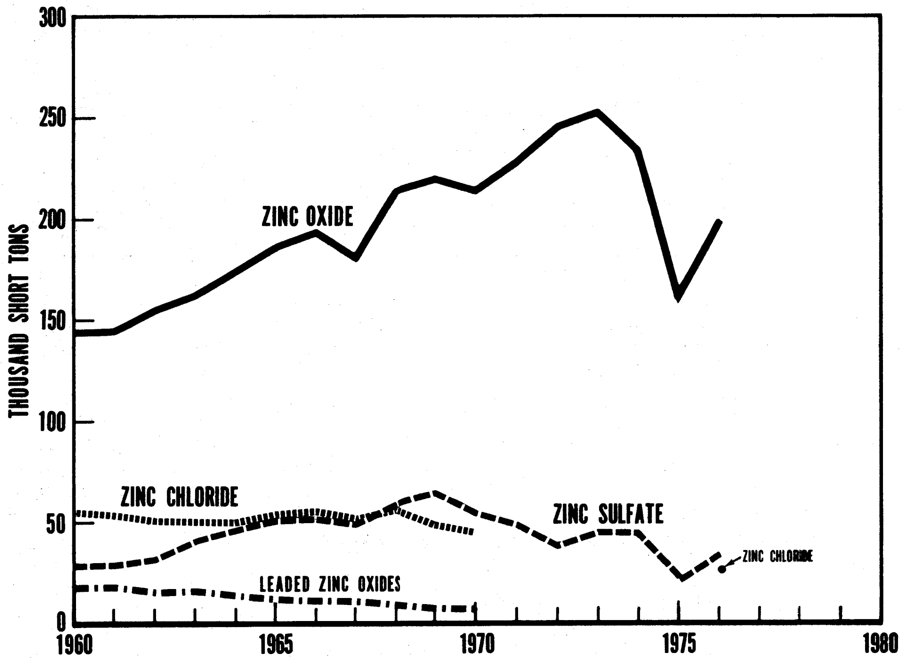

Figure 4.—Trends in shipment of zinc pigments.

STOCKS

Producer Stocks.—Stocks of slab zinc at producer plants at the beginning of the year were 74,676 tons, increasing to 93,893 tons by yearend. The Zinc Institute Inc. reported that producer stocks at smelters dropped to 59,092 at the end of September, but by yearend had climbed to the monthly high for the year.

Consumer Stocks.—Slab zinc inventories at consumer plants were 107,276 tons at the beginning of the year, but by yearend consumer stocks had risen to 121,154 tons. In the January to October period, consumer stocks gradually climbed to about 136,000 tons, but fell off in the last 2 months.

PRICES

ASARCO led a price cut of 1.5 to 2 cents per pound of zinc on January 5 to 37 cents for Prime Western, 37.5 cents for Special High Grade and Continuous Galvanizing Grade, and 37.25 cents for Controlled Lead Grade. Competition from imports was given as the major reason for the decline. Other domestic producers also cut prices as did foreign producers selling zinc in the United States. In April, speculation arose of a price increase, but a clause in the agreement between GSA and producers on stockpile purchases that would have allowed the opening of a closed quarter if the price of zinc increased dampened the possibility. In July, when GSA could no longer sell zinc because FPA raised the stockpile goal, the possibility of producers being required to buy stockpile metal if prices were increased was removed. Effective August 3, Texasgulf Inc. increased its U.S. price by 3 cents per pound across the board. St. Joe, the first U.S. company to follow, quoted prices of 40 cents for Prime Western and High Grade, 40.25 cents for Controlled Lead, and 40.5 cents for Continuous Galvanizing Grade. ASARCO sold its zinc on a Metals Week weighted average of Prime Western metal.

Bunker Hill increased its Prime Western price by 2 cents per pound, as did ASARCO and National Zinc at the end of August. By September 1 a two-tier price was in effect for Prime Western, High Grade, and Special High Grade zinc. By mid-October the depressed zinc market forced a price cut of 3 cents, initiated by AMAX, which most companies made retroactive to the August increase date. Discounting, price protection, and a weak LME price led to the drop. The average price of Prime Western zinc in 1976 was 37.01 cents per pound.

In May the U.S. Department of Justice opened an antitrust investigation into pricing practices abroad. The Department requested information and documents on the European producer price, agreements, and sales receipts. Later in the year U.S. producers were queried.

On the LME, zinc prices varied widely during the year. The price rose from 31 cents per pound in January to 37.1 cents in April, higher than the prevailing U.S. price, on speculation of a price increase. In May a voluntary ban on LME speculative zinc accounts, less expectation of a U.S. price increase, and the first arrivals of significant quantities of North Korean zinc led to a decline to 33.6 cents per pound in June. The turnover of 483,170 tons of zinc on the LME in the first 4 months was 58% above that of the same period in 1975. Lifting of the LME trading ban and news of GSA contract cancellations in the United States started a rally to more than 36 cents in midsummer. Despite the U.S. price increase in August, the LME reportedly was more influenced by arrivals of North Korean zinc and the accumulation of over 100,000 tons of LME stocks. By November the price had fallen to 26 cents, but recovered by yearend to almost 30 cents because producers supported the price by allowing customers to purchase part of their needs from LME stocks through the producer agent.

FOREIGN TRADE

Exports of unwrought zinc and alloys were 5,106 tons in 1976, a 47% decrease from those of 1975. The Netherlands received 56% of the exports; Canada, 19%; and Saudi Arabia, 7%. Wrought zinc and zinc alloy exports were 9,998 tons in 1976, of which 48% went to Belgium-Luxembourg and 33% to Canada.

Exports of lead and zinc ores and concentrates, which have been reported as a combined category since 1965, are shown in table 32, and a 3-year breakdown of recipient countries is given in table 33. Exports have increased from 434 tons (gross weight) in 1965 to 148,787 tons in 1976.

General imports of zinc in ore were 97,115 tons in 1976, a decrease of 33% from those of 1975. Canada supplied 72% and Honduras 17%. Imports from Peru fell 84%. General imports of zinc metal were 714,489 tons, an increase of 88% over those of 1975. Canada supplied 44% of the total; Mexico, 9%; and West Germany, 7%. Other leading suppliers, in decreasing order, were Zaire, Belgium-Luxembourg, Australia, and Finland. Countries that more than doubled shipments to the U.S. market over those of 1975 included France, West Germany, Italy, Mexico, Poland, the People's Republic of China, Yugoslavia, and Zaire; together, these countries provided 31% of the total. In 1976, developed market economy countries provided 78% of the total, developing market economy countries, 17%; and centrally planned economy countries, 5%; compared with 85%, 13%, and 2%, respectively, in 1975.

Imports of concentrate for consumption were 155,803 tons in 1976, a decrease of 428,544 tons from those of 1975 when large tonnages were withdrawn from bonded warehouses after removal of the tariff on concentrates. Metal imports for consumption were 695,131 tons in 1976, 85% more than in 1975.

The U.S. Department of the Treasury investigated charges by U.S. zinc producers that a tax rebate allowed by Spanish tax laws subsidized zinc exports from that country. A finding against Spain could lead to the imposition of countervailing duties by the United States.

There were no changes in the basic tariff rates in 1976 for slab zinc at 0.7 cent per pound, and zinc dust at 0.3 cent per pound. The duty rate for unwrought alloys of zinc, which include diecasting alloys, was 19% ad valorem.

Table 2.—Principal Canadian zinc producers in 1976

Company	Mine	Mill capacity (thousand tons per day)	Recoverable metals	Ore milled (thousand tons)	Zinc content of ore percent	Reserves: Ore (thousand tons)	Reserves: Zinc (percent)

WORLD REVIEW

Preliminary data from the World Bureau of Metal Statistics[15] indicated that the world consumption of slab zinc increased 14% over that of 1975. Western Europe gained 17%; Australia, 8%; Japan, 28%; and centrally planned economy (CPE) countries, 4%; but Canadian consumption fell 10%. Bureau of Mines data showed world mine production up 1%, and slab zinc production up 7%, over 1975 levels. In mining, increases were especially noted in Brazil, France, Greece, Sweden, the Republic of South Africa, and the Republic of Korea; Australia, Canada, Mexico, Zaire, and Zambia made significant cutbacks. Mine production in the CPE countries gained 4%. Increases in smelter production were prominent in Australia, Canada, France, Japan, Spain, the United States, and the U.S.S.R. Production in Zambia fell because of mechanical problems at the smelter. Production in the United Kingdom declined owing to a labor strike at the Avonmouth smelter that did not end until March. Zinc metal production in CPE countries increased 2% over that of 1975.

Stocks in LME warehouses increased from 80,772 tons on January 3 to 98,299 tons by yearend. Most of the increase occurred from April through November, with a falloff in the last month. Producer stocks worldwide decreased 7% to about 763,000 tons during the year. European producers held about 257,000 tons; Japanese producers, about 201,000 tons; and other countries, the remainder. Consumer stocks were about 171,000 tons.[16]

World mine capacity increased 322,000 tons of zinc per year with the opening of the Huari-Huari mine (30,000 tons) in Bolivia, four new mines or expansions in Canada (108,000 tons), the LaPlata mine (3,000 tons) in Ecuador, the Noailhac-Saint Salvy mine (23,000 tons) in France, the Balaria mine (22,000 tons) in India, six mines (66,000 tons) in Peru, the Stekenjokk mine (13,000 tons) in Sweden, the Zamanti mine (44,000 tons) in Turkey, and the Brskoro mine (23,000 tons) in Yugoslavia. Two mines closed, one in Canada and one in Australia.

World smelter capacity for slab zinc increased slightly to 7.545 million tons per year. A new 44,000-ton-per-year electrolytic plant was brought onstream by CINKUR (Zinc and Lead Metal Industry, Inc.) Turkey. The Ghazaouet smelter in Algeria reached its full capacity of 40,000 tons, and Española del Zinc, S.A., increased capacity of its Cartagena smelter in Spain by 33,000 tons. In Poland, a capacity reduction of 29,000 tons took place at the Katowice horizontal retort plant. An agreement was reached between the Thai Government and Thai Zinc Co., Ltd. on the construction of a smelter, but formal approval had not been received by yearend.

Australia.—Zinc production from the Mount Isa mine in Queensland, operated by Mount Isa Mines Ltd., was 123,000 tons, down from 126,000 tons in 1975. Reserves at the mine were 61 million tons of ore assaying 6.5% zinc. Development of the new Hilton lead-zinc-silver mine was scaled down, where reserves are 41 million tons of ore grading 9.6% zinc and 7.7% lead. The company planned to begin pilot operations at the McArthur River lead-zinc-silver deposit in the Northern Territory.[17] The ore body contains proven reserves of 210 million tons of ore assaying 9.5% zinc.

In late 1976 North Broken Hill Holdings Ltd. became the holding company for the operating subsidiary North Broken Hill Ltd. During the fiscal year the company mined 491,511 tons of ore grading 9.79% zinc, to produce 83,610 tons of zinc concentrate assaying 52.32% with a mill recovery rate of 91.2%. The concentrates are smelted in Australia.[18] At the West Coast mine in Tasmania, EZ Industries Ltd. produced 71,509 tons of zinc from ore grading 12.6% zinc. The company also treated zinc-rich tailings at the site. Reserves were given as 8.8 million tons of ore grading about 17% zinc. Mining of the willemite (zinc silicate) ore deposit at Beltana, South Australia, continued, with 5,896 tons being shipped to the Risdon smelter and 23,346 tons being exported. However, the mine was placed on standby pending new contracts. Exploration of the Elura prospect near Cobar indicated a resource of about 24 million tons of lead-zinc-silver ore grading about 8.6% zinc. The company planned to sink a shaft to obtain ore samples for pilot plant testing.[19]

EZ Industries produced 151,303 tons of zinc metal and 7,674 tons of zinc dust from

[15] World Bureau of Metal Statistics (London). World Metal Statistics. V. 29, No. 5, August 1977, pp. 91-93.

[17] M.I.M. Holdings Ltd. 1976 Annual Report. Pp. 4, 7, 30.

[18] North Broken Hill Holdings Ltd. 1977 Annual Report. P. 10.

[19] EZ Industries Ltd. 1976 Annual Report. Pp. 7-9, 14.

its Risdon smelter in the fiscal year ending June 30, 1976. Production at the Cockle Creek smelter of Sulfide Corporation Pty. Ltd., which operated at about 65% capacity most of the year, was 54,000 tons. Pollution control equipment was installed at a cost of $2.4 million. The Broken Hill Associated Smelters Pty. Ltd. embarked on a $9 million pollution control program at its Port Pirie smelter, which produced 34,000 tons of zinc in 1975.

St. Joe Minerals, Phelps Dodge Corp., and Australian Mining and Smelting will each have a one-third interest in the Woodlawn zinc-lead-silver-copper deposit in New South Wales. The deposit is estimated to contain 10 million tons of ore averaging 9.1% zinc, 3.5% lead, 1.8% copper, and 1.8 ounces of silver per ton. The cost for the open pit mine and mill, which is to be operational in 1978, is $88 million.

Minerals, Mining and Metallurgy closed its South mine at Broken Hill, New South Wales, because of lower ore grades and higher costs, but retreatment of old tailings will continue.

Bolivia.—Corporación Minera de Bolivia (COMIBOL) produced 37,529 tons of zinc in 1976, up from 34,963 tons in 1975. A new 400-ton-per-day plant was installed at the Colquiri mine, and a second concentration plant to treat the marmatitic ore was under construction. The Matilde mine, the largest in Bolivia with a mill capacity of 1,100 tons per day, produced 23,145 tons of zinc. A new shaft was being sunk that was expected to increase production significantly in 1977. Production began from New Jersey Zinc's Huari-Huari mine, where both silver and cadmium are found in the ore.

Canada.—Mine output, at 1,321,500 tons, was 3% lower than that of 1975. About 38% came from zinc ores, 13% from copper ores, and the balance from mixed ores. Depleted reserves forced the closure of one mine, but three new mines came into production. Mill capacity at yearend was 103,220 tons of ore per day. The Sullivan Mining Group Ltd. planned to close the Cupra and D'Estrie mines in early 1977, which had a combined capacity of 1,400 tons per day.[20]

The leading producing provinces were Ontario with 31% of the total zinc production, followed by New Brunswick, 17%; Northwest Territories, 14%; Quebec, 12%; and British Columbia, 11%. Data for the principal producing mines are given in table 2. Slab zinc output was 521,200 tons, up 11% over that of 1975. Consumption of slab zinc was estimated at 138,000 tons, up slightly over that of 1975.

Texasgulf Inc. mined about 1.55 million tons of ore from the open pit and about 2.05 million tons from underground workings at the Kidd Creek mine in Timmins, Ontario. The program to increase mine capacity to 5 million tons of ore per year by the addition of the No. 2 underground mine and fourth concentrator circuit was on schedule. Work was already in progress to develop the ore between the 2,600- and 2,800-foot levels.[21]

In New Brunswick, Brunswick Mining & Smelting Corp. Ltd. continued its expansion of the No. 12 mine to increase capacity to 11,000 tons per day by 1979. The company experienced a total operating cost per ton of ore milled of $20.06, compared with $15.81 in 1975 at its No. 12 underground mine. The cost was $11.84 at the open pit mine, up from $9.83 in 1975.[22] Texasgulf continued evaluation work at its Half Mile Lake project but deferred sinking an exploration shaft.

On Baffin Island in the Northwest Territories, Nanisivik Mines Ltd., in which Texasgulf has a 35% net profits interest, began production in September at the Nanisivik mine, which has a capacity of 1,500 tons of ore per day. Texasgulf continued drilling at Izok Lake and estimated that the deposit contained 12 million tons of ore assaying 13.8% zinc.

In British Columbia, Northair Mines Ltd. began production in March at its gold-lead-zinc mine near Brandywine Falls. Concentrate from the 300-ton-per-day mill was shipped to Cominco at Trail for smelting. Ore reserves were estimated at 460,000 tons averaging 3.1% zinc and 2.3% lead.

Lemoine Mines Ltd., a wholly owned subsidiary of Patino Mines (Quebec) Ltd., began commercial operation of its mine in early 1976. Mattagami Lake Mines, Ltd., shipped 76% of its zinc concentrate from the Mattagami mine in Quebec to the Valleyfield smelter in Quebec and 24% was exported.[23] Almost 70% of the mill feed came from pillars because the major part of the stoping sections have been mined to the extremities of the ore body. Orchan Mines Ltd. supplemented production from the Orchan main mine with ore from the Norita division. Site preparation was begun for

[20]Brown, D. H. Canadian Mineral Survey 1976. Department of Energy, Mines, and Resources, Ottawa, Canada. February 1977, pp. 30-37.

[23]Mattagami Lake Mines Ltd. 1976 Annual Report. P. 8.

development of a low-grade zinc-copper deposit acquired from Phelps Dodge of Canada.[24]

In Manitoba, ore production by Hudson Bay Mining & Smelting Co., Ltd., was 92,333 tons more than that of 1975 owing to improved mining methods and initial production from the Centennial mine in the Flin Flon-Snow Lake area. The Schist Lake mine closed due to ore depletion. Development work continued on the Centennial and Westarm mines.[25] Production at the Ruttan and Fox mines of Sherritt Gordon Mines Ltd. decreased owing to operating problems, but the decreases were partially offset by higher metallurgical recoveries. Favorable results from the underground drilling program at Ruttan led to the decision to mine a substantial part of the reserves during 1979-86.[26]

Zinc production in the Yukon was adversely affected by a 169-day strike at the Cyprus Anvil mine, where output fell by about one-half. A 2-month strike cut production 16% at United Keno Hill Mines Ltd.[27] The evaluation of the Grum zinc-lead-silver deposit, in which Kerr Addison held a 60% interest, was completed and feasibility and ecological studies were underway.

Texasgulf Canada Ltd. produced 107,700 tons of zinc metal at its smelter in Ontario, up from 93,000 tons in 1975. Cominco Ltd. produced 224,000 tons at Trail, British Columbia, up from 194,000 tons in 1975. [28] Canadian Electrolytic Zinc completed a 50% expansion of its Valleyfield, Quebec smelter to a capacity of 225,000 tons per year. Production of metal in 1976 was 125,800 tons, compared with 117,700 tons in 1975. Hudson Bay Mining & Smelting Co., Ltd., produced 60,340 tons of zinc.

Canadian zinc reserves on January 1, 1976, were given as 31 million tons at the producing mines and deposits under development, with the Provinces of New Brunswick and Ontario containing about one half of the total.[29]

France.—Société Minière et Métallurgique de Peñarroya began operations at its Noailhac-Saint Salvy mine in January. The capacity of the mill is 1,300 tons per day to produce a concentrate containing 52% zinc and 5% lead. The concentrate is moved by road and rail to Peñarroya's Imperial Smelting furnace at Noyelles-Godault.

Honduras.—Production from the El Mochito mine of Rosario Resources Corp. was 353,907 tons grading 8.38% zinc, 7.26% lead, and 9.68 ounces silver per ton, and containing minor quantities of gold.[30] Zinc in concentrates was 24,063 tons. Reserves decreased 155,000 tons to 1.51 million tons averaging 8.16% zinc and 4.84% lead.

Ireland.—Tara Mines Ltd. completed construction of the mine site surface and ore treatment facilities at its Navan zinc-lead mine, and crushed ore was hoisted to the surface for stockpiling. The mine was expected to provide about 2.5 million tons of ore per year to the 7,500-ton-per-day concentrator during the 25-year lease. About 440,000 tons of zinc concentrates and 80,000 tons of lead concentrates were to be exported to nine European smelters under contracts that provided for diversion of the concentrate to an Irish smelter, should one be built. Ore reserves total about 67 million tons grading 11% zinc and 2.4% lead. [31]

Irish Base Metals, a subsidiary of Northgate Exploration Ltd., treated 594,823 tons of ore from the Tynagh mine, County Galway. The ore grade was 3.02% zinc, compared with 4.27% in 1975. Metallurgical recovery of zinc was 77%, down from 80% in 1975. Direct operating costs per ton of ore mined during 1976 were $12.02, down from $13.78 in 1975. Ore reserves were given at 2.8 million tons assaying 3.89% lead, 3.75% zinc, 0.18% copper, and 0.9 ounce of silver per ton. Sufficient diamond drilling was completed to establish ore reserves over the full extent of Zone III. At the Tatestown zinc-lead prospect in the Navan area, Northgate indicated the possibility of a 1.6-million-ton deposit containing close to 7% combined zinc and lead.[32]

Mogul of Ireland Ltd., of which Kerr Addison bought 75% interest in 1976, mined 1 million tons of ore grading 6.26% zinc and 2.27% lead.[33] Operating costs increased 18% over those of 1975, with energy costs increasing 24%. Metal recovery of zinc was 87%. Ore reserves after dilution were 5 million tons grading 6.05% zinc and 2.57% lead.

[33] Silvermines Ltd. 1976 Annual Report. Pp. 18-19.

Japan.—Japanese zinc metal producers operated at about 75% capacity in 1976, turning out 818,000 tons of metal compared with 773,600 tons in 1975. A stockpile program to stabilize supply and contribute to national security was begun with Government support for several metals including zinc. By October, 13,228 tons of zinc metal had been purchased from domestic refiners. Mitsui Mining & Smelting Co., Ltd., and Sumitomo Metal Mining Co. began toll-refining zinc concentrates from Mt. Isa in Australia for ASARCO. The arrangement utilized excess Japanese capacity and made up for some of the metal loss experienced by ASARCO when it closed its Amarillo, Tex., smelter in 1975.

Korea, Republic of.—A 55,000-ton-per-year electrolytic zinc plant was being constructed at Onsan by Korea Zinc Co., with technical assistance from Toho Zinc Co. of Japan. When completed in late 1977, the plant will use concentrates from the Renka mine and from Toho zinc purchases.

Mexico.—Industrial Minera Mexico, S.A., completed expansion programs at the San Martin and Charcas mines, where capacities were increased 85% and 30%, respectively. The first phase of an expansion plan to increase capacity of the Santa Barbara mine by 25% was almost completed. The expanded Taxco mine became fully operational in 1976. Zinc production of Industrial Minera was 146,700 tons compared with 127,300 tons in 1975.[34]

Nicaragua.—Neptune Mining Co., owned 51.8% by ASARCO, treated 182,632 tons of ore averaging 9.1% zinc and 0.8% lead.[35] Reserves were estimated at 1.16 million tons grading 8.61% zinc, and 1.15% lead, with lesser amounts of copper, silver, and gold.

Peru.—Minero Perú signed a contract with Sybetra of Belgium for the construction of a 110,000-ton-per-year zinc refinery to be built at Cajamarquilla at a cost of $200 million. Centromin, through its Casapalca, Cerro, Morococha, San Cristobal, and Yauricocha mines, was the country's major zinc producer. Work began at the La Oroya zinc plant to increase its capacity to 99,000 tons per year. The Puquio Cocha mine closed after 70 years owing to depletion of its copper-silver-zinc ore. The principal zinc producing mines, in order of quantity produced, were San Ignacio, Sta. Luisa, Huaron, Santander, Atacocha, Milpo, Volcan, Raura, Gran Bretaña, and Madrigal.

Cía. Minerales Santander, Inc., a subsidiary of St. Joe Minerals Corp., produced 44,089 tons of zinc concentrate for export, down from 49,103 tons in 1975.

Cia. Minera del Madrigal, a division of Homestake Mining Co., milled 277,373 tons of copper-lead-zinc ore to produce 19,249 tons of zinc concentrate.[36] The capacity of the plant was being increased from 770 tons to about 1,100 tons per day. Ore reserves totaled 1.2 million tons grading 5% zinc, 2.6% lead, and 1.5% copper. ASARCO, through Northern Peru Mining Corp., produced 6,200 tons of zinc from the Quiruvilca mine.

South Africa, Republic of.—Prieska Copper Mines (Pty.) Ltd., the sole zinc producer, milled 2.4 million tons of ore containing 3.55% zinc to produce 165,261 tons of concentrate containing 52.4% zinc. The company sold its concentrate for domestic consumption to Zinc Corp. of South Africa (ZINCOR), and exported concentrate under contract to Metallgesellschaft. Most of ZINCOR's imported concentrate for its smelter feed came from Canada and Australia.

Phelps Dodge Corp. reported that one of its three ore bodies at Aggeneys in northern Cape Province could be developed as an underground rather than open pit mine. Ore reserves minable by underground methods were estimated at 38 million tons, averaging 6.35% lead, 2.85% zinc, 0.45% copper, and 2.6 ounces of silver per ton.[37]

Newmont Mining Corp. and O'okiep Copper Co. Ltd. continued metallurgical testing and underground work on the Gamsburg zinc deposit in Cape Province. A total of 8,878 tons of ore was tested in the 50-ton-per-day pilot plant. The presence of manganese in the concentrates was successfully controlled in electrolytic refining.[38]

South-West Africa, Territory of.—At the Tsumeb mine, Tsumeb Corp. Ltd. mined and milled 488,796 tons of ore grading 2.39% zinc, 9.04% lead, and 4.25% copper, a slight increase compared with 1975 production. Zinc in concentrates was 2,000 tons. Ore reserves at the mine at yearend were estimated at 5.2 million tons containing 7.43% lead, 4.53% copper, and 1.96% zinc.[39]

TECHNOLOGY

Studies on the activation of sphalerite during flotation were pursued at the Bureau of Mines College Park Metallurgy Research Center.[40] The reduction of zinc sulfide concentrates with iron was demonstrated to be technically feasible on a semicontinuous bench-scale operation at the Albany Metallurgy Research Center.[41] Work continued at the Reno Metallurgy Research Center on the fused salt electrolysis of zinc chloride to produce zinc and recycle the chlorine.[42]

AMAX began using a technique for preleaching zinc concentrate from dolomitic limestone ores at its Sauget, Ill., refinery. Preleaching in weak sulfuric acid prevents buildup of magnesium in the electrolyte.[43] A new acid leach process was developed for treating zinc silicate ores so that the silica can be easily separated from the solution.[44] A study was done on the sphalerite content of coals from the Illinois Basin and it was found that the zinc content was as high as 5,350 parts per million and cadmium, as high as 65 parts per million. The sphalerite was readily removed from the coal by washing.[45]

An evaluation was made of the capital requirements to expand U.S. primary metals production capacity, and the factors which influence costs and prices. For zinc the average construction cost per ton of capacity per year was $1,600 for a 50,000-ton-per-year plant; operating costs for mining, milling, and refining were estimated at 19 cents per pound.[46]

A comprehensive coverage of zinc-related investigations and an extensive review of current world literature on the uses of zinc and its products are contained in bimonthly issues of the 1976 Zinc Abstracts published by the Zinc Institute Inc., 292 Madison Avenue, New York, N. Y. 10017, and provided free of charge.

Progress reports of the projects supported by the International Lead Zinc Research Organization, Inc., are released annually in the ILZRO Research Digest.

Old scrap:			In zinc-base alloys	9,569	11,688
Zinc-base	56,605	71,117	In brass and bronze	145,009	204,530
Copper-base	19,686	23,764	In aluminum-base alloys	337	314
Aluminum-base	240	282	In magnesium-base alloys	393	340
Magnesium-base	208	229	In chemical products:		
Total	76,739	95,392	Zinc oxide (lead free)	19,329	26,069
Grand total	283,201	372,891	Zinc sulfate	4,373	8,724
			Zinc chloride	8,898	13,862
			Miscellaneous	366	510
			Total	188,274	266,037
			Grand total	283,201	372,891

[1]Includes zinc content of redistilled slab made from remelt die-cast slab.

Table 16.—Zinc dust produced in the United States

Year	Quantity (short tons)	Value	
		Total (thousands)	Average per pound
1972	59,358	$24,669	$0.208
1973	56,154	29,279	.261
1974	50,775	46,398	.457
1975	r42,149	r40,294	.478
1976	46,358	45,282	.488

rRevised.

Table 17.—Consumption of zinc in the United States

(Short tons)

	1972	1973	1974	1975	1976
Slab zinc	1,418,349	1,503,938	1,287,696	925,330	1,134,141
Ores (zinc content)[1]	118,305	129,651	127,113	82,732	101,241
Secondary (zinc content)[2]	307,369	298,336	258,204	223,753	306,508
Total	1,844,023	1,931,925	1,673,013	1,231,815	1,541,890

[1]Includes ore used directly in galvanizing.
[2]Excludes redistilled slab and remelt zinc.

Table 18.—Slab zinc consumption in the United States, by industry use

(Short tons)

Industry and product	1972	1973	1974	1975	1976
Galvanizing:					
Sheet and strip	294,205	321,927	291,008	185,795	246,744
Wire and wire rope	30,769	34,315	27,579	24,945	26,801
Tubes and pipe	64,549	68,048	59,995	47,180	48,968
Fittings (for tube and pipe)	11,106	11,969	9,294	6,359	6,450
Tanks and containers	3,645	2,941	3,203	1,917	3,326
Structural shapes	20,302	21,714	36,784	41,235	34,568
Fasteners	4,310	4,782	5,703	4,426	4,028
Pole-line hardware	8,437	8,193	6,783	4,934	4,728
Fencing, wire cloth, and netting	21,995	25,418	26,284	20,051	22,006
Other and unspecified uses	58,886	64,530	56,636	40,045	35,464
Total	518,204	563,837	523,269	376,887	433,083
Brass products:					
Sheet, strip, plate	105,405	109,582	99,971	64,958	91,157
Rod and wire	63,143	63,164	57,725	33,415	54,552
Tube	8,886	10,858	9,930	6,451	7,388
Castings and billets	6,840	6,000	4,431	3,079	4,240
Copper-base ingots	7,137	6,895	8,244	6,623	7,681
Other copper-base products	736	1,151	1,262	800	1,226
Total	192,147	197,650	181,563	115,326	166,244
Zinc-base alloy:					
Diecasting alloy	566,932	598,725	436,377	330,190	419,708
Dies and rod alloy	56	111	384	149	1,028
Slush and sand casting alloy	12,773	11,770	3,498	3,852	6,295
Total	579,761	610,606	440,259	334,191	427,031
Rolled zinc	45,216	40,763	39,393	27,308	29,859
Zinc oxide	51,992	61,734	65,376	39,020	39,027
Other uses:					
Light-metal alloys	6,300	7,466	9,690	5,832	5,767
Other [1]	24,729	21,882	28,146	26,766	33,130
Total	31,029	29,348	37,836	32,598	38,897
Grand total	1,418,349	1,503,938	1,287,696	925,330	1,134,141

[1]Includes zinc used in making zinc dust, wet batteries, desilverizing lead, powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

Table 19.—Slab zinc consumption in the United States in 1976, by grade and industry use

(Short tons)

Industry	Special High Grade	High Grade	Intermediate	Brass Special	Prime[1] Western	Remelt	Total

Total[4]	432,231	166,051	426,814	107,783	1,132,879

W Withheld to avoid disclosing individual company confidential data; included with 'Undistributed.'
[1]Includes brass mills, brass ingot makers, and brass foundries.
[2]Includes producers of zinc-base alloy for diecastings, stamping dies, and rods.
[3]Includes slab zinc used in rolled zinc products and in zinc oxide.
[4]Excludes remelt zinc.

Table 22.—Production and shipments of zinc pigments and compounds[1] in the United States

Pigment or compound	1975 Production (short tons)	1975 Shipments Quantity (short tons)	1975 Shipments Value[2] Total (thousands)	1975 Shipments Value[2] Average per ton	1976 Production (short tons)	1976 Shipments Quantity (short tons)	1976 Shipments Value[2] Total (thousands)	1976 Shipments Value[2] Average per ton

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, Vietnam also produces zinc, but information is inadequate to make reliable estimates.

[2]Zinc content of concentrates.

[3]Production by COMIBOL plus exports by medium, small, and other mines.

[4]Data are compiled from operating company reports of Tsumeb Corp. Ltd. and South African Iron and Steel Industrial Corp., Ltd. (ISCOR), for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[5]Year beginning March 21 of that stated.

[6]Contained in zinc concentrates. Additional quantities of zinc may be contained as a byproduct in lead concentrates produced, but information is inadequate to make reliable estimates of such production, if any.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]An attempt has been made to restrict the contents of this table to primary production only. Where secondary metal is inseparably included it has been so noted.

[2]In addition to the countries listed, Vietnam also produces zinc, but information is inadequate to make reliable estimates.

[3]Known to include secondary production recovered from reclaimed scrap.

[4]May include secondary production recovered from reclaimed scrap.

Zirconium and Hafnium

By Sarkis G. Ampian[1]

Zircon production and sales by domestic mining companies decreased nearly 7% in tonnage and more than 20% in value in 1976. Zircon exports decreased 50% from 18,766 tons in 1975 to 9,428 tons in 1976, but imports increased 61% from 40,205 short tons in 1975 to 64,643 short tons in 1976. Total exports of zirconium metal and zirconium alloys generally decreased in 1976, while zirconium oxide increased substantially. Production of zirconium-bearing compounds for chemicals and refractories also decreased slightly. Zircon consumption by foundries increased from 46,200 tons in 1975 to 67,000 tons in 1976. Some hafnium was also produced.

The 1976 worldwide zircon supply-demand picture was characterized by a growing demand owing to increased industrial activity and Australian production capacity, resulting in an oversupply, which depressed prices. Domestically, zircon reflected the worldwide situation, with continued strong demand, largely in manufacturing specialized refractories and abrasives, and the return of foundries to the depressed priced zircon. This increased demand was largely met by imports.

Recycling of spent foundry zircon and substitution of chromite and aluminum silicate-minerals for some zircon foundry applications were commonplace.

Zircon was principally used in foundry sands, refractories, abrasives, ceramics, and as a source of zirconium metal. The metal was used mostly in nuclear reactors, in corrosion resistant equipment for industrial plants, and in refractory alloys. Hafnium was used in nuclear reactors, in flashbulbs, and in refractory alloys.

Legislation and Government Programs.—The Statistical Supplement to the Stockpile Report to Congress, Dec. 31, 1976, showed no objectives for zirconium and hafnium materials. The Energy Research and Development Administration (ERDA) had an inventory, as of June 30, 1976, of approximately one-half ton of zirconium crystal bar and scrap, 937 tons of zirconium sponge, 163 tons of Zircaloy ingot and shapes, one-half ton of hafnium scrap, 5 tons of hafnium oxide, one-half ton of hafnium sponge and shapes, and 39 tons of hafnium crystal bar.

DOMESTIC PRODUCTION

E. I. du Pont de Nemours & Co. and Titanium Enterprises, Inc., were the only major producers of zircon mineral concentrate in the United States. Zircon was recovered from mineral sands at the dredging and milling facilities owned by Du Pont at Starke, Fla.; by Humphreys Mining Co. for Du Pont, near Folkston, Ga.; and Titanium Enterprises at Green Cove Springs, Fla. Production data were withheld from publication to avoid disclosing individual company confidential information. The combined zircon capacity of these three plants is estimated to be 135,000 tons per year.

Domestic producers were examining several beach sand ore bodies in the southeastern States and studying the practicality of adding zircon flour to their product lines. NL Industries, Inc., continued feasibility studies on recovering heavy minerals from The Trail Ridge extension in Florida. A decision on the project was expected by midyear 1977.

Statistical data on production of zirconium sponge, ingot, and scrap and on hafnium sponge and oxide are also withheld to avoid disclosure of company confidential data.

Table 2.—Producers of zirconium and hafnium materials in 1976

Babcock & Wilcox Co., Nuclear Materials Div	Leechburg, Pa	Crystal bar.
Teledyne Wah Chang Albany Corp	Albany, Oreg	Oxide, sponge, crystal bar, ingot.

Approximately 2,100 tons of alloys containing 3% to 70% zirconium was produced in 1976.

Three firms produced 27,015 tons of milled (ground) zircon, a decrease of 10% from the reported production in 1975. Six companies, excluding those that produced metal, produced 8,000 tons of zirconium oxide. Oxide production in 1976 decreased from that reported in 1975.

Hafnium crystal bar production was estimated at 30 tons in 1976, compared with 35 tons estimated in 1975.

CONSUMPTION AND USES

Zircon consumption in the United States in 1975 was estimated at 155,000 tons. Consumption of zircon concentrate and milled zircon was 67,000 tons for foundries, 39,500 tons for refractories, 14,000 tons for zirconium oxide, 1,800 tons for zirconium alloys (excluding zirconium-base alloys), and 32,700 tons for all other uses. Foundries consumed approximately one-half of the domestic zircon production; the remaining half was consumed by refractory, abrasive, ceramic, metal, and other industries. Domestic zircon was marketed in proprietary mixtures for use as weighting agents, zircon-TiO_2 blends for welding rod manufacture, and zircon-refractory, heavy-mineral (kyanite, sillimanite, and staurolite) sand blends for foundry sand and sandblasting applications. The zircon-bearing foundry sand was reportedly designed to provide consistent high-quality performance at low cost for critical casting applications.

Table 3.—Zircon consumption in selected zirconium materials as reported by producers in the United States in 1976

(Short tons)

Use	Quantity
Zircon refractories[1]	29,000
AZS refractories[2]	10,500
Zirconia [3] and AZ abrasives[4]	14,000
Alloys[5]	1,800

[4]Alumina-zirconia-based abrasives.
[5]Excludes alloys above 90% zirconium.
[6]Includes chemicals, metallurgical-grade zirconium tetrachloride, sandblasting, welding rods, and miscellaneous uses.

Table 4.—Zirconium oxide[1] [2] consumption in selected zirconium materials as reported by producers in the United States in 1976

(Short tons)

Use	Quantity
AZ abrasives	4,500
AZS refractories[3]	2,400
Other refractories	2,100
Chemicals	800
Glazes, opacifiers, colors	700
Total	10,500

[1]Excludes oxide produced by zirconium metal producers.
[2]Includes baddeleyite.
[3]Fused cast and bonded.

Imported Republic of South Africa baddeleyite ore in 1976 was used principally in the manufacture of alumina-zirconia abrasives and also in ceramic colors, refractories, and for other uses.

Preliminary Bureau of the Census figures for 1976 showed that shipments of zircon and zirconia brick and shapes, composed mostly of these materials, totaled 1.8 million brick, expressed in terms of equivalent 9-inch brick, valued at $13.3 million. In 1975, final figures for shipments were 2.1 million brick valued at $16.7 million.[2]

Zirconium metal was used in nuclear reactors, in chemical plants for corrosion-resistant material, in refractory alloys, and in flashbulbs for photography. Pechiney Ugine Kuhlman Corp., Greenwich, Conn. (a subsidiary of the French firm) and Western Zirconium, Inc., Salem, Oreg. (a group of former Teledyne Wah Chang Albany officials), agreed in principle to manufacture zirconium products in a proposed $30 million to $40 million integrated facility at Dallesport, Wash. The new facility, with construction scheduled to begin in 1977 and startup expected during 1978, will first convert zircon to sponge metal and then semifabricate about 3 million to 4 million pounds per year of the products, plus chemical byproducts.[3]

Zirconium compounds, natural and manufactured, were used in refractories, abrasives, polishes, glazes, enamels, welding

[2]U.S. Bureau of the Census. Refractories. Series MQ-32C, Quarterly, 1976.
[3]Chemical Engineering. News Flashes - Joint Venture Slated for Zirconium Products. V. 83, No. 18, Aug. 30, 1976. p. 55.

rods, chemicals, and sandblasting. Zirconium chemicals were finding increased application in the paint, textile, and pharmaceutical industries. The operating assets of Tizon Chemical Corp. in Metuchen, N. J., a manufacturer of fine zirconia-based polishing materials for the glass and electronic industries, have been acquired by Transelco Co., Inc., Penn Yan, N.Y., and relocated at Penn Yan.[4]

Hafnium metal, alloys, and compounds continued to have few uses. The metal was used for nuclear reactor control rods, in special refractory alloys, and in photographic flashcubes. Nonnuclear hafnium metal uses were reportedly increasing.

PRICES

Published yearend prices for standard grade domestic zircon declined from $257 per ton (1975) to $150 per ton in 1976. Prices for comparable Australian zircon were adjusted downward approximately $25 per ton. Prices for zirconium oxides were either unchanged or unlisted for the entire year. The prices of zirconium chemicals and zirconium sponge, powder, and hafnium metal, sponge, and nitride were unchanged. Zirconium sheet prices advanced slightly. The baddeleyite prices furnished by Ronson Metals Corp. were unchanged from those of 1975.

The Australian Department for Natural Resources again reduced the minimum export prices of zircon sand in bulk, from $A140 to $A115 per metric ton for sand containing 0.1% or more iron oxide; and from $A150 to $A125 per metric ton for sand containing less than 0.1% iron oxide. The new prices apply to new contracts for standard grades of zircon for 1977 delivery, with differentials for premium grade material. These new minimum export prices are generally $A25 per metric ton below the 1976 prices.[5]

At yearend 1974, the spot price for standard-grade Australian zircon was around $A400 per metric ton free in Australian Container Depot (FID). Prices rose rapidly in 1975 when a shortage developed owing to a sharp increase in demand by the Japanese steel industry for zircon-bearing ladle refractories.

Table 6.—Published prices of zirconium and hafnium materials in 1976

Specification of material	Price
Zircon:	
Domestic, standard grade, f.o.b. Starke, Fla., bulk, per short ton[1]	$150.00
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, Fla., bulk, per short ton[1]	90.00
Imported sand, containing 65% ZrO_2, c.i.f. Atlantic ports, bags, per long ton[2]	135.00
Domestic, granular, 30-ton lots, from works, bags, per short ton[3]	$435.00—440.00
Domestic, milled, 220-mesh, 18-ton lots, from works, bags, per short ton[3]	490.00—495.00
Baddeleyite imported concentrate:[4]	
96% to 98% ZrO_2, minus 100-mesh, c.i.f. Atlantic ports, per pound	.18— .25
99+% ZrO_2, minus 325-mesh, c.i.f. Atlantic ports per pound	.56— .72
Zirconium oxide:[3]	
Powder, commercial-reactor grade, drums, from works, bags, per pound	NA
Chemically pure white ground, barrels or bags, works, per pound	2.22
Lump electric fused, bags, 500 to 1,999-pound lots, from works, per pound	NA
Lump electric fused, bags, smaller lots, from works, per pound	NA
Milled, bags, carlots, from works, per pound	NA
Glass-polishing grade, ton lots, bags, 94% to 97% ZrO_2, from works, per pound	1.11
Opacifier grade, 3,300-pound lots, 85% to 90% ZrO_2, bags, per pound	.81
Stabilized oxide, 100-pound bags, 91% ZrO_2, milled, per pound	1.57
Zirconium oxychloride: Crystal, cartons, 5-ton lots, from works, per pound	.515
Zirconium acetate solution:	
13% ZrO_2, drums, carlots, 15-tons minimum, from works, per pound	.22
22% ZrO_2, same basis, per pound	.38
Zirconium hydride: Electronic grade, powder, drums, 100 to 990-pound lots, from works, per pound	14.50— 16.00
Zirconium:[5]	
Powder, per pound	16.00
Sponge, per pound	5.50— 7.00
Sheets, strip, bars, per pound	10.00— 15.00
Hafnium:[5]	
Sponge, per pound	75.00
Bar and plate, rolled, per pound	120.00
Nitrided, per pound	34.25

FOREIGN TRADE

Exports of zirconium oxide increased in 1976 over those of 1975, while exports of zirconium ore and concentrate declined. Exports of wrought zirconium metal and alloys rose in 1976 compared with 1975, but the other forms declined. Hafnium again was not exported.

Zirconium ore and concentrate, exported to 13 countries in 1976, decreased from 37,531,345 pounds valued at $4,786,779 in 1975 to 18,855,595 pounds valued at $2,783,994. The quantity and value exported decreased nearly 50% and 42%, respectively, below that shipped in 1975. The 1975 value was an alltime high. The average value of the zirconium ore and concentrate exported in 1976, $295.29 per ton, represented an increase of $40.21 over the 1975 average value. This increase was attributed more to a larger proportion of higher-priced granular and milled zircon shipped than to the value of the zircon sand. The increased proportion of higher-priced zircon shipped also indicates a return to the normal zircon exporting pattern. The major recipients of the exported zirconium ore and concentrate were Mexico (43%), the Netherlands (17%), Brazil (15%), Canada (12%), West Germany (5%), and the United Kingdom (5%).

Exports of zirconium oxide, which were made to 29 countries, increased from 2,832,128 pounds valued at $2,905,711 in 1975 to 5,325,238 pounds valued at $6,104,200 in 1976. Export quantity increased 88%, and the value more than doubled in 1976. The five major recipients in 1976 were France, (29%), West Germany (22%), Japan (15%), Canada (13%), and the Netherlands (10%).

Total exports of other classes of zirconium decreased more than 13%, from 2,649,694 pounds in 1975 to 2,304,202 pounds in 1976. The value of this material increased about 70% in 1976 to $43,808,525 from the 1975 value of $25,828,888. Of these classes, zirconium and zirconium alloys, wrought, and zirconium and zirconium alloy foil and leaf had increased in both value and quantity in 1975. However in 1976, only the zirconium and zirconium alloys, wrought class, increased in both quantity and value. The unwrought and waste and scrap class decreased 29% in quantity but rose 12% in value. Exports of the foil and leaf class were only 11% of the quantity and 52% of the value of 1975 exports.

Imports for consumption of zirconium ores in 1976 totaled 64,643 short tons, a 61% increase compared with 40,205 tons in 1975. The 1975 figure represented the lowest tonnage of ore imported since 1968 (59,900 tons). Zirconium ore imported from the Republic of South Africa is chiefly baddeleyite (ZrO_2) and, prior to 1974, was reported by the Bureau of Census under a single category listing both quantity and value. This ore is now apparently also imported under a blanket category that reports value only. An estimated 2,000 short tons of South African baddeleyite was imported in 1976.

The average value of imported zircon at foreign ports decreased slightly in 1976 to $212.44 per ton, compared with $220.72 in 1975.

Imports for consumption of zirconium and hafnium in 1976 increased both in quantity and value in the following categories: Zirconium, wrought; zirconium alloys, unwrought and waste and scrap; and hafnium, wrought. Imports for consumption decreased in quantity and value in the zirconium chemicals and zirconium oxide categories. Hafnium in the unwrought and waste category was also imported in 1976.

WORLD REVIEW

Australia leads the world in production of zircon, which is recovered from sand mining operations along its eastern coast (68%) and in Western Australia (32%). Production of zircon, a coproduct of rutile in east Australia, is expected to remain relatively constant due to lower grades and reserves coupled with persistent environmental problems. However, substantial zircon reserves with coproduct ilmenite have been located in Western Australia that, when fully developed, will assure Australia's continuing role in the world zircon markets.

Zircon sand is also produced in Brazil, the People's Republic of China, India, Malaysia, the Republic of South Africa, Spain, Sri Lanka, Thailand, and the U.S.S.R.

Baddeleyite is produced in the Republic of South Africa and Brazil and also is found in east Africa, Sri Lanka, and the U.S.S.R.

Australia.—The Federal Government acted to implement the recommendations of the Fraser Island Environmental Inquiry by prohibiting exports, effective December 31, 1976, of mineral sands (zircon and rutile) from Fraser Island, which lies off Maryborough on the Queensland coast.[6] This export ban would effectively end mining on the island. The company most affected by the decisions was D. M. Minerals (DM), whose processing facility was entirely dependent on the island's raw material. The other company, Queensland Titanium, Ltd., was less seriously affected since its mainland processing plant was also fed by other sand operations. DM is a joint-venture of the U.S.-owned Dillingham Corp. and the Australian Murphyores Holdings; Queensland Titanium is a subsidiary of NL Industries.

The Canadian Ionarc Smelters, Ltd., its subsidiary, Ionarc/TAFA Inc., Bow, N. H., and Associated Minerals Consolidated, Ltd. (AMC), have formed an operating company to produce zirconium dioxide directly from AMC's zircon, using Ionarc's unique

plasma-arc technique.[7] AMC also established a zirconium silicate opacifier plant at its Southport works near Brisbane.[8] The plant planned to treat zircon from its Dunwich operation on North Stradbroke Island. In another action, AMC merged with Western Titanium Ltd., a fellow member of the Gold Fields Group.[9] The two companies have a combined production capacity of 170,000 tons of zircon per year.

In Western Australia, Western Titanium completed its mineral sand mining and concentration complex near Eneabba on schedule and started plant commissioning.[10] Shipments were targeted at yearend from its yet incomplete handling facilities at the port of Geraldton. The cost for this complex was estimated at $18.5 million. The AAR group has taken a 50% interest in the holdings of International Nickel Australia in its Eneabba mineral sands prospect,[11] and Westralian Sands Ltd. resumed full-scale mining operations, on standby since November 1975, at its Yoganup beach sand deposit.[12]

Bangladesh.—A feasibility study, including the calculation of ore reserves, assessments of likely products, market studies, preliminary process definitions, and cost studies of beach sand deposits, near Cox's Bazaar, was to be made by the Australian Mineral Development Laboratories (Amdel).[13]

Canada.—AMAX Incorporated and Ontario Hydro abandoned, as uneconomic, plans to construct an integrated plant (zircon-sponge metal-semifabricated products) after an exhaustive study. The project had the backing of experienced metal producers and major customers.[14]

India.— Amdel, in another sand project, was to define a process for a mineral sand operation in Kerala State.[15] The project, on the Arabian Sea, was to include order-of-magnitude capital cost estimates and operating cost estimates.

Sierra Leone.— Sierra Rutile, Ltd., partially owned by Nord Resources Corp., was proceeding with development of its mineral sands deposit at Gbangbama, after receiving Government assurances on tax and fiscal matters and of future Government participation in the project.[16] Production engineering studies were being completed and mining equipment orders placed. The mining project was to be financed in part by a $9 million loan from the Export-Import Bank of the United States.

In another mineral sands venture, Bayer-Preussag Mining Group of West Germany brought a pilot plant for recovering rutile onstream at Rotifunk. The trials should show whether the sands containing rutile, ilmenite, and zircon can be mined and processed economically.[17] The deposit is capable of supplying the entire 50,000 tons per year of rutile consumed in West Germany.

South Africa, Republic of.— The R250 million needed for the new mineral sand project at Richards Bay in Natal has been

secured, and the export of minerals is scheduled to begin in 1978.[18] The project is being developed by Tisand (Pty.) Ltd. and Richards Bay Iron and Titanium (Pty) Ltd. Share capital is held by Quebec Iron and Titanium Corp. (QIT) of Canada (40%), Union Corp. Ltd. (30%), Industrial Development Corp. of South Africa (20%), and a local insurance group (10%).

Preliminary work on the mineralized sands concentrated in an 11-mile strip of dunes, north of Richards Bay, began during 1976, with full mine production scheduled for late 1977.[19] Zircon production, estimated at 115,000 tons per year at full capacity, was slated largely for export. The deposit was said to have reserves for 30 years of operation.

Sri Lanka.— Amdel was to provide plant specifications, selection of tenders, on-site supervision, and general consultation for a major plant expansion program of the country's beach sand operations.[20]

Tanzania.— Feasibility studies were underway on the heavy mineral sand deposits located near Mtwara on the southeastern coast.[21] The Titanium State Mining Corp., which made the announcement, described similar deposits found at Pemba Island and Bagamoyo, north of Dar es Salaam.

TECHNOLOGY

Bureau of Mines research efforts were directed toward recovering heavy minerals, including zircon, from ores and waste materials; alternate methods for zirconium/hafnium separation; zirconia in titanium and TZM (Mo-0.5Ti-0.08Zr-0.015C) castings, and developing improved ceramic and optical materials. In heavy minerals ore research, the Bureau, in cooperation with Tennessee Valley Authority geologists, investigated the feasibility of recovering zircon and titanium-bearing minerals from the Snowbird Formation in Tennessee. Samples from gold dredging and sand and gravel operations in northern California were also studied, and physical beneficiation schemes were developed for concentrating the heavy minerals from selected localities. Recyclable zircon concentrate and zircon-periclase mixtures were reclaimed from steel foundry sands and investment casting wastes.[22] The studies on alternate methods for zirconium/hafnium separation have delineated a new solvent-extraction process that uses nontoxic eagents and reagents that are less flammable than those used in presently practiced methods.[23] This technique also appears to create fewer environmental problems. Two additional methods for solubilizing and separating zirconium and hafnium, after an alkaline fusion technique, were also under consideration. Results from the casting studies showed that a fused stabilized zirconia mold wash, when bonded with zirconium acetate and coupled with either zircon or olivine sand, gave satisfactory titanium castings. However, whether castings were of aircraft quality was still to be determined. Preliminary results on the TZM castings indicated that shells with a fused calcium stabilized zirconia innerface gave what appeared to be satisfactory castings. To date, of all nonmetal-faced shells (oxides, silicates, carbides, and silicides), only those faced with fused stabilized zirconia were capable of containing molten TZM without serious mold-metal reaction. The improved ceramics materials research concentrated on developing sialons and zirconias suitable for high-temperature combustion and furnacing operations. The effects of various additives on selected physical properties, such as hardness, sintered density, abrasion resistance, and porosity, were being selectively determined. Ambient data indicated that rare-earth-doped sialons have very high modulus-of-rupture values and the rare-earth-doped, calcium-stabilized zirconia exhibited superior abrasion resistance. A contract was also let for investigating the calcia-stabilized zirconia-alumina system as a potential refractory in coal gasification processes.[24] This work was to emphasize microstructural and phase changes in this system after subjection to temperatures as high as 1,300° C for up to 2,000 hours. A

report on the continuing optical-materials research detailed preparation of spectrally selective solar absorbers by depositing a semiconducting film on a reflective base.[25] Zirconium compounds with the general formula, ZrC(x)0(y)N(z), or similar titanium compounds or pure silicon were applied over a silver film. Recent work has revealed two ways of increasing solar adsorption without appreciably increasing the emittance.

A generalized flowsheet and discussion of the Richards Bay, Republic of South Africa, mineral sands mining and ilmenite smelting complex was summarized.[26] This summary covered the entire operation from the mining by two dredges to the final ilmenite-smelting process. Included also was the separation scheme for recovering zircon, magnetite, ilmenite, and rutile concentrates. The dredge fed a primary Reichert cone concentrator floating plant followed by conventional wet and dry mills, high-intensity magnets and tension separators, and spirals. This article covered all facets of the project, including the history, metallurgical investigations, financing, mining, concentrating, smelting, markets, services, and environmental planning. A more detailed treatment of the Richards Bay beach sand project was offered in another article.[27] A brief state-of-the-art article on wet gravity separation, used extensively in mineral sands processing, was published.[28] The article cataloged recent advances in high-feed-densities and high-capacities, improved pumping and instrumentation, which have provided the new tools necessary for designing efficient, compact gravity circuits. The Bartles Mosely concentrator, capable of recoveries below 15 micrometers, with a throughput capacity of 4 to 6 tons per hour, was also included in the discussion.

A comprehensive study dealt with the role of thermal plasma techniques in meeting the future demand for new raw materials.[29] The study, advocating electric power economy, discussed the thermal fundamentals of thermal processing, including reaction models and heat transfer analysis, as well as different types of reactors, their construction, and several successful applications. An application of particular interest, the plasma dissociation of zircon to zirconia, was included.

A partially stabilized zirconia (PZS) ceramic material of unusual properties was developed.[30] The new, high-performance ceramic reportedly would have great potential where toughness and resistance to thermal attack and temperature were required. Life tests on extrusion dies, an important use for fabricated zirconia products, indicated that this ceramic outlasted conventional dies. Other works on high-performance ceramics on another PZS and an Al_2O_3-ZrO_2 material were also published. In the PZS research, finely divided yttria-stabilized zirconia powders were fabricated into specimens by die-pressing, extrusion, and slip-casting methods, and tested for flexural strength.[31] The investigation showed that the gross pores present in unfired specimens varied with fabrication procedures and persisted in the fired microstructures. It appeared that the ultimate flexural strength of extruded and pressed specimens were limited by residual coarse pores near the surface. However, the pressure-cast specimens, with no apparent internal pores larger than grain, exhibited unusually high flexural strengths. This research should improve the conventional fabrication of these new high-performance ceramics. In the Al_2O_3-ZrO_2 study, the fracture toughness of Al_2O_3 was increased considerably by dispersing a second phase of unstabilized zirconia particles.[32] The toughness of these materials was found to increase when uniform, evenly dispersed ZrO_2 particles with a diameter slightly greater than a theoretically determined critical particle size were added. This concept of using unstabilized ZrO_2 inclusions should be applicable in toughening other ceramics.

Phase relations and thermal expansion in the system HfO_2-TiO_2 were investigated in the 0- to 60-mole-percent TiO_2 region using X-ray diffraction and differential thermal analysis, melting point studies, and dila-

tometry.[33] This work, in a system of compositions with extremely low coefficients of thermal expansion, related this desirable physical property to microcracking. Refractory oxide-metal eutectics were identified and tabulated in a study along with those reported by other investigators.[34] These oxide-metal composite structures formed by directional solidification of eutectic systems show promise for use in high-temperature structural materials, owing to the additive properties of the oxide and metal phases present, and in electronic application where the highly directional properties of the structures can be utilized. A report presents the experimental results on the photochromic effect in iron-doped PLZT (lanthanum-modified lead zirconate-titanate) ceramics, a new class of ferroelectric materials with high optical transparency in the visible light region and strong electrooptics.[35] Considering the results, a mechanism for the effect was proposed in terms of a photoinduced charge-transfer process between the doped impurity atoms. The photochromic effect in transparent ceramic materials may lead to new types of applications, including optical memory and display devices.

A new approach was outlined to investment casting (a large zircon sand and flour consuming industry) which would result in more pieces per mold, lower pouring temperature, less poured weight per part, and higher metallurgical quality, all at reduced costs.[36] The new approach uses a vacuum to draw the molten metal into the bottom of a mold instead of the conventional top pouring method.

Work on producing zirconium and hafnium by reducing oxide ores was described in a recent patent.[37] A mixture of finely divided ore, sodium hydroxide, and sugar is heated to a predetermined ignition temperature, and the reactants flushed and boiled with water to preferentially leach the waste chemical compounds. This residue is then leached with hydrochloric acid and a hydrocarbon solvent, boiled again with water, and subsequently flushed and dried. This purified material is then smelted to a commercial-grade ingot or powder.

Advanced refractory superalloy materials, such as dispersion-strenghthened alloys and directionally solidified eutectics, will be used to increase the operating life of the new gas turbine engines. These nickel-based superalloys, large consumers of zirconium and hafnium, are presently being subjected to increasingly more hostile environments; research is being conducted toward improved high-temperature coatings to permit burning cheaper liquid fuels derived from coal or, if possible, gaseous fuels from a fluidized bed reactor. Research in this area was highlighted in a review article[38]. Test data presented show that plasma-sprayed zirconia-based ceramic coatings, on suitable bond coatings, provide an effective thermal and/or protective barrier for nickel base alloys. Cyclic tests at elevated temperatures up to 1,000° C were most encouraging. Several new aluminum and titanium high-performance aircraft alloys were developed, including several promising, high-strength aluminum powder alloys.[39] These alloys, all containing zirconium, showed increased tensile properties while retaining excellent corrosion resistance, fatigue resistance, and toughness. A new series of beryllium-titanium-zirconium amorphous or "glassy" alloys, offering lightweight, high strength and excellent stiffness, were produced in pilot quantities.[40] Hafnium-nitride-coated tungsten carbide cutting tool inserts were undergoing extensive field tests.[41] Preliminary results showed that hafnium nitride, with its high temperature hardness, appeared to last twice as long as titanium-nitride-coated inserts.

ARSENIC[1]

Legislation and Government Programs.—The Occupational Safety and Health Administration (OSHA) accepted written comments until July 23, 1976, and held an informal hearing on August 24, 1976, to receive oral testimony regarding an economic and inflation impact statement prepared by OSHA on the proposed standard for occupational exposure to inorganic arsenic. These written and oral submissions were to be used in conjunction with information supplied at 1975 hearings to promulgate emission standards.

An in-depth study for the Environmental Protection Agency (EPA) assembled and interpreted comprehensive information on arsenic and its compounds and the effects of these substances on people, animals, and plants.[2] Another study for EPA assessed the role of arsenic and its compounds in the environment and in the economy of the United States and evaluated the need for and the projected effect of controlling its production, use, dissipation, and emission.[3]

The Puget Sound Air Pollution Control Agency (PSAPCA), in February, granted a 5-year variance from the State of Washington air quality standards to ASARCO Incorporated for operation of its Tacoma arsenic-producing facility.

Domestic Production.—Arsenic trioxide (As_2O_3) was produced domestically only at the Tacoma, Wash., copper smelter of ASARCO Incorporated. Production data cannot be published. Compared with the 1975 figure, output declined 14%, shipments were 5% lower, and stocks advanced 1%. Production of arsenic metal, begun by ASARCO in 1974, continued in 1976.

Consumption and Uses.—Apparent consumption of arsenic, essentially all as white arsenic (As_2O_3), was substantially less than in 1975.

The use of chromated copper arsenate (CCA compounds) in 1975, the latest year for which data are available, was 7,938 tons, an increase for the eigth consecutive year. Consumption of fluor chrome arsenate phenol (Wolman salts and osmosalts) continued to decline; with 584 tons consumed in 1975. Data on consumption of other arsenic compounds, such as calcium and lead arsenate, cannot be published. Small quantities of high-purity arsenic were used in the manu-

[1]Prepared by H. J. Schroeder, physical scientist.

[3]Burruss, R. P., Jr., and D. H. Sargent. Technical and Microeconomic Analysis of Arsenic and its Compounds. Versar Inc., Rept. 454-2, Apr. 12, 1976, 228 pp; available from National Technical Information Service, Springfield, Va., PB 253980.

facture of gallium and indium arsenides for semiconductors.

Prices.—The price of refined white arsenic, 99.5%, at New York docks, quoted at 20 to 23 cents per pound at the start of 1976, decreased to 20 to 21 cents per pound on December 6. Refined white arsenic at Laredo increased from 16.5 to 17 cents per pound on August 8, 1976. The price quotation on arsenic metal at Tacoma advanced from $1.60 to $1.75 per pound on April 1, 1976.

Arsenic metal was quoted in £ London at £ 2,175 per metric ton with advances to £ 2,400 on April 14, to £ 2,550 on July 15, to £ 2,750 on September 30, and to £ 2,950 on December 16.

Foreign Trade.—Imports of white arsenic slumped to only 35% of the 1975 level owing to negligible imports from Sweden, historically the principal supplier. Mexico became the dominant supplier of white arsenic imports, accounting for 89% of the total. All of the arsenic acid (39,628 pounds) came from West Germany; and all of the arsenic sulfide (550,273 pounds) was received from Sweden; 37,478 pounds of sodium arsenate came from the United Kingdom, and 1,684 pounds came from West Germany. Of the 80,831 pounds of other arsenic compounds imported in 1976, 77,161 pounds came from France, 3,393 pounds came from the United Kingdom, 165 pounds came from Switzerland, and the remaining 112 pounds came from West Germany, the Netherlands, and Japan.

Arsenic metal imports totaled 288 tons, only one-half the 1975 level. Sweden supplied 269 tons, Canada 13 tons, and West Germany 4 tons. Smaller quantities were received from Japan, the United Kingdom, the Netherlands, and Belgium-Luxembourg.

Tariff.—Arsenic oxide (white arsenic) enters the United States duty free. A duty of 2 cents per pound was applicable to arsenic metal.

Table 1.—U.S. imports for consumption of white arsenic (As_2O_3) content, by country

[e]Estimate. [p]Preliminary. [r]Revised. W Withheld to avoid disclosing individual company confidential data.
[1]Including calculated arsenic trioxide equivalent of output of elemental arsenic and arsenic compounds other than white arsenic, where inclusion of such materials would not duplicate reported white arsenic production.
[2]In addition to the countries listed, Austria, Belgium, the People's Republic of China, Czechoslovakia, East Germany, Finland, Hungary, Southern Rhodesia, United Kingdom, and Yugoslavia have produced arsenic and/or arsenic compunds in previous years, but information is inadequate to make reliable estimates of output levels.
[3]Output of Tsumeb Corp. Ltd. only.

Technology.—Results of a study to determine any potential arsenic contamination of a proposed reservoir by geothermal springs were published.[4] The study concluded that the effect of the arsenic on the water quality of the reservoir would be minimal.

Research was reported on the effect of four arsenicals — cacodylic acid, cacodylate acid plus sodium cacodylate, arsenic trioxide, and arsenic pentoxide — on the survival of exposed meadow katydids. Life expectancies were reduced to less than 10% of unexposed populations by levels above 5 micrograms of arsenic per gram dry weight in dosing formulations.[5]

CESIUM AND RUBIDIUM[6]

Domestic Production.—There was no domestic production of cesium- or rubidium-bearing minerals during 1976. Cesium and its compounds were produced from imported cesium ore (pollucite). ALKARB, a residue from the processing of lithium ores in previous years, and lepidolite were the sources of domestically produced rubidium and its compounds.

Total production of cesium and rubidium chemical compounds increased 13% and 20%, respectively, compared with 1975 levels. No production of cesium or rubidium metal was reported, but small quantities of both metals were shipped from stocks.

The following companies were the major sources of cesium and rubidium chemicals: Kawecki Berylco Industries, Inc., Revere, Pa.; Kerr-McGee Corp., Trona, Calif.; and Great Western Inorganics, Inc., Golden, Colo.

Consumption and Uses.—Definitive data pertaining to consumption and end use distribution of cesium and rubidium metals and compounds were not available. However, these materials found commercial application in the manufacture of pharmaceuticals, ultracentrifuge separation of organic compounds, and electronic apparatus such as scintillation counters, photomultiplier tubes, and photoelectric cells. Cesium, rubidium, and their compounds can be substituted for each other in some end uses.

While there were no large-scale commercial uses for cesium, cesium metal and compounds have been used in experimental magnetohydrodynamic (MHD) power generators. If MHD electrical generation is successfully developed, demand for cesium may increase.

Prices.—The American Metal Market quotation for cesium metal, 99+% purity, remained unchanged at $100 to $375 per pound. At yearend Metal Bulletin quoted the nominal price for pollucite concentrates containing a minimum 24% Cs_2O, f.o.b. source, at $12.40 to $13 per metric ton unit (22.046 pounds of Cs_2O). No prices were published for rubidium metal.

Source: Kawecki Berylco Industries, Inc.

Foreign Trade.—Pollucite import data were not available. However, reported receipts by consumers indicated that pollucite was imported. Imports of cesium compounds increased from 3,156 pounds valued at $136,203 in 1975 to 4,506 pounds valued at $197,553 in 1976. No cesium or rubidium metal was imported during the year.

Table 5.—U.S. imports for consumption of cesium compounds in 1976, by country

Country	Cesium chloride		Cesium compounds, n.s.p.f.	
	Pounds	Value	Pounds	Value
Germany, West	1,797	$78,830	2,389	$108,955
United Kingdom	308	8,671	12	1,097
Total	2,105	87,501	2,401	110,052

World Review.—The Tantalum Mining Corp. of Canada, Ltd., the major world source of pollucite, made no pollucite shipments from its Bernic Lake, Manitoba, Canada, property during 1976. Late in the year, the Canadian Government placed cesium in all forms on its export control list, banning exports of all cesium-containing materials to any centrally planned economy countries.

GERMANIUM[7]

The new use of germanium as a substrate material for gallium arsenide-phosphide light emitting diodes compensated for the gradual decline in consumption of germanium in semiconductor devices.

Domestic Production.—The only primary producer of germanium in the United States was Eagle-Picher Industries, Inc., of Quapaw, Okla. Much of its output was derived from zinc smelter residues stockpiled in past years from treatment of concentrates from the Kansas-Missouri-Oklahoma district. These residues were supplemented by secondary material from waste and from scrap produced in the manufacture of electronic components and semifabricated shapes.

Other producers of germanium using imported metal, oxide, and scrap or domestic secondary materials were Kawecki Berylco Industries, Inc., Revere, Pa.; Atomergic Chemetals Corp., Plainview, N.Y.; and Texas Materials Laboratory, Garland, Tex.

Production of germanium from domestic sources during 1976 was estimated to be 32,000 to 40,000 pounds. The value of domestic production was approximately $5 million, based on the producer price for refined germanium.

[7]Prepared by John M. Hague, physical scientist.

Consumption and Uses.—During 1976 the use of germanium increased in light-emitting diodes made from heteroepi wafers with gallium arsenide phosphide epitaxial deposits on germanium substrates. Two companies, Texas Instruments, Inc., and Texas Materials Laboratory, announced that they could supply such material for use in digital calculators and digital watches. This development compensated somewhat for the continued decline in use of germanium in conventional types of semiconductors such as transistors and signal diodes. Several manufacturers of power transistors believe that germanium is superior to silicon for heavy-current semiconductors, and they foresee a growing market for such devices. Another use that may become important is in glass fiber light guides, which are likely to find applications in urban communications systems. Germanium was in increased demand for infrared optical systems. Forward-looking infrared detection devices (FLIR systems) often contain several large germanium lenses. Contracts for programs using these instruments were awarded in 1976 and were expected to extend into 1977. Nuclear radiation detectors consumed a small fraction of the germanium supply. Other uses included glass microscope lenses, fluorescent lamps, experimental catalysts, and alloys for brazing and soldering materials.

The estimated distribution of consumption by classes was about 65% in electronic components and accessories, 25% in optical instruments and lenses, 3% for research, and 7% for other uses.

Prices.—The prices of domestic zone-refined germanium and domestic germanium dioxide were $293 and $167.50 per kilogram, respectively, from 1970 through 1976. Prices for imported germanium, quoted as a New York dealer price in Metals Week, have been $330 per kilogram for metal and $174.50 for germanium oxide since March 3, 1975.

Foreign Trade.—U.S. imports of germanium metal (unwrought, waste and scrap) totaled 7,600 pounds in 1976, less than half the quantity imported in 1975. West Germany and the U.S.S.R. were the leading suppliers. The value per pound of imports from Belgium-Luxembourg was high, probably because the Belgian material was high-purity single crystal, whereas other imports were partly concentrates or scrap.

Table 6.—U.S. imports for consumption of germanium in 1976, by country

Country	Quantity (pounds)	Value
Unwrought, and waste and scrap:		
Belgium-Luxembourg	830	$643,907
Germany, West	4,171	184,402
Japan	21	507
Netherlands	663	32,536
Switzerland	8	439
U.S.S.R.	1,914	150,118
Total	7,607	1,011,909
Wrought: Belgium-Luxembourg	39	10,214

World Review.—World production of germanium in 1976 was estimated to be 150,000 to 200,000 pounds, slightly less than in 1975.

Major producing countries reported to have primary sources of supply were the United States, Japan, the U.S.S.R., Zaire, Territory of South-West Africa, and Italy. Other countries with major refining capability were Belgium, West Germany, the Netherlands, and the United Kingdom.

Japan reported production of 35,000 pounds of germanium and 48,000 pounds of germanium oxide. The Kipushi mine in Zaire was the source of germanium-bearing byproducts to be refined in Belgium, but the rate of production at Kipushi in 1976 was less than in recent years.

Technology.—Research continued in 1976 on the future use of germanium in solar cells, superconductors, optical fibers, and antimicrobial organogermanium.

Bell Laboratories and Western Electric Co. were testing an experimental optical communications system in Atlanta, Ga., using optical fibers drawn from quartz tubes after layers of germanium-doped silicon dioxide had been deposited on the inside walls of the tubes.[8]

[8]Chemical and Engineering News. Tests Aim at Fiber Optics Phone System. V. 54, No. 31, July 26, 1976, pp. 17-18.

INDIUM[9]

Domestic Production.—Indium was produced during 1976 by ASARCO Incorporated at its Denver, Colo., plant and by Indium Corp. of America in Utica, N.Y. In May, The New Jersey Zinc Co. and Indium Corp. of America formed a partnership to produce refined indium. The new company, NJZ Alloys, Inc., would use production facilities at the Palmerton plant of New Jersey Zinc, and technical guidance and marketing would be provided by Indium Corp. Other companies, such as Metal Specialties, Inc., in Fairfield, Conn., processed or refined imported material to produce alloys or high-purity metal components and compounds. More than half of U.S. consumption was supplied from domestic production or from stocks, and the balance was furnished by imports and secondary or scrap materials.

Consumption and Uses.—Indium supplies became rather tight in 1976 as demand improved and imports remained at a relatively low level. Demand was estimated to be in the range of 650,000 to 700,000 troy ounces, with 40% being consumed in solders, low-melting alloys, and coatings, 29% in instrument applications and holding devices, 10% in electronic components, and 21% in research and other uses.

Stocks.—Producer stocks continued to decline and at yearend probably represented less than a year's supply.

Prices.—The tight supply situation in 1976 set off a series of price increases. Indium pricing is based on the standard-grade metal, 99.97% pure. During 1975 the price was $5.50 to $6 per troy ounce and it remained at that level until April 1976. As a result of price increases in April, June, August, September, and October, the yearend price was $10 to $10.25 per troy ounce. Higher purity grades, 99.999% plus, sold at a premium.

Foreign Trade.—Imports of indium in 1976 did not return to the high level of the 1970-74 period but were more than twice the small quantity imported in 1975. The value of imports, $1.8 million, reflected the fourfold increase in price during the last 3 years. Canada, Peru, and Japan were the major sources of supply with East Germany moving up to fourth place. No direct imports were reported from the U.S.S.R.

The duty on unwrought, waste and scrap indium has been 5% ad valorem since January 1, 1972, for the most favored nations. Duties on waste and scrap have been suspended until June 30, 1978. The duty on wrought indium was 9%. Statutory duties for the U.S.S.R. and East Germany were 25% ad valorem on unwrought and 45% ad valorem on wrought metal.

[9]Prepared by John M. Hague, physical scientist.

Total	1	8	(1)	2	16	7

[1]Less than 1/2 unit.

World Review.—The short supply situation for indium in 1976 was caused by several factors working to reduce world supply. Cominco Ltd., the sole Canadian producer, released only 197,000 troy ounces compared with 224,000 troy ounces in 1975 and 259,000 troy ounces in 1974. ASARCO, one of two U.S. producers, had announced in 1975 that production would be phased down at its Denver plant with intermittent production through 1976 and 1977. The U.S.S.R., which at times has placed large amounts of indium on the market, chose to make no sales to the United States in 1976. Japan, usually an indium exporting nation, had an unexpected increase in demand and imported more than 138,000 troy ounces in 1976. World production was estimated to be about 1.8 million ounces, higher than the 1.5 million ounces in 1975 but lower than the 2.0 million troy ounces estimated for 1974.

Technology.—Polycrystalline indium phosphide films without pinholes were grown on molybdenum sheets using indium and phosphorus trichloride as source materials.[10] Energy use in processing primary indium-bearing materials was estimated in connection with a study of energy use in the production of other commodities by Battelle Columbus Laboratories; the energy required to produce 1 ton of indium metal was estimated to be 509 million British thermal units.[11]

RADIUM[12]

The major use for radium was in therapeutic treatment of cancer. Replacement of radium by other radioisotopes continued.

Domestic Production.—There was no reported radium production in the United States during 1976. Imports, withdrawals from company stocks, and reprocessing supplied sufficient radium to meet the small domestic demand. Radium Chemical Co., Inc., New York, was the main domestic dealer.

Consumption and Uses.—Radium was mostly used in the therapeutic treatment of cancer. A few tens of millicuries of radium were consumed in the production of home alarm smoke detectors. Other uses of radium were as a source of gamma radiation, used in soil moisture density gages and in static eliminators, although polonium-210 was replacing radium. One traditional use of radium, as an illuminator on alarm clocks, was almost completely replaced by tritium; however, at least 24 millicuries of radium-226 was applied to about 1 million timepiece hands and dials. Radium is also used in calibration sources and laboratory standards.

About 900 grams of radium was used in the United States, and around 93 grams was stored in a Government-owned depository in Alabama during 1976. About 48 requests for storage of materials containing a total of 3,500 milligrams of radium were received by the Bureau of Radiological Health, U.S. Department of Health, Education, and Welfare.

Prices.—Radium prices, per milligram unencapsulated, were quoted by Radium Chemical Co. as follows: Less than 100 milligrams, $26.50; 100 to 199 milligrams, $25; 200 to 499 milligrams, $22; and 500 milligrams to 5 grams, $18. There was no change from the 1975 prices.

Foreign Trade.—Official trade statistics did not report trade in radium as such, but included radium with other radioactive commodities. Belgium remained the principal source of imported radium.

World Review.—Information on radium in world markets was not readily available. The largest radium producer and supplier was the Belgian company Union Minière S.A. Small quantities of radium were also apparently produced in Canada, the United Kingdom, and some countries having centrally controlled economies. The industrial nations consumed most of the radium; use patterns were similar to those of the United States.

Technology.—During uranium extraction nearly all the radium remains in

[12]Prepared by M. L. Kahn, physical scientist.

the mill tailings, causing storage and possible environmental problems.

The U.S. Environmental Protection Agency, Nuclear Regulatory Commission, Energy Research and Development Administration, and Bureau of Mines continued studying potential health hazards and possible seepage and erosional problems of radioactive uranium tailings. The radiation level within structures built on reclaimed phosphate lands in Florida was under investigation. The radioactivity of 1,000 structures was to be studied. In addition, the radium-226 content of well water was to be measured, aerial radiation surveys were to be made, and mined phosphate lands in central Florida were to be inventoried and categorized. A 50-foot core sample from an area in Polk County emitting high levels of radiation was obtained for analysis.

A tentative reference method for the measurement of total radium and radium-226 in environmental water sources was described.[13]

SCANDIUM[14]

Minor quantities of scandium were consumed during 1976, mostly in research applications. There was no mine production of scandium, and imports and industrial stocks were sufficient to meet demand. One domestic producer provided the majority of the scandium metal and compounds consumed.

Domestic Production.—In 1976 there was no domestic mine production of scandium. Imports and company stocks of scandium were sufficient to supply domestic demand. There were two major producers of scandium metals and compounds—Research Chemicals, a division of Nucor Corp., Phoenix, Ariz., supplier of about 90% of domestic demand; and Atomergic Chemetals Corp., Plainview, N.Y. During 1976 there was a slight increase in the demand for scandium products, although this demand still totaled only a few tens of pounds.

Consumption and Uses.—Research and development continued to be the major consumer of scandium. In addition, there were three main industrial uses. High-purity scandium metal was a component in special high-intensity mercury vapor lamps used for providing outdoor lighting for events televised in color. These lamps emit an illumination approaching the quality of sunlight. Small quantities of scandium strengthen magnesium alloys. Scandium-46 was used for tracing underground fluid flows in petroleum production. Some scandium was consumed by the chemical and electronic industries.

Prices.—During 1976 the prices of scandium metal and compounds remained stable at the 1975 levels, listed in the following tabulation as quoted by Research Chemicals. Scandium was also available in sheet foil 0.001 to 0.1 inch thick at $22 to $130 per square inch in 1- to 10-square-inch lots.

Metal	Per gram, 1 to 99 grams	Per gram, 100 to 453 grams
Ingots	$10.50	$8.00
Powder	11.50	10.35
Chips	11.50	10.35
Distilled	19.00	15.00
Oxide:		
99.99%	5.00	4.00
99.9%	3.50	2.80
Salts [1]	2.50	2.00

[1]Salts include acetates, carbonates, chlorides, nitrates, and oxalates in most stable, hydrous form produced from oxides of 99.9% minimum purity.

Foreign Trade.—There were no official U.S. foreign trade statistics for scandium. Scandium was included in other minerals and metals statistics, however, scandium trade is believed to be minor. Based on available information, Australia and the centrally controlled economy countries were the principal suppliers of scandium-bearing raw materials.

World Review.—Information on scandium-related activities in foreign countries was not readily available. The industrialized nations were involved in scandium research and used small quantities of scandium in industrial applications.

Technology.—Scandium is used in research and a few industrial applications. Most research is basic and oriented toward study of scandium behavior in different environments. However, some results may lead to uses of scandium in metallurgy and in production of ceramics, catalysts, electronic equipment, light bulbs, nuclear reactors, and radioactive tracers.[15]

[13]Environmental Protection Agency. Measurement of Total Radium and Radium-226 in Environmental Waters. A Tentative Reference Method. EPA 600 4-76 012, March 1976, 37 pp.

[14]Prepared by M. L. Kahn, physical scientist.

[15]Horovitz, A. C., K. A. Gschneider, G. A. Melson, D. H. Youngblood, and H. H. Schock. Scandium—Its Occurrence, Chemistry, Physics, Metallurgy, Biology, and Technology. Academic Press, London, 1975, 525 pp.

In metallurgy, the addition of scandium as an alloying element is effective in strengthening magnesium alloys and in refining the grain size of aluminum and increasing its strength. Scandium spheroidizes graphite much more effectively than rare earths or magnesium in cast iron. The addition of scandium carbide to titanium carbide increases hardness, making this carbide the second hardest material known, exceeded only by diamond. Scandium oxide has better heat resistance and thermal shock properties than conventional materials used in glass compositions for flame spray coatings. In electronics, ferrites containing scandium are used in rapid-switch memory cores, and scandium lowers the magnetic induction of these ferrites by about one-half.

A magnetically controlled switch is used that modulates light passing through a single-crystal yttrium-gallium-scandium-iron-garnet film. It may be used in telecommunications where laser beams are used. Scandium metal is also used as a neutron filter because it is transparent to 2-kilavolt neutrons but stops all other neutrons.

Some recent research results were described in Chemical Abstracts in 1976. A self-destructive gamma ray source for guided-missile guidance systems, containing scandium oxide or tantalum oxide as an active material, was described.[16] Tritides of scandium were found to be useful materials for determining the effects of helium accumulation in metallic solids.[17] A scandium salt was reported to be a satisfactory activatable tracer for evaluating the performance of waste water treatment plants.[18] Release of radioactivity from a scandium tritide electron capture detector used in gas chromatography was studied.[19] Significant tritium buildup in gas chromatography equipment and in the mailing container was reported as a possible health hazard to laboratory personnel.

SELENIUM[20]

Domestic production of selenium from primary materials was 400,600 pounds in 1976, a 12% increase over the 1975 production of 357,700 pounds. Shipments by domestic producers increased 30% to 369,600 pounds of selenium. Producer stocks increased 16% over yearend 1975 stocks to 176,700 pounds. Apparent consumption for the year was 989,800 pounds, the lowest since 1972. Continuing the 1974-76 trend, net imports remained at relatively high levels, accounting for 617,800 pounds, or 62% of apparent consumption for the year. Major new copper byproduct refineries in Amarillo, Tex., and Ndola, Zambia, began production in 1976. Led by Japan, world production increased 8% to 2.8 million pounds.

Legislation and Government Programs.—On May 26, 1976, the General Services Administration (GSA) sold the last lot of 2,500 pounds of selenium from the national stockpile. Bids ranged from a low of $9.05 per pound to the winning bids of $17.015 per pound of selenium. Selenium is no longer a stockpile item and was excluded from the list of proposed new stockpile goals released by the Federal Preparedness Agency on October 1.

[e]Estimate.

Domestic Production.—In the United States in 1976 primary selenium was recovered at three copper refineries; AMAX Copper, Inc., Carteret, N.J.; ASARCO Incorporated, Amarillo, Tex.; and Kennecott Copper Corp., Magna, Utah.

In addition anode slimes recovered from the electrolytic tanks of copper refineries and residues of pollution abatement plants at nonferrous smelters and refineries owned by other foreign and domestic mining companies were shipped to these plants for recovery of gold, silver, selenium, and tellurium.

High-purity selenium and various selenium compounds were produced by primary and other processors from commercial-grade metal.

ASARCO began production of selenium from its byproduct recovery circuit at the new Amarillo, Tex., copper refinery in early 1976. Selenium production continued to be affected by the sluggish copper market and the reduced levels of available slimes. In 1976 the U.S. electrolytic copper refineries operated at about 70% of capacity.

Data on actual recovery of selenium from secondary material were not available, but it has been estimated that in 1976 around 190,000 pounds of selenium were refined from scrap recovered from rectifiers and from xerographic and chemical processes.[21] Part of the scrap supply is reprocessed in Canada and returned to U.S. markets for consumption.

Consumption and Uses.—Apparent consumption of selenium in 1976, consisting of shipments from primary producers, net imports, and stockpile releases, decreased 7% to 989,000 pounds from 1975 and nearly 37% from 1974. The reduced demand for selenium-bearing materials in glass, pigments, specialty steels, and electronic components still mirrored the impact of the 1974-75 recession on construction and manufacturing activity in the U.S. economy during this period. Trends in 1976 suggested the following estimate of selenium purchases and consumption by end use categories: Electronic and photocopier components, 35%; glass manufacturing, 30%; chemicals and pigments, 25%; and other, 10%.

In electronic and photocopier applications selenium is used in semiconductors, photoelectric cells, and calculators, and as the key photoreceptor element in xerography. High-purity grades of selenium are preferred in these applications.

A major consumer of selenium is the glass-manufacturing industry; 0.02 to 0.03 pound of selenium is added per ton of glass to neutralize the green iron discoloration. Dark-colored selenium-bearing environmental glass is used as an energy conservation material in office windows to reduce glare and heat transfer.

The main use of selenium in the industrial chemical field is in cadmium sulfoselenate compounds, which are used widely as yellow and red pigments in plastics, paints, inks, and enamels where long life, brilliancy, light, heat, and chemical stability are required. Selenium is also used as a dandruff treatment and in other pharmaceutical preparations.

Demand for selenium in other end uses included the addition of small amounts of ferroselenium to stainless steel to improve casting, forging, and machining characteristics. There are also minor applications for elemental selenium and selenium diethyldithiocarbamate in the processing of natural and synthetic rubber. Selenium in the form of sodium selenite is added to premixed chicken, swine, and turkey grain feed additives as a nutrient to control diseases and to increase the rate of growth.

Stocks.—The drop in consumer demand for selenium contributed to an increase in

[21]Baltrusaitis V. A. Selenium—Demand Rises From Depressed '75. Eng. and Min. J., v. 178, No. 3, March 1977, pp. 190-191.

U.S. producer stocks. Yearend stock levels of 176,700 pounds were the highest since 1971. Stock levels represent about 2 months' supply at the 1976 rate of consumption.

Prices.—Selenium is usually sold as minus 200-mesh commercial-grade powder containing 97% to 99.94% selenium or as high-purity grade in pellets, sticks, and powder containing 99.95% to 99.99+% selenium. Pellets containing 99.999+% selenium are also available.

Domestic producer prices for commercial-grade selenium remained at $18 per pound, unchanged since May 1974; prices for high-purity grades remained at $21 to $22 per pound, unchanged since January 1975. U.S. and European dealer prices moved approximately in unison during 1976, increasing from a January low of $9.50 for commercial-grade selenium to a high of $20 per pound in late April. Dealer prices held at $17 to $18 per pound from May to October, then declined to $12 to $14 per pound by yearend.

Foreign Trade.—Selenium exports increased 65% over 1975 to 193,484 pounds valued at $2,559,258, with an average value of $13.23 per pound. As shown in table 9, the United Kingdom (35%), Canada (28%), West Germany (9%), and the Netherlands (9%) took delivery of the major share of exports.

Selenium imports for consumption decreased to 811,257 pounds from the record high 1975 level of 889,320 pounds; the value of imports increased 18% to $12,117,580. The average value of unwrought selenium metal imported during the year was $15.06 per pound and for selenium dioxide $12.06 per pound. Canada supplied 43% by quantity and 56% by value, and Japan, 23% and 18%, respectively, of all selenium imported.

U.S. import tariff schedule items 632.40—selenium metal, unwrought, other than alloys, and waste and scrap; 420.40—selenium dioxide; and 420.52—selenium salts, were duty-free at yearend. The duty on Item 420.54, other selenium compounds, was 5% ad valorem.

Table 9.—U.S. exports of selenium in 1976, by country

Total all forms	811,257	12,117,580

World Review.—Japan continued as the world's leading selenium producer in 1976 with an output of 1,015,000 pounds, followed by Canada with 760,000 pounds. The U.S.S.R. is known to be a major producer, but data are not sufficient to estimate annual production.

Australia.—Peko-Wallsend Ltd. has been Australia's largest producer of gold, bismuth, and selenium since 1973. No selenium production was reported by the company in 1976. The three copper mines and copper smelters at Tennant Creek, Northern Australia, were shut down all year owing to the weak copper market. Of the two gold mines still operating, Juno and Warrego, the Juno was nearly depleted by yearend. Until copper operations resume and underground development work at the Warrego mine is completed, production of recoverable selenium at Tennant Creek is expected to be small.

The only source of refined selenium in Australia continued to be The Electrolytic Refining & Smelting Co. of Australia Ltd. at Port Kembla, New South Wales.

Belgium.—As part of a 5-year expansion program begun in 1974, Metallurgie Hoboken-Overpelt, one of Europe's largest selenium producers, is increasing its selenium production capacity. At yearend its annual capacity was approximately 331,000 pounds.

Canada.—Selenium production from primary raw materials has decreased since 1971 as an increasing amount of copper production from Canadian mines is derived from selenium-poor ores. The major selenium producers, Canadian Copper Refiners Ltd. (CCR) owned by Noranda Mines Ltd. and The International Nickel Co. of Canada Ltd., have annual capacities of 500,000 pounds and 180,000 pounds of selenium, respectively. In 1976 production of selenium in all forms, from Canadian copper refineries, plus refined selenium from domestic primary materials amounted to 760,000 pounds valued at Can$12.2 million, compared with 755,000 pounds valued at Can$13.9 million in 1975. In 1975 Canada consumed

21,900 pounds of selenium domestically, 75% in glass manufacturing and the remainder in steel and pharmaceutical uses.

Japan.—The output of selenium by the six Japanese producers increased 10% in 1976 to 1,014,586 pounds. Stocks at yearend amounted to 205,800 pounds, representing a 17% decrease from 1975.[22]

Zambia.—The new precious metals refinery at Ndola, designed to recover gold, silver, and selenium from copper tankhouse slimes, became operational in late 1976. This is the first African selenium refinery and will recover seleninum from materials previously refined in Europe.

Table 11.—Selenium: World refinery production, by country[1]

(Pounds)

Total	[r]2,667,679	2,560,517	2,773,256

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]Insofar as possible, data relate to refinery output only; to avoid double-counting countries are excluded that produce selenium contained in copper ores, copper concentrates, blister copper, and/or refinery residues, but that do not recover refined selenium from these materials indigenously.
[2]In addition to the countries listed, West Germany, the U.S.S.R., and Zambia produce refined selenium, but output is not reported, and available information is inadequate for formulation of reliable estimate of output levels.
[3]The output of Peko-Wallsend Ltd., reported in the previous edition of this chapter as Australian output, has been deleted because it represented the content of intermediate products of metallurgical operations which are treated elsewhere to recover elemental selenium. Australia has one metallurgical facility that can recover selenium (the Port Kembla refinery of The Electrolytic Refining & Smelting Co. of Australia Ltd.), but output, if any, by this facility is unreported and no basis is available for estimation.
[4]Net exports (exports minus imports) plus an estimate for domestic consumption.
[5]Refinery output from all sources, including imported materials and secondary sources.

Technology.—A symposium, Selenium and Tellurium in the Environment, held at Notre Dame, Ind., in May highlighted the continued medical and biochemical research into the essential nature of selenium in animal and human nutrition. Studies indicated that excess exposure to most industrially generated selenium compounds may cause temporary but not lethal toxic effects. More research is required to better understand and to control the possible effects of selenium released into the atmosphere from coal-burning plants and into the groundwater from uranium-processing plants.[23]

The National Academy of Sciences published the results of a study on selenium, giving natural sources and methods of analysis; describing its physical and chemical nature, its biologic effects, and its relation to other pollutants; and discussing margins of safety. The report suggests that selenium is probably not a significant pollution problem but recommends a number of areas where further research is needed.[24]

Results of a study showed that the energy required to produce 1 net ton of selenium powder was equal to 297 million Btu.[25]

TELLURIUM[26]

Domestic Production.— Tellurium was recovered domestically as a byproduct of electrolytic copper refining only by AMAX Copper, Inc., at Carteret, N.J., and ASARCO Incorporated, at its newly opened plant at Amarillo, Tex. Commercial-grade tellurium and tellurium dioxide were also produced from the precious- metal-rich anode slimes shipped from other domestic copper refinery tankhouses. High-purity tellurium, tellurium master alloys, and tellurium compounds were produced by primary and intermediate processors from commercial-grade metal and tellurium dioxide. Tellurium production and shipments by producers in 1976 increased relative to the 1975 levels of 131,000 pounds and 163,000 pounds, respectively. Producer stocks dropped from the preceding yearend inventory of 55,000 pounds.

Table 12.—Salient tellurium statistics

rRevised. NA Not available. W Withheld to avoid disclosing individual company confidential data.

Consumption and Uses.—Apparent consumption of tellurium increased substantially over the 1975 demand of 260,000 pounds. Tellurium consumption by end use in 1976 was estimated as follows: Iron and steel production, 77%; nonferrous metal production, 14%; chemical uses, 5%; and other uses including rubber manufacturing, 4%. Tellurium is used in its elemental state as a free-machining agent in stainless steel and copper production, in the chilling of malleable cast iron, and as a curing agent and accelerator in rubber compounding. Bismuth and lead telluride alloys are used in semiconductor and minor thermoelectric applications. Tellurium is used in the dioxide state in the forming and tinting of glass and as a chemical catalyst. Applications for tellurium are somewhat limited by the relatively small availability of refined material and by price. These factors make tellurium susceptible to substitution, particularly by lead in free-machining applications, where the lead exhibits many of the same properties as tellurium. Selenium and sulfur can substitute for tellurium in rubber compounding, and germanium or selenium also substitute in some semiconductor applications.

Prices.—The U.S. producer price for commercial-grade tellurium was $10 per pound from January through October. On November 1, U.S. producers increased the price to the Canadian producers' level of $12 per pound, which became effective on July 1, and where it remained through yearend. In response to high demand and tight supplies of tellurium, the North American producer price increased to $15 per pound in early January 1977. Dealer prices were reportedly near $20 per pound by yearend.

Tellurium is usually marketed in the form of minus 200-mesh powder or as slabs, tablets, or sticks. Normal commercial grades contain a minimum of 99% or 99.5% tellurium. Further refining through distillation and sublimation processes produces high-purity grades, chiefly for use in semiconductors containing 99.95%, 99.999%, and 99.9999% tellurium.

Foreign Trade.—Tellurium metal imports nearly doubled in 1976 to 182,487 pounds valued at $1,583,375, with an average delivered value of $8.68 per pound. In addition 21,047 pounds of tellurium in compounds was also imported. Canada with 70% and Peru with 26% supplied the major share of all imports. There are no data on tellurium exports.

The U.S. tariff for 1976 on TSUS Item 632.48, tellurium metal, unwrought, other than alloys, and waste and scrap, was 4% ad valorem; the tariffs on TSUS Items 421.90, tellurium compounds, and 427.12, tellurium salts, were 5% ad valorem.

[26]Prepared by George J. Coakley, physical scientist.

Table 13.—U.S. imports for consumption of tellurium in 1976, by country

Country	Pounds	Value
Unwrought, and waste and scrap:		
Canada	121,380	$804,418
Germany, West	1	364
Japan	300	5,861
Netherlands	3,516	46,377
Peru	53,787	675,086
United Kingdom	3,503	51,269
Total	182,487	1,583,375
Compounds:		
Belgium-Luxembourg	11	623
Canada	21,018	158,997
Germany, West	11	856
United Kingdom	7	658
Total	21,047	161,134
Grand total	203,534	1,744,509

World Review.—The United States maintained its position as the world's largest producer and consumer of tellurium. Between 1971 and 1975 domestic production accounted for over half of the reported new refined tellurium in market economy countries. During the same period the United States consumed nearly 80% of this reported world production. Production of tellurium outside the United States was estimated at 200,185 pounds. The other main producing countries were Canada, Japan, and Peru. The U.S.S.R. is known to be a substantial producer of tellurium, but insufficient information is available to estimate production. During the tight supply situation of 1976, the U.S.S.R. reportedly was selling tellurium at premium prices on the open market. In Fiji low gold prices threatened to close the Emperor gold mine. Government and corporate subsidies would be required to continue future gold and byproduct tellurium recovery operations.

Table 14.—Tellurium: World refinery production, by country[1]

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available. W Witheld to avoid disclosing individual company confidential data.

[1]Insofar as possible, data relate to refinery output only; thus countries that produce tellurium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but that do not recover refined tellurium, are excluded to avoid double counting.

[2]In addition to the countries listed, Australia, Belgium, West Germany, and the U.S.S.R. are known to produce refined tellurium, but output is not reported, and available information is inadequate for formulation of reliable estimates of output levels. Moreover, other major copper refining nations such as Chile, Zaire, and Zambia may produce refined tellurium, but output in these nations is conjectural.

[3]Refinery output from all sources, including imports and secondary sources.

[4]Not totaled because of the exclusion of United States' data owing to company confidentiality.

THALLIUM[27]

Domestic Production.—The only domestic producer of thallium and its compounds was the Globe plant of ASARCO Incorporated at Denver, Colo. The plant recovered thallium as a byproduct from residues of base metal ore smelting, principally zinc. Production of compounds in 1976 was about 50 times greater than in 1975. No metal was produced, but shipments almost doubled over those of 1975.

Uses.—Apparent consumption in 1976 was about 1,800 pounds. The current uses for thallium include low-melting alloys, low-temperature thermometers and mercury switches, additives for altering the refractive index of glass, high-density liquids for sink-float separation of minerals, photosensitive devices, infrared light transmission devices, and as an additive to mercury lamps.

Prices.—The price of thallium in 25-pound lots has been $7.50 per pound since the end of 1957.

Foreign Trade.—U.S. imports for consumption in 1976 were 66 pounds of unwrought thallium, waste and scrap, valued at $799, and 775 pounds of compounds valued at $17,018. The amount of imported metal was 93% less than in 1975.

World Review.—In addition to the United States, Belgium, West Germany, and the U.S.S.R. produced refined thallium metal.

[27]Prepared by V. Anthony Cammarota, Jr., physical scientist.

GREENSAND[1]

Greensand, which is widely distributed in the Eastern United States, was produced in 1976 only by the Inversand Co., a subsidiary of Hungerford & Terry Inc., near Clayton, N. J. Production and sales information is withheld by the Bureau of Mines.

Raw greensand produced by the company was sold for agricultural use as a soil conditioner. Processed greensand was sold for use as a filter medium for the removal of manganese, iron, sulfide, and other elements from water.

IODINE[2]

The world iodine industry, characterized by short-lived economic cycles, began to recover in 1976 from the surplus supply accumulated in 1975, but greater demand was easily met by withdrawals from stocks. Of the three major market economy countries producing crude iodine, only Japan, by far the largest supplier, increased output over the 1975 level. The output of both the United States and Chile declined in 1976. In all three countries iodine is a byproduct, and therefore is dependent on the primary product. Japanese iodine is processed from natural gas brines, Chilean iodine is associated with the nitrate industry, and U.S. iodine, with bromine. The quoted market price of $2.59 per pound remained stable during 1976, but actual sales were discounted 10% to 20%. Increased U.S. demand for crude iodine was reflected in greater consumption by the major chemical companies, up 20% from that of 1975, and an increase in imports of 22%; furthermore, company inventories decreased 20% during the year.

The small production of The Dow Chemical Co., the only domestic producer, fell significantly from the 1975 level. With the entrance of a new U.S. producer early in 1977, the ratio of domestic supply to demand is expected to change significantly. The new plant near Woodward, Okla., owned jointly by PPG Industries, Inc. and Amoco Production Co., will have a capacity to produce 2 million pounds per year from brines averaging 300 parts per million iodine, which will be the only product of the operation.

Plans to expand iodine operations in Japan were not fully realized in 1976. Although total production increased 2.1% over that of 1975, Japanese plants were not

[1]Prepared by Richard H. Singleton, physical scientist.
[2]Prepared by Sandra T. Absalom, physical scientist.

operating at full capacity, and may not reach capacity in the near future because world demand is being met from excess inventories. The Japanese will be assessing the effect of the new U.S. producer on the world market, as well as the effect of possible release of iodine supplies from the U.S. Government stockpile. Chile's output of crude iodine in 1976 was only about three-fourths of 1975 production; nearly a quarter of this was exported to the United States. The industry is studying possibilities for new markets that would further improve the supply/demand situation.

Legislation and Government Programs.—On December 31, 1976, the U.S. Government strategic stockpile contained 8,011,814 pounds of iodine, the same quantity reported at yearend 1975. The stockpile goal for iodine was changed during the year to 3,333,000 pounds. No iodine disposals were authorized.

The depletion allowance for iodine remained at 14% of gross income, and may not exceed 50% of net income without the depletion deduction.

Domestic Production.—The Dow Chemical Co., supplied a small part of the total U.S. requirement for 1976. A coproduct of bromine, calcium and magnesium compounds, and potash from subterranean brines at Midland, Mich., iodine is recovered by the standard two-step process used by Dow since 1964. Iodine production in 1976 declined from the 1975 level in both quantity and value.

Consumption and Uses.—According to the Bureau of Mines canvass for 1976, approximately 5.3 million pounds of iodine, representing a 20% increase over total iodine consumption in 1975, was consumed by 31 plants in 14 States. Eighteen of these plants, which were located in the leading consumer States of Missouri, New York, New Jersey, and Pennsylvania (in decreasing magnitude of consumption), accounted for 71% of total iodine consumption.

While the canvass information indicates a general consumption pattern, establishing an accurate pattern of demand by end use is difficult because iodine is frequently converted into intermediate compounds and marketed as such before reaching its ultimate end use. Moreover, iodine and iodides used in catalytic and other dissipative processes are not well covered. This situation has been revealed consistently in recent years by import figures that exceeded reported consumption figures; in 1976 iodine imports exceeded reported consumption by 1.2 million pounds. Coupling imports with domestic production and inventory withdrawals, apparent consumption in 1976 was about 7.2 million pounds. Comparision of the results of the 1976 canvass with 1975 figures showed increased consumption of crude iodine for making iodine chemicals in all major categories except one. Following are comparative percentages: Organic compounds, up 9%; total inorganic compounds, up 32%, including potassium iodide, up 72.5%, ammonium iodide, down 7%, sodium iodide, up 28%; and resublimed iodine, up 10%.

The major downstream uses for iodine in 1976 were divided into the following categories: Catalysts for synthetic rubber, 22%; stabilizers (as in nylon precursors), 15%; animal feed supplements (mainly for cattle), 15%; inks and colorants, 14%; pharmaceuticals, 14%, sanitary and industrial disinfectants, 10%; photographic film, 4%; and other uses, 6%. The category "Other uses" includes the making of high-purity metals, motor fuels, iodized salt, smog inhibitors, and lubricants. Iodine also has application in cloud seeding and radio-opaque diagnosis in medicine.

The prospect of expanding demand for iodine appears most promising for catalytic uses. At present, iodine catalysts are used to produce synthetic rubber, stabilized rosin, and tall oil. Proposed new uses for iodine

Table 1.—Crude iodine consumed in the United States

Products	1975			1976		
	Number of plants	Consumption: Thousand pounds	Consumption: Percent of total	Number of plants	Consumption: Thousand pounds	Consumption: Percent of total
Resublimed iodine	6	633	14	6	697	13
Potassium iodide	9	730	17	9	1,259	24
Other inorganic compounds	15	845	19	14	953	18
Organic compounds	21	2,193	50	20	2,389	45
Total	[1]31	[2]4,400	100	[1]31	5,298	100

[1]Nonadditive total because some plants produce more than one product.
[2]Data do not add to total shown because of independent rounding.

catalysts are related to two processes, coal gasification and thermonuclear production of hydrogen, that could provide alternatives to fuel oil. Proven economic feasibility of either process, which may not be achieved for many years, could lead to substantial new demand for iodine. Wider use of iodine as an alternative to chlorine in water purification is also anticipated.

Prices.—The quoted price for crude iodine remained at $2.59 per pound throughout 1976, but actual sales were discounted from 10% to 20%. As the leading vendor of crude iodine in the world market, Japan exemplified this trend in discount sales with total exports for the year averaging $2.14 per pound, 17.5% below the official price and 5% below the average price of $2.28 per pound for Japanese exports in 1975. Although U.S. demand for iodine and iodine compounds in 1976 increased somewhat over that of 1975, and surplus stocks in the United States were decreased about 20%, the continued existence of these inventories plus a new source of U.S. production planned for 1977, combined to exert downward pressure on prices. Higher production costs may have counterbalanced this pressure to some extent, however. The quoted U.S. prices for the element and its primary compounds at yearend 1976, unchanged from yearend 1975, were as follows:

	Per pound
Iodine, crude, drums	$2.59
Resublimed iodine, USP, gran., 100-pound drums, works	$4.00-5.25
Calcium iodate, drums, delivered	3.32
Calcium iodide, 35-pound drums, works	5.98
Potassium iodide, USP, gran., crystals, drums, 1,000-pound lots, delivered	3.76
Sodium iodide, USP, crystals, 300-500 pound lots, drums, freight equalized	5.16
Iodoform, NF, 300-pound drums, f.o.b. works	7.75-14.30

Source: Chemical Marketing Reporter, Dec. 27, 1976.

Foreign Trade.—The quantity and value of crude iodine imported by the United States in 1976 exceeded that of 1975 by 22% and 18%, respectively, but remained below 1974 levels. The average value of imported crude iodine dropped from $2.21 per pound in 1975 to $2.13 per pound in 1976. Of the 6.5 million pounds imported, 90% was from Japan and 10% was from Chile. Although Chilean iodine did not find the ready market in the United States that it traditionally enjoyed prior to 1972 (in 1971 U.S. imports from Chile amounted to 41% of total imports), imports did increase by 81% over those of 1975. Total imports of other iodine compounds, including resublimed iodine, were insignificant compared with crude iodine imports.

Tariff rates were 8 cents per pound on resublimed iodine and 12 cents per pound on potassium iodide. Crude iodine enters the United States duty free.

Table 2.—U.S. imports for consumption of crude iodine, by country

(Thousand pounds and thousand dollars)

Country	1974		1975		1976	
	Quantity	Value	Quantity	Value	Quantity	Value
Chile	1,505	2,972	365	856	661	1,253

Total	7,970	14,849	5,309	11,721	6,482	13,824

World Review.—*Chile.*—Production of crude iodine dropped in 1976 to 3.1 million pounds, a decrease of 28% from the 4.3 million pounds produced in 1975. Iodine, a byproduct of potassium and sodium nitrates extracted from Chile's caliche deposits, is tied to nitrate production, which decreased 15% in 1976. Because of its dependence on the nitrate industry, Chilean iodine has limited flexibility with respect to supply and demand. With the development of synthetic fertilizers after World War I, the once-flourishing natural nitrate industry has suffered considerably, and gradual obsolescence of the extraction technology has limited production as well. In 1976, Government-owned Sociedad Quimica y Minera de Chile S.A. (SOQUIMICH) produced all reported nitrates and iodine from only three mines and plants: Pedro de Valdivia, Maria Elena, and Victoria. Combined capacity for all three amounted to about 4.8 million pounds per year of crude iodine, but this is expected to decrease as equipment wears out. After realizing a $25 million deficit in 1975, SOQUIMICH abandoned all investment projects to increase production and retained only those that would reduce costs. In 1976, the industry began to operate without the need for subsidies.

Exports to the United States increased by 81% in 1976 to 661,000 pounds, a quantity still well below the 1974 figure of 1,505,000 pounds. About 21% of Chile's iodine production was exported to the United States in 1976; most of the balance went to Western Europe and Latin America.

To support employment objectives, Chile's nitrate/iodine industry is labor intensive, maintaining more than 8,000 workers in caliche processing plants and complementary port operations. While most of the nitrate products are produced at a loss, in 1976 the byproduct iodine showed a profit, costing $0.90 per pound to produce, and selling for $2.26 per pound.

China, People's Republic of.—Although data are not available, it is believed that China consumes about one-fourth the quantity of iodine consumed in the United States. Demand is increasing for iodine for food supplements and catalysts. Domestic production from brines and possibly seaweed appears sufficient to satisfy present needs, with few if any imports required. No exports of iodine from Japan to China were reported in 1976, and figures on Chilean exports for the year are not available; however, any exports to China were probably insignificant.

Indonesia.—About 60,000 pounds of crude iodine was produced during 1976. This represented a decrease of 18% from the quantity produced in 1975. The Government of Indonesia and two Japanese firms, Ise Chemical Industries, Ltd. and Mitsui & Co., are building an iodine operation that eventually will have a productive capacity of 600,000 pounds per year.

Japan.—Japan, the foremost producer of crude iodine for the world market, outproduced its closest competitor, Chile, by nearly five to one in 1976. Although production increased 2.1% over that of 1975, reaching 15.3 million pounds, this total was 7% below the 1972 record of 16.5 million pounds. The softening of world iodine demand, which deteriorated through 1975, led to an accumulation of inventories into 1976; however, during 1976, this trend began to reverse, and reviving demand precipitated inventory withdrawals that were expected to continue through 1977. By 1978, inventories are likely to return to basic reserve levels. Japan increased crude iodine exports in 1976 by 884,000 pounds. Export prices averaged $2.14 per pound, or 17.5% below the quoted market price of $2.59 per pound. Exports to the United States amounted to 48% of the total of 12.2 million pounds of iodine shipped to 36 countries. The nine countries of the European Community bought 36% of Japan's iodine, and other significant markets included Switzerland (4%), Canada (2%), and Poland (1.5%). No iodine exports to the U.S.S.R. were reported for 1976, although in 1975, 3.5% of Japan's export total went to the U.S.S.R.

Ise Chemical Industries, Ltd., which produces more than half of Japan's iodine, clearly dominates the industry. All six producers operate on the Chiba peninsula, the original site of the industry, but only Ise has developed additional resources in other parts of the country. As irreversible subsidence problems caused by removal of the subterranean natural gas brines have forced well closings at Chiba, opportunities to increase industrial capacity are available to Ise, but not to the other producers. However, recent depressed-market conditions have inhibited Ise's expansion plans to the extent that the new Miyazaki plant is operating at only one-fifth of capacity and the proposed enlargement of the Niigata plant was never started.

U.S.S.R.—Soviet iodine production capacity is estimated at 3.8 million pounds per year. No iodine imports from Japan were reported for 1976, although imports of 396,000 pounds were reported for 1975, therefore it is believed that the Soviet iodine industry is operating near capacity.

MEERSCHAUM[3]

Crude meerschaum imported for consumption in 1976 totaled 1,200 pounds valued at $310, or $0.26 per pound, c.i.f. Source of the imports was West Germany. This was the first time since 1967 that the United States imported crude meerschaum from that country. Compared with 1975 data, imports declined 89% in quantity and 98% in value in 1976.

QUARTZ CRYSTAL[4]

Production of cultured quartz continued its upward trend, reaching 849,000 pounds in 1976, which was an increase of 17% over that of 1975. Consumption of cultured and natural quartz increased to more than 349,000 pounds compared with 240,000 pounds for 1975. Exports of cultured quartz climbed to a record 457,000 pounds. Production of finished crystal units rose to 82,730,000 units, more than double 1975 production.

Legislation and Government Programs.— The stockpile goal for natural quartz crystal was reduced to zero in October. This action made 2,372,536 pounds of crystal available for disposal as of December 31, 1976. Sales of stockpile excesses totaled 443,392 pounds in 1976. Some of the material sold from the stockpile was purchased and consumed by fused quartz operations.

Domestic Production.— The publication, Arkansas Mineral Producers and Production 1976, prepared by the Arkansas Geological Commission, listed three companies as producers of natural quartz crystal: Quartz Processing Co., Hot Springs, Ark., 500,207 pounds; Ocus Stanley, Mount. Ida, Ark., 5,400 pounds; and Terry Mining Corp. Midwest City, Okla., 7,695 pounds. The large quantity produced by Quartz Processing Co., is used primarily as lasca (lump quartz used as a feedstock for growing cultured quartz).

Cultured Quartz production increased from 724,343 pounds in 1975 to 848,688 pounds in 1976. Production was stimulated by the continued interest in citizens band (CB) radios, and in electronic watches. The cultured crystals were produced for domestic and export markets.

The eight producing companies reported consumption of 1,032,284 pounds of lasca.

[3]Prepared by A. C. Meisinger, industry economist.
[4]Prepared by Stanley K. Haines, physical scientist.

The bulk of this material was imported from Brazil but production from Arkansas added to the total.

The eight companies reporting production of cultured quartz were as follows: P. R. Hoffman Co., Carlisle, Pa.; Motorola, Inc., Chicago, Ill.; Bliley Electric Co., Cortland, Ohio; Sawyer Research Products, Inc., Eastlake, Ohio; Thermodynamics Corp., Shawnee Mission, Kans.; Western Electric Co., Inc., North Andover, Mass.; Electro Dynamics Corp., Shawnee Mission, Kans.; and Crystal Systems, Inc., Chardon, Ohio.

Consumption and Uses.— Consumption of raw cultured quartz crystal increased to 190,021 pounds, 28% over the 148,724 pounds consumed in 1975. Natural quartz consumption increased 77% to 159,407 pounds in 1976. Total consumption of natural and cultured quartz was 349,428 pounds.

Production and consumption data for 1976 were derived from reports of 63 operations. There were 37 crystal cutting operations in 17 States. Of the total cutting operations, 22 cut cultured quartz only, 14 cut both natural and cultured quartz, and 1 company cut natural crystal only. Pennsylvania was the leading quartz-crystal-consuming State, followed by Kansas, Illinois, and Massachusetts.

Finished crystal units were produced at 54 operations in 20 States. Oscillator plates comprised 73% of production, followed by filter plates, (22%), and telephone resonators and other uses (5%).

Stocks.—Total stocks of raw quartz crystal (cultured and natural) decreased from 311,556 pounds in 1975 to 281,971 pounds . Of this total, 127,628 pounds was cultured quartz and 156,343 pounds was natural quartz.

Foreign Trade.—Exports of natural quartz from the United States declined 40%, from 313,330 pounds in 1975 to 188,130 pounds. The total value was $1,625,955, a unit value per pound of $8.65, up from $5.29 in 1975. The principal countries of destination were Japan, (53,680 pounds), Hong Kong (30,000 pounds), and Switzerland (21,095 pounds).

Exports of cultured quartz increased 165% to a record 457,410 pounds in 1976. The unit value was $20.29 per pound, a decrease of $3.20 per pound. Japan with 321,369 pounds, Taiwan with 52,294 pounds, and West Germany with 19,883 pounds were the principal receiving countries.

Imports of raw natural quartz crystal, valued at more than $0.50 per pound, decreased from 584,647 pounds in 1975 to 187,243 pounds. This category includes both electronic grade and some lasca or lower quality material. Brazil was the source country for 98% of this material. Imports of quartz valued at less than $0.50 per pound were 961,558 pounds valued at $185,401. Brazil supplied 49%, followed by Mexico (26%), and Canada (25%).

World Review.—*Brazil.*—As in past years, Brazil was the leading world source for electronic-grade and lasca-grade quartz. The high prices for lasca set in 1975 have relaxed slightly but still remain considerably above the 1974 levels.

Hong Kong.—Solider (Hong Kong) Ltd., a subsidiary of Solitron Devices, announced plans to increase output of finished crystal units to 500,000 pieces per year. New equipment is being added to enable the company to process raw quartz crystal through the various stages into finished crystal units.

STAUROLITE[5]

Staurolite is a naturally occurring mineral of uncertain and variable composition, but with the general formula $FeAl_5Si_2O_{12}(OH)$. It occurs as reddish-brown to black opaque crystals with specific gravity of 3.65 to 3.77 and hardness of between 7 and 8 (Moh's scale). Staurolite begins to melt at 2,800° F and has a high rate of thermal conductivity and a low rate of thermal expansion.

Aside from a small rock-shop trade in cruciform-twinned crystals (sometimes called fairy crosses) from some deposits in Georgia, North Carolina, and Virginia that are sold as curios or amulets, all the staurolite in the United States is produced commercially by E. I. du Pont de Nemours & Co., Inc. This staurolite is a byproduct of heavy minerals recovery from beach sand from a glacial age deposit in Clay County, in north central Florida. After caustic scrubbing and drying, the staurolite is removed by electromagnetic separation. This staurolite concentrate, about 77% of which is

[5]Prepared by W. Thomas Cocke, physical scientist.

mineral staurolite with uniformly sized, clean, and rounded grains, may contain minor proportions of various other minerals; but has a nominal composition of 45% Al_2O_3(min.), 18% Fe_2O_3(max.), 3% ZrO_2(max.), 5% TiO_2(max.), and 5% SiO_2. Although originally marketed only for use in portland cement manufacture, it is now being marketed as a specialty foundry sand under the trade name "Biasill," and as a sandblast abrasive under the trade name "Starblast."

Quantitative production data are not released for publication, but the 1976 output of staurolite was 2% over that of 1975. Shipments decreased 21% in tonnage but increased 50% in price per ton over that of 1975.

STRONTIUM[6]

Domestic consumption of strontium on a carbonate basis was estimated at 26,000 short tons in 1976, representing a 73% increase from that of the previous year. Imports of strontium minerals increased 65% from 1975 to 35,711 short tons in 1976. Imports of strontium chemicals, primarily from Canada, increased 73% compared with those of 1975.

Legislation and Government Programs.—Government stockpiles contained 14,408 short tons of nonstockpile-grade celestite at yearend. This material has been declared excess, but legislation authorizing its disposal must be obtained before the material can be released for sale.[7]

Domestic Production.—Strontium minerals have not been produced commercially in the United States since 1959. However, a number of firms produced strontium compounds from imported celestite, a strontium sulfate. Approximately 20,000 short tons of strontium carbonate was produced in 1976 from which about 5,500 short tons of strontium nitrate was processed.

Table 4.—Major producers of strontium compounds, 1976

Company	Location	Compounds
Atomergic Chemetals Co	Carle Place, N. Y	Various compounds.
J. T. Baker Chemical Co	Phillipsburg, N. J	Do.
Chemical Products Corp	Cartersville, Ga	Carbonate.
FMC Corp	Modesto, Calif	Carbonate, nitrate.
King Laboratories, Inc	Syracuse, N. Y	Metal alloys.
Mallinckrodt Chemical Works	St. Louis, Mo	Various compounds.
Mineral Pigments Corp	Beltsville, Md	Chromate, molybdate.
NL Industries, Inc., Tam Div	South Amboy, N. J	Titanates.

Consumption and Uses.—Domestic consumption of celestite on a carbonate basis is estimated at 26,000 short tons, up 73% over that of 1975. Although quantitative information concerning consumption is incomplete, sales of domestically produced strontium carbonate to manufacturers of glass panels for color television picture tubes increased. Strontium nitrate consumption in the manufacture of pyrotechnics appeared to have stabilized.

Miscellaneous applications for strontium compounds included ferrites, greases, ceramics, plastics, toothpaste, pharmaceuticals, paint, electronic components, welding fluxes, and high-purity zinc. Small quantities of strontium metal were produced by research companies.

Prices.—At yearend, prices quoted in the Chemical Marketing Reporter were as follows: Strontium carbonate-technical, bags, carlots, works, 18 to 18.8 cents per pound; strontium nitrate-bags, carlots, works, $24 per 100 pounds (unchanged from 1975). Prices for strontium minerals are usually determined by direct negotiations between buyer and seller and are seldom published. The average value of imported strontium minerals at foreign ports was $41.61 per ton, up $3.40 from 1975.

Foreign Trade.—Imports of strontium minerals totaled 35,711 short tons, a 65% increase from that of 1975. All the material was imported from Mexico and represented a 133% increase over 1975 imports of Mexican celestite. Imports of strontium compounds increased 73% above those of 1975, with 94% of the material coming from Canada. Imports of strontium carbonate were up 74%, and imports of strontium nitrate up 65% over those of 1975. Quantitative data on U.S. exports of strontium compounds were not available.

[6]Prepared by W. Thomas Cocke, physical scientist.

World Review.—*Canada.*—Kaiser Strontium Products, Ltd,. has shut down its strontium chemicals plant at Point Edward, Cape Breton Island, Nova Scotia.[8] Technical problems and overcapacity in the strontium industry appears to have been the causes.

Spain.—A study is being conducted pertaining to the mining of strontium salts and celestite near Granada.[9]

Turkey.—A large deposit of celestite, with reserves in excess of 4 million tons, is located in the Vivas area.[10] Bilfer Maden Ltd., Sirketi, has an open pit operation capable of producing 10,000 tons of celestite (97% $SrSO_4$) per year. Trial shipments have been made to Japan.

United Kingdom.—The Bristol Mineral Co., Ltd., operators of the Yate celestite deposits, has recently undergone some significant reorganization.[11] In order to raise the capital necessary for expansion, three new investors were brought into the company. Bristol has received a large number of orders, particularly for carbonate, and is hoping to increase production still further. Ninety-five percent of its production is exported.

Table 7.—Strontium minerals: World production by country

(Short tons)

Country[1]	1974	1975	1976[p]
Algeria	r e2,000	--	--
Argentina	r331	1,102	e1,100
Canada[e]	60,000	28,000	13,200
Iran[e 2]	330	330	220
Italy	827	e800	e770
Mexico	32,568	16,228	e36,000
Pakistan	400	1,121	756
Spain	9,370	8,818	e8,300
United Kingdom	2,646	2,094	e2,200
Total	r108,472	58,493	62,546

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the countries listed, West Germany, Poland and the U.S.S.R. produce strontium minerals, but output is not reported quantitatively and available information is inadequate for formulation of reliable estimates of output levels.

[2]Year beginning March 21 of that stated.

Technology.—Globe Union has introduced a lead strontium alloy for use in maintenance-free batteries.[12] The lead strontium system combines the best features of lead calcium and lead low antimony alloys. It exceeds the water loss capability of lead low antimony, without the manufacturing problems inherent in the lead calcium systems.

Kaiser Aluminum has developed an aluminum-silicon alloy containing strontium, which, it is claimed, improves the mechanical strength and ductility of finished castings.[13] The strontium is used in place of sodium.

WOLLASTONITE[14]

Wollastonite is a natural calcium metasilicate, usually white or light-colored, with a specific gravity of 2.87 to 3.09 and a Moh's hardness of 4.5 to 5. Ito 5. It theoretically consists of 48.3% lime combined with 51.7% silica. Wollastonite from selected deposits has found increasing use as an ingredient in ceramic mixes for glazes and enamels and especially for floor and wall tile; in the building industry for the production of mineral wool and cold-setting insulation foams, and as a pigment and extender for paints; as a filling agent for plastics, rubber, and asphalt products; in agriculture as a fertilizer and soil conditioner; and in a wide variety of other applications still being developed.

Wollastonite was produced in the United States in 1976 from the underground mine operated by Interpace Corp., at Willsboro, Essex County, N. Y.; output tonnage was 32% greater than in 1975, and the corresponding total value was 49% higher. Specific output data were not released for publication. The company purchased additional property containing reserves of wollastonite in early 1976 to supply the growing market.[15]

Chemical Marketing Reporter quoted wollastonite prices in bags, carlots, works, at $43.80 per ton for paint grade, fine, and $33.00 per ton for paint grade, medium, unchanged (both quotations) December 1971 through early December 1976. However, the December 13, 1976, issue quoted prices as $124.00 per ton for paint grade, fine, and $107.50 per ton for paint grade, medium. The price range quoted in the December 1976 issue of Industrial Minerals (London) for wollastonite (imported, ground, bagged, c.i.f. main European port) was approximately equivalent to from $114 to $128 per ton.

ZEOLITES[16]

The emergence of markets of sufficient size to make natural zeolite production more than sporadic did not happen in 1976. Several hundred tons, principally clinoptilolite, were mined at various sites, mainly to meet the demand for ammonia removal

from the effluent of waste water treatment plants.

Prices received for clinoptilolite varied so widely ($160 to $600 per short ton) that no pattern emerged.

About 50 tons of natural chabazite was marketed by Union Carbide Corp. at prices well over $2,000 per ton, and Letcher & Associates offered pelletized, activated, natural chabazite at prices between $1,040 and $1,480 per ton, depending on quantity.

Some applications research into uses for natural zeolites was underway, both in the United States and abroad. The principal market areas being studied were agriculture, aquaculture, and waste treatment.

ZEOLITE '76, an international conference on the occurrence, properties, and utilization of natural zeolites, was held in Tucson, Ariz., in June. The total of 185 engineers and scientists from 21 countries attending the conference was indicative of the great interest in these minerals. The potential markets for natural zeolites were discussed, among other things. It was demonstrated that they can be used as inexpensive, selective ion exchangers and sorbents in direct competition with the synthetic zeolites. Uses foreseen were in the fields of energy development, pollution control, waste recovery, and animal nutrition. A paper that aroused considerable interest demonstrated that clinoptilolite and chabazite can be used to increase the efficiency of solar energy systems.

The synthetic zeolite industry apparently continued to expand, and the emergence of a probable major new market highlighted the year. Both Henkel, G.m.b.H. in Dusseldorf, West Germany, and the Proctor & Gamble Co., in Cincinnati, Ohio, announced new detergent formulations in which half of the phosphate levels would be replaced by synthetic zeolites. Henkel plans to manufacture its zeolite in cooperation with Degussa, G.m.b.H., and market it under the trade name "Sasil." J. M. Huber Corp. will reportedly manufacture the zeolite for Proctor & Gamble in a 50,000-ton-per-year plant; it will sell for about $400 to $500 per ton. Two other companies were reportedly considering new zeolite capacity.

The Bureau of Mines was preparing to initiate a survey to determine the number of potential mines and producers of natural zeolites.
